SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 14, PART 1

18TH ANNUAL MEETING
TORONTO, ONTARIO
NOVEMBER 13-18, 1988

Made in the United States of America
International Standard Book Numbers
Part 1 ISBN 0-916110-29-X
Part 2 ISBN 0-916110-30-3
Both parts ISSN 0190-5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 14, Part 1, p. xxx, 1988.

Published by
Society for Neuroscience
11 Dupont Circle, N.W., Suite 500
Washington, D.C. 20036

CONTENTS—PART 1

*7,809 volunteer abstracts, 18 symposium and workshop abstracts.

1988 PROGRAM COMMITTEE

Richard P. Bunge, M.D., *Chairperson*
Washington University School of Medicine

David P. Corey, Ph.D., *Incoming Chairperson*
Massachusetts General Hospital

Richard W. Aldrich, Ph.D.
Stanford University Medical School

Theodore W. Berger, Ph.D.
University of Pittsburgh

Suzanne H. Corkin, Ph.D.
Massachusetts Institute of Technology

William C. deGroat, Ph.D.
University of Pittsburgh Medical School

Robert P. Elde, Ph.D.
University of Minnesota

Howard L. Fields, M.D., Ph.D.
University of California Medical School,
San Francisco

Eric Frank, Ph.D.
University of Pittsburgh Medical School

John P. Horn, Ph.D.
University of Pittsburgh Medical School

Edward G. Jones, M.D., Ph.D.
University of California College of Medicine

Robert L. MacDonald, M.D., Ph.D.
University of Michigan

Marek-Marsel Mesulam, M.D.
Beth Israel Hospital, Boston

J. Anthony Movshon, Ph.D.
New York University

Louis F. Reichardt, Ph.D.
Howard Hughes Medical Center
University of California

David L. Sparks, Ph.D.
University of Alabama

Felix Strumwasser, Ph.D.
Marine Biological Laboratory

Wylie W. Vale, Ph.D.
The Salk Institute

Stanley J. Watson, Jr., M.D., Ph.D.
University of Michigan School of Medicine

Roy A. Wise, Ph.D.
Concordia University

Barry B. Wolfe, Ph.D.
University of Pennsylvania School of Medicine

Albert J. Aguayo, M.D., *ex officio*
Montreal General Hospital

David H. Hubel, M.D., *ex officio*
Harvard Medical School

Joe Dan Coulter, Ph.D., *ex officio*
University of Iowa College of Medicine

CHRONOLOGICAL LIST OF SESSIONS

(see page xii for Thematic List of Sessions)

TUESDAY

THURSDAY

Thematic List of Sessions

(Includes slide and poster sessions, symposia, and workshops only.)

Theme A: Development and Plasticity

Session Number	Session Title	Type	Day and Time
509.	Aging: physiology	Poster	Fri AM
167.	Biochemical and pharmacological correlates of development I	Poster	Tue AM
258.	Biochemical and pharmacological correlates of development II	Poster	Wed AM
518.	Biochemical and pharmacological correlates of development III	Poster	Fri AM
132.	Cell lineage and determination I	Slide	Tue AM
359.	Cell lineage and determination II	Slide	Thu AM
453.	Cell lineage and determination III	Poster	Thu PM
416.	**Development of Functional Heterogeneity Among Sensory Neurons**	**Symp.**	**Thu PM**
39.	Differentiation and development I	Poster	Mon AM
69.	Differentiation and development II	Slide	Mon PM
171.	Differentiation and development III	Poster	Tue AM
291.	Differentiation and development IV	Poster	Wed AM
311.	Differentiation and development V	Slide	Wed PM
407.	Differentiation and development VI	Poster	Thu AM
414.	Differentiation and development VII	Poster	Thu AM
483.	Differentiation and development VIII	Slide	Fri AM
510.	Differentiation and development IX	Poster	Fri AM
112.	Endocrine control and development I	Poster	Mon PM
113.	Endocrine control and development II	Poster	Mon PM
282.	Endocrine control and development III	Poster	Wed AM
478.	Endocrine control and development IV	Slide	Fri AM
354.	Limbic system I	Poster	Wed PM
401.	Motor systems I	Poster	Thu AM
458.	Motor systems II	Poster	Thu PM
12.	Neural plasticity in adult animals: LTP I	Slide	Mon AM
225.	Neural plasticity in adult animals: LTP II	Poster	Tue PM
454.	Neural plasticity in adult animals: anatomy and behavior	Poster	Thu PM
245.	Neural plasticity in adult animals: central	Slide	Wed AM
338.	Neural plasticity in adult animals: cerebral cortex	Poster	Wed PM
197.	Neural plasticity in adult animals: induced effects I	Poster	Tue PM
334.	Neural plasticity in adult animals: induced effects II	Poster	Wed PM
277.	Neural plasticity in adult animals: neuromuscular and autonomic	Poster	Wed AM
487.	Neural plasticity in adult animals: peripheral	Slide	Fri AM
150.	Neuronal death I	Poster	Tue AM
449.	Neuronal death II	Poster	Thu PM
290.	Neurotoxicity in development I	Poster	Wed AM
352.	Neurotoxicity in development II	Poster	Wed PM
507.	Neurotoxicity: studies in tissue culture	Poster	Fri AM
122.	**New Approaches to the Functional Development of the Neocortex**	**Wksh.**	**Tue AM**
235.	Nutritional and perinatal factors in development	Poster	Tue PM
108.	Process outgrowth, growth cones, and guidance mechanisms I	Poster	Mon PM
184.	Process outgrowth, growth cones, and guidance mechanisms II	Slide	Tue PM
231.	Process outgrowth, growth cones, and guidance mechanisms III	Poster	Tue PM
240.	Process outgrowth, growth cones, and guidance mechanisms IV	Slide	Wed AM
300.	Process outgrowth, growth cones, and guidance mechanisms V	Slide	Wed PM
346.	Process outgrowth, growth cones, and guidance mechanisms VI	Poster	Wed PM

Theme B: Cell Biology

372.	Membrane composition and cell surface macromolecules I	Slide	Thu AM
406.	Membrane composition and cell surface macromolecules II	Poster	Thu AM
508.	Membrane composition and cell surface macromolecules III	Poster	Fri AM
11.	Messenger RNA regulation I	Slide	Mon AM
302.	Messenger RNA regulation II	Slide	Wed PM
350.	Messenger RNA regulation III	Poster	Wed PM
463.	Messenger RNA regulation IV	Poster	Thu PM
529.	Messenger RNA regulation V	Poster	Fri AM
62.	**Molecular Biological Approaches to Study Neuropeptide Biosynthesis**	**Symp.**	**Mon PM**
173.	Neuroglia: biology of astrocytes I	Poster	Tue AM
425.	Neuroglia: biology of astrocytes II	Slide	Thu PM
317.	Neuroglia: myelin forming cells	Poster	Wed PM
48.	Neuroglia: myelin mutants	Poster	Mon AM
219.	Staining and tracing techniques I	Poster	Tue PM
220.	Staining and tracing techniques II	Poster	Tue PM

Theme C: Excitable Membranes and Synaptic Transmission

Session Number	Session Title	Type	Day and Time
121.	**At Last! Potassium Channels: Expression and Regulation**	**Symp.**	**Tue AM**
54.	Ion channels: calcium channels I	Poster	Mon AM
55.	Ion channels: calcium channels II	Poster	Mon AM
56.	Ion channels: calcium channels III	Poster	Mon AM
363.	Ion channels: calcium channels IV	Slide	Thu AM
117.	Ion channels: cell function I	Poster	Mon PM
118.	Ion channels: cell function II	Poster	Mon PM
261.	Ion channels: chloride and other	Poster	Wed AM
260.	Ion channels: ligand-gated I	Poster	Wed AM
419.	Ion channels: ligand-gated II	Slide	Thu PM
57.	Ion channels: modulation and regulation I	Poster	Mon AM
64.	Ion channels: modulation and regulation II	Slide	Mon PM
262.	Ion channels: modulation and regulation III	Poster	Wed AM
303.	Ion channels: modulation and regulation IV	Slide	Wed PM
438.	Ion channels: modulation and regulation V	Poster	Thu PM
484.	Ion channels: potassium, chloride and other	Slide	Fri AM
241.	Ion channels: sodium channels I	Slide	Wed AM
335.	Ion channels: sodium channels II	Poster	Wed PM
358.	**Non-Uniformity of Synaptic Physiology and Implications for Plasticity in the Nervous System**	**Wksh.**	**Thu AM**
207.	Pharmacology of synaptic transmission I	Poster	Tue PM
325.	Pharmacology of synaptic transmission II	Poster	Wed PM
110.	Postsynaptic mechanisms I	Poster	Mon PM
111.	Postsynaptic mechanisms II	Poster	Mon PM
369.	Postsynaptic mechanisms III	Slide	Thu AM
186.	Potassium channels I	Slide	Tue PM
382.	Potassium channels II	Poster	Thu AM
439.	Presynaptic mechanisms I	Poster	Thu PM
486.	Presynaptic mechanisms II	Slide	Fri AM
31.	Presynaptic mechanisms: ions	Poster	Mon AM
440.	Presynaptic mechanisms: modulators	Poster	Thu PM
30.	Presynaptic mechanisms: toxins	Poster	Mon AM
44.	Synaptic structure and function I	Poster	Mon AM
252.	Synaptic structure and function II	Slide	Wed AM

Theme D: Neurotransmitters, Modulators, and Receptors

Session Number	Session Title	Type	Day and Time
432.	Acetylcholine	Poster	Thu PM
257.	Acetylcholine: basal forebrain and brainstem	Poster	Wed AM
530.	Acetylcholine: receptors and choline uptake	Poster	Fri AM
523.	Adrenergic receptor modulation and regulation	Poster	Fri AM
166.	Adrenergic receptors I	Poster	Tue AM
374.	Adrenergic receptors II	Poster	Thu AM
63.	**Afferent Regulation of the Locus Coeruleus**	**Wksh.**	**Mon PM**
71.	Amino acids: GABA and benzodiazepines I	Slide	Mon PM
143.	Amino acids: GABA and benzodiazepines II	Poster	Tue AM
144.	Amino acids: GABA and benzodiazepines III	Poster	Tue AM
183.	Amino acids: GABA and benzodiazepines IV	Slide	Tue PM
326.	Amino acids: GABA and benzodiazepines V	Poster	Wed PM
393.	Amino acids: GABA and benzodiazepines VI	Poster	Thu AM
125.	Behavioral pharmacology	Slide	Tue AM
455.	Behavioral pharmacology: acetylcholine	Poster	Thu PM
340.	Behavioral pharmacology: dopamine	Poster	Wed PM
506.	Behavioral pharmacology: miscellaneous	Poster	Fri AM
404.	Behavioral pharmacology: monoamines	Poster	Thu AM
91.	Behavioral pharmacology: psychostimulants	Poster	Mon PM
16.	Catecholamines I	Slide	Mon AM
163.	Catecholamines II	Poster	Tue AM
293.	Catecholamines III	Poster	Wed AM
376.	Catecholamines IV	Poster	Thu AM
433.	Catecholamines V	Poster	Thu PM
490.	Catecholamines VI	Poster	Fri AM
164.	Catecholamines: electrophysiology I	Poster	Tue AM
377.	Catecholamines: electrophysiology II	Poster	Thu AM
294.	Catecholamines: *in vivo* measurements	Poster	Wed AM
242.	Characterization of cholinergic receptors	Slide	Wed AM
94.	Characterization of muscarinic receptors I	Poster	Mon PM
435.	Characterization of muscarinic receptors II	Poster	Thu PM
95.	Characterization of nicotinic receptors	Poster	Mon PM
107.	Cholinergic receptor modulation and regulation	Poster	Mon PM
375.	Dopamine receptor modulation and regulation	Poster	Thu AM
165.	Dopamine receptors I	Poster	Tue AM
185.	Dopamine receptors II	Slide	Tue PM
378.	Dopamine receptors III	Poster	Thu AM
434.	Dopamine receptors IV	Poster	Thu PM
40.	Excitatory amino acids I	Poster	Mon AM
97.	Excitatory amino acids II	Poster	Mon PM
98.	Excitatory amino acids III	Poster	Mon PM
198.	Excitatory amino acids IV	Poster	Tue PM
199.	Excitatory amino acids V	Poster	Tue PM
318.	Excitatory amino acids VI	Poster	Wed PM
380.	Excitatory amino acids VII	Poster	Thu AM
381.	Excitatory amino acids VIII	Poster	Thu AM
421.	Excitatory amino acids IX	Slide	Thu PM
480.	Excitatory amino acids X	Slide	Fri AM
168.	Excitatory amino acids: excitotoxicity I	Poster	Tue AM
169.	Excitatory amino acids: excitotoxicity II	Poster	Tue AM
299.	Excitatory amino acids: excitotoxicity III	Slide	Wed PM
46.	Interactions between neurotransmitters I	Poster	Mon AM
348.	Interactions between neurotransmitters II	Poster	Wed PM
489.	Interactions between neurotransmitters III	Slide	Fri AM
2.	**Interleukin-1: Immune and Neural Modulator**	**Symp.**	**Mon AM**
182.	**Neuronal Gene Expression: Physiological Activation, Transcriptional Control and DNA Binding Proteins**	**Symp.**	**Tue PM**
218.	Opiates, endorphins and enkephalins: anatomy and chemistry I	Poster	Tue PM
280.	Opiates, endorphins and enkephalins: anatomy and chemistry II	Poster	Wed AM

18.	Opiates, endorphins and enkephalins: physiological effects I	Poster	Mon AM
162.	Opiates, endorphins and enkephalins: physiological effects II	Poster	Tue AM
191.	Opiates, endorphins and enkephalins: physiological effects III	Slide	Tue PM
461.	Opiates, endorphins and enkephalins: physiological effects IV	Poster	Thu PM
146.	Peptides: anatomical localization I	Poster	Tue AM
271.	Peptides: anatomical localization II	Poster	Wed AM
395.	Peptides: anatomical localization III	Poster	Thu AM
13.	Peptides: biosynthesis, metabolism and biochemical characterization I	Slide	Mon AM
161.	Peptides: biosynthesis, metabolism and biochemical characterization II	Poster	Tue AM
349.	Peptides: biosynthesis, metabolism and biochemical characterization III	Poster	Wed PM
462.	Peptides: biosynthesis, metabolism and biochemical characterization IV	Poster	Thu PM
58.	Peptides: physiological effects I	Poster	Mon AM
59.	Peptides: physiological effects II	Poster	Mon AM
60.	Peptides: physiological effects III	Poster	Mon AM
370.	Peptides: physiological effects IV	Slide	Thu AM
10.	Peptides: receptors I	Slide	Mon AM
145.	Peptides: receptors II	Poster	Tue AM
270.	Peptides: receptors III	Poster	Wed AM
394.	Peptides: receptors IV	Poster	Thu AM
45.	Receptor modulation and regulation I	Poster	Mon AM
229.	Receptor modulation and regulation II	Poster	Tue PM
423.	Receptor modulation and regulation III	Slide	Thu PM
43.	Regional localization of receptors and transmitters I	Poster	Mon AM
73.	Regional localization of receptors and transmitters II	Slide	Mon PM
314.	Regional localization of receptors and transmitters III	Poster	Wed PM
315.	Regional localization of receptors and transmitters IV	Poster	Wed PM
35.	Second messengers I	Poster	Mon AM
36.	Second messengers II	Poster	Mon AM
37.	Second messengers III	Poster	Mon AM
52.	Second messengers IV	Poster	Mon AM
53.	Second messengers V	Poster	Mon AM
175.	Second messengers VI	Poster	Tue AM
485.	Second messengers VII	Slide	Fri AM
129.	Serotonin receptors I	Slide	Tue AM
247.	Serotonin receptors II	Slide	Wed AM
15.	Serotonin, histamine and other biogenic amines I	Slide	Mon AM
88.	Serotonin, histamine and other biogenic amines II	Poster	Mon PM
89.	Serotonin, histamine and other biogenic amines III	Poster	Mon PM
221.	Serotonin, histamine and other biogenic amines IV	Poster	Tue PM
222.	Serotonin, histamine and other biogenic amines V	Poster	Tue PM
339.	Serotonin, histamine and other biogenic amines VI	Poster	Wed PM
99.	Transmitter uptake, storage, secretion and metabolism I	Poster	Mon PM
275.	Transmitter uptake, storage, secretion and metabolism II	Poster	Wed AM
479.	Transmitter uptake, storage, secretion and metabolism III	Slide	Fri AM
17.	Transmitters in invertebrates I	Slide	Mon AM
155.	Transmitters in invertebrates II	Poster	Tue AM
216.	Transmitters in invertebrates III	Poster	Tue PM
76.	Transmitters in invertebrates: gastropods	Slide	Mon PM
365.	Transmitters: acetylcholine	Slide	Thu AM

Theme E: Endocrine and Autonomic Regulation

Session Number	Session Title	Type	Day and Time
14.	Cardiovascular regulation I	Slide	Mon AM
82.	Cardiovascular regulation II	Poster	Mon PM
136.	Cardiovascular regulation III	Slide	Tue AM
206.	Cardiovascular regulation IV	Poster	Tue PM

250.	Cardiovascular regulation V	Slide	Wed AM
391.	Cardiovascular regulation VI	Poster	Thu AM
392.	Cardiovascular regulation VII	Poster	Thu AM
422.	Hypothalamic-pituitary-adrenal regulation I	Slide	Thu PM
514.	Hypothalamic-pituitary-adrenal regulation II	Poster	Fri AM
515.	Hypothalamic-pituitary-adrenal regulation III	Poster	Fri AM
176.	Hypothalamic-pituitary-gonadal regulation I	Poster	Tue AM
177.	Hypothalamic-pituitary-gonadal regulation II	Poster	Tue AM
431.	Hypothalamic-pituitary-gonadal regulation III	Slide	Thu PM
528.	Neural control of adrenal function	Poster	Fri AM
93.	Neural control of immune system I	Poster	Mon PM
304.	Neural control of immune system II	Slide	Wed PM
512.	Neural control of immune system III	Poster	Fri AM
513.	Neural control of immune system IV	Poster	Fri AM
209.	Neuroendocrine controls: other I	Poster	Tue PM
426.	Neuroendocrine controls: other II	Slide	Thu PM
469.	Neuroendocrine controls: other III	Poster	Thu PM
33.	Neuroendocrine controls: pituitary I	Poster	Mon AM
126.	Neuroendocrine controls: pituitary II	Slide	Tue AM
256.	Neuroendocrine controls: pituitary III	Poster	Wed AM
130.	Regulation of autonomic function I	Slide	Tue AM
217.	Regulation of autonomic function II	Poster	Tue PM
527.	Regulation of autonomic function III	Poster	Fri AM
189.	Respiratory regulation I	Slide	Tue PM
255.	Respiratory regulation II	Poster	Wed AM
379.	Respiratory regulation III	Poster	Thu AM
297.	**Specificity in the Control of Regional Sympathetic Outflow: Physiological, Neurochemical and Anatomical Approaches**	**Symp.**	**Wed PM**

Theme F: Sensory Systems

Session Number	Session Title	Type	Day and Time
473.	Chemical senses: gustatory pathways	Poster	Thu PM
474.	Chemical senses: olfactory pathways	Poster	Thu PM
428.	Chemical senses: peripheral mechanisms I	Slide	Thu PM
466.	Chemical senses: peripheral mechanisms II	Poster	Thu PM
296.	**Coding of Visual Signals at the Photoreceptor Synapse**	**Wksh.**	**Wed PM**
476.	**Form and Synaptic Function in Retinal Ganglion Cells**	**Symp.**	**Fri AM**
3.	**Functional Properties of Somatic Sensory "Barrel Field" Cortex**	**Wksh.**	**Mon AM**
153.	Invertebrate sensory systems I	Poster	Tue AM
154.	Invertebrate sensory systems II	Poster	Tue AM
341.	Pain modulation: biogenic amines	Poster	Wed PM
75.	Pain modulation: central pathways I	Slide	Mon PM
342.	Pain modulation: central pathways II	Poster	Wed PM
284.	Pain modulation: opioid mechanisms	Poster	Wed AM
134.	Pain modulation: pharmacology	Slide	Tue AM
283.	Pain modulation: stress and sensory stimulation	Poster	Wed AM
368.	Pain pathways	Slide	Thu AM
49.	Pain pathways: central mechanisms	Poster	Mon AM
224.	Pain pathways: inflammation, sensitization and hyperalgesia	Poster	Tue PM
223.	Pain pathways: long-term changes	Poster	Tue PM
464.	Pain pathways: trigeminal system	Poster	Thu PM
19.	Retina I	Poster	Mon AM
68.	Retina II	Slide	Mon PM
147.	Retina III	Poster	Tue AM
244.	Retina IV	Slide	Wed AM
396.	Retina V	Poster	Thu AM
450.	Retina VI	Poster	Thu PM
133.	Sensory systems: auditory systems I	Slide	Tue AM
200.	Sensory systems: auditory systems II	Poster	Tue PM
201.	Sensory systems: auditory systems III	Poster	Tue PM

263.	Sensory systems: auditory systems IV	Poster	Wed AM
264.	Sensory systems: auditory systems V	Poster	Wed AM
321.	Sensory systems: auditory systems VI	Poster	Wed PM
441.	Sensory systems: auditory systems VII	Poster	Thu PM
442.	Sensory systems: auditory systems VIII	Poster	Thu PM
289.	Somatic and visceral afferents	Poster	Wed AM
159.	Somatic and visceral afferents: dorsal root ganglion cells	Poster	Tue AM
285.	Somatic and visceral afferents: somesthetic afferents	Poster	Wed AM
92.	Somatosensory cortex I	Poster	Mon PM
286.	Somatosensory cortex II	Poster	Wed AM
306.	Somatosensory cortex III	Slide	Wed PM
279.	Spinal cord	Poster	Wed AM
50.	Subcortical somatosensory pathways: brainstem and thalamus	Poster	Mon AM
465.	Subcortical somatosensory pathways: trigeminal system	Poster	Thu PM
20.	Subcortical visual pathways I	Poster	Mon AM
127.	Subcortical visual pathways II	Slide	Tue AM
333.	Subcortical visual pathways III	Poster	Wed PM
397.	Subcortical visual pathways IV	Poster	Thu AM
8.	Visual cortex I	Slide	Mon AM
85.	Visual cortex II	Poster	Mon PM
187.	Visual cortex III	Slide	Tue PM
243.	Visual cortex IV	Slide	Wed AM
362.	Visual cortex V	Slide	Thu AM
451.	Visual cortex VI	Poster	Thu PM
502.	Visual cortex VII	Poster	Fri AM

Theme G: Motor Systems and Sensorimotor Integration

Session Number	Session Title	Type	Day and Time
34.	Basal ganglia and thalamus: motor systems I	Poster	Mon AM
66.	Basal ganglia and thalamus: motor systems II	Slide	Mon PM
287.	Basal ganglia and thalamus: motor systems III	Poster	Wed AM
408.	Basal ganglia and thalamus: motor systems IV	Poster	Thu AM
409.	Basal ganglia and thalamus: motor systems V	Poster	Thu AM
430.	Basal ganglia and thalamus: motor systems VI	Slide	Thu PM
417.	**Coding and Execution of Movement in Three Dimensions**	**Symp.**	**Thu PM**
400.	Invertebrate motor function	Poster	Thu AM
202.	Motor systems and sensorimotor integration: cerebellum I	Poster	Tue PM
305.	Motor systems and sensorimotor integration: cerebellum II	Slide	Wed PM
497.	Motor systems and sensorimotor integration: cerebellum III	Poster	Fri AM
9.	Motor systems and sensorimotor integration: circuitry and pattern generation I	Slide	Mon AM
104.	Motor systems and sensorimotor integration: circuitry and pattern generation II	Poster	Mon PM
67.	Motor systems and sensorimotor integration: cortex I	Slide	Mon PM
142.	Motor systems and sensorimotor integration: cortex II	Poster	Tue AM
208.	Motor systems and sensorimotor integration: cortex III	Poster	Tue PM
274.	Motor systems and sensorimotor integration: cortex IV	Poster	Wed AM
329.	Motor systems and sensorimotor integration: cortex V	Poster	Wed PM
248.	Motor systems and sensorimotor integration: oculomotor system I	Slide	Wed AM
320.	Motor systems and sensorimotor integration: oculomotor system II	Poster	Wed PM
386.	Motor systems and sensorimotor integration: oculomotor system III	Poster	Thu AM
387.	Motor systems and sensorimotor integration: oculomotor system IV	Poster	Thu AM
28.	Motor systems and sensorimotor integration: posture and movement I	Poster	Mon AM
29.	Motor systems and sensorimotor integration: posture and movement II	Poster	Mon AM

105.	Motor systems and sensorimotor integration: posture and movement III	Poster	Mon PM
106.	Motor systems and sensorimotor integration: posture and movement IV	Poster	Mon PM
192.	Motor systems and sensorimotor integration: posture and movement V	Slide	Tue PM
384.	Motor systems and sensorimotor integration: posture and movement VI	Poster	Thu AM
385.	Motor systems and sensorimotor integration: posture and movement VII	Poster	Thu AM
496.	Motor systems and sensorimotor integration: posture and movement VIII	Poster	Fri AM
74.	Motor systems and sensorimotor integration: vestibular system I	Slide	Mon PM
137.	Motor systems and sensorimotor integration: vestibular system II	Poster	Tue AM
138.	Motor systems and sensorimotor integration: vestibular system III	Poster	Tue AM
383.	Muscle: function and biochemistry	Poster	Thu AM
495.	Muscle: structural characteristics	Poster	Fri AM
319.	Reflex function: general	Poster	Wed PM
521.	Reflex function: human I	Poster	Fri AM
522.	Reflex function: human II	Poster	Fri AM
427.	Spinal cord and brainstem	Slide	Thu PM
140.	Spinal cord and brainstem: anatomy	Poster	Tue AM
78.	Spinal cord and brainstem: electrophysiology	Poster	Mon PM
139.	Spinal cord and brainstem: immunocytochemistry	Poster	Tue AM
32.	Spinal cord and brainstem: lesion studies	Poster	Mon AM
79.	Spinal cord and brainstem: motor output	Poster	Mon PM

Theme H: Other Systems of the CNS

Session Number	Session Title	Type	Day and Time
328.	Association cortex and thalamocortical relations	Poster	Wed PM
472.	Brainstem systems	Poster	Thu PM
23.	Cerebral metabolism and blood flow I	Poster	Mon AM
371.	Cerebral metabolism and blood flow II	Slide	Thu AM
399.	Cerebral metabolism and blood flow III	Poster	Thu AM
488.	Cerebral metabolism and blood flow IV	Slide	Fri AM
26.	Comparative neuroanatomy: amphibians, reptiles, birds	Poster	Mon AM
504.	Comparative neuroanatomy: cerebral cortex	Poster	Fri AM
25.	Comparative neuroanatomy: fish	Poster	Mon AM
51.	Hippocampus and amygdala I	Poster	Mon AM
100.	Hippocampus and amygdala II	Poster	Mon PM
343.	Hippocampus and amygdala III	Poster	Wed PM
470.	Hypothalamus I	Poster	Thu PM
471.	Hypothalamus II	Poster	Thu PM
373.	Limbic system II	Poster	Thu AM
181.	**New Insights into the Functions of the Basal Forebrain Cholinergic System**	**Symp.**	**Tue PM**

Theme I: Neural Basis of Behavior

Session Number	Session Title	Type	Day and Time
21.	Alcohol I	Poster	Mon AM
83.	Alcohol II	Poster	Mon PM
281.	Alcohol III	Poster	Wed AM

477.	**Neuropeptides, Steroids and Behavior**	**Symp.**	**Fri AM**
22.	Psychotherapeutic drugs I	Poster	Mon AM
87.	Psychotherapeutic drugs II	Poster	Mon PM
151.	Psychotherapeutic drugs III	Poster	Tue AM
239.	**Sex Differences and Hormonal Influences on Cognitive Brain Function**	**Symp.**	**Wed AM**
178.	Stress, hormones and autonomic nervous system I	Poster	Tue AM
179.	Stress, hormones and autonomic nervous system II	Poster	Tue AM

Theme J: Disorders of the Nervous System

Session Number	Session Title	Type	Day and Time
42.	Alzheimer's disease I	Poster	Mon AM
65.	Alzheimer's disease II	Slide	Mon PM
259.	Alzheimer's disease: amyloid	Poster	Wed AM
437.	Alzheimer's disease: neuropathology	Poster	Thu PM

SYMPOSIUM: INTERLEUKIN-1: IMMUNE AND NEURAL MODULATOR. D. Felten, Univ. of Rochester, (Chairperson), C.A. Dinarello*, Tufts Univ., C. Blatteis, Univ. of Tenn., C. River, Salk Inst., C.B. Saper, Univ. of Chicago, M. Schultzberg, Univ. of Stockholm.

Interleukin-1 (IL-1) is a lymphokine that is secreted by monocytes and macrophages during inflammation, resulting in a variety of neurally mediated responses including fever, sleepiness, and corticosteroid secretion. This symposium will explore the recent advances in understanding the role of IL-1 in modulating interactions between the immune and nervous system.

D. Felten will address the field of immune-neural interactions, and place the role of IL-1 into perspective. C.A. Dinarello will then describe the basic cellular and molecular biology of IL-1.

C. Blatteis will describe the effects of IL-1 on hypothalamic neurons involved in thermoregulation and sleep. C. Rivier will focus on the effects of IL-1 on neuroendocrine function in the hypothalamus.

The final two speakers will examine the possibility that IL-1 may serve as a neuromodulator as well as a circulating hormone. C.B. Saper will describe the organization of IL-1β immunoreactive neurons in the central nervous system, and M. Schultzberg will address the distribution of IL-1α immunoreactivity in the peripheral nervous system.

The twin roles of IL-1 as a circulating hormone and as a neuromodulator underscore the close coordination of immune and neural function. The dual role for this peptide may reflect a general organizing principle of the nervous system.

WORKSHOP. FUNCTIONAL PROPERTIES OF SOMATIC SENSORY "BARREL FIELD" CORTEX. F.F. Ebner, Brown Univ (Chairperson); B.W. Connors, Brown Univ; M. Armstrong-James*, Univ of London; D.J. Simons, Univ of Pittsburgh; R.B. Masterton, Florida State Univ.

The "barrel field" region of SI cortex that receives sensory information from the contralateral mystacial vibrissae has emerged as an important model system for studying 1) normal mechanisms of cortical function, 2) the effects of sensory deprivation and 3) the response of cortex to central and peripheral injury. This workshop will provide a forum for discussion of recent physiological and behavioral results on barrel field cortex.

Dr. Connors will describe techniques for the study of the barrel thalamocortical system *in vitro*. He will discuss thalamic activation of cortical circuits as well as the mechanisms and functions of multiple forms of intrinsic GABAergic inhibition. Dr. Armstrong-James will discuss the receptive field organization of barrel field neurons, comparing 1) features that depend upon thalamic inputs with those dependent upon cortical circuitry and 2) the responses of cells in the barrel to those of cells in the septa. In addition, he will explore the role of NMDA-type amino acid receptor mechanisms in regulating cortical cell excitability. Dr. Simons will discuss the thalamocortical response transformation in normal and neonatally sensory deprived animals: the anatomical relationship of a thalamic barreloid with its corresponding cortical barrel, the role of GABAergic neurons in shaping the spatial and temporal aspects of receptive field properties and the effect of sensory deprivation on the development of these properties. Dr. Ebner will discuss the response of barrel field cortex to direct injury and/or infraorbital nerve damage; whether such lesions affect the innervation and subsequent sensory response properties of embryonic neurons implanted into the cortical lesion site. Dr. Masterton will illustrate the distinction between barrel field-dependent and -independent vibrissal discriminations. He will summarize recent results on the agnosia-like deficits produced by aspiration of barrels and their use as a behavioral assay of barrel field function. An open panel discussion of issues raised during the sessions will follow the last presentation.

LEARNING AND MEMORY: ANATOMY I

4.1

LAYER IV ENTORHINAL PATHOLOGY DISRUPTS HIPPOCAMPAL-CORTICAL FEEDBACK IN ALZHEIMER'S DISEASE. W.G. Tourtellotte, G.W. Van Hoesen, B.T. Hyman and A.R. Damasio. Depts. of Anatomy and Neurology, Univ. of Iowa, Iowa City, IA 52242.

In Alzheimer's disease (AD) laminar specific neurofibrillary tangles are a consistent feature in the entorhinal cortex (EC) of the parahippocampal gyrus. In addition to layer II, the pyramidal neurons of layer IV (nomenclature of Lorente de Nó, 1933) are selectively affected. Little is known regarding the extent of their involvement or the functional relationships they have with hippocampal processing. Neurons in this region were examined for disease related involvement in 18 AD cases and 5 age compatible nondemented controls utilizing thioflavin S to detect neurofibrillary tangles (NFT) and Alz-50 to detect AD related immunoreactivity. In all cases studied, these neurons were extensively involved throughout the rostral-caudal axis of the EC. In addition, Alz-50 neuropil staining in the layer IV zone was noted in many cases. This was particularly prominent in cases with extensive subicular and CA1 involvement and suggest strongly that the subicular-entorhinal pathway may be compromised as well.

To highlight some of the connections established by these neurons, 6 rhesus monkeys were injected with neural tracing compounds. One case injected with ^{3}H leucine/lysine highlights the subicular-entorhinal pathway terminating in layer IV. Retrograde fluorescent tracers demonstrate direct projections from layer IV to rostral superior temporal, anterior cingulate, and posterior parahippocampal gyri as well as the temporal polar cortex. Labeled neurons were topographically distributed within the EC with very few double labeled in those cases receiving two tracers. Finally, a retrograde tracer placed in the superficial layers of the EC demonstrates intrinsic transport to layer IV.

These data demonstrate extensive involvement of layer IV neurons in AD and experimental studies demonstrate projections to some unimodal and multimodal association areas as well as an intrinsic entorhinal pathway. It is expected that all may be compromised in AD. Focal pathology of this nature may be devastating for hippocampal feedback to higher order association areas. (Supported by NS 14944, PO NS 19632, and the Mathers Foundation.)

4.2

LIMBIC CORTICAL PROJECTIONS TO SENSORY AND MULTI-MODAL ASSOCIATION AREAS IN THE OLD-WORLD MONKEY. S.E. Arnold*, D.R. Brady, G.W. Van Hoesen, B.T. Hyman and A.R. Damasio. Depts. of Neurology and Anatomy, Univ. of Iowa, Iowa City, IA 52242.

It is well-known that the entorhinal cortex (EC) is a convergence zone for limbic and association cortex projections that can influence the hippocampal formation via the perforant pathway. Less well-appreciated is the fact that hippocampal output, from the subiculum and CA1 zone is directed toward layer IV of the EC (nomenclature of Lorente de Nó, 1933) and that neurons of this layer project widely to cingulate, temporal polar, perirhinal and posterior parahippocampal cortices. We have investigated the cortical projections of temporal cortical areas that receive direct projections from layer IV of the EC using autoradiographic methodology. Although topographical differences exist, the cortical projection of these areas are remarkably similar, and two or more project to the following cortical areas: medial frontal; orbitofrontal; anterior cingulate; anterior insular; superior temporal; inferior temporal; and inferior peristriate. The posterior parahippocampal cortex projects in addition to the inferior parietal and dorsolateral prefrontal cortices. Together these connections form a host of cortical neural systems via which hippocampal-entorhinal output feeds back to widespread limbic and association cortices. (Supported by NS 14944 and PO NS 19632.)

4.3

LONG-TERM EFFECTS OF NEONATAL TEMPORAL CORTICAL AND LIMBIC LESIONS ON HABIT AND MEMORY FORMATION IN RHESUS MONKEYS. J. Bachevalier and M. Mishkin. Lab. Neuropsychol., NIMH, Bethesda, MD 20892.

Assessment of the effects of neonatal damage to temporal cortical area TE and limbic structures on the early development of habits and memories pointed to greater compensatory potential after the neonatal cortical removals (Bachevalier and Mishkin, Soc. Neurosci. 12:22, 1986). To determine the long-term effects of these early lesions, we retested 3 animals with neonatal area TE lesions and 3 others with neonatal limbic lesions at the age of 4 years on the same behavioral tasks, i.e. object discrimination learning with 24-hr ITIs to measure habit formation, and delayed nonmatching-to-sample with trial-unique objects to measure memory formation. The performance of the animals was compared to that of 4-year-olds that received the same lesions in adulthood. At 4 years of age, neonatal damage to area TE yielded a significant sparing of both habit and memory formation that was of the same magnitude as that found earlier when the animals were 3 to 12 months of age. By contrast, at 4 years of age, both neonatal and adult limbic lesions left habit formation intact but severely impaired memory formation. Apparently compensatory mechanisms operate early to promote permanent recovery from neonatal temporal cortical lesions but not from neonatal limbic lesions.

4.4

PLASTICITY OF VISUAL MEMORY CIRCUITS IN DEVELOPING MONKEYS. M.J. Webster, J. Bachevalier, and L.G. Ungerleider. Lab Neuropsychol., NIMH, Bethesda, MD 20892.

Object recognition, as measured by delayed nonmatching-to-sample, is severely impaired in monkeys that receive lesions of temporal cortical area TE as adults but not in those that receive the same lesions as infants. This sparing of function in animals with neonatal lesions appears to be permanent since such animals were found to perform well not only at one but also at four years postsurgically. Because object recognition normally depends on interactions between area TE and limbic structures, we investigated whether other visual cortical areas connected with limbic structures but not necessary for object recognition become necessary if area TE is removed in infancy. Thus, areas PG, TF, TEO, and STP were ablated in a 2-year-old rhesus monkey that had undergone neonatal area TE removal and had shown sustained recovery of object recognition. Following the secondary removals, the monkey demonstrated significant impairment, which became progressively greater with increasing delays and list lengths. Apparently, one or more areas removed in the secondary lesion had assumed a critical role in object recognition as a result of the neonatal TE lesion. Presumably, such compensation is possible because visual cortical areas are not yet fully mature at birth and possess significant functional plasticity.

4.5

FUNCTIONAL MATURATION OF INFERIOR TEMPORAL CORTEX IN INFANT RHESUS MONKEYS. C. Hagger, J. Bachevalier, K.A. Macko*, C. Kennedy, L. Sokoloff, and M. Mishkin. Lab. of Neuropsychology, and Lab. of Cerebral Metabolism, NIMH, Bethesda, MD 20892.

Although lesions of area TE in adults yield severe impairment in visual discrimination learning and recognition memory, the same lesions in neonates result in significant sparing of function, suggesting that area TE is still immature early in life (Bachevalier and Mishkin, Soc. Neurosci., 12:22, 1986). Support for this conclusion was provided by tracing the functional development of area TE by use of the 2-deoxyglucose method. Before local cerebral glucose utilization (LCGU) was measured, eight infant monkeys were subjected to unilateral optic tract section and forebrain commissurotomy at 1 day, 1 week, 3 weeks, and 1, 2, 3, and 5 months of age. The weighted average of LCGU for area TE was calculated by means of a computerized image-processing system. Differences in rates of glucose utilization between the "seeing" and "blind" hemispheres were small until 3 months of age and reached adult levels only at about 6 months. These results also help account for the recent finding that electrophysiological activity in area TE does not show the adult pattern before about 4 to 6 months of age (Rodman et al., Soc. Neurosci., 14, 1988).

4.6

DEVELOPMENTAL TIME COURSE AS WELL AS NATURE OF SOCIO-EMOTIONAL DISTURBANCES IN RHESUS MONKEY FOLLOWING NEONATAL LIMBIC LESIONS RESEMBLE THOSE IN AUTISM. P. M. Merjanian, J. Bachevalier, K. D. Pettigrew, and M. Mishkin. NIMH, Bethesda, MD 20892.

To investigate further the development of socio-emotional disturbances in animals with limbic lesions, we analyzed behavior at 2 months of age and compared it with a previously reported analysis of behavior at 6 months of age in the same group of 18 monkeys (Soc. Neurosci. Abstr., 12, 1986). Six monkeys had received combined amygdalo-hippocampal lesions (AH) neonatally, 6 were normals (N/AH) reared with monkeys from Group AH and 6 were normals reared with other normals (N/N). At both ages, each animal from Group AH was paired in a play cage with its age-matched control (N/AH), and their behavior was observed for 12, 5-minute intervals on 6 days. Similarly, each N/N was paired with another N/N. At 2 months only, the animals of Group AH had more temper tantrums when first placed in the novel play cage, showed more passive behavior, and manipulated objects less than the controls. On the other hand, Group AH animals at 2 months of age did not display the more striking pathology they exibited at 6 months, namely, lack of social contact, extreme submissiveness including active withdrawal, and gross motor stereotypies. The developmental time course and the nature of these disturbances in animals with limbic lesions resemble those seen in autism.

4.7

ROLE OF THE AMYGDALA AND HIPPOCAMPUS IN VISUAL-VISUAL ASSOCIATIVE MEMORY IN RHESUS MONKEYS. E.A. Murray, D. Gaffan, and M. Mishkin, Lab. of Neuropsychology, NIMH, Bethesda, MD 20892, and Dept. of Expt. Psychology, Oxford University, Oxford OX1 3UD, UK.

Naive normal monkeys (Macaca mulatta) were trained in an automated apparatus at the rate of 100 trials per day to associate in memory a set of 10 pairs of visual stimuli, i.e. 10 paired associates. Each trial began with the presentation in the middle of a TV screen of a single visual stimulus which disappeared when the monkey touched it. 0.5 s later, two other stimuli appeared on the sides of the screen, one the paired associate, and the other a member of a different pair. The monkey could obtain a food reward only by touching the paired associate. Following training to a criterion of 3 consecutive days of 90% correct responses, the monkeys received bilateral amygdalectomy (A), hippocampectomy (H), or both (AH), or were left unoperated (C), and were then retrained. Groups C and H relearned almost immediately ($\bar{X} \doteq 80$ errors each), Group A was retarded in relearning ($\bar{X} \doteq 800$ errors), whereas Group AH did not relearn within the training limit of 5000 trials ($\bar{X} \doteq 2000$ errors). The results suggest that the retrieval of recently learned visual-visual associations as well as their reacquisition are mediated by both the amygdala and the hippocampus.

4.8

PERFORMANCE ON A NONSPATIAL SELF-ORDERED TASK AFTER SELECTIVE LESIONS OF THE PRIMATE FRONTAL CORTEX. M.Petrides.Dept.Psychology and Montreal Neurological Institute,McGill Univ.,Montreal, Quebec,Canada.

It has been shown that patients with damage to the frontal cortex are impaired on tasks in which they have to monitor the execution of a series of self-initiated responses (Petrides and Milner, Neuropsychologia,20:249,1982). The frontal cortex is a structurally heterogeneous region of the brain. To establish the critical area within the dorsolateral frontal cortex for the performance of such responses,a nonspatial self-ordered task modelled on those that had been used with the patients was developed for monkeys. Nine monkeys (macaca nemestrina) were trained on this task. Three monkeys were subjected to a bilateral excision of the dorsolateral frontal cortex lying within,around and dorsal to the sulcus principalis (areas 46 and 9),three monkeys had the posterior dorsolateral frontal cortex within and around the arcuate sulcus removed (area 8 and rostral area 6),and three animals served as unoperated controls. Postoperatively,the monkeys with excisions of areas 46 and 9 were impaired,whereas those with lesions of areas 6 and 8 performed as well as the normal control animals.

4.9

MNEMONIC CAPACITY IN SPLIT-BRAIN MACAQUES. J.D. Lewine and R.W. Doty, U. of Rochester, Roch., N.Y.

Two macaques, each with transected optic chiasma and forebrain commissures, were tested on a probe recognition task. When required to determine if a monocularly viewed probe image is a member of a previously viewed target list, for which all targets were presented to the probed eye and hemisphere, the accuracy of the evaluation decreases as a function of the number of initial targets. For example, animal ART, working with left eye and hemisphere and right hand, performs at 90% with 2 targets, 83% with 4 targets, and 77% with 6 targets. As expected, ART performs at chance levels when classifying monocular probes on the basis of target information initially presented to only the contralateral hemisphere. For all animals, when the target list is divided between the hemispheres, the accuracy of monocular probe evaluations still reflects the total memory-load rather than the load of the probed hemisphere (e.g., When ART is given 2 targets to the left hemisphere, 4 to the right, and probed on the left with a positive probe matching one of the left hemisphere's targets, performance is only 75% rather than 90%). Thus, while the performance deficit caused by an increase in memory-load cannot be attributed to direct interference between memory traces, transection of the commissures is not sufficient to completely dissociate the mnemonic systems of the two hemispheres. The data suggest that performance depends upon a limited resource, allocated by the intact brainstem.

4.10

DOUBLE-DISSOCIATION OF EGOCENTRIC AND ALLOCENTRIC SPACE FOLLOWING MEDIAL PREFRONTAL AND PARIETAL CORTEX LESIONS IN THE RAT. R.P. Kesner, Dept. of Psychology, University of Utah, Salt Lake City, Utah 84112.

Animals with medial prefrontal cortex, parietal cortex lesions, or sham-operated and nonoperated controls were tested for the acquisition of an adjacent arm tas that accentuated the importance of egocentric spatial localization and a cheese board task that accentuated the importance of allocentric spatial localization. Results indicated that relative to controls and animals with parietal cortex lesions, animals with medial prefrontal cortex lesions are impaired on the adjacent arm task, but displayed facilitation on the cheese board task. In contrast, relative to controls and animals with medial prefrontal cortex lesions, rats with parietal cortex lesions are impaired on the cheese board task, but show no impairment on the adjacent arm task. The data suggest a double dissociation of function between medial prefrontal cortex and parietal cortex in terms of coding of egocentric versus allocentric spatial information.

4.11

REFLEX MODIFICATION (RM) AND CLASSICAL CONDITIONING OF THE RABBIT'S NICTITATING MEMBRANE RESPONSE (NMR) TO ELECTRICAL STIMULATION OF BRAINSTEM STRUCTURES AS AN UNCONDITIONED STIMULUS (UCS). A. J. Nowak and I. Gormezano, Dept. of Psychology, Univ. of Iowa, Iowa City, Iowa 52242.

An impressive body of research has accumulated indicating that the cerebellum may contain the neural circuitry necessary for NMR conditioning. Nevertheless, the possibility that the brainstem may also contain the circuitry sufficient for NMR conditioning has not been eliminated from consideration. The present study employed electrical brain stimulation (EBS) of the pars oralis of the spinal trigeminal nucleus (TRIG), accessory abducens nucleus, abducens nucleus and reticular formation to determine their role in elicitation, RM (i.e., alteration of UCRs by a preceding neutral stimulus), and classical conditioning of the NMR. The major findings were that robust and significant levels of RM and CR acquisition occurred with EBS of TRIG but there were no significant effects of EBS upon RM or CR acquisition at each of the other three sites. These results indicate a convergence of CS and UCS pathways at TRIG and are in agreement with the well-documented findings that CS-UCS interactions occur at sensory nuclei. However, whether the convergence at TRIG reflects neural plasticity at this brainstem structure or at sites efferent to TRIG (e.g., inferior olive, cerebellum, red nucleus) remains to be determined. (Supported by NSF Grant BNS-8419772 to I.G.)

4.12

LOSS OF CONDITIONED RESPONSES FOLLOWING CEREBELLAR CORTICAL LESIONS IS NOT A PERFORMANCE DEFICIT.
C.H. Yeo and M.J. Hardiman. Dept. Anatomy, University College London, London WC1E 7JG, U.K.

Lesions of cerebellar cortical lobule HVI (Yeo et al Behav. Brain Re. 13:261,1984) or cerebellar deep nuclei (McCormick and Thompson, Science 223:296,1984) abolish classically conditioned nictitating membrane responses (NMR) in rabbits. Welsh and Harvey have recently reported deficits in the unconditioned NMR to airpuff. Loss of conditioned responses may be due to a general performance deficit.

Here we made aspiration lesions of cerebellar cortex. NMR conditioning to light and white noise conditioned stimuli (CS) was abolished and there was no sustained reacquisition within 6000 trials over 30 sessions though some responses were emitted erratically in some sessions. Unpaired presentation of the CS did not reveal any extra long latency responses. In contrast to nuclear lesions, these cortical lesions elevated NMR amplitudes and reduced response thresholds to periorbital stimulation, consistent with a loss of cortical inhibition upon the deep nuclei.

We may conclude that loss of conditioned responses is not due to a simple performance deficit. The cerebellar cortex may be crucial for the formation of conditioned responses, their expression, or both.
(SPON:EBBS)

TRANSPLANTATION FOR MOVEMENT DISORDERS

5.1

THE EFFECT OF INTRAVENTRICULAR DA INFUSION ON ROTATION AND STRIATAL BIOCHEMISTRY IN THE RAT. L.C. Kao, P.M. Carvey, J. Kroin*, T.J. Zhang* R. Penn and H.L. Klawans*. Neuropharmacology Research Laboratories. Rush University, Chicago,IL 60612.

It has been assumed that autologous adrenal medulla transplants will secrete significant quantities of DA, and therefore have therapeutic benefit in the treatment of Parkinson's Disease (PD). To examine this hypothesis we evaluated the effect of intraventricular (VENT) or intrastriatal (STR) DA infusion for 10 days in animals that had unilateral 6-OHDA lesions of the medial forebrain bundle (MFB) and compared them with animals with MFB lesions only (UNI).

18 animals with stable contralateral rotation rates for 1 month (apomorphine 0.2 mg/kg) were assigned to 1 of the 3 treatment groups. Cannulae were placed in the striatum or the lateral ventricle ipsilateral to the lesion and connected to 14 day minipumps delivering 10 mcg DA/hr. In contrast to UNI and VENT animals, STR animals exhibited spontaneous contralateral rotations which gradually diminished over the 4 days following implantation. After 7 days UNI and VENT animals did not exhibit significant reductions in apomorphine-induced rotation rate while STR animals exhibited a 58% reduction. After 10 days all animals were sacrificed and the brains frozen in liquid freon within 90 secs of sacrifice. HPLC analysis of 1 mm striatal punches revealed that DA on the ipsilateral side was only able to diffuse a distance of approximately 1 mm in either STR or VENT animals and in neither group was contralateral DA content elevated in any striatal punch. These results strongly suggest that striatal tissue acts as a barrier to DA penetration and that mechanisms other than medullary DA release must be responsible for the clinical efficacy observed in patients following medullary transplants.

5.2

THE EFFECT OF INTRAVENTRICULAR ADRENAL MEDULLA TRANSPLANTS INTO INTACT RATS. P.M. Carvey, J. Kroin*, L.C. Kao, R. Singh*,T.J. Zhang*, R. Penn and H.L. Klawans*. Neuropharmacology Research Labs. Rush U. Chicago,IL 60612

Rat-pup adrenal medulla was transplanted into the lateral ventricle of adult rats in an effort to examine the mechanisms responsible for the reported efficacy of autologous adrenal medulla transplants in Parkinson's Disease patients. Stereotypic behavior (SB) induced by apomorphine (0.6 mg/kg) was decreased in medulla transplant- ed animals (n=6) relative to sham-operated controls (n=6) 3 months following implantation. DA and DA activity ([HVA]/[DA]) were increased in the striatum bilaterally (ipsilateral > contralateral) although both sides were elevated relative to shams. DA-2 receptor numbers were decreased in the striatum (ipsilateral > contralateral) although both sides were reduced relative to shams. This profile of decreased SB and DA-2 receptor number with increased DA activity is consistent with an increase in striatal DA tone subsequent to medulla transplantation. In a second study alterations in [14]C-2 deoxyglucose incorporation were evaluated in intraventricular medulla transplanted animals (n=4) and compared to animals in which sciatic nerve was transplanted into the ventricle (n=4). After 2 months, 3 of 4 medulla transplanted animals exhibited a disproportionate increase in glucose metabolism in the striatum ipsilateral to the transplant (primarily in the dorso-lateral quadrant). Other asymmetries were also observed in the lateral habenula and substantia nigra whereas sciatic implanted animals exhibited no asymmetries. This data also suggests that adrenal medulla transplants increase striatal DA tone. The lack effect in sciatic implanted animals argues against the probability that the effects observed following adrenal medulla transplant are a nonspecific injury potential.

5.3

AUTOLOGOUS ADRENAL MEDULLA TRANSPLANTS REDUCE A DA NEURON SPECIFIC CSF ANTIBODY. H.L. Klawans*, P.M. Carvey, R.D. Penn, C.G. Goetz*, C.M. Tanner*, A. Dahlstrom (1) and A. McRae (1). Rush U. Chicago,IL 60612; (1) U. Goteborg, Sweden 40033.

It has been previously observed that the CSF from 2 Parkinson's Disease (PD) patients contains an antibody (ab) which reacts with dopamine (DA) neuronal populations in the CNS. We have examined the ventricular CSF of PD patients undergoing autologous adrenal medulla transplantation for the presence of this ab. Rat brains were perfusion fixed with 5% glutaraldehyde, coronally sectioned, and incubated overnight with the CSF from patients. Prior to transplantation all 7 transplant patients exhibited immunocytochemical reactivity against rat substantia nigra (SN) neurons. This reactivity gradually decreased in the months following surgery and, in 4/7 patients, disappeared. In contrast, ventricular CSF collected from 7 non-parkinsonian patients did not exhibit this reactivity. In additional studies, 6/7 lumbar CSF samples collected from non-transplanted PD patients exhibited this reactivity whereas lumbar CSF from non-neurologic controls (n=20) did not. In addition, 50 Alzheimer's and multi-infarct dementia as well as 2 multiple sclerosis CSF samples have been examined and were found immunonegative in the rat SN.

Taken together this data suggests that PD patient CSF contains an ab which appears to react with SN neurons and may therefore participate in the patho-physiology of this disease.

5.4

IMPLANT INDUCED CATECHOLAMINERGIC SPROUTING IN MPTP PARKINSONIAN MONKEYS: BEHAVIORAL AND HISTOCHEMICAL STUDIES.
K.S.BANKIEWICZ,R.J.PLUNKETT*,D.M.JACOBOWITZ,I.J.KOPIN, A.CUMMINS*,E.H.OLDFIELD*, NIH,NINCDS/NIMH,Bethesda,MD,20892

We used MPTP hemiparkinsonian (HPD) monkeys as recipients of the brain implants. Tissue was implanted into preformed cavities in the medial caudate nucleus using an open microsurgical technique. We implanted fetal dopaminergic tissue (n=4), fetal non-dopaminergic tissue (n=6), adrenal medullary allografts (n=4) and autografts (n=3), non-dopaminergic adult allografts (n=2). Cavities were left unfilled in six monkeys. Two monkeys were implanted stereotaxicly with an adrenal medulla cell suspension, seven HPD monkeys were left unoperated. Three months after the implantation animals fell into three groups:(i) non-operated and needle implanted monkeys did not change their apomorphine-induced turning over seven months,(ii) 30-60% recovery was observed in animals in which cavities were left unimplanted, non-dopaminergic and adrenal allo and autografted animals,(iii) 70-95% recovery was observed in the fetal tissue-implanted monkeys. Only animals implanted with fetal dopaminergic tissue regained the use of the parkinsonian arm. When examined histochemically we found no tyrosine hydroxylase (TH) activity in the group (i), some TH-positive fibers in group (ii), abundant TH fiber sprouting in the caudate nucleus in the fetal tissue implanted animals [group (iii)]. The sprouted fibers appeared to emanate from the ventral asepect of the striatum in proximity to the n.accumbens. We believe that the sprouted fibers arise from the A-10 cells. These obsrvation indicate that neural sprouting may account for recovery of patients and animals with Parkinson's syndrome after surgical implants.

5.5

MAGNETIC RESONANCE IMAGING OF BLOOD BRAIN BARRIER DISRUPTURE AFTER CATECHOLAMINERGIC IMPLANTS TO THE CAUDATE NUCLEUS OF HEMIPARKINSONIAN MONKEYS. R.S. Miletich,K. Bankiewicz,R.J. Plunkett*,J. Alger*,A. Brunetti*,J. Frank*, G. Di Chiro,E.H. Oldfield*. NINCDS,NIH,Bethesda,MD 20892.

Human trials with adrenal implants for Parkinson's Disease are ongoing with some early favorable results. Several mechanisms have been proposed to explain the post-operative improvement, including blood brain barrier disrupture (BBBD). We investigated the presence of BBBD at the implant site of rhesus monkeys using Magnetic Resonance Imaging with the contrast agent Gadolinium-DTPA,0.1mmol/kg. Animals studied included adrenal autografts, fetal mesencephalic grafts, cavitation without implant and unoperated hemiparkinsonian monkeys. BBBD was manifested as a thin rim of contrast enhancement surrounding the graft bed. BBBD was present within the first 3 months after cavitation or implantation only at the operative site. In one adrenal autograft monkey studied 1 and 3 months after surgery the degree of contrast enhancement decreased over time despite a stable clinical state. After 3 months, no contrast enhancement was seen in any of the animals. The behavioral improvement sometimes seen within a few days of implantation may be partly explained by BBBD. However, these results suggest that BBBD is not the primary mechanism responsible for the long-term clinical improvement seen after certain catecholaminergic implants to the caudate nucleus of hemiparkinsonian monkeys.

5.6

GRAFTING OF HUMAN SYMPATHETIC GANGLIA INTO THE BRAIN OF MPTP-TREATED MONKEYS. P. Pasik, J.F. Martínez*, M.D. Yahr, T. Pasik, G.Holstein and H. Schanzer*. Depts. Neurol., Anat. & Surg., Mount Sinai Sch. Med., CUNY, N.Y., N.Y., 10029.

Sympathetic ganglia were evaluated as a source of dopamine-producing neurons for brain transplants in parkinsonian monkeys. It was expected that the dopaminergic interneurons, contrary to the long-axoned noradreneregic cells, might not be readily damaged by the excision of the ganglia. Two adolescent cynomolgus monkeys were rendered parkinsonian by MPTP treatment. Paravertebral sympathetic ganglia were removed from a patient for the treatment of severe Reynaud's syndrome. After a pathologist verified the nature of the specimen, the remainder was dissected free of connective tissue and divided into small fragments which were deposited stereotaxically into 2-3 loci of the right putamen, after producing a bed by aspiration of putaminal tissue and injecting 10 µl of 0.01% nerve growth factor. One of the monkeys was sacrificed 5.6 months later by aldehyde perfusion, and brain sections were processed for tyrosine-hydroxylase (TH) immunocytochemistry using the PAP technique.

Animals developed parkinsonism after MPTP treatment: hypokinesia, kyphotic posture, rigidity and tremor, and required feeding by nasogastric tube. They recovered spontaneously in about six weeks, and after a second course of MPTP, the full syndrome reappeared. One week following the transplant, they showed improvement and became progressively better, remaining with minimal hypokinesia by 3-4 weeks, and appearing normal by 6-7 weeks. Light microscopy showed: (1) A space at the end of the needle track, partly filled with cells, some of which had neuronal characteristics, lightly stained globular somata, and broad processes. Occasionally, a deeply immunoreactive neuron could be recognized, exhibiting bipolar dendritic branching and an axon penetrating into the host tissue. (2) The neostriatum contained few labeled fibers and, contrary to the n. accumbens septi, appeared very pale. (3) The substantia nigra had few TH+ neurons, but the ventral tegmental area, hypothalamus and locus ceruleus contained numerous labeled cells.

Conclusions: (1) Cross species (human-monkey) grafts of sympathetic ganglia into brain can survive for long periods. (2) Some of its neurons retain the capacity to produce TH. (3) Most probably these neurons are dopaminergic. (4) The behavioral improvement may or may not be attributed to the function of the implant.

IMMUNOHISTOCHEMISTRY OF ADRENAL AUTOGRAFTED AND CAVITATED HEMIPARKINSONIAN MONKEYS. R.J Plunkett*, K. S. Bankiewicz, D.M. Jacobowitz, I.J. Kopin, E.H. Oldfield*, A.C. Cummins*(SPON: A.M. DeLuca) SNB, NINCDS, NIH, Bethesda, Md. 20892 Four hemiparkinsonian Macaque monkeys received adrenal autografts (AM) via an open microsurgical delayed implantation technique; four others had a surgical cavity (CAV) created in the head of the caudate but no tissue implant. In each group, the response to 0.2 mg/kg apomorphine decreased over the ensuing months to less than 50% of the pre-implantation level. Neither group regained use of the MPTP-affected extremity. The AM monkeys were sacrificed 10 days to 8 months after implantation; only the 10 day animal had a significant number of surviving chromaffin cells visualized by tyrosine hydroxylase (TH) immunohistochemistry. The predominant cell at the implant site was the macrophage; there was also a prominent glial response surrounding the site when antibody to gliofibrillary acidic protein was utilized. In 2 of the AM monkeys, and in 3 of the 4 CAV monkeys, there was significant TH reactivity on fibers in the MPTP-lesioned caudate. These TH-positive fibers appeared to be sprouted from the mesolimbic dopaminergic system, in the region of nucleus accumbens. We believe the sprouted fibers are responsible for the behavioral improvement seen.

5.8

ELECTROPHYSIOLOGICAL ASSESSMENT OF REACTION TIME AND MOVEMENT TIME IN PARKINSON DISEASE PATIENTS UNDERGOING ADRENAL-CAUDATE TRANSPLANTATION. R.L. Watts, A.S. Mandir*, B. Hirschfield*, R.A.E Bakay, J.C. Hemphill III*, E.B. Montgomery, Jr. Emory Univ. Sch. of Med., Atlanta, GA 30322 and Washington Univ. Sch. of Med., St. Louis, MO. 63110.

Transplantation of autologous adrenal medullary tissue into the caudate nucleus is a new therapeutic approach for Parkinson disease (PD) patients. Prolonged Reaction Time (RT; a measure of pre-movement neural processing) and Movement Time (MT; the physiological correlate of bradykinesia) are characteristic of PD and are quantitative correlates of functional disability. We are employing a visually instructed RT/MT wrist flexion paradigm in patients both prior to transplantation and at 3, 6, and 12 months post-operatively. We have studied 4 patients with stage IV-V PD when off drugs (ages 48,56,57 & 62), as well as age-matched control subjects for comparison. We measure RT from a "GO" signal both to movement onset (RT/MO) and to onset of agonist EMG (RT/EMG), and MT is measured from movement onset to achievement of a final target. For control subjects, RT/MO is 252±17 (x±SEM msec), RT/EMG is 171±23, and MT is 239±26. At time of RT/MT testing, all patients are examined clinically using a Parkinson disability rating scale. In each patient, pre-op RT/MO (#1-413±26, #2-475±29, #3-434±27, #4-380±32) and RT/EMG (#1-285±47, #2-375±37, #4-280±41) were significantly prolonged from normal controls. Pre-op MT for three of the four patients (#1-418±28, #2-460±40, #3-517±31, #4-220±38) was also significantly prolonged from the control population. At 3 and 6 months post-op, preliminary results from Pt #1 reveal improvement in all movement parameters (3 mo. RT/MO 323±35, RT/EMG 194±46, and MT 348±15; 6 mo. RT/MO 210±16, RT/EMG 120±22, and MT 290±28). Results at 3 and 6 months post-op will be presented for all patients.

131-I-META-IODOBENZYLGUANIDINE SCINTIGRAMS OF ADRENOMEDULLARY AUTOTRANSPLANTS TO THE CAUDATE NUCLEUS OF PARKINSONIANS. A. Graef*, R.E. Franco-Bourland*, A. Márquez*, I. Madrazo, R. Drucker-Colín, C. Torres*, F. Alvarez*, and E. Manzano* (SPON: V. Alemán). Especialidades "La Raza" IMSS 02990 DF, Inst Nal Nutrición SZ 14000 DF, UNAM 45000 DF MEXICO

The autotransplantation of adrenomedullary tissue to the caudate nucleus has been reported by Madrazo et al. (N Engl J Med 316:831,1987; Surg Forum 38:510,1987) to ame - liorate Parkinson's disease symptoms in humans. We now report on the location and viability of the graft after surgery using 131-I-meta-iodobenzylguanidine (131-I-MIBG). This radiopharmaceutical is used to locate pheochromocytoms. It is selectively taken up by storage granules of chromaffin cells by an active, ouabain sensitive mechanism (J Nucl Med 25:P124,1984). Three autotransplanted parkinsonians(P) one patient who underwent neurosurgery of the right frontal lobe(FL) and one suspected of having a pheochromocytoma(PH) received iv 2.5 mCi (P,FL) or 1.25 mCi (PH) 131-I-MIBG. 131-I thyroid uptake was blocked with oral Isodine (5ml,3/d) before (3d) and after (7d) receiving the tracer. The 48h and 72h scintigrams were obtained with a scintillation camera (360 keV, 15% window, high energy parallel collimator) and a Scintiview data processor. Only the brain images of the autotransplanted parkinsonians showed the specific uptake of the label to the caudate nucleus, thus demonstrating the viability of the adrenomedullary graft.

BIOCHEMICAL ANALYSES OF LUMBAR AND VENTRICULAR CSF FROM PARKINSONIANS BEFORE AND AFTER ADRENOMEDULLARY AUTOTRANSPLANTATION TO THE CAUDATE NUCLEUS. R.E. Franco-Bourland*, I. Madrazo, R. Drucker-Colín, C. Torres*, F. Alvarez*, P. Carvey*, D. O'Connor*, R. Sierra & J. Tamayo (SPON: J. Villarreal). Inst. Nal. Nutrición SZ 14000 DF, "La Raza" IMSS 02990 DF, UNAM 45000 DF, MEXICO; Rush-Presbyterian Chicago IL 60612, Vet Adm Med Ctr San Diego CA 92161 USA.

Madrazo et al. (N Engl J Med 316:831,1987; Surg Forum 38:510,1987) have reported on the amelioration of Parkinson's disease symptoms after adrenomedullary autografting to the caudate nucleus in humans. In order to acquire an insight into the biochemical mechanisms underlying the beneficial effects of this procedure we have undertaken a collaborative study to assess in 6 operated parkinsonians their pre- & post-transplantation levels of HVA, 5-HIAA, MHPG (by HPLC-ED, PC), chromogranin A (by RIA, DO) & cAMP (by RIA, RS & JT) in lumbar (L) and ventricular (V) CSF over a period of 3-4 months. Pre- & post-surgery,L & V levels of HVA & 5-HIAA were not significantly different; L levels ranged between 20 & 120 ng/ml, & between 20 & 60 ng/ml, respectively; V levels ranged between 120 & 300 ng/ml & between 60 & 100 ng/ml, respectively. Pre- and post-surgery, L & V levels of MHPG were indistinguishable & fluctuated between 5 & 20 ng/ml. L & V levels of chromogranin A also remained unchanged after surgery. L levels varied between 20 & 80 ng/ml and V levels between 0 & 20 ng/ml. Pre and post cAMP,L & V levels were similar(20-60 pm/ml).

5.11

HUMAN FETAL SUBSTANTIA NIGRA AND ADRENAL MEDULLARY TISSUE HOMOGRAFTS TO THE CAUDATE NUCLEUS OF PARKINSONIANS.
I. Madrazo, R. Drucker-Colín, R.E. Franco-Bourland*, F. Ostrosky*, M.C. AGuilera*, and C. Torres*. Especialidades La Raza, IMSS, 02990 DF, UNAM, 45000 DF, INNSZ, 14000 DF, México.

We recently made a preliminary report (N Engl J Med : 318:51,1988), of two cases of human fetal transplants to relieve Parkinson's disease (PD). One case is a 50-year-old man with a 9 year history of PD, who received a substantia nigra fetal homograft to the caudate nucleus. At the time of surgery he had a UPRS score of 59 points and was on a dose of Sinemet of 1000 mg. Three months after surgery he had a score of 45 points. Now, 6 months after surgery he has a score of 5 points, and is receiving 375 mg Sinemet to control the remaining tremor and an oral dose of cyclosporine of 1 mg/kg bw/day.

The second case is a 35-year-old woman with a 5 year history of PD, who had a preoperative UPRS score of 71 points, while under treatment with 750 mg Sinemet. She received a fetal adrenomedullary homograft to the caudate nucleus. Three months after surgery her score was 35 points and now she has a score of 13 points, and is receiving a dose of 375 mg Sinemet, and 1 mg/kg bw/day cyclosporine.

The excellent postoperative tolerance to the procedure in these patients, and the extensive neurobiological data appear to support human fetal grafting as the best procedure to treat PD, but further experience is needed to confirm this contention.

5.12

CATECHOLAMINES AND METABOLITES IN TISSUES AND IN CSF OF PATIENTS WITH PARKINSON'S DISEASE AFTER AUTOLOGOUS TRANSPLANTATION OF ADRENAL MEDULLA TO CAUDATE NUCLEUS.
G. M. Tyce, J. E. Ahlskog*, S. W. Carmichael, S. L. Chritton*, S. L. Stoddard, J. A. van Heerden*, and P. J. Kelly*. Dpts. of Physiology, Neurology, Anatomy, Surgery, and Neurosurgery, Mayo Clinic, Rochester, MN 55905.

Measurements were made of the concentrations of norepinephrine (NE), epinephrine (E), and dopamine (DA) in host and in transplanted tissues in seven patients who were undergoing autologous transplantation of adrenal medulla to caudate nucleus as treatment for Parksinson's disease. In addition, free and sulfated NE, E, and DA, 3-methoxy-4-hydroxyphenylglycol (MHPG) and homovanillic acid (HVA) were measured in lumbar CSF taken before and at two 6-weekly intervals after the surgery. Quantitation of analytes was by HPLC with electrochemical detection. The concentrations of DA in small samples of caudate (removed to create a donor bed) and in samples of adrenal medulla were similar (~4 µg/g). NE and E were barely detectable in caudate but were ~502 and 3,492 µg/g, respectively, in adrenal medulla. In all CSF samples the concentrations of MHPG and free and sulfated NE and E were in the normal range. Free DA was never detected (<40 pg/ml) in CSF. After the transplant sulfated DA increased modestly in CSF, but HVA was unchanged. In summary, analyses of catecholamines in lumbar CSF suggested that the adrenal graft did not produce NE and E after the transplantation, and that production of DA sulfate was modestly increased.

5.13

IMPLANTS OF HUMAN VENTRAL MESENCEPHALIC NEURONS AND PERFUSED ADRENAL MEDULLARY TISSUE INTO THE CAUDATE NUCLEUS OF PARKINSON'S PATIENTS PRELIMINARY RESULTS.
Juan J. Lopez-Lozano[1,2], G. Bravo[3*], J. Abascal[4*] and CPH Neural Transplantation Group*. Dept. of Exp. Surgery[1], Neurology[2], Neurosurgery[3] and Surgery[4]. Clinica Puerta de Hierro. University Autonoma. Madrid. Spain.

The encouraging results obtained by Madrazo et al., Jiao et al, Molina et al. and Lopez-Lozano et al., after transplantation of autologous adrenal medulla (AM) into the caudate nucleus of patients with Parkinson's disease seem to indicate this technique as an alternative treatment of the disorder. Since the clinical improvement reported has not been completely satisfactory, because of the high morbidity and mortality, we attempt new sources of donor tissue. This report examines and compare the effect of transplanting perfused neonatal adrenal medullary or fetal ventral mesencephalic (VM) tissue into right caudate nucleus of Parkinson's patients. VM was dissected from human fetuses of different ages of gestation. In the case of AM tissue, the adrenal gland was cannulated and perfused (JJLL,'88) to improve the dissection procedure. Fragments of either ventral mesencephalon or adrenal medulla were selected to be implanted into the right caudate nucleus, in contact with the lateral ventricle wall, of immunosuppressed Parkinson's patients. To analyze the viability and purity of the implanted tissue, the remaining VM or AM tissue was dispersed by an enzymatic-mechanical procedure. The recovered cell suspension were cultured or implanted into 6-OHDA lesioned rats and subsequently studied by catecholamine-containing histofluorescence and TH-ICC, showing that they contained catecholamine and expressed TH. All patients have been evaluated pre- and post-operative with video, Columbia rating scale, NWDS, Unified Parkinsonism rating scale. Catecholamines and their metabolites have been measured in CSF by HPLC before and after transplantation. This report will show the clinical and neurochemical data obtained after transplantation and will evaluate and discuss the clinical usefulness of cited source donors vs autotransplanting adrenal medullary tissue.

EPILEPSY I

6.1

ABNORMALITIES IN TEMPORAL LOBE EVENT-RELATED POTENTIALS PREDICT HIPPOCAMPAL CELL LOSS IN TEMPORAL LOBE EPILEPSY.
C.C. Wood, G. McCarthy, J.H. Kim, D.D. Spencer, and P.D. Williamson. VA Medical Center, West Haven, CT 06516 and Yale University School of Medicine, New Haven, CT 06520.

Relationships between task-related Event-Related Potentials (ERPs) recorded intracranially from sites in the temporal lobes of epileptic patients and the side of seizure onset have been noted by a number of investigators (*e.g.*, Squires *et al.*, 1983; McCarthy *et al.*, 1987; Meador *et al.*, 1987). Here we demonstrate that abnormalities in task-related ERPs predict the severity of hippocampal cell loss in the affected temporal lobe.

Twenty-four patients in whom both temporal lobe ERPs and cell counts on excised temporal lobe tissue were available were studied. Cell counts (neurons per mm^3 in CA1, CA2, CA3, CA4, and dentate gyrus) and ratings of ERP normality were made blind with respect to each other. Correlations (Pearson *r*) between ERP ratings and cell counts in the four CA fields and dentate gyrus ranged from .57 – .67 and were all statistically significant ($P < .01$). Corresponding rank-order correlations were lower by about .05 and were again all significant ($P < .01$). Cell counts in the CA fields and dentate gyrus were themselves highly correlated ($.5 \leq r \leq .7$); mean cell count across fields was correlated .72 with ERP ratings ($P < .01$).

These results demonstrate that task-related ERPs recorded from the medial temporal lobe are as highly correlated with cell counts in the hippocampal CA fields and dentate gyrus as the cell counts are among themselves. Such ERPs may therefore be of value in estimating the severity of hippocampal pathology before temporal lobe excisions. These results also implicate the hippocampal CA fields and dentate gyrus as generators of, or part of the circuit which generates, task-related ERPs in the medial temporal lobe.

6.2

INCREASED AMYGDALA ACTIVATION OF SUBICULAR NEURONS IN HUMAN TEMPORAL LOBE EPILEPSY.
M. Isokawa-Akesson, C.L. Wilson and T.L. Babb. Brain Research Institute and Dept. Neurology, UCLA, Los Angeles, CA 90024-1761.

In our previous study (Isokawa-Akesson et al., 1987, NS Abstr. 13:365), interictal recordings showed a decreased neurotransmission in hippocampal-subicular pathways of human temporal lobe epilepsy based on extracellular single unit recording and single pulse stimulation. The present study was designed, using the same experimental procedure, to investigate whether another afferent to the subiculum, i.e. the amygdalo-subicular path, is altered in its neurotransmission in correlation with the decreased hippocampal-subicular path in temporal lobe epilepsy. Single pulse electrical stimulation was administered to the amygdala (AMYG) and single unit recordings were obtained from the presubiculum (PRESUB). In controls (in the temporal lobe contralateral to the seizure origin), 3 out of 14 (21.4%) PRESUB neurons responded to AMYG stimulation and the responses were only inhibitory with an average latency and duration of 75 msec and 273 msec, respectively. By contrast, in the epileptic, AMYG stimulation evoked PRESUB responses in 6 out of 8 neurons (response probability: 63.6%), and the responses were characterized by excitation (3/6cells), inhibition (2/6cells), or preceding excitation followed by inhibition (1/6cells). The average latency of excitation was 32 msec and the average latency of inhibition was 52 msec. Mean inhibition lasted 165 msec. Interestingly, this response pattern in PRESUB by epileptic AMYG stimulation could be elicited in the normal PRESUB 56% of the time by normal hippocampal (HIPP) stimulation. (When epileptic HIPP was stimulated, neither excitation nor inhibition was evoked in any of the 7 neurons recorded from the adjacent PRESUB.) Our results suggest that AMYG activation of the PRESUB is enhanced in epileptic human hippocampal formation during interictal periods.

6.3

SOMATOSTATIN AND β-ENDORPHIN LEVELS IN INTERICTAL AND POSTICTAL CSF OF EPILEPTIC PATIENTS. A. Pitkänen* and P.J. Riekkinen. Dept. of Neurology, Univ. of Kuopio, P.O.Box 6, SF-70 211 Kuopio, Finland.

Neuropeptides are proposed to play a role in the regulation of interictal behavior and seizure threshold in experimental models of epilepsy. In this study we, firstly, compared the levels of somatostatin (SLI) and β-endorphin (BEP) by radioimmunoassay in interictal CSF of unmedicated (n=18) and medicated (n=24) epileptic patients with the levels of peptides in controls (n=20). Patients with chronic medicated epilepsy had SLI level 80 % (p=0.003, Mann-Whitney U-test) that of the controls and 76 % (p=0.011) that of the unmedicated patients. BEP in the interictal CSF did not differ in unmedicated, medicated and control patients. Secondly, to study the peptidergic systems in postictal stage of human epilepsy we collected CSF from nine patients within two hours after generalized tonic-clonic convulsion (GM), and the second sample from the same patients was obtained interictally after 1-4 days without any kind of clinically observable seizures. BEP was elevated postictally (p=0.044, Wilcoxon's test) compared with the interictal level. SLI was similar in both samples. The present study suggests that BEP is released into extracellular space during GM and may be involved in the depression of seizures. Instead, during the period when epilepsy becomes chronic the somatostatinergic cells are affected.

6.4

ELECTROGRAPHIC RECORDINGS DURING AUDIOGENIC SEIZURES IN FREELY MOVING RATS. N. Ludvig* and S.L. Moshé, Dept. of Neurology, Albert Einstein College of Medicine, Bronx, NY 10461

The EEG changes during audiogenic seizures (AS) have not been well described in freely moving rats because of the technical difficulties introduced by the movement artifacts. With the use of a special recording apparatus equipped with a field effect transistor and a liquid commutator we were able to eliminate most of the movement artifacts and could study the EEG of the AS in the genetically AS-susceptible GEPR-9 rats. Recordings were made from the inferior colliculus (IC) which is considered to be a crucial structure in the pathogenesis of AS. We found that 7.6 ± 1.7 (mean ± S.E.M.) sec after the acoustic stimulus (104 dB), repetitive spike and wave discharges occurred lasting 20-50 sec. The epileptiform discharges were initially associated with wild running seizures and later on with clonic-tonic convulsions. One - two minutes after the end of the convulsions interictal spikes appeared. During this period the rats were immobile with fixed gaze. The data indicate that AS are associated with paroxysmal electrographic discharges recorded from the IC.

6.5

PRINCIPAL COMPONENT ANALYSIS OF LAMINAR CURRENTS PRODUCED BY PENICILLIN SPIKES IN RAT CORTEX. D.S.Barth., S.Di* and C. Baumgartner*(1) Dept. of Neurology and Psychology, Univ. of California, Los Angeles, CA 90024. (1).Neurological Univ. Clinic, Vienna, Austria.

Recent studies using laminar microelectrode recordings have suggested a systematic sequence of neuronal activation in distinct cortical lamina during both normal evoked responses and epileptic spiking. In the present study, we mapped laminar field potentials from the temporal cortex of 5 rats during the direct cortical response (DCR) produced by electrical stimulation and during electrically evoked interictal spikes (EIIS) of the penicillin focus. Current source-density (CSD) distributions were computed from the field potentials to highlight laminar changes in transmembrane currents during the time course of the evoked responses. Finally, the spatial and temporal pattern of CSD was studied with principal component analysis (PCA).

PCA indicated that cellular currents overlapping in space and time during both the DCR and the EIIS are produced by a highly stereotyped interaction between neurons in the upper and the deepest cortical lamina. The sequence, polarity, and location of neuronal activation was not altered by penicillin. The main effect of penicillin was to triple the duration and amplitude of membrane currents during the EIIS as compared to the DCR. These data suggest that penicillin spikes use the same neuronal circuitry as the DCR, but with pathologically enhanced synaptic currents.

6.6

CHRONIC EFFECTS OF SYSTEMIC APPLICATIONS OF KAINIC ACID ON mRNA LEVELS OF NEUROPEPTIDES IN RAT BRAIN. D.K. Meyer*, C. Olenik* and G. Sperk* (SPON: D.J. Dooley). Dept. of Pharmacol., University of Freiburg, D-7800 Freiburg (FRG); Dept. of Pharmacol., University of Innsbruck, A-6020 Innsbruck (Austria).

Intraperitoneal injection of kainic acid causes in rats acute limbic motor seizures and subsequently long-lasting changes in levels of the neuropeptides somatostatin and cholecystokinin in substantia nigra, striatum, frontal cortex and hippocampus. To find out whether these changes are concomitant with altered gene transcription, concentrations of mRNA's coding for the respective prepropeptides were measured with a filter hybridisation technique.
In all areas investigated, concentrations of mRNA's coding for both prepropeptides were enhanced 2 days after kainic acid. This suggested an increased synthesis of both peptides subsequent to their presumed enhanced release during the acute seizures. With the exception of the frontal cortex, levels had returned to control values 8 days later. In frontal cortex, the increases in mRNA concentrations for both prepropeptides persisted up to 30 days.
These changes in mRNA together with the previously observed increases in peptide levels indicate that somatostatin- and cholecystokinin-neurons in frontal cortex have a persistently increased activity, which may be related to the enhanced seizure susceptibility of these rats.

6.7

DIFFERENTIAL RESPONSES OF SOMATOSTATIN, NPY, CCK-8 AND VIP IN KAINIC ACID-INDUCED EPILEPSY IN THE RAT. G. Sperk*, J. Marksteiner* and D.K.Meyer* (SPON: O. Hornykiewicz). Dept. of Pharmacology, Univ. of Innsbruck, Innsbruck, Austria.

Somatostatin, neuropeptide Y (NPY), cholecystokinin octapeptide (CCK-8) and vasoactive intestinal polypeptide (VIP) were measured in various brain areas after limbic seizures induced by kainic acid (10 mg/kg, i.p.) in the rat. Reversible decreases (20-60%) in immunoreactivities of the peptides were found 3 h after injection of the toxin suggesting significant release during the preceding acute seizures. In contrast to this, marked increases of somatostatin, NPY and CCK-8 occurred in the frontal cortex (somatostatin by 60%; NPY, 200%; CCK-8, 35%) and of NPY and CCK-8 in the hippocampus (150% and 50%, respectively) after 10-60 d. The time course of maximal elevation of these peptides was slow but long lasting and was accompanied by an increase of glutamate decarboxylase (Vmax, 22%) in the frontal cortex. This was contrasted in the cortex by an only transient increase of VIP (50%) already 3 d after kainic acid which was again normalized after 10 d. Whereas the reversible increase in VIP (partly contained in local cholinergic neurons) may relate to the acute seizures, the late and non-reversible increases of somatostatin, NPY, CCK-8 and of glutamate decarboxylase may reflect activation of a family of neuropeptide/GABA neurons as a response to the long lasting decreased seizure threshold in the animals.

6.8

SEIZURE ACTIVITY OF TWO PEPTIDES DERIVED FROM DIAZEPAM BINDING INHIBITOR (DBI) AFTER INTRAHIPPOCAMPAL INJECTION IN RATS. C.Ferrarese[1], M.A.Stasi*, R.Samanin* and A.Vezzani. [1]Clinica Neurologica, Università di Milano, Ospedale S.Gerardo, Monza and Istituto "Mario Negri", Milano, Italy 20100

Fragments (FR) 42-50 and 43-50 are products of tryptic digestion of DBI (104 aminoacids), an endogenous peptide that modulates GABAergic neurotransmission. The two peptides were unilaterally injected into the dorsal hippocampus (granule cells of dentate gyrus) of freely-moving adult rats. The EEG pattern was continuously recorded from bilateral hippocampal and cortical electrodes. 100 nmol FR 42-50 induced in all the rats seizures and EEG alterations quantitated as follows: total No seiz.11±2.5 with a latency of 11± 3.5 min, a total time in seiz. of 947±322 sec and a total time of EEG alterations (seiz.+spikes) of 1338±289 sec (n=7). 150 nmol FR 43-50 induced a qualitatively similar but less intense EEG pattern. During EEG seizures the rats had the typical "frozen appearance" and "wet dog shakes" often occurred. Tonic-clonic seizures were not observed. Protection from seizures induced by FR 42-50 occurred with 90 mg/kg PK 11195, a selective antagonist of the peripheral-type of the benzodiazepine receptors. Blockade of the N-methyl-D-aspartate-type receptors in the hippocampus did not suppress seizures. The two fragments induced only marginal, possibly non-specific, neuronal degeneration. The possible role of DBI-related peptides in the pathophysiology of epilepsy will be discussed.

6.9

MODULATION BY SMS 201-995, A SYNTHETIC ANALOG OF SOMATOSTATIN (ST), OF LIMBIC SEIZURES INDUCED BY INTRAHIPPOCAMPAL INJECTION OF QUINOLINIC AND KAINIC ACIDS IN RATS.
A. Vezzani, M.A. Stasi*, R. Serafini*, M.G. De Simoni*, F. Fodritto* and R. Samanin* Istituto "Mario Negri", Milano, Italy

One hundred twenty and 60 nmol quinolinic acid (QUIN) or 0.19 nmol kainic acid (KA) were unilaterally injected in the dorsal hippocampus of freely-moving adult rats. Fifteen min later, 5 μg SMS 201-995 (SMS), a ST analog highly resistant to enzymatic degradation, were delivered at the same site. The EEG pattern was continuously recorded from bilateral hippocampal and cortical electrodes. SMS displayed neither anticonvulsant nor proconvulsant activity when EEG seizures were induced by 120 and 60 nmol QUIN injected in stratum radiatum (SR) CA1. SMS significantly protected from seizures induced by 0.19 nmol KA injected in SR CA1 (PBS+KA: No seiz.11±1 (8), total time in seiz. 1085±174 sec; SMS+KA: No seiz. 2.6±0.8 (8), total time in seiz. 199±60 sec) and a delay in the onset of seizures was also observed (16±3.9 min vs 66±24 min) ($p < 0.05$ for all measures, Student's t-test). SMS was ineffective on seizures when KA was injected within the hilus of the dentate gyrus. KA was equipotent as a convulsant after injection in the SR CA1 and in the hilus.

The effects of QUIN and KA on the endogenous hippocampal ST, measured by in vivo voltammetry, will be shown.

The role of the cholinergic system in the modulatory action of ST on seizures will be discussed.

6.10

A_1 ADENOSINE RECEPTOR ACTIVATION BLOCKS SEIZURES INDUCED BY BICUCULLINE METHIODIDE IN THE RAT PREPIRIFORM CORTEX.
P.H. Franklin, Ge Zhang*, E.D. Tripp* and T.F. Murray. College of Pharmacy, Oregon State University, Corvallis, OR 97331.

It is now clear that adenosine receptors play a primary role in the mediation of CNS inhibitory function. In accordance adenosine or metabolically stable adenosine analogs express anticonvulsant activity in a number of experimental models of epilepsy. Neither the anatomical nor the functional basis for the anticonvulsant effects of adenosine (ADO), however, have been well established in the CNS. We have previously reported (Franklin et al., European J. Pharmacol., in press, 1988) that seizures induced by microinjection of bicuculline methiodide (BMI) into the prepiriform cortex (PC) are potently (ED_{50}= 32.2±0.3 pmol) and completely blocked by prior injection of the ADO agonist 2-Chloroadenosine (2-ClA). To characterize the ADO receptor involved in this response, dose response relationships for a series of ADO agonists were evaluated. The rank order of potencies for these compounds is as follows: N-Ethylcarboxamidoadenosine>Cyclohexyladenosine> Cyclopentyladenosine>R(-)(2-Phenylisopropyl)-adenosine> 2-ClA>>S(+)(2-Phenylisopropyl)-adenosine>>2-Phenylamino-adenosine. These results suggest that potency at adenosine A_1 receptors is the basis for protection by these compounds against seizures induced by BMI in the PC. (supported by NS-23227 to T.F.M.)

D-1 BUT NOT D-2 DOPAMINE RECEPTOR STIMULATION REDUCES THE THRESHOLD FOR PILOCARPINE-INDUCED EPILEPTIC ACTIVITY IN RATS.
P. Barone*, S.A. Parashos, V. Palma*, C. Marin*, G. Campanella* and T.N. Chase. Experimental Therapeutics Branch, NIH, Bethesda, MD 20892; Dept. of Neurology, University of Naples, Italy; Ist. Sci. Sanatrix. Venafro, Italy.

Experimental evidence indicates a role for GABAergic striatonigral projections in inhibiting the propagation of epileptic activity. D-1 dopamine receptors, found on such terminals in nigra pars reticulata probably modulate GABA release. The present study evaluated the effects of dopamine receptor stimulation on pilocarpine-induced limbic seizures. Pilocarpine produces limbic stereotypies, but not convulsions or seizure-related brain damage at a dose of 200 mg/kg ip. Administration of the D-1 agonist SKF38393 5 min prior to this dose of pilocarpine induced generalized convulsive activity as revealed by behavioral and electroencephalographic alterations and histopathological findings (ED_{50}=1 mg/kg, ip). Similar effects were produced by a high dose of pilocarpine (400 mg/kg, ip). The D-1 antagonist SCH23390 prevented both pilocarpine (400 mg/kg) and SKF 38393 plus pilocarpine (200 mg/kg) induced seizures in a dose dependent manner. Response to pilocarpine was unaffected by the D-2 agonist LY171555 (0.1-10 mg/kg, ip). Conceivably pharmacologic manipulation of dopaminergic transmission could provide an alternative approach to the treatment of secondarily generalized epilepsy.

6.12

KINDLING ANTAGONISM: THE EFFECTS OF COMBINED NEONATAL AND ADULT 6-HYDROXYDOPAMINE TREATMENT.
J. Burchfiel and C. Applegate. Dept. Neuroscience The Children's Hospital, Boston, MA 02115.

Recent evidence suggests a role for norepinephrine (NE) in the development of site suppression and dominance observed following concurrent, alternate stimulation of the septal nucleus (S) and entorhinal cortex (EC; kindling antagonism). Neonatal treatment with 6OHDA produces a forebrain depletion but a hindbrain hyperinnervation by NE at adulthood, and the development of kindling antagonism remains intact. To what degree is brainstem innervation by NE necessary for the development of antagonism?

Rats treated with 6OHDA as neonates were subsequently administered a low dose (75ug; N=8) or a high dose (200ug; N=9) of 6OHDA or vehicle (N=8) as adults. Rats were implanted with stimulating electrodes into the S and EC and were stimulated in the antagonism paradigm. High dose treatment, but not low dose or vehicle treatment interfered with the development of kindling antagonism. This suggests that some brainstem innervation by NE is necessary for the development of antagonism. The quantitative relationship between regional biochemical treatment effects and antagonism seizure profiles are currently being assessed.

6.13

SENSORY KINDLING IN GERBILS IS A PROTEIN DEPENDENT PROCESS REQUIRING PREVIOUS SEIZURE.
Paul L. Prather* & W.B. Iturrian, Pharmacology, Univ. of GA, Athens, GA 30602.

We show "sensory"kindling" (KIN) in gerbils with planned periodic reexposure to handling and report pharmacological correlates of KIN development and expression. In naive animals over 90 days old, only 40% seizure on initial test. Four seizure tests with a 3 day inter-test interval and a 5th test a week later produces kindling with 95% seizures. Seizure incidence and severity were recorded at all tests and drugs were given before tests 2, 3, and 4 only. Diazepam (1mg/kg) before testing was anticonvulsant reducing seizure incidence about 75%. Phenytoin (50mg/kg) was only half as effective. Both drugs retard full expression of KIN since test 5 (drug free) seizure incidence was reduced 20-30% relative to saline control. Cycloheximide (CXM) (25mg/kg) inhibited KIN development 40% and expression by 32%. Clonidine (0.075 mg/kg) was unique in that although seizure incidence during development was reduced 40%, KIN was fully expressed at test 5. Yohimbine (1mg/kg) and CGS 8216 (4mg/kg) had no effect on either KIN development or expression. These results indicate that CXM sensitive proteins induced by testing facilitate, while alpha$_2$ mechanisms inhibit KIN development. Full KIN expression depends on a prior CXM sensitive convulsive experience suggesting a protein dependent memory-like process. Endogenous BDZ's do not appear to be involved. Finally, development and expression of KIN are controlled by different endogenous systems.

7.1

SELECTIVE VULNERABILITY OF MESENCEPHALIC NEUROMELANIN-PIGMENTED NEURONS IN PARKINSON'S DISEASE. E. C. Hirsch*, A. M. Graybiel, Y. A. Agid*. (SPON: F. O. Schmitt) Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

It is well established that mesencephalic dopaminergic neurons are affected in Parkinson's disease (PD), but it is not yet clear whether a subpopulation of these neurons is more vulnerable than the others. The number of catecholaminergic (CA) neurons (immunostained with antiserum against tyrosine hydroxylase), neuromelanin-pigmented neurons and non-CA neurons in mesencephalic dopamine-containing cell groups was estimated in control (n=3) and parkinsonian (n=4) midbrains. Only a subpopulation of the catecholaminergic neurons contained pigmented neuromelanin in controls. These cells were most numerous in the substantia nigra pars compacta, less common in cell group A8 and least common in the central gray substance. In PD the cell loss among the catecholaminergic neurons was directly correlated (r=0.97) with the percent of pigmented neurons normally in these cell groups. The non-pigmented-CA neurons were relatively spared compared to those containing visible neuromelanin pigment. The preferential vulnerability of neuromelanin-pigmented neurons in PD could be related to the capacity of neuromelanin to bind toxic compounds such as MPP+. The topography of cell loss may also be important. *Supported by the Seaver Institute, the Edith C. Blum Foundation, the Tourette Syndrome Association, the McKnight Foundation, the Whitaker Foundation, the Fondation Simone et Cino del Ducca, and INSERM.*

7.2

LOCALIZATION OF TYROSINE HYDROXYLASE mRNA IN TYROSINE HYDROXYLASE IMMUNOSTAINED CELLS IN HUMAN MESENCEPHALON BY IN-SITU HYBRIDIZATION. F.JAVOY-AGID*,S.DUMAS* (1),E.HIRSCH*, J.C.BISCONTE*(2),Y.AGID*,J.MALLET*(1),(SPONS:E.L.GUSTAFSON) Inserm U 289 Hopital Salpêtriere,75013 Paris,(1) Neurobiologie Cellulaire et Moleculaire CNRS,Gif-sur-Yvette 91190, (2) Biocom S.A. Çourtaboeuf 91942, FRANCE.

In Parkinson's disease,dopamine cells in the substantia nigra are more dramatically affected than those in ventral tegmental area suggesting biochemical distinctions between the two cell groups. Detection of specific messenger RNA (mRNA) by in situ hybridization histochemistry was investigated to study the level of tyrosine hydroxylase (TH) gene expression in the two populations of dopamine cells identified by their content in TH. 35-S-labelled cDNA probe complementary to TH mRNA was used on paraformaldehyde picric acid fixed tissue sections. In situ hybridization was followed by TH immunohistochemistry on the same section. Radiolabelled hybrids were detected by autoradiography with nuclear emulsion.

TH mRNA was detected in TH immunoreactive neurons. Differences in the levels of TH mRNA were observed among the dopamine cells. The number of cells expressing TH mRNA decreased dramatically in patients with Parkinson's disease.

DIVERSITY OF ULTRASTRUCTURAL CHANGES OBSERVED IN THE NEUROPILE OF THE CAUDATE NUCLEI OF PARKINSONIAN PATIENTS. JP.Machado-Salas,D.Martínez*J.Aceves A.Cornejo*O.Ibarra*J.Valadez*J.Kuri*J.Guzmán*and A. Bazaldúa*Neuromorfología,Neurocs,ENEP Iztacala UNAM,Neurociencias,CIEA,IPN,México,D.F.,Neurocir Neurología Cto Med Occid IMSS Guad,Jal.,and Neurocir,Hosp Espec. Puebla, Puebla. MEXICO

Recent attempts to cure Parkinson's disease by autologous implant of adrenal medulla into the Caudate nucleus, have shown rather diverse and incongruous clinical evolution.Our multidisciplinary and interinstitutional research group has approached this question.Here, we report our preliminary E/M findings made in the neuropile of caudate nuclei obtained during surgery, while lodging the implant in Parkinsonians.Each patient showed a different degree of neuropile degeneration, but the presence of cytoplasmic neuronal vacuoles, spinulae (at axo-spinous synapses),elongated nuclei in degenerated cells, axonal degeneration and diverse amount of dense-core vesicles were the most oustanding differences from one case to another. Our findings provide the first ultrastructural data that allow to postulate the existence of several populations of PK patients, who shall respond differently to medical and surgical therapies.

AUTOPSY FINDINGS IN A PARKINSON'S DISEASE PATIENT TREATED WITH ADRENAL MEDULLARY TO CAUDATE NUCLEUS TRANSPLANT F.C. Dohan* J.T. Robertson* C. Feler* J. Schweitzer* C. Hall * J.H. Robertson* (SPON:A.R.Wyler)Dept of Neuropathology,Univ. of TN,Memphis, TN 38163

We report a patient with Parkinson's disease transplanted with autologous adrenal medulla to caudate necleus who had multiple post operative complications and died 121 days after surgery. During hospitalization she showed no clinical improvement. At autopsy, microscopic examination revealed the characteristic CNS findings of Parkinson's disease, but examination of the graft showed necrotic tissue, macrophages, blood vessels, fibroblasts, collagen, chronic inflammatory cells, and occasional foreign body giant cells. No chromaffin cells could be identified in numerous sections stained by both H & E as well as the immunoperoxidase method. The results of this study suggest the need for caution in interpreting the mechanism for any long term beneficial result that might be obtained from this procedure.

7.5

CATECHOLAMINE LEVELS ARE REDUCED IN THE ADRENAL MEDULLA OF PARKINSON PATIENTS RECEIVING AUTOLOGOUS TRANSPLANTATION. M.G. Hartman*, N.G.F. Cooper and J.T. Robertson* (SPON: W. L. Byrne). Depts. of Neurosurgery, Anatomy and Neurobiology, Univ. of Tenn., Memphis, TN 38163.

Adrenal medulla harvested at the time of autologous transplantation into caudate nucleus for treatment of intractable Parkinsonism was assayed for catecholamines. Tissue was obtained from five patients age 46 to 64 (mean 56.6) with symptom duration of 5 to 27 years (mean 11.8). All had severe bradykinesia, with varying degrees of rigidity and tremor. Each was maintained on carbidopa/L dopa until surgery. Grossly, the medullary tissue appeared atrophic and was unremarkable on histologic examination. Medulla was disected free from the gland in Euro-Collins solution (4 ^{0}C) and then stored in liquid nitrogen prior to analysis. High performance liquid chromatography with electrochemical detection was used to assay the tissue levels of norepinephrine, epinephrine, and dopamine. Catecholamine levels (ug/mg protein) were markedly decreased in four of five patients. Mean reductions of 75% from post mortum controls were noted in each catecholamine assayed, although one patient had a level approaching that of age-matched controls. Compared to medulla obtained from brain-dead patients at the time of organ procurement, concentrations were significantly reduced. Epinephrine was the predominate catecholamine, with mean level of 84.4 µg. It accounted for 91.5% of the total assay,and norepinephrine 8.2%. Mean norepinephrine concentrations of 7.6 µg were found. Dopamine was present in small amounts, mean 0.21 µg, or 0.3% of the total catecholamines measured. No age, drug, dose, or duration of symptom correlation was identified. Since anesthetic technique, and timing of surgery were identical in each case, and as no post mortum interval was involved, these levels are felt to be highly representative of the *in vivo* status of medullary tissue. This data suggests that the catecholamine depleted adrenal medulla from Parkinson's patients may be unsuitable for autologous transplantation. Supported in part by NIH:NEI EY02708.

TRANSCORTICAL INTRAVENTRICULAR ADRENAL MEDULLARY GRAFTING IN THE TREATMENT OF HEMI-PARKINSON MONKEYS. R. A. E. Bakay, K. Sweeney,* H. Colbassani,* R. L. Watts, P. M. Iuvone, L. Byrd. VA Medical Center, Emory University, Atlanta, Georgia 30322.

In order to investigate the most commonly used adrenal medullary (chromaffin) grafting technique. Nine M mulatta (2-4 years old) were used in this study. After baseline studies were obtained, hemiparkinsonism was induced by titrated intracarotid injections of 0.4-0.8 mg/kg MPTP. Followup studies performed for at least 4 months following MPTP intoxication. Once an adequate data base was achieved, chromaffin tissue was grafted to the head of the caudate.

Apomorphine (0.15 mg/kg)-induced rotation varied up to 35% in control subjects but did not improve over 6 mos. or longer. A marked decrease in rotational behavior was observed 1 mo. after grafting and persisted for at least 9 mos. Amphetamine (0.5 mg/kg)-induced rotation was significantly less in transplanted subjects as compared to controls. Biochemical and electrophysiological studies were also performed. Symptomatic hemiparkinson animals anatomical studies demonstrated a >80% depletion of substantia nigra TH immuno-reactive cells. Chromaffin volume was reduced to 30-20% of original implant size and surviving chromaffin cells were less than 10% of the original graft. Chromaffin cells were identified by TH, DBH, PTNM immunocytochemical staining and two separate types of chromaffin histological techniques.

REJECTION OF FETAL SUBSTANTIA NIGRA ALLOGRAFTS IN MONKEYS WITH MPTP-INDUCED PARKINSON'S SYNDROME. C.R. Freed, J.B. Richards, C.J. Hutt*, E.H. Kriek, and M.L. Reite, Depts. of Med., Pharm. and Psych., Univ. of Colo. Health Sci. Ctr., Denver, CO 80262.

A severe Parkinsonian syndrome was established in a male Bonnet monkey (m. Radiata) with the neurotoxin MPTP-HCl. Two months after lesioning, the animal was transplanted unilaterally into right caudate, putamen and globus pallidus with substantia nigra from an 8 weeks' gestation fetus. By 11 weeks after transplant, the animal could sustain a posture and the left hand became the preferred hand. Seven months after transplant, a second graft was placed into left caudate and putamen to improve motor function on the right side. Within six days, the animal lost function of the previously improved left arm and leg. Pathologic examination showed the continued presence of tyrosine hydroxylase positive cells and fibers in all transplant tracks on the right. A focus of lymphocytes was seen in one transplant track. The newly transplanted tracks on the left showed only tissue debris. Transplant rejection was then studied in a group of eight Patas monkeys which were lesioned with MPTP and then transplanted with fetal substantia nigra from 7 to 9 week monkey fetus. Three months after transplant, the animals were challenged with a second fetal transplant to look for graft rejection. These results indicate that rejection may occur following a second transplant of fetal tissue.

7.8

CEREBRAL METABOLIC EFFECTS OF DOPAMINERGIC IMPLANTS IN CAUDATE NUCLEI OF HEMIPARKINSONIAN MONKEYS. L.J.Porrino[1,2], E.Palombo[2]*, K.S.Bankiewicz[1], J.Viola[2,3], J.Jehle[2]*, and I.J.Kopin[1]. [1]NINCDS; [2]NIMH; [3]HHMI, Bethesda, MD 20892.

A recent approach to the treatment of Parkinson's Disease has been the use of dopamine-producing tissue implanted into the brains of patients with the disease. We have used the quantitative autoradiographic 2-[^{14}C]deoxyglucose method to assess alterations in functional activity that accompany implants of dopamine-producing adrenal and fetal tissue into the caudate nuclei of MPTP-induced hemiparkinsonian monkeys. After implant of adrenal medullary tissue, recovery of voluntary movement of the affected limbs was observed, but did not persist. The pattern of local cerebral glucose utilization (LCGU) seen in monkey with adrenal implants was identical to that seen in untreated hemiparkinsonian monkeys. In contrast, following fetal mesencephalic tissue implants, recovery of motor function was observed, along with reversal of the LCGU changes associated with hemiparkinsonism; i.e. the increase in the external globus pallidus, the decrease in the subthalamus, and the increases in the striatum on the lesioned side appear to be normalized. Fetal mesencephalic implants not only normalize motor performance, but also restore symmetry in cerebral metabolic rates not seen after adrenal implants.

7.9

HEMIPARKINSONISM IN MONKEYS AFTER UNILATERAL CAUDATE NUCLEUS INFUSION OF MPTP : BEHAVIOR, HISTOLOGY AND CHEMISTRY. H. Imai, T. Nakamura*, N. Miyashita*, K. Nishi*, and H. Narabayashi*. Dept. of Neurology, Juntendo Univ. Sch. of Med., Tokyo 113, Japan.

In an attempt to clarify the role of the dopamine nerve terminals and cell body in MPTP toxicity and to construct a model for pure hemiparkinsonism, we administered 1-4 mg of MPTP HCl directly into the unilateral caudate nucleus of crab-eating monkeys via an Alzet 200-µL osmotic minipump for 14 days. Within a week after the start, the monkeys exhibited a flexed posture and hypokinesia of the contralateral limbs, and spontaneous circling toward the MPTP-treated side. After treatment with apomorphine the circling motion was reversed. These disturbances continued to increase for 3 months and then reached a plateau. No parkinsonian tremor at rest was observed in any of the monkeys. The number of tyrosine hydroxylase (TH) immunoreactive cell bodies in the MPTP-treated side of the substantia nigra was markedly reduced along the entire rostrocaudal extent relative to the untreated side. Neuronal loss in the MPTP-treated side of the ventral tegmental area was slight and dorsal raphe and locus ceruleus neurons were completely spared. TH activity in the MPTP-treated side of the caudate mucleus and putamen was also markedly reduced. In conclusion, MPP^+ uptake at the dopamine nerve terminals alone and retrograde axonal transport to the cell body seemed to be sufficient to destroy nigral dopamine cells in the monkey.

7.10

DOSE RELATED CONTRALATERAL DOPAMINE DEPLETION AFTER INTRA-CAROTID MPTP ADMINISTRATION IN CYNOMOLGUS MONKEYS: VALIDATION OF THE UNILATERAL MPTP MONKEY MODEL M. Guttman, H.C. Fibiger, A. Jakubovic, D.B. Calne, University of British Columbia, Vancouver Canada, V6T 1W5

N-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) has been employed to produce a primate model for Parkinson's disease. In an attempt to create a unilateral lesion, MPTP has been administered directly into the internal carotid artery to produce hemiparkinsonism (Bankiewicz et al. 1986). Four animals had infusion of normal saline and two groups of four monkeys had either 1.25 mg or 2.5 mg of MPTP-HCl infused into the left carotid. Six to ten weeks later, all MPTP-lesioned animals displayed right sided parkinsonism. Two of the higher dose animals displayed signs of flexed trunk posture and reduced activity. HPLC analyses of caudate nucleus and putamen showed that in all MPTP-lesioned animals there was greater than 97% reduction of dopamine (DA) on the left. In the 2.5 mg MPTP group, the right side also showed reduced DA; in the caudate by 61.4%, and in the putamen by 37.8%. Contralateral DA reduction and abnormalities of DA utilization (HVA/DA ratios) were not present in the 1.25 mg MPTP-treated monkeys. These findings demonstrate that unilateral carotid injection of MPTP can damage contralateral DA systems; caution should therefore be exercised in the interpretation of data with this model. With the lower dose, the lesion appears to be purely unilateral, enabling the use of the contralateral side as an internal control.

7.11

IN VIVO BRAIN IMAGING OF THE BASAL GANGLIA (BG) OF NORMAL AND RECOVERED MPTP-TREATED MONKEYS BY POSITRON EMISSION TOMOGRAPHY (PET) USING 6-FLUORO-L-DIHYDROXYPHENYLALANINE (6FDOPA). D.J. Doudet, R.M. Cohen*, R.D. Finn*, H. Miyake*, T.G. Aigner, T. Bruecke*, R.Q. Wan*, C.A. McLellan*, B. Francis*, R. Adams*, J.J. Chen* and C.C. Chiueh. Clinical Brain Imaging/LCM; Lab. of Neuropsychology, NIMH and Radiopharmacy, NMD, NIH, Bethesda, MD 20892.

The sensivity of PET measurements of 6FDOPA accumulation to detect clinical and preclinical damages to the dopaminergic (DA) system of the BG was assessed in 1-Methyl-4-Phenyl-1,2,3,6- Tetrahydropyridine (MPTP)-treated rhesus monkeys. Four animals were given MPTP (2 to 4.8 mg/kg i.v.) 20 to 24 months before the PET studies. They acutely displayed akinesia and rigidity but spontaneously recovered and were evaluated normal neurologically by investigators blind to their previous treatment. Two monkeys received .8 and 1.5 mg/kg in the right internal carotid artery and, after recovery of the acute effects, remained impaired in their left body side. Five normal rhesus matched for age and sex were used as controls. For the PET study, the anesthetized monkeys were first injected with O-15 labeled water to verify that the BG were visualized in at least one slice and that differences in blood flow did not account for variations in 6FDOPA accumulation. The injection of 2 to 5 mCi of highly purified 6FDOPA demonstrated a substantial loss of 6FDOPA accumulation in the BG of the MPTP-treated animals and in the lesioned side of the hemiparkinsonian monkeys compared to controls. The ratio between BG and a non-rich DA area (occipital/parietal cortex) reached 2.5 to 3 in normals compared to 1.4 to 1.8 in the DA depleted animals and dropped to 1 in the affected side of the hemi-lesioned monkeys.

Thus, 6FDOPA, a PET tracer which preferentially labeled DA neurons appears to be a useful tool in the detection of clinical and preclinical changes in the DA system.

7.12

GM1 GANGLIOSIDE EFFECTS ON THE MPTP-DAMAGED DOPAMINE SYSTEM IN MICE AND CATS. J.S. Schneider and A. Yuwiler, Dept. of Neurology, UCLA School of Medicine and Neurobiochem. Lab., Brentwood VA Hosp., Los Angeles, CA 90024-1769.

Exogenously administered GM1 ganglioside has been suggested to act as a neurotrophic factor in central aminergic and cholinergic systems. The present experiments were performed to see if GM1 ganglioside might have beneficial effects on the MPTP-damaged dopamine (DA) system in mice and cats. Young mature (8-10 wks) C57 black mice which received MPTP and GM1 had significant increases (dependent upon length of GM1 exposure) in striatal DA content as compared to mice which received only MPTP. This DA increase was accompanied by a significant increase in the striatal DAergic terminal field. GM1 had no protective effects against MPTP toxicity, was effective when its onset was delayed in relation to MPTP administration, and its effects appear to be permanent. Interestingly, GM1 did not cause significant striatal DA increases when administered to aged (8-10 mos) MPTP-treated mice. While cats administered MPTP all showed massive striatal DA depletions, animals which received GM1 had significantly increased DA levels as compared to cats which only received MPTP. GM1 appeared to stimulate both terminal and axon collateral sprouting within the denervated striatum but seemed to have no protective effect on nigral cell degeneration. These results suggest that GM1 can stimulate recovery in the DA system in the striatum of young mature animals but that the beneficial effects of GM1 treatment may decline with age.

8.1

BOTH BEHAVIORAL AND NEURONAL PERFORMANCE ARE IMPROVED BY INCREASED ATTENTION. H. Spitzer*, R. Desimone, and T. Moran (SPON. N. Allon). Lab. Neuropsychology, NIMH, Bethesda, MD 20892; Dept. Biomedical Engineering, Technion, Haifa, Israel; and Lab. Clinical Studies, DICBR, NIAAA, Bethesda, MD 20892.

To test whether increasing the amount of attention devoted to a stimulus influences neuronal activity, we studied the responses of neurons in area V4 of two rhesus monkeys to stimuli presented within the context of a discrimination task performed at two different levels of difficulty. The task was a modified version of matching-to-sample. The stimuli were bars varying in size, orientation, and color. Some cells were tested with orientation as the discriminative feature, and others were tested with color. In the nonmatching trials of the easy condition, the sample and test stimuli differed by 90° in orientation or about 77 nm in wavelength, whereas in the difficult condition they differed by 22.5° or 19 nm, respectively. Behavioral evidence indicated that the monkeys' discriminative abilities improved when the task was made more difficult. Correspondingly, neuronal responses to stimuli became larger and more selective in the difficult condition. It was demonstrated in a control experiment that larger responses and narrower bandwidths during the difficult condition occurred only for attended stimuli within the receptive field.

8.2

TASK-SPECIFIC SIGNALS IN AREA V4 OF MONKEY VISUAL CORTEX. J.H.R. Maunsell, G. Sclar* and T.A. Nealey*. Dept. Physiology, Univ. of Rochester, Rochester NY 14642.

In macaque monkeys trained to perform an orientation match-to-sample task, many neurons in area V4 show response modulation that depends critically on which orientation the animal has been cued to look for (Haenny *et al.* **Exp Brain Res.** 1988). Such neurons may be very active during trials in which the animal is cued to look for one orientation, yet unresponsive when identical visual stimuli appear during trials in which the animal is looking for other orientations. Thus these cells seem to encode information about the orientation the animal is looking for, rather than the orientation falling on the retinas.

We have recorded from V4 in a monkey trained to perform an orientation match-to-sample task in which the sample was either presented visually (by showing the animal the correct orientation at the start of each trial) or tactilely (by having the animal feel the orientation of a bar he can not see). Of 36 neurons tested under both conditions, eight (22%) showed statistically significant changes in activity related to the sample orientation in both cases. Because these neurons convey an identifiable signal that can be dissociated from any particular sensory input or any immediate motor response, their signal must be considered an abstract representation of the cued orientation.

Supported by ONR 86-K-0646 and an Alfred P. Sloan Fellowship to JHRM.

8.3

RESPONSES OF VISUAL CORTICAL NEURONS DURING A FOCAL ATTENTIVE TASK. B.C. Motter (SPON: S.Mitchell) V.A. Medical Center and Depts. Physiology and Neurosurgery, SUNY Health Science Center, Syracuse, NY 13210.

Reponses of neurons in V1, V2, & V4 to flashed stimuli were recorded during the performance of a task requiring visual attention to events at selected spatial locations. Monkeys were trained to discriminate the orientation of a briefly (200ms) flashed bar stimulus appearing 2 to 10 degrees from a central fixation point. The target stimulus was presented alone (25%) or in a circular array (75%) of identical but randomly oriented stimuli. At the beginning of a trial each position of the array was marked by a small dot cue. The target stimulus position was then explicitly cued by removal of all other cues prior to the presentation of the stimulus array. The arrays were positioned so that either the target or another array stimulus was located in the neuron's receptive field. The composition of stimuli and arrays were based on quantitative assessments of the field position and size, and the preferred orientation, color and stimulus size for each neuron studied. Response differences between stimuli presented at attended versus non-attended locations were found in about 50% of V2 & V4 neurons and in about 20% of V1 neurons studied. Such differences were usually limited to responses evoked by stimuli with orientations near the tuning point of the neuron. Stimulus response latencies for V4 neurons at attended locations were often increased.

8.4

BEHAVIORAL ROLE OF STIMULUS SELECTIVE NEURONAL ACTIVITIES IN THE SUPERIOR TEMPORAL SULCUS OF MACAQUE MONKEY. A.MIKAMI and K.NAKAMURA Dept. Neurophysiol., Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484 JAPAN

In the superior temporal sulcus (STS) of macaque monkey, neurons showed selective response to the complex visual feature including human and/or monkey faces (Bruce et al 1981, Perret et al 1982, Mikami 1987). In order to test behavioral role of the stimulus selective neurons in STS, neuronal activities were recorded during the sequential discrimination task with delay. With pressing lever, the first sample picture was presented for 1 sec. After 1-3 sec of delay period, a picture appeared again. This sequence was repeated until a new picture appeared. Monkey was trained to release the lever when a new picture appeared. In about two third of stimulus selective STS neurons, activities were modulated depend on the number of repetitions and/or the reward contingency. A small number of neurons showed stimulus selective activities during the delay period. These data suggest that the STS neurons may be involved in the process to attend and memorize a specific visual pattern.

8.5

ATTENTIONAL MODULATION OF INFEROTEMPORAL NEURON RESPONSES TO VISUAL FEATURES. J.M. Fuster. Department of Psychiatry and Brain Research Institute, School of Medicine, University of California, Los Angeles, CA 90024.

Neurons of inferotemporal (IT) cortex discriminate and temporarily retain colored stimuli (Fuster and Jervey, J. Neurosci., 2:361, 1982). Are such discriminant and mnemonic neural properties dependent on the degree of attention that the animal devotes to the chromatic stimulus attribute? Four monkeys were trained to perform a delayed match-to-sample task with compound stimuli. The six sample-stimuli utilized were coextensive, isoluminous, and briefly presented, one per trial, in a central location; each consisted of a colored disk (red or green) with a gray symbol in the middle, which indicated whether the symbol itself or the background color had to be remembered for later behavioral decision. Thus, the relevance of color and the attention that the animal was assumed to pay to it were determined by the symbol embedded in it. Extracellular activity was recorded and analyzed from 301 IT units. Analysis of their reactions to the stimuli revealed both symbol- and color-differentiating cells. Some of the latter discriminated the two colors equally well--i.e., with the same differential firing rates--whether color was relevant or not. Others did it better if color was relevant than if it was not; their reaction to their preferred color was enhanced if the contextual cue (symbol) indicated that color had to be attended to. In a few cells, the relevance effect was detectable during the retention period, when the sample stimulus was no longer present. No effects of relevance were noted in 92 striate cortex cells. The latency of the color response of IT cells was correlated with susceptibility to attentional modulation. Long-latency (>180 ms) attention-sensitive cells, were especially common in the lower bank of the superior temporal sulcus. The results indicate that the discrimination and memory functions of IT neurons are facilitated by the focusing of attention on the attributes of the visual scene to which they are attuned; the latency data validate the psychophysical inference of serial processing in selective visual attention (Koch and Ullman, Human Neurobiol., 4:219, 1985).

DIRECTING ATTENTION TO COMPLEX OBJECTS. Jeremy M Wolfe*, Kyle R Cave*, and Karen P Yu* (SPON: J. Sandell), Dept. of Brain & Cog. Sci., MIT, E10-137, Cambridge, MA 02139

Visual processing is divided between an initial "pre-attentive" stage where simple features can be processed in parallel across the visual field and a later stage where complex processing is accomplished by directing attention to parts of the field. If pre-attentive processes can only analyze simple features (e.g. color, motion, etc.), how is attention guided in a search for an object (e.g. a cat) not defined by a unique feature? Visual search data suggest that without guidance, attention moves at random in a serial search for a target. However, the apparent ease with which real-world objects are found argues against a haphazard search. We believe that attention may be directed to a complex object by combining information from several feature processors. Thus, while a color processor cannot identify a cat, it can divide the field into loci that can and cannot contain a cat. Attention should not be directed to a locus labelled "green" if one is seeking a cat. In our visual search experiments, target items are defined by triple conjunctions of color, size, and form. Though all other items share one feature with the target, search times are independent of the number of items, as they would be if the target was defined by a unique color or size. This "parallel" search for triple conjunctions strongly suggests that the pre-attentive processes can guide attention even when no single feature defines the target.

VANISHING TARGETS IN SIMULTANAGNOSIA: FAILURE TO SUSTAIN VISUAL ATTENTION OVER AN ARRAY. M. RIZZO AND D. ROBIN. Div. Behavioral Neurology and Cognitive Neuroscience, Univ. of Iowa, College of Medicine, Iowa City 52242

Simultanagnosia (visual disorientation), the erratic disappearance of targets from direct vision, offers an important opportunity to probe human attention. We studied two subjects with simultanagnosia due to CT/MR verified lesions of the superior visual association cortices. Their defect was not explainable by poor acuity, abnormal eye movements, or visual field defects. Both could orient attention to spatial targets in vision, audition, and even to cross modal targets, comparably to 30 controls. Here we report on a separate paradigm which allowed further assessment of the defect. The task required an immediate response to the appearance or extinction, at unpredictable intervals, of any dot in a static CRT display of 1000 random dots. The subject failed to detect 50% of 400 events without predilection for location, had 19% false alarms, and had prolonged reaction times. The results support the hypothesis that simultanagnosia is due to inability to maintain visuospatial attention across an array. The inefficient processing of simultaneous signals in parallel neural channels may lead to failure to detect targets which thus seem to vanish. The finding suggests that operations of directed and sustained visual attention are dissociable at the level of the visual association cortices.

ABSENCE OF VISUAL RESPONSIVENESS IN INFERIOR TEMPORAL CORTEX IN MACAQUES LESS THAN FOUR MONTHS OF AGE. H.R. Rodman, J.P. Skelly* and C.G. Gross. Dept. of Psychology, Princeton University, Princeton, NJ 08544.

Although inferior temporal (IT) cortex is necessary for visual learning and pattern perception in adult monkeys, several lines of behavioral and anatomical evidence suggest that IT takes on its full adult role only slowly; moreover, this maturation process may be sexually dimorphic (Bachevalier & Mishkin, 2nd Conf. Neurobiol. of Beh., 1984). Previously, we reported that single-unit response properties in IT are adult-like in female macaques by 4-6 months of age (Rodman et al., Neurosci. Abs. 13: 1539). We now present data on IT properties in male macaques 4-7 months old (139-219 days at the time of recording) and in younger macaques of both sexes (41-113 days at the time of recording).

Recordings were made in repeated sessions under immobilization and N_2O anesthesia. Single units were tested with slits of light, dark edges and a set of complex 3-D objects similar to those used for our previous studies. Models and photographs of monkey faces were also used.

Visual responsiveness in IT was virtually absent in each of the five younger monkeys (three males and two females), except for a few responsive units found in one male in the fourth month of age. Control recordings in striate cortex and extrastriate visual area MT showed normal responsiveness and stimulus selectivity.

In one of the two older males, visual properties in IT (including receptive field size and location and stimulus selectivity) were adult-like, similar to what we found in 4-6 month old females. In the other animal, however, most IT units were unresponsive, despite the presence of normal activity in striate cortex.

8.9

CIRCUIT PROPERTIES OF INFERIOR TEMPORAL CORTEX IN THE MACAQUE. **P.M. Gochin, E.K. Miller, C.G. Gross, G.L. Gerstein.** Dept. Psychol., Princeton Univ., Princeton, NJ 08544, Dept. Physiol., Univ. Penn. Sch. Med., Phila., PA 19104.

We have suggested that the visual scene is represented in inferior temporal (IT) cortex by the pattern of activity across a population of IT neurons each selective for some aspect or aspects of the visual stimulus (Gross et al., in Pattern Recognition Mechanisms, 1985). This view of IT cortex is similar to that postulated for the later stages of some contemporary models of pattern recognition. The purpose of this study was to obtain information about interactions among IT neurons that could help to constrain and develop such models.

We recorded IT activity from bundles of three microelectrodes. Multi-unit activity on each electrode was segregated into single unit activity with a spike sorting apparatus enabling us to study the simultaneous activity of up to nine isolated neurons. The monkey fixated a small spot while stimuli were presented extrafoveally.

Cross-correlation analysis demonstrated that some neuron pairs interact with some combination of shared excitatory input and direct synaptic connections, while other pairs show independent patterns of firing. Furthermore, neurons recorded on the same electrode were more likely to have functional connections and similar stimulus selectivity than neurons recorded on adjacent electrodes. These results will be discussed in relation to models of pattern recognition.

ORGANIZATION OF VISUAL PROJECTIONS TO PARIETAL AND TEMPORAL CORTEX IN THE MACAQUE. I.S. Baizer, L.G. Ungerleider and R. Desimone. Laboratory of Neuropsychology, NIMH, Bethesda, Maryland, 20852.

Visual information is relayed from striate through prestriate to parietal cortex, which has visuospatial functions, and to temporal cortex, which is critical for object recognition. To identify and compare the distributions of cells in prestriate cortex that project to these two destinations, we made multiple injections of two different fluorescent tracers into the lower bank of the intraparietal sulcus (following removal of the upper bank) and into the inferior temporal cortex in 3 rhesus monkeys. Cells projecting to parietal and temporal cortex were located mainly in different prestriate areas: MT, MST, STP, and peripheral V2 projected only to parietal cortex, whereas TEO projected only to temporal cortex. Areas containing cells projecting to both destinations were V4 (including its ventral and two dorsal subregions, AL and PM) and the posterior bank and floor of the superior temporal sulcus (STS) outside MT. In both V4 and STS, labeled cells projecting to parietal and temporal cortex were intermingled, though the projection to parietal cortex was heavier from peripheral than from central V4. The laminar distribution of labeled cells suggests that V4 provides feedforward information to both parietal and temporal cortex, whereas zones within the STS provide both with feedback information. RESPONSE PROPERTIES OF NEURONS IN MACAQUE INTRAPARIETAL SULCUS. C.L. Colby, J.-R. Duhamel and M.E. Goldberg Laboratory of Sensorimotor Research, National Eye Institute, N.I.H., Bethesda, MD 20892.

We have used visual, oculomotor and attentional tasks to study neurons in and around the intraparietal sulcus (IPS) in the alert monkey and have found a variety of cell types which fall into two broad classes.

Cells in the first class have relatively simple visual responses. Receptive fields are restricted and stationary stimuli evoke on/off responses. More robust responses are elicited by moving stimuli and some cells exhibit directional selectivity. Cells in this class appear to have no eye movement related activity and no attentional component to their responses.

Cells in a second class have more complex response properties. These respond well to stationary visual stimuli and their visual responses are enhanced when the stimulus is also the target for a subsequent eye movement or an attentional response. Two types of cells also discharged before the saccade in a task where the target is flashed on briefly and the saccade is made in total darkness. One type fired separate bursts at the time of target appearance and again just prior to the saccade. A second type produced a tonic response, beginning at target onset and continuing until initiation of the saccade, as though it were holding the target position. When tested in a learned saccade task, where no target appeared, some but not all cells in each category fired before saccades to a remembered location.

The results suggest that the IPS contains anatomically and physiologically distinct cell populations.

ORBITAL POSITION EFFECTS ON SACCADE RESPONSES OF AREA LIP NEURONS. R. Andersen, J. Gnadt, L.Fogassi, M. Bracewell, S. Barash, G. Robertson and G. Essick. Dept. Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Area LIP is a subdivision of the posterior parietal cortex buried within the intraparietal sulcus whose cells have saccade-related activity. The effect of eye position on the saccade responses was examined using a memory saccade task designed to separate visual from saccade-related activity. The task required the animal to memorize the location of a briefly flashed target and to make a saccade to that remembered location after a variable period of time. It was found that the direction and amplitude tuning of the motor fields of the cells did not change but the *magnitude* of the saccade response was modulated by eye position.

Standard linear regression techniques were used to test whether a first order linear model with independent variables of horizontal and vertical eye position would describe the change in gain of the saccade response with change in eye position. Two-thirds of 39 neurons tested showed a statistically significant ($p<.05$) effect of eye position; these cells are said to have gain fields. Of the cells with gain fields a plane was the best fit of the data for 52% of the cells and another 38% showed a significant planar component. Only 8% of the cells had no planar component in their gain fields

These data indicate that a planar model describes a large majority of the gain fields of the saccade cells. A similar planar function for the variation of visual response with eye position has been found for area 7a neurons and a network model trained to localize the location of visual stimuli in head centered coordinate space produced these same planar gain fields (Andersen et al., Science, 1985; Zipser and Andersen, Nature, 1988). The present results suggest that the planar gain function could represent a general strategy by the brain to perform coordinate transformations. In this instance the gain function could be used to transform from the retinal coordinates of the visual target to the head centered coordinates of the location of the eyes in the orbits required to foveate the target.

EFFECTS OF FMRFamide ON ISOLATED HEART MUSCLE CELLS OF THE MEDICINAL LEECH. K.J. Thompson and R.L. Calabrese, Dept Biology, Emory Univ., Atlanta, GA 30322.

The neurogenic/myogenic leech heart responds to the neuropeptide FMRFamide. Bath application of FMRFamide or nerve stimulation can cause tonic contraction, acceleration of the myogenic rate, and induction of myogenic activity in quiescent hearts (Kuhlman et al, 1985; Li and Calabrese, 1987). Intracellular recording and voltage clamp methods were used to examine the electrical responses of dissociated heart muscle cells to bath applied FMRFamide. Muscle cells depolarize in response to FMRFamide at concentrations as low as $1X10^{-12}M$. This depolarization is accompanied by a conductance increase and continues as long as FMRFamide is present. Response amplitude increases in saline containing 10 mM Ba^{++}, and is severely attenuated by 5 mM Mn^{++} or 50 µM Cd^{++}. In voltage clamp, FMRFamide induces a net inward current that appears to underlie the depolarization observed in current clamp. This FMRFamide-gated conductance increase in isolated heart cells may account for some of the modulatory actions of FMRFamide observed in the intact heart. Supported by NIH NS24072-04 to R.L.C.

VOLTAGE CLAMP ANALYSIS OF A HYPERPOLARIZATION-ACTIVATED INWARD CURRENT IN HEART INTERNEURONS OF THE MEDICINAL LEECH. J.D. Angstadt and R.L. Calabrese. Dept. of Biology, Emory University, Atlanta, GA 30322.

Previous current clamp studies of heart interneurons (HN cells) in the leech suggested that intrinsic ionic conductances may contribute to the recovery from inhibition exhibited during normal bursting activity (Peterson, 1983; Arbas and Calabrese, 1987). In this study, we used the single-electrode voltage clamp technique to characterize a voltage-sensitive inward current (I_h) activated by hyperpolarization of HN cells. I_h is a slow, non-inactivating inward current with an activation threshold near -50 mV. I_h persists in the presence of Mn^{++} or Co^{++} (5 mM) but is blocked by extracellular Cs^+ (2-5 mM). The reversal potential (-21 ± 5 mV) is shifted by changes in extracellular Na^+ or K^+ but not Cl^-, suggesting that I_h is produced by a mixed Na^+/K^+ conductance. The steady state conductance ($g_{h\infty}$) reaches a maximum between -70 and -80 mV. The voltage sensitivity and kinetics of I_h are consistent with a role for this current in recovery from inhibitory inputs and subsequent burst generation. Supported by NRSA postdoctoral fellowship #NS08089-02.

9.3

CONSTRUCTION OF A COMPUTER MODEL OF THE LEECH HE-MOTONEURON: IMPORTANCE OF SYNAPTIC POTENTIALS.
E. DE SCHUTTER* (SPON: European Neuroscience Association) and R.L. CALABRESE, *Dept. of Neurology, Univ. of Antwerp (UIA), B-2610 Antwerp, Belgium, and Dept. of Biology, Emory Univ., Atlanta, GA 30322.

The HE-cell is the motoneuron that controls the leech *(Hirudo medicinalis)* heart muscle. A compartmental model of the cell was constructed, computer simulations of the response to a hyperpolarizing pulse and of IPSPs were used to determine the equivalent cable parameters of the neuron.

In 13 HE-cells (isolated ganglia, normal Ringer) the response to 10 -0.3nA pulses during the bursting period was averaged (single electrode current clamp, sampling rate 3.6 kHz). Two time constants were always present: 2.1±0.7 ms and 35.5±2.1 ms, in some cells a long time constant of 185±214 ms was found. Average input resistance was 118±12 MΩ. Ten IPSPs in a HE(L4)-cell were digitized and averaged. The hyperpolarization phase could be fitted to a single exponential with a time constant of 2.4±0.6 ms, the final phase of the repolarisation slope had a time constant of 71.9±7.1 ms.

The cell was filled with HRP, developed, fixed and mounted for microscopy without dehydratation. Morphometrical analysis was used to construct a 113 compartmental model. All simulations were done with the Nodus software on a Macintosh computer.

The hyperpolarization experiment was simulated with a membrane capacitance (C_M) of 2.0 µF/cm², a membrane resistance (R_M) of 19 kΩcm² and a cytoplasmic resistance (R_i) from 100 to 200 Ωcm. IPSPs were simulated with a simple kinetic scheme (alpha-function). A normal sized IPSP (5 to 10mV at the soma) was obtained if synapses on at least 50% of the 36 dendrites were fired, IPSPs at 75% of the dendrites gave the best results. The hyperpolarizing phase of the IPSP was approximated with an alpha of 0.9 $^1/_{ms}$, but the repolarisation could only be simulated with higher values for R_M: 38 kΩcm². Both the hyperpolarization experiment and IPSPs could be simulated if different values for R_M in soma, main segment and axon (16 kΩcm²) versus dendrites (50 kΩcm²) were used, with C_M 1.85 µF/cm² and a minimum for R_i of 200 Ωcm.

Conclusion: in this motoneuron membrane resistance is higher in dendrites than in soma and main segment. IPSPs are caused by firing of synapses on most of the dendrites.

9.4

THE ONTOGENY OF THE RESPIRATORY PATTERN GENERATING SYSTEM OF THE FETAL LAMB. L.R.C. Cooke* and P.J. Berger (SPON: D. L. Macmillan). Monash University Centre for Early Human Development, Clayton, Vic., 3168, Australia.

The ontogeny of the neural system which produces the ventilatory rhythm was investigated using a chronically-instrumented fetal lamb preparation. Electrodes were placed in the diaphragm (Di), external intercostal (EIC) and external oblique (EOb) muscles of 13 fetal lambs (47-62 days gestation), using maternal general anaesthesia. After recovery (3 days), electromyogram activity was recorded for 2-hour periods at 5-day intervals until 135 days gestation (term =147 days). Early in gestation (50-70 days), the predominant form of activity recorded consisted of approximately coincident periods of continuous discharge of all three muscles, which lasted up to several minutes. In addition, two stereotyped forms of phasic activity were recorded from the Di. Isolated bouts of up to 50 brief (60-100 ms) bursts, lasting up to 1 min, occurred 1-3 times per hour while prolonged (up to 15 min) sequences of repeating clusters of brief (30-60 ms) bursts occurred every 2-3 hours. The EIC and EOb were silent during short bouts of phasic Di activity; occasionally the EIC discharged in synchrony with the Di during prolonged sequences. The left and right sides of the Di fired synchronously in all episodes of phasic activity. Unilateral phrenectomy abolished all activity on the ipsilateral hemidiaphragm, demonstrating its neural origin. High cervical (C1) transection of the spinal cord abolished all phasic Di activity, but not trains of continuous discharge. Thus, early in gestation, phasic Di activity was generated by neural pathways organised in a manner similar to the mature respiratory pattern generating system. Subsequent development involved progressive increases in the incidence of phasic Di activity and the occurrence of synchronous EIC bursting, together with an increase in burst duration and progressive elaboration of the structure of inspiratory muscle bursts into the mature, progressively augmenting form.

NEURONAL MECHANISMS CONTRIBUTING TO THE ALTERATION OF THE RESPIRATORY RHYTHM AT FLIGHT ONSET IN THE LOCUST. J.M.Ramirez*, K.G.Pearson, Department of Physiology, University of Alberta, Edmonton, Canada, T6G 2H7.

It has been well established that the respiratory rate in locusts increases at flight onset, but the neural processes underlying this increase are not understood. By means of intracellular recordings from respiratory neurons in quiescent and tethered flying locusts we have found that the respiratory rhythm is reset at flight onset by an activation of inspiratory and inhibition of expiratory neurons. This reset also occurs in deafferented animals thus demonstrating that flight and respiration are centrally coupled. Neurons which may contribute to this coupling were identified in the suboesophageal ganglion. These neurons were tonically active in the quiescent locust and strongly inhibited at flight onset. Injection of hyperpolarizing currents into these neurons increased the respiratory rate and release of excitation following depolarizing current injection sometimes led to the initiation of flight. Reduction of activity also led to an activation of inspiratory neurons, suggesting that the increase in the respiratory rate may be caused by disinhibiting inspiratory neurons in the respiratory rhythm generator. Consistent with this was our finding of a pair of inspiratory interneurons in the metathoracic ganglion which were strongly activated during flight and which increased the respiratory rate when injected with depolarizing currents. We conclude that one mechanism contributing to the increase in respiratory rate at flight onset is a simultaneous disinhibition of the flight and respiratory systems by neurons descending from the suboesophageal ganglion.

9.6

FEEDBACK AND FREQUENCY REGULATION IN LOBSTER (HOMARUS AMERICANUS) CARDIAC GANGLION. A. Berlind, Biology Dept., Wesleyan Univ., Middletown, CT 06457.

The crustacean cardiac ganglion (CG) has traditionally been viewed as a two layered system in which pacemaking is a function of the four small cells. The work reported here shows that there is strong electronic feedback from the five motorneurones (MNs) to the small cells by which endogenous burst-organizing potentials (driver potentials, or DPs) and their hyperpolarizing afterpotentials contribute to regulation of bursting frequency. When the MNs of isolated CGs were selectively silenced with TTX, the small cells continued organizing bursts of activity, which recurred at an average frequency 38% higher than full bursting in normal saline. The average burst duration was not altered. DPs were evoked in TTX-treated MNs by electrical stimulation, by ionic alteration of the medium, or by treatment with the peptide proctolin. DPs which occurred synchronously with small cell bursts prolonged and intensified the bursts. DPs evoked in MNs during the interburst triggered small cell bursts even at very short intervals after a spontaneous burst had occurred. All small cell bursts which were associated with MN DPs were followed by interburst intervals of longer than normal duration. The decrease in instantaneous burst frequency (increase in total burst cycle duration) caused by MN DPs was similar in magnitude to the drop in burst frequency observed when the ganglion recovered normal activity after TTX washout.

9.7

EFFECTS OF LONGTERM REMOVAL OF EXTRINSIC SYNAPTIC INFLUENCES ON BURST-GENERATING PROPERTIES IN THE LOBSTER PYLORIC NETWORK. J.Simmers* and M.Moulins. Lab. Neurobiol. Comp., CNRS, 33120 Arcachon, FRANCE.

The pyloric network in the stomatogastric ganglion (STG) of Jasus produces rhythmic motor output in vitro as a result of the oscillatory properties of pyloric neurons. These properties are conditional, however, since suppression of unpatterned central inputs to the STG by cutting the stomatogastric nerve (stn) rapidly causes loss of bursting in pyloric neurons.

In contrast, when such deafferented quiescent STG are maintained in vitro on a longterm basis (max. 10 days), pyloric rhythmicity returns (from day 4-6) and is identical to the basic pattern normally expressed when the stn is intact. This transition is longlasting since reacquisition of rhythmicity has been observed in in vitro preparations from animals in which the stn was cut up to 12 months previously. Moreover, the fundamental change appears to occur in the intrinsic properties of the pyloric neurons themselves; in rhythmic deafferented ganglia, individual pyloric cells continue to oscillate after further experimental isolation from all other elements in the pyloric network. The results therefore suggest that the prolonged absence of extrinsic inputs to pyloric neurons allows the expression of a true endogenous oscillatory capability that is normally maintained in a conditional state by these same synaptic influences.

MULTISECOND STORAGE OF STIMULUS-EVOKED EXCITABILITY IN THE SPINAL CIRCUITRY FOR POCKET SCRATCH REFLEX IN THE TURTLE. Scott N. Currie and Paul S.G. Stein. Department of Biology, Washington University, St. Louis, MO 63130.

The Ventral-Posterior Pocket (VPP) cutaneous nerve innervates part of the pocket scratch receptive field in the turtle. Electrical stimulation of the VPP nerve at 1-10 Hz elicits fictive pocket scratch motor patterns in spinal, immobilized preparations. A single "maximal" pulse to the VPP nerve that is sufficiently strong to activate all VPP axons evokes no motor output in a rested preparation. The pulse raises the excitability of the pocket scratch central pattern generator (CPG) for several seconds, however. We reveal the duration of raised excitability by presenting single pulses to the VPP nerve at multisecond intervals. Pulses delivered 5 seconds apart evoke strongly summating central activity: the first pulse elicits no motor response; the second pulse elicits one or more cycles of pocket scratch. The VPP pulse also interacts with pocket scratch activity evoked by natural stimulation of sites far outside of the VPP nerve receptive field, but does not interact with rostral scratch activity. Our data are consistent with the following hypothesis: tactile input from the entire pocket scratch receptive field converges upon a common locus in the spinal cord that 1) stores excitability for seconds after a brief tactile stimulus and 2) drives the pocket scratch CPG. Supported by NIH Grants NS07850 to S.N.C. and NS15049 to P.S.G.S.

IN SITU APPLICATION OF APV, AN NMDA RECEPTOR ANTAGONIST, ONTO THE SPINAL CORD REDUCES THE EXCITABILITY OF SPECIFIC CUTANEOUS REFLEXES IN THE TURTLE. Paul S.G. Stein and Carla P. Schild*. Department of Biology, Washington University, St. Louis, MO 63130.

A brief mechanical tap to the dorsum of the foot in an immobilized, spinal turtle elicits a flexion reflex in hip flexor (VP-HP) motor neurons. 5 spinal segments comprise the turtle hindlimb enlargement: 3 pre-sacral (D8-D10) and 2 sacral (S1-S2) segments. Afferents from the dorsum of the foot enter the spinal cord in the D10 dorsal root; the D8-D9 segments contain VP-HP motor neuron somata. We apply 50-250 μM APV (D(-)-2-amino-5-phosphonovaleric acid), a specific competitive antagonist of the NMDA (N-methyl-D-aspartic acid) receptor, onto segments D8-D10 and portions of adjacent segments D7 and S1. There is either no Mg or 2.2 mM Mg in the bathing solution. APV reduces flexion reflex excitability. APV also reduces excitability of the ventral-posterior pocket scratch but not that of the rostral scratch. Ventral-posterior pocket scratch afferents enter the spinal cord in the D8 dorsal root; rostral scratch afferents enter in the D3-D6 dorsal roots. Thus excitability of a cutaneous reflex is reduced if APV is applied to spinal segments whose dorsal roots contain the tactile afferents for that specific cutaneous reflex. These results support the hypothesis that NMDA receptors play a role in spinal cord processing of tactile input. Supported by NIH NS15049.

DIRECT EVIDENCE THAT IDENTIFIED INTERNEURONS MEDIATE THE CROSSED INHIBITION IN THE SPINAL NETWORK OF THE MAUTHNER CELL IN GOLDFISH. J.R. Fetcho and D.S. Faber. Dept. Physiol., SUNY at Buffalo, NY 14214.

We previously identified crossing spinal interneurons that were electrotonically coupled to a M-axon, and we proposed that they produced the short-latency, chloride dependent crossed inhibition of spinal interneurons and motoneurons. We now have direct evidence supporting this prediction. In three experiments we simultaneously recorded intracellularly from a M-axon, an interneuron electrotonically coupled to it, and a probable primary motoneuron inhibited by excitation of the M-axon. In one case an HRP injection confirmed that the coupled interneuron was a crossing interneuron. Firing the M-axon resulted in an action potential in the interneuron and an IPSP (inverted by Cl^- loading) in the spinal cell. Firing the coupled interneuron alone produced a short latency postsynaptic potential in the spinal neuron very similar in time course to the IPSP resulting from activation of the M-axon. In two cases this response was as large as the IPSP produced by firing the M-axon; in the third it was smaller. Hyperpolarizing a coupled interneuron while firing the M-axon blocked the Mauthner initiated spike in the interneuron and substantially reduced the amplitude of the IPSP in the inhibited cell. We conclude that 2 or more of these crossing interneurons mediate the short latency crossed inhibition of each postsynaptic cell. (Support:NIH NS 07593(JRF), 15335(DSF))

CONSTRUCTION OF THE ADULT ECDYSIS MOTOR PATTERN IN MANDUCA SEXTA: ROLE OF THORACIC DESCENDING INTERNEURONS. K.A. Mesce and J.W. Truman. Dept. of Entomology, Univ. of Minnesota, St. Paul, MN 55108, and Dept. of Zoology, Univ. of Washington, Seattle, WA 98195.

The ecdysis behavior expressed by the pharate adult hawkmoth, Manduca sexta, is quite distinct from that expressed by larvae and pupae. Construction of this novel adult ecdysis motor pattern is thought to occur, in part, through the conservation and modulation of the larval ecdysis motor program (K.A. Mesce and J.W. Truman, 1988, J. Comp. Physiol. A, in press).

Expression of the adult-specific motor pattern or the un-masking of the larval-like ecdysis pattern is determined by the activity of descending neurons located solely in the fused pterothoracic ganglion. Anatomical studies indicate that there are only about 15 pairs of thoracic neurons which descend to the unfused abdominal ganglia and whose cell bodies originate in the pterothoracic ganglion. An intracellular study is in progress to determine which of these neurons plays a role in the generation of the adult ecdysis pattern. Thus far, a thoracic descending interneuron (TDI-1) has been identified that, when stimulated to fire at 10-15 Hz for 2-3 secs., causes the co-activation of segmentally repeated abdominal muscles, an adult-specific component of the ecdysis motor pattern. It is not yet known whether some of these descending interneurons are re-modeled larval neurons or specific to the adult stage.

A NETWORK SIMULATION FOR MODELING OF COMPLEX EXCITATORY AND INHIBITORY INTERCONNECTIONS

C.D. Myre, S.F. Sawyer*, W.K. Smith, D.J. Woodward. *Dept. of Cell Biology and Anatomy, UT Southwestern, Dallas, Texas 75235.*

The simulation of a network of one thousand neurons was conducted to examine influences of membrane properties and connectivity patterns on the activity of units. The work was motivated by the extensive local inhibitory feedback system found in the neostriatum. Computation was done in the C language under UNIX on a Motorola 16 MHz MC68020 microprocessor. Neurons in the model occupied positions in a 10 X 10 X 10 cubic array. Each neuron gave inhibitory output connections to all neighboring neurons within a given radius. Neuron characteristics were modeled using state variables representing membrane and threshold values, similar to models reported elsewhere. State variables were tracked using difference equations which accounted for membrane voltage decay, refractory period, and threshold accommodation. Output of the network was recorded as spike events occurring on each neuron at each time increment. One update of a simulation cycle took about 2 seconds of computation in real time, representing about 40,000 synaptic interactions and state variable updates on 1000 neurons. A variety of parameters within the modeling system may be altered to suit the needs of the user. For example, local phasic excitatory input to a zone of 200 neurons was modeled to reveal fine structure of entrainment of neurons near the excited area. These results show that a complex neuronal model can be used in a large network simulation with many interconnections, yet still execute fast enough for realistic modeling experiments to be performed. In the future, modeling experiments will be designed and run, and more realistic neuronal models will be tested.

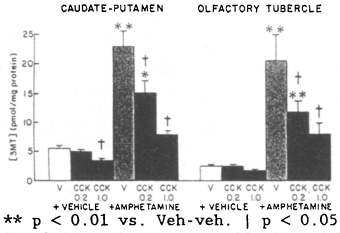
CENTRAL CCK-B RECEPTORS MODULATE DOPAMINE RELEASE. 1. CCK REVERSAL OF BASAL AND DRUG-STIMULATED RELEASE. W. C. Boyar, P. L. Wood; and C. A. Altar. Res. Dept., Pharma. Div., Ciba-Geigy Corp., Summit, NJ 07901.

The sulfated octapeptide of CCK (CCK-8S; 0.2-1 mg/kg, s.c.) lowered dopamine release (3-MT) and metabolism (DOPAC) in the striatum and frontal cortex in a dose- and time-related manner. 12 Fold higher CCK-8S doses mimicked these actions in the olfactory tubercle. Increases in dopamine release following amphetamine (15 mg/kg i.p., 10') were lowered in a dose-related manner by CCK-8S (s.c, 30'):



* $p < 0.05$; ** $p < 0.01$ vs. Veh-veh. † $p < 0.05$ below veh.

Haloperidol (0.12 mg/kg, i.p., 25 min) increases in dopamine release and metabolism were also attenuated by CCK-8S. CCK-8S appears to be a suppressor of striatal, limbic, and cortical dopamine release, especially when release is augmented. CCK receptor agonists may be antipsychotic by inhibitng hyperactive dopamine neurons.

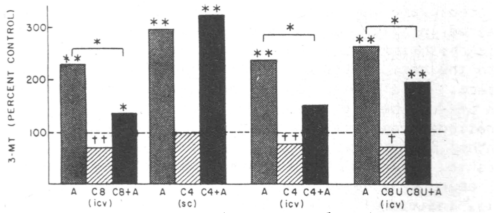
CENTRAL CCK-B RECEPTORS MODULATE DOPAMINE RELEASE. 2. INTRAVENTRICULAR INJECTIONS OF CCK TETRA- AND OCTAPEPTIDES. C. A. Altar and W. C. Boyar. Res. Dept., Pharma. Div., Ciba-Geigy Corp., Summit, NJ 07901.

Butoxycarbonyl CCK tetrapeptide (t-Boc CCK-4) and CCK-8U bind to the brain (CCK-B) but not alimentary (CCK-A) receptor. Basal and d-amphetamine- ("A", 15 mg/kg, 10 min, i.p.) increases in striatal dopamine release were attenuated when 1 or 5 ug of these peptides or 1 ug of CCK-8S was infused into the brain ventricles 12 min before amphetamine but not when t-boc CCK4 (1 mg/kg) was injected s.c:



S.c. CCK-8S lowered basal and stimulated release even with pretreatment of the CCK-A antagonist, L 364,718. These data are the first to demonstrate that CCK-B receptors in brain mediate the suppression of dopamine release by CCK, especially when release is augmented. Thus, lessened peripheral side-effects and treatment of psychotic patients may be obtained with centrally-available CCK-B agonists.

10.3

EXPRESSION AND CHARACTERIZATION IN XENOPUS OOCYTES OF A CHOLECYSTOKININ (CCK) RECEPTOR FROM A HUMAN NEUROBLASTOMA CELL LINE. **TP Segerson*, R Barrett*, J McKelvy, G Mandel*, RH Goodman* (SPON: LP Henderson). Div. of Molecular Med., Dept. of Med., New England Med. Ctr., Boston, MA 02111 and Neurosci. Res. Div., Pharmaceutical Discovery, Abbott Labs., Abbott Park, IL.**

The human neuroblastoma cell line CHP212 expresses peripheral-type CCK receptors (CCK-Rs). Activation of these CCK-Rs causes a 4-5 fold increase in PI hydrolysis. In Xenopus oocytes, an IP_3-dependent increase in intracellular Ca^{++} activates a Ca^{++}-dependent Cl- channel causing transient depolarization. To express the CHP212 CCK-R, Xenopus oocytes were injected with CHP212 RNA, and treated after 72 h with 1 uM CCK while monitoring for changes in either transmembrane voltage or current. RNA injected oocytes depolarized from a mean resting potential of -60 mV to the Cl- equilibrium potential (-25 mV). No response was seen in uninjected oocytes. The size of the CCK-R mRNA was determined by fractionating poly A+ CHP212 RNA on a denaturing agarose gel. Sequential RNA fractions differing by 500 nt screened in oocytes during CCK application. Fractions between 5 and 6 kb elicited a CCK-dependent depolarization. Other fractions demonstrated no depolarization. We conclude that 1) we have expressed CCK-Rs in Xenopus oocytes using mRNA from a human neuroblastoma cell line that expresses peripheral-type CCK-Rs and 2) the size of this CCK-R mRNA is between 5 and 6 kb.

10.4

CHARACTERIZATION OF VASOACTIVE INTESTINAL PEPTIDE BINDING TO RAT BRAIN AND RETINA. J.T. Laitinen and J.M. Saavedra (SPON: F.M.A. Correa). Unit Preclin. Neuropharmacol., Sect. Clin. Pharmacol., Lab. Clin. Sci., NIMH, Bethesda MD 20892.

Vasoactive intestinal peptide (VIP), despite its name, has a wide distribution in endocrine glands and the central nervous system (CNS). Recently, VIP and noradrenaline have been shown to interact synergistically to increase cyclic AMP in rodent nervous tissue in vitro (Schaad et.al. 1987, Nature 328,637; Ho et.al. 1987, BBRC 146,1478). Quantitative autoradiography offered us a tool for a closer look at VIP binding in rat CNS.

Displaceable binding of $^{125}I\text{-}Tyr^{10}$-VIP was seen in several brain areas, including cerebral cortex, dentate gyrus (DG), various thalamic and hypothalamic nuclei. Moreover, binding was detected in the retina and the anterior pituitary. VIP and peptide histidine isoleucine to lesser extent displaced labeled ligand from its binding sites. Neither VIP10-28 nor peptide T (nor its fragment T4-8), the proposed attachment sequence of the human immunodeficiency virus, were able to compete at 1 uM concentration for the binding sites with the ligand. In suprachiasmatic nuclei (SCh), homogeneous anterior-posterior distribution of binding was apparent, when quantified per unit area. Kinetic studies of several brain areas and retina may suggest the presence of two binding sites with K_ds around 0.1-0.5 and 5 nM.

The results further support a functional role for VIP in CNS and possibly also in the retina.

10.5

BIOCHEMICAL PROPERTIES OF BRAIN SOMATOSTATIN RECEPTORS. Kyriaki Thermos, Hai-Tao He*, Neil Margolis and Terry Reisine, Dept. Pharmacology, Univ. Pennsylvania, Phil. PA, 19104

The physical properties of brain and pituitary somatostatin (SRIF) receptors were characterized using photocrosslinking techniques. SRIF receptors in rat corpus striatum and anterior pituitary membranes were covalently bound to the non-reducible SRIF analog, [125I] CGP 23996 using the crosslinking agent n-hydroxysuccinimidyl-4-azidobenzoate and ultraviolet light. In striatal membranes, a protein of 60 kilodaltons was labeled by [125I] CGP 23996. The binding was potently inhibited by SRIF analogs but not by other biologically active peptides. The labeling of the 60 kilodalton protein by [125I] CGP 23996 was diminished by GTPgS, which is consistent with the labeling of a receptor coupled to GTP binding proteins. The migration of the [125I] CGP 23996 labeled protein in native SDS-gels was not affected by the reducing agent DTT indicating that there is a lack of disulfide bridges in the striatal SRIF receptor. The striatal SRIF receptor was solubilized with CHAPS and specifically bound to wheat germ agglutinin suggesting that the receptor is a glycoprotein. [125I] CGP 23996 also labeled a 60 kilodalton protein in anterior pituitary membranes. The characteristics of the binding were consistent with the labeling of a SRIF receptor. Interesting, a comparison of the [125I] CGP 23996 labeled material from striatal and anterior pituitary membranes by 2-dimensional PAGE revealed the presence of several striatal SRIF receptors of varying charge (pI between 6 and 6.5) but only one pituitary receptor. These findings indicate that physical differences may exist between subtypes of SRIF receptors. Supported byNIH grants DK37404 and GM 34781 and the Office of Naval Research (N00014-88-K-0048).

10.6

DEVELOPMENT AND SPECIFICITY OF GONADOTROPIN RELEASING HORMONE (GnRH) RECEPTORS IN RAT BRAIN. **L. Jennes, H. Dine* and B. Dalati*. Department of Anatomy, Wright State University School of Medicine, Dayton, OH 45435.**

The development and structure/function relationships of brain GnRH receptors were studied with "in vitro" autoradiography using the ^{125}I-labeled GnRH agonist D-tert-butyl-Ser^4-Pro^9-ethylamide-GnRH (Buserelin, Hoechst) as ligand. Specific, displaceable binding was first seen on postnatal days 7 and 8 in the hippocampus of young female rats. The distribution of the binding sites in the hippocampus was similar to the adult animal in that the binding was restricted the dorsal and ventral subiculum and to the areas CA_1 through CA_4. In the adult female rat, binding of Buserelin to the hippocampal tissue was inhibited by GnRH as well as by the GnRH agonists D-Ala^6-GnRH and D-Trp^6-Fujino-GnRH and by the antagonist [N-Ac-D-(pyro)Cl-Phe^1,^{2}-D-Trp^3-DLys^6-D-Ala^{10}]-GnRH. In addition, the GnRH fragment Des^{10}-GnRH competed for the brain GnRH binding sites, however with a lower affinity. The binding of Buserelin to the hippocampal GnRH receptors was not inhibited by Salmon-, Lamprey-, and Chicken I-GnRH nor by the GnRH fragments Des^1-GnRH, Des^1-GnRH, 4-10-GnRH and 5-10-GnRH.

In eight days old rats, intraventricular injections of labeled Buserelin resulted in "in vivo" labeling of similar areas of the hippocampus as described for "in vitro" autoradiography. Competition studies with 1 uM unlabeled GnRH show that the "in vivo" labeling is specific and saturable.

The results suggest that specific GnRH binding sites are present in the brain of young female rats and that these brain GnRH binding sites have similar binding characteristics when compared to the pituitary GnRH receptor.

EFFECTS OF DITHIOTHREITOL (DTT) ON OPIOID RECEPTORS: EVIDENCE FOR A POSSIBLE ROLE FOR DISULFIDE BONDS. T.L. Gioannini*, Y.F.Liu*, H-Y. Park*, J.M. Hiller* and E.J. Simon, NYU Medical Center, New York, NY 10016.

We have reported that purified μ opioid binding protein has a mobility on SDS-PAGE suggesting an apparent M.W. of 65kDa under reducing conditions. In the absence of DTT the apparent M.W. is 53kDa. We attributed this shift to a reduction of disulfide bridges resulting in a more linear conformation of the molecule. This finding has prompted us to study the effects of DTT on both purified denatured μ receptor protein and native opioid receptors. Different concentrations of DTT (from 0.65-325mM) caused SDS-PAGE patterns of purified μ receptor to undergo a stepwise shift in apparent M.W. from 53kDa to 65Da, suggesting the progressive breakage of multiple disulfide bonds. Treatment of cell membranes from various tissues with DTT produced a dose-dependent inhibition of opioid binding. The sensitivity to DTT inhibition varied from type to type in the order $\mu > \delta > > \kappa$. For μ receptors agonist binding was considerably more sensitive than antagonist binding. DTT inhibition is readily reversible and is unaffected by the presence of Na^+ or Mg^{++} ions. Scatchard analysis of saturation data shows that DTT causes a pronounced reduction in K_D with only a slight reduction in Bmax. Receptors solubilized by a modified CHAPS procedure are also inhibited by DTT, but higher concentrations are required than for membrane-bound receptors. These findings, especially the difference in DTT sensitivity between agonists and antagonists, suggest that disulfide bond breakage may play a role in the activation of the receptor induced by opioid agonist binding. (Supported by grant DA-00017 from the National Institute on Drug Abuse).

ZETA (ζ): A NEW OPIOID RECEPTOR RELATED TO GROWTH. I.S. Zagon, S.R. Goodman* and P.J. McLaughlin. Depts. Anat. and Physiol., Penn. State Univ. College of Medicine, Hershey, PA 17033

Endogenous opioid systems (i.e., opioids and receptors) regulate neural cancer. Utilizing ^{3}H-methionine enkephalin (ME), a ligand prototypic for growth, receptor binding assays were performed with homogenates of S20Y neuroblastoma transplanted into Ajax mice. Specific, high-affinity, and saturable binding to ^{3}H-ME was recorded; K_d = 0.49 nM, binding capacity Bmax = 5.3 fmol/mg protein. Dependency on time, pH, temperature, and tissue concentration was recorded. Na^+ and guanyl nucleotides (GppNHp) markedly reduced binding. Binding assays required a cocktail of protease inhibitors and was sensitive to trypsin, indicating the proteinaceous character of the binding site. An excess of DAGO, DADLE, and/or EKC, to suppress μ, δ, and κ binding, did not alter the profile of binding. Displacement studies showed that ME was the most potent displacer, binding was stereospecific, and ligands prototypic for μ, δ, κ, or ϵ receptors exhibited no distinct pattern of potency. Miscellaneous opioids (e.g., codeine) and non-opioids (e.g., somatostatin) exhibited little ability in displacing ME. These results, in conjunction with functional studies, identify a new opioid receptor, termed zeta (ζ) (G, zoe = life) related to growth. Supported by NIH grants NS-20623 and NS-20500.

10.9

BOMBESIN RECEPTORS ARE PRESENT ON HUMAN GLIOBLASTOMA CELL LINES. T.W. Moody, S. Mahmoud, R. Kris, L. Naldini, D Cirillo and J. Schlessinger. Dept. Biochemistry, George Washington Univ. Med. Ctr., Washington, D.C. and Rorer Biotechnology Inc., King of Prussia, PA.

Bombesin (BN) receptors are present in numerous cells. These include pituitary GH_4C_1 cells, Swiss 3T3 cells where BN stimulates ^{3}H-thymidine uptake, pancreatic acinar cells and SCLC cells where BN stimulates clonal growth. Because BN receptors are present in the mammalian CNS, we investigated if BN receptors were present on certain human neuroblastoma and glioblastoma cell lines.

Continuous human neuroblastoma and glioblastoma cell lines were cultured in serum supplemented medium, harvested and assayed for specific ^{125}I-GRP binding activity. High levels of binding were present on glioblastoma cell lines U-118, U-138 and GM-340 but not neuroblastoma cell line KCNR. On cell line U-118, binding was specific and reversible; ^{125}I-GRP bound with high affinity (Kd = 0.5 nM) to a single class of sites (Bmax = 25,000/cell). Structure-activity studies indicated that the C-terminal of BN or GRP was essential for high affinity binding activity. ^{125}I-GRP was cross linked to a 75 Kdalton protein using 1 mM dissuccinimidylsuberate at 4°C. At 37°C but not 4°C the ^{125}I-GRP receptor complex was internalized. These data indicate that glycoprotein BN receptors are present on human glioblastoma cell lines. Supported by NSF grant BNS 85-00552.

10.10

DISTRIBUTION OF NEUROTENSIN BINDING SITES IN HUMAN BASAL FOREBRAIN. E. Szigethy, R. Quirion and A. Beaudet. Montreal Neurol. Inst., Montreal, PQ, H3A 2B4; Douglas Hosp. Res. Ctr., Verdun, PQ, H4H 1R3.

We have previously demonstrated a selective association of NT receptors with cholinergic neurons in the rat basal forebrain (Neurosci. Lett., 83:47, 1987). In the present study, we sought to document the distribution of ^{125}I-NT-labeled binding sites with respect to that of cholinesterase (AChE) reactivity in human basal ganglia and adjoining forebrain. Slabs of normal human forebrain were cryostat-cut and adjacent sections processed for radioautography (using either conventional film or liquid emulsion dipping techniques) and AChE histochemistry. Dense ^{125}I-NT labeling was observed throughout the caudate and putamen nuclei, where it was found to mirror the diffuse pattern of heavy AChE-reactivity seen in adjacent sections. Moderate ^{125}I-NT labeling was also observed in both the diagonal band nucleus and the nucleus basalis of Meynert (NBM). In both these regions, labeled binding sites were localized predominantly although not exclusively over the large magnocellular neurons identified as AChE-positive in adjacent sections. These data provide an anatomical substrate for NT action on cholinergic neurons in human forebrain. They also suggest that the loss of AChE-positive neurons observed in the NBM of patients with Alzheimer's disease may be correlated with changes in the density of NT binding sites in this area. Supported by MRC.

NEUROTENSIN: EFFECTS ON THE DEPHOSPHORYLATION OF NEOSTRIATAL PHOSPHOPROTEINS. S.T. Cain, M. Johnson* and C.B. Nemeroff. Depts. of Psychiat. & Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710.

Neurotensin (NT) is a tridecapeptide which is widely distributed in the mammalian central nervous system. NT displays many of the characteristics of neurotransmitter substances such as synaptosomal localization, calcium-dependent release and specific, saturable high-affinity binding to brain membranes. We have previously reported that NT accelerates the rate of dephosphorylation of a synaptosomal protein with a molecular weight of approximately 51,000 (Cain and Nemeroff, Soc. Neurosci. Abst. 12, 802, 1986). We have now further characterized the effects of NT on the dephosphorylation of this protein.

A lysed synaptosomal preparation containing both synaptosomal membranes and synaptosomal cytosol was phosphorylated for 10 min. in the presence of 500 μM ATP containing [γ^{32}P-ATP]. Identical aliquots of the phosphorylated sample were then incubated for 10 min. in the presence of 7.5 nM NT or vehicle. At various intervals after the addition of NT or vehicle, aliquots were removed and processed for SDS-PAGE. Gels were dried, autoradiographs prepared and the phosphate incorporation into individual proteins quantitated by densitometry. Thirty seconds after the addition of NT to the previously phosphorylated sample, the phosphorylation of the 51,000 MW protein was decreased 29 ± 6.4% (n=3) relative to control values. The rate of subsequent dephosphorylation of the 51 KD protein was not altered by NT. Between 0.5 and 7.5 min., phosphorylation decreased 45 ± 5.31% in the control samples and 52.3 ± 7.31% (n=3 in both groups) in the NT samples. Thus, the stimulation by NT of 51 KD dephosphorylation is of rapid onset and offset. (Supported by NIMH MH-39415 and NARSAD)

10.12

SUBSTANCE P RECEPTOR ANTIBODIES. M. L. SWENBERG*, R. Liu (SPON: M. B. Carpenter). Hypertension & Endocr. Branch, NHLBI, NIH, Bethesda, MD 20892; Dept. of Anatomy, Georgetown Univ. Sch. of Med., Washington, D. C.,20007.

One way to demonstrate isolated receptors is to prepare their antibodies and further clarify the function of the preparations. The scheme for substance P (SP) receptor purification was reported last year (Abstr. Neuros. 87: 118.2, P412.). This presentation provides evidence of their antibody-activities against the receptors.

Purified SP receptors from acrylamide gel were directly emulsified with complete adjuvant and immunized on the back of New Zealand white rabbits. Antisera against both olfactory bulb and intestinal mucosa membrane receptors as well as monoclonal anti substance p antibody, were tested for their activities on : (1) Binding of SP receptors on the Phastgel or western blot and detected by double labeling with radioactive or fluorescent anti-rabbit IgG; (2) Immunocytochemical reactivity on fixed brain slices; (3) Binding inhibition of receptor antibodies on labelled ligand (SP) to fresh tissue slices.

All three antibodies showed similar reactivity but with different titer. Biological effect on guinea pig ileum and rat uteri also showed enhanced contraction (agonistic) for SP.

Fluorescent immunoreactivity can be performed and observed directly on Phastgel(from Pharmacia) or on the nitrocellulose western blot.

Based on this evidence the receptor isolated is homogeneous and antibodies react with specific nerve cells, fibers and terminals of brain tissues which could not be observed in regular autoradiograms.

10.13

NEUROPEPTIDE Y RECEPTORS IN THE RABBIT IRIS ARE RELATED TO SUPPRESSION OF SENSORY NERVE-MEDIATED INFLAMMATION. C. Wahlestedt*, E. Costa, M. Walker*, L. Grundemar *and R. Hakanson*, FIDIA-Georgetown, Univ. of Chicago and Univ. of Lund, Sweden.

Neuropeptide Y (NPY) is a 36 amino acid peptide widely distributed in the central and peripheral nervous systems. Much attention has been given to the coexistence of NPY and catecholamines. The peptide mediates and modulates a wide range of physiological processes.

In the mammalian eye, NPY nerve fibres are found in both the uvea and the retina. The iris is particularly rich in NPY fibres, the vast majority being of sympathetic origin (Sundler et al., Ann. Rev. Cytol. 102:234, 1986). We have examined the rabbit iris with regard to NPY binding and second messenger coupling as well as possible functional roles by means of in vitro and in vivo assays.

By use of 125I-NPY and homogenized iridal tissue, we established the presence of NPY binding sites, the density being high (Bmax 257 ± 19 fmol/mg protein). Scatchard analysis indicated that the peptide bound to two populations of sites (Kd:s 0.09 and 3.2 nM).

NPY inhibited the forskolin-evoked, but not the basal, cyclic AMP formation in pieces of iris. No effect of NPY on basal or adrenergically stimulated accumulation of inositol phosphates could be detected.

NPY did not affect the pupil size upon injection into the aqeuous humour in vivo, nor did the peptide produce any motor effect on isolated iris sphincter and dilator muscles in vitro. The isolated sphincter responded to electrical field stimulation in a complex manner; pharmacological analysis revealed cholinergic, adrenergic and tachykininergic (e.g. substance P-ergic) components. NPY selectively suppressed the tachykininergic component, indicating that it has the capacity to suppress local sensory reflexes. In the rabbit eye, such reflexes are closely related to the inflammatory response to injury (e.g. Wahlestedt et al., Regul. Peptides 16:107, 1986). Preliminary in vivo experiments (infrared irradiation followed by measurement of aqeuous flare response) further support that NPY and thus the sympathetic nervous system has the capacity to attenuate local sensory nerve reflexes, which are known to play a role in intraocular inflammation. (SPON: R. Ekman)

MESSENGER RNA REGULATION I

11.1

EFFECT OF CHRONIC HYPONATREMIA ON TRANSLATION RATE OF VASOPRESSIN (AVP) AND OXYTOCIN (OT) IN RATS. A.G. Robinson, W.A. Evron*, M.M. Roberts*, J.G. Verbalis, L.E. Janocko* and T.G. Sherman. School of Medicine, University of Pittsburgh, Pittsburgh, PA 15261, and Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Secretion of AVP and OT varies with osmolality in the rat. Plasma levels of AVP and OT and changes in the content of the posterior pituitary have been described during hyper- and hypo-osmolality, but there are few data on translation. We studied the down-regulation of translation in the neurohypophysis of a rat model of chronic hyponatremia. Sodium was 105-115 mEq/L for up to 14 days. We devised a novel method to measure total translation of AVP and OT by blocking microtubular transport to the posterior pituitary with intraventricular colchicine (7 ug) and measuring accumulation of AVP and OT over 18 h. We measured mRNA with specific riboprobes.

	Days of Hyponatremia			
Translation rate	0	3	7	14
AVP pg/h	1,470	523	0	0
OT pg/h	2,316	1635	211	294
mRNA % control				
AVP mRNA	100	38	16	11
OT mRNA	100	62	40	32

This is the first demonstration of the rapidity with which mRNA and translation of AVP and OT can be shut off. Thus, the neurohypophysis down-regulates promptly with hyponatremia and ongoing stimulated release of AVP and OT is essential to maintain message levels and hormone translation.

11.2

DOWN REGULATION OF VASOPRESSIN AND OXYTOCIN mRNAs: DECAY PROFILE DIFFERENCES BETWEEN HYPONATREMIA AND REHYDRATION. T.G. Sherman, A.G. Robinson, and S.J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109 and Department of Medicine, University of Pittsburgh, Pittsburgh, PA 15260.

The down regulation of hypothalamic magnocellular neuropeptide mRNAs were studied in two independent paradigms: 1) rehydration, the return to baseline decay following six days of salt-loading; and 2) hyponatremia, a down regulation of magnocellular mRNAs during a chronic period of low plasma sodium (see abstract: A.G. Robinson et al.). During a 14-day period of hyponatremia, vasopressin (AVP) mRNA in the paraventricular and supraoptic nuclei decreased to 11% of control values. Analysis of the parallel decay profiles in PVN and SON indicated a close fit to first-order kinetics with $k = 3.6\ hr^{-1}$ and a half-life of 4.6 days. Oxytocin (OT) mRNA was similar to AVP mRNA, whereas dynorphin mRNA decreased much more slowly ($t_{1/2} \approx 7.5$ days). The rate of decay exhibited by AVP during rehydration, on the other hand, did not follow first-order kinetics. Levels of AVP mRNA remained significantly different from controls for as long as 21 days following 6-days of salt-loading. Curve fit analysis of rehydration decay profiles indicated that the data was more consistent with zero-order accumulation/first-order decay kinetics. These results have led to the hypothesis that rehydration decay of AVP mRNA occurs in the presence of control transcription rates, whereas, hyponatremic down-regulation occurs in the absence of significant transcriptional activity. This hypothesis is being tested by examining AVP, OT and dynorphin transcriptional activity occurring during salt-loading, rehydration and hyponatremia.

11.3

VASOPRESSIN mRNA IN THE HYPOTHALAMUS: CIRCADIAN AND OSMOTIC REGULATION OF POLY(A) TAIL LENGTH. B.G. Robinson*, D.M. Frim*, J.M. Gleason*, W.J. Schwartz, and J.A. Majzoub* (SPON: E. Spindel). Neuroendocrine Genetics Lab, Brigham and Women's Hosp, Harvard Med Sch, Boston, MA 02115 and Dept of Neurology, U Mass Med Sch, Worcester, MA 01605.

Vasopressin (AVP) mRNA is localized in the supraoptic (SO), paraventricular (PV), and suprachiasmatic (SC) nuclei of the hypothalamus. We have studied circadian and osmotic regulation of AVP gene expression in these nuclei in male Sprague-Dawley rats. In the circadian experiment, animals entrained to 12 h:12 h LD and DL cycles were sacrificed at various times spanning the 24 h day. RNA was extracted from individual punches of either SO, PV, or SC nuclei, and analyzed by Northern blot. Oligonucleotide-directed RNAase H cleavage was used to determine AVP mRNA poly(A) tail length. In the SC nuclei, location of an endogenous circadian pacemaker in mammals, two distinct AVP mRNA species, with poly(A) tails 250 and 20 nucleotides long, were found predominantly in animals sacrificed in the dark. Only the longer-tailed species was found in the SC nuclei of animals sacrificed in the light. This longer-tailed species was also the sole AVP mRNA found in the SO or PV nuclei at all times. In contrast, an osmotic stimulation experiment (72 h dehydration) resulted in the gradual increase in the size of AVP mRNA poly(A) tails from 250 to 400 nucleotides in the SO and PV nuclei. These data are the first to show circadian and osmotic regulation of mRNA structure in discrete hypothalamic nuclei. Since the poly(A) tail may enhance translational efficiency of mRNA, the circadian and osmotic variation in AVP mRNA poly(A) tail length may provide an additional level of genetic regulation, and may contribute to both the circadian rhythm of AVP peptide levels in cerebrospinal fluid and to the increase in vasopressin synthesis following osmotic stimulation.

11.4

STEROID DEPENDENCY OF VASOPRESSIN mRNA EXPRESSION BY CELLS IN THE BED NUCLEUS OF THE STRIA TERMINALIS BY IN SITU HYBRIDIZATION. M. A. Miller*, J. H. Urban, and D. M. Dorsa (SPON: L. Standish). GRECC, VA Medical Center, Seattle, WA 98108.

Vasopressinergic (AVP) neurons in the bed nucleus of the stria terminalis (BNST) of the rat have been shown by immunohistochemical techniques to be steroid sensitive. To determine whether steroids modulate biosynthetic capacity, we have used in situ hybridization and quantitative autoradiography to measure propressophysin mRNA levels in neurons in the BNST of intact (n=3), castrated (n=6), and castrated male rats treated with testosterone (n=6).

Frozen brain sections (15μm) were hybridized with an oligonucleotide probe and coated with NTB2 emulsion. Sections through the BNST were anatomically matched (4/animal) and read blindly. The number of labeled cells (unilateral) and the average number of grains/cell (based on readings of up to 10 cells/slide) were compared.

Castration significantly decreased ($p<0.01$) the number of labeled cells in the BNST (X ± SEM: 3.2±2.2, castrates; 83.7±20.0, intacts) and reduced ($p<0.01$) the average number of grains/ cell (X ± SEM: 40.4±5.8, castrates; 83.1±10.2, intacts). Testosterone treatment reversed the effects of castration on cell number (90.0±4.6) and grains/cell (108.5±7.0). These results indicate that testosterone and/or its metabolites modulate the expression of mRNA by AVP cells in the BNST of the rat.

11.5

GLUCOCORTICOID (GL) REGULATION OF SOMATOSTATIN (S) GENE EXPRESSION IN NORMAL TISSUES AND IN A S-PRODUCING TUMOR CELL LINE (1027 B2). D.N. Papachristou* and Y.C. Patel* (SPON: J. Randle). Fraser Labs, McGill Univ., Mtl., QUE.

GL have been reported to reduce S secretion and mRNA accumulation in S-producing rat thyroid carcinoma cells whilst adrenalectomy in dogs augments pancreatic S content and induces hypersomatostatinemia. By contrast, GL have been shown to promote S secretion from cultured rat islets. To explain these discrepancies, we examined the effect of dexamethasone (DXM) on S secretion and mRNA accumulation in normal tissues in vivo and in vitro and in 1027 B2 islet cells. S-mRNA was determined by Northern analysis using in vitro synthesized antisense S-mRNA as riboprobe and sense strand S-mRNA as standard. 1027 B2 cells cultured for 24 h with DXM (10^{-10}-10^{-8} M) exhibited a dose dependent increase in S release (from 1.9 to 3.2 ng/ml) accompanied by a 40% increase in S-mRNA accumulation (from 204 ± 26 to 352 ± 32 pg /dish, $p < 0.05$). DXM (10^{-7}-10^{-6} M) reduced S secretion and mRNA by 30% ($p < 0.05$). A similar dose dependent biphasic effect of DXM on S secretion and mRNA was observed in cultured rat islets. Normal rats were injected with saline or DXM (40 ug/day for 7 days and studied on day 7 and 14). DXM increased pancreatic S content (from 0.79 ± 0.15 to 2.6 ± 0.1 pg/ug prot, $p < 0.01$) and mRNA (from 0.57 ± 0.05 to 1.75 ± 0.1 pg/ug, $p < 0.01$) with partial recovery after stopping DXM (1.8 pg/ug S content, and 1.1 pg S-mRNA/ug RNA). Identical changes in S content and mRNA accumulation were observed in cerebral cortex, stomach and jejunum. Conclusions: 1) GL modulate S gene expression in normal and neoplastic S cells. 2) GL effect on S secretion and mRNA accumulation is dose-related and biphasic and may explain their reported stimulatory and inhibitory actions on S gene function.

11.6

MORPHINE DECREASES PROENKEPHALIN mRNA LEVELS. R.E. Harlan and S.L. Chang*. Dept. of Anatomy, Tulane University Medical Center, New Orleans, LA 70112.

Opiate drugs act on the neuronal system mostly through their ability to modify the level of neurotransmitters. We have examined the influence of morphine treatment on the regional expression of the proenkephalin gene, which codes for the principle brain opioid peptide precursor. Six female rats were injected with morphine sulfate (10 mg/kg) or saline vehicle subcutaneously 60-100 min. prior to killing. The rats were injected with pentobarbital prior to decapitation. Brains were removed, dissected and frozen on dry ice. Total cellular RNA prepared from caudate-putamen, hypothalamus and amygdala was subjected to dot-blotting analysis with ^{32}P-cDNA probes complementary to proenkephalin mRNA. Proenkephalin mRNA levels in the caudate-putamen and amygdala of morphine-treated rats were suppressed approximately 45% ($p < 0.001$) and 25% ($p < 0.05$), respectively, relative to those of saline-treated animals. No significant difference was observed in the hypothalamus. Previous studies indicated both caudate-putamen and hypothalamus have high densities of μ-type receptors. The amygdala has few sites of μ-receptors (PNAS, 1980, 6239-6243). Our data suggest that the effect of morphine is not predicted only by the localization of opioid receptor in brain tissue. Our ongoing effort is on the post-receptor mechanism of opiate addiction underlying gene regulation of neuropeptide precursors.

STEROID REGULATION OF VASOACTIVE INTESTINAL PEPTIDE (VIP) GENE EXPRESSION - EVIDENCE FOR SEXUAL DICHOTOMY. I. Gozes. Dept. of Hormone Research, The Weizmann Institute of Science, Rehovot, 76100, Israel.

VIP gene expression is differentially regulated during ontogeny. Hypothalamic VIP-mRNA reaches a peak at 39 days of age concomitant with rat sexual maturation. Hence, we sought to analyze the influence of sex steroids on rat hypothalamic VIP gene expression. Using densitometric hybridization assays, VIP-mRNA was found to significantly decrease following ovariectomy. This decrease was largely reversed after 3 days of treatment with estradiol dibenzoate (Gozes, Werner, Fawzi, Shani, Fridkin and Koch, J. Molec. Neurosci., in press). In situ hybridization histochemistry suggests that the main changes occur in the suprachiasmatic nucleus as well as in the thalamus (Avidor, Biegon, Baldino, Rostene and Gozes, unpublished results). In contrast to the female rats, no change in VIP-mRNA was observed in the male rats following orchidectomy. Similar sex dependent differences were seen when the peptide levels were measured. These results imply a sexual dimorphism with regard to steroid regulation of hypothalamic VIP-gene expression in the rat, which may reside in sex specific regulatory factors. This sexual dimorphism is VIP specific, indeed, the amounts of somatostatin mRNA in the dorsal portion of the hypothalamic periventricular nucleus were significantly decreased following gonadectomy in both male and female rats (Werner, Koch, Baldino and Gozes, J. Biol. Chem., in press). Finally, our results imply a link between VIP gene expression and the regulation of the oestrous cycle.

11.8

REGULATION OF PREPROCHOLECYSTOKININ mRNA IN THE MEDIAL AMYGDALA BY ESTROGEN: AN IN SITU HYBRIDIZATION STUDY IN THE RAT. R.B. Simerly, B.J. Young* and L.W. Swanson. Howard Hughes Medical Institute and The Salk Institute, La Jolla, CA 92037.

The posterodorsal part of the medial nucleus of the amygdala (MeAp) receives its major sensory input from the accessory olfactory bulb, and projects massively to the encapsulated part of the bed nucleus of the stria terminalis and medial preoptic nucleus (MPN), two sexually dimorphic nuclei thought to play key roles in mediating steroid-sensitive reproductive functions. The MeAp also contains numerous cells that accumulate gonadal steroid hormones and many of these cells project to the MPN (Akesson et al. Soc. Neurosci. Abstr. '87). Recently we reported that levels of CCK-immunoreactivity within cells of the MeAp can be reversibly altered by gonadectomy in male rats (Simerly et al., PNAS, '87), and also appear to vary over the estrous cycle in response to corresponding changes in circulating estrogen in females (Oro et al., Neuroendocrinol., '88). By using a combined retrograde transport/double-immunohistochemical method we have determined that nearly half of the CCK-immunoreactive cells in the MeAp co-contain substance P (SP), and a substantial number of these cells project to the MPN. In order to localize the level at which estrogen regulates CCK expression, as well as to examine the specificity of this regulation, we used ^{35}S-labeled cRNA probes for in situ hybridization histochemistry to evaluate whether preprocholecystokinin (pCCK; see Deschenes, et al., PNAS, '84) and β-preprotachykinin (βPPT, see Krause et al., PNAS, '87) expression are regulated by estrogen at the mRNA level. In male rats, orchidectomy reduced, and treatment with diethylstilbestrol (0.1 mg) increased the number of pCCK mRNA cells within the MeAp. Similarly, the number of pCCK mRNA-containing cells detected within the MeAp was lowest in female animals during metestrus (when blood levels of estrogen are low), and were significantly increased in proestrous animals, which have peak levels of circulating estrogen. Subcutaneous implants of estradiol (0.5 mg) prevented the dramatic decline in pCCK mRNA-containing cells seen following ovariectomy, confirming that changes in pCCK mRNA during the estrous cycle are due, at least in part, to the normally occurring changes in levels of circulating estrogen. In contrast, levels of βPPT mRNA within the MeAp do not appear to be sensitive to acute changes in circulating gonadal steroids in either sex. Although the possibility that post-transcriptional regulation of pCCK mRNA stability may contribute to the observed effects, it appears likely that estrogen stimulates pCCK expression within the MeAp by inducing transcription of the pCCK gene, thereby altering the relative amounts of CCK and SP that are co-expressed within individual cells of the MeAp.

11.9

CLONING AND REGULATION OF RAT HIPPOCAMPAL STEROID RECEPTORS. P. D. Patel, T. G. Sherman, J. P. Herman, and S. J. Watson. Mental Health Research Institute, University of Michigan Medical School, Ann Arbor, MI 48109.

Several lines of evidence implicate the hippocampus in regulation of the hypothalamic-hypophyseal-adrenal axis. The pyramidal cells of the rat hippocampus contain two distinct pools of steroid binding proteins, one showing relative specificity for corticosterone, and the other for the prototypic glucocorticoid, dexamethasone. These are now referred to as the type I and type II corticosterone receptors, respectively. Utilizing the human glucocorticoid (type II) receptor cDNA as a probe in low stringency hybridization screening of a rat hippocampal cDNA library, we have isolated a message encoding the rat hippocampal type I (mineralocorticoid) receptor. The 6.5 kb message has an open reading frame coding for 973 amino acids. The entire open reading frame and 3'-untranslated regions are uniformly high in homology to the human kidney mineralocorticoid receptor (R. Evans), however, the sequence of the 5'-untranslated region diverges abruptly. RNase protection is being used to fully characterize this finding and to determine its tissue specific distribution. Complementary sense RNA probes to unique regions of the rat type I and type II corticosterone receptor messages have been used in protection assays to quantitate their respective mRNAs in a time course after adrenalectomy and after chronic corticosterone treatment. Preliminary results indicate that whereas type II receptor message does vary under this paradigm, type I receptor message is resistent to change, suggesting that control may be exerted at the level of message translatability or in the turnover of a cryptic receptor pool.

11.10

LOCALIZATION AND STEROID REGULATION OF HIPPOCAMPAL GLUCOCORTICOID AND MINERALOCORTICOID RECEPTOR mRNA: A SEMI-QUANTITATIVE *IN SITU* HYBRIDIZATION ANALYSIS. J.P.Herman, P.D.Patel, M.K.-H.Schafer*, S.Burke*, H.Akil and S.J.Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Glucocorticoid (GR) and mineralocorticoid (MR) receptors can be localized to the hippocampal formation of the rat, where they are believed to play a role in feedback inhibition of the hypothalamo-pituitary-adrenocortical axis. In these experiments, we examined localization and regulation of mRNAs coding for these receptor species within discrete hippocampal subfields using semi-quantitative in situ hybridization analysis. Examined were adrenalectomized rats (ADX), ADX rats replaced with daily dexamethasone (DEX) injections (ADX-DEX), sham ADX rats (SHAM), and SHAM rats administered daily DEX injections.

In all groups, GR and MR mRNA could be localized to all hippocampal subfields examined (CA1-2, CA3, CA4 and dentate gyrus (DG)). In SHAM rats, GR mRNA signal was heaviest in subfields CA1-2, with CA3-4 and DG showing approximately equal staining densities. MR mRNA signal was heavy throughout all hippocampal subregions, with no observable tendency toward preferential localization in any given subfield. In ADX rats, GR mRNA underwent a two-fold increase in subfields CA1-2, with no concomitant increases in CA3-4 or DG. The up-regulation of GR mRNA was not observed in the ADX-DEX group, indicating that the adrenalectomy-induced increase in hippocampal GR mRNA was steroid reversible. No change in GR mRNA was observed following chronic DEX treatment. In contrast to GR mRNA, MR mRNA did not respond to adrenalectomy or steroid treatment; no changes in MR mRNA levels were observed among the four groups. These results suggest that hippocampal GR-producing neurons respond to changes in circulating glucocorticoid levels in a region-specific manner, and therefore that neurons localized to subfields CA1-2 play a potentially important role in feedback inhibition of the hypothalamo-pituitary-adrenocortical axis. Evidence for a dynamic response of MR mRNA expression to circulating glucocorticoid levels is presently lacking.

11.11

ESTROGEN INCREASES PROGESTERONE RECEPTOR mRNA LEVELS IN THE HYPOTHALAMUS OF THE RAT. G.J.Romano, P.Chambon*[1] and D.W.Pfaff. The Rockefeller University, New York, NY 10021 and [1]Institute de Chimie Biologique, Strasbourg, France.

Previous studies have shown that estrogen increases progesterone binding in the hypothalamus. To determine whether this results from increased synthesis of new progesterone receptors, we have examined the effects of estrogen on progesterone receptor mRNA levels. Ovariectomized rats were injected s.c. with 10µg estradiol benzoate (EB) and sacrificed 4, 24 or 48 hr later. The 48h group received a second injection of EB after 24h. For in situ hybridization: brain sections were hybridized with a ^{3}H-labelled, single stranded DNA probe complementary to a portion of the human progesterone receptor mRNA. Labeled cells were observed only in regions known to contain progesterone binding sites. As evidenced by the lack of signal in the paraventricular nucleus, the probe did not hybridize to glucocorticoid receptor mRNA. Grain counting analysis revealed that 24h after injection of EB the number of labelled cells increased 3.9-fold in the ventrolateral-ventromedial nucleus and 5.3-fold in the arcuate nucleus. The number of grains/labelled cell in these nuclei also increased by 50%. Despite the second EB injection, the number of labeled cells and grains/cell declined by 48h. Both of these nuclei contain estrogen-inducible progestin binding sites. No effect of EB was observed in the medial amygdaloid nucleus, which contains progesterone binding sites that are not inducible by estrogen.

11.12

DIFFERENCES IN RESPONSE TO VIBRATORY STRESS OF TWO GLUCOCORTICOID REGULATED GENES IN RAT HIPPOCAMPUS. J.N. Masters, N.R. Nichols and C.E. Finch. Andrus Gerontology Center, USC, Los Angeles, CA 90089-0191

To study the molecular mechanisms of glucocorticoid effects on aging, stress and neurodegeneration we have isolated corticosterone-responsive clones from a rat hippocampal cDNA library. Two of these clones were chosen to analyze the effects of stress on their regulation. One of the clones is an unknown neuronal clone (pCR16) while the other has been identified as glycerol phosphate dehydrogenase (GPDH, pCR3) an oligodendrocyte marker. Adrenalectomized (ADX) or intact (INT) animals were placed on a mechanical shaker for two hours followed by isolation of total hippocampal RNA; non-stressed INT animals were used as controls. The abundance of CR16 and GPDH RNA were quantified by RNAse protection experiments using anti-sense cRNA probes. The results are summarized in the table below as pg transcript / ug total RNA. A clone for proteolipid protein (PLP) was used as a non-changing probe.

Clone	ADX	INT	INT + STRESS
CR16	1.4	2.6	3.1
GPDH	0.8	0.9	2.8
PLP	10.9	11.8	12.6

The amount of GPDH RNA is increased 3 fold by stress (INT + STRESS vs INT) but CR16 does not change (1.2 fold). However the amount of CR16 RNA responds to INT levels of CORT (2 fold, ADX vs INT) where GPDH does not. One interpretation of these results is that the high affinity CORT receptor mediates the expression of CR16 while the type II receptor mediates expression of GPDH. Both CR16 and GPDH RNA responses show type II glucocorticoid receptor specificity (RU28362 ≥ CORT > ALDO > DHT = ADX) but this does not preclude an additional type I interaction. We are currently pursuing other experiments to determine what aspects of CORT regulation accounts for the differential responses to stress. Supported by the John D. and Catherine T. NEURAL PLASTICITY IN ADULT ANIMALS: LTP I

12.1

INDUCTION, MAINTENANCE AND EXPRESSION OF LONG-TERM POTENTIATION (LTP) ARE DISTINGUISHED BY BLOCKERS AND STIMULATORS OF PROTEIN KINASE C. *D. V. Madison, R. Malinow and R. W. Tsien.* Dept. of Cellular and Molecular Physiology, Yale School of Medicine, New Haven, CT 06510.

We have previously reported that in the rat hippocampal slice preparation, sphingosine, an inhibitor of PKC at the regulatory domain, blocks LTP when applied before but not after the inducing tetanic stimulation (J. Physiol. 398, 18P). In contrast, H-7, a blocker of PKC at its catalytic site, will reduce potentiated transmission to basal levels, even when applied hours after the tetanus; unpotentiated pathways are unaffected. Upon washout of H-7, LTP is restored. Thus, there must be a signal that persists even in the presence of H-7; the expression of this signal is blocked by H-7.

Synaptic transmission is enhanced by bath application of phorbol diacetate, an activator of PKC, but returns to baseline levels upon washout of the phorbol ester. Thus, PKC activation alone is not sufficient to maintain LTP, even though it mimics the expression of LTP.

To account for these results, we propose a model in which induction of LTP is mediated by sphingosine-sensitive PKC. The model attributes the maintenance of LTP to formation of a sphingosine-insensitive, H-7-sensitive enzyme, such as PKM, the catalytic fragment of PKC. During induction of LTP, PKM levels could be jointly regulated by activation of PKC (as with phorbol esters) and proteolysis of PKC by a Ca-dependent protease.

12.2

SELECTIVE ACTIVATION OF PRE-SYNAPTIC PROTEIN KINASE C (PKC) ENHANCES SYNAPTIC TRANSMISSION IN RAT HIPPOCAMPAL SLICES. R. Malinow, D.V. Madison and R.W. Tsien. *Dept of Cellular and Molecular Physiology, Yale University School of Medicine, New Haven CT 06510.*

Bath application of phorbol ester enhances synaptic transmission in rat hippocampal slices, mimicking tetanus-induced long-term potentiation (LTP) (Malenka, Madison and Nicoll, 1986). We are developing a new technique using selective drug application together with conventional field potential recording to assess the role of pre-synaptic and post-synaptic PKC in LTP. We activate pre-synaptic PKC by focal application of lipophilic agents such as phorbol diacetate or dibutyrate to a selected subset of afferent fibers. When a fluorescent lipophilic agent (Di-I) is applied in the same manner, it can be seen to diffuse within the pre-synaptic axonal membrane to the recording site. The focally applied phorbol ester causes an enhanced synaptic transmission from those fibers (increase to 242 ± 20% of control; n=10). The enhancement decays within about 2 hrs, similar to the effects of bath applied phorbol ester. The action appears to be selectively pre-synaptic since synaptic transmission from independent input fibers to the same post-synaptic cells generally shows no enhancement. The enhancement by focal phorbol ester application is not due to an increased recruitment of axons at the stimulus site, as the pre-synaptic action potential remains unchanged. The relation between this enhancement of synaptic transmission induced by pre-synaptic PKC activation and LTP will be discussed.

12.3

LTP-INDUCED PROTEIN F1 PHOSPHORYLATION IN VITRO: DOES IT REPRESENT AN INCREASE OR DECREASE IN PHOSPHATE INCORPORATION IN VIVO? S. Chan, P. Colley* and A. Routtenberg. Cresap Neuroscience Laboratory, Northwestern University, Evanston, IL 60208.

After long-term potentiation (LTP) protein F1 phosphorylation measured in vitro is increased (Brain Res. 399:205). We report here a method to examine the in vivo mechanism for this increased phosphate incorporation in vitro. Rat hippocampal homogenates were boiled for 5 min to deactivate all enzymes. Samples were divided into two aliquots: one was treated with alkaline phosphatase (AP, 37°C, 1 hr, pH 9) to dephosphorylate occupied in vivo phosphorylation sites (AP+), and the other served as a control (AP-). The dephosphorylated protein F1 was then phosphorylated under optimal conditions by exogenous purified PKC (J. Neurosci. 6:3618) in the presence of gamma-^{32}P-ATP. The phosphorylation of protein F1 was quantified by densitometric analysis of audioradiograms. ^{32}P incorporation after AP+ estimated the total amount of protein F1 in the tissue. The value (AP+)-(AP-)/(AP+) * 100 was taken as the % of total sites endogenously phosphorylated.

Initial results indicate that LTP increased the % of endogenously phosphorylated sites (one-way ANOVA test: F=8.96, p<.05, N=4). In addition, there was greater exogenous F1 phosphorylation in controls without AP treatment in 3 out of 4 cases. Such results indicate that the in vivo phosphorylation of F1 is indeed increased after LTP suggesting increased PKC activity, as reported previously (Science 231:587). Thus, no apparent decrease in phosphate incorporation into protein F1 is occurring in vivo, though an inhibition of phosphatase activity cannot be ruled out. An increase in protein F1 substrate is suggested since exogenous protein F1 phosphorylation after AP+ treatment was greater in all cases at 2-4 hrs after LTP. These results suggest that after LTP an increase in kinase activity initially and an increase in protein F1 substrate at later time points (>1 hr) may contribute to the final in vivo increase in F1 phosphorylation. SYNAPTIC TRANSMISSION BETWEEN INDIVIDUAL CA3 AND CA1 NEURONS IN THE HIPPOCAMPUS. M.J. Friedlander, R.J. Sayer* and S.J. Redman, Experimental Neurology, John Curtin School, A.N.U., Canberra, A.C.T. 2601, AUSTRALIA.

Neurons of the CA3 region of the hippocampal formation provide excitatory input to neurons of the CA1 region. However, the synaptic potentials that underly this convergent input have not been described for connections between individual pairs of neurons. Thus, we employed dual intracellular recording to evaluate the EPSPs in CA1 neurons evoked by impulses in single CA3 neurons. Recordings were made from CA3-CA1 cell pairs in 450-500 µm thick slices of hippocampus prepared in conventional manner from guinea pigs that had been deeply anesthetized with ether. Records from CA1 neurons were averaged in response to single action potentials elicited by brief depolarizing pulses at 2 Hz to a single CA3 neuron. Of 975 cell pairs tested, functional synaptic connections were observed in 65 cases. In most cases (60/65), the unitary CA3 evoked synaptic potential was excitatory onto CA1 pyramidal cells with a mean amplitude of 131.8 µV (range 54-311 µV). The time course of these synaptic potentials is characterized by a mean 10-90% rise time of 3.9 ms (range 0.9-7.4 ms) and mean half width of 14.7 ms (range 5.3-42.4 ms). IPSPs were evoked in 3 cases and EPSPs were evoked in 2 presumptive CA1 interneurons.

12.5

LONG-TERM POTENTIATION COMPARED FOR UNITARY AND COMPOUND EPSPS IN CA1 NEURONS. R.J. Sayer,* M.J. Friedlander and S.J. Redman, Experimental Neurology, John Curtin School, A.N.U., Canberra, A.C.T. 2601, AUSTRALIA.

To determine whether LTP can be expressed at single cell-to-cell synaptic connections in the hippocampal slice, intracellular recordings of unitary EPSPs were made from CA1 neurons before and after conjunction with tetanic stimuli to the CA1 stratum radiatum. Slices were prepared by standard techniques from guinea pigs deeply anaesthetised with ether. Unitary EPSPs (75-450 μV) were evoked at 2Hz by action potentials elicited in single CA3 neurons by brief intracellular current pulses. Compound EPSPs (2-8 mV) were evoked through the same cathode as the tetani and were interleaved with the unitary EPSPs at 15s intervals. In six experiments in which CA3-CA1 pairs were held for 15-60 min after the tetani and the compound EPSPs showed a persistent post-tetanic increase in amplitude, the unitary EPSPs were unchanged. Trains of depolarizing pulses were delivered to the CA3 neurons coincident with each tetanus to ensure that the CA3 axon was repetitively activated. Implications for LTP mechanisms include a) cooperativity may be required not only for induction but also for expression, b) functional connections may develop for afferents which were previously ineffective.

12.6

ASSOCIATIVE LONG-TERM POTENTIATION (LTP) OR DEPRESSION (LTD) IS PRODUCED IN HIPPOCAMPUS DEPENDENT UPON THE PHASE OF RHYTHMICALLY ACTIVE INPUTS. P.K. Stanton, J. Jester, S. Chattarji, and T.J. Sejnowski. Dept. Biophysics, Johns Hopkins Univ., Balto., MD 21218.

Hippocampal LTP is an enduring increase in synaptic efficacy following brief high-frequency afferent stimulation. Separate afferents activated together exhibit associative LTP of inputs that alone do not elicit LTP, and inputs silent during postsynaptic burst firing show reduced synaptic efficacy termed LTD. LTP also occurs following short, rhythmic high-frequency bursts (100 Hz) separated at θ rhythm frequencies (5 Hz). We report here that phase of arrival of a weak input within the rhythm of a strong (potentiating) one determines whether associative LTP (inputs in phase) or LTD (out of phase) occurs.

Extra- and intracellular recordings were made in rat hippocampal slices (400 μm thick) in an interface chamber at 34°C. Stimuli were to separate inputs on the Schaffer collateral and subicular sides of CA1 pyramidal cell apical dendrites, or to commissural and mossy fiber inputs to CA3. Strong stimuli consisted of trains of 10 bursts of 5 pulses each (100 Hz burst frequency, 200 msec interburst interval). Weak stimuli (5 Hz trains) were positively correlated (in phase) by superimposing on the middle of each burst, or negatively correlated (out of phase) by symmetric placement between bursts.

When weak and strong inputs were in phase, associative LTP of the weak input epsp and population spike was seen 15-60 min post-tetani in field CA1, if either the Schaffer collateral or subicular side received the weak stimuli (ΔEPSP = +49.8 ± 7.8%, n=20; ΔSpike = +65.4 ± 16.0%, n=14). In contrast, if weak and strong inputs were 180° out of phase, a specific associative LTD of the weak input population spike was observed (-46.5 ± 11.4%, n=10), with no change in epsp slope. In field CA3, commissural fiber synapses also exhibited associative LTP when in phase with strong mossy fiber stimuli, and associative LTD when out of phase. Thus, pyramidal cells show enhanced or reduced efficacy of specific synapses depending upon precise timing between inputs. (Supported by Office of Naval Research Grant #N00014-88-K-0198)

12.7

EVIDENCE FOR THE INVOLVEMENT OF A GTP-BINDING PROTEIN (G-PROTEIN) IN HIPPOCAMPAL LONG-TERM POTENTIATION (LTP). Joanne W. Goh and Peter S. Pennefather, Faculty of Pharmacy, University of Toronto, Toronto, Ontario, Canada M5S 2S2.

Repetitive activation of presynaptic fibres in the hippocampus results in LTP of synaptic transmission. The mechanisms underlying LTP are not entirely clear but there is some indication that activation of protein kinase C (PKC) plays a role (Akers *et al.*, Science 231: 587, 1986; Malenka *et al.*, Nature 321: 175, 1986). The events leading to PKC stimulation during LTP induction, however, are not known. The results presented below suggest that a G-protein is involved in tetanus-induced LTP. It is possible that activation of this G-protein increases phosphoinositide turnover to produce diacylglycerol which, in turn, stimulates PKC.

Experiments were conducted on transversely sectioned rat hippocampal slices. Extracellular population spikes were recorded in the CA_1 cell body layer in response to stimulation of stratum radiatum. Pertussis toxin (PT, 3-4 μg total), an agent that inactivates some G-proteins, or vehicle alone was stereotaxically injected at 2 sites directly above the right hippocampus. Slices were obtained from the rats at 2,3 and 4 days post-injection. It has been shown that PT-uncoupling of G-proteins from their receptors reduces hippocampal neuronal responses to baclofen (Andrade *et al.*, Science 234: 1261, 1986). By monitoring the effect of baclofen on slices from vehicle-injected control and PT-treated hippocampi, it can be established whether PT is indeed inactivating G-proteins. In controls obtained at 3 and 4 days post-injection, LTP could be induced by tetanic stimulation of the input (271 ± 39% SEM of control at 30 min post-tetanus, n = 11) and baclofen (10 μM) produced a marked suppression of the population spike (13 ± 6% of control, n = 11). Experiments performed on the 3rd and 4th days post-PT injection indicated that LTP could not be induced (3rd day: 107 ± 11% of control at 30 min post-tetanus, n = 9; 4th day: 115 ± 11%, n = 6). The blockade of LTP developed in parallel with reduction of the ability of baclophen to inhibit the response (3rd day: 58 ± 4% of control, n = 9; 4th day: 48 ± 9%, n = 6). LTP could be elicited in slices obtained at 2 days post-PT injection (219 ± 47% of control, n = 5) and inhibition of the population spike by baclophen was normal (8 ± 5% of control, n = 5). It, thus, appears that the minimum time required for PT to exert its effect is greater than 2 days. This is not unexpected as the activity of PT is dependent upon a relatively slow uptake process that is followed by intracellular release of the active A protomer (Nogimori *et al.*, Biochem. 25: 1355, 1986).

12.8

TIME-COURSE OF STRESS-INDUCED IMPAIRMENT OF LTP IN RODENT HIPPOCAMPUS. M.R. Foy, T.J. Shors, S. Levine and R.F. Thompson. Dept. Psychology, Loyola Marymount University, Stanford Univ., & USC, Los Angeles, CA 90045

A marked impairment of long-term potentiation (LTP) recorded from the CA1 cell field of hippocampal slices immediately taken from rats exposed to acute stress has recently been reported (Foy et al., Behav. & Neural Bio., 1987,48,138-149). Some variable(s) in the temporal pattern of the PTP (post-tetanic potentiation)/LTP interaction appear to be modulated by dexamethasone (Foy et al., Neurosci. Abstr.,1987,13,976). In the present study, we examined the effects of stress on the pituitary-adrenal axis by measuring the time course of the stress response of LTP impairment.

The procedure was the same as in our previous experiment (Foy et al.,1987), except that following acute stress, rats were either immediately sacrificed (t=0) or returned to their home cages for a period of 1 hr before sacrifice (t=1). In vitro hippocampal slices were then prepared and recordings were made according to standard methods. Control animals (no shock) exhibited LTP following tetanus, whereas both groups of stress animals (t=0) and (t=1) exhibited no LTP following tetanus.

These data indicate that stress can significantly modulate neural plasticity within the rodent hippocampus which may involve long-lasting humoral and/or other effects within the animal following acute stress.

Supported by grant HD 02881 (NICH & HD).

12.9

PLASTICITY OF RECURRENT EXCITATORY SYNAPSES BETWEEN CA3 HIPPOCAMPAL PYRAMIDAL CELLS. R. Miles* (SPON: T.A. Pedley), Dept of Neurology, Columbia Univ., New York, NY 10032.

CA3 hippocampal pyramidal cells possess axon collaterals which form recurrent excitatory synapses with other CA3 pyramidal cells. Some unitary properties of these synapses have emerged but their plasticity has not been directly examined.

Recurrent synapses were selectively activated in two ways to examine their plasticity. Firstly, CA2-3a pyramidal cells were antidromically activated to evoke recurrent epsps in CA3b cells, while synaptic inhibition was suppressed and divalent cations were elevated. A persistent potentiation of recurrent EPSPs, with constant pre-synaptic activity, was observed 12-20 min after tetanic stimulation. Secondly, recurrent EPSPs were elicited by stimulating one cell and recording from a post-synaptic cell. 4 out of 5 mono-synaptic EPSPs were potentiated 12-20 min after tetanic stimulation of afferent fibres. The mean number of transmission failures at these synapses was reduced from 22% to 9%. The mean number of quanta released, calculated by the variance method, was increased while the quantal amplitude was slightly reduced.

The possibility that modulating transmitters facilitate the plasticity of recurrent synapses is also being investigated. Muscarine (5 uM) and carbamylcholine (5 uM) reduced the amplitude of single recurrent EPSPs but enhanced the post-synaptic depolarization during repetitive stimulation at 20-50 Hz. The probability and magnitude of potentiation of recurrent EPSPs (at 15 min) were enhanced when tetani were delivered in the presence of muscarinic agonists.

In conclusion, plasticity at recurrent excitatory synapses appears to result from a pre-synaptic modification and is facilitated by a transient activation of muscarinic receptors.

12.10

PROTEIN KINASE C IN HIPPOCAMPUS AND SEPTUM FOLLOWING FIMBRIA-FORNIX TRANSECTION. S. SHIMOHAMA, T. SAITOH, AND F.H. GAGE, Dept. of Neurosciences, UCSD, La Jolla, CA 92093, USA.

Protein kinase C (PKC) plays a pivotal role in the regulation of neuronal functions. We have studied the distribution and concentration of PKC in the intact and lesioned septum and hippocampus. Throughout this study, we have employed three anti-(PKC) antisera raised against C-terminal variable region of PK-C α, β-I and γ.

In the intact septum, PKC-α immunoreactive neurons were dense in the lateral septum and PKC-β immunoreactive neurons were present evenly throughout while PKC-γ immunoreactivity was highest in the medial septum. A decrease in the PKC-β and PKC-γ immunoreactive neurons was observed in the medial septum on the side of the lesion and a slight increase in the PKC-β and PKC-γ immunoreactive glia-like cells in the lateral septum.

In the intact hippocampus intense PKC-α immunoreactivity was observed in the subiculum, CA1, CA2 and CA3 regions. The molecular layers of the dentate gyrus (DG) were moderately stained and some PKC-α immunoreactive interneurons were observed in the hilus. Moderate PKC-β and PKC-γ immunoreactivity was observed in the subiculum, CA1, CA2, CA3 and the DG. Some PKC-β and PKC-γ immunoreactive glia-like cells were present in the subiculum and CA1 regions. Following damage there was a large decrease in PKC-α immunoreactivity in the CA1 and CA2 regions. In addition, there was a marked increase in PKC-β and PKC-γ immunoreactive glia-like cells in the subiculum, CA1 and CA2.

These results show that different isoforms of PKC are expressed in neurons and glia, and they may be under distinct regulatory mechanisms.

12.11

CURRENT SOURCE DENSITY (CSD) ANALYSIS OF THE EFFECTS OF PHORBOL ESTERS IN RAT PRIMARY VISUAL CORTEX. N.A. Lambert* and T.J. Teyler. Dept. of Neurobiology, Northeastern Ohio Univ. College of Medicine, Rootstown, OH 44272.

Protein kinase C (PKC) activation has been shown to be involved in the generation of long-term potentiation (LTP) in the hippocampus. Phorbol esters, which activate PKC, produce an effect similar to LTP when applied to hippocampus *in vitro* and blockade of PKC activation by polymyxin B causes an accelerated decay of tetanus-induced LTP. It has recently been demonstrated that activation of PKC induces long-term changes in postsynaptic currents in neocortical neurons (Baranyi, A. *et al.*, *Brain Res. 440*:341, 1988). To determine if PKC activation is involved in LTP induction in the neocortex this study examines the effects of phorbol esters in rat primary visual cortex *in vitro*.

Slices of rat visual cortex were prepared using standard procedures and CSD profiles were obtained from area OclM before and after bath application of phorbol 12,13-diacetate (PDAc). Initial results indicate that PDAc has an effect similar to the potentiation seen in hippocampus. PDAc also made slices susceptable to seizures. This suggests that induction of LTP in rat primary visual cortex also involves activation of PKC. (Supported by grants from NIH, EPA and ONR.)

PEPTIDES: BIOSYNTHESIS, METABOLISM AND BIOCHEMICAL CHARACTERIZATION I

13.1

TWO DISTINCT cDNAs FOR RAT PEPTIDYL GLYCINE α-AMIDATING MONOOXYGENASE (PAM) D.A. Stoffers, C.B.-R. Green* and B.A. Eipper, Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD, 21205.

About half of known bioactive peptides require an amidated C-terminus for bioactivity. The copper and ascorbate dependent enzyme responsible for this post-translational modification, PAM, was purified and the cDNA cloned from bovine pituitary (Eipper et al (1987) Mol Endo 1: 777). PAM is found throughout the endocrine and nervous systems. Unexpectedly high levels of PAM activity and mRNA are found in adult rat atrium, where 3.6 and 3.8 kb mRNAs are identified by Northern analysis.

A λZAP cDNA library constructed from rat atrial RNA and screened with bovine PAM cDNA probes yielded two distinct types of rPAM cDNA, rPAM-1 and -2. A 3.8 kb cDNA of the rPAM-1 type was sequenced and exhibits 84% nucleotide identity to the bovine PAM cDNA in the protein coding region. Major features of the protein predicted by bovine PAM cDNA are conserved in rat including signal and propeptide, a lengthy intragranular domain, a putative transmembrane domain, and a short cytoplasmic segment. The positions of all 14 cysteines, the His-rich potential copper binding regions, 8 of 10 pairs of basic amino acids, and 3 potential phosphorylation sites in the cytoplasmic domain are conserved.

Restriction mapping identified cDNAs of the rPAM-2 type which closely resemble the rPAM-1 type cDNA but lack ~200 bp in the protein coding portion.

13.2

EXPRESSION AND POST-TRANSLATIONAL PROCESSING OF TRANSFECTED MUTATED NEUROPEPTIDE Y cDNAs. I.M. Dickerson, J.E. Dixon, and R.E. Mains. Dept. Neuroscience, The Johns Hopkins School of Medicine, Baltimore, MD 21205.

Most neuropeptides are synthesized as a large biologically inactive precursor, which is proteolytically cleaved to a smaller bioactive form. Cleavage occurs primarily at pairs of basic amino acids in the precursor. We have begun to probe the substrate requirements for cleavage by transfecting cDNAs for human proNPY into the mouse corticotrope tumor cell line AtT-20 and isolating stable NPY-producing transformants.

ProNPY is 69 amino acids long and undergoes a single endoproteolytic cleavage at the sequence -Lys^{38}-Arg^{39}- during maturation. Using in vitro mutagenesis, point mutations encoding all possible permutations of this pair of basic residues have been introduced into the wild-type cDNA: -Arg^{38}-Arg^{39}-, Arg^{38}-Lys^{39}-, and -Lys^{38}-Lys^{39}-. We have compared the ability of cell lines transfected with wild-type or mutant proNPY cDNA to synthesize, process and secrete proNPY-derived peptides. ProNPY molecules containing the mutated cleavage sites -Arg^{38}-Arg^{39}- and Arg^{38}-Lys^{39}- are cleaved in AtT-20 cells as is the wild type proNPY which has been previously described (Dickerson et al, (1985) J. Biol. Chem. 262:13646). Like the uncleaved -Lys-Lys- pair in the endogenous β-endorphin, proNPY molecules containing -Lys^{38}-Lys^{39}- are not cleaved.

13.3

DISTRIBUTION OF CARBOXYPEPTIDASE E (EC 3.4.17.10) IN RAT PITUITARY. J. Rossier and E. Barrès*. Lab. de Physiol. Nerveuse du CNRS, 91198 Gif-sur-Yvette Cédex, France.

Carboxypeptidase E, EC 3.4.17.10, also known as enkephalin convertase, carboxypeptidase H and crino carboxypeptidase B, is an important enzyme involved in the biosynthesis of bioactive peptides. Rat anterior, intermediate and neural lobes were homogenized in 1 ml of 0.025 M Tris HCl buffer pH 8 with 5 mg/ml of BSA. After centrifugation, the supernatant was brought to pH 5.6 and centrifuged again. Following a 20 min preincubation with 2 mM $CoCl_2$, supernatant was incubated in a 1.5 ml tube with 0.1 mM of the radioactive substrate (^{3}H)Benzoyl-Phe-Ala-Arg. The 100 µl reaction mixture was stopped with 680 µl of a mixture of 0.25 N HCl/Acetonitrile (4/2.8) and the tube was transferred into a scintillation vial. Econofluor, a water non miscible scintillation fluid, was added. The product, Benzoyl-Phe-Ala, recovered in the organic phase, was counted with no interference from the substrate remaining in the aquous phase. The values expressed in nmol/min/lobe of the product formed were: 193 ± 28, 25.8 ± 1.9 and 10.3 ± 2.0 for anterior, intermediate and neural lobes respectively. After 3.5 days dehydration, these values did not change in anterior and intermediate lobes, but decreased by more than 50% in the neural lobe. In all the extracts 25 µM of GEMSA, a specific inhibitor of carboxypeptidase E, inhibited completely the activity.

13.4

IDENTIFICATION OF PREPROTACHYKININ SPECIFIC PROCESSING ENZYMES. Y.Y.H. Hook, T.J. Krieger*, D. Hegerle*, and H.-U. Affolter*+. Dept. of Biochemistry, Uniformed Services University of the Health Sciences, Bethesda, MD. and +Brain Research Institute, University of Zurich, Switzerland.

The neuropeptides substance P, neurokinin A, and neuropeptide K are derived from a large precursor, that must be specifically cleaved to form the bioactive peptides. In contrast to bovine and human species, rat shows no tissue-specific splicing of the tachykinin gene product. Therefore, the mechanism of tissue-specific production of tachykinin peptides must occur at the level of precursor processing. To identify the endopeptidase(s) that cleave this precursor, authentic ^{35}S-(Met)-ß-preprotachykinin was synthesized by in vitro translation, using a human cDNA derived mRNA (SP6 in vitro transcription system). Processing enzyme activity was found bovine adrenal medulla granules, which have been shown to contain substance P. Sequential cleavage of substrate followed by processing of resultant intermediate products appears to require distinct activities. ^{35}S-(Met)-ß-preprotachykinin cleavage was abolished by pepstatin, whereas further processing of an intermediate product was inhibited by leupeptin, and processing of a second product was inhibited by chymostatin. These data support the hypothesis that multiple types of protease activities may be involved in substance P precursor processing.

13.5

PARTIAL PURIFICATION AND CHARACTERIZATION OF MULTIPLE PREPROTACHYKININ PROCESSING ENZYME ACTIVITIES. T.J.Krieger*, H.-U. Affolter*+, and V.Y.H. Hook. (SPON: G. Mueller). Dept. of Biochemistry, Uniformed Services University of the Health Sciences, Bethesda, MD. and +Brain Research Institute, University of Zurich, Switzerland.

The tachykinins substance P, neurokinin A, and neuropeptide K are synthesized as a larger prohormone which undergoes proteolytic processing to yield the active peptide hormones. A rapid assay for ß-preprotachykinin processing has been utilized in the partial purification of 3 distinct activities from bovine adrenal medulla chromaffin granules. Affinity chromatography on conconavalin A - agarose followed by size exclusion chromatography on Sephacryl S200 yields 3 peaks of activity capable of cleaving human ^{35}S-(Met)-ß-preprotachykinin. The 3 peaks have apparent molecular weights of 205 kD, 58 kD, and 11 kD. The 58 kD activity is the major activity comprising over 60% of the total activity. The 58 kD activity is inhibited by the aspartyl protease inhibitor pepstatin A. The pH optimum for the activity is near 5.0 when the conversion of the prohormone into products is limited. In addition, pH has a profound influence on the extent of proteolytic processing and the identity of the products formed.

13.6

A NOVEL SOMATOSTATIN PEPTIDE CORRESPONDING TO PROSOMATOSTATIN (PRO-S) WITHOUT THE C-TERMINAL S-28 SEQUENCE: CHARACTERIZATION AND TISSUE DISTRIBUTION. S.N. Rabbani*, H. Bennet*, and Y.C. Patel* (SPON: H.H. Zingg). Fraser Laboratories, McGill University, Montreal, Quebec H3A 1A1.

Processing of pro-S to S-28 should theoretically generate a molecule equivalent to pro-S minus S-28 (pro-$S_{[1-64]}$). To identify such a molecule, 1 N acetic acid- pepstatin extracts of rat hypothalamus, antrum, jejunum, and pancreas were fractionated by reverse phase HPLC. The column effluent was monitored by region specific RIAs using antibodies directed against pro-$S_{[1-10]}$, S-$28_{[1-12]}$, and S-14. The concentration of pro-$S_{[1-10]}$ LI (pg/mg) was high in the antrum (56 pg/mg) and hypothalamus (28.5), moderate in the jejunum (12.7) and virtually undetectable in the pancreas (0.3). Eight HPLC peaks of pro-$S_{[1-10]}$ LI were identified and rechromatographed by gel permeation HPLC to reveal the following m.w. forms: 1K, 1.5K, 2.5K, 3.5K, 4.5K, 7K, 8K, and 10K. Only the 10K form was detectable as S-14 LI; it thus corresponded to the full length pro-S molecule. Only the 8K form was detectable as S-$28_{[1-12]}$ LI. The 1K form corresponded to pro-$S_{[1-10]}$. The 7K form was not detectable as S-14 LI or S-$28_{[1-12]}$ LI and thus appeared to represent pro-S without the S-28 sequence. It was relatively abundant in the hypothalamus (50% of pro-$S_{[1-10]}$ LI), present in moderate quantities in the antrum and jejunum (19%, 18% of pro-$S_{[1-10]}$ LI respectively), but undetectable in the pancreas. Conclusions: 1) Pro-$S_{[1-10]}$ LI is heterogeneous. 2) Its concentration is strikingly low in the pancreas compared to other tissues. 3) A novel 7K form corresponding to pro-$S_{[1-64]}$ exists and provides indirect evidence for pro-S to S-28 conversion. Its variable tissue distribution suggests that such conversion is important in the hypothalmaus and gut but not in the pancreas.

13.7

REGULATION OF NEUROPHYSIN PROCESSING IN THE RAT NEURAL LOBE. Robert Newcomb, Daniel Hartline and Jean Nordmann. Békésy Laboratory, Honolulu, HI and CNRS, Strasbourg, France.

An HPLC procedure has been developed for the direct analysis of all major neural lobe peptides (Neurochem. Int. 11, 229). This allows quantitation of the extent conversion of the oxytocin neurophysin (OTNP) to its alternate form, missing the C-terminal glutamate (OTNP'). This conversion occurs on the time scale of secretory granule turnover, making the ratio OTNP'/(OTNP+OTNP') a useful indirect measure of neural lobe secretory granule age. Combination of the HPLC procedure with introduction of 35S-Cys over the supraoptic nucleus provides the in-vivo conversion rate of OTNP to OTNP'. This proceeds with an initial rate constant of 0.1 days-1, and a rate constant for inactivation of this initial rate of 0.14 days-1. With chronic osmotic stress (21 days imbibition of 2% NaCl) the conversion rate shows only a slight increase, suggesting that changes in synthesis with increased secretory activity are comparable for the major secretory granule constituents. Measurements of OTNP'/(OTNP+OTNP') have been made in single neural lobes of animals under varying physiological conditions. Computer simulations incorporating these data show that compartmental models of secretory granule movements are capable of simulating changes in neural lobe (OTNP')/(OTNP+ OTNP'). From these studies, it is concluded that about 60% of secretory granules transported to the neural lobe are not released in the lifetime of a 300 g rat. Changes in affinity for release of aged secretory granules provide an alternative to compartmentation as an explanation for the observed changes in neurophysin content with depletion.

13.8

AN ENDOGENOUS CLONIDINE-DISPLACING SUBSTANCE IS PRESENT IN PERIPHERAL TISSUES OF THE RAT. *M.P.Meeley, M.L.Hensley*, P.M.McCauley*, P.Ernsberger and D.J.Reis* Div. of Neurobiology, Cornell Univ. Med. Coll., New York, NY 10021

Clonidine-displacing substance (CDS) is present in extracts of brain and inhibits the binding of clonidine to brain membranes (Meeley et al., *Life Sci* 38: 1119, 1986). Since CDS also contracts smooth muscle of the gastric fundus in rat (Felsen et al., *Eur J Pharmacol* 142: 453, 1987), we sought to determine whether CDS is contained in tissues other than brain. Rats were decapitated and whole blood was collected and serum prepared; the brain and peripheral tissues were dissected, homogenized in boiling water, then centrifuged at 4°C and 100,000xg for 30min. Supernatants and sera were made 7% in trifluoroacetic acid, re-centrifuged and neutralized. Samples were filtered to remove >10,000MW material, then dried and extracted with methanol. The CDS content was measured by radioimmunoassay (RIA) using a polyclonal antiserum to *p*-aminoclonidine (Meeley et al., *Neurosci Lett* 84: 84, 1988). Values are in RIA-Units; ie., the amount of extract giving 50% inhibition *per* gram wet wt. CDS-like radioimmunoactivity was higher in fresh rat brain (8.1±2.5; n=9) than in bovine brain (0.3-0.8). In rat, CDS-like activity was also present in the periphery (n=5-10). Adrenal gland (113±20) and gastric fundus (61±16) contained significantly greater levels of CDS than in any of the other tissues assayed ($p<0.01$, ANOVA with Neuman-Keuls). The heart (7.2±1.7), small intestine (3.1±1.2), kidney (1.6±0.4) and liver (1.3±0.3) also contained measurable amounts. CDS-like radioimmunoactivity in lung and skeletal muscle was near background (0.1-0.6; n=5), whereas CDS levels in serum were substantial (6.2±1.2Units/mL). Dose-dependent CDS-like smooth muscle contractions were elicited by extracts of serum> gastric fundus> small intestine, liver, brain, heart, kidney. These persisted during adrenergic blockade (10µM phentolamine and 1µM propranolol), confirming the presence of bioactive CDS. We conclude that (a) CDS is a unique, biologically-active substance of undetermined origin; (b) two independent assays confirm the presence of CDS in tissues other than brain and in the circulation; and, therefore (c) CDS may play a role as a novel transmitter or modulator, and as a hormone.

13.9

ANGIOTENSIN-(1-7) IS AN ENDOGENOUS PEPTIDE IN THE RAT BRAIN. M.C. Chappell*, K.B. Brosnihan, D.I. Diz, R.A.S. Santos*, M.C. Khosla*, and C.M. Ferrario. Brain and Vascular Research, Cleveland Clinic Fdn, Cleveland, OH 44195.

Recently, we showed that Asp-Arg-Val-Tyr-Ile-His-Pro [Ang-(1-7)] is a potent vasopressin secretatogue (Schiavone et al., PNAS, 1988). Here we compare the distribution of Ang-(1-7) and Ang II in the brain and adenohypophysis (PIT) of 40 male Sprague-Dawley rats (250-350g). Tissue regions were homogenized in ethanol/HCl, cryoprecipitated, and concentrated on a Bond Elut C18 column. Ang peptides were eluted (80% methanol), resolved by HPLC (HFBA solvent system), and quantitated by separate RIAs (Chappell et al., Peptides, 1987). A new RIA (range 1-2000 fmol, sensitivity 5 fmol) was developed which recognized Ang-(1-7) and Ang-(2-7), but not Ang I, Ang II or other N-terminal fragments (<0.05%). ^{125}I-Ang I, -Ang II, and -Ang-(1-7) added prior to extraction yielded recoveries >85%. HPLC revealed that the major immunoreactive Ang peptides detected coeluted with Ang I, Ang II and Ang-(1-7) standards. In PIT and amygdala (AMYG), Ang-(1-7) values were twice those of Ang II [PIT: 1426±85 vs 771±169 pmol/g; AMYG: 689±106 vs 300±75 pmol/g; (n=4 pools of 10 each)]. In contrast, in the hypothalamus(HYPO) and medulla (MED), Ang-(1-7) and Ang II were present in similar amounts (HYPO: 1086±92 vs 1175±75 pmol/g; MED: 683±139 vs 773±125). Thus Ang-(1-7) is present in brain regions and the different ratios of Ang-(1-7) to Ang II suggest that regulation of tissue content may be regionally specific. (Supported by NIH grant HL-6835)

13.10

NEUROPEPTIDE Y-LIKE PEPTIDE IN ADRENAL GLANDS: ISOLATION AND CHARACTERIZATION. H.Y-T. Yang, J. Rubenstein and E.A. Majane, NIMH, St. Elizabeths Hospital, Washington, D.C. 20032.

Neuropeptide Y (NPY) is present in high concentrations in adrenal glands of various species. The analysis of adrenal extract with HPLC-coupled with RIA revealed the presence of an additional NPY-like peptide with a retention time shorter than that of NPY. In rat adrenal glands, NPY-like peptide was detected in older animals but not in younger ones. In bovine adrenal glands, NPY-like peptide was detected in primary culture of chromaffin cells and can be released by 45 mM KCl. In order to explore the possible role of this peptide in adrenal function, NPY-like peptide was purified to homogeneity from bovine adrenal chromaffin granules by BioGel chromatography followed with successive steps of HPLC. The purified material was characterized by sequencing, other chemical analysis and carboxypeptidase digestion. A high degree of homology with NPY was observed and biological activity of this peptide still remains to be studied.

13.11

OXYTOCIN-GLYCINE (OT-G) CIRCULATES IN PLASMA OF HUMANS ADMINISTERED ESTROGEN. J.A. Amico and J. Hempel*. Depts. of Medicine and Biochemistry, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

The OT prohormone contains OT at its N-terminus, OT-neurophysin (Np) at its C-terminus, and glycine (G)-lysine (K)-arginine (R), intervening between OT and Np. Stimuli which release the hormone should also release its associated Np. Estrogen releases into plasma the human OT-Np. The OT immunoreactive (I.R.) material, temporally associated with release of the OT-Np, is not OT but an OT-like peptide (JCEM 60:5, 1985). Co-release of the OT-like peptide with OT-Np suggests that the OT-like peptide originates from the OT prohormone and may be a partially processed form of OT. To test this hypothesis, synthetic OT-G-K-R was cleaved with trypsin and the digest was cleaved with carboxypeptidase-B to form OT-G-K and OT-G, respectively. The identity of each synthetic peptide was verified by compositional analysis and the purified peptides were tested for cross reactivity with the various OT antisera used in this laboratory to distinguish the OT-like peptide from OT. OT-G, but not OT-G-K or OT-G-K-R, showed extensive cross reactivity with the OT antiserum (Ab-1), which is known to detect the OT-like peptide of human plasma. The HPLC separation of plasma from individuals administered estrogen had OT Ab-1 I.R. in fractions eluting with the same retention time as synthetic OT-G. The OT-like peptide of human plasma is a glycine-extended form of OT. Estrogen may alter posttranslational cleavage of the OT prohormone, releasing C-terminal non-amidated forms of OT into human plasma.

13.12

DEMONSTRATION OF THE PRESENCE OF HYPOTHALAMIC HYPOPHYSIOTROPIC FACTORS DISTINCT FROM KNOWN HYPOTHALAMIC HORMONES. A. Arimura*, A. Miyata, N. Minamino, A. Uehara, G. Katsuura, R. Dahl, M. Culler. U.S.-Japan Biomed. Res. Labs., Tulane Univ. Hebert Ctr, Belle Chasse, LA 70037

In order to seek novel hypothalamic hypophysiotropic factors, we began by purifying substances in ovine hypothalamic extracts (OHE) which stimulate adenylate cyclase activity (a nonspecific second messenger involved in the secretion of pituitary hormones) in rat pituitary cell cultures. Boiled and acetone-treated extracts of 3500 ovine hypothalami were loaded on a C18 column, eluted stepwise with 0.1% TFA containing 10, 20, 30, 40, 50, and 60% CH_3CN, and the eluent designated as fr. A, B, C, D, E, or F, respectively. Fr. C and D showed the greatest activity. Fr. C and D were then, respectively, loaded on SP-Sephadex and eluted stepwise with 1 M acetic acid (SP-I), 2 M pyridine (SP-II) and 2 M pyridine acetate (SP-III), respectively. Both SP-II and SP-III derived from C18 fr. C and D showed considerable activity. Both were then subjected to molecular sieving on Sephadex G-50. For each SP fraction a few to several bioactive peaks ranging from approximate mw of 1000 to 5000 were demonstrated. Active peak fractions were pooled and then purified by IEX-HPLC, followed by repeated RP-HPLC until pure materials were obtained. Net charge and hydrophobicity as determined by the retention time on IEX- and RP-HPLC were plotted on the ordinate and abscissa, respectively. Those for synthetic ovine LHRH, CRH, GRH and other neuropeptides were plotted on the same map. About 50% of points for bioactive materials obtained from OHE did not overlap the points for known synthetic neuropeptides. These results indicate the presence of at least several hypothalamic hypophysiotropic peptides which are distinct from known hypophysiotropic hormones. (Supported by NIH DK09094 and a grant from Takeda Chem. Industries.)

CARDIOVASCULAR REGULATION I

14.1

CENTRAL RESPIRATORY GENERATOR (CRG)-RELATED ACTIVITY OF SYMPATHETIC PREMOTONEURONS IN THE RAT ROSTRAL VENTROLATERAL MEDULLA (RVL). J.R. Haselton and P.G. Guyenet. Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

The CRG modulation of the lumbar sympathetic nerve discharge (LSND) was examined in 8 rats anesthetized with halothane, vagotomized, paralyzed and artificially ventilated with 100% O_2. At end-expiratory CO_2 levels>6%, phrenic-trigger averaged LSND decreased during early inspiration and exhibited a large peak that occurred at, or immediately after the cessation of the phrenic burst.

In 7 rats prepared as above, recordings of baro-sensitive units were made in the RVL. Forty of 44 neurons exhibited a large CRG modulation at end-expiratory CO_2 levels of 6-10%. Twenty cells displayed a pattern that was strikingly similar to that of LSND. Of these 20, 12 were antidromically activated exclusively from the thoracic spinal cord, 3 from both the spinal cord and pontine central tegmental tract (CTT), 3 only from the CTT and 2 were not driven from any location. The remaining 24 neurons were reticulospinal cells exhibiting one of four CRG-related patterns of activity distinct from that of LSND. The vast majority of the barosensitive cells tested were activated by raising end-expiratory CO_2 to 9-10%.

These results support the notion that RVL sympathetic premotoneurons are involved in cardiorespiratory integration.

Supported by a Fellowship from the A.H.A., Va. Affiliate to J.R. Haselton and NIH Grants HL 28785 and HL 39841.

14.2

BETA-ADRENOCEPTOR AND CYCLIC-AMP-MEDIATED EXCITATION OF ROSTRAL VENTROLATERAL MEDULLARY PACEMAKER NEURONS WITH PRESUMED SYMPATHOEXCITATORY FUNCTION. M.-K. Sun and P.G. Guyenet. Dept. of Pharmacology, Univ. of Virginia School of Medicine, Charlottesville, VA 22908.

The rostroventrolateral reticular nucleus (RVL) contains reticulospinal pacemaker cells with presumed tonic sympathoexcitatory and vasomotor function. These cells (N=72) were recorded in 500 μm-thick coronal tissue slices of the rat medulla (Sprague-Dawley 70-110 g). Their mean resting firing rate at 31°C was 8 spikes/s (±1, SEM). Their activity was reversibly increased by forskolin (adenylate cyclase activator, 10 μM; + 57± 12%, SEM) but unchanged by the inactive analog forskolin 1,9-dideoxy, 10 μM N=5). 8-br cAMP (0.5 mM, a membrane-permeable cAMP analog) also increased the activity of these neurons (+ 52 ± 7%, SEM, N=7) while adenosine produced opposite effects (-61 ± 12% at 0.5-1mM, N=8).

RVL pacemaker neurons were also activated by epinephrine (EPI, =+31 ± 7% at 10^{-5}M, N=5) or isoproterenol (ISO, + 52 ± 6% N=5 at 10^{-5}M). The effects of EPI or ISO (both at 10^{-5}M) were antagonized (50-100%) by 10 μM propranolol (N=5). Propranolol alone (10^{-5}M), the alpha-adrenergic agonist phenylephrine (10^{-4}M) or the alpha-antagonist phentolamine (10^{-4}M) were without effect.

It is concluded that the pacemaker activity of RVL cells with putative vasomotor function is regulated by cAMP which is a probable intracellular mediator of the excitatory action of catecholamines on these cells. HL 28785

14.3

AMYGDALA, VAGAL, AND BARORECEPTOR AFFERENT CONVERGENCE ON NUCLEUS TRACTUS SOLITARIUS (NTS) NEURONS IN THE CAT. R.J. Person, Dept. of Physiology and Biophysics, Univ. Okla. Health. Sci. Ctr., Oklahoma City, OK 73190.

Responses of NTS neurons excited from the ipsilateral central amygdala nucleus (AM) were recorded with tungsten microelectrodes in acute cats under chloralose and pancuronium. Stimulating electrodes were also placed on the ipsilateral carotid sinus (CSN) and cervical vagus (V) nerves. AM, V, and CSN responses were evaluated via peristimulus histograms; interactions between inputs were evaluated in conditioning-test (CT) paradigms.

Units received initial excitation from AM at a latency of 8.2 ± 0.7 (SE) msec; 35% had a subsequent 50-200 msec inhibition of spontaneous activity. Of these, many showed a late period of excitation at 175-250 msec. The remainder of the units had a pattern of early excitation with no following inhibitory period or had minimal or no background spontaneous activity.

Twenty-eight % and 16% received convergent CSN or V excitation, respectively, while 10% received convergent excitation from all 3 afferent sources. CT analysis showed that AM input was capable of significantly (>50%) attenuating subsequent CSN and V excitation over a 10-150 msec period.

The AM is apparently capable of modulating carotid sinus baroreceptor input. The inhibition may be interpreted by the as baroreceptor unloading with a subsequent rise in blood pressure. Supported by Ok. Health Research Program, Contract 1702.

14.4

THE ROLE OF ROSTRAL MEDULLA IN THE MEDIATION OF THE CENTRAL ANGIOTENSIN II (ANG-II) PRESSOR RESPONSE. L.R. Portis* and M.J. Brody. Dept. of Pharmacol. and C.V. Center, Univ. of Iowa., Iowa City, IA 52242.

Previous studies in our laboratory have provided functional evidence for mediation of the central ANG II pressor by a periventricular pathway from the antero-ventral third ventricle region to ventromedial peri-aqueductal gray. Our laboratory has also described two functionally and anatomically distinct sites in rostral medulla; rostral ventrolateral (RVLM) and rostral ventro-medial (RVMM) medulla that are both involved in the maintenance of vasomotor tone. Bilateral injection of 4% lidocaine (LIDO) in either RVLM or RVMM produced depressor responses. The present study was designed to determine if either RVLM or RVMM are also involved in the mediation of the ANG-II pressor response. Experiments were performed on Urethane anesthetized rats instrumented for measuring arterial pressure (AP) and heart rate and ventilated artificially. Bilateral injection of LIDO in either RVLM or RVMM produced the expected marked reduction in AP and significantly attenuated the ANG-II pressor response (20 ± 1 vs. 3 ± 1 mmHg) and (20 ± 1 vs. 7 ± 5 mmHg) respectively. The pressor responses and AP both returned to control levels within a 30 minute recovery period. These data suggest that the functional integrity of both RVLM and RVMM are required for mediation of the central ANG-II pressor response. (Supported by HLB-14388.)

14.5

ANGIOTENSIN II AND ANGIOTENSIN (1-7) EXCITE NEURONS IN THE CANINE MEDIAL NUCLEUS TRACTUS SOLITARII (mnTS) IN VITRO. Karen L. Barnes, W. Douglas Knowles, and Carlos M. Ferrario. Brain & Vascular Research and Neurology, Research Institute, Cleveland Clinic Fndn, Cleveland, OH 44195.

Because angiotensin (Ang) II and its heptapeptide fragment Ang (1-7) produce similar dose-related cardiovascular effects when microinjected into the mnTS, we compared the effects of these Ang peptides on mnTS neurons recorded from in vitro slices of the canine dorsomedial medulla. The medulla was removed from halothane anesthetized dogs and blocked in the horizontal plane. 300 μm slices were perifused with artificial cerebrospinal fluid (aCSF, 36°C). Extracellular recordings were obtained from 13 mnTS neurons during microdrop application of Ang II (8 ng/μl), Ang (1-7) (80 ng/μl), or aCSF onto the slice surface. As shown previously [Barnes et al., Hypertension 11: 1988 (in press)], Ang II substantially increased the firing rate of half the neurons tested (6 of 12 cells). Ang (1-7) also excited 4 of 10 neurons tested, eliciting a prolonged (5-10 min) increase in firing rate with a time course similar to the effects of Ang II. In 9 of these neurons the effects of Ang II and Ang (1-7) were compared. Excitatory responses to both Ang II and Ang (1-7) were seen in 3 cells. The other 6 neurons did not respond to either peptide. No inhibitory effects of either Ang peptide on mnTS cells were seen. These studies establish neuronal actions for a member of the Ang peptide family devoid of agonist effects on blood vessels, and suggest a common neuronal substrate for the similar cardiovascular effects of Ang II and Ang (1-7) given into the mnTS. (Supported in part by NHLBI grant HL-6835).

ALPHA-1 ADRENERGIC DEPRESSION OF SYNAPTIC RESPONSIVENESS IN SOLITARY TRACT NUCLEUS (nTS). P.D. Feldman and R.B. Felder, Dept. of Med., Univ. of Iowa, Iowa City, IA 52242

Our recent work has shown that alpha-2 adrenoceptor activation enhances synaptic excitability in the nTS. To determine the effects of alpha-1 receptor activation extracellular recordings were made from 9 nTS neurons in an in vitro rat brain slice preparation before and during infusion of the alpha-1 agonist methoxamine (MET). A microcomputer generated histograms of postsynaptic spike responses to electrical stimulation of the solitary tract at a fixed stimulus intensity. Agonist was allowed to wash out between drug infusions, and control responses were remeasured before each subsequent infusion of MET. The number of evoked action potentials was not affected by 1 nM or 2.5 nM MET ($P > 0.1$), but fell to 59.9 ± 9.8 % (mean ± SE) of control at 5 nM ($P < 0.05$) and 12.4 ± 0.1 % of control at 25 nM ($p < 0.001$). Infusion of the alpha-1 antagonist prazosin (200 nM) had no effect on synaptic excitability, but completely blocked the decrease of excitability induced by MET ($N = 2$). In contrast, the alpha-2 antagonist yohimbine (200 nM) had no effect on neuronal activity or responses to MET ($N = 2$). These data suggest that activation of alpha-1 adrenoceptors suppresses the responsiveness of nTS neurons to visceral sensory input. We postulate that an opponent process involving alpha-2 and alpha-1 adrenergic receptors may modulate the responsiveness of nTS neurons to autonomic sensory input.

CORTICOTROPIN-RELEASING FACTOR: ANATOMICAL SUBSTRATES OF AUTONOMIC REGULATION. *R. Giuliano, D.A. Ruggiero, T.A. Milner, M. Anwar and D.J. Reis.* Div. of Neurobiol., Cornell U. Med. Coll., NY, NY 10021

We sought to determine whether areas of nucleus tractus solitarii (NTS) and rostral ventrolateral medulla (RVL) subserving tonic and reflex control of arterial pressure contain corticotropin-releasing factor immunoreactive (CRF-I) neurons and processes and, if so, their source. Antisera against rat/human or ovine CRF were localized in colchicine-treated rats by the peroxidase-antiperoxidase method. Afferents and efferents were identified by injection of wheat germ agglutinated horseradish peroxidase (WGA-HRP) into RVL and NTS. Single sections were processed for HRP histochemistry and immunocytochemical localization of CRF. In NTS CRF-I punctate varicosities filled subnuclei (dorsal, intermediate and ventral) which receive primary sinoaortic baroreceptor afferents and harbor cells projecting to the C1 area of the RVL. Other CRF-I processes were distributed in the gastrointestinal afferent field (parvocellular subnucleus) or lay in close proximity to dorsal motor vagal neurons and surrounded the central canal. CRF-I cells were limited to caudal regions of NTS including an area transitional with area postrema. In RVL relatively few labeled perikarya and processes, distinct from larger CRF-I precerebellar relay cells of the lateral reticular nucleus, were seen. In transport studies WGA-HRP retrogradely labeled neurons in areas containing CRF-I perikarya. After NTS injections dual-labeled neurons were seen primarily in the medial parvocellular division of the paraventricular nucleus of hypothalamus (PVN) and to a lesser extent in RVL. Most HRP-labeled neurons in PVN were adjacent to those with CRF-I. After RVL injections dual-labeled neurons were seen in the dorsal hypothalamic area. Abundant anterograde label from NTS overlapped nuclear groups containing CRF in parabrachial and laterodorsal tegmental nuclei, central nucleus of amygdala, PVN and bed nucleus of the stria terminalis. We conclude that (a) CRF-I processes are distributed viscerotopically in NTS overlapping cardiovascular, gastrointestinal and other primary visceral afferent fields; and (b) CRF-I processes in NTS and RVL may derive from intrinsic and distal sources. CRF in NTS and RVL may contribute to cardiovascular regulation and other autonomic functions. (Supported by NIH HL 18974.)

THE DISTRIBUTION OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVITY IN THE MEDULLARY AND PONTINE TEGMENTUM OF THE CAT. V. John Massari, P.J. Hornby, E.K. Friedman*, R.A. Gillis and P.J. Gatti*, Depts. of Pharmacology; Howard Univ. Med. Sch. & Georgetown Univ. Med. Sch., Washington, D.C. 20059

We have examined the distribution of NPY perikarya and nerve terminals in the brain-stem of the cat. Four cats received IVT injections of colchicine (1000ug/200uL) 24-36 hours before sacrifice. Another cat did not receive colchicine. Sections were processed for immunohistochemistry according to a peroxidase antiperoxidase method. NPY immunoreactive perikarya were found predominantly in the medullary tegmentum. They were found in the medial nucleus of the solitary tract, the lateral tegmental field, in the area of the lateral reticular nucleus, and in the superficial layer of the spinal trigeminal nucleus. Tyrosine hydroxylase immunoreactive neurons with similar morphology and location were also observed in the first 3 areas noted above. Dense plexuses of NPY terminals were seen in the nuclei of the solitary tract, the first two layers of the spinal trigeminal nucleus, and in the Nn. raphe pallidus, obscurus, and magnus. Less dense terminal labelling was seen in the lateral tegmental field, the ventrolateral medulla and the N. locus coeruleus. These data indicate that the distribution of NPY in the medullary and pontine tegmentum of the cat is similar to, but not identical to that of the rat.

RECIPROCAL POTENTIATION OF NEUROPEPTIDE Y AND α_2 AGONISTS IN THE NUCLEUS TRACTUS SOLITARII. C.J. Tseng*, R. Mosqueda-Garcia, D. Robertson* (SPON: R.A. Margolin). Pharmacology Department, Vanderbilt University, Nashville, TN 37232.

In several systems, α_2-adrenoreceptor agonists and neuropeptide Y (NPY) potentiate one another. We reported recently that NPY is a potent depressor agent in the nucleus tractus solitarii (NTS). The purpose of this study is to investigate the possible modulation of α_2 agonist effect by NPY in this site. Microinjection (60 nl) of NPY, anti-NPY antiserum, the α_2 agonist α-methylnorepinephrine (α-MNE), clonidine, and the α_2 antagonists yohimbine and idazoxan were made into the NTS.

Administration of idazoxan (0.2 nmol) prior to the injection of NPY (2.3 pmol) attenuated the potent depressor and bradycardic effect of NPY (from -32±3 to -10±2 mmHg for MBP and from -110±9 to -43±2 bpm for HR, respectively, n=6, p<0.001). There was a similar attenuation of yohimbine's effect. Similarly, prior administration of the anti-NPY antiserum attenuated the depressor effect of the central antihypertensive agents, α-MNE (from -23±1 to -9±1 mmHg after 20 nmol α-MNE, n=9, p<0.001), and clonidine (from -23±2 mmHg, -49±6 bpm to -9±1 mmHg, 12±4 bpm after 5 nmol clonidine, n=7, p<0.001), whereas inactivated antiserum or control normal rabbit serum were not able to attenuate these effects. Even a subdepressor dose of NPY (47 fmol) could potentiate the effect of α-MNE .

These studies demonstrate a reciprocal potentiation of NPY and α_2 agonist in the brainstem, and suggest that NPY and catecholamines interact in central cardiovascular regulation.

14.10

SYMPATHO-INHIBITORY AND EXCITATORY MECHANISMS IN THE MEDIAN FOREBRAIN BUNDLE (MFB) OF RATS. H. Ohta and M.J. Brody. Department of Pharmacology and Cardiovascular Center, University of Iowa, Iowa City, IA 52242.

We reported previously that neuronal interruption by lidocaine or electrolytic lesion in the MFB produced pressor and tachycardic responses in conscious rats. These results indicate that tonic sympathoinhibitory neurons are either located in or pass through the MFB. To investigate whether cell bodies or fibers of passage are activated in MFB to produce hemodynamic responses, the effects of lidocaine and several excitatory amino acids were compared. When kainate (KA; 1-10 ng) and N-methyl-D,L-aspartate (NMDA; 5-200 ng) were injected into the MFB, pressor and tachycardic responses were observed that were similar to those induced by lidocaine. Glutamate (1000 ng) had no effect. The responses induced by lidocaine, KA and NMDA were all blocked by ganglionic blockade but not by adrenal demedullation. The pressor response induced by all three agents was potentiated by sino-aortic deafferentation but the tachycardia was not affected. These data demonstrate that the injection of lidocaine, KA and NMDA into the MFB increases sympathetic outflow to the cardiovascular system. Since the same actions were produced by local anesthetic and excitatory amino acids, it appears that complex sympatho-inhibitory and excitatory mechanisms exist in the MFB. (Supported by HLB-14388.)

PREGANGLIONIC STIMULATION ALTERS THE PATTERN OF IMMUNOREACTIVITY TO NEUROPEPTIDES IN THE SUPERIOR CERVICAL GANGLION (SCG) OF THE CAT. J. Ciriello, M. Bachoo*, M.M. Caverson and C. Polosa*. Depts. of Physiology, Univ. of Western Ontario, London, Canada and McGill Univ., Montreal, Canada.

The effect of supramaximal stimulation (120 min at 40Hz) of the preganglionic input (cervical sympathetic trunk) and of the postganglionic output of the SCG on the pattern of immunoreactivity (IR) to neurotension (NT), enkephalin (ENK), somatostatin (SS), substance-P (SP) and corticotropin releasing factor (CRF) was studied in the acutely decentralized SCG of the cat. In the presence of the cholinergic antogonists preganglionic stimulation evoked a contraction of the nictitating membrane (NM) that outlasted the stimulus and decayed slowly. With continuous stimulation the NM response was lost after about 1 hr. In the non-stimulated SCG fibers and terminals containing NT, ENK, SS, SP and CRF IR were observed throughout the SCG, but with regional differences in density of labelling for the different peptides. This pattern did not change after postganglionic stimulation. However, after preganglionic stimulation the IR for NT and ENK was drastically reduced. These data suggest that NT and LE are released from preganglionic axon terminals and are involved in mechanisms mediating the non-cholinergic NM response. (Supported by HSFO, QHF and MRC).

14.12

EFFECT OF PROLONGED PREGANGLIONIC STIMULATION ON RADIOIMMUNOASSAYABLE NEUROTENSIN (NT) IN THE SUPERIOR CERVICAL GANGLION (SCG) OF THE CAT. M.M. Caverson, M. Bachoo*, J. Ciriello and C. Polosa. Depts. of Physiology, McGill Univ., Montreal, Canada & Univ. Western Ontario, London, Canada.

During block of cholinergic transmission, stimulation of the cut cervical sympathetic trunk (CST) evokes a slow contraction of the nictitating membrane. Prolonged stimulation produces an irreversible loss of the slow response and a coincident loss of NT-like immunoreactivity in SCG fibers. This finding suggests that stimulation depletes preganglionic axon terminals of NT and that the depletion contributes to the loss of the response. In the present experiments, a radioimmunoassay specific for the C-terminal 5 amino acid sequence of NT was used to estimate the effect of CST stimulation on NT content of the SCG. After stimulation of the R-CST (2h, 40Hz, supramaximal intensity), the content of NT was determined in 0.5M acetic acid extracts of R- and L-SCG tissue (n=3 animals). NT content of the stimulated R-SCG (6.3±1.8 pmol/g tissue wt) was 44.3±2.6% lower than that in the unstimulated L-SCG (11.9±4.1 pmol/g tissue wt). In animals in which the CST was not stimulated, NT content was similar in the R-SCG (6.5±0.3 pmol/g tissue wt;n=3) and L-SCG (6.3±0.6 pmol/g tissue wt;n=2). These findings suggest that NT is released by stimulation of preganglionic axons in the CST and that NT acts as a transmitter at the sympathetic ganglionic synapse in the SCG.

ISOLATION OF PEPTIDE FRAGMENTS OF SBP THAT CONTAIN 5-HT BINDING SITES: LABELING WITH A NOVEL PHOTOAFFINITY PROBE. M. Adlersberg, H. Tamir*, P.Y.Yu, S.H. Hsiung and K.P. Liu. N.Y. State Psych. Inst. Div. Neurosci. N.Y., NY 10032.

Serotonin binding protein (SBP) is a soluble constituent of synaptic vesicles of central and peripheral (enteric) serotonergic neurons that form *in situ* a complex with serotonin (5-HT). Two forms of the protein that differ in molecular weight (45 kDa and 56 kDa) but share antigenic determinants, have been charecterized. The current study was undertaken in order to define the relationship of the two forms of SBP to each other. The 45 and 56 kDa SBP were purified as previously described (J. Neurochem. 44, 1289,1985; J. Neurochem. 49, 1105, 1987) and were labeled with a new photoaffinity probe, N-(4-azido-2-nitrophenyl)-5-hydroxytryptamine (NAP-5-HT) and its tritiated counterpart, ^{3}H-NAP-5-HT were synthesized by condensation of 5-HT or ^{3}H-5-HT with 3-fluoro-4-nitrophenyl azide. NAP-5-HT inhibited the binding of ^{3}H-5-HT to 45 and 56 kDa SBP (ID_{50}=1nM). ^{3}H-NAP-5-HT was found to bind strongly to both forms of SBP,and when photolysed (visible light; 4° C; 6min.) to bind irreversibly. The structure of NAP-5-HT presents the advantage of having the azido group remote from the hydroxyindole moeity which is essential for binding. ^{3}H-NAP-5-HT-SBP (45 and 56 kDa) were fractionated by SDS/PAGE and their migrating positions were determined by slicing a strip of the gel and counting. The radioactive bands were excised from the gel and overlaid with 5 µg S. aureus V_8 protease or 0.4 µg proteinase K/well in 5% stacking gel and digested for 2.5 hr. The generated peptides were fractionated by 13%-16% SDS/PAGE. The resulting peptides were located and quantitated by staining with Coomassie Blue and densitometry, followed by excising the protein bands and counting. Partial proteolysis with V_8 protease generated very similar pattern of radiolabeled peptides from 45 and 56 kDa SBP (10.5; 12; 14 kDa). Partial proteolysis with proteinase K generated only one radiolabeled peptide from the two forms of SBP that shared the same M.W (15kDa) .The radiolabeled peptides generated from the two forms of SBP were electroblotted to PVDF membranes and excised in order to sequence them by the method of Matsudaira(1987).It is expected that if the 56kDa form of SBP is the precursor of the 45 kDa form,there will be a strong sequence homology between radiolabeled peptides generated from the two proteins. The sequence study will also enable the synthesis of a DNA probe. Supported by NIMH grant 37575.

ULTRASTRUCTURE OF THE SEROTONIN INNERVATION IN THE RAT NEOSTRIATUM: RADIOAUTOGRAPHIC AND IMMUNOCYTOCHEMICAL CHARACTERIZATION. J.J. Soghomonian, L. Descarries and K.C. Watkins, Centre de recherche en sciences neurologiques (Département de physiologie), Université de Montréal, Montréal, Québec, Canada H3C 3J7.

High resolution radioautography after cerebroventricular administration of tritiated serotonin (5-HT) and PAP immunocytochemistry with an antiserum against 5-HT-glutaraldehyde-protein conjugate (kindly donated by M. Geffard) were used in parallel to investigate the intrinsic and relational features of 5-HT axon terminals (varicosities) in the neostriatum of adult rat. The uptake-labeled varicosities were examined in single thin sections from the paraventricular neostriatum and their immunostained counterparts in serial thin sections from the same area plus a dorsal neostriatal sector. These 5-HT axon terminals were generally small (0.5-0.6 µm in average diameter). Their internal features, best viewed in radioautographs, included small, pleomorphic synaptic vesicles with occasional large granular vesicles and mitochondria. Junctional 5-HT terminals from both sectors synapsed exclusively, and with equal frequency, on dendritic spines or shafts, almost always with asymmetric membrane differentiations. However, only 10-12% of the 5-HT varicosities from either sector exhibited synaptic junctions, as opposed to at least 70% of randomly selected unlabeled or immunonegative varicosities similarly sampled in the surrounding neuropil. Whether synaptic or not, the 5-HT varicosities were directly apposed to a variety of structures comprising mostly other axon terminals, dendritic spines and branches, but rarely neuronal somata. This microenvironment appeared similar in both neostriatal sectors examined. These results indicate that the 5-HT innervation of adult rat neostriatum is predominantly non junctional. They also suggest that, in neostriatum, 5-HT could exert its action upon a multiplicity of cellular targets in addition to the dendritic spines and shafts which are synaptically contacted by this type of terminal. (Supported by MRC grant MT-3544).

15.3

SELECTIVE IN VIVO MEASUREMENT OF SEROTONIN WITH NAFION COATED CARBON FIBRE ELECTRODES (CFE) COMBINED WITH DIFFERENTIAL PULSE VOLTAMMETRY. F. Crespi*, K.F. Martin* and C.A. Marsden* (SPON: S Auerbach). Medical School, Queen's Medical Centre, Nottingham NG7 2UH, UK.

CFE were made with single carbon fibres (30 µm o.d.) which were washed in chromic acid, electrically pretreated then coated 4 times with Nafion, a polymer selectively permeable to cations (Crespi. F. et al, Br. J. Pharmac., 92:565P, 1987). These nafion-CFE combined with differential pulse voltammetry (DPV) detect oxidation of dopamine (Peak A at 70 mV) and serotonin (5HT, Peak B at 250 mV) but not that of ascorbate, DOPAC, 5HIAA or uric acid (UA) 10 µM in vitro. In vivo, in the frontal cortex (FC), an oxidation peak at 250 mV with an amplitude of 0.5 nA (corresponding to 5 nM 5HT in vitro) was recorded every 5 min with the Nafion-CFE and was stable up to six hours. 5HT (1 µM) but not 5HIAA or UA (10 µM) increased Peak B when infused into the FC close to the Nafion-CFE (+130%). Infusion of KCl (0.1M) or p-chloro amphetamine (4 µg) also increased Peak B by 170 and 200% respectively without changing 5HIAA or UA measured with a conventional CFE (Crespi, F. et al, Neurosci. Lett., 43:203, 1983). Administration of the MAO inhibitor pargyline (100 mg/Kg i.p.) increased Peak B (+65%) but 5HIAA was decreased by 70%, while the 5HT$_1$ receptor agonist RU 24969 (10 mg/kg s.c.) decreased both Peak B and 5HIAA levels in FC by ~50%. Peak B was also increased by electrical stimulation of the dorsal raphe (10V, 10Hz, 10 min) but only during the stimulation period (+330%) while 5HIAA did not increase until after stimulation reaching a maximum 30 mins later (+75%).
These data indicate that Nafion CFE selectively detect 5HT in vivo.

15.4

SEROTONIN RELEASE AND METABOLISM IN RAT CORTEX IN VIVO. E.Carboni, L.Perezzani and G.Di Chiara. (SPON. G.De Montis). Inst.of Exp.Pharmacology and Toxicology, Univ.of Cagliari, 09100 Cagliari, Italy.

Transcerebral dialysis has been utilized for measuring brain levels of serotonin (5-HT) and 5-hydroxyindolacetic acid (5-HIAA). Dialysis tubes were implanted in the frontal cortex and perfused with Ringer. 5-HT and 5-HIAA were quantified in awake rats by reverse phase HPLC with electrochemical detection 24 hours after surgery. Out-put of 5-HT was calcium-dependent and abolished by tetrodotoxin (1 /uM) added to Ringer 5HT output was increased by the addition of chlorimipramine to the Ringer. The MAO-A inhibitor moclobemide (15 mg/kg s.c.) but not the MAB-B inhibitor RO-19.6327 (5 mg/kg s.c.) stimulated 5-HT output, while lisuride (30 /ug/kg s.c.) and metergoline (2 mg/kg s.c.), respectively reduced and stimulated 5-HT release. It appears that brain dialysis is a suitable method for the study of "in vivo" 5-HT release.

15.5

TRYPTOPHAN AND FOOD INCREASE EXTRACELLULAR SEROTONIN IN THE LATERAL HYPOTHALAMUS AS MEASURED BY MICRODIALYSIS IN RAT. D. H. Schwartz, S. McClane*, L. Hernandez and B. G. Hoebel. Dept. Psychol. Princeton Univ., Princeton, NJ 08544

Administration of l-tryptophan and the ingestion of certain foods are both known to increase brain serotonin synthesis. In order to examine whether this increase in serotonin synthesis leads to an elevation of extracellular serotonin, we used *in vivo* microdialysis. Male, albino Sprague-Dawley rats were stereotaxically implanted with 21 g guide cannulas aimed at the perifornical lateral hypothalamus (PFH). A small, removable microdialysis probe (0.2 mm x 3 mm tip) inserted directly into the guide cannula allowed collection of successive 30 min samples in freely moving animals. Samples were analyzed for serotonin and 5-HIAA using high pressure liquid chromatography with electrochemical detection. After the collection of baseline samples, animals were given one of three experimental manipulations: l-tryptophan (100 mg/kg i.p.), sight and smell of inaccessible diet (mash of Purina Chow plus sweetened condensed milk) or the same diet to eat. The tryptophan injected animals were further divided into two groups: free-feeding and 48-hr food deprived. Tryptophan injection caused a slight increase in extracellular serotonin (186% of saline controls) in *ad lib* fed rats (n=4). Food deprivation enhanced this effect (297% of saline control; n=4). Tryptophan had a similar effect on serotonin's metabolite, 5-HIAA. The sight and smell of an inaccessible, highly palatable diet did not affect extracellular serotonin (n=8). Ingestion of this same diet during a 30 min period caused an increase in extracellular serotonin during the same period. Unlike tryptophan loading, ingestion of the diet had no effect on 5-HIAA. These data suggest that serotonin in the lateral hypothalamus could be involved in the control of feeding behavior.

15.6

RELATIONSHIP BETWEEN DIALYSATE SEROTONIN AND RAPHE UNIT ACTIVITY. L.O. Wilkinson, S.B. Auerbach, and B.L. Jacobs. Program in Neuroscience, Princeton University, Princeton, NJ 08544

Extracellular serotonin (5-HT) was measured in awake, freely moving cats during increases and decreases in dorsal raphe 5-HT unit activity. 5-HT was separated by HPLC and dual amperometric detection was used to verify the authenticity of the 5-HT peak. Activation of dorsal raphe serotonin neurons, (induced either by low intensity electrical stimulation or observed during behavioral arousal) lead to increased dialysate 5-HT (32% and 14% above baseline, respectively) in striatum. Reciprocally, administration of the 5-HT autoreceptor agonist 8-OH-DPAT, which decreased raphe unit activity, produced a dose-dependent decrease in dialysate 5-HT. Though administration of 8-OH-DPAT completely suppressed the activity of 5-HT neurons within 5 mins, the maximal decrease in dialysate 5-HT (40% following 50 ug/kg s.c., and 58% following 250 ug/kg, s.c.) was observed 1 and 3 hours following drug administration. Thus, changes in dialysate 5-HT are less dynamic than those observed in unit activity. These data also suggest that ~60% of measured extracellular 5-HT is released as a consequence of neuronal activity. Finally, we examined dialysate 5-HT from the anterior hypothalamus following fever induced by the pyrogen muramyl dipeptide (50 ug/kg i.p.). Though 5-HT unit activity is unchanged during this manipulation, we observed a decrease in dialysate 5-HT preceeding fever peak. This suggests that 5-HT release may be uncoupled from unit activity in some situations.

15.7

NOREPINEPHRINE-STIMULATED RELEASE OF PINEAL SEROTONIN MAY BE MEDIATED BY ALPHA ADRENERGIC RECEPTORS. B. Benson and W.D. Reynolds*. Dept. of Anatomy, Univ. of Arizona, Tucson, AZ 85724.

The role of alpha and beta receptors was explored in the norepinephrine (NE)-stimulated release of pineal serotonin (5-HT) in vitro. Adult male Harlan SD rats were housed in 12L:12D and sacrificed at mid-light. Pineals were incubated under 95%O_2/5%CO_2 for 4 h at 37° C in vials containing 10^{-4} M ascorbic acid in 100 µl of medium TC-199, in the presence or absence of adrenergic agonists and/or antagonists. Pineal and medium levels of 5-HT were quantitated by HPLC/ECD. NE (10^{-4} M) significantly increased medium levels of 5-HT; this response was not affected by the addition of the beta antagonist propranolol (10^{-4} M). Also, the beta adrenergic agonist isoproterenol (10^{-4} M) was ineffective in the release of 5-HT. On the other hand, the alpha adrenegic receptor agonist phenylephrine (10^{-4} M) markedly stimulated the release of pineal 5-HT into the incubation medium; this stimulatory effect was significantly attenuated by the addition of 10^{-6} M prazosin. The results suggest that NE-stimulated release of 5-HT is mediated by alpha adrenergic receptors. This project was supported by N.I.H. grant HD 19521.

TRICYCLICS INHIBIT BRAIN MAST CELL SECRETION AND NEURONAL DEPOLARIZATION. M. Lambracht-Hall*, A.D. Konstantinidou*, M. Holdridge* and T.C. Theoharides. (SPON: J.E. Marchand). Dept. of Pharmacology, Tufts University School of Medicine, Boston, MA 02111.

Tricyclics are now widely used for the treatment of major depression because they inhibit the reuptake of serotonin and norepinephrine. We looked at the effects of tricyclics on brain mast cells and neurons in the thalamic-hypothalamic region because they can store and release serotonin (5-HT) and histamine, which have been implicated in mood disorders. We tested imipramine and the tricyclic antihistamine hydroxyzine in a custom-made perfusion system, using fresh rat thalamic slices labelled with ^{3}H-5-HT. The perfusate was assayed for 5-HT, histamine, b-hexosaminidase (a secretory granule enzyme) and LDH. There was no LDH release in any of the concentrations tested. The drugs alone at 0.5x10-^{4}M and 10-^{4}M caused release from mast cells but not neurons. However, over the range of 10^{-5}-10^{-4}M they inhibited subsequent mast cell release induced by the classic mast cell secretagogue, compound 48/80, and neuronal depolarization evoked by high K^+. Tricyclic drugs may, therefore, owe their antidepressant, analgesic, and other psychotropic effects at least in part to their ability to regulate release of certain mediators from brain mast cells and neurons.

15.9

MONOAMINE MODULATION OF HIPPOCAMPAL REACTIVITY TO PERFORANT PATH STIMULATION. G. Richter-Levin*, S.J. Sara and M. Segal*. Center for Neuroscience, The Weizmann Institute of Science, Rehovot 76100 Israel.

Electrical stimulation of the perforant path (PP) in anesthetized rat brain produces a typical EPSP and a superimposed population spike (PS) recorded in the dentate granular layer. Previous studies indicate that norepinephrine (NE) of locus coeruleus (LC) origin and 5-HT of the midbrain raphe can modulate hippocampal reactivity to afferent stimulation. In the present experiments we examined effects of drugs known to interact with the monoamines on hippocampal reactivity to PP stimulation. Fenfluramine (FFA), a 5-HT releaser, enhances PP-evoked PS by 40% without affecting the slope of the population EPSP, indicating that its effect is exerted postsynaptically. FFA is not effective in 5-HT depleted rats and its effects are reestablished when 5-HT levels are restored. FFA does not affect feedback inhibition but may reduce feed-forward inhibition. Idazaxon, an alpha-2 antagonist also enhances PP evoked PS in the dentate gyrus. This is probably mediated by increasing spontaneous activity of LC cells and releasing NE from its hippocampal terminals. The differences between noradrenergic and serotonergic drugs in the sites of action are now being examined.

15.10

SEROTONIN ATTENUATES SLOW IPSP'S IN HIPPOCAMPAL NEURONS. M. Segal* (Spon: M.E. Cohen) Center for Neurosciences, The Weizmann Institute, Rehovot 76100 Israel.

Topical application of 5-HT onto hippocampal slices produces several effects recorded intracellularly in Ca1 pyramidal neurons. These include activation of an outward K current, a blockade of a slow Ca dependent K current underlying the slow afterhyperpolarization, and an occasional late slow depolarization. Afferent stimulation evokes in hippocampal neurons a fast EPSP followed by a fast Cl^- mediated IPSP (fIPSP) followed by a slow K^+ mediated IPSP (sIPSP). The sIPSP and to a smaller extent the fIPSP are reduced by 5-HT while the EPSP is enhanced. The enhanced EPSP is not simply due to a reduced inhibition as its time course is faster and input relations different from those of the IPSP's. These effects are probably mediated by a 5-HT1a receptor as they are sensitive to spiperone. The reduction in sIPSP is seen with a low 5-HT concentration that has no other effects. The reduction in sIPSP is not accompanied by a change in postsynaptic sensitivity to GABA or baclofen. These experiments indicate that 5-HT has a potent presynaptic action to reduce inhibition in hippocampal neurons.

15.11

QUANTITATIVE INHIBITION OF HUMAN AXON REFLEXES BY EPICUTANEOUS APPLICATION OF CAPSAICIN AND LOCAL ANALGETICS. P.Bjerring* and L.Arendt-Nielsen. Dept. of Dermatology, Marselisborg Hospital, Aarhus and Dept of Medical Informatics, Aalborg University, Aalborg, Denmark.

The flare reaction after intracutaneous injection of histamine could be inhibited by epicutaneous application of 1) capsaicin 1% in EtOH once daily and 2) lignocaine 2.5% + prilocaine 2.5% in an emulsion cream (EMLA, ASTRA, Sweden). The cream was applied for 30, 60, 90 and 120 minutes. During the capsaicin treatment the flare area gradually decreased from 12.9 to 1.3 cm^2 after 6 days, when the treatment was stopped. After termination of the treatment the flare area reached the normal range 7 days later.
Analgesia by EMLA cream induced an application time-dependent decrease of the flare area from 9.9 to 2,5 cm^2. As a control dermal infiltration of lignocaine reduced the flare to 0.8 cm^2.
This study indicates, that the axon reflex can be reduced both by capsaicin treatment and by local analgetics. This demeonstrate that the axon reflex may be entirely intracutaneously.

15.12

PHOTOPERIOD-MODULATED MELATONIN BIOSYNTHESIS IN ASEXUAL PLANARIA. J.B. Best, M. Morita* and L. Pei*. Depts. Environmental Health and Anatomy, Colorado State Univ., Ft. Collins, CO 80523.

Previous studies indicate photoperiod modulation of asexual reproduction in planaria analogous to similar modulation of sexual reproduction in higher vertebrates, with evidence that melatonin may mediate such effects. Present studies, of enzymes involved in photoperiod-dependent melatonin biosynthesis in planaria, seek to elucidate these enzymes in asexual Dugesia dorotocephala and ascertain whether they are isoenzymes of the N-acetyltransferase (NAT) and hydroxyindole-O-methyl transferase known to be involved in melatonin biosynthesis in vertebrate pineals. NAT assays utilized tryptamine·HCl and [^{3}H] acetyl-CoA as substrates, and extraction of the [^{3}H] N-acetyl-tryptamine product with toluene:isoamyl alcohol (97:3). HIOMT assays utilized [^{3}H] S-adenosyl-methionine and N-acetylserotonin as experimental substrates, and extraction of the [^{3}H] melatonin product with chloroform. Results of these experiments will be reported.

IN VIVO TYROSINE HYDROXYLATION IN RAT RETINA: EFFECTS OF PHENYLALANINE INJECTION IN PARACHLOROPHENYLALANINE(PCPA)-PRETREATED RATS. J.D. Fernstrom and M.H. Fernstrom. Departments of Psychiatry and Behavioral Neuroscience, University of Pittsburgh School of Medicine, Pittsburgh PA 15213.

Phenylalanine (PHE), normally hydroxylated to tyrosine (TYR) in liver, may also be converted to TYR in neurons by TYR hydroxylase (TH) and thus be a substrate for TH. However, PHE is also reputed to be an inhibitor of neuronal TH. It is presently not clear which role(s) of PHE occur(s) in vivo. The problem experimentally is that rat liver rapidly converts PHE to TYR after PHE administration. The central nervous system (CNS) levels of both TYR and PHE thus rise, making it difficult to distinguish effects on TH due to increments in PHE from those due to increments in TYR. To circumvent this problem, we have identified a model system in rats in which only serum and CNS PHE levels rise following PHE injection, and applied it to the study of PHE effects on TYR hydroxylation rate in retina. Rats receive PCPA (300 mg/kg ip). Four days later, they receive an injection of PHE or vehicle, followed 1 hr later by NSD-1015 (100 mg/kg ip), and are then killed 30 min later. Four days after PCPA, TYR hydroxylation rate is normal in light-activated retinas, while tryptophan hydroxylation in brain is totally suppressed. In these rats, PHE injection (50-500 mg/kg ip) produces up to 10-fold increments in PHE levels, but neither stimulates nor inhibits TYR hydroxylation rate in light-activated retina. These and other results suggest that PHE is not acutely active in vivo as an inhibitor of TH in retina, even at abnormally high levels.

16.2

PHOSPHORYLATION OF THE N-TERMINAL REGION OF TYROSINE HYDROXYLASE BY A NOVEL PROTEIN KINASE. P.R. Vulliet, F.L. Hall*, J.P. Mitchell, and D.G. Hardie*. Dept. of Vet. Pharm/Tox., Univ. of Calif., Davis, CA 95616 and Dept. of Biochem., Univ. of Dundee, Dundee, Scotland DD1 4HN.

Previous studies have shown that tyrosine hydroxylase isolated from rat pheochromocytoma is phosphorylated in vitro by at least four different protein kinases. Screening for the phosphorylation of TH by a variety of well-characterized protein kinases has demonstrated phosphorylation of the enzyme predominantly at Ser-19 and Ser-40 in the N-terminal region of the native protein. Recently, we identified a novel protein kinase that phosphorylates TH at Ser-8. The site specificity of this kinase enabled the development of an assay for its activity. Originally detected as a contaminant in preparations of highly purified TH, the kinase was found to copurify with TH through ammonium sulfate precipitation and DEAE cellulose chromatography and was only partially resolved from TH by heparin-agarose chromatography. Separation of the kinase from TH was achieved by either phosphocellulose chromatography or sucrose density gradient centrifugation. The kinase eluted during gel filtration as a protein with an apparent molecular weight of 45 kDa. Substrate specificity, activity toward various synthetic peptides, and kinetic properties were investigated. Current investigations are aimed at examining the functional role of this kinase in vivo.

16.3

ISOLATION OF BOVINE cDNA CLONES WITH HOMOLOGY TO HUMAN DOPAMINE BETA-HYDROXYLASE. E.J. Lewis and V. Claflin*. Depts. Biochem. & Med. Genetics, Oregon Health Sciences Univ., Portland, OR 97201.

Dopamine beta-hydroxylase (DBH), the enzyme which catalyzes the conversion of dopamine to norepinephrine, is expressed specifically in noradrenergic and adrenergic tissues. We are interested in understanding the parameters which regulate the expression of the DBH gene.

We have constructed a bovine adrenal medulla cDNA library in lambda gt11 and have screened this library with a 34 base oligonucleotide probe designed to detect DBH sequences. The oligonucleotide contains a mixture of DNA sequences with complementary coding potential for amino acids 471-483 of human DBH (Lamouroux et al, EMBO J. 6: 3931;1987). The ^{32}P-oligonucleotide probe was used to screen 60,000 plaques from the cDNA library. Three positive phage were isolated with cDNA inserts of 0.7, 1.2 and 2.4 kb. Northern blot analysis demonstrated a major band of 2.3 kb when either oligonucleotide or nick-translated cDNA probes were hybridized to bovine adrenal medulla poly A(+) RNA. DNA sequence analysés predict amino acid identity between our cDNA and human DBH in 16/18 residues spanning 432-449 of human DBH. It is likely that these cDNAs code for bovine DBH. (Supported by grants from the NIH and Oregon MRF).

16.4

CHARACTERIZATION AND SEQUENCE ANALYSIS OF BOVINE DOPAMINE B-HYDROXYLASE cDNA. O. Hwang, J. Smith* and T.H. Joh. Cornell Univ. Med. Coll., Burke Rehab. Center, White Plains, NY 10605 and Mass. General Hosp., Boston, MA 02114.

Toward an analysis of the primary structure of dopamine -hydroxylase (DBH), we have independently isolated a 2.3kb cDNA from a bovine adrenal medullary lambda gt11 library using antisera against deglycosylated DBH. To verify the cDNA, we have determined three amino acid sequences of soluble DBH. One of these internal sequences is included in the amino acid sequence deduced from the nucleotide sequence of this cDNA, identifying it as representing DBH. The complete sequence of the coding region representing 351 C-terminal amino acids (41kd) was determined. Comparison with the human DBH sequence (Lamouroux et al, EMBO J. 6:3931, 1987) revealed the following: 1) Both potential glycosylation sites are conserved; 2) 87% homology is found at both nucleotide and amino acid levels in the coding region; 3) The 3′ untranslated regions exhibit low homology (48%); 4) 11 out of 12 cysteine residues are conserved.

Bovine adrenal medulla DBH mRNA is low in abundance (0.018%) and approximately 2.9kb in size. Southern blot analysis revealed that DBH is represented by a single copy gene. (MH24285)

16.5

PRIMARY SEQUENCES FOR BOVINE ADRENAL DOPAMINE β-HYDROXYLASE. D. L. Wong, C. L. Bildstein*, K. Lau* and J.S. Schilling*. Dept. of Psychiatry and Behavioral Sciences, Stanford Univ. Sch. of Med., Stanford, CA 94305.

The three subunits of soluble bovine adrenal dopamine β-hydroxylase (DBH), α (71 kD), β (75 kD) and γ (78 kD), were separated on SDS-polyacrylamide gels, transferred to PVDF paper and localized by Coomassie Blue R250 staining [Matsudaira, 1981]. Bands were excised and amino terminal sequences generated by gas phase/gas-liquid phase sequencing. To generate internal sequences, the purified protein was cleaved with cyanogen bromide since only 16 methionine residues were found by amino acid content analysis. Nine peptide fragments were identified on silver stained denaturing gels. Each was immunoreactive with a polyclonal antiserum specific for the DBH protein backbone. Based on relative molecular weights and comparison to the deduced human DBH primary structure (Lamouroux et al., 1988), five of the fragments represented partial digests. The peptides were separated as described above, and the most intensely staining bands sequenced. Amino terminal sequences and partial internal peptide sequences (19-25 residues) for the bovine enzyme showed considerable homology (61-95 percent) to the human enzyme, and represented fragments distributed throughout the polypeptide chain. Synthetic oligonucleotides developed against these amino terminal and carboxy terminal fragments have been used to screen a λgt11 rat adrenal medullary library to bias for the selection of full length rat DBH cDNA clones.

16.6

PRIMARY SEQUENCES FOR BOVINE ADRENAL PHENYLETHANOLAMINE N-METHYLTRANSFERASE. Y.S. Yoo*, K. Lau*, J.S. Schilling* and D.L. Wong (SPON: K.F. Faull) Dept. of Psych. and Behav. Sci., Stanford Univ. Sch. Med., Stanford, CA 94305.

We have previously shown that native bovine adrenal medullary phenylethanolamine N-methyltransferase (PNMT) consists of four charged isozymes. Characterization of these isozymes and preliminary sequencing data suggested that they were very similar, and differences might be primarily attributed to post-translational modifications. This would be consistent with identification of a single cDNA and mRNA for the enzyme by recombinant methodologies (Baetge et al., 1986). Microsequencing of the enzyme should provide further evidence for this hypothesis.

Amino terminal sequencing of purified PNMT showed that the 5' amino acid was blocked. Therefore, tryptic proteolysis and cyanogen bromide cleavage were used to generate peptides. Thirteen tryptic fragments and six cyanogen bromide fragments were obtained. These were separated on 20 percent SDS-polyacrylamide gels or on 20-27 percent gradient SDS-polyacrylamide gels and electroblotted onto polyvinylidene difluoride (PVDF) membranes. Following staining with Coomassie Blue, the bands were excised and were sequenced by automated Edman degradation using a gas/gas-liquid phase microsequencer equipped with on-line detection. Preliminary results show sequence homologies for the peptides ranging from 65-100 percent compared to the deduced sequences. In several cases, non-conservative changes represent single base alterations.

16.7

THE EFFECT OF REMOVAL OF CALCIUM (Ca^{+2}) BY EGTA ON MONOAMINE OXIDASE (MAO) ACTIVITY IN THE RAT BRAIN HOMOGENATE. N.T. Buu and C.Lussier*. Clinical Research Institute of Montreal, Montreal, Que.,Canada.

Mobilisation of intracellular stores of Ca^{+2} and cytosolic Ca^{+2} are necessary for the activation, through phosphorylation, of tyrosine hydroxylase (TH), the rate-limiting step in the synthesis of catecholamines (CA). Because mitochondria is a source of intracellular Ca^{+2} and mitochondrial MAO is the most important enzyme in the metabolism of brain CA, it is of interest to know whether Ca^{+2} availability can influence MAO activity.

MAO-A and MAO-B activities in rat brain homogenates were determined in the presence of 1 mM calcium chloride ($CaCl_2$), 10μM of Ca^{+2}/calmodulin inhibitor N-6-aminohexyl-5-chloro-1-napthalenesulfonamide (W7) or EGTA (2-10 mM).

The results indicated that neither $CaCl_2$ nor W7 affected MAO-A or MAO-B activities. On the other hand EGTA inhibited (from 20 to 60%) both forms of MAO in rat brain homogenates.

Thus the exit of Ca^{+2} from mitochondria which may be required for activating TH to increase CA synthesis may at the same time inhibit mitochondrial MAO suggesting a possible coordination between CA biosynthetic and metabolic pathways. (Supported by MRC of Canada and Canadian Heart Foundation).

ARE PNMT-CONTAINING CATECHOLAMINERGIC NEURONS ADRENERGIC? Alan F. Sved, Department of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh PA 15260

The intermediolateral cell column (IML) in the spinal cord is densely innervated by the PNMT-containing neurons of the ventrolateral medulla (C1 cell group). Since PNMT converts norepinephrine (NE) to epinephrine (EPI) and the PNMT-containing neurons in the ventrolateral medulla also contain the other enzymes required for EPI biosynthesis, it has been accepted that EPI is the major catecholamine neurotransmitter produced by these neurons. To examine this hypothesis, a sensitive HPLC-EC assay for EPI has been combined with a microdissection technique to determine the concentration of EPI in the IML. In dissections of rat thoracic spinal cord enriched in IML, as well as total thoracic cord, EPI levels were below the limit of sensitivity of assay, indicating levels less than 0.2 pg/mg tissue. In the region of the IML, EPI levels were less than 0.05% of the NE content. These results suggest that nerve terminals that contain all the enzymes required for EPI synthesis do not necessarily utilize EPI as a neurotransmitter.

FURTHER OBSERVATIONS ON THE LONG-TERM EFFECTS OF REPEATED COCAINE EXPOSURE ON RAT BRAIN DOPAMINE TURNOVER AND METABOLISM. F. Karoum, R.L. Suddath* and R.J. Wyatt. Neuropsychiatry Branch, NIMH, Saint Elizabeths Hospital, Washington, D.C. 20032.

We have previously reported a preferential long-term reduction in dopamine (DA) turnover in the frontal cortex (FX) and hypothalamus (HY) of rats exposed to 7 days (10 mg 1 kg, twice daily by intraperitoneal injection) cocaine administration (17^{th} annual meeting of neuroscience, 1987, 407.9). DA turnover was assessed by following the changes in central DA and 3,4 - dihydroxyphenylacetic acid (DOPAC) contents. In this communication we report on a replication of our previous work and expand our observations to the effect of a 7 day cocaine exposure on FX and HY DA, DOPAC and homovanillic acid (HVA) concentrations 6 weeks and 3 months after termination of cocaine administration. Ten rats were used at each test point and all analyses were carried out by combined gas chromatography mass spectrometry. Consistent with our previous report, DOPAC concentration in both the HY and the FX remained significantly reduced 6 weeks after termination of cocaine treatment. In the FX, but not the HY, DA content was also reduced. The combined molar concentrations of DOPAC and HVA (HVA + DOPAC) in both the FX and HY were significantly lower than those in the appropriate controls. These results signify a reduction in the total amount of DA released in the FX and HY and suggest a reduction in DA turnover. Interestingly, although DOPAC and HVA concentrations were about normal in the HY one week after treatment, 6 weeks later both DOPAC and HVA were reduced. Three months after termination of cocaine treatment, hypothalamic concentration of DA, DOPAC and HVA returned to baseline levels. In the FX on the other hand, DA and DOPAC concentrations were low but did not reach statistical significance. Rather unexpectedly, HVA concentration in the FX was now significantly low. Combined FX DOPAC and HVA molar concentrations 3 months after cocaine exposure were significantly lower than those of the controls. Apparently, DA turnover continued to be low even 3 months after a 7 day cocaine exposure. The results of the present study support and expand our previous report of a long-term effect of cocaine exposure on HY and FX DA turnover. The previously reported 6 week reduction in FX DA turnover and metabolism following a relatively short period of cocaine exposure is now extended to up to 3 months. The significance of the delayed emergance of a reduction in HVA concentration as compared with that of DOPAC will be discussed.

16.10

ALTERATIONS IN DOPAMINE SYNTHESIS INDUCED BY CHRONIC NEUROLEPTIC ADMINISTRATION: A POSSIBLE BIOCHEMICAL CORRELATE OF DEPOLARIZATION INACTIVATION. A. Y. Deutch and R. H. Roth. Depts. of Pharmacology & Psychiatry, Yale University School of Medicine, New Haven, CT 06510.

Electrophysiological studies have revealed that chronic neuroleptic administration results in certain midbrain dopamine (DA) neurons entering a state of depolarization inactivation; biochemical correlates of this condition are lacking. We have examined DA synthesis following chronic haloperidol (HPD) administration. Animals received 20 days of either haloperidol (HPD) or vehicle; on day 21, half of the animals administered chronic HPD received HPD and the other half vehicle injection. Acute HPD (chronic vehicle-HPD challenge) resulted in a marked increase in DA synthesis (as reflected by DOPA accumulation) in the striatum (CP), a somewhat smaller increase in the nuc. accumbens (NAS), and a still smaller increase in the prefrontal cortex (PFC). Corresponding increases in synthesis were seen in the A9 and A10 (but not A8) DA cell body regions. Chronic HPD followed by HPD challenge resulted in a blunted response in the NAS and CP as well as the cell body regions. In animals receiving chronic HPD followed by vehicle on day 21, DA synthesis rates in the CP and NAS (but not cell body regions) were decreased below normal control values. Such decreases in DA synthesis may indicate that the DA neurons innervating these areas are in a state of depolarization inactivation.

16.11

CHRONIC THYROTROPIN-RELEASING HORMONE (TRH) UPREGULATES MAZINDOL (Maz) BINDING AND INCREASES DOPAMINE (DA) METABOLISM IN THE RAT STRIATUM. H. Ikegami*, S.A. Spahn and C. Prasad. Sect. of Endocrinology, Dept. of Medicine, LSU Med. Ctr., New Orleans, LA 70112.

Administration of exogenous TRH, a peptide endogenous to basal ganglia, exhibits a variety of DA-related biologic activities, such as stimulation of DA release. To understand global role of TRH on DA neurotransmission, we have examined effects of chronic TRH on two elements of nigro-striatal DA neuron--DA receptors and DA reuptake sites. Male rats were treated for 10 days with TRH using s/c Alzet-osmotic pumps (0.51±0.02 mg TRH/kg/day). On 11th day rats were killed, striata dissected from brain, and stored frozen. The data presented below show a significant ($p < 0.025$) increase in not only striatal dihydroxyphenylacetic acid (DOPAC) levels (pmol/mg tissue), but also both K_D and Bmax (pmol/mg prot.) of Maz-binding after TRH treatment. In contrast, levels of DA and HVA, or properties of D-1 and D-2 receptors were not affected. While DOPAC elevations may be due to sustained stimulation of DA release by TRH, the mechanism(s) underlying modulation of DA uptake sites remains to be explored.

Treatment	DOPAC	Maz-K_D,nM	Maz-Bmax
Vehicle	20±2(21)	30±6(8)	4.8±0.7(8)
TRH	32±2(7)	51±6(11)	11.3±1.9(11)

16.12

NICOTINE-INDUCED RELEASE OF ENDOGENOUS AND NEWLY-SYNTHESIZED DOPAMINE IN FREELY-MOVING UNANESTHETIZED RATS. T.C. Westfall and L.E. Vickery*. Dept. of Pharmacology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

We have previously observed that nicotine (NIC) causes a dose-dependent release of dopamine (DA) from superfused rat striatal slices. In the present study we examined if such a response could be seen in freely moving unanesthetized rats in vivo. Animals were anesthetized with ketamine/acepromazine and a 21 gauge guide cannula stereotaxically placed in the striatum (A +1.0, L +3.0, V -6.0 with respect to bregma). Five to seven days later, the rats were lightly anesthetized with metofane and a 28 gauge push-pull cannula assembly introduced into the guide cannula to perfuse the striatum with artificial CSF (18 µl/min). Rats were allowed to recover from the anesthesia and CSF effluent collected in 10 min fractions for analysis of DA by HPLC-EC detection. In other experiments newly synthesized DA was measured following perfusion with ^{3}H-tyrosine (40-50 µCi/ml). Drug treatments were carried out 120 min after the start of perfusion to allow the release of ^{3}H-DA to reach a steady-state. Samples were passed over amberlite and alumina columns and analyzed by liquid scintillation spectrometry. Release of endogenous DA (pg/min) was: basal, 9 ± 3; NIC (1 mM) 22.6 ± 6; NIC (1 mg/kg s.c.) 54 ± 4; K^+ (56 mM) 121 ± 23. NIC (1 µM) increased the release of ^{3}H-DA by 117% over control. It is concluded that NIC releases DA from the striatum of freely-moving unanesthetized rats. (Supported by DA02668.)

16.13

INTRACEREBRAL MICRODIALYSIS MONITORING OF STRIATAL DOPAMINE RELEASE AND METABOLISM IN MPTP-INDUCED HEMI- PARKINSONIAN MONKEYS. S.L.Skirboll*, J.Hsaio*, I.Mefford*, R.Miletich, J.Alger*, A.Brunetti*, I.Kopin and K.Bankiewicz (SPON:J.Q.Trojanowski). NINCDS, NIH, Bethesda, MD 20892

In monkeys, unilateral intracarotid infusion of MPTP produces a useful model of hemiparkinsonism. In order to evaluate MPTP-induced neurochemical changes in-vivo, we have employed brain microdialysis to measure extracellular levels of dopamine(DA) and its metabolites (HVA) and (DOPAC) in the putamen. In-vitro recovery rates of these substances averaged 30% at a flow rate of 1 ul/min. 3 mos. after MPTP infusion, the probes were implanted bilaterally into the putamen on a horizontal plane at coordinates calculated from magnetic resonance imaging. Perfusion at 1 ul/min using 0.9% NaCl + 0.1 mM Ascorbate was carried out while the monkey was in a restraining chair under mild ketamine anesthesia. Samples were assayed for DA,HVA,DOPAC, and the 5-HIAA, via HPLC with ECD. Stable baseline values were reached 90 min. after implant of probes. The most striking effect of the MPTP lesion was seen in the 90% reduction in perfusate levels of HVA as compared to the unlesioned side (5.7 vs. 57.5 pimoles/20 ul inj.). A similar reduction was seen with DOPAC though the perfusate levels of it were 230 fold less than that of HVA. Interestingly, DA levels were very low (0.03-0.04 pimoles/inj) equally on both sides. Perfusate levels of 5-HIAA were reduced 32% on the lesioned side. Post-mortem tyrosine-hydroxylase(TH)immunocytochemistry revealed a complete unilateral denervation in the Putamen and total loss of TH(+) cells in the substantia nigra pars compacta. This initial data demonstrates that brain microdialysis can be valuable in describing in-vivo neurochaemical changes in the unilateral Parkinsonian primate model.

16.14

MECHANISM OF MPTP-INDUCED DEPLETION OF NORADRENALINE FROM NERVES IN THE MOUSE ATRIUM. Arthur Hess, Dept. of Anatomy, Robert Wood Johnson Med. Sch., UMDNJ, Piscataway, NJ 08854.

As seen by glyoxylic acid histofluorescence, noradrenergic (NA) nerve fibers extensively innervate the mouse atrium. Two hours after MPTP injection, the fibers are depleted of NA. The atrial nerve fibers, as seen by tyrosine hydroxylase immunohistochemistry, are intact. Inhibition of monoamine oxidase (MAO)-A and B affords no protection from the depletion of NA by MPTP. Desipramine, an NA uptake blocker, provides considerable protection against the depletion of NA by MPTP. Reserpine and amphetamine deplete NA from atrial nerves. Experiments with reserpine--MAO inhibitors--L-dopa sequential administration result in no refluorescence of fibers and indicate that extravesicular storage sites are inadequate for sequestering catecholamines. The refluorescence of many nerve fibers (after MPTP or amphetamine--L-dopa) or almost all fibers (after MPTP or amphetamine--MAO inhibitors--L-dopa) indicate that MPTP or amphetamine causes discharge of NA from the vesicle into extracellular space, with the vesicles themselves left behind in the axon. MPTP depletes NA from atrial nerves by causing release of NA. MPTP (or a metabolite) is taken up selectively by NA axons through NA uptake mechanisms. MPTP then causes discharge of NA from the storage vesicles. Exogenous L-dopa can be sequestered in the vesicles left behind after MPTP-induced depletion of NA. Supported by NIH grant #NS21469.

TRANSMITTERS IN INVERTEBRATES I

17.1

PLASTICITY OF TRANSMITTER EXPRESSION: INDIVIDUALLY IDENTIFIED PEPTIDERGIC NEURONS ALTER THEIR TRANSMITTER PHENOTYPE DURING POST-EMBRYONIC DEVELOPMENT IN THE MOTH. N.J. Tublitz and A.W. Sylwester, Inst. of Neurosci., U. Oregon, Eugene, OR 97403.

It is well known that during embryonic development neurons have the capacity to express a wide variety of transmitters. It is also generally assumed that following differentiation, a mature neuron will synthesize and secrete the same transmitter(s) throughout its lifetime. We present evidence here suggesting that this latter notion might not always be valid and that transmitter phenotype can indeed be altered after completion of embryonic development. The moth, Manduca sexta, contains two cardioregulatory neuropeptides, the cardioacceleratory peptides (CAPs), that had been previously localized in adults to four pairs of midline neurosecretory cells in each ventral ganglion. In contrast larva contain only one pair of medial CAP cells. Results from immunocytochemical studies in larva using the anti-CAP monoclonal antibody revealed, in addition to the 2 midline CAP cells, 8 other neurons that were CAP immunoreactive in larva but not in adults. These cells, whose somata were bilaterally clustered as a group of 4 along the lateral ganglionic margins, have been previously described as synthesizing another neuropeptide, Bursicon (Taghert and Truman, J. exp. Biol., 1982). To understand the physiological significance of the immunocytochemistry results, cell clusters or single cells were dissected from Vth instar larva or day 8 pupa, the stage when the full complement of adult neurons are present, and bioassayed for either CAP or bursicon bioactivities. In larvae, lateral cells contained a small but measureable amount of bursicon combined with high CAP levels. By day 8 of adult development, these proportions were reversed: very high bursicon levels and no detectable CAP activity. By comparison, midline cells contained no bursicon and elevated CAP levels in both larva and developing adults. HPLC analysis of larvae revealed that the cardioactivity present in the midline and lateral cells were due to a single peak that co-eluted with one of the CAPs. By showing that the lateral neurons synthesize primarily one CAP in larva and switch in adults to produce bursicon, these results strongly support the hypothesis that certain neurons can alter their transmitter phenotype during post-embryonic life.

This research is supported by NIH Grant #24613, a NIH Research Career Development Award and a Sloan Fellowship to NJT.

17.2

REGULATION OF TRANSMITTER CHOICE IN AN IDENTIFIED LINEAGE IN *MANDUCA SEXTA*. J.L. Witten & J.W. Truman, Dept. Zoology, U. Washington, Seattle, WA 98195.

We are investigating the interaction of cell lineage and steroid hormones on the regulation of transmitter expression in an identified lineage of neurons ("L") born during postembryonic development of the moth, *Manduca sexta*. The L lineage is heterogeneous in terms of transmitter phenotype, containing neurons immunoreactive to GABA and a peptide similar to molluscan small cardioactive peptide$_B$ (SCP$_B$). We are studying the neurochemical differentiation of these clonally related cells and the influence that lineage position, lineage size and ecdysteroid hormones have on determining transmitter phenotype.

During larval life the L neuroblast generates a discrete cluster of progeny. The differentiation of these neurons is arrested at an early stage of development and their maturation resumes when the appearance of ecdysteroids initiates the onset of metamorphosis. We have followed the neurochemical differentiation of L lineage progeny throughout the postembryonic life stages. GABA and the SCP$_B$-like peptide are not expressed in the partially differentiated cells but first appear halfway through adult development in response to a large rise in ecdysteroid titers. By manipulating ecdysteroid levels during this stage, we are examining steroid regulation of transmitter expression.

To determine the role of cell lineage, we have used immunohistochemical and birth dating methods to map the distribution of these putative transmitters within the L lineage. Preliminary results show that transmitter phenotype is not segregated according to lineage position, which suggests that birth order may not play a critical role in determining transmitter phenotype. Cell lesion techniques are being applied to neurons in the L cluster to investigate the influence of lineage size on transmitter expression.

Supported by grants NS 07936 (JLW) and NS-13079 (JWT).

17.3

THE EGPS - ECLOSION HORMONE AND cGMP REGULATED PHOSPHOPROTEINS IN THE CNS OF *MANDUCA SEXTA*: EFFECTS OF CYCLOHEXIMIDE AND ACTINOMYCIN D. D.B. Morton and J.W. Truman, Department of Zoology, University of Washington, Seattle, WA 98195

Eclosion hormone (EH) is a 62 amino acid neuropeptide that acts on the CNS to trigger the stereotyped ecdysis behavior which occurs at the end of each molt. In *Manduca sexta*, the action of EH is mediated via an increase in cGMP levels followed by the phosphorylation of two 54kDa phosphoproteins, the EGPs (EH and cGMP regulated phosphoproteins)

At 24hrs before ecdysis, injected EH will elevate cGMP levels but will not trigger ecdysis behavior. Two dimensional SDS-PAGE analysis of CNS proteins at this time show that the EGPs are absent or cannot be phosphorylated. The EGPs first appear on fluorograms at the same time that EH will first trigger ecdysis behavior, 8 hrs before ecdysis and the appearance is regulated by the steroid hormone, ecdysone.

The need for protein and RNA synthesis for the development of both EH triggered ecdysis and the appearance of the EGPs has been investigated using the protein and RNA synthesis inhibitors, cycloheximide (CX) and actinomycin D (ACT). Injections of CX (150ug) and ACT (100ug) 4hrs before ecdysis did not prevent either EH triggered ecdysis or the appearance of the EGPs. Injection of CX or ACT at earlier times, however, prevented both EH triggered ecdysis and the appearance of the EGPs on fluorograms. These data are consistent with the hypothesis that *de novo* synthesis of the EGPs is necessary for EH to trigger ecdysis.

Supported by NIH grant NS 13709.

CLONING OF ADIPOKINETIC HORMONE cDNA M.H. SCHAFFER M.O'SHEA, and B.E. NOYES*. Dept. Psychiatry, Univ. of Texas Health Science Center Dallas,TX 75235.

Adipokinetic hormone (AKH I) is a grasshopper neuropeptide which is of interest as a hormone, neurotransmitter, and member of a structurally related family of neuropeptides which extends throughout the arthropods. cDNA clones of AKH I were selected from a library constructed from polyA enriched RNA derived from 700 S. nitans corpora cardiaca. The library was screened with a 25-base oligonucleotide whose sequence was derived from the peptide sequence and results of a variation of the primer extension method of direct RNA sequencing. The DNA sequence of the recombinants predicts that the AKH I precursor contains one copy of the AKH sequence which is preceded by a signal peptide and followed by the amidation sequence gly-lys-arg. The precursor also contains a second peptide which is abundant in the c.c. named alpha chain by Hekimi and O'Shea (abstract this meeting). Minor variations in sequence found in different cDNAs likely reflect allelic variation. The high abundance of AKH I cDNAs suggests that this library is a favorable source of AKH II cDNAs. The status of this search and that for the AKH I gene will be discussed. A similar cDNA has been identified from another species by Schulz et al. (abstract this meeting).

MOLECULAR BIOLOGICAL STUDIES ON THE SYNTHESIS OF LOCUST ADIPOKINETIC HORMONES. M.F. Schulz*, E. Roulet*, J. Fischer* and M. O'Shea. Lab. de Neurobiologie, Université de Genève, Geneva, Switzerland. (SPON: G. Kato)

The peptide hormones AKH I and AKH II are synthesized in the neurosecretory cells of the locust corpora cardiaca (CC). Two dimer precursors P1 and P2 are involved in AKH biosynthesis. They produce the monomer AKHs as well as two dimers, the AKH Precursor Related Peptides, APRP 1 and APRP 2 (Hekimi and O'Shea, J. Neurosci. 7:1773-1784). To study the molecular mechanism leading to the P1 and P2 precursors, we have isolated and sequenced candidate clones from a CC cDNA library and analysed in vitro translation products from CC mRNA. Translation of CC mRNA in vitro results in two major proteins of 5 and 6 Kd whose production is blocked in the presence of precursor related oligonucleotides. This indicates that the two in vitro products are related to the P1 and P2 dimers. The sequence of an AKH I and APRP 1 cDNA clone encodes a signal peptide followed by AKH I, a Gly-Lys-Arg processing site, the 28 amino acids of the monomer of APRP 1 α-chain followed by a stop codon. Thus the P1 homodimer is formed from two monomer translation products. Although the α-chain peptide contains an Arg-Lys processing site it is not used during AKH and APRP biosynthesis (see also Hekimi and O'Shea, ibid).

Supported by Ciba-Geigy.

PRECURSORS OF ADIPOKINETIC HORMONES (AKHs) ARE N-TERMINALLY BLOCKED DIMERS GENERATING DIMER PEPTIDE PRODUCTS IN ADDITION TO THE AKHs. S. Hekimi* and M. O'Shea. Lab. de Neurobiologie, Université de Genève, Geneva, Switzerland.

The neurosecretory cells of the corpus cardiacum (CC) of the locust Schistocerca gregaria produces two peptides called AKH I (10 aa) and AKH II (8 aa). These are released into the blood during prolonged flight and serve to mobilize lipid metabolism. By performing pulse-chase experiments on in vitro cultured CC we have identified two precursors (P1 and P2) of the AKHs. Structural analysis of P1 and P2 by protein sequencing and reduction shows that P1 is a homodimer and P2 is a heterodimer. Both dimers are formed by a single disulphide bond. During processing the P1 and P2 dimers generate the monomer AKHs and dimers we call AKH Precursor Related Peptides or APRPs. Three APRPs have been identified in the CC and complete structures determined. APRP 1 is a homodimer of two 28 residue chains (called α-chain) and is processed from P1. APRP 2 is a heterodimer of the α-chain plus a homologous 28 residue chain (β-chain) and is processed from the heterodimer P2. We have also found and sequenced the β-β homodimer (APRP 3). The APRPs are released peptides and may have functions related to flight as do the co-synthesized AKHs. The APRPs are produced in markedly different proportions at different stages of development.

EXPRESSION AND ORGANIZATION OF A NEUROPEPTIDE-ENCODING GENE IN *DROSOPHILA MELANOGASTER*. Paul H. Taghert and Lynne E. Schneider*. Dept. of Anatomy & Neurobiology, Washington University School of Medicine, Saint Louis, MO 63110.

We are interested in the mechanisms that underlie cell-specific neuropeptide gene expression in the nervous system. The *Drosophila* gene that encodes multiple FMRFamide-like neuropeptides (Schneider and Taghert (1988), PNAS **85**, 1993; Nambu et al (1988), Neuron **1**, 55) is expressed in a small subset of CNS neurons. It is transcribed throughout post-embryonic life with a relatively simple pattern as detected by Northern blot analysis; a single band of ~1.7 kb is found in larval, pupal, and adult stages. A smaller band (of ~0.7 kb) is also detected if the probe includes the 3' untranslated region of the cDNA. We are currently examining embryonic stages to detect the initial period of gene transcription. Sequencing of genomic DNA and protection assays indicate that the gene spans ~4 kb and contains a single intron. Exon 1 is 254 bp with a short (27 bp) untranslated region and includes a 41 bp sequence identical to the 5' end of the longest cDNA recovered (Nambu et al, *op. sit.*). The intron is ~2.3 kb in length. Exon 2 is 1351 bp long and contains all 15 FMRF-NH2 encoding sequences. This neuropeptide gene is expressed by a specific complement of CNS neurons (see Schneider, Sun, and Taghert, this volume). In order to identify *cis*-regulatory genomic regions, and as a prelude to germ-line transformation studies, we are currently sequencing the intron and the regions that are 5' to the gene. In addition we are examining comparable regions adjacent to the gene in a related Drosophalid species to find conserved sequences.

CELLULAR ANALYSIS OF A NEUROPEPTIDE GENE EXPRESSION IN *DROSOPHILA MELANOGASTER*. L. E. Schneider*, E. Sun#*, and P. H. Taghert (SPON: R. Sinclair). Washington University School of Medicine, St. Louis 63110 and #Monsanto Co., Chesterfield, MO 63198.

The *Drosophila* FMRFamide gene encodes a variety of different peptides that end in Phe-Met-Arg-Phe-amide (Schneider and Taghert (1988), PNAS **85**, 1993 ; Nambu et al (1988), Neuron **1**, 55). In *Drosophila*, antisera raised against synthetic FMRFamide recognize ~30 neurons in the larval and adult nervous systems (White et al (1986) J. Comp. Neurol. **247**, 430). We have examined the expression of the authentic *Drosophila* gene by immunohistochemistry and in situ hybridization. We have raised a rabbit antiserum to the octapeptide FRGDPKQD, a portion of the deduced *Drosophila* FMRFamide precursor. This sequence spans a suspected cleavage site between two adjacent peptides. In larvae, this antiserum specifically labels a single pair of neurons at the ventral mid-line of the subesophogeal ganglion, and a single pair in each thoracic ganglion. The thoracic ganglion neurons correspond to previously identified neuroendocrine cells that are laterally-placed and that project to the Transverse Nerve. This pattern is retained in adults with the addition of a second pair of neurons in each thoracic ganglion and a single cell in the optic lobe areas of the brain. Hence, these immunoreactive neurons comprise only a subset of those recognized by antisera against authentic FMRFamide. To examine the cellular distribution of transcripts from this gene, we used a 41 bp probe (from the 3' end of the translated region) that was tailed with ~15 bases of ^{35}S-dATP. Although this method lacks precise cellular resolution, strong hybridization signals are seen in each CNS region that also contains immunoreactive cells. The regions corresponding to adult-specific cells (optic lobes and in the dorsal region of the third thoracic ganglion) typically contain weaker signals. We are currently studying the establishment of these patterns during embryogenesis and adult development.

17.9

STRUCTURE AND EXPRESSION OF THE *DROSOPHILA* GLUTAMATE DECARBOXYLASE GENE. F. Rob Jackson, Worcester Fndn. Exptl. Biol., Shrewsbury, MA 01545.

The enzyme glutamate decarboxylase (GAD) catalyzes the synthesis of gamma-aminobutyric acid (GABA), a well-documented inhibitory neurotransmitter of vertebrate and invertebrate nervous systems. We previously reported the isolation of *Drosophila* DNA clones that hybridize to mammalian GAD gene sequences. On the basis of the following experimental results, we now conclude that these clones represent a *Drosophila* GAD gene: (1) The sequence of one *Drosophila* cDNA clone (GAD1) predicts a protein with extensive homology to mammalian GAD (overall sequence identity = 52%). Moreover, a tetrapeptide sequence (NPHK) thought to represent the pyridoxal binding site of mammalian GAD is conserved in the deduced *Drosophila* protein. (2) The GAD1 cDNA hybridizes to RNA transcripts which are more abundant in head than in body poly(A)+ fractions, suggesting that homologous mRNAs are preferentially expressed in nervous tissue. The results of preliminary tissue *in situ* hybridization studies are in agreement with this conclusion. (3) A chromosomal deletion which removes the genetic locus represented by the *Drosophila* clones is associated with reduced GAD enzyme activity.

Northern analyses demonstrate that expression of the *Drosophila* GAD gene commences early in embryogenesis (4-8 h) and continues throughout development. A major 3.1-kb size class of mRNA is detected throughout development, while a minor 2.6-kb transcript is observed only in embryos and pupae. The analysis of multiple cDNA and genomic DNA clones suggests that the 3.1-kb class of mRNA consists of a population of variably spliced transcripts. Such transcripts might encode a family of GAD protein isoforms.

SPIDER VENOM TOXINS ACTING ON THREE CLASSES OF SYNAPTIC ION CHANNELS AT THE INSECT NEUROMUSCULAR JUNCTION. M. E. Adams, V. P. Bindokas*, L. Hasegawa* and V. J. Venema*. Div. Toxicology and Physiology, Dept. of Entomology, University of California, Riverside, CA 92521

Spider venoms contain a diversity of paralytic toxins which may serve as useful probes for the characterization of synaptic ion channels. The venom of *Agelenopsis aperta*, a funnel web spider, paralyzes flies (*Musca domestica*) and disrupts neuromuscular transmission by affecting ion channels on pre- and postsynaptic membranes. Multiple acylpolyamine "α-Agatoxins" related in structure to argiotoxins (Adams, M.E. et al, *Biochem. Biophys. Res. Comm.* 148, 678-683, 1987), exert use-dependent block of postsynaptic glutamate-sensitive receptor channels. Such blockade is slowly reversible and is correlated with temporary paralysis produced by the toxins *in vivo*. Two additional classes of presynaptic toxins produce irreversible effects on transmitter release. "μ-Agatoxins" appear to be sodium channel activators, causing spontaneous repetitive activity and massive transmitter release. They synergize the paralysis caused by α-Agatoxins. We have identified six μ-Agatoxins as homologous, cysteine-containing peptides 36-37 amino acids long. A second class of presynaptic toxins ("ω-Agatoxins") irreversibly blocks transmission at nanomolar concentrations without affecting iontophoretic glutamate potentials. Block of neuromuscular transmission by one of these, ω-Aga I, appears to involve presynaptic calcium channels (Bindokas, V.P. and Adams, M.E., this volume).

Supported by NIH grant NS24472 and USDA grant 86-CRCR-1-2097.

17.11

ω-AGA I, A SPIDER VENOM TOXIN FROM *AGELENOPSIS APERTA*, IRREVERSIBLY BLOCKS TRANSMITTER RELEASE AT INSECT AND FROG NEUROMUSCULAR JUNCTIONS. V. P. Bindokas*, and M. E. Adams (SPON: M. A. Baker). Div. Toxicology and Physiology, Dept. of Entomology, University of California, Riverside, CA 92521

In addition to α- and μ-Agatoxins, (Adams, M. E. et al, this volume), venom of the spider *Agelenopsis aperta* contains ω-Agatoxins, a group of irreversible presynaptic blockers. The most abundant of these, ω-Aga I blocks transmission in the fly (*Musca domestica*) longitudinal ventrolateral muscle and in the frog (*Rana pipiens*) cutaneous pectoralis muscle. Studies on the fly neuromuscular junction suggest that ω-Aga I acts on calcium channels involved in transmitter release. Loose patch recordings from individual junctions reveal that the toxin reduces quantal content without apparantly affecting the frequency or amplitude of spontaneous miniature junctional currents. ω-Aga I appears not to affect spike invasion of the nerve terminal. Dose-dependent block of EPSP's by ω-Aga I can be partially reversed by elevating extracellular calcium or by repetitive stimulation. Graded release of transmitter elicited by direct field stimulation of nerve terminals, which is TTX-insensitive but cobalt-sensitive, is blocked by the toxin.

The effects of ω-Aga I are not confined to neuromuscular junctions. For example, the toxin suppresses the calcium component of action potentials recorded in the somata of insect dorsal unpaired median (DUM) neurons. Our data indicate that ω-Aga I may have widespread actions on calcium currents in the nervous system.

PEPTIDE CO-TRANSMITTER IN SKELETAL MUSCLE ACTS AT MULTIPLE SITES WITHIN THE EXCITATION-CONTRACTION COUPLING PATHWAY. C.A. Bishop, Dept. of Psychology, Stanford Univ., Stanford, CA 94305.

We have been investigating the site of action of the pentapeptide proctolin in the crayfish tonic flexor muscle, where the peptide serves as a co-transmitter in 3 of 5 excitatory motoneurons and greatly potentiates the tension generated by the conventional conductance-increasing, EPSP-producing neurotransmitter (Bishop et al., *J. Neurosci.* 7: 1769, 1987). Proctolin acts directly on the muscle; it does not affect the EPSP amplitude and therefore probably acts through a separate receptor from that used by the conventional neurotransmitter. The peptide's action is eliminated when extracellular Ca^{2+} is replaced by equimolar Co^{2+}. We have shown previously that proctolin-induced tension enhancement can be elicited in Ca^{2+}-free, Co^{2+}-substituted saline after treatment with the Ca^{2+} ionophore A23187, which causes the release of Ca^{2+} from intracellular stores (Bishop and Wine, *Neuro. Abst.*, 1986). This result suggests that at least part of the peptide tension enhancement may be due to an enhanced release of Ca^{2+} from intracellular stores and is not associated with changes in membrane Ca^{2+} conductance. Recent experiments, however, indicate that proctolin can also potentiate membrane Ca^{2+} conductance in this muscle: Patch-clamp experiments reveal at least one voltage-activated Ca^{2+} channel that is gated by proctolin and voltage-clamp experiments show that an early, transient, voltage-dependent Ca^{2+} current is potentiated by 10^{-8} M proctolin. Together, these results indicate that the proctolin tension enhancement effect in this muscle is probably the result of the peptide's action at multiple sites along the excitation-contraction coupling pathway. PEPTIDES MODULATE THE LOBSTER CARDIAC SAC RHYTHM. P.S. Dickinson and E. Marder. Biology, Bowdoin College, Brunswick, ME 04011 and Brandeis Univ., Waltham, MA 02254.

The cardiac sac rhythm is one of four rhythms generated in the lobster stomatogastric nervous system. We have found that red pigment concentrating hormone (RPCH) is present in the stomatogastric (STG), commissural, and oesophageal ganglia of the Panulirus interruptus nervous system; previous work had shown the presence of proctolin in these ganglia. Bath application of either 10^{-6} M proctolin or RPCH activates the cardiac sac rhythm in quiescent preparations; it increases the frequency of the rhythm and the duration of dilator bursts in spontaneously active preparations. When applied to any single ganglion, RPCH alters the cardiac sac rhythm; proctolin is generally effective only on the commissural ganglia. These two peptides may interact in their control of the cardiac sac rhythm, since proctolin, which does not normally induce a cardiac sac rhythm in an isolated STG, will provoke such a rhythm in the presence of sub-threshold levels of RPCH. Moreover, cardiac sac dilator bursts lead to perturbations of the other 3 rhythms (pyloric, gastric, oesophageal) produced by the stomatogastric nervous system. Thus, RPCH and proctolin may modulate these rhythms not only directly, but also indirectly via their effects on the cardiac sac rhythm. NEUROBEHAVIORAL EVIDENCE FOR KAPPA AGONIST ACTIVITY OF THE MORPHINAN DERIVATIVE 14-ß-METHYL 8-OXACYCLORPHAN. F.B. Jolicoeur[1] R. Rivest[1], D. Menard*[1] S. Lemaire[2] and B. Belleau*[3]. [1]Dept. Psychiatry, Fac. of Med., University of Sherbrooke, Sherbrooke, Quebec, J1H-5N4, [2]Dept. Pharmacology, School of Med., University of Ottawa, Ottawa, K1H 8N5 and [3]Dept. Chemistry, McGill University, Montreal, Quebec, H2A 2K6

The purpose of the present study was to determine if the in vivo neurobehavioral effects of the morphinan 14-ß-8-oxacyclorphan would reflect the kappa agonist activity found in our previous in vitro studies (Lemaire, S. et al., Can. J. Physiol. Pharmac. 64:707, 1986). The effects of intracisternal (IC)administration of various doses (10-80 µg) of 14-ß-8-oxacyclorphan on body termperature, muscle rigidity, nociception of thermal, chemical and mechanical stimuli as well as its ability to induce catalepsy were examined. The effects of intrathecal administration of the same doses of the compound on reactivity of animals to a thermal stimulus were also assessed. Results indicate that the analgesic properties of 14-ß-8-oxacyclorphan resemble those of typical kappa agonists: (IC) administration of the drug failed to affect nociception to a thermal stimulus but markedly reduced the reactivity of animals subjected to chemical or mechanical stimuli. On the other hand, intrathecal administration of the drug significantly attenuated nociception of animals to a thermal stimulus. The in vivo neurobehavioral effects of 14-ß-8-oxacyclorphan appear to be kappa selective since the drug did not decrease body temperature, increase muscular tone or induce catalepsy, three effects generally attributed to µ agonists. Furthermore, the (IC) administration of the compound in a similar dose range was found to significantly antagonize the catalepsy, muscular rigidity, akinesia as well the analgesia in the hot-plate test produced by IC administration of morphine (60µg). In summary, the present results reveal that 14-ß-8-oxacyclorphan displays many features similar to those of well known kappa agonists.

Functional U69593 receptors exist in the spinal cord of the 9-16 day old rat.

J.C. Hunter, J.A.M. Smith, C.A. Allerton, G.E. Leighton, P.R. Boden, R.G. Hill and J. Hughes. Parke-Davis Research Unit, Addenbrooke's Hospital Site, Hills Road, Cambridge, CB2 2QB, U.K. (SPON: L.C. Thomas)

The benzeneacetamide U69593 is a highly selective ligand for the kappa opioid receptor. In contrast to intracerebroventricular or intravenous administration, intrathecal application of U69593 and related compounds into adult rats failed to produce analgesia (Leighton, G.E. et al., Br. J. Pharmacol. 93, 553, 1988). Consistent with this observation is the apparent absence of ^{3}H-U69593 binding sites in the spinal cord of the adult rat (Lahti, R.A. et al., Eur. J. Pharmacol. 109, 218, 1985). In this study we have shown the equilibrium binding of ^{3}H-U69593 to homogenates of 9-16 day old rat spinal cord (B_{max} = 60fmol/mg protein, K_D = 2.3nM). The presence and distribution of these sites in 10uM transverse sections of spinal cord was demonstrated using autoradiographical techniques. Superfusion of U69593 onto an in vitro spinal cord preparation resulted in depression of spontaneous and electrically evoked synaptic activity. In these immature rats, intrathecal administration of benzeneacetamides produced dose-dependent analgesia. In conclusion, we have shown that in contrast to the adult, the spinal cord of the immature rat has a high level of U-69593 binding sites, with functional correlates.

18.3

ANALYSIS OF THE DEPRESSION AND LOCOMOTOR EXCITATION INDUCED BY U50, 488, A SELECTIVE KAPPA OPIATE AGONIST. L.B. Estall*, B. de Costa*, K. Rice*, A. Pert (SPON: J. Malick). BPB, NIMH and IN, NIDDK, Bethesda, MD 20892.

In our previous studies, we found that the (S,S) form of U50, 488, a potent kappa agonist, was much more active than the (R,R) form in several behavioral tests following central administration. One of the most profound effects of U50, 488 was on locomotor output. The purpose of this series of studies was to further characterize the effects of U50, 488 on locomotor activity and to define the neurochemical circuits involved. Systemic injections of U50, 488 produced an initial dose-dependent decrease in locomotor output, which was followed by excitation. No tolerance was observed to the locomotor depression following chronic administration while the excitatory effects increased with repetitive injections. Neither MR 2266 nor naloxone antagonized the excitatory effects of U50, 488. 6-OHDA lesions of the nucleus accumbens also failed to alter the locomotor stimulatory effects. The effects of systemically administered U50, 488 on locomotar activity appear to be mediated through different mechanisms than those mediating the effects of centrally administered U50, 488 and do not involve mesolimbic dopamine.

18.4

NEONATAL NALTREXONE ADMINISTRATION: SOMATIC AND BEHAVIORAL EFFECTS ON THE INFANT AND ADULT RAT.

B.Caldarone* & P.Kehoe. Dept. of Psychology, Trinity College, Hartford, Ct. 06106

In an effort to examine the functional changes following neonatal opiate receptor antagonist treatment, naltrexone in doses 1, 25 and 50 mg/kg or saline was injected daily IP from postnatal day 1 until either day 9 or day 21. Pups receiving treatment until day 9 were conditioned on day 12 with exposure to a novel odor in conjunction with morphine (.5 and 2 mg/kg) IP. On day 15 the pups were given an odor preference test. All pups given morphine paired with the odor acquired the preference, whereas prior naltrexone administration had no effect. Additionally, naltrexone treatment resulted in no difference in their daily weight gain. Pups treated with naltrexone until day 21 showed little difference in weight except that males given 50mg/kg weighed somewhat less than saline controls and even significanlty less than those given 1 mg/kg. Female weight gain was unaffected. While females in general showed earlier eye opening, naltrexone in a dose-dependent manner hastened eye opening in males and females. As adults, females defecated less in a novel open field situation than males but both were affected by neonatal naltrexone in that the high dose was associated with an increase in fecal boli number during exploration. These data suggest that while daily naltrexone may accelerate some maturational milestones, certain opiate-mediated functions are either unaffected or altered in complex ways.

Receptor types involved in opioid-induced antinociception in neonatal rat spinal cord in vitro. **I.F.James, S.B.Ketchum*, M.N.Perkins* and A.Dray. Sandoz Institute for Medical Research, Gower Place, London, England.**

A nociceptive response can be recorded in vitro from the spinal cord of the neonatal rat following stimulation of the tail. Opioids depress this response and we have now characterized the spinal opioid receptor types involved.

Receptor binding, performed in homogenates of spinal cord from 1-2 day old rats, showed high affinity sites for [3H]-DAGO and [3H]-EKC. The DAGO sites showed a mu-receptor profile while the EKC sites that remained after blocking mu-sites with 100nM DAGO, showed a kappa receptor profile. No [3H]-DPDPE binding could be detected. In functional studies where the spinal cord and attached tail were separately superfused, noxious stimulation of the tail with capsaicin or heat produced a ventral root depolarization. Depression of noxious responses was produced by DAGO, DPLPE and U50488 (ED50 = 2, 150 and 130nM respectively) superfused on the spinal cord. The effect of an ED50 dose of DAGO and DPLPE was reversed by a similar concentration of naloxone (2-10nM) but a higher concentration (0.2-1.0 µM) was required to reverse U50488.

These data show that the neonatal rat spinal cord contains functional mu and kappa receptors and while no delta binding is detectable, delta ligands may activate another receptor.

18.6

STEREOSPECIFIC MODULATION OF SOMATIC GROWTH IN PREWEANLING RATS BY OPIOID ANTAGONISTS. S. Pileggi*, P.J. McLaughlin and I.S. Zagon (SPON: T. Pritchard). Dept. Anatomy, Penn. State Univ. Coll. of Med., Hershey, PA 17033.

Somatic and neurobiological growth of rats are regulated by endogenous opioid systems. Perturbation of endogenous opioid-opioid receptor interaction by opioid antagonists has been an important experimental paradigm. To determine if somatic growth is regulated at the level of opioid receptors, a stereospecific response to (-) and (+) isomers of naloxone, an opioid antagonist, was studied. Newborn Sprague-Dawley rats were injected i.p. with various dosages of (-)naloxone. At day 21, rats injected with 20-60 mg/kg (-)naloxone had deficits of 10-23% in body weights from control levels. To study stereospecificity, a dosage of 40 mg/kg (-)naloxone or (+)naloxone, or sterile water was injected daily into rats from birth to day 21. Relative to controls, 21-day old rats injected with 40 mg/kg (+)naloxone did not differ in body or organ weights, whereas rats receiving 40 mg/kg (-)naloxone were 23% lighter in body weight and had 19-52% reductions in weight of liver, thymus, heart, spleen, and skeletal muscle. Opioid agonist challenge experiments indicated that (+)naloxone did not block receptors, while (-)naloxone blocked receptors for at least 6 hr/day. These results suggest that opioid antagonists can perturb the interaction of endogenous opioid systems in a stereospecific manner. Support by NIH grants NS-20623 and NS-20500.

18.7

INTERACTION OF MIDAZOLAM AND MORPHINE IN RATS SPINAL CORD. M. Sabbe*, A. Yanez Gonzalez*, C.W. Stevens and T.L. Yaksh (SPON: J.D. Grabow). Mayo Clinic, Rochester, MN 55905.

GABA-benzodiazepine ionophore complex has been implicated in pain modulatory processing. The present studies sought to characterize the antinociceptive interaction between morphine (MOR) and benzodiazepines given in the intrathecal (IT) space. We used the water soluble agent midazolam (MID). Rats with chronic IT catheters received MOR, MID, or a combination (10 µl). IT MOR (0.5-15 µg) evoked a dose-dependent increase in hot plate (HP)/tail flick (TF) response latency with no effect on motor function. IT MID (20-100 µg) had no effect on HP or TF response, but evoked hindlimb paralysis at 100 µg. Consideration of the effects of IT MOR in the presence of MID (20 µg) revealed no change in the maximum effect produced by any given dose of MOR on the HP, but significantly increased the area under the time effect curve. Naloxone (1 mg/kg, i.p.) antagonized the effects of MOR, MID + MOR, but not MID (100 µg) alone. The benzodiazepine antagonist Ro15-1788 (1 mg/kg, i.p.) had no effect on any dose of MOR, significantly antagonized the motor dysfunction of MID (100 µg), but had little effect on the antinociceptive actions of the MOR + MID antinociceptive effects. These data suggest a probable interaction between intrathecally administered opiate and benzodiazepine agonists. Whether this interaction is pharmacokinetic or pharmacodynamic is not known. (Supported by Janssen (MS) and grant DA-02110 (TLY).)

18.8

THE ROLE OF EFFICACY IN THE MAGNITUDE OF SPINAL ANTINOCICEPTIVE TOLERANCE. C.W. Stevens and T.L. Yaksh, Dept. of Pharmacology, Mayo Clinic, Rochester, MN 55905.

Tolerance is manifest by the decrement of agonist effect with the continued administration of the same dose of agonist or by an increment of dose to produce a previously obtained effect. Using a constant-rate, constant-dose intrathecal (IT) infusion model in the rat (JPET 244: 63, 1986) we have shown that the time course of tolerance development to daily hot plate (HP) testing is not different among µ or δ opioid, α_2 or synergistic combinations of opioid and α_2-agonists. In experiments designed to assess the magnitude of tolerance on HP after 7-day IT infusion we now report that the degree of tolerance induced is related to the efficacy of the infused agent. Morphine (MOR), sufentanil (SUF), DAGO (µ opioid specific), DADLE (δ opioid) and ST-91 (α_2-adrenergic) were each infused in 3 log-spaced concentrations and full dose-response curves obtained by IT bolus of the respective agents. ED_{50} and tolerance ratios (tolerant ED_{50}/saline-infused ED_{50}) were calculated for saline and each infusion dose. At the middle infusion doses, the most efficacious agents, DAGO and SUF, produced minor tolerance ratios (7; 2) whereas the less efficacious MOR, DADLE and ST-91 produce higher ratios (55, 46 and 29, resp.). These results support the view that highly efficacious agents may produce less tolerance as they necessitate a lower fractional occupancy of available receptor pool for a given effect. (Supported by grant DA-02110 and Mayo Foundation.)

18.9

β-FUNALTREXAMINE (β-FNA) VERSUS OPIOID RECEPTORS IN THE SPINAL CORD. E. Mjanger* and T.L. Yaksh (SPON: A.G. Engel). Mayo Clinic, Rochester, MN 55905.

Five opioid receptors are implicated in the mediation of spinal analgesia (µ, μ_1, δ and κ). This study is done to systematically classify the potency of the different receptor agonists in the spinal cord. All injections were given intrathecally in volume of 10 µl saline. Antinociception was measured by hot plate (HP; 52.5°C) and tail flick (TF) tests. Each rat was used only once.

The ED_{50} ± 95% CI (nmol) (n = 12-25 per drug)

Drug	Hot Plate	Tail Flick
DAGO	0.3 (0.1-0.9)	0.6 (0.3-1.2)
β-endorphin	1.1 (0.5-2.4)	1.8 (1.1-2.8)
DSTLE	4.1 (0.8-21.1)	4.4 (0.4-56.1)
DPLPE	13.1 (16.5-29.4)	7.0 (2.4-20.6)
Morphine	20.4 (10.9-38.0)	26.7 (15.2-46.9)
Meptazinol	>100	>100
U50488H	>100	>100

IT β-FNA (1 µg) given 24 hrs prior to test, resulted in a reduction in effect such that as a percent of saline control: morphine (2%) > DAGO (60%) > DPLPE (96%). Given the relative preference of these agonists and the effects of β-FNA, these results suggest a role for distinguishable spinal µ and δ receptors in modulating thermal nociception. THE EFFECT OF DOSAGE AND TIMING OF ADMINISTRATION OF NALOXONE ON NEUROLOGIC OUTCOME IN THE RAT VENTRAL COMPRESSION MODEL OF SPINAL CORD INJURY. Edward C. Benzel, M.D., and John Lancon*, B.S. Depart. of Neurosurgery, LSU School of Med., Shreveport, LA 71130

The effects of dosage and timing of administration of Naloxone on rats following spinal cord injury via the ventral compression technique is presented. The ventral compression technique for rat spinal cord injury allows a ventral compression of the spinal cord without the requirement for a prior laminectomy. The first part of this two part study involved the determination of the optimal dose of Naloxone, administered intraperitoneally, at 45 minutes following the creation of the lesion. Of the groups studied (control-10.0 mg/kg), 2.0 mg of Naloxone proved to be superior to both lesser and greater dosages ($P < 0.05$).

The second part of the study involved the administration of a 2.0 mm/kg dose of Naloxone at varying intervals ranging from 10 minutes prior to lesioning to 24 hours following lesioning. A biphasic response was again demonstrated with an optimal time of administration occurring at 45 minutes following the creation of the lesion ($P < 0.05$).

In summary, a significant effect was offered by a mid range dose of Naloxone (2.0 mm/kg), administered at 45 minutes following injury. Experiments not accounting for these biphasic dose and timing of administration responses may lead to erroneous conclusions.

EFFECTS OF THE ENKEPHALINASE INHIBITOR ANALGESIC SCH 34826 ON EEG ACTIVITY AND SLEEP PATTERNS IN THE RAT. M. Trampus*, A. Conti*, A. Monopoli* and E. Ongini. Research Labs., Essex Italia, I-20060 Comazzo (Milan), Italy.

SCH 34826 is a new orally active enkephalinase inhibitor analgesic (1). We investigated whether the molecule induces sedation by evaluating EEG activity and sleep patterns in the rat. EEG was recorded for 6h. SCH 34826 was tested at 30-300 mg/kg p.o., and compared with morphine (10 mg/kg s.c.) and acetorphan (30 mg/kg p.o.), another enkephalinase inhibitor. Morphine decreased waking and REM sleep, and increased slow wave sleep. There was dissociation between EEG patterns of sleep and behavior. Bursts of paroxysmal activity (spikes) were observed in the EEG. Acetorphan did not modify the sleep patterns. SCH 34826, at 30 and 100 mg/kg, did not alter the sleep-waking cycle. At 300 mg/kg, rats appeared to sleep less than controls and a reduction of REM was observed. This dose is 10-30 times that required for inhibiting the enzyme and at no time did SCH 34826 elicit any of the EEG and behavioral effects observed after morphine. SCH 34826 appears to be devoid of liability for sedation and other EEG changes at doses far above those predicted to be clinically effective. (1) Chipkin et al. (1987), J. Pharm. Exp. Therap., in press, 1988.

18.12

PHARMACOLOGICAL ACTIONS OF A NOVEL MIXED AGONIST-ANTAGONIST OPIATE, NalBzoH. **M.A. Gistrak,* D. Paul,* E.F. Hahn,* and G.W. Pasternak** (SPON: R. Price) The Cotzias Lab. of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Cornell U. Medical College, NY, NY 10021.

NalBzoH, the benzoylhydrazido derivative of naloxone, is an opiate analgesic with mixed agonist-antagonist properties. In binding studies, it potently labels opioid receptors: mu_1>mu_2>kappa>>delta. The sodium effect on ^{3}H-NalBzoH binding is intermediate between that of a pure agonist and a pure antagonist, suggesting a mixed agonist-antagonist. We therefore examined the actions of NalBzoH in tailflick assays alone and against morphine analgesia. NalBzoH antagonizes morphine analgesia (6 mg/kg s.c.) with an ID_{50} of 2 µg/kg (s.c.), a potency 4 times that of naloxone. NalBzoH (1 mg/kg s.c.) also precipitated withdrawl in morphine-dependent mice. These data indicate that NalBzoH is an antagonist at mu receptors. At higher doses, NalBzoH alone is an analgesic, with an ED_{50} of 10-20 mg/kg, s.c. Peak effect occurs 15 to 30 min following administration, with a duration of 90 min. Although it is reversed by naloxone, NalBzoH analgesia was at least 5 times less sensitive than morphine analgesia, implying a non-mu mechanism. Thus, NalBzoH, an analgesic with potent antagonist actions at mu receptors, may be free of many of the side-effects mediated through mu receptors, such as respiratory depression and constipation.

18.13

Chronic naltrexone exposure enhances morphine analgesia but not defeat induced analgesia in mice. M.L. Thompson* and C. A. Paronis* (SPON: L. Shuster), Dept of Pharmacology, Tufts Medical School, Boston, MA 02111

Chronic naltrexone (NTX) exposure via pellet implantation has been shown to increase the number of opiate receptors in certain regions in the brains of mice or rats. These increases have been suggested to be functional in the sense that analgesic response to morphine is enhanced for a period of time following pellet removal. In this expt. we investigated the effects of NTX pellet exposure on the analgesic response observed in mice following defeat in a social encounter.

Male B6AF1 mice, aged 3-4 mo., were implanted sc. with pellets containing roughly 7.5 mg of NTX. A comparison group of mice received cholesterol implants. Pellets were removed after 10 days. 24 hours later mice were injected with 3 mg/kg ip morphine or exposed to social conflict in a resident-intruder paradigm. Analgesia was assessed in the tailflick test to a radiant heat stimulus, (baseline response of 1.5-2.5 sec. and a cutoff of 6 sec.) TF latencies were recorded every 30 min. for 2 hours following morphine, or after bouts of 20 bites in the social conflict paradigm. Latencies were expressed as % maximum possible effect (MPE). Mice tested with morphine showed significantly enhanced analgesia compared to placebo pelleted mice at 30 (75% mpe vs 40%) and 60 min (65% mpe vs 35% mpe) following morphine injection. In contrast, social conflict analgesia was significantly reduced in the NTX pelleted mice. The placebo mice achieved 50% MPE after roughly 20 bites whereas NTX pelleted mice required on average around 40 bites. This data suggests that analgesia produced by morphine or defeat may be mediated by somewhat different subpopulations of receptors with different profiles of response to chronic antagonist exposure.

18.14

THE SELECTIVE μ OPIOID PEPTIDES DAGO AND PLO-17 STIMULATE PROLACTIN SECRETION WHEN ADMINISTERED TO LACTATING FEMALE RATS. M. Baumann, J. Janik and J. Rabii, Dept. of Biological Sciences, Rutgers Univ., Piscataway, NJ 08855.

We have recently reported that morphine does not stimulate prolactin secretion in lactating female rats (Callahan *et al.*, *Brain Res.*, 442:214, 1988). The insensitivity of the prolactin-releasing mechanism to opiates during lactation is dependent upon the suckling stimulus and not related to altered drug metabolism. These data suggested to us that the μ opioid receptor sites mediating opiate-induced prolactin secretion may be down regulated in the lactating female. In this study, the effects of selective μ receptor activation on prolactin release were determined in lactating rats.

Lactating dams were implanted with intracerebroventricular (ICV) cannulae and chronic indwelling jugular cannulae. On the day of the experiment, dams were separated from their pups for 4 hours. DAGO [Tyr-D-Ala-Gly-(Me)Phe-gly-ol] and PLO-17 [Tyr-Pro-(Me)Phe-D-Pro-NH_2] were injected ICV at concentrations of 0.1, 0.5, and 2.5 ug. Serial blood samples were withdrawn immediately before and at selected time periods after opioid treatment.

Both DAGO and PLO-17 elicited dose-related increases in plasma prolactin in lactating females. Moreover, naloxone pretreatment (1.0 mg/kg, iv) completely blocked the effects of both peptides. These results indicate that the μ opioid receptor site is not down regulated during lactation. Thus, the insensitivity of the prolactin-releasing mechanism to morphine stimulation in the lactating female appears to be a phenomenon unique to narcotic analgesic drugs. FURTHER EVIDENCE FOR MU OPIATE RECEPTOR SUBTYPES: DIFFERENTIAL BLOCKADE BY NALOXONAZINE OF MORPHINE ANALGESIA AND INHIBITION OF GASTROINTESTINAL TRANSIT. D. Paul* and G.W. Pasternak. (SPON: D. Rottenberg). The Cotzias Lab. of Neuro-Oncology, Memorial Sloan-Kettering Cancer Cntr and Cornell U. Medical College, NY, NY 10021.

Administered systemically, morphine elicits both analgesia and inhibits gastrointestinal (GI) transit through activation of mu opioid receptors. Work from our group has suggested the presence of two distinct subtypes of mu receptors and has correlated mu_1 receptors with supraspinal analgesia. We now report the relative contribution of mu_1 and mu_2 receptor subtypes to the inhibition of GI transit by systemic morphine by examining the effect of the selective mu_1 antagonist naloxonazine (NAZ) on morphine analgesia and inhibition of GI transit in mice. Blockade of mu_1 receptors by NAZ (35 mg/kg) completely antagonizes morphine analgesia at doses of either 2 mg/kg, or 6 mg/kg (s.c.). In contrast, NAZ treatment had no effect on the distance traveled by a charcoal meal through the small intestine. Both morphine analgesia and inhibition of GI transit are mediated through mu receptors, but only analgesia was antagonized by NAZ, supporting the concept of mu receptor subtypes. Based upon its sensitivity towards NAZ, morphine analgesia involves mu_1 receptors, whereas mu_2 sites mediate inhibition of transit following systemic morphine.

18.16

THE ANTAGONIST WIN 44,441-3 DOES NOT BLOCK THE β-ENDORPHIN OR DADLE INDUCED PROLACTIN INCREASE DURING LACTATION. J. Janik, M. Baumann and J. Rabii. Department of Biological Sciences, Rutgers Univ., Piscataway, N.J. 08855.

We have previously reported that lactating female rats are not sensitive to morphine or methadone stimulation of prolactin release. However, this model does show a prolactin secretory response to both β-endorphin and d-ala-d-leu-enkephalin (DADLE) administration which is reversed neither by naloxone nor naloxonazine, a specific antagonist of the μ-1 receptor site. The antagonist WIN 44,441-3 has been shown to effectively block the μ, δ and κ receptor sites (Wood et al., *Pharm. Res.*, 1:46, 1984). The purpose of this study was to attempt to determine the receptor subtype mediating the prolactin increase by examining the effects of this antagonist on the β-endorphin and DADLE induced increases in the lactating female model.

Lactating females between days 6 and 10 post-partum received β-endorphin (0.5, 2.5 or 5 μg, ivt) or DADLE (2.5 or 5 μg., ivt). All doses of β-endorphin and DADLE produced a significant increase in circulating levels of prolactin. However, the magnitude of the response seen in animals pretreated with WIN 44,441-3 was significantly attenuated compared to the saline pretreated controls. Thus, it appears that while the μ receptor may not be involved in the prolactin response to these opiates in the lactating female model, at least part of the response is occurring via the δ and/or κ receptor subtypes. (Supported by the Busch Memorial Fund and the Anne B. and James H. Leathem Scholarship Fund)

A NOVEL, HIGHLY POTENT AND SELECTIVE DERIVATIVE OF [D-PEN^2,D-PEN^5]ENKEPHALIN: OPIOID ACTIVITY IN VITRO AND IN VIVO. T.H. Kramer*, G. Toth*, V.J. Hruby*, and T.F. Burks. Depts. of Pharmacology and Chemistry, University of Arizona, Tucson, AZ 85724.

Cyclic [D-Pen^2,D-Pen^5]enkephalin (DPDPE) is a conformationally constrained enkephalin analog with demonstrated high affinity and potency at the delta opioid receptor. A newly synthesized derivative, cyclic [D-Pen^2,p-Cl-Phe^4,D-Pen^5]enkephalin (Cl-DPDPE) shows greater potency and selectivity than DPDPE in radioligand binding assays. Cl-DPDPE was tested in the guinea pig ileum (GPI) and mouse vas deferens (MVD) bioassays for in vitro opioid activity. Intracerebroventricular (ICV) injections of Cl-DPDPE were performed in mice, and analgesia was measured using the hotplate test. Cl-DPDPE demonstrated agonist activity in both the GPI (IC50=4.4±0.6 uM) and MVD (IC50=1.9±0.3 nM). Delta receptor selectivity (IC50 GPI/IC50 MVD) of 2304 (±273) indicates improved selectivity in vitro relative to DPDPE. Cl-DPDPE was antagonized by the selective delta antagonist ICI 174,864 in MVD, and the mu antagonist CTP in GPI. ICV Cl-DPDPE caused dose-dependent analgesia in the hotplate test (ED50=1.09 ug±2.1), and was antagonized by naloxone. Cl-DPDPE is a highly delta-selective opioid agonist in vitro, and potently produces opioid analgesia in vivo. We confirm that opioid analgesia is mediated by delta receptors at the supraspinal level (supported by USPHS grants NS19972, DA02163, and DK36289).

REGULATION OF CYCLIC AMP-DEPENDENT PROTEIN PHOSPHORYLATION BY ACUTE AND CHRONIC MORPHINE TREATMENT IN RAT BRAIN. X. Guitart* and E.J. Nestler (SPON: S. Stine). Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Previous studies have shown that chronic treatment of rats with morphine increases the levels of specific G-proteins, adenylate cyclase, and cyclic AMP-dependent protein kinase in the locus coeruleus (LC), but not in several other brain regions examined. In the present investigation, we have identified a number of phosphoproteins termed "MARPPs" (Morphine and cyclic AMP-Regulated Phospho-Proteins) as additional targets of chronic morphine action.

Rats were treated with morphine for 5 d and used on day 6. Isolated brain regions were then analyzed by endogenous and back phosphorylation assays and by one- and two-dimensional electrophoresis and autoradiography. Among the MARPPs identified were: 1) **MARPP-58**, a 58 kD protein, whose phosphorylation level and total amount were increased by chronic morphine treatment in the LC, but not in other brain regions studied; this protein has been identified as tyrosine hydroxylase. 2) **MARPPs-51, 55, 62, and 165**, proteins whose phosphorylation levels were regulated by chronic morphine in the LC only, despite their presence in other brain regions; their phosphorylation level was also regulated by acute forskolin and morphine in the LC. 3) **MARPPs-14-20** and **145**, proteins whose phosphorylation levels were regulated by chronic morphine in all brain regions studied, as well as by acute forskolin and morphine in the LC; MARPPs-14-20 have been identified as myelin basic proteins.

It is possible that these various phosphoproteins mediate some of the acute and chronic actions of morphine on the nervous system, including the development of tolerance and dependence.

ACUTE TOXICITY OF METHADONE, MEASURED AS HYPOXIA AND HYPERCAPNIA, IN PREGNANT RATS. R. C. Pleus and S. B. Sparber Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

Two groups of pregnant SD rats were transcutaneously (tc) monitored for CO2 and O2 tension to determine the degree of hypoxia and hypercapnia after treatment with 5 mg methadone/kg, i.p. (M). The acute M group (MA) received saline daily and the chronic M group (MC) received M daily until tc monitoring. Daily treatments for both groups began on gestation day (GD) four. Respiratory depression, leading to significant hypoxia/hypercapnia, is caused by injection of M in early (GD 4 or 5), mid (GD 11 or 12), and late (GD 17-20) pregnancy. Tolerance to this effect is evident 7-14 days after treatment is initiated (Table 1.), although stable (*i.e.* 24 hr) dependence may not yet be achieved (Sparber, *Neuro Toxicol.*, 7:335-348, 1986).

TABLE 1.

		tcpO2		tcpCO2

19.1

TRANSDUCTION IN LOCUST PHOTORECEPTORS: FLASH AND WHITE-NOISE STIMULATION. **A.E.C.Pece, A.S.French, M.J.Korenberg*, J.E.Kuster*. Department of Physiology, University of Alberta, Edmonton, Canada T6G 2H7.**

The response of photoreceptors to light is believed to be mediated by a biochemical cascade between rhodopsin excitation and channel opening. Simple cascade models predict a linear relationship between light intensity and depolarization with small stimuli. However, some photoreceptors are nonlinear even when only a few photons are transduced. In locust receptors, nonlinearities have been demonstrated by measuring interactions between flash responses as a function of flash separation, and by comparing the linear transfer functions of the process at different background levels. We have now measured the linear (first order) and second order components of photoreceptor responses by conventional intracellular recordings, while stimulating with a light source modulated by white noise. Kernels were measured at different noise amplitudes. These results are compared with nonlinear effects demonstrated previously, to obtain a more complete characterization of the input-output relationship of these photoreceptors. The nonlinearities demonstrated experimentally will be compared with simulations of some simple nonlinear cascade models of phototransduction.

OUTER SEGMENT CABLE PROPERTIES SET UPPER LIMIT TO cGMP-INDUCED CLAMP CURRENT OF SALAMANDER RODS. D.A. Cameron* & E.N. Pugh* (SPON: L. M. Hurvich) Inst. of Neurological Sciences & Dept. of Psychology, U. of Pennsylvania, Philadelphia, Pa. 19104.

Rods with o.s. in a suction electrode (s.e.) were infused with cGMP from a gigaseal pipette in voltage-clamp mode, and the hv-sensitive current, J, measured. (1) (dJ/dt)max but not Jmax depended on pipette [cGMP] in range 10-20 mM. Means ± 2sem for Jmax & (dJ/dt)max: [cGMP]=10 mM, 1150 ± 160 pA & 350 ± 49 pA/sec (n=12); [cGMP]=20 mM, 1300 ± 160 pA & 556 ± 72 pA/sec (n=29). These data make it unlikely that either Na gradient collapse or [cGMP] distribution in o.s. limited Jmax. (2) When the o.s. was completely drawn into the s.e., the average ratio of s.e. to clamp current was 0.75; for o.s. partially drawn in, this ratio decreased steeply as a function of o.s. length excluded from the s.e. (n=18, [cGMP]=20 mM). (3) Transient analysis showed that whole-cell pipette access resistance did not limit measured Jmax. From analysis of our results with a cable model, we conclude (1) that a longitudinal resistance of 1-3 megohm/um in the o.s. limits Jmax measured by point-clamp, setting a "space constant" of 6-8 um and (2) that a perfectly spaced-clamped rod, with all cGMP-gated conductances instantly gated open, would have a maximum cGMP-induced current of 7-10 nA.

LIGHT ADAPTATION DYNAMICS OF THE PHOTORECEPTOR CELLS REVEALED WITH A STIMULATION FEEDBACK CONTROL SYSTEM. K.Djupsund, E.Kouvalainen*, M.Weckström*, M.Kallio* and M.Järvilehto. Dept of Physiology and Dept of Zoology, Univ of Oulu, 90100 Oulu, Finland.

In contrast to conventional open-loop stimulation and recording, a continuous stimulus-response feedback system offers the advantage of monitoring directly the cell sensitivity at a constant or changing level of the response voltage, i.e. the operating point.

The intracellularly recorded voltage response of the photoreceptors of the blowfly (Calliphora erythrocephala) was controlled by changing the light intensity of a LED (green, 555 nm), in order to force the response to an intended time-course. This was performed by comparing the sampled cell response point by point with a reference function. The LED output was calculated with a PID algorhithm by a µPDP-11. The control process ran at 166 Hz.

The changes in sensitivity and the adaptational process, as indicated by the respective changes of the LED intensity, show faster onset for larger amplitude maxima of forced responses. These changes are furthermore accentuated, when the derivative of the forced response step increases. The sensitivity also shows several changes of slope during the ongoing control process. The on- and offset of screening pigment-linked processes temporally fit the findings, but also gain-control mechanisms inherent to the transduction process can be involved.

19.4

INTERACTION BETWEEN CHEMICAL EXCITATION AND PHOTOTRANSDUCTION MUTATIONS IN FLY PHOTORECEPTORS. B. Minke*, C.T. Rubinstein*, S. Barash.*, E. Suss* and Z. Selinger*[+] (Spon: S. Rotshenker). Dept. of Physiology and Biol. Chem.[+] The Hebrew University, Jerusalem, Israel 91010.

Chemicals which affect different steps of the phototransduction cascade were used to localize the site of action of the defective gene products of three mutants; the transient receptor potentials (trp) and retinal degeneration B (rdgB) mutants of Drosophila and the no steady state (nss) mutant of Lucilia. The trp and nss mutants fail to maintain excitation during continuous illumination and become temporarily non-responsive following intense light. In the rdgB mutant the peripheral photoreceptors in each ommatidium degenerate only after exposure to light for several days (24°C). We have found that GTP analogs and F^-, which are known to activate G-proteins and to excite fly photoreceptors, mimicked the effects of light in causing retinal degeneration when applied daily (for 8 days; 24°C) to the eyes in the dark. The metabolic inhibitors CN^- and 2-deoxy-D-glucose did not cause more degeneration than Ringer's solution, while $GDP_\beta S$ reduced the degeneration below the control dark level. GTP analogs, F^- and a combination of inositol trisphosphate + diphosphoglycerate ($InsP_3$+DPG) were applied to the trp and nss photoreceptors. Intracellular recordings and shot-noise analysis revealed that F^- neither excited nor adapted the trp and nss photoreceptors, while $GTP_\gamma S$ markedly reduced the light-response of the mutants without exciting the photoreceptors. $InsP_3$+DPG, in contrast, mimicked the effect of background light on the response of the nss. The results suggest that the defect in trp and nss is at a stage which follows the production of $InsP_3$ and that GTP analogs and F^- activate both G-protein and an unknown step subsequent to $InsP_3$ production. The G-protein operates prior to the rdgB gene-product in the phototransduction cascade.

19.5

OCTOPAMINE SUPPRESSES INHIBITION IN THE *LIMULUS* LATERAL EYE

George Renninger and Claudia Farrell, Biophysics Group, University of Guelph, Ontario

Octopamine, a putative circadian neurotransmitter in *Limulus*, and other exogenous agents applied to the lateral eye *in vitro* increase the rate at which the eccentric cell (the second-order neuron of each photoreceptor unit) generates impulses at a given level of membrane depolarization during exposure to light [Renninger *et al.* (1988) J Comp Physiol]. The modulation of impulse generation is consistent with a decrease in self-inhibition by the exogenous agents. Activity in efferent nerve fibers from the circadian clock, however, has no significant effect on the impulse generator.

We have now observed directly that self-inhibition is suppressed by octopamine, but not by efferent activity. Positive current steps injected into a eccentric cell *in vitro* in the control condition produced impulses at a steady rate which was about 3 times lower than the initial firing rate. The addition of octopamine (500 μM) suppressed self-inhibition: the same current steps produced a final steady rate which was only about 1.5 times lower than the initial rate. Calculations show that this suppression is consistent with a five-fold decrease in the conductance change underlying self-inhibition. *In vivo*, however, similar current steps produced the same fall in firing rate both before and during natural efferent activity.

Octopamine also suppresses lateral inhibition *in vitro*. Lateral inhibition depressed eccentric firing rates in the control condition. This reduction in firing rate was no longer observed after the addition of octopamine. Furthermore, hyperpolarization of the eccentric cell membrane due to lateral inhibitory interactions was significantly reduced by an octopamine agonist. These results support the notion that the circadian clock reduces lateral inhibition in the compound eye at night [Renninger & Barlow (1979) Soc Neurosci Absts 5:804; Batra & Barlow (1983) Soc Neurosci Absts 8:49].

Suppression of self-inhibition by octopamine agonists, but not by efferent nerve activity, suggests that exogenous agonists can reach receptors on the eccentric cell membrane which are not accessible to the neurotransmitter released from efferent nerve terminals.

19.6

ULTRASTRUCTURE OF RETINAL SYNAPSES IN CULTURE. E.L. Gleason* and M. Wilson. Dept. of Zoology, Univ. of Calif., Davis, CA 95616.

In the simplified conditions of low density culture, synapses between retinal neurons might be more amenable to physiological analysis than is the case in the intact retina. With this in mind, we have followed the time course of synapse formation in culture.

Eight day chick embryo retinal neurons were put into culture (medium consisting of DMEM, 5% FCS and 100units/ml pen-strep), fixed on embryonic equivalent days 12, 14, 16 and 18, then processed for TEM. By day 12, the cells have extended processes and contacted distant cells. These contacts are often characterized by densities at each of the opposing membranes. Vesicles can also be found in processes but are usually not localized to sites of contact. Short synaptic ribbons are seen at the base of some cone cells. Day 14 cultures show a marked increase in the number of vesicles and these vesicles are now localized to sites of contact. After 16 days in culture, conventional synapses are mature. By day 18, synaptic ribbons similar to those found in the innerplexiform layer are observed.

The time course of synaptic development for these dispersed retinal neurons will be compared with that of retinal cells grown in aggregates and neurons in the intact retina.

PHYSIOLOGICAL AND MORPHOLOGICAL CORRELATIONS OF MUDPUPPY HORIZONTAL CELLS. H.G. Kim* and R.F. Miller (SPON: T.J. Cicero). Dept. of Ophthalmology, Washington U. St. Louis, Mo 63110

The morphology of mudpuppy horizontal cells is unknown even though numerous physiological studies of these cells have been reported, including one observation of both "luminosity" (L-type) and "chromaticity" (C-type) horizontal cell subtypes. We stained physiologically identified horizontal cells of the mudpuppy using intracellular electrodes filled with horseradish peroxidase (HRP: 10%) and/or Lucifer Yellow (LY: 6%) to determine structure/function relationships of these cells. We used cone-matched monochromatic light stimuli to evaluate rod/cone contributions and small slits of light to determine receptive field size.

We found that most mudpuppy horizontal cells receive inputs from rods and cones; staining results show that these cells have one or more long axons, exhibiting diverse morphologies. Receptive fields sizes, determined by displaced slits, varied from 200 μm to 650 μm and could not be correlated with morphological subtype. We found C-type horizontal cells with different morphologies although these cells were rarely encountered. One type responded better to shorter wavelength stimulation, and did not have an axon. Another C-type horizontal cell responded better to longer wavelength stimulation and displayed an axonless morphology different from that of the short wavelength preferring cell. The presence of C-type horizontal cells confirms an earlier observation by Fain and suggests that complex synaptic mechanisms, which underlie C-type responses in teleosts and turtles, may also be present in the mudpuppy, although the receptor basis of this interaction is unknown. Our study extends to the mudpuppy, the concept that the vertebrate retina contains axon-bearing and axonless horizontal cell subtypes.

HORIZONTAL CELLS FROM DARK-ADAPTED GOLDFISH RETINAS RESPOND TO ANNULAR ILLUMINATION AND SHOW INCREASED GAP JUNCTION PARTICLE DENSITIES. W.H. Baldridge*, A.K. Ball*, R. Miller Dept. Anatomy, McMaster University, Hamilton, Ont., L8N 3Z5

The density of goldfish retinal horizontal cell (HC) gap junction (GJ) particles increases with presumed coupling (J. Comp. Neurol. 265:428, 1987). To test the correlation of presumed coupling conditions with HC GJ particle density, we have made intracellular recordings from dark-adapted goldfish HCs and measured the responses to spot and annular illumination to determine coupling state. The retinas were then processed for freeze-fracture electron microscopy and the particle density of HC somas GJs measured. Goldfish were dark-adapted for at least 2 hrs. and intracellular recording of S-potentials made from isolated retinas maintained in a chamber superfused with fish Ringers. HCs showed increasing responses (10-25 mV) to spots ranging from 350 um to 2,750 um. Potentials (20-25 mV) were also recorded in response to annular illumination (3,750 um illuminated surround with a 2,500 um center and 5,250 um illuminated surround with a 2,500 um center). Particle densities of HC soma GJs from these retinas were about 5,000 particles per square micron. The responsiveness of HCs to surround illumination demonstrates that these cells were coupled. The corresponding high HC GJ particle density was nearly identical to previous results where coupling was presumed. We are currently testing the effect of dopamine on the responses to annular illumination and HC soma GJ particle density.

RECEPTIVE FIELD PROPERTIES OF HORIZONTAL CELLS CORRELATE WITH THE CONNEXON DENSITY WITHIN THEIR GAP JUNCTIONS

R. Weiler, K. Poser*, W. Kolbinger*, G. Kurz-Isler*, W.H. Baldridge*. Dept. Neurobiol. Univ. Oldenburg, 2900 Oldenburg, FRG.

In the fish and turtle retina, dopamine (DA) alters the gap junction coupling resitance of horizontal cells (HC) and consequently their receptive field (RF) properties. DA also influences the connexon density (CD) within the gap junctions and we therefore examined a possible correlation of CD with RF properties. The RF size of HC was measured by intracellular recordings in: a) dark- and b) light-adapted retina; c) DA-incubated and d) DA-depleted retina. DA content was subsequently measured and the CD value was determined in freeze fracture replicas. The largest RF were recorded in DA-depleted retinas where the CD value was significantly higher than in dark-adapted retinas having smaller RF. Light adaptation and incubation in DA resulted in an increasing decline of the overall RF size. These RF properties correlated significantly with a decrease of the CD value. The observed correlation between the RF properties of HC and the CD opens the possibility that DA does not only act through a phosphorylation of a gap junction channel protein. Supported by DFG and NATO.

SALAMANDER HORIZONTAL CELL RESPONSES IN BICARBONATE- AND IN HEPES-BUFFERED MEDIUM

Jochen Kleinschmidt, Dept. of Ophthalmology, New York University Medical Center, New York, NY.

The dominant extra- and intracellular pH-buffering system in the retina in vivo is likely to be HCO_3/CO_2. Much of previous work on photoreceptor physiology and synaptic transmission in the amphibian retina has been done in HCO_3-free, HEPES-buffered medium. The present study demonstrates dramatic differences in horizontal cell responses recorded in the eyecup superfused with these two media. Changing from HCO_3/CO_2 to HEPES under photopic stimulus conditions (a) depolarizes H cells, (b) increases their response amplitudes, (c) greatly reduces their depolarizing rollback, (d) dramatically alters waveforms of incremental responses during bright background adaptation. Under mesopic and scotopic conditions, rod-to-H cell transmission is greatly enhanced. These changes are completely reversible. Experiments using chloride substitution and the chloride transport inhibitor SITS indicate that chloride plays an important role in shaping H cell responses. These findings suggest that HCO_3 is a physiologically important anion which is involved in chloride regulation in photoreceptors and/or H cells, presumably via Cl/HCO_3 exchange.

DEVELOPMENT OF NPY REACTIVE NEURONS IN RAT RETINA. D.M. Ferriero and S.M. Sagar. Dept. of Neurology, Univ. of Calif., San Francisco, CA 94143

Neuropeptide Y (NPY) is present in very high concentrations in brain and is colocalized with somatostatin (SLI) in a subpopulation of neurons in rat striatum. SLI has been well documented in retina of many species. Although NPY has been implicated in visual function because of its localization in the suprachiasmatic nucleus, it has been reported only in guinea pig retina. In developing rat retina, SLI concentration is very high prenatally and falls dramatically prior to synapse formation. There is a gradual rise postnatally to adult levels. We have now studied the ontogeny of NPY in rat retina by radioimmunoassay (RIA) and gel permeation chromatography (GPC) from embryonic day (E) 15 to adult. NPY concentration and content gradually increases over pre- and postnatal development with a small surge at eye opening. The different patterns of ontogeny for NPY and SLI in developing retina suggest that phenotypic expression of neuronal subtypes changes over development, and that peptides may have prenatal functions other than "transmission".

L-GLUTMATIC ACID DECARBOXYLASE mRNA IN MAMMALIAN RETINA: LOCALIZATION BY IN SITU HYBRIDIZATION. P.V. Sarthy and M. Fu*. Department of Ophthalmology, University of Washington School of Medicine, Seattle, WA 98195.

GABAergic neurons in mammalian retinas have been previously localized by ^{3}H-GABA or ^{3}H-muscimol uptake autoradiography, or by immunocytochemistry using L-glutamate decarboxylase (GAD) or GABA-antisera. In this study, we have used a GAD cDNA probe to localize GAD mRNA by in situ hybridization. ^{35}S-labeled DNA and RNA probes were hybridized to cryostat sections of paraformaldehyde-fixed retinas, and localization was carried out using established protocols. In the cat retina, labeled cell bodies were found in the INL and GCL. The majority of labeled cells (~72%) were located in the vitread side of the INL bordering the INL/IPL boundary. The second class of cells (~20%) in the INL had larger somata and were found at the INL/OPL boundary. Double labeling experiments with antisera to parvalbumin, a horizontal cell marker, showed that these perikarya belong to horizontal cells. In the monkey retina, labeled cell bodies were found only in the INL (~83%) and the GCL. In the mouse retina, labeled somata were again observed in the INL and the GCL. No evidence for horizontal cell labeling was, however, found in these retinas. Northern blot analysis showed that these retinas contain a single species of GAD mRNA that is ~4 Kb in size. These results are in general agreement with immunocytochemical data on the localization of GABAergic neurons in the inner retina. Supported by NIH Grants EY03664 and EY01730.

CORTICOTROPIN RELEASING HORMONE IN FROG RETINA - QUANTITATIVE AND DETAILED ANATOMICAL ANALYSIS. T. Z. Baram*, M. C. Citron and L. Schultz*. Dept.of Neurology Research, U. Southern California and Childrens Hospital of L A., Los Angeles, CA 90027.

Corticotropin Releasing-Hormone (CRH) has recently been demonstrated in avian and rat retina. This neuropeptide forms an important link in the organism's stress response; it functions as both a hypothalamic neurohormone and as a neuromodulator in other central nervous system (CNS) regions. Its role in the retina has not been defined.

We have detected CRH in frog retina. CRH-like immunoreactivity was present in retinal homogenates subjected to radioimmunoassay utilizing antiserum to rat/human CRH. (35.5± 2.4 pg/retina). Furthermore, immunofluorescence, enhanced by an avidin-biotin complex and visualized with phycoerythrin (Vector, CA), has allowed the visualization of CRH-containing retinal cells. Specificity was ascertained by the use of normal serum instead of antibody, and by the elimination of fluorescence after pre-adsorption of the CRH-antiserum with an excess of the peptide.

Study of the role of CRH in frog retina may provide information about the mechanisms of neuropeptide actions in the CNS, for which the retina is a well defined, relatively simple model.

LOCALIZATION OF cAMP IN THE TELEOST RETINA FOLLOWING EXPOSURE TO DOPAMINE (DA). L.H.Y. Young and J.E. Dowling. M.E.E.I. and The Biological Labs., Harvard, Boston/Cambridge, MA.

Many studies have shown that the lateral inhibitory effects mediated by the horizontal cells (HCs) in the outer plexiform layer are modulated by the interplexiform cells and DA. In 1981, using both homogenates of carp retina and enriched HC fractions, Dowling and coworkers provided evidence that DA receptors on the HCs are linked to adenylate cyclase. The present study provides information on the localization of cAMP in the white perch retina by immunohistochemical and autoradiographic methods. Using a goat anti-cAMP antiserum with an immunofluorescent staining technique, retinas incubated in DA showed a marked increase in staining in the distal inner nuclear layer where HCs are located. Autoradiography of whole retinas incubated in 20 μM tritiated ATP showed minimal radioactivity distributed homogeneously throughout the retinal layers. However, in the presence of DA, there was enhanced radioactivity in the HC layer. Tissue culture HCs also showed increased labeling following exposure to DA. These experiments provide further evidence that DA receptors on the HCs are linked to adenylate cyclase and that their activation results in the accumulation of cAMP.

IMMUNOHISTOCHEMICAL LOCALIZATION OF GABA$_A$ RECEPTORS IN THE RETINA OF THE PRIMATE *Saimiri sciureus*. [1]T.E. Hughes, [2]R.G. Carey, [3]J. Vitorica*, [3]A.L. de Blas, and [1]H.J. Karten. [1]Dept. of Neurosci., UCSD, La Jolla, CA 92093, [2]Div. of Neurobiol., St. Joseph Hosp. and Med. Centr., Barrow Neurol. Inst., Phoenix AZ 85013, [3]Dept. of Neurobiol. & Behav., SUNY Stony Brook, NY 11794.

Some amacrine cells in the retina are thought to use gamma-aminobutyric acid (GABA) as an inhibitory neurotransmitter, yet little is known about which neurons express the receptors for GABA. Monoclonal antibodies against the GABA$_A$ receptor have provided a means to identify some of these neurons (Mariani et al., Brain. Res., 415:152, 1987; Richards et al., J. Neurosci., 7:1866, 1987). In the squirrel monkey, such an antibody labeled somata in the inner nuclear (INL) and ganglion cell (GCL) layers. The staining was confined to the cell's plasmalemma and cytoplasmic granules. The labeled neurons in the INL had small somata at the vitreal edge of the layer. Most arborized only in the inner plexiform layer, but a few also had labeled processes that extended into the inner half of the outer plexiform layer. The labeled cells in the GCL were among the largest present, and their arbors were, at any given eccentricity, similar in appearance. Many were ganglion cells which were retrogradely labeled following injections of Fluro-Gold into the optic tract. The antibody labeled their axons, suggesting that GABA$_A$ receptors move anterogradely to the retinal terminal fields. Sections labeled for both L-glutamic acid decarboxylase (GAD), or GABA, and the receptor revealed that GAD/GABA was distributed much more widely in the IPL than was the receptor. This variance may reflect either the presence of other GABA receptors in the IPL or GABA in portions of the IPL where it is ineffective as a neurotransmitter. IMMUNOLOGICAL AND ELECTROPHYSIOLOGICAL IDENTIFICATION OF SUBSETS OF RETINAL GANGLION CELLS. B.A.Barres, D.P.Corey, and L.L.Y.Chun*, Program in Neuroscience, Harvard Medical School, Howard Hughes Medical Institute, and Dept. of Neurology, Mass. General Hospital.

In cell suspensions from postnatal day 8 rat retinas labelled retrogradely with granular blue injections in the superior collicular brachium, nearly 100% of retinal ganglion cells (RGCs) were labelled (Perry, 1983). We observed that 100% of RGCs could also be labelled by the Thy-1 antibodies 2G12 and MRC-OX-7, as previously reported (Barnstable and Drager, 1984). However, we observed an approximately equal number of Thy-1-labelled cells that were *not* retrogradely labelled. These cells are probably not RGCs because they did not express voltage-dependent sodium or calcium currents while 100% of retrogradely labelled cells did.

We observed that one Thy-1.1-specific antibody, T11D7 (Lake and Clark, 1979) stained only 1/3 of retrogradely labelled RGCs. Size histograms revealed two peaks: 2/3 of cells were 12 um in diameter and T11D7-negative, while 1/3 of cells averaged 13.5 um and were T11D7-positive. Further evidence that these cells represent a genuine subset of RGCs was obtained by whole-cell patch recordings. Acutely dissociated RGCs were electrophysiologically heterogeneous. For all cells the maximal sustained firing rate was limited by a spike adaptation mechanism, but among cells we observed a continuum of spike adaptation. The T11D7-positive cells fired at the highest sustained frequencies and spike adapted only with large currents, half of T11D7-negative cells fired at a slower rate, and the other half spike adapted at all currents injected. The mechanism of spike adaptation in these cells cannot be accounted for by the recruitment of an "M" current (Adams *et al.*, 1982) or a K_{Ca} current (Madison and Nicoll, 1984).

These RGC subsets may have developmental significance; preliminary experiments suggest that T11D7 labelling fails to correlate with cell size in the adult.

IMMUNOCYTOCHEMICAL LOCALIZATION OF GLYCINE IN THE TURTLE RETINA. W. D. Eldred and K. Cheung*. Department of Biology, Boston University, Boston, MA 02215.

Previous workers have localized ^{3}H-glycine uptake within amacrine cells in the turtle retina. We have examined glycine-like immunoreactivity (GLY-IR) to provide more detail on its localization in the turtle retina. We used a rabbit antiserum directed against glycine (gift of R. Wenthold) and employed standard fluorescent and avidin-biotin labeling techniques. There were isolated immunoreactive somata in the ganglion cell layer (GCL) and numerous immunoreactive somata in the inner nuclear layer (INL), including several types of amacrine cells. One amacrine cell type had somata adjacent to the inner plexiform layer (IPL) which gave rise to processes which arborized primarily at the border of strata 1 and 2 and in stratum 3 within the IPL. A second type of labeled amacrine cell had smaller somata in the central INL, which gave rise to processes which arborized more diffusely within the IPL. A third cell type resembled interplexiform cells in that it gave rise to extensive arborizations in the outer plexiform layer and the IPL. In the GCL some of the immunoreactive cells were apparently true ganglion cells because they gave rise to labeled axons. The present localization of GLY-IR within several amacrine cell types, possible interplexiform cells and ganglion cells, indicates that glycine may be involved in many diverse synaptic interactions in both the IPL and OPL of the turtle retina. SYNAPTIC ORGANIZATION OF ENKEPHALIN-LIKE IMMUNOREACTIVE AMACRINE CELLS IN THE GOLDFISH RETINA. Carl B. Watt. Alice R. McPherson Laboratory of Retina Research , Center for Biotechnology, Baylor College of Medicine, The Woodlands, Texas 77381.

A total of 194 synaptic relationships were observed that involved the immunostained processes of enkephalin (enk)-like immunoreactive amacrine cells in the goldfish retina. Corresponding to light microscopic studies, the large majority of these enk-processes were observed in sublayer 5 of the inner plexiform layer. In greater than 95% of the synaptic relationships, the enk immunostained profile served as the presynaptic element. Fifty-nine percent of the time, enk profiles synapsed onto amacrine cell processes, while 30% of their synapses were onto profiles that lacked synaptic vesicles. They also occasionally formed synaptic contacts onto the somas of cells located along the outer border of the inner plexiform layer and in the ganglion cell layer. Enk profiles received synaptic input only from amacrine cells (4% of the time), while no direct synaptic interaction was observed between enk profiles and bipolar cells. However, enk processes were found to synapse onto amacrine cell profiles that in turn formed synaptic contacts onto large bipolar endings in sublamina b of the inner plexiform layer.

ANTISERUM TO ASPARTATE AMINOTRANSFERASE LABELS RETINAL GABA-ERGIC NEURONS. C. Brandon. Dept. Cell Biology & Anatomy, Chicago Medical School, North Chicago, IL

Aspartate aminotransferase (AAT) may be a marker for aspartate/glutamate neurons, but may also be present in some GABAergic neurons (Donoghue, J. Neurosci. 5, 2597 (1985)). AAT has been identified in retinas from rat, guinea pig, and primate (Brandon, PNAS 80, 5117 (1983); Mosinger, JCN 233, 255 (1985)). We have used immunocytochemistry to compare AAT-IR and GABAergic neuronal populations in the ferret retina.

In the ferret, cones were AAT-IR while rods were not labeled. Some horizontal cells were strongly AAT-IR; these may be cone horizontal cells. A small number of regularly-spaced bipolar cells were AAT-IR; these may be cone bipolar cells. Several types of amacrine cell bodies were AAT-IR; their processes branched in three sublaminae of the IPL, at depths of 17%, 36%, and 61%. Most neurons in the ganglion cell layer were AAT-IR.

GABAergic neurons were identified with an antiserum to rabbit brain GAD. Amacrine cells were the only cells that were GAD-IR. Their labeled processes branched in exactly the same three IPL sublaminae that contained AAT-IR processes.

We conclude that, in the ferret retina: 1) glutamate or aspartate may be cone transmitters; 2) some horizontal cells may use glutamate as a transmitter; and 3) antiserum to AAT stains GABAergic amacrine cells. The simultaneous labeling of AAT-IR cone bipolar cells and GABAergic amacrine cells may facilitate the study of the synaptic interactions between these two neuronal populations. Supported by USPHS.

TRANSIENT EXPRESSION OF CRF-LIKE IMMUNOREACTIVITY BY HORIZONTAL CELLS IN THE DEVELOPING RAT RETINA. L. Trojanczyk*, D. Zhang and H.H. Yeh (SPON: M.L. Blair). Dept. Neurobiology and Anatomy, Univ. Rochester School of Medicine, Rochester, NY 14642.

In the developing rat and mouse retina, horizontal cells have been reported to express transiently GAD-like immunoreactivity. Here, we report a similar phenomenon, one which involves the transient expression of a peptidergic phenotype and one which was uncovered in the course of studying the emergence and maturation of corticotropin releasing factor like immunoreactivity (CRF-LI) in the rat retina.

Examination of 4-um epon-embedded transverse sections revealed that, between postnatal days(PD)-4 and -15, faint CRF-LI staining could be observed in cells that were aligned at regularly-spaced intervals along the developing inner nuclear layer-outer plexiform layer junction. In tangential sections through this stratum, they exhibited large, round somata and appeared to be evenly distributed in a regular mosaic pattern. These features are typical of horizontal cells in their location and morphology. Tangential sections further revealed a central-to-peripheral gradient, being more prevalent in the central retina on PD-4 and then in the periphery by PD-10. By eye-opening (PD-15), CRF-LI in horizontal cells were no longer detectable. Birth dating using [^{3}H]thymidine indicated that these cells were generated between embryonic day 14 and 18, slightly earlier than those CRF-LI cells that are destined to become amacrine or displaced amacrine cells.

Although the mammalian horizontal cell transmitter(s) remains to be established, our finding is consistent with the notion of a switch in transmitter phenotype by developing, pluripotential horizontal cells.

HISTOGENESIS OF CRF-LIKE IMMUNOREACTIVE NEURONS IN THE RAT RETINA. D. Zhang[1], M. Gallagher*[1,2], C.D. Sladek[1,2] and H.H. Yeh[1], Depts. of Neurobiology and Anatomy[1] and of Neurology[2], Univ. Rochester School of Medicine, Rochester, NY 14642.

Work from our laboratory has demonstrated a system of corticotropin releasing factor-like immunoreactive (CRF-LI) amacrine and displaced amacrine cells in the rat retina. During development, CRF-LI can be detected by postnatal day(PD)-3 and assumes adult-like pattern of distribution by PD-19. Here, we examined the histogenesis of CRF-LI retinal neurons using a double-label approach combining [^{3}H]thymidine autoradiography and immunohistochemistry and also measured CRF-LI levels throughout retinal development by radioimmunoassay (RIA).

The bulk of CRF-LI neurons appear to cease mitotic activity prenatally between embryonic day(ED)-16 and 20. Within this population, approximately 20% are "born" on ED-18. No specific accumulation of autoradiographic label has been detected following exposure to [^{3}H]thymidine beyond the day of birth (PD-0). Preliminary results of RIA indicate that CRF-LI is present on PD-3 at threshold levels (5-10 pg/retina) of our detection system, increases dramatically between PD-7 and -9, reaches peak levels between PD-13 and -15 (eye-opening) and, thereafter, declines gradually to reach adult levels.

Overall, CRF-LI amacrine and displaced amacrine neurons are generated 5-7 days prior to their detection by immunohistochemistry. In addition, consistent with the developmental profiles of CRF-LI cell number and distribution, our RIA data lead us to postulate that increased synthetic activity rather increased number of CRF-LI cells may account for the transient surge in CRF-LI around eye-opening.

DEVELOPMENT OF GLIAL CELL LAMINATION IN THE FERRET LATERAL GENICULATE NUCLEUS (LGN). Vivien A. Casagrande and James B. Hutchins, Dept. of Cell Biology, Vanderbilt Univ. Sch. Med., Nashville TN 37232.

We have shown that glial cell lamination precedes neuronal cell lamination in the tree shrew LGN. We now present evidence that this result is, if not ubiquitous, at least present in both tree shrews and ferrets. Ultrastructural immunohistochemistry confirms that antibodies to glial fibrillary acidic protein (GFAP) label glial cell intermediate filaments early in development. GFAP+ processes are found in bands in the tree shrew at birth, and in ferrets at about three weeks after birth. In both cases, banding of glial cells is only evident several days before the first clear interlaminar spaces form in the nucleus. No banding and only radial glia are seen during the early postnatal period of retinal afferent segregation. Glial cell banding is also absent in adults of both species. However, while few GFAP+ perikarya are present in the adult tree shrew LGN, a significant number of GFAP+ cell bodies and their processes persist in the adult ferret LGN. Differences also exist in the pattern of GFAP and vimentin immunoreactivity in the developing LGN of these two species, but the arrangement of fine, filamentous glial cell processes appears to consistently precede neuronal cell lamination. These results suggest that glial cells may acts as guides during the process of LGN cell layer development.

PERSISTENCE OF RETINAL TERMINALS IN CAT DORSAL LATERAL GENICULATE NUCLEUS FOLLOWING KAINIC ACID LESIONS. H.E. Pearson. Dept. of Anatomy, Temple Univ. School of Medicine, Philadelphia, PA 19140.

Kainic acid (KA) lesions of the CNS can provide useful models for studying the effects of rapid cellular degeneration, particularly in the adult where the response to axotomy is protracted. However, the possibility that KA disrupts the integrity of afferents to the lesion site must also be addressed. HRP was injected intraocularly in six adult cats, three of which had received multiple injections of KA into dLGN one week earlier. After a survival of 72 hr. adjacent sections of each brain were processed for microscopy. Thionin staining revealed large areas of degeneration within dLGN after KA injection. These areas were characterised by the absence of neurons and increased numbers of glia. Sections reacted for HRP showed dense terminal and preterminal labelling within these regions of degeneration, indicating that retinal ganglion cell terminals remain intact. At the ultrastructural level, neuron loss and gliosis were confirmed, as was the presence of RLP terminals, believed to be characteristic of those of retinal origin. These findings confirm the validity of KA as a model for rapid neuron loss in the dLGN of the adult cat and permit further investigation of the long-term effects of target removal on retinal ganglion cells.

MORPHOLOGY AND DISTRIBUTION OF RETINAL TERMINALS IN THE DORSAL LATERAL GENICULATE NUCLEUS (LGBd) OF THE HAMSTER. S. Jhaveri*, R.S. Erzurumlu and G.E. Schneider, Dept. Brain & Cognitive Sciences, M.I.T., Cambridge, MA, 02139.

The morphology and distribution of retinal terminals within the LGBd were studied in normal and monocularly enucleated adult hamsters by labeling optic tract (OT) axons with HRP and processing the tissue with DAB. Analysis included use of both camera-lucida tracings and computer-aided reconstructions. Three types of morphologically distinct retinogeniculate terminals were distinguished: Type R1 terminals have very large, ovoid swellings and are most commonly associated with large-caliber axons. Type R2 terminals emerge from fine-caliber axons and are in the form of small varicosities. Frequently, three or more preterminal axons contribute to the formation of rosette-like clusters of R2 terminals. Type R3 terminals have medium-sized boutons and display considerable variability in morphology and configuration. Type R3 terminals may be comprised of more than one subpopulation.

Type R1 terminals arise from both the ipsi- and contralateral retinae and are distributed predominantly within a medial core of the LGBd. Type R2 terminals originate exclusively from the contralateral retina and are located laterally and ventrally, forming an outer laminar shell. Type R3 terminals arise from both retinae and have a widespread distribution within their respective terminal zones. We are currently using the M.I.T. *Neurotrace* System for 3-D reconstruction and quantification to evaluate the relationship between these terminal types and single, parent axons in the OT.

CHOLINERGIC PROFILES IN THE LATERAL GENICULATE NUCLEUS (LGN): LIGHT AND ELECTRON MICROSCOPIC OBSERVATIONS. James B. Hutchins and Vivien A. Casagrande, Vanderbilt University School of Medicine, Dept. of Cell Biology, Nashville, TN 37232.

In order to better understand the role of cholinergic input to the LGN, we have used histochemical, immunohistochemical, and autoradiographic techniques to characterize the ultrastructure of cholinergic contacts in the tree shrew LGN. At the light microscopic level, choline acetyltransferase (ChAT) immunocytochemistry reveals thin, varicose processes in all six LGN cell layers and in interlaminar zones. No ChAT+ cell bodies are seen in the adult LGN. At the electron microscopic level these ChAT+ terminals are seen as densely filled thin processes. Although ChAT immunohistochemistry obscures the ultrastructure of the terminal, the profiles appear to have round vesicles and sometimes contain dark mitochondria. EM histochemistry of acetylcholinesterase reveals reaction product surrounding apparent dendrites as well as round and flat vesicle-containing profiles. Preliminary EM autoradiography of muscarinic cholinergic receptors labels asymmetric synapses between profiles with round vesicles and dark mitochondria and an apparent dendrite. These data point to a consistent cholinergic terminal and synaptic morphology in the LGN which is probably shared by several other species.

CHOLINERGIC INNERVATION OF THE LATERAL GENICULATE NUCLEUS: COLLATERAL PROJECTIONS TO OTHER THALAMIC AND MIDBRAIN STRUCTURES IN TREE SHREW. A. Jacobs*, D. Fitzpatrick, D. Raczkowski, and I.T. Diamond. School of Medicine and Departments of Neurobiology and Psychology, Duke University, Durham, NC 27710.

The lateral geniculate nucleus (GL) receives a dense projection from cholinergic neurons located in the ponto-mesencephalic reticular formation. These projections are not limited to the GL; they also terminate in other thalamic nuclei and in the superior colliculus (SC). Here the goal was to determine whether individual cholinergic neurons that project to the GL send axon collaterals to other structures. In each experiment WGA-HRP was injected into the GL on one side and rhodamine beads were placed in another thalamic nucleus or the SC. Brainstem sections were processed to demonstrate both retrograde transport and ChAT immunoreactivity in the same neurons. The results show that cholinergic neurons projecting to the GL send collaterals to every other injected structure, but the percentage of individual neurons containing both tracers varied from 35% to 1% depending on the target. The highest percentages (20-35%) were found following injections of rhodamine beads into the SC and contralateral GL, while the lowest (<5%) were found following injections of the ventral posterior nucleus, anteroventral nucleus, and the central lateral and medial dorsal nuclei.

20.6

QUANTITATIVE IMMUNOGOLD EVIDENCE FOR GLUTAMATE AS A NEUROTRANSMITTER OF RETINAL AND CORTICAL TERMINALS IN THE LATERAL GENICULATE NUCLEUS OF THE MACAQUE. V.M.Montero. Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53705.

Current neurochemical evidence suggests that the neurotransmitters in the retinal and cortical pathways to the lateral geniculate nucleus (LGN) might be excitatory amino acids. In this study I have used a postembedding quantitative immunogold procedure on ultrathin sections (Somogyi et al., Neurosci. 19:1045, 1986) to measure the intensity of immunoreactivity to an antibody against glutamate (R. Wenthold, NIH) over profiles of retinal, cortical, and F type terminals, and of glial cells in the parvo- and magnocellular layers of LGN of the rhesus monkey. In two samples of 160 electronmicrographs taken from each of the two main subdivisions of LGN the mean gold particles densities per μm^2 ± SEM over the different profiles were as follows: Parvocellular layers, cortical terminals 23.6 ± 0.67; retinal terminals 16 ± 0.37; F terminals 7.3 ± 0.42; glial cells 5.8 ± 0.49. Magnocellular layers, cortical terminals 28 ± 0.78; retinal terminals 19.9 ± 0.5; F terminals 10 ± 0.46; glial profiles 9.6 ± 0.58. The results thus revealed significantly higher concentrations of glutamate in the retinal and cortical terminals than in the F terminals (demonstrated to be immunogold GABA+ in the same material) and glial cells ($p \leq 0.0001$), which probably reflect glutamate levels in the "transmitter pool" of this amino acid. The lower gold particles densities over the F and glial profiles, which were not significantly different, probably reflect glutamate levels in the "metabolic pool". These results support the notion that glutamate is a neurotransmitter in cortical terminals and in M and P retinal ganglion cells terminals in LGN of the macaque.

THE RETINAL EPSP IS VOLTAGE DEPENDENT IN GENICULATE Y (BUT NOT X) CELLS OF CATS. F.-S. Lo* and S.M. Sherman. Dept of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

The dependence of retinal EPSP amplitude on membrane voltage (V_m) in geniculate X and Y cells was studied in anesthetized, paralyzed cats. We evoked EPSPs by optic chiasm stimulation and altered V_m by passing current through the intracellular recording electrode. For 18 of the 20 X cells, EPSP amplitude correlated negatively and linearly with V_m over the tested V_m range of -120mV to -10mV. This is expected for conventional synapses: EPSP size decreases as V_m nears the EPSP reversal potential. However, EPSP amplitude in each of the 18 Y cells (and the other 2 X cells) dramatically increased with membrane depolarization over a wide V_m range (roughly -120mV to -40mV); further depolarization of V_m reduced EPSP amplitude. We saw no changes in input resistance (e.g., anomalous rectification) that could explain the voltage dependency of EPSP amplitude in Y cells. Instead, this dependency is remarkably similar to that reported for NMDA receptors. Perhaps the retinogeniculate Y synapse is glutamatergic and uses many NMDA receptors, while the X pathway does not prominently do so. Whatever its explanation, this voltage dependency affords a mechanism by which retinogeniculate transmission can be gated: various nonretinal inputs (e.g., corticogeniculate axons) that can affect V_m in Y cells can thereby control the gain of the retinogeniculate EPSP and thus the efficacy of signal transfer to the visual cortex.

EFFECTS OF BRAINSTEM STIMULATION ON X AND Y CELLS IN THE LATERAL GENICULATE NUCLEUS OF THE CAT. D.J. Uhlrich, S.A. Bloomfield & S.M. Sherman. Dept. Neurobiology, SUNY, Stony Brook, NY 11794.

We studied the intra- and extracellular responses of geniculate cells in cats to electrical stimulation of the parabrachial region of the brainstem. Brainstem stimulation consisted of pulse trains of 16msec at 250Hz delivered through bipolar electrodes. The typical response to such stimulation is depolarization followed by hyperpolarization. However, some X cells respond with depolarization only, and some Y cells with hyperpolarization only. Similar effects on spontaneous activity are seen with extracellular recording, although the time course of responses may be extended compared to the intracellular responses. When brainstem stimulation precedes visual stimulation, the former can affect responses to the latter (i.e., amplitude, duration, and direction) nonlinearly: that is, these interactive effects cannot be predicted from the effects of brainstem stimulation on spontaneous activity alone. For some cells, brainstem stimulation affected the responses to visual stimulation for up to 1sec or more. On average, X cells show such nonlinear effects more strongly than do Y cells. Y cells, however, often show differential effects depending on whether the visual stimulus is a small spot limited to the receptive field center or one large enough to cover the surround as well; X cells rarely show such a difference depending on stimulus size.

20.9

TEMPORAL RESPONSE PROPERTIES OF LAGGED AND NON-LAGGED CELLS IN THE CAT LATERAL GENICULATE NUCLEUS. A.B. Saul and A.L. Humphrey, Dept. of Neurobiology, Anatomy, and Cell Science, U. of Pittsburgh, Pittsburgh PA 15261.

Two major groups of X-relay neurons in the A-laminae of the cat's LGN have recently been described[1,2]. These lagged (X_l) and non-lagged (X_n) cells have similar spatial response properties, but differ dramatically in their temporal behavior. Responses of these cells were studied by presenting small counterphasing spots and drifting gratings, which induce responses dominated by the component at the stimulus temporal frequency. We measured the amplitude and phase of the first harmonic response component over a range of temporal frequencies. X_l-cells have lower preferred temporal frequencies and weaker responses to high frequencies than do X_n-cells. The clearest differences appear in the timing of responses, however. At 1Hz, X_n-cells respond slightly ahead of the stimulus, with a phase lead of about .06 cycles. Y-cells respond similarly, leading the stimulus by about .1 cycles. X_l-cells, however, lag the stimulus by about .23 cycles at 1Hz. This quarter-cycle difference between lagged and non-lagged units could play a functional role in providing quadrature pairs as inputs to direction-selective cortical cells[3]. However, the phase difference between X_n- and X_l-cells does not remain constant as temporal frequency is varied. Response phase increases linearly with temporal frequency. The slope of the phase-frequency curve is response latency. X_l-cells have latencies of 100-300msec measured by this slope, as compared to 40-100msec for X_n- or Y-cells. Therefore, at higher frequencies the phase difference between lagged and non-lagged cells increases. At about 4 Hz X_l-units fire ¼ cycle after X_n-units of the same center-type.

These differences in tuning and timing of responses correspond to the prolonged, partly inhibitory effect of a visual stimulus on lagged cells as opposed to the predominantly excitatory, transient effect on non-lagged cells. The inhibition on X_l-cells is of intrageniculate origin[1,2]. The present findings support the suggestion[1,2] that a major function of intrageniculate inhibition is to tranform retinal signals in the temporal domain.

RESPONSES OF X AND Y CELLS IN THE CAT LATERAL GENICULATE NUCLEUS TO MOVING BARS AND EDGES. Y.H.Kwon*, M.Esguerra, A.W.Roe, and M.Sur (SPON: W.Richards). Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

One proposal for the function of X and Y cells in early vision requires that X cells in the retina and LGN provide the cortex with a convolution of image intensity with a receptive field function and that Y cells provide a time-derivative of the same (Marr and Ullman, Proc.R.Soc.Lond. B211, 151-180, '81). To test this notion we measured the responses of X and Y cells in the cat LGN to "thin" light and dark bars (with widths 0.1-0.25 times receptive field center widths) and edges both moving at constant velocity. We also obtained spatiotemporal contrast sensitivity functions and visual latencies, and located zero-crossings and peaks in the bar and edge reponses for comparison with predicted crossings and peaks.

The response of X cells (n=6) to a thin bar moving at low velocity is, as expected, similar to the line weighting function of their receptive fields. The X cell response to an edge is well-predicted by convolving their receptive fields with a step function. The response of Y cells (n=7) to an edge also agrees well with the predicted time-derivative of a step convolution. The response of Y cells to thin bars, however, is often broader than the time-derivative of the line weighting function.

This suggests that the thin bars elicit additional responses from Y cells, such as from small, spatially dispersed, subfields that add to or rectify the differentiated (dipole) responses to thin bars (cf. Hochstein and Shapley, J.Physiol. 262, 265-284, '76). Stimuli such as moving edges that effectively engage the linear components of Y cell receptive fields yield time-derivative (transient) responses that are consistent with the band-pass temporal characteristics of these cells, just as the X cell responses follow from their low-pass temporal transfer functions.

20.11

EXTRATHALAMIC CONTROL OF X AND Y CELL ENCOUNTER RATES IN THE LGN OF THE MONOCULARLY PARALYZED CAT. R.J. Moore*, J.W. Vaughan, W.L. Salinger, H.H. Willis, III, and L.R. Cole*. Dept. of Psychology, Univ. of North Carolina at Greensboro, Greensboro, NC 27412.

The lateral geniculate nucleus (LGN) is the target of extrathalamic influences, including those that are derived from proprioceptive and binocular processes. The operation of these processes is revealed in the LGN by monocular paralysis (MP), which results in a decrease in the encounter rate of X cells relative to Y cells. It is clear that this effect is a manifestation of binocular and proprioceptive interactions because it is seen in the LGN layers innervated by the mobile as well as the paralyzed eye, and it can be reversed by visual or proprioceptive deafferentation of the mobile eye.

In the present experiments we have continued our assessment of the role of visual and proprioceptive interactions in producing and maintaining the effects of MP by lesioning key extrathalamic structures in anesthetized subjects. To accomplish this, LGN cells with receptive fields within the central 5 degrees of visual space were classified as X or Y using a standard battery of tests before and immediately after lesioning the target structure. Cryogenic blockade or aspiration of visual cortex ipsilateral (but not contralateral) to the recorded LGN reversed the MP effect (i.e., increased the encounter rate of X cells relative to Y cells) in both laminae A and A1 ($P < .05$, 10 cats, 643 cells). In addition, aspiration of the cerebellum produced a similar effect ($p < .05$, 4 cats, 188 cells), but lesions of the superior colliculus did not (4 cats, 128 cells). These results reveal that the extrathalamic circuit, which controls the X and Y cell encounter rates in the LGN and is sensitive to binocular and proprioceptive signals, includes the cerebellum and visual cortex, but not the superior colliculus.

20.12

ECCENTRICITY-SPECIFIC ANESTHESIA EFFECTS ON RELATIVE ENCOUNTER RATES FOR X- AND Y-CELLS IN ADULT CAT LGN. H.H. Willis,III, W.L.Salinger, J.W. Vaughan, R.J. Moore*, & L.R.Cole*. Dept. of Psych., UNCG, Greensboro NC 27412

The relative recording probabilities of X- and Y-cells in regions representing central visual space in the cat lateral geniculate nucleus (LGN) have been shown to be dynamically controlled by mechanisms which are sensitive to levels of anesthesia and to disruption of normal binocular interactions. In the present experiments, we have extended the analysis of these mechanisms to more peripheral representations within the LGN A and A_1 laminae of binocularly paralyzed adult cats.

Using painless head restraint, we recorded LGN cells, classifying 298 as X or Y. Matched pairs of penetrations were made at various eccentricities, with animals either anesthetized or sedated. Although the average number of cells per pass was unchanged between them, the two conditions differed dramatically. In penetrations when the cats were sedated (n=148 cells), there were roughly equal numbers of X- and Y-cells, with no systematic changes in X/Y ratios across the representation of the central 18 degrees of visual space. In marked contrast, when animals were anesthetized, recordings in the matched penetrations (n=150 cells) yielded a surprisingly steep and tight exponential fit ($R^2>.92$, $p < .0001$), declining from near 100% X-cells at area centralis to under 23% within 18 degrees of eccentricity.

One of these paired sets of observations could reflect anatomic distributions of LGN X and Y cells. However, the other must reflect activities of physiological processes powerful enough to affect relative encounter rates for X and Y cells, and doing so in opposite directions in central and peripheral representations of visual space. This raises questions about the functional role and perceptual consequences of such processes.

EFFECTS OF DORSAL RAPHE STIMULATION ON NEURONAL ACTIVITY IN THE RAT LATERAL GENICULATE NUCLEUS.
Y. Kayama[1], S. Shimada*, Y. Hishikawa* and T. Ogawa*.
Dept. of Physiology, Akita Univ. Sch. of Med., Akita 010; [1]Fukushima Medical College, Fukushima 960-12, Japan.

The dorsal raphe nucleus (DR) of rats anesthetized with urethane was penetrated by a stimulating electrode, whose position was confirmed histochemically after experiment. During repetitive stimulation of the DR at 200 Hz for several to 10 seconds, spontaneous firing of lateral geniculate relay neurons changed variably from neuron to neuron. However, their firing was consistently depressed for 20 seconds to 2 minutes after the cessation of DR stimulation. This depression was seen in many cases concurrently with strengthening of slow activity in cortical EEG, but in others without any change in EEG. The DR-induced depression was blocked by methysergide applied ionophoretically. In some cases the depressive effects of DR stimulation disappeared after several neurons were tested, possibly because of depletion of serotonin. In such cases, intraperitoneal administration of 5-hydroxy-tryptophan could recover the depression.

These results show that the serotonergic system arising from the DR exerts an inhibitory influence on relay neurons. Together with the noradrenergic and cholinergic systems, both of which give excitatory influences to relay neurons, thalamic neuronal activity is controlled by triple diffuse projection systems from the brainstem.

PHYSIOLOGICAL AND MORPHOLOGICAL PROPERTIES OF TECTO-RECIPIENT CELLS IN THE HAMSTER'S DORSAL LATERAL GENICULATE NUCLEUS.
W.H. Rohrer, R.D. Mooney and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

The stratum griseum superficiale of the superior colliculus (SC) projects to the dorsal lateral geniculate nucleus (LGNd), but relatively little is known about the morphology or receptive field properties of the neurons that receive this input. We characterized, filled with horseradish peroxidase, and recovered 27 LGNd cells that were tested for responsivity to SC stimulation. We obtained electrophysiological data from another 8 cells in which "spills" or incomplete fills provided histological verification of a recording site in the LGNd. Of these 35 cells, 54% (N=19) were excited by SC shocks. The average response latency was 3.7 ms. Seven of the SC driven cells had X-like receptive fields, 4 had Y-like receptive fields, 4 were unresponsive, and 4 were not completely tested. Seven of the cells activated by SC shocks were projection neurons and 10 could not be antidromically activated from visual cortex. Two cells were not tested. The somas and dendritic arbors of projection neurons were larger than those of interneurons. Surprisingly, the soma and dendritic areas of cells with X-like receptive fields tended to be larger than those with Y-like receptive fields. Supported by BNS 85-00142, EY 04170, and NS 07229.

EFFECTS OF REMOTE STIMULI ON VISUAL RESPONSES OF LATERAL GENICULATE NEURONS: SPATIAL PARAMETERS.
Cérat, A., S. Molotchnikoff and P. Rouillon. Département de Sciences biologiques, Université de Montréal, Montréal, Québec. H3C 3J7.

We have previously demonstrated that a conditioning stimulus (CS) presented in the periphery of the visual field (VF) modifies the visual responses of a geniculate cell to a LED. This effect is mediated by the superior colliculus (SC) as its inactivation suppresses the interaction. This investigation analyzes the spatial parameters of these interactions. Anesthetized rabbits were prepared for extracellular recordings of LGN cells. In addition, a lidocaine hydrochloride filled micropipette was lowered in to the SC. A LED was positioned in the center of the geniculate receptive field (RF) while a moving slit was presented in the periphery of the VF. Several conclusions emerge from these results. 1) The CS produces a larger attenuation of the visual responses of tested neurons if the RF is eccentric. Conversely, the CS increases the discharges of cells whose RF are close to the optic axis. There is also a positive correlation between the amplitude of the effects and the size of the RF. 2) It seems that there is an optimal interstimuli distance where the effects are largest. 3) In most cases, the effects are abolished if the SC is rendered inactive.

MODIFICATION OF VISUAL INPUT AT LGN BY CORTICAL AND BRAINSTEM FEEDBACKS.
K. P. Unnikrishnan and *E. Harth*. AT&T Bell Laboratories, Molecular Biophysics Research Department, Murray Hill, NJ 07974 and Physics Department, Syracuse University, Syracuse, NY 13244.

Through computer simulations, we have investigated the role of feedback pathways in sensory information processing. We show that at the mammalian dorsal lateral geniculate nucleus (dLGN) feedback from cortex and brainstem reticular formation is capable of modifying retinal input in feature specific ways. In the presence of visual input, incomplete information is filled in and in the absence of input quasi-sensory images are created. GABAergic interneurons in the perigeniculate (PGN) with the NMDA receptors in the LGN (for which there is recent evidence) can carry out the necessary computations in the model.

THE EFFECT OF GASTRIC VAGOTOMY ON VOLUNTARY ETHANOL INTAKE IN THE RAT.
P. Toth*, L.A. Grupp, E. Perlanski*, S. Harding* and M.A. Linseman. Dept. of Pharmacology, Univ. of Toronto, and Addiction Research Foundation of Ontario, Toronto, Ont., Canada M5S 1A8.

Ethanol as a drug acts on the central nervous system; however, it also has food properties (i.e., calories, taste) and is consumed orally. Given that gastric vagal afferents have been shown to be important in the control of feeding, we investigated the effect of gastric vagotomy (GVX) on ethanol intake. Free-fed GVX and sham-operated control rats were offered ethanol using the limited access procedure which is known to produce a robust level of ethanol intake and detectable blood ethanol levels. Compared to the sham group, the GVX animals drank less ethanol at the two concentrations (3%, 6% w/v) that were offered ($p<0.01$). These findings suggest that in a procedure that elicits consumption of pharmacologically and behaviorally significant amounts of ethanol, intake can nevertheless be influenced by a manipulation that has been shown to alter feeding behavior. Supported by the Labatt Brewing Company.

21.2

BEHAVIORAL INTERACTIONS WITH ETHANOL (ET) AND CNS EFFECTS OF ICV ADMINISTERED DILAZEP AND ITS METABOLITES IN MICE.
M.S. DAR, Department of Pharmacology, School of Medicine, East Carolina University, Greenville, NC 27858.

Dilazep (ip), a coronary vasodilator and an uptake inhibitor of adenosine (Ad), dose dependently potentiated acute ethanol-induced motor incoordination (EIMI) in mice. In view of peripheral cardiovascular depressive effects of dilazep, the effect of icv dilazep (25, 50 & 75ug), and its metabolites BHPD (15, 31 & 62ug) and TBPD (62 & 125ug) on EIMI was studied. Dose related potentiation of EIMI was noted with dilazep and its metabolites. Whereas dilazep (ip) produced no apparent CNS effects, by icv route it caused tonic-clonic seizures. AD uptake inhibition, Ca^{++} entry blockade or direct activation of AD receptors was ruled out as the mechanism of seizures because dipyridamole, verapamil or R-PIA, respectively, did not produce these. The CNS excitation was minimal with BHPD and none with TBPD. Theophylline pretreatment partially blocked potentiation of EIMI by dilazep and BHPD and none by TBPD. Data suggested dilazep-induced potentiation of EIMI is partly due to AD receptor mechanism and partly due to other yet unknown mechanism(s) and further supported our earlier reports about AD involvement in the CNS effects of ET. Data also suggested that dilazep(icv)-induced seizures are due to mechanism(s) other than AD uptake inhibition, Ca^{++} entry blockade or direct AD receptor activation.

21.3

SPECIFICITY OF RESPONSE STRATEGIES IN BEHAVIORAL TOLERANCE TO ETHANOL. D.A. King* and F.A. Holloway. Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190-3000.

Chronic exposure to ethanol (ETOH) results in the development of persistent tolerance to ETOH's rate-decreasing effects on rat operant behavior. Such data are consistent with a functional interpretation of tolerance in which animals acquire, through "intoxicated practice" (IP), some compensatory response strategy specific to the task demand characteristics. The present study attempted to directly assess the nature of this hypothetical learned response strategy in rats given IP on an FR task. Male Sprague-Dawley rats were trained on a DRL-15 s (a.m.) and a FR-30 task (p.m.) to respond for food reinforcers. Half of the rats received 30 days of pre-session ETOH injections prior to the FR-30 task only, while the other half received p.m. saline (SAL) injections. If rats acquire tolerance to ETOH's rate-decreasing effects on FR performance by developing a "learned rate-increasing strategy," then such an effect may be reflected in these rats' DRL performance by significant response-rate increases. The results confirm this expectation. Dose-effect analysis indicated the development and retention of significant tolerance on the FR task in the ETOH-treated rats which was absent in the SAL-treated controls. On the DRL task, SAL-treated controls evidenced no change in ethanol sensitivity. As anticipated, however, ETOH-treated rats demonstrated significant increases in response rates on the DRL task. Supported by NIAAA AA06351.

21.4

THE 5-HT$_3$ ANTAGONIST GR38032F DECREASES ALCOHOL CONSUMPTION IN RATS. E.M. Sellers*, H.L. Kaplan*, M.O. Lawrin*, G. Somer*, C.A. Naranjo* and R.C. Frecker* (SPON: W.G. Tatton). Depts. of Pharmacol. and Med., Univ. of Toronto, and Clin. Psychopharmacol. Program, Toronto, Ontario M5S 2S1.

Ethanol consumption is regulated by multiple neural systems. Effective ways to decrease alcohol consumption in humans are needed. A micro-drinking monitoring system detects decreases in rat ethanol drinking at doses of fluoxetine (a serotonin uptake inhibitor) 20-50 fold lower than reported using a 24-hour preference paradigm, e.g. 500-1000 µg/kg (Sellers, E.M., et al, Clin. Pharmacol. Ther. 43(2): 187, 1988). The drinkometer may have predictive value since the effects correspond with results from clinical studies with zimelidine, citalopram, viqualine and fluoxetine (Naranjo, C.A. and Sellers, E.M. In: Recent Developments in Alcoholism, Volume VII. Galanter, M. (ed.), Plenum Publishing Corporation, New York, 1988).

Male Wistar rats (200 g, n = 5-6/group) with a > 50% free-choice preference for 6% v/v ethanol received GR38032F, a specific selective 5-HT$_3$ antagonist (Glaxo), 1, 10 and 100 µg/kg i.p. once 1.0 hour prior to the 12-hour dark cycle. Differences between first treatment and last baseline day showed GR39032F at 1 µg/kg decreased ethanol intake and minutes in which drinking occurs by 40% and 33% over 12 hours respectively (ANOVA $p < 0.05$). Effects were less pronounced at higher doses suggesting an inverted "U" shaped dose-effect relation. In another study, decreases in ethanol consumption volume were found at lower doses, e.g. 0.01 µg/kg, however the effects did not persist after 3 days of treatment.

These data are the first to suggest 5-HT$_3$ receptors may modulate consummatory behaviour. GR38032F may be a new clinical lead for treatment of alcohol abuse.

21.5

GENETICALLY SELECTED LINES OF HIGH- AND LOW-ALCOHOL-DRINKING RATS: OPERANT STUDIES. A.D. Levy, W.McBride, J.Murphy, L.Lumeng, & T.-K.Li. Inst Psych Res, Indiana Univ Sch Med, VA Med Ctr, Regenstrief Inst, Indianapolis, IN 46223

Lines of high- and low-alcohol-drinking rats (HAD and LAD) have been selectively bred from a heterogeneous N/Nih stock. This study compared ethanol (EtOH) reinforcement between HADs and LADs in an operant task, similar to studies with Wistar-derived P and NP lines of rats selected for EtOH preference (PBB 8:475, 1978).

HAD and LAD male rats (6/line), were trained to bar press for sweetened milk on an FR5 schedule during daily 1 hr sessions, until reaching criteria of 100 reinforcements for 3 consecutive days. Rats were then tested for bar pressing for varying concentrations of EtOH (2-30% v/v). LADs exhibited few responses for EtOH, while moderate rates were obtained for the HAD's across all EtOH concentrations (reaching approximately 0.8 g/kg for 30% EtOH, $p<.05$). Similar to the P line, the HAD line clearly demonstrated that they will work to obtain EtOH without food or water restriction, suggesting that EtOH is reinforcing in these rats. (Supported by AA-03243 and AA-07462).

21.6

EFFECTS OF ALCOHOL ON THE SEXUAL BEHAVIOR OF FEMALE RATS. J.P.J. Pinel and J.G. Pfaus. Dept. Psychology, Univ. British Columbia, Vancouver, B.C. V6T 1Y7 Canada.

Much of the experimental evidence for a disruptive effect of alcohol on sexual behavior comes from the study of male rats and dogs; no studies had examined the effect of alcohol on the sexual behavior of female laboratory animals. Accordingly, we examined the effects of a wide range of doses of alcohol (0.125 to 2.0 g/kg) on the sexual behavior of ovariectomized Sprague-Dawley rats (N = 12) rendered **moderately** sexually receptive with SC injections of 10 ug estradiol benzoate 48 hr and 250 ug progesterone 4 hr before each test. The female rats were tested at 4-day intervals with sexually active male rats in small Plexiglas testing chambers during the dark phase of their circadian light cycle. Doses of ethyl alcohol (25%, v/v) or saline were injected IP 1 hr before each test in a latinized, repeated measures design. The highest dose of alcohol (2 g/kg) completely abolished lordosis behavior and a moderate dose (1 g/kg) significantly reduced both lordosis quotients and magnitudes. In contrast, a low dose (.5 g/kg), which had no effect on lordosis behavior, significantly increased the incidence of proceptive behaviors (i.e., hopping, darting, and ear-wiggling). These results are consistent with anecdotal reports that alcohol can have both facilitatory and disruptive effects on human sexual behavior.

21.7

RAPID TOLERANCE TO THE DISRUPTIVE EFFECTS OF ETHANOL ON HIGH-SPEED REACTION TIME IN YOUNG AND OLD RATS. R. D. Mayfield*, M. Grant*, D. Lowe*, W. W. Spirduso[a] and T. Schallert[b]. Institute for Neurol. Sciences, Depts. of Kinesiology & Health Education[a] and Psychology[b], Univ. Texas at Austin, Austin, TX 78712

We have recently reported that rapid tolerance develops to the detrimental effects of ethanol (EtOH) on reactive capacity (RC) in rats. The RC model is a high-speed reaction time task that measures the overall success in avoiding mild footshock (percent avoidance) as well as the response latency of the successful avoidances (measured in msec). The purpose of this study was to examine the effect of age on the development of tolerance to the effects of EtOH using the RC model. Young (8 - 11 mo) and old (24-26 mo) Fischer 344 rats were shaped to release a lever in response to an auditory/visual stimulus. Shaping was continued until the animals could reliably release the lever in less than 500 msec. The animals were given blocks of ten trials at 5, 10, 20, 45, 65, and 90 min post-EtOH/or -saline. Animals of each age either received RC sessions while intoxicated (Behavior While Intoxicated; BWI) or while sober (Behavior While Sober; BWS). The BWS group was administered EtOH immediately after the RC session except on Day 5 when they received EtOH immediately before the RC test session. EtOH (17-20% w/v; 1.6-2.5 g/kg) was administered to both the BWI and BWS groups 3 times per day at 8 hr intervals for 5 days via intragastric intubation. EtOH doses were increased slightly each day so that blood EtOH concentrations (BECs) were greater than or equal to the BECs of the previous day. The performance of both the young and the old animals in the BWI group was significantly impaired after the first EtOH challenge (Day 1), as measured by both percent avoidance and response latency. Percent avoidance scores significantly improved in both age groups by Day 5 in spite of higher BECs. The same degree of improvement was not observed for response latencies. In general, the old animals were more impaired than the young on Days 1 through 4; however, by Day 5 there were no significant age-related differences in performance. The performance of the BWS animals (young and old) was impaired as measured by both percent avoidance and response latency. There were no clear age-related differences in performance in the BWS animals on Day 5. GRANTS: AA06761 and NS20827.

ETHANOL-INDUCED MOOD CHANGES CORRELATE WITH CHANGES IN REGIONAL CEREBRAL METABOLISM. J.T. Metz, H. de Wit*, J.B. Brunner*, S.J. Gatley*, M.D. Cooper*. University of Chicago, Chicago, IL

This study used positron emission tomography (PET) to examine the effects of ethanol on regional cerebral metabolism (rCM) and subjective mood.

Nine adult males were tested on two occasions each. On one day, subjects consumed 0.5 mg/kg of ethanol dissolved in a citrus flavored beverage; on the other day, they received the vehicle beverage only. They were injected with 6-8 mCi 2FDG and for 45 minutes performed a visual monitoring task. Before the beverage and 20 and 40 minutes after 2FDG injection, subjects completed a Profile of Mood States (POMS). rCM was determined using Sokoloff's model with standard rate constants and fourteen ROIs obtained from tomographic metabolic images.

Although all subjects attained marked blood levels of ethanol, across subjects average metabolic rate for the whole brain did not change in response to ethanol (9.06 mg/100g/min with placebo, vs. 8.71 with ethanol). No region showed a consistent metabolic change in response to ethanol.

Changes in rCM relative to whole brain metabolic changes after ethanol, however, were related to changes in mood. Changes in three positive moods (Vigor, Friendliness, and Elation) had strong negative correlations ($r > 0.70$ in absolute value) with changes in relative rCM in left temporal cortex; they had comparable positive correlations with changes in left parietal cortex. Changes in three negative moods (Anxiety, Depression, and Anger) had strong positive correlations with changes in relative rCM in left temporal cortex and strong negative correlations with changes in left parietal cortex. Homologous regions on the right had similar correlations. Other regions were uncorrelated with mood changes.

These data suggest that changes in rCM may be related to ethanol's mood-altering effects. Individual differences in mood associated with the drug may underlie differential risk for alcohol abuse. The data also show that PET may be useful in the study of mood.

DIFFERENTIAL ETHANOL AND HABITUATION EFFECTS ON OPEN-FIELD ACTIVITY MEASURES. H.L. June*, T.O. Moore*, K.L. Edwards* and M.J. Lewis. Dept. of Psychology, Howard University, Washington, D.C. 20059.

Ethanol (E) has been found to produce differential effects on habituation of exploration and locomotion (Lister, R.G., Psychopharm., 92: 78, 1987). To further investigate E and habituation effects on activity, the present study examined E-induced stimulation effects and habituation in rats selected for low spontaneous activity.

Male Charles River rats who were selected for low-wheel running activity were habituated to the open field over a six week period by repeated testing. Rats received E (0.75 g/kg) or saline 5 minutes prior to being placed in a Digiscan activity apparatus. Horizontal (H) and nonhorizontal (NH) activity were measured for 10 minutes. Saline treated rats showed initial higher levels of activity which declined with subsequent testing, indicating habituation. A similar profile occurred with E-treated rats in H activity, although their activity levels were higher than saline controls. In contrast, E-treated rats showed increases in NH activity with subsequent testing. The E group showed higher levels of both activities in comparison with saline controls. These results suggest that E may be differentially affecting qualitative components of locomotor activity and their habituation.

ETHANOL INDUCED MOTOR BEHAVIOR IN NORMAL AND ACATALASEMIC MICE. C.M.G. Aragon*, C. Pesold*, F. Rogan*, and Z. Amit (SPON: Z.W. Brown). Center for Studies in Behavioral Neurobiology, Concordia Univ., Montreal, Quebec H3G 1M8.

The role of brain catalase in modulating the psychopharmacological effects of ethanol was investigated by examining ethanol induced locomotor activity in normal, C3H-N, and a corresponding colony of acatalasemic C3H-A, mice. Following administration with i.p. injections of one of three doses of ethanol (0.8, 1.6 and 3.2 g/kg) or saline, mice were placed in open field chambers and locomotor activity was measured during a 10 minute testing period. A significant increase in locomotor activity was recorded in both mice at lower doses of ethanol, while the higher dose produced a marked depression. Normal mice demonstrated more locomotor activity than acatalasemic at all ethanol doses. No differences in blood ethanol levels were observed between the two strains. Acatalasemic brain and liver residual catalase activity was found to be 40% of normal mice. These results suggest a role for brain catalase in ethanol effects and support the notion that centrally formed acetaldehyde is a factor mediating some of ethanol's psychopharmacological effects.

INTERACTIONS OF THE ALPHA$_2$-ADRENOCEPTOR ANTAGONIST, ATIPAMEZOLE, WITH ETHANOL ON EXPLORATION AND LOCOMOTOR ACTIVITY. M.J. Durcan, R.G. Lister and M. Linnoila. Laboratory of Clinical Studies, NIAAA, Blg10 3C218, 9000 Rockville Pike, Bethesda, MD 20892, USA.

Atipamezole (Farmos Ltd.) is a highly potent and selective alpha$_2$-adrenoceptor antagonist. In this study its behavioral effects and its interactions with ethanol were explored in mice using a holeboard test of directed exploration and locomotor activity. When administered alone, atipamezole (0.1-3.0 mg/kg i.p.) had no effect on either exploratory head-dipping or locomotor activity 30 min after administration. However the drug completely antagonized the effects of the alpha$_2$-adrenoceptor agonist medetomidine (0.1 mg/kg). In the ethanol study, atipamezole was administered at the same time as a contralateral i.p. injection of 2 g/kg ethanol 30 min prior to testing. Ethanol significantly reduced exploratory head-dipping ($p<.01$) and increased locomotor activity ($p<.001$). Atipamezole (1 and 3 mg/kg) significantly antagonized the ethanol-induced reduction in exploratory head-dipping ($p<.05$); no change in ethanol's locomotor stimulant property was seen. We have found that atipamezole antagonizes the ataxic effects of ethanol (Lister et al., this meeting). These results suggest alpha$_2$-adrenoceptor mediation of some of the behavioral effects of ethanol.

ODOR AS A CUE FOR ALCOHOL AVERSION LEARNING IN RATS LACKING GUSTATORY NEOCORTEX. S.W. Kiefer, N.S. Morrow, and C.W. Metzler*. Department of Psychology, Kansas State University, Manhattan, KS 66506.

The hypothesis that the normal alcohol aversion learning found in rats lacking gustatory neocortex (GN) is based on the odor cue of alcohol was tested. Control rats (n=23) and GN rats (n=17) were trained to drink for 5 min from a modified drinking spout with an odor disc attached. On training day, half the rats from each group drank water in the presence of the odor of alcohol; the remaining rats consumed 5% (v/v) alcohol from the drinking tube (experiencing the odor and taste of alcohol). Illness was induced after a delay of 30 min. All rats were then tested for drinking water in the presence of the alcohol odor. Results showed that both control rats and GN rats given alcohol in the drinking tube during training showed strong avoidance of drinking in the presence of the alcohol odor, an avoidance which extinguished after four test sessions. Rats given odor-illness pairings failed to show avoidance of the odor. The results support the hypothesis that rats lacking GN are capable of using the odor of alcohol as a salient cue in developing learned alcohol aversions.

TEMPERATURE DEPENDENCE OF ETHANOL DEPRESSION IN MICE: DOSE RESPONSE. R.L. Alkana, D.A. Finn,* G.G. Galleisky,* M. Bejanian and B. Jones.* University of Southern California, School of Pharmacy, Los Angeles, CA 90033.

Previous studies indicate that body temperature alters brain sensitivity to ethanol in C57BL/6 and BALB/C mice following injection of 3.6 g/kg ethanol. The current study tested the generality of this effect across a range of hypnotic ethanol doses. Drug naive, male C57BL/6J mice were injected with 3.2, 3.6 or 4.0 g/kg ethanol (20% w/v) and were exposed to one of six designated temperatures from 15 to 34 ^{o}C. Ambient temperature significantly affected wake-up rectal temperatures, sleep-times and wake-up blood and brain ethanol concentrations at all three doses. Wake-up temperatures were significantly positively correlated with sleep-times and significantly negatively correlated with wake-up blood and brain ethanol concentrations at all three doses. The sleep-time duration was dose dependent at each ambient temperature, but the degree of body temperature change and the wake-up blood and brain ethanol concentrations did not appear to be dose-dependent. The latter finding suggests that the threshold ethanol concentration for return of function was not influenced by dose. These results demonstrate the generality of temperature dependence across hypnotic doses and emphasize the importance of body temperature as a variable in ethanol research. (Supported by research grant RO1 AA05234, NIAAA, ADAMHA).

GANGLIOSIDES, OR SIALIC ACID, ANTAGONIZE ETHANOL INTOXICATION. R. Boyles,* J. Mathew,* L. Cherian,* and W. R. Klemm. Dept. Vet. Anat., Texas A&M U., Col. Sta., TX 77843.

Because ethanol had a dose-dependent effect on hydrolysis of brain sialogangliosides, we tested the possibility that injected gangliosides might antagonize ethanol (3.9-4.5 gm/kg). Clear anti-intoxication effects were seen at 24 hr post-injection of 125-130 mg/kg of mixed gangliosides, but not at lower or higher doses. Sleep time was reduced on the order of 50%, and roto-rod agility was significantly enhanced. Sialic acid (SA) similarly antagonized ethanol, but not ceramide or the prescursor of SA, N-acetyl-D-mannosamine (100 mg/kg each).

As intoxication level directly correlates with brain sialoconjugate hydrolysis, any compound that interferes with SA hydrolysis might reduce intoxication. Thus, injection of ganglioside or SA might prevent/compensate for at least part of ethanol-induced SA hydrolysis. The results show that SA is a key component in mediating ethanol effects. Changes in ganglioside not only correlate with intoxication, but we must also consider that they cause many signs of intoxication.

21.15

MUSCARINIC CHOLINERGIC INFLUENCES ON ETHANOL SENSITIVITY IN LONG-SLEEP AND SHORT-SLEEP MICE. V.G. Erwin and B. Jones.* Alcohol Research Center, School of Pharmacy, University of Colorado, Boulder, CO 80309.

Sensitivity to the hypnotic effects of ethanol were selectively increased by central administration of muscarinic agonists. Carbachol or oxotremorine, but not nicotine, icv, enhanced hypnotic sensitivity to ethanol, in short-sleep (SS) but not long-sleep (LS) mice. Likewise, the acetylcholinesterase inhibitor, neostigmine, icv, differently enhanced hypnotic sensitivity to ethanol in these mouse lines. LS and SS mice were equally sensitive to the hypothermic effects of oxotremorine, icv. The muscarinic antagonists, atropine or pirenzepine, icv, were without effect on ethanol sensitivity, but at doses of 0.5 µg to 1.5 mg these compounds effectively antagonized oxotremorine- or neostigmine-enhanced ethanol sensitivity in SS mice. Pirenzepine, an M_1 selective antagonist, produced a parallel shift in the oxotremorine dose-response curve, indicating that the enhanced hypnotic sensitivity to ethanol may be due to interaction of oxotremorine with M_1 muscarinic receptors. The results suggest that LS and SS mice differ genetically in neuronal processes activated by specific muscarinic agonists and are consistent with the hypotheses that ethanol acts in part via membrane receptor coupling to intracellular processes known to mobilize intracellular Ca^{++}. (This research was supported in part by USPHS grants AA03527 and AA07330.)

21.16

ROLE OF PHARMACOKINETIC FACTORS IN CONDITIONED TOLERANCE TO ETHANOL HYPOTHERMIA. M. Singh*, A.D. Le*, J.M. Khanna and H. Kalant*. Department of Pharmacology, University of Toronto and Addiction Research Foundation of Ontario, Toronto, Canada.

The role of pharmacokinetic factors in conditioned tolerance to ethanol (EtOH) was examined using a counterbalanced design. One group of rats received EtOH in a distinctive environment (DE) and an equal volume of saline in their home environment (HE), on alternate days. The DE located 3 rooms away from the HE was characterized by dim light and static noise. The other group received EtOH in their HE and saline in the DE. Control animals received saline injections in both environments. After 12 EtOH training sessions, rats treated with EtOH in the HE showed less hypothermia than their controls when tested in both environments. However, those treated with EtOH in the DE showed tolerance only when tested in the DE. Rats which previously received EtOH in the DE absorbed EtOH more slowly than their saline controls when both were tested in the DE, but not when tested in the HE. However, those treated with EtOH in the HE absorbed EtOH at the same rate as their controls when tested in either environment. These results show clearly that conditioned tolerance to EtOH can occur in the absence of change in pharmacokinetics.

SEIZURE SUSCEPTIBILITY IN MICE GENETICALLY SELECTED FOR ETHANOL WITHDRAWAL SEVERITY: SENSITIVITY TO GABA-BZ-CL-COMPLEX DRUGS IN WSP AND WSR MICE. A. Kosobud, D.A. Feller and J. Crabbe. VA Med. Center and Oregon Health Sci. Univ., Portland, OR 97201 USA

WSP mice have been genetically selected to express severe handling induced convulsions (HIC) following ethanol withdrawal, and WSR mice to show minimal HIC. Other differences between lines should be due to the influence of genes affecting EtOH withdrawal severity. We tested the hypothesis that WSP mice were more sensitive than WSR to drugs affecting the GABA-benzodiazepine-picrotoxin receptor/chloride ionophore (GABA-BZ-CL) complex. WSP and WSR mice were tested for the severity of HIC at several times before and after ip bicuculline, picrotoxin, pentylenetetrazole, RO15-4513, and strychnine. In each case, WSP mice showed either a greater or a longer lasting stimulation of HIC than WSR mice after drug treatment. Thus, some genes acting at the GABA-BZ-CL complex may be implicated in ethanol withdrawal severity. That strychnine also differentiated WSP and WSR mice suggests that some more general seizure mechanisms may also be implicated. Threshold seizure susceptibility was also determined by tail-vein infusion of several compounds including the above. A different pattern of results from the two seizure testing methods was seen in the WSP and WSR lines. Supported by Grants AA05828, AA06243, AA06498, NIDA Contract No. 271-87-8120, and by a grant from the VA.

ETOH EFFECTS ON LOCOMOTOR ACTIVITY IN MOUSE LINES SELECTED FOR ETOH HYPOTHERMIA AND ACTIVATION. T.J. Phillips*, D. Baxter*, and J.C. Crabbe (SPON: D.J. Feller). VA Med. Center and Oregon Health Sci. Univ., Portland, OR 97201.

We examined locomotor activity (ACT) after ethanol (ETOH) in 2 sets of selectively bred mouse lines. HOT and COLD lines were selected for degree of ETOH hypothermia, and FAST and SLOW lines were bred for high and low ETOH-induced ACT. ACT was recorded for 30 min. after i.p. saline or 2.0 g/kg ETOH. HOT and COLD mice were similarly activated by ETOH in the first 5 min., however, ACT of HOT mice returned to control levels by 15 min. after injection while COLD mice were depressed between 15 and 30 min. FAST mice were stimulated for the first 10 min., and then their ACT approached control levels. SLOW mice exhibited no activation, and their ACT was depressed at 10 min. and later. These sets of mice, selectively bred for different ETOH responses, are heterogeneous in the relative locomotor activity differences they display to ETOH. Further characterizations of locomotor activity responses and detailed examinations of correlated responses to ETOH and their genetic associations are in progress.

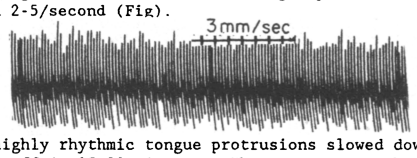
REMARKABLY RAPID AND RHYTHMIC TONGUE PROTRUSIONS PRODUCED BY ACUTE HYPNOTIC DOSES OF ETHANOL IN FISCHER F344 RATS. M.K. Menon. Psychopharmacol. Res. Lab., V.A. Med. Ctr, Sepulveda, CA 91343 and Dept. Psychiat. UCLA. Sch. Med. Los Angeles, CA 90024.

Male Fischer F344 rats (NIH/NCI, 180-220g) were injected with ethanol diluted with isotonic NaCl solution. (1 ml/100g body wt, i.p.). Soon after the animal lost its righting reflex it was placed on its back on a board, the tongue was attached to a strain gauge and the movements recorded on a Grass polygraph. In rats treated either with 23 percent (1.81 g/kg) or with 25 percent (1.97 g/kg) ethanol, the rate of tongue jerks varied between 2-5/second (Fig).



These highly rhythmic tongue protrusions slowed down and tapered off in 15-30 minutes. These movements, however, could be re-initiated by touching the tongue with a saline-soaked cotton swab. Rats treated with 28 percent ethanol (2.2 g/kg) showed either a weak response or were non- responsive. The influence of drug treatments on this remarkable acute effect of ethanol is being investigated. Supported by the Veterans Administration.

DEVELOPMENTAL THERMOREGULATION IN LONG- AND SHORT-SLEEP MICE FOLLOWING PRENATAL EXPOSURE TO ALCOHOL. D.M. Gilliam, L.E. Kotch*, and E.P. Riley*. Center for Behavioral Teratology, SUNY Albany, Albany, NY 12222.

Long-Sleep (LS) and Short-Sleep (SS) mice, selectively bred for differences in ethanol-induced narcosis, provide a tool to investigate how genetic differences in alcohol sensitivity influence susceptibility to prenatal alcohol effects. The ontogeny of core body temperature regulation was measured in offspring of LS and SS mice, following prenatal exposure to alcohol. LS and SS dams were intubated twice per day, 6 hrs apart, with either ethanol (3.0 or 4.0 g/kg) or an amount of maltose-dextrin made isocaloric to the 4.0 g/kg ethanol dose on days 7 through 18 of pregnancy. Non-intubated control groups were maintained for each line. Litters were fostered at birth. One male and female from each litter were tested every other day from post-natal day 7 through 21. On each test day, rectal temperatures were taken at 0, 60, and 120 min after isolation from the nest. Results show that LS and SS offspring prenatally exposed to the 8.0 g/kg/day ethanol dose had lower body temperatures at 60 and 120 min, but not at 0 min, following isolation from the nest compared to offspring from all other treatment groups ($p's < .05$). These data suggest prenatal exposure to alcohol results in thermoregulatory deficits in offspring of both alcohol sensitive and insensitive mice.

22.1

BEHAVIORAL TOLERANCE AND SENSITIZATION TO CGS 19755, A COMPETITIVE N-METHYL-D-ASPARTATE RECEPTOR ANTAGONIST.
C. A. Boast, G. Pastor, S. C. Gerhardt and J. M. Liebman. Res. Dept., Pharmaceuticals Div., CIBA-GEIGY Corp., Summit, NJ 07901.

Competitive N-methyl-D-aspartate (NMDA) receptor antagonists, including CGS 19755, show a variety of behavioral effects when administered acutely. To evaluate the possibility of tolerance or sensitization, a high dose of CGS 19755 (54 mg/kg i.p./injection) was administered to mice twice daily for 14 days (CGS group); a separate group of mice received vehicle (VEH group). One day after the last repeated injection, mice were challenged with vehicle or one of several doses of CGS 19755 (10, 30, 54 or 100 mg/kg) and were tested for ataxia (righting and traction reflexes), spontaneous locomotor activity and the threshold i.v. dose of NMDA required to induce convulsions. In the VEH group, challenge doses of 54 and 100 mg/kg CGS 19755 reduced motor activity. In contrast, the CGS group markedly increased motor activity in response to challenge doses of 30 and 54 mg/kg. A comparison of the VEH and CGS groups showed only slight tolerance to CGS 19755-induced ataxia. Neither the threshold dose of NMDA required to induce seizures, nor the elevation of this threshold dose by acute challenge with CGS 19755, differed significantly between groups. The divergent effects of repeated CGS 19755 in each of these measures suggest that each may be mediated by distinct neuronal systems.

22.2

MK 801 INCREASES LOCOMOTOR ACTIVITY AND INDUCES PCP-LIKE BEHAVIORS: COMPARISON OF SYSTEMIC, INTRA-ACCUMBENS AND INTRA-FRONTAL CORTEX ADMINISTRATION.
R. Gerber, G. Pastor* and J. M. Liebman. Res. Dept., Pharmaceuticals Div., CIBA-GEIGY Corp., Summit, NJ 07901.

The drug, MK 801, has been characterized as a noncompetitive NMDA receptor antagonist with a potentially unique site of action (Foster and Wong, Br. J. Pharmac. 91:403-409, 1987). The present experiments compared its behavioral effects in rats with those of a competitive NMDA receptor antagonist, CPP, and a dissociative anesthetic-type noncompetitive NMDA receptor antagonist, PCP, using Omnitech Digiscan animal activity analyzers. When administered i.p., MK 801 markedly increased motor activity at 0.3 mg/kg with a peak effect at 50 min post-injection, and at 1.0 mg/kg with a slower onset to peak activity. Abnormal motor behaviors induced by MK 801 resembled those associated with PCP, which also increased motor activity. In contrast, CPP at doses as high as 30 mg/kg i.p. induced only a small increase in motor activity and no abnormal behaviors other than ataxia. Intra-accumbens or intra-frontal cortex adminis-tration of MK 801 (10 ug) did not increase motor activity; solubility limitations precluded administration of higher doses. Previous studies have shown that CPP is effective at 0.3-1.0 ug but that doses of 100-300 ug PCP are required. These results associate the behavioral effects of MK 801 with those of the noncompetitive, rather than the competitive, NMDA receptor antagonists.

22.3

HYPERACTIVITY INDUCED BY INTRA-FRONTAL CORTEX INJECTIONS OF NMDA RECEPTOR ANTAGONISTS: EVIDENCE FOR PHARMACOLOGICAL SPECIFICITY AND DOPAMINE MEDIATION.
K. A. O'Neill, G. Pastor* and J. M. Liebman (SPON: B. Petrack). Res. Dept., Pharmaceuticals Div., CIBA-GEIGY Corp., Summit, NJ 07901.

A distinctive motor hyperactivity syndrome is induced by microinjections of competitive N-methyl-D-aspartate (NMDA) receptor antagonists, such as CPP, into the medial prefrontal cortex of rats (O'Neill and Liebman, Brain Res. 435: 371-375, 1987; Pastor et al., this meeting). The pharmacological selectivity of this effect was examined. Rats were anesthetized and bilaterally implanted with stainless steel cannulae in medial prefrontal cortex. At least one week later, they were placed in Omnitech Digiscan animal activity chambers and, following a 1 hour adaptation period, drugs were injected in 0.5 µl solution. No motor hyperactivity was induced by the local anesthetic lidocaine (10 µg), the mixed sigma and PCP agonist, SKF 10047 (30 and 100 µg) or the putative sigma receptor ligand, BW 234U (30 and 100 µg). At high doses (2.0 and 20 µg), NMDA also did not cause motor hyperactivity. Thus, it seems unlikely that this effect of CPP is mediated by local anesthetic effects, NMDA receptor-mediated neurotoxicity, or sigma or PCP binding sites. Haloperidol, at a dose (0.03 mg/kg i.p.) having minimal effects on spontaneous motor activity, markedly attenuated the effects of CPP, suggesting dopaminergic mediation of these behaviors.

22.4

LOCALIZATION OF MOTOR STIMULANT EFFECTS INDUCED BY INTRA-FRONTAL CORTEX MICROINJECTIONS OF CPP, A COMPETITIVE NMDA RECEPTOR ANTAGONIST.
J. M. Liebman, K. A. O'Neill and G. Pastor (SPON: R. G. Browne). Res. Dept., Pharm. Div., CIBA-GEIGY Corp., Summit, NJ 07901.

Microinjections of competitive NMDA receptor antagonists, such as AP-7 or CPP, into rat frontal cortex (FC) induce an unusual pattern of locomotor activation (O'Neill and Liebman, Brain Res. 435: 371-375, 1987). The present experiments assessed the neuroanatomical selectivity of this effect. Under surgical anesthesia, rats were bilaterally implanted with stainless steel cannulae. In behavioral experiments, rats were microinjected with CPP (1 ug in 0.5 µl) or saline vehicle after 60 min of baseline motor activity recording, then were immediately replaced in the chambers and behavioral observations were initiated. Short-latency (within 20 min) increases in motor activity, and episodic darting behaviors, were associated with placements in medial FC. Slightly posterior placements, located in the anterior margins of the nucleus accumbens and corpus striatum, induced short-latency hyperactivity but no darting behaviors. Ataxia was produced by placements in nucleus accumbens and in cerebral cortex dorsal to the genu of the corpus callosum, but the latter placement yielded no increases in motor activity. In conclusion, the effects of intra-frontal cortex CPP microinjections show a high degree of neuroanatomical specificity.

22.5

ACTIVATION OF BIOGENIC AMINE TURNOVER BY MK-801.
T.A. Pugsley, S. Z. Whetzel* and C. R. Clark. Department of Pharmacology, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The novel anticonvulsant MK-801, like phencyclidine (PCP) and ketamine (K), has been described as a non-competitive antagonist of N-methyl-D-aspartate (NMDA). These drugs exert part of their action via PCP binding sites linked to the activation of NMDA receptors. PCP and its analogs are known to act as indirect DA agonists. This study examines the effects of MK-801 on biochemical indices of dopamine (DA), norepinephrine (NE) and serotonin (5-HT) turnover in rat brain. MK-801 (0.2-6.6 mg/kg i.p.) caused dose-dependent increases in the levels of the DA metabolites 3,4-dihydroxyphenylacetic acid (DOPAC) or homovanillic acid (HVA) in striatum (ST), mesolimbic (ML) and frontal cortex (FC) regions as well as levels of the 5-HT metabolite 5-hydroxyindoleacetic acid (5-HIAA). High doses of PCP (10 mg/kg i.p.) and K (50 mg/kg i.p.) elevated HVA levels in ML and ST, while DOPAC levels were elevated only in FC and 5-HIAA levels were generally not altered except for increases in FC. MK-801 (0.2 mg/kg i.p.) also increased the rate of DA synthesis in ST and NE synthesis in brain stem. These findings indicate that MK-801 *in vivo* accelerates biogenic amine turnover resembling somewhat agents such as amfonelic acid. However, unlike the latter, these effects of MK-801 may be mediated by NMDA receptor antagonism.

22.6

ACUTE EFFECTS OF THE ANTIDEPRESSANT/ANXIOLYTIC TRIAZALO-BENZODIAZEPINES ON CRF CONCENTRATIONS IN RAT BRAIN.
M.J. Owens*, G. Bissette and C.B. Nemeroff. Duke Univ. Med. Ctr., Durham, NC 27710.

Preclinical and clinical evidence indicates that corticotropin releasing factor (CRF) integrates the endocrine, autonomic and behavioral responses of an organism to stress and may be involved in the pathophysiology of major depression. We postulated that clinically efficacious antidepressants and anxiolytics may alter neuronal CRF.

Male Sprague-Dawley rats received i.p. injections of: vehicle, a classical tricyclic antidepressant (imipramine 10 mg/kg), or the anxiolytic/antidepressant triazalobenzodiazepines (alprazolam 1 mg/kg, or adinazolam 10 mg/kg). Animals were killed one hour later and trunk blood collected for radioimmunoassay of ACTH and corticosterone concentrations. The frozen brains were dissected into 18 brain regions. The tissues were radioimmunoassayed for CRF utilizing ^{125}I-Tyr^{0}-CRF prepared in our laboratory.

Treatment with either alprazolam or adinazolam produced significant reductions in plasma concentrations of ACTH when compared to either controls or imipramine treated rats. In agreement with this, both the alprazolam and adinazolam-treated animals had correspondingly increased hypothalamic concentrations of CRF. In addition, the concentration of CRF was significantly reduced in the locus coeruleus, amygdala, piriform cortex and cingulate cortex in both the alprazolam and adinazolam-treated animals.

We have previously demonstrated that stress decreases hypothalamic but increases locus coeruleus CRF concentrations. Thus the two triazalobenzodiazepines exert effects on CRF concentrations opposite to those of stress. The present findings support the possibility that the therapeutic anxiolytic and purported antidepressant properties of these benzodiazepines may be the result of their direct or indirect actions on CRF neurons. (Supported by NIMH MH-42088).

22.7

BRIGHT ARTIFICIAL LIGHT ADMINISTERED DURING THE REGULAR PHOTOPERIOD PRODUCES SUBSENSITIVITY TO NICOTINE. S. C. Dilsaver. Psychopharmacology Program, Department of Psychiatry, Neuroscience Program, The Ohio State University, Columbus, Ohio 43210-1228.

Eleven (11) adult, male Sprague-Dawley rats were treated with bright artificial light during the regular photoperiod for 14 days. This treatment was associated with blunting of the thermic response to nicotine.

Mean core temperature prior to the first (before treatment) and second nicotine challenges was 37.4 ± 0.7°C (n = 12) and 37.4 ± 0.2°C. Data were analyzed by assessing the change in thermic response during each of the two 60-minute periods comprising the 120-minute nicotine challenge. The mean thermic response to nicotine during the first 60-minute period was -0.47 ± 0.48°C before treatment compared to -0.07 ± 0.48°C following two weeks of phototherapy ($p < 0.02$, $t = 2.86$). the mean thermic response during the second 60-minute period before chronic administration of bright artificial light was -0.85 ± 0.68°C compared to -0.13 ± 0.59°C afterwards ($p < 0.003$, $t = 3.99$).

The effect of bright artificial light measured in this experiment is consistent with the effects of traditionally used antidepressants. The results may be related to the mechanism of action of bright light in the treatment of seasonal depression.

22.8

LACTIC ACID HAS AN ANTIDEPRESSANT-LIKE EFFECT ON RATS PERFORMING UNDER A DIFFERENTIAL-REINFORCEMENT-OF-LOW-RATE 72-SECOND SCHEDULE. J.E. Lim*, A. Li*, and L.S. Seiden. Dept. Pharm/Phys. Sci., Univ. of Chicago, Chicago, IL 60637.

The differential-reinforcement-of-low-rate 72-second (DRL 72-s) schedule is an operant procedure that has been demonstrated to be a behavioral screen for antidepressant drugs that is both sensitive and specific. Antidepressants and electroconvulsive shock, but not drugs from any other class, cause an increase in reinforcement rate and improvement in temporal discrimination in rats performing under this schedule (O'Donnell & Seiden, 1982; Seiden et al., 1985; Seiden & O'Donnell, 1985). In the present study, we examined effects of lactic acid administration on DRL 72-s performance. Lactic acid is often used as a vehicle for dissolving drugs being tested in behavioral experiments. We found that lactic acid significantly increased reinforcement rate ($F(3,9)=5.321$, $p<0.05$) in a dose-dependent manner while it did not have an effect on response rate. Lactic acid also enhanced temporal discrimination. On the other hand, neither acetic acid nor pyruvic acid, two metabolites of lactic acid, affected reinforcement rate, response rate or temporal discrimination. These results indicate that lactic acid has some direct antidepressant-like activity on the DRL 72-s behavioral screen. This research was supported by NIMH MH-11191; RSA MH-10562 (L. Seiden), and Short Term Training Grant NIH 5 T35GM08140-02 (J. Lim).

22.9

METHIONINE ENHANCES THE ANTIDEPRESSANT EFFECT OF CLENBUTEROL ON THE DIFFERENTIAL-REINFORCEMENT-OF-LOW-RATE 72-SECOND SCHEDULE. R. Dunn* and L. Seiden (SPON: R. McCrea). Dept. Pharm/Phys. Sci., U. of Chicago, Chicago, IL 60637.

Antidepressants increase the reinforcement rate and decrease the response rate of rats performing on a DRL 72-s operant schedule. Drugs from other psychopharmacological classes do not produce this same effect (Seiden et al., Psychopharmacol. 86:55, 1985). Clenbuterol, the lipophilic beta-2 adrenergic agonist produces effects on the DRL 72-s schedule similar to those produced by antidepressants (O'Donnell, J. Pharmacol. Exp. Ther. 241:68, 1987). We have found that agents affecting the one carbon cycle augment the effects of clenbuterol on the DRL 72-s schedule. Thus, methionine, betaine, and guanidoacetic acid (GAA) were found to significantly enhance clenbuterol increases in reinforcement rate and decreases in response rate. Methionine loading will increase the concentration of S-adenosylmethionine (SAM) in rat brain (Baldessarini, Biochem. Pharmacol. 15:741, 1966). Betaine is trimethylglycine, and may also increase brain levels of SAM. GAA, however, is methylated in the liver to form creatine and decreases the availability of methyl groups for the one carbon cycle. Elucidation of the biochemical basis for the enhancement of the antidepressant effect of clenbuterol on the DRL 72-s schedule by agents affecting the one carbon cycle is being pursued. This research was supported by PHS MH-14274 Training Grant; RSA MH-10562 (L. Seiden) and PHS MH-11191.

22.10

CHRONIC ANTI-DEPRESSANT TREATMENT ALTERS ELECTROPHYSIOLOGICALLY RECORDED β-ADRENERGIC BUT NOT 5-HT RESPONSES IN RAT HIPPOCAMPAL SLICES. S.G. Beck and W.P. Clarke, Department of Pharmacology, Mount Sinai School of Medicine of CUNY, New York, NY 10029-6574.

Chronic anti-depressant treatment down regulates β-adrenergic receptors, decreases β-adrenergic stimulation of adenylyl cyclase, and has been reported to increase sensitivity of 5-HT inhibition of neuronal firing in hippocampus. We investigated the effects of chronic anti-depressant treatment on electrophysiologically recorded responses mediated by 5-HT and β-adrenergic receptors in area CA1 of rat hippocampal slices in vitro. Sprague Dawley rats were treated for two weeks with 10 mg/kg imipramine or saline by i.p. injections or osmotic mini-pumps implanted subcutaneously. In contrast with previous reports we found no change in the concentration-response curves for the decrease in the extracellularly recorded population spike amplitude (PSA) mediated by the 5-HT_{1A} receptor or the increase in PSA elicited by the β-adrenergic receptor in control and anti-depressant treated animals. Intracellular recordings revealed no change in the hyperpolarization or reduction in AHP elicted by 5-HT. However, the reduction of the AHP mediated by the β-adrenergic receptor was significantly less, even though the depolarizing response was not altered. These results contrast with the acute and short term effects of imipramine on 5-HT and β-adrenergic responses (Halloran, P. & Beck, S.G., this meeting). These results are consistent with the biochemical evidence of a down-regulation of β-adrenergic receptors after chronic anti-depressant treatment. Supported by MH 41917.

EFFECTS OF ACUTE AND SHORT TERM ADMINISTRATION OF ANTIDEPRESSANTS ON ELECTROPHYSIOLOGICALLY RECORDED 5-HT AND β-ADRENERGIC MEDIATED RESPONSES. P.M. Halloran* and S.G. Beck (SPON: C.J. Molineaux), Department of Pharmacology, Mount Sinai School of Medicine of CUNY, New York, NY 10029.

Imipramine, a tricyclic antidepressant, blocks the reuptake of 5-HT and NE. Imipramine's effect as a neuronal uptake inhibitor is seen immediately whereas its antidepressant action takes several weeks. The acute and short term effects of imipramine on responses elicited by 5-HT and β-adrenergic receptors are being investigated using intracellular recording in rat hippocampal slices (CA1 region) in vitro. Acute administration involves addition of antidepressant into the perfusion medium after pyramidal cell penetration; short term administration involves injection of antidepressant (10 mg/kg) s.c. 24 hours prior to the experiment. Concentration response curves for the 5-HT mediated hyperpolarization were shifted to the left by acute imipramine treatment. Short term administration of imipramine did not alter the hyperpolarization or reduction in after hyperpolarization (ahp) mediated by 5-HT receptors or the depolarization and reduction in ahp mediated by β-adrenergic receptors. The acute and short term effects of imipramine differ from those responses following chronic administration. (See Beck et. al., this meeting). Supported by USPHS grant MH 41917.

ANTIDEPRESSANT SPECIFICITY IN THE REVERSAL OF PERFORMANCE DEFICITS IN INTRACRANIAL SELF-STIMULATION FROM MESOLIMBIC AND MESOCORTICAL SITES IN THE DBA/2J MOUSE STRAIN. Pamela Baillie*, Cindy Wolfe*, Glenda MacNeil*, Marilyn Kasian* and Robert M. Zacharko, Dept. of Psychology, Carleton Univ., Ottawa, Ont., CANADA

Previous work in this laboratory revealed that the performance alterations induced by uncontrollable stressors on intracranial self-stimualtion (ICSS) vary as a function of the strain of animal examined, the chronicity of the stressor employed as well as the brain region under investigation. We also noted that the reversal of ICSS deficits in various strains of mice was dependent on the antidepressant employed. We now report that ICSS deficits following uncontrollable footshock from both mesolimbic and mesocortical sites (i.e., frontal cortex, nucleus accumbens, ventral tegmental area) in the DBA/2J mouse strain are resistant to the effects of desmethylimipramine (DMI). While DMI appeared to be marginally effective, and in some cases detrimental, to the reversal of ICSS deficits in DBA/2J mice, amitriptyline and trazadone rapidly reinstated responding. This profile appeared consistent with both prophylactic or therapeutic administration regimens. The differences in pharmacological specificity afforded by amitriptyline and trazadone over DMI, with respect to 5-HT, presumably underlie such an effect. This interpretation would be consistent with the proposed neurochemical substrate mediating ICSS in the DBA/2J mouse.

22.13

ANTIDEPRESSANT AND OPIATE ANTAGONISTIC EFFECTS OF MIF-1 IN AN ANIMAL MODEL OF DEPRESSION. M.F. Pignatiello*, G.A. Olson, A.J. Kastin, R.H. Ehrensing*, J.H. McLean, and R.D. Olson. Dept. of Psychology, Univ. of New Orleans, New Orleans, LA 70148 and V.A.M.C., New Orleans, LA 70146

Given the relationship of stress and depression to the endogenous opiate system (EOS), MIF-1 was tested in Katz's chronic stress model. In this model, 70-day-old rats received either no stressors or a chronic daily protocol of a variety of stressors, during which time daily injections of MIF-1, naloxone, or control were given. After three weeks, rats were tested in an open field for activity and defecation. Five doses (0.01 to 10.0 mg/kg) of both MIF-1 and naloxone were tested. MIF-1 (0.1 and 1.0 mg/kg) showed significant antidepressant effects. No dose of naloxone was significant. MIF-1 (10.0 mg/kg) and naloxone (1.0 mg/kg) exacerbated the effects of the chronic stress. Tail-flick tests showed less analgesia with increasing doses of both compounds and more analgesia in chronically-stressed rats. In a second study, in which several compounds (MIF-1, Tyr-MIF-1, naloxone, and imipramine) were given after the chronic stress, spontaneous remission resulted for all groups within two weeks. Thus, low doses of MIF-1 showed antidepressant effects. Results also indicated that these effects of stress may be mediated by the endogenous opiate system.

22.14

EFFECTS OF THYMOLEPTIC DRUGS ON SEROTONERGIC FUNCTION IN AFFECTIVE DISORDER PATIENTS. L.H. Price, D.S. Charney, P.L. Delgado,* G.R. Heninger, Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508.

Abnormal serotonergic (5HT) function may be involved in the pathogenesis of affective disorders. Depressed patients show blunted prolactin (PRL) responses to the 5HT precursor i.v. tryptophan (TRP), indicating diminished 5HT function. Long-term treatment with the tricyclic antidepressants (TCAs) desipramine (DMI) and amitriptyline, and short- and long-term treatment with the monoamine oxidase inhibitor (MAOI) tranylcypromine, enhance net PRL responses to i.v. TRP in depressed patients. We used the PRL response to i.v. TRP to assess the effects of short- and long-term treatment with 3 thymoleptic drugs on 5HT function in affective disorder patients. METHOD: A total of 84 patients participated after meeting DSM-III criteria. After ≥3 weeks psychotropic drug-free, patients received TRP 7 grams i.v. infused over 20 minutes. Samples for plasma PRL were obtained at intervals before and after the TRP infusion. The test procedure was repeated after <1 week and after >3 weeks of treatment with lithium (LI) (n=23), DMI (n=25), or the selective 5HT reuptake inhibitor fluvoxamine (FLUV) (n=36). PRL was measured by RIA. RESULTS: TRP significantly increased PRL. The PRL response was significantly enhanced after short-term, but not long-term, LI treatment. DMI enhanced the PRL response after long-term, but not short-term, treatment. FLUV markedly enhanced the PRL response after both short- and long-term treatment. CONCLUSION: These findings are consistent with evidence that enhanced 5HT function may be a necessary, but not sufficient, condition for efficacy for some antidepressants, such as TCA's, MAOI's, and 5HT reuptake inhibitors. Homeostatic responses of the 5HT system to long-term LI treatment may limit that drug's antidepressant efficacy. The mechanism of action of some atypical antidepressants which do not enhance the PRL response to i.v. TRP, such as trazodone and mianserin, remains to be determined.

CHRONIC ADMINISTRATION OF SERTRALINE DESENSITIZES SEROTONIN AUTORECEPTORS. J. Heym and L.S. Reynolds . Central Research Division, Pfizer Inc., Groton, CT 06340.

Sertraline is a member of a new class of antidepressants characterized by potent and selective inhibition of 5HT uptake. We previously demonstrated that sertraline inhibits 5HT neuron firing in the dorsal raphe nucleus (DRN) when administered acutely to anesthetized rats (Neurosci. Abstr. 12, 473, 1986). This effect presumably is due to elevated synaptic levels of 5HT producing negative feedback inhibition of 5HT neurons via somatodendritic autoreceptors. De Montigny et al. (Neuropharmacol. 23, 1511, 1984) have proposed that the latency for antidepressant efficacy of 5HT uptake inhibitors observed in the clinic may reflect 5HT autoreceptor desensitization, a process which permits greater enhancement of 5HT neurotransmission to be achieved over time. The present studies were conducted to see if chronic exposure to sertraline produces an alteration of 5HT autoreceptor sensitivity.

Male Sprague-Dawley rats were implanted with osmotic pumps set to deliver either sertraline (10 mg/kg/day) or vehicle by continuous s.c. infusion for 14 days. On day 14 electrophysiological recording from the DRN was carried out under chloral hydrate anesthesia using conventional extracellular techniques. Despite continued exposure to sertraline, spontaneously active units matching the criteria for 5HT cells were found. When the inhibitory effect of the 5HT autoreceptor agonist 8-OH-DPAT was assessed by i.v. injection, 5HT neurons recorded from sertraline treated animals were 3 - 5 fold less sensitive than those recorded from rats receiving vehicle infusion.

These data suggest that chronic exposure to sertraline does desensitize 5HT autoreceptors thereby attenuating negative feedback inhibition of 5HT neurons. Under such circumstances a maximal enhancement of 5HT function in forebrain can be achieved which may be critical for antidepressant efficacy.

22.16

DOWN-REGULATION OF β-ADRENOCEPTORS IN RAT BRAIN BY SERTRALINE: EFFECTS OF CO-ADMINISTERING SEROTONERGIC AGENTS. B. K. Koe and L. A. Lebel*. Central Research Division, Pfizer Inc., Groton, CT 06340.

Recent studies demonstrated that sertraline, a new antidepressant and selective 5-HT uptake blocker, desensitizes the cyclic AMP generating system of limbic forebrain (Koe et al., 1983, 1987) and down-regulates β-adrenoceptors of cerebral cortex (Byerley et al., 1987; Koe et al., 1987). Moreover, these effects of sertraline appeared to be facilitated by co-administration of the 5-HT agonist quipazine. Our present studies included the co-administration of other serotonergic compounds with sertraline, such as 8-HO-DPAT (5-$HT1_A$ agonist), TFMPP (5-$HT1_B$ agonist), ritanserin (5-HT_2 antagonist), methiothepin (5-HT releaser), racemic norfenfluramine (5-HT releaser) and gepirone (5-$HT1_A$ agonist). Experiments consisted of i.p. injection of test drug plus sertraline to rats, b.i.d., for 4 days and determining K_D and B_{max} of [^{3}H]dihydroalprenolol ([^{3}H]DHA) binding in homogenates of anterior cortex one day after dosing. We found that down-regulation of β-adrenoceptors by sertraline was neither facilitated nor antagonized by co-administered 8-HO-DPAT, TFMPP or ritanserin. On the other hand, methiothepin, norfenfluramine or gepirone, in combination with sertraline (17.8 μmol/kg; non-down-regulating dose), elicited a decrease in receptor density without affecting affinity of [^{3}H]DHA binding. Our findings indicated that other ways of enhancing serotonergic activity can facilitate down-regulation of β-adrenoceptors by sertraline.

22.17

EFFECTS OF IMIPRAMINE ON THE NOCTURNAL BEHAVIOR OF OLFACTORY BULBECTOMIZED (OB) RATS R.J. Radek* and W.J. Giardina Dept. of Pharmacology, Abbott Laboratories, Abbott Park, IL 60064.

After removal of olfactory bulbs, rats show a marked increase in locomotor activity in novel environments. The chronic administration of imipramine and other antidepressants reduces this hyperactivity. The present study assessed the effect of imipramine on OB rat activity in the undisturbed home cage environment. Seven days after surgery, sham operated and OB rats were placed in Omnitech Animal Activity Monitor cages (42x42x30cm) and maintained on a 13 hour light - 11 hour dark cycle. Food and water were provided ad lib. Locomotor activity was recorded hourly for up to 18 days. OB rats were significantly more active during the dark phase than sham operated rats. The dark phase hyperactivity persisted throughout the observation period. Both sham and OB rats were inactive during the light phase. After 7 to 10 daily injections of imipramine at 10.0 or 15.0 mg/kg, i.p., activity of OB rats was significantly reduced during the dark phase. This reduction persisted until imipramine was withdrawn. Imipramine (10.0 mg/kg, i.p.) had no effect on the activity of sham rats. The delayed effect of imipramine in OB rats mimics its delayed antidepressive effect in man. This experimental approach may be useful in evaluating the onset of action of antidepressants.

22.18

DOWN-REGULATION OF BETA-ADRENERGIC AND SEROTONINERGIC RECEPTORS IN OLFACTORY BULBECTOMIZED RATS FOLLOWING SUB-CHRONIC IMIPRAMINE ADMINISTRATION. A.A. Hancock, R.J. Radek*, W.J. Giardina, and J.F. Debernardis*. Department of Pharmacology, Abbott Laboratories, Abbott Park, IL 60064.

Chronic treatment of normal rats using various antidepressants has been shown to reduce the concentration of both beta-adrenergic (B) and serotoninergic ($5HT_2$) receptors. We have evaluated B and $5HT_2$ receptors in sham operated and olfactory bulbectomized (OB) rats using 10 concentrations each of either ^{125}I-Cyanopindolol or ^{3}H-Ketanserin. After 10 days administration of imipramine (10 mg/kg, i.p.) both sham operated and OB rats possessed 10 and 15% fewer B receptors, respectively, while $5HT_2$ receptors were decreased 25 and 20%, respectively. No changes were observed in the affinity of the radioligands for their receptors. R. J. Radek and W. J. Giardina reported (see "Effects of Imipramine on the Nocturnal Behavior of OB rats", this proceedings) that 7-10 daily injections of imipramine (10 mg/kg, i.p.) reversed the hyperactivity of OB rats in the home cage environment. Together, these two studies suggest that it may be possible to relate changes in receptor concentrations with the onset of behavioral changes in the OB rat after antidepressant treatment.

23.1

COMPARISON OF NMDA ANTAGONISTS ON LOCAL CORTICAL BLOOD FLOW IN THE RAT. M.E. Mann, P.A. Boxer and F.W. Marcoux. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The dissociative anesthetic ketamine has been shown to increase cerebral glucose utilization and blood flow unlike most other centrally acting anesthetics which are metabolic depressants. We compared the effects of ketamine and MK-801 on local cortical blood flow (LCBF) in Sprague-Dawley rats (350-450 g). Rats were instrumented with a chronically implanted platinum-iridium electrode (125μ diameter) in the anteroparietal cortex. LCBF was measured by H_2 clearance in unanesthetized, freely moving rats housed in plexiglass chambers. Ketamine (IP) at the subanesthetic 25 mg/kg dose produced LCBF increases which were of short duration (<90 min). The increase in LCBF was less with the 62.5 mg/kg dose and the anesthetic 150 mg/kg dose. MK-801 (IP) produced LCBF increases of long duration (>2 hrs) which were equivalent at 0.2, 0.66 and 2.0 mg/kg doses; gross behavioral disruption, but not anesthesia, was noted at these doses. Ketamine at 4.2 mg/kg and MK-801 at 0.02 mg/kg had little or no effect on LCBF. Both of these noncompetitive NMDA antagonists increased LCBF, but with different profiles of activity, which may be related to their different anesthetic properties.

23.2

CHOLINERGIC MODULATION OF FRONTAL CORTICAL BLOOD FLOW IN RATS. J.J. Kinsora*, C. Bay-Gemmill* and R.E. Davis (SPON: J.P. Symons). Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

Cholinergic agents have been shown to increase local cortical blood flow (LCBF). It is not known, however, if cholinergic-induced changes in LCBF are mediated by central or peripheral cholinergic action. In addition, the brain areas mediating central cholinergic alterations in LCBF also are not known. However, because basal forebrain neurons provide a major source of cholinergic afferents to the cortex, this area is likely to contribute to cholinergically-driven changes in LCBF. The purpose of this experiment was to determine the effects of centrally and peripherally acting cholinergic agents on LCBF and to determine the role of basal forebrain cholinergic neurons on LCBF under basal and cholinergically- driven conditions.

LCBF was measured indirectly using the H2 clearance technique from bilaterally or unilaterally implanted platinum-iridium electrodes placed in the frontal cortex of male, Long-Evans rats. At least 4 weeks prior to measurement of LCBF some rats were infused unilaterally with the excitotoxin ibotenic acid (1.0ug in 1.0ul) or an equivalent volume of vehicle (0.9% saline, sham operated) through cannulae directed at basal forebrain cholinergic neurons (BF). Two 15 minute baseline LCBF measurements were taken prior to administration of a variety of cholinergic agents. Following administration of these agents LCBF was measured every 15 minutes for the next 1 to 2 hrs.

Cholinomimetics induced increases in LCBF which were blocked by scopolamine but not by methylscopolamine. This suggests that these agents act centrally to increase LCBF. Baseline LCBF was not altered by BF lesions. In sham operated rats, cholinomimetics induced bilaterally symmetrical increases in LCBF in the frontal cortex. Similar increases in LCBF were induced by these agents on the side contralateral to the BF lesion in unilaterally lesioned animals. In contrast, there was a dose dependent decrease in the ability of cholinesterase inhibitors but not direct agonists to increase LCBF on the side ipsilateral to the BF lesion.

23.3

EFFECTS OF YOHIMBINE ON REGIONAL CEREBRAL BLOOD FLOW IN PATIENTS WITH PANIC DISORDERS. SW Woods, K Koster*, JH Krystal, EO Smith*, IG Zubal*, PB Hoffer*, DS Charney. Clinical Neuroscience Research Unit, Yale University School of Medicine, New Haven, CT 06508

Previous studies have demonstrated increased behavioral, cardiovascular, and biochemical responses in patients with panic disorder (PD) to the alpha-2 adrenergic antagonist yohimbine (YOH). In order to examine possible alterations in regional blood flow (rCBF) induced by YOH in PD, 4 drug-free patients (PTS) with PD (mean ± SD = 26 ± 2 yrs) and 4 healthy subjects (HS) (24 ± 2 yrs) in an ongoing study each gave informed consent and received intravenous YOH 0.4 mg/kg and saline placebo (PLA) over 10 minutes in random sequence on separate days, followed immediately by injection of the rCBF radiopharmaceutical Tc-99m d,l- hexamethylpropyleneamine oxime (20 mCi). Injections were performed with eyes closed in a dimly lit, quiet room. One hour later subjects underwent single photon emission computed tomography scanning. Using a neuro-dedicated multicrystal camera, ten transaxial images spaced 10 mm apart and starting from and parallel to the orbitocanthal-meatal line were obtained per study. Seven bilateral regions of interest (ROI), (frontal,parietal, temporal, and visual cortices, striatum, thalamus and cerebellum) were identified independently by two investigators, blinded to drug or placebo, using CT scans and a brain atlas of identical cerebral levels. Reported values are the mean of the two determinations. Ratios of ROI/cerebellum and asymmetry indices were calculated on the average counts per pixel. Greater increases in self-rating scales of anxiety occurred after YOH than after PLA in all PTS and one HS. Decreases in frontal cortex to cerebellar bloodflow ratios were observed in all PTS on the YOH day relative to PLA (10.8 ± 9.7 and 11.2 ± 7.7 % on left and right, respectively. In contrast, frontal rCBF on YOH and PLA days was similar in the HS. YOH-induced shifts in thalamic blood flow symmetry were also observed consistently in the PTS but not in the HS. No robust changes were identified in other cortical areas or striatum in either group. These preliminary data may suggest roles for altered noradrenergic regulation of frontal cortical and thalamic function or perfusion in the pathophysiology of PD.

23.4

EFFECT OF HYPOCAPNIA ON REGIONAL CEREBRAL GLUCOSE UTILIZATION. Satwant K. Samra, M.D.*, Patricia Turk*. (SPON: W.D. Willis, Jr., M.D., Ph.D.). Department of Anesthesiology, University of Texas Medical Branch at Galveston, Texas 77550-2778.

Deliberate hypocapnia is a common clinical practice in the management of patients with raised intercranial pressure. While effect of hypocapnia on cerebral blood flow has been well studied, only two recent studies have looked at effect of blood carbon dioxide tension ($PaCO_2$) on regional cerebral glucose utilization (rCMRg). Both looked at the effect of *hypercapnia* only and reported a significant decrease in rCMRg with *hypercapnia*. This study reports the effect of *hypocapnia* on rCMRg. Institutional approval of the protocol was obtained and guidelines of NIH for the care and use of laboratory animals were followed. Fourteen Sprague-Dawley male rats were randomly assigned to either normocapnia (n=7, $PaCO_2$=40±2mm) or hypocapnia (n=7, $PaCO_2$=25±2mm) group. Rats were anesthetized with N_2O and oxygen and mechanically ventilated to achieve desired $PaCO_2$. rCMRg was measured by the [^{14}C] deoxyglucose method described by Sokoloff et al. rCMRg in 26 brain structures was studied. Values of rCMRg in normocapnic group were comparable to those previously reported by Sokoloff in awake rats. Hypocapnic group showed slightly higher values in all structures studied but in none of the structures was the difference statistically significant.

23.5

DEVELOPMENT OF EARLY COLLATERAL BLOOD FLOW TO CEREBRUM IS COMPROMISED IN CHRONIC HYPERTENSION. P. Coyle. Dept. of Anatomy and Cell Biology, The University of Michigan, Ann Arbor, MI 48109.

The objective of this study was to measure collateral blood flow to cerebrum by laser Doppler flowmetry during 20-30 seconds (sec) of ipsilateral common carotid artery occlusion in stroke-prone spontaneously hypertensive rats (SHRSP) and normotensive Wistar rats (NW). Blood pressure (BP) was measured bilaterally in the external carotid artery. Blood flow (ml/minx100gm) and BP (mm Hg) results:

Strain	n	Before (control)		During (15sec)		After (15sec)	
		flow	BP	flow	BP	flow	BP
SHRSP	11	111±5	180±9	57±4*	90±9*	120±5	176±10
NW	10	118±3	122±4	98±12	53±5*	129±4	123±5

BP and blood flow ipsilateral to the occlusion fell to minimal levels within seconds of the occlusion. Blood flow escaped to control levels by 15 sec of occlusion in NW, but in SHRSP blood flow failed to escape ($*p < 0.05$). Treatment with eserine prior to occlusion produced escape in SHRSP and accelerated escape in NW. Atropine blocked the escape in NW and was without significant effect in SHRSP. After chronic occlusion the anastomosing collaterals were enlarged. Thus after common carotid artery occlusion in chronic hypertension, blood flow through collateral vessels to cerebrum is impaired but there is sensitivity to a cholinergic vasodilatory mechanism.

23.6

USE OF [6-^{3}H]DEOXYGLUCOSE IN THE MEASUREMENT OF LOCAL CEREBRAL METABOLIC RATE FOR GLUCOSE . H. Nakanishi*, B. Agranoff, C.Kennedy, C.B. Smith and L.Sokoloff. LCM, NIMH, Bethesda, MD & NSL, MHRI, U. of Mich., Ann Arbor, MI

The autoradiographic deoxyglucose (DG) method for the determination of LCMRglu usually employs [^{14}C]DG as the radiolabeled tracer. [^{18}F]Fluorodeoxyglucose and [^{3}H]DG have also been used, particularly in conjunction with [^{14}C]DG in a sequential double label experimental design in which an experimental animal may serve as its own control. For quantification it is essential that the 2 isotopic forms of DG are metabolized identically. In the present studies, mixtures of [1-^{14}C]DG and [1,2-^{3}H]DG were injected IV into rats, and the time course of the plasma [^{3}H]/[^{14}C] ratio was determined. The ratio increased with time, reaching 112% of the zero time value by 60 min. If samples were dried before counting, the ratio at 60 min approached the zero time level. A possible explanation is that there is an exchange of ^{3}H from the C2 position of DG with water and that clearance of [^{3}H]water from plasma is slower than that of DG. To circumvent this problem, similar experiments were carried out in which [6-^{3}H]DG (custom-synthesized by ARC, St. Louis, MO.) and [1-^{14}C]DG were simultaneously injected. The plasma ^{3}H/^{14}C ratio remained constant throughout the 60 min time course. These results show that in sequential double label experiments the use of [6-^{3}H]DG is preferable to any DG with ^{3}H in the C2 position.

23.7

DIRECT ESTIMATION OF REGIONAL LUMPED CONSTANT BY DYNAMIC POSITRON TOMOGRAPHY WITH LABELED FLUORODEOXYGLUCOSE IN HUMANS. *A. Gjedde,* H. Kuwabara**. (SPON: *G.W.Dauth*) McConnell Brain Imaging Unit, Montreal Neurological Institute, McGill University, Montreal, Canada H3A 2B4

The lumped constant (Λ), ratio between net brain uptake of positron-labeled fluorodeoxyglucose (FDG) and glucose, must be known to calculate the glucose utilization by the FDG method. Assuming symmetrical transport across the blood-brain barrier and constant ratios for transport (τ) and phosphorylation (π) of FDG and glucose, $\Lambda = \tau\rho + \pi(1-\rho)$ where ρ is the ratio of net to unidirectional uptake of FDG (K/K_1). Michaelis-Menten kinetics indicated that the ratio between transport rates in the two directions across the BBB (K_1/k_2) must be the same for FDG and glucose. Thus, $k_2 + k_3 = (K_1 + [K\tau\gamma/\Lambda])/[(1-\rho)V_d]$ where γ is the ratio between the plasma glucose concentration and Michaelis constant, and V_d the brain water content. The relationship allowed us to reduce the number of the parameters in the operational equation from 4 to 3, i.e. K, K_1, and plasma volume V_p. In seven healthy elderly males (age 63 ± 6), cortical regions were analyzed assuming $\tau = 1.1, \pi = 0.25, K_t = 4.8$ (mM), and $V_d = 0.77$ (ml/g). Despite the constraint, the fit was as good as that of four parameters. Λ averaged 0.55 ± 0.04 and varied from 0.49 to 0.60 between subjects. The transfer coefficients averaged: K_1 0.09±0.02 (ml/g/min), k_2 0.21±0.04 (min^{-1}), k_3 0.12±0.04 (min^{-1}). V_e, which often exceeded the physiological limit (0.77) in the four-parameter fits, was 0.44±0.03 and strikingly uniform.

23.8

BRAIN SLICE 2-DEOXYGLUCOSE (2DG) METABOLISM. G. Newman, F. Hospod, C. Patlak. Depts. of Neurology and Neurological Surgery, SUNY, Stony Brook, NY 11794.

Our kinetic analysis of brain slice 2DG metabolism differs from prior *in vivo* studies insofar as we incubate at constant glucose and 2DG, measure 2DG and 2DG6P separately rather than total radioactivity, and obtain 8 to 10 slices (and time points) per animal. Hypothalamic or hippocampal brain slices are pre-incubated in K-R, and then either exposed to 0.3 μCi of ^{14}C-2DG for 3 to 90 min followed by a very brief rinse for uptake experiments or exposed to radioactive tracer for 60 min followed by 0.5 to 300 min rinses for washout experiments. Frozen slices are extracted with perchloric acid and the 2DG and 2DG6P separated on anion exchange resin before scintillation counting. The four resulting data curves (2DG and 2DG6P, uptake and washout) are then analyzed by simultaneous non-linear least squares analysis using the solutions of differential equations for kinetic models based upon particular biochemical hypotheses of the fate of the 2DG tracer.

Our results reveal a previously unidentified kinetic compartment. Entry into the compartment follows phosphorylation of 2DG to 2DG6P with a rate constant similar to that usually ascribed to the phosphatase reaction in prior *in vivo* 2DG studies. However, efflux from this compartment is sufficiently slow that the radioactivity is effectively trapped in the tissue. The chemical form of the trapped material is unknown at present but appears in our assays as 2DG following acid extraction of the tissue. De-phosphorylation with rapid efflux from the tissue appears negligible and so that the model can be reduced to a 5 parameter model which closely fits all of the data for 1000μ hypothalamic or hippocampal slices and 540μ hypothalamic slices. An alternative five parameter model based upon sequential organellar transport of 2DG6P and de-phosphorylation with rapid efflux of 2DG fits the data poorly.

23.9

PHOTIC STIMULATION CAUSES ENHANCED GLYCOLYSIS IN THE SUPERIOR COLLICULUS. W.P. Pulsinelli, R.P. Kraig. Cornell Univeristy Medical College, New York, N.Y. 10021

Recent studies (Fox and Raichle PNAS, 1986; Collins et al., J. Neurochem., 1987) question the classic teaching that the energy needs of physiologic cerebral activity are met largely by oxidative-phosphorylation. We addressed this question by comparing lactate (Lac) production in the superior colliculi (S.C.) of rats subjected to unilateral photic stimulation. The left eye of halothane anesthetized, mechanically ventilated adult rats was stimulated photically at 20 Hz while the right eye was patched. These conditions caused a significant increase of glucose metabolism in the right superior colliculus. The brains of these animals (n= 10) were frozen in situ and lactate, ATP and phosphocreatine (PCr) levels were measured in 5 sets of pooled tissue dissected from the superior gray zone of the left and right superior colliculi.

	Left S.C.	Right S.C.	Paired t-test
Lac	1.98±0.24	2.71±0.29	p = 0.0006
ATP	2.13±0.12	1.95±0.28	p = 0.2096
PCr	5.04±0.15	4.59±0.61	p = 0.5239

The results demonstrate significantly higher levels of lactate in the stimulated superior colliculus, but no change in ATP or PCr levels. We conclude that increased energy demands in the superior colliculus associated with physiologic stimuli are at least partially met by enhanced glycolysis not coupled to oxidative phosphorylation.

23.10

CEREBRAL MATURATION OF OXIDATIVE METABOLISM IN THE CAT. *D. A. Hovda, H. T. Chugani*, B. Badie*, M. E. Phelps, and J. R. Villablanca, Depts. of Psychiat., Anat., Neurol., and Div. of Nuc. Med. and Biophys., UCLA Sch. Med., Los Angeles, CA 90024*

Optical density readings were obtained from cat brain tissue processed for cytochrome oxidase histochemistry at postnatal days 7, 30, 45, 60, 90, 120, 180 and adulthood. The results indicated: (1) most structures reached adult values by 30d with some motor structures (i.e., cerebellum, s. nigra, VPL thalamus, and red n.) exhibiting adult values by 7d; (2) thereafter, a number of structures exceeded adult values as follows: e.g., motor cortex and basal ganglia (by 24% peaking at about 90d); red n. (by 48% at about 30d); s. colliculus (by 37% at about 60d); visual cortex and lateral geniculate n. (by 8% peaking at 45-90d); (3) some structures did not show a substantial increase over adult rates (e.g., limbic system areas, dentate n., s. nigra). These results indicate an earlier maturation of cerebral oxidative metabolism than we previously described for glucose utilization (Soc. Neurosci. Abst., 13:1139, 1987). However, like for glucose utilization, some structures exceed adult values of oxidative metabolism during development. (NIH, PO1 NS 15654-09S1, HD 05 958.)

POSITRON EMISSION TOMOGRAPHY MEASUREMENT OF HUMAN REGIONAL CEREBRAL GLUCOSE UTILIZATION FOLLOWING 48 HOURS OF SLEEP DEPRIVATION. M. Thomas*, H. Sing*, G. Belenky, D. Thorne*, T. Balkin*, D. Penetar*, D. Redmond*, J. Norcross*, & P. Newhouse. Department of Behavioral Biology, Walter Reed Army Institute of Research, Washington, DC 20307-5100; H. Mayberg, H. Holcomb, B. Sadzot*, R. Dannals*, J. Links*, & H. Wagner*. Divisions of Nuclear Medicine and Radiation Health Sciences, The Johns Hopkins Medical Institutions, Baltimore, MD 21205

We measured regional cerebral glucose utilization using Fluorine-18 2-deoxyglucose (FDG) and positron emission tomography (PET) in six right-handed normal male subjects (Ss), ages 21-29, in two conditions: 1) after 48 hours during which the Ss were totally deprived of sleep; and 2) after 48 hours during which the Ss were permitted 7 hours of sleep each night. Magnetic resonance imaging (MRI) scans were obtained on all Ss and used to register the PET images. Ss served as their own controls, and were scanned twice, in counterbalanced fashion, once while sleep deprived and once while rested. During the injection and uptake of the FDG, Ss performed a continuous performance task and were instrumented for polysomnographic evaluation (EEG, EMG, and EOG) of level of alertness. We are currently analyzing the data with regard to between condition differences in: 1) regional cerebral glucose utilization; 2) performance on the continuous performance task; and 3) polysomnographically defined level of alertness.

23.12

SENSORY-MOTOR ACTIVATION OF BRAIN AREAS IN NORMALS AND SCHIZOPHRENICS AS MEASURED BY PET. J. D. Brodie*, E. Bartlett*, F. Barouche*, S.L. Dewey, A. P. Wolf*, (P. Brink, Spon), NYU Medical Center, New York, NY 10016; Brookhaven National Laboratory, Upton, NY 11973

Brain areas activated by specific sensory-motor functions were identified in normal and schizophrenic subjects using positron emission tomography and ^{11}C-2-deoxyglucose to measure changes in cerebral glucose metabolism. In normals, the SIMPLE finger-tapping produced significant ($p<0.01$) increases from BASELINE metabolism in the contralateral sensory-motor hand area left and right basal ganglia and thalamus. COMPLEX finger movement produced significant increases in the supplementary motor area as well as contralateral sensory-motor hand area, left and right basal ganglia and thalamus. The schizophrenics showed a normal pattern of cortical activation during simple finger-tapping, but showed higher than normal metabolism in thalamus. During the complex finger movement, the schizophrenics failed to show activation in the supplementary motor area. These results are consistent with known patterns of metabolic dysfunction in schizophrenia (i.e., hypofrontality; increased subcortical metabolism) and demonstrate the potential effectiveness of these sensory-motor tasks in eliciting metabolic patterns that may prove to be pathognomic for the disease. ENERGY METABOLISM, HEMOGLOBIN SATURATION, AND CYTOCHROME c OXIDASE REDOX RESPONSES IN THE BRAIN OF NICOTINE TREATED RATS. Avis L. Sylvia. Dept. of Physiology, Duke University Medical Center, Durham, N.C. 27710

Anesthetized rats were subjected to acute iv injection or constant infusion of nicotine (dose range 2-1000μg/kg). Differential wavelength visible spectrophotometry was used to measure changes in cytochrome oxidase (CYT a,a3) redox state, hemoglobin saturation (HbO2/Hb), and blood volume in the parietal cortex of skull intact animals. EEG activity and systemic arterial pressure were concurrently monitored. In vitro measurements of changes in cortical metabolites (glucose, pyruvate, lactate, PCr, ATP, ADP) were made in brain samples from normoxic (30%O2/70%N2)rats subjected to constant iv nicotine infusion. Doses of nicotine were tested in normoxic, hyperoxic (100%O2), and hypoxic (12%O2/balance N2) rats. Findings from these studies include: 1) Nicotine does not significantly alter cerebrocortical bioenergetics as evaluated by direct metabolite measurements; 2) Low doses of nicotine cause increased CYT a,a3 oxidation and Hb oxygenation while high doses produce increased CYT a,a3 reduction, Hb deoxygenation, and elevated blood volume; 3) These responses to nicotine are independent of increases in arterial pressure and are O2-dependent in vivo; 4) Constant iv nicotine infusion appears to cause down regulation of CNS nicotinic receptors resulting in inhibition of both the cytochrome redox and microvascular responses. (Supported by STRC Grant-0096).

CROSSED CEREBELLAR AND UNCROSSED BASAL GANGLIA DIASCHISIS IN ALZHEIMER'S DISEASE BY POSITRON EMISSION TOMOGRAPHY. P.L. McGeer, H. Akiyama*, R. Harrop*, E.G. McGeer, R. Peppard* and the UBC-TRIUMF PET Team. Kinsmen Lab, Dept Psychiatry, Univ of British Columbia, Vancouver, Canada, V6T 1W5

We analyzed PET-fluorodeoxyglucose scans for diaschisis on a series of 26 consecutive demented patients meeting the clinical and radiological criteria of Alzheimer's disease (SD) and 10 age-matched controls. The local cerebral metabolic rates for glucose (LCMR) were calculated for corresponding left and right areas in numerous regions of interest (ROI) in the cerebral cortex, as well as the basal ganglia, thalamus and cerebellum. An asymmetry index (AI) was calculated for each ROI: AI = $[LCMR_L-LCMR_R]/[LCMR_L+LCMR_R]$. The correlation between the AI for each cortical area and the AI for each subcortical area was calculated by linear regression analysis. In SD significant negative correlations ($p<0.0005$ in each case), suggesting crossed diaschisis, were found between AIs for the frontal, parietal, angular and temporal cortices and AIs for cerebellar hemispheres. A significant positive correlation ($p<0.001$), suggesting uncrossed diaschisis, was found between AIs in the frontal cortex and AIs in the basal ganglia. Autopsy examination established SD in 5 of the cases and demonstrated that the depressed LCMR in the basal ganglia and cerebellum was not due to primary degeneration, but was a genuine result of diaschisis. (Supported by grants from the MRC of Canada and the Alzheimer Society of B.C.)

23.15

EFFECT OF DEγE (ORG 5878) ON REGIONAL CEREBRAL GLUCOSE UTILIZATION IN FREELY MOVING RATS. P. Room*, J.A.D.M. Tonnaer and Th. de Boer*. Dept. CNS Pharmacology, Organon International B.V., Oss, The Netherlands.

The effect of the potential antipsychotic non-opioid β-endorphin (βE) fragment desenkephalin-γ-endorphin (DEγE, βE_{6-17}) has been studied on local cerebral glucose utilization (LCGU). Two modifications were introduced to the classical ^{14}C-Deoxyglucose technique as described by Sokoloff (J. Neurochem. 28:897,1977). First, the animals were cannulated one week prior to the experiment to allow blood sampling and/or drug administration under unrestrained conditions. The second modification involved the image analysis program and included superposition of autoradiogram and identical histologically-stained section in order to improve the neuroanatomical resolution. Male Wistar rats acutely received either DEγE (20 μg/kg, i.v.) or saline and LCGU was measured in about 150 brain structures. The majority of brain areas were unaffected by DEγE, including areas of the cortex, the thalamus and the nigro-striatal system. However, significant reductions were observed in the medial septum and diagonal band complex, the hippocampal formation, the ventral tegmental area (VTA) and in the cerebellum. These data indicate that, whereas the nigrostriatal, serotonergic and cortical/thalamic systems remained unaffected by the dose of DEγE used, parts of the cholinergic and mesolimbic dopaminergic systems showed reduced glucose utilization, indicating that DEγE's action on LCGU is distinct from those of antipsychotics currently used in the clinic.

BIOLOGICAL RHYTHMS: NEUROANATOMICAL ASPECTS

CROSS-SPECIES TRANSPLANTATION OF FETAL HYPOTHALAMIC TISSUE RESTORES CIRCADIAN LOCOMOTOR RHYTHM TO SCN-LESIONED HOSTS. P.J. Sollars and D.P. Kimble, Institute of Neuroscience, University of Oregon, Eugene, OR 97405

It has long been recognized that complete lesions of the hypothalamic suprachiasmatic nucleus (SCN) abolish the circadian locomotor rhythm in hamsters, and it has recently been reported by several laboratories that homografts of fetal hypothalamic tissue into SCN-lesioned hosts restore the circadian rhythm of locomotor activity. We have attempted a cross-species transplantation of whole tissue grafts using fetal mouse (Mus musculus) hypothalamus as donor tissue and SCN-lesioned hamsters (Mesocricetus auratus) as hosts, in order to examine the possibility that the resultant rhythm manifests a species-specific characteristic (i.e., period length) determined either by the donor or by the host species.

While these are on-going experiments, we report herein the results of two completed preliminary trials. The heterograft tissue has survived in the third ventricle of the host brain for up to two months. A circadian rhythm of locomotor activity has developed between five and thirty days after the implantation surgery. In all cases to date, the resultant rhythm has had a period shorter than 24 hrs. This period is similar to that expressed by the intact mouse and by homograft transplants of dispersed cell suspensions, and is distinct from the period expressed by intact hamsters and by hamster whole tissue homografts. Supported by the Medical Research Foundation of Oregon.

24.2

IS THE FETAL SCN SUFFICIENT TO INDUCE RHYTHM RECOVERY WHEN TRANSPLANTED TO SCN-LESIONED HAMSTERS? R.A.Aguilar-Roblero*, L.P. Morin and R.Y.Moore. (SPON: R. Salceda). Depto. de Neurociencias, IFC, UNAM, México and Depts. of Neurology and Neurobiology, HSC SUNY at Stony Brook, USA.

Transplantation of fetal suprachiasmatic nuclei (SCN)induce restoration of circadian rhythms in previously arrhythmic SCN-lesioned hamsters. The present study attempted to obtain additional information regarding the mechanisms involved in restoration of rhythmicity. Fifteen male golden hamsters (90-110 gr) which sustained electrolytical lesion aimed to the SCN showed loss of the wheel running circadian rhythm (CR). Fetal anterior hypothalamic tissue (E-15) was transplanted to the third ventricle of 9 of the SCN-lesioned animals, the remaining 6 were used as long term lesion controls.

Restoration of CR after transplantation of hypothalamic tissue was found in 6 animals, in these cases the SCN within the graft was identified by immunohystochemistry. The grafted tissue was found either in the third or the lateral ventricles. Three animals did not recovered CR in spite that 2 of these showed clear development of the SCN in the graft. In these 3 cases the graft was found in the third ventricle. No spontaneous recovery of rhythmicity was found in SCN-lesion animals.

The present results indicate that recovery of rhythmicity does not depends only of the presence of the SCN in the graft nor the placement of the graft in the third ventricle. (Supported by NIH grant NS-16304 to RYM).

24.3

TIME COURSE OF PEPTIDERGIC EXPRESSION IN SUPRACHIASMATIC NUCLEUS TRANSPLANTED INTO 3rd VENTRICLE AND IN AGE-MATCHED INTACT HAMSTERS. M.-T. Romero and R. Silver. Psychology Department, Barnard College of Columbia University, New York, NY 10027.

Fetal tissue containing the SCN implanted into the 3rd ventricle of hamsters made arrhythmic by SCN lesions restore free-running rhythms of locomotor activity (Lehman, M.N., et al., J. Neurosci.. 7:1626, 1987). The grafted tissue of recovered animals express neuropeptides characteristic of the normal SCN. Behavioral recovery usually occurs 2 to 6 weeks post-implantation.

We used immunocytochemistry to determine the time course of peptidergic expression in the SCN grafted into the 3rd ventricle of adult hosts compared to the SCN in situ. VIP, VP and NPY immunoreactivity was examined at regular intervals post-implantation and in same age neonatal SCN. Preliminary results indicate that the grafted SCN expresses some neuropeptides within 2 to 3 weeks after implantation, which is within the time frame of behavioral recovery. (Supported by NIH grant NS24292 to RS.)

NEUROGENESIS OF THE SYRIAN HAMSTER SUPRACHIASMATIC NUCLEUS. F.C. Davis, R. Boada* and J. LeDeaux*. Dept. of Biology, Northeastern Univ., Boston, MA 02115 and Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22901.

The relationship between the initiation of circadian pacemaker function and the development of the suprachiasmatic nucleus (SCN) is not understood. In the hamster, entrainment of a circadian pacemaker appears to occur on or before day 14 of gestation. Crossland and Uchwat (Develop. Brain Res. 5:99, 1982) reported that SCN neurogenesis occurs only 1-3 days earlier. The present study was done to confirm and extend this finding. Pregnant hamsters (Mesocricetus auratus) were given single injections of 3H-thymidine at 7 times from 10.5 to 13.5 days postfertilization. Brains of 33 pups were processed for autoradiography. Labelled cells were mapped by superimposing a 9x10 grid on the SCN. Greatest labelling occured on days 11, 11.5 and 12. Maps of labelled cells indicated that the ventrolateral SCN was formed before the dorsomedial SCN. This gradient suggests that functionally distinct cell populations are produced at different times (e.g. VIP vs VP cells) and that the fetal cell population selected for transplantation or for culture might be biased by the precise time when tissue is obtained. The results indicate that either the SCN need not be formed for entrainment to occur or that entrainment can occur within only two days after SCN neurogenesis. Supported by NIH grant HD18686 to FCD.

DEVELOPMENT OF THE RETINOHYPOTHALAMIC TRACT IN THE RAT. Joan C. Speh and Robert Y. Moore. Depts. of Neurology and Neurobiology, State University of New York, Stony Brook, NY 11794-8121,

The retinohypothalamic tract (RHT) is a visual pathway from the retina to the suprachiasmatic nucleus (SCN) of the hypothalamus which participates in the entrainment of circadian rhythms. Recent studies using cholera toxin conjugated to HRP (CT-HRP) indicate that the rat RHT has three components: 1.a dense projection to the ventrolateral SCN with some extension into the dorsomedial portion of the nucleus, 2.a projection to the anterior hypothalamic area (AHA) and retrochiasmatic area (RCA) and 3.a projection to the lateral hypothalamic area (LH). In this study we examined the development of the RHT projections using the CT-HRP method. All components of the projection achieve an adult pattern by P15. The LH projection is the first to develop. It is present on E21 and increases strikingly between P1 and P6. At this point the projection is more dense and more extensive than in the adult and the projection is gradually reduced to the adult pattern between P6-P15. The projection to the SCN first appears as scattered varicosities ventrally at P1. These gradually increase in number until P4 and thereafter the projection develops rapidly until the adult pattern appears at approximately P10. As with the LH innervation, the projection to the SCN is initially more extensive than in the adult and is restricted between P6-P10. The projection to the AHA and RCA first appears at P2-P3 and gradually becomes more extensive to approximate the adult pattern by P15.

Thus, the development of the RHT is complex with components appearing at different times with different patterns of development that indicate specialized interactions of the developing axons with the neurons to be innervated. Supported by NIH grant NS-16304.

FLUORESCENT LATEX MICROSPHERES INJECTED INTO THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS (PVN) LABEL GANGLION CELLS IN THE GOLDEN HAMSTER RETINA. G.E. Pickard. Dept. of Anatomy, Health Sciences Center, West Virginia University, Morgantown, WV 26506.

A direct retinal projection to the hypothalamic suprachiasmatic nucleus (SCN) is well established. In addition, several laboratories have described retinal fibers in the periventricular zone dorsal to the SCN. HRP injections into this region dorsal to the SCN label hamster retinal ganglion cells (Pickard, G.E., J. Comp. Neurol., 211:65, 1982). Recently, retinal fibers have been described in the hamster which course through the SCN and continue to the caudal PVN (Youngstrom et al., Brain Res. Bull., 19:747, 1987). In the present study, fluorescent microspheres (0.25 ul) were unilaterally injected into the PVN of male golden hamsters. After 24 -48 hr, animals were perfused with physiological saline followed by 10% buffered formalin, retinae were prepared as whole mounts, and brains were sectioned at 50 um with a cryostat. A small number of labeled ganglion cells were observed in the ipsilateral and contralateral retinae. To assess whether labeling was a result of microspheres diffusing into the retinal terminal field of the SCN, another cell group afferent to the SCN, the intergeniculate leaflet (IGL), was examined for labeled neurons; no labeled cells were noted in the IGL.

Supported by NIH grant NS 21165.

RETINAL AND NEUROPEPTIDE Y INNERVATION OF THE HAMSTER SUPRACHIASMATIC NUCLEUS: LIGHT AND ELECTRON MICROSCOPIC OBSERVATIONS. L.M. Wyatt, R.B. Norgren, Jr.* and M.N. Lehman. Dept. of Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH 45267.

Photic information which entrains the suprachiasmatic nucleus (SCN) reaches it directly via the retinohypothalamic tract (RHT), and indirectly from the intergeniculate leaflet (neuropeptide Y [NPY] fibers). We have used double label immunocytochemistry at both a light and EM level to examine the distribution of hamster retinal and NPY input, particularly with respect to vasoactive intestinal polypeptide (VIP) cells of the SCN. Adult male hamsters received intraocular injections (10 ul) of 0.1% unconjugated cholera toxin (CT), subunit (List Biological). After 1 day survival, hamsters were perfused with 4% paraformaldehyde; for light microscopy, a combined immunoperoxidase/immunofluorescence procedure was used to visualize VIP cells and either CT- or NPY-labelled fibers; a double label EM technique recently developed in our lab was used to analyze NPY input to VIP cells. At a light microscopic level, the densest concentration of NPY fibers in the hamster SCN closely overlaps the location of VIP cells in the ventral SCN. In contrast, heavy accumulations of CT-labelled retinal varicosities extend over a much wider extent of the SCN, particularly in a rostral and dorsolateral direction. EM analysis of the ventral SCN revealed NPY axon terminals in direct axosomatic contact with both VIP and non-identified cells. Several adjacent NPY axon terminals were sometimes seen synapsing upon a single non-immunoreactive dendrite. We are currently examining the synaptic arrangements of retinal afferents with VIP cells and non-identified neurons, and comparing them to those of NPY inputs. [Supported by NIH NS24642 to M.N.L.]

24.8

STRUCTURAL ORGANIZATION OF THE RAT INTERGENICULATE LEAFLET. J.P. Card, R.P. Meade* and R.Y. Moore. Medical Products Dept., E.I. du Pont de Nemours and Co., Wilmington, Delaware 19898 and Neurology Dept., SUNY @ Stony Brook, Stony Brook, New York 11790.

The intergeniculate leaflet (IGL) of the thalamus is a distinct subdivision of the lateral geniculate complex which has recently been implicated in the neural control of circadian rhythmicity. In the present study we have analyzed the cytoarchitecture, structure and circuitry of the IGL. The cytoarchitectural boundaries of the IGL are most effectively demonstrated by retrograde transport of fluorescent dyes from the suprachiasmatic nuclei and/or the contralateral IGL as well an anterograde transport of CT-HRP from the eye. These data demonstrate that the IGL consists of a 10 mm lamina of neurons interposed between the dorsal and ventral geniculate nuclei which also extends ventromedially to the zona incerta. Neurons exhibiting NPY and mENK immunoreactivity are distinguished by their projections (NPY projects to the SCN; mENK neurons project to the contralateral nucleus), but show no differential distribution within the nucleus. Golgi impregnations of IGL neurons reveal small, bipolar neurons with 2-3 primary dendrites confined to the nucleus. Examination of retinal afferents with electron microscopy demonstrates that these afferents terminate within distinct glomeruli which are presynaptic to apical dendrites and axons. These data demonstrate that the IGL is both structurally and functionally distinct from other subdivisions of the lateral geniculate complex and provide further information on the means through which this thalamic nucleus exerts its control over circadian rhythms.

24.9

NPY, GFAP, GAD, 5-HT AND ENKEPHALIN IN THE INTERGENICULATE LEAFLET AND SUPRACHIASMATIC NUCLEI OF THE HAMSTER. L.P. Morin, L. Smale, K. Michels, R. Johnson and R.Y. Moore. Depts. Psychiatry and Neurology, HSC, SUNY, Stony Brook, NY 11794

A retinohypothalamic tract projects directly to the suprachiasmatic nucleus and provides photic information to a circadian clock. There is also a retinal projection to the intergeniculate leaflet (IGL) of the thalamus. The IGL projects to the SCN through a geniculohypothalamic tract, cells of which contain neuropeptide Y (NPY). The present research has identified the IGL using cholera HRP localization of retinal projections and compared its location with immunohistochemically identified glial fibrillary acidic protein (GFAP), glutamic acid decarboxylase (GAD), 5-HT and enkephlin (ENK) in the IGL and SCN of the hamster.

The rostral IGL starts in the lateral dorsal thalamus, ventrolateral part, in contact with the horizontal cerebral fissure. The middle half of the IGL lies medial to the optic tract, between the dorsal and ventral lateral geniculate nuclei. In the caudal quarter, the IGL is in contact with the lateral thalamic surface, ventral to the medial geniculate nucleus and dorsal to the cerebral peduncle. At the caudal extreme, the IGL is contiguous with the lateral terminal nucleus (LTN) of the accessory optic tract. A distinction can be made between the IGL and LTN during evaluation of cholera-HRP product, but not based on immunoreactivity of NPY. The general morphological features of the IGL are the same whether derived from material reacted with NPY, GFAP or ENK antibody by the location of retinal efferents. GAD and 5-HT are also evident in the IGL throughout its length, but do not delineate it as clearly. All the antigens are localized in the hamster SCN where ENK is co-extensive with NPY. The data are consistent with available functional studies of the IGL and SCN with respect to circadian rhythm regulation. Supported by grant NS22168.

24.10

PHOTIC SENSITIVITY OF HAMSTER GENICULATE NEURONS THAT PROJECT TO EITHER THE SUPRACHIASMATIC NUCLEI OR THE CONTRALATERAL GENICULATE. D.X. Zhang and B. Rusak, Dept. of Psychology, Dalhousie Univ., Halifax, Canada B3H 4J1.

Cells in and near the intergeniculate leaflet (IGL) of the Syrian hamster are known to project to the suprachiasmatic nuclei (SCN); they appear to play a role in mediating photic responses of circadian rhythms. Other cells in this region project to the contralateral IGL. We are investigating the photic responsiveness of cells that project to these targets. Hamsters were anesthetized with urethane and prepared for recording from the area of the intergeniculate leaflet (IGL). Stimulating electrodes were aimed at an analogous site in the contralateral geniculate and at the SCN. Photic responses of cells in the IGL and adjacent areas were assessed with diffuse binocular illumination. Cells were also tested for antidromic activation from the two targets. Most cells identified as projecting to the SCN (by high-frequency following, collision tests and constant latencies of 1.7-16.7 ms) showed a sustained, intensity-dependent activation to retinal illumination. A few cells were suppressed or phasically activated by retinal illumination. The few cells so far identified as projecting to the contralateral geniculate did not project to the SCN and showed little photic sensitivity. Cells that form the projection to the contralateral geniculate appear to differ from those projecting to the SCN in their responses to illumination. Supported by MRC and NSERC of Canada and Dalhousie RDFS.

24.11

THE AFFERENT AND EFFERENT ORGANIZATION OF THE RAT LASCN. D.M. Murakami* and C.A. Fuller. Dept. of Animal Physiology, Univ. of California, Davis, CA 95616.

To further examine the possibility that the region lateral to the SCN and dorsal to the optic chiasm (LASCN) may play a role in circadian function, this study examines the morphological distinction of the LASCN from the surrounding hypothalamus. Coronal sections through the hypothalamus were either nissl stained with thionin or impregnated with the Golgi Kopsch technique. Soma profiles were sampled from the LASCN and medial preoptic region (MPO) in nissl stained sections, and measured for mean soma diameter and soma shape (ratio of long and short diameters). Golgi stained neurons were examined for dendritic morphology and orientation. LASCN neurons had smaller soma diameters ($x=10.82\pm2.11, n=100$) than MPO neurons ($x=12.09\pm1.85$, $n=109$) The LASCN neuron soma profile ($x=2.70 \pm 0.99$) was more elongated than that of MPO neurons ($x=1.93 \pm 0.59$). LASCN neurons typically exhibit two bipolar dendrites oriented parallel to the chiasm, and very few extending dorsally into the MPO or anterior hypothalamus. MPO neurons typically exhibit multipolar arrangements of dendrites with many extending ventrally into the LASCN. LASCN neurons closest to the SCN extend a dendritic arbor that will intermix with a plexus of SCN dendrites at the outer border of the SCN. SCN dendrites rarely extend into the LASCN. These morphological features suggest that the LASCN may be a distinct region from the surrounding hypothalamus. [Supported by NIH Grant MH41477, Smokeless Tobacco Res Council Grant 0167 and NASA Grant NAG 2-349.]

24.12

THE MORPHOLOGY OF NEURONS IN THE RAT LASCN. J.R. Nayduch*, D.M. Murakami* and C.A. Fuller (SPON: J. Miller). Dept. of Animal Physiology, Univ. of California, Davis, CA 95616.

Previously we suggested that the region lateral to the SCN and dorsal to the optic chiasm (LASCN) may play a role in circadian function. To further investigate the potential role of the LASCN in circadian function, this study examines the afferent and efferent connections of the LASCN, particularly the neural interconnections with the SCN, a nucleus known to play a major role in circadian function. HRP injections were made into either the LASCN or the SCN as a retrograde marker. Following injections, the animal was sacrificed and the brain prepared for histology. Coronal sections through the brain were reacted with either TMB or Hanker-Yates reagents. Injections into the SCN demonstrated that neurons located in the LASCN were labelled with HRP. Injections into the LASCN resulted in a high density of labelled neurons in the ventral portion of the SCN. The dorsal SCN exhibited a low density of labelled neurons. Other regions that contained well labelled HRP neurons include the locus coeruleus, dorsal raphe, paragigantocellular reticular, anterior hypothalamic, medial preoptic region, diagonal band and paraventricular nuclei. The distinct pattern of interconnections between the LASCN and SCN further suggests that the LASCN may play a role in circadian function and recieves neural input from a variety of neural regions that may modulate this function. [Supported in part by NIH Grant MH41477, Smokeless Tobacco Res. Council Grant 0167 and NASA Grant NAG 2-349.]

24.13

DISRUPTION OF FEEDING BUT NOT WHEEL-RUNNING CIRCADIAN RHYTHMS BY HYPOTHALAMIC KNIFE-CUTS AND EFFECTS OF GANGLIOSIDES. J.D. Levine*, A.M. Rosenwasser, J.A. Witcher*, J.A. Yanovski*, R.R. Miselis and N.T. Adler (SPON:D. Levitt). Dept Anat. and Psych. Univ. Pennsylvania, Phila. Pa. 19104

Knife-cuts passing through or around the SCN have been used to study the relationship between neural connectivity and behavioral circadian rhythms. In this ongoing investigation, wheel-running and feeding rhythms were monitored concurrently. Following entrainment to LD12:12, female rats were maintained in constant dim red light. While free-running, some animals received coronal knife-cuts aimed at the mid-SCN. Chi-square periodogram analysis revealed that the knife cuts resulted in disruption of feeding but not wheel-running rhythms. We are also looking at variation in recovery of function and its possible acceleration by exogenous administration of purified GM-1 gangliosides: in two pilot animals, it appeared that vehicle+ganglioside treatment led to an earlier and more complete recovery of the rhythm than vehicle only.

These preliminary results suggest that output pathways from the circadian pacemaker underlying the expression of these two rhythms may be dissociated, and that neural support of at least one rhythm, feeding, possesses considerable potential for functional plasticity. (Supported by BRSG-RR-07083-21 to N.T.A., NIH-HD04522 to N.T.A. and Purified GM-1 was a gift of FIDIA)

24.14

CIRCADIAN RHYTHMS IN HAMSTERS AFTER SCN ISOLATION. H.J. Hakim* and R. Silver, Psychology Department, Barnard College of Columbia University, New York, NY 10027.

Transection of most efferents from the suprachiasmatic nucleus (SCN) results in the loss of circadian activity patterns (Nishio, T. et al., Psyhiol & Behav, 23, 1979; Stephan, FK & Nunex AA, Beh Biol, 20, 1977) suggesting that, at least in rats, SCN efferents are necessary for the expression of circadian rhythmicity.

We examined locomotor activity in male golden hamsters after isolating the SCN using a Halasz wire microknife. Hamsters were housed in constant dim red illumination (LL) for at least ten weeks. Brains were immunocytochemically stained for SCN peptides, VIP and VP, and antisera to glial fibrillary acidic protein (GFAP) was used to delimit the border of the knife cut.

Preliminary results indicate that free running rhythms persist in hamsters in which the knife substantially isolated and/or slightly damaged the SNC (N=9). These animals show both VIP and VP immunoreactivity within the island. Hamsters showing arrhythmic activity sustained severe damage to the SCN (N=4). Animals with cuts that missed the SCN (N=2) and all sham operated animals (N=4) maintained circadian rhythmicity. (Supported by NIH grant NS24292)

24.15

LESIONS DORSAL TO THE SUPRACHIASMATIC NUCLEUS (SCN) ABOLISH SPLIT RHYTHMS IN HAMSTER RUNNING-WHEEL ACTIVITY. M.E. Harrington, G. Eskes, P. Dickson* and B. Rusak. Dept. of Psychology, Dalhousie Univ., Halifax, NS B3H 4J1 Canada.

Constant light exposure (LL) can result in "splitting" of circadian rhythms into two components coupled about 12 h apart. Splitting has been interpreted as evidence for the presence of two main oscillators underlying circadian rhythms. Abolition of splitting after unilateral SCN ablation suggested that each SCN could correspond to one of these component oscillators.

We examined whether lesions outside the SCN would abolish split activity rhythms of hamsters in LL. Wheel-running activity was recorded for at least 3 months after surgery. Damage was assessed by Kluver-Barrera staining. Large bilateral lesions of the medial aspect of the paraventricular nucleus (with little or no SCN damage) generally abolished the split condition immediately. Bilateral damage to the anterior SCN or complete unilateral SCN ablation also abolished the split pattern. Other behavioral effects of surgery included phase shifts and period changes of both components of the split rhythm.

These results indicate that destruction of one SCN is not essential for the elimination of split rhythms since lesions dorsal to the SCN or partial bilateral SCN damage are also effective. Damage to SCN efferents and/or indirect lesion effects on SCN function may account for the loss of the split condition. (Supported by NSERC and MRC of Canada and Dalhousie RDFS.)

THE EFFECTS OF KNIFE CUTS IN THE HYPOTHALAMIC SUB-PARAVENTRICULAR ZONE OF THE FEMALE RAT ON ESTROGEN-INDUCED DIURNAL RHYTHMS OF PROLACTIN (Prl) AND LUTEINIZING HORMONE (LH), AND CIRCADIAN WHEEL RUNNING ACTIVITY. A.G. Watts, W.J. Sheward* & D. Whale*. MRC Brain Metabolism Unit, Edinburgh, U.K.

The efferent projections of the suprachiasmatic nucleus (SCh) have been traced, using various techniques, to areas within the hypothalamus and forebrain. A substantial terminal area was identified in the region between the SCh and the paraventricular nucleus (PVH)—the sub-paraventricular zone (Watts et al., JCN, 258:204, 1987). In an attempt to determine the importance of this area in the maintenance of SCh generated rhythms, knife cuts were made in the sPVHz region in ovariectomized female rats given an oestradiol-17β (E2) capsule; here, surges of plasma LH and Prl can be seen every afternoon at a time corresponding to those present on the afternoon of pro-oestrus in intact animals. In addition, the effect of the knife cuts on circadian wheel running activity was investigated. At the end of the experiment sections from all knife cut animals were stained for VIP-immunoreactivity (IR) to check for the effects of the knife cut on SCh efferents to the sPVHz and to the paraventricular nucleus of the thalamus (PVT). In animals where the sPVHz VIP-IR was absent the incremental rise in both LH and Prl were markedly reduced for at least 14 days following the knife cut. A similar result was obtained when animals were grouped according to presence or absence of VIP-IR in the PVT. The incremental rise in both LH and Prl was significantly lower in animals with deafferented PVT when compared to intact animals. When animals were grouped according to presence or absence of damage to the preoptic area, there were no significant differences between the 2 groups. When a knife cut was given to animals whose circadian activity cycles were monitored, no substantial disruption was observed in either the ability to synchronize to the light/dark cycle or to free-run in a constant light environment. These results show that the efferent pathway which leaves the SCh in a dorsocaudal direction to innervate the sPVHz is capable of influencing the magnitude of incremental rise in both plasma LH and Prl concentrations. The knife cut did not disrupt any rostrally directed fibres from the SCh, e.g., the SCh derived NP-II innervation of the anteroventral periventricular nucleus was unaffected by knife cuts which disrupted VIP-IR to the sPVHz. When animals were grouped according to presence or absence of damage to the preoptic area, there were no significant differences between the 2 groups. These results suggest that any rostrally directed fibres do not play as significant a role in maintaining diurnal LH and Prl release as do the dorsocaudally directed fibres.

KNIFE CUTS DORSAL TO THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS DISINHIBIT GONADOTROPIN SECRETION IN MALE GOLDEN HAMSTERS KEPT IN LONG OR SHORT DAYS. L.L. Badura, C.L. Sisk, and A.A. Nunez, Psychology Dept. and Neuroscience Prog., Michigan State University, E. Lansing, MI 48824

Male hamsters housed in a long-day photoperiod show a rise in plasma levels of gonadotropins following castration. Exposure to a short-day photoperiod attenuates the post-castration rise in LH and FSH. The present experiment was designed to determine if manipulations that abolish gonadal responses to photoperiod also abolish the short-day induced inhibition of gonadotropin release following castration.

Testicular regression was induced in male hamsters by exposure to short days (6L:18D) for 10 weeks. Half of the animals then received a horizontal knife cut aimed just dorsal to the PVN; the remaining hamsters received sham surgery. Following surgery, half of the animals were transferred to long days (16L:8D). Blood samples were drawn from all animals via cardiac puncture 1 week before surgery, and again at 10, 20, and 30 days post-surgery. Plasma levels of FSH in each sample were determined by radioimmunoassay.

The post-castration rise in FSH was lower and more protracted in sham-operated animals in 6L:18D than those in 16L:8D. At 10 and 20 days post-surgery, knife cut animals in both photoperiods had higher plasma levels of FSH than sham-operated animals in either photoperiod, although FSH was slightly higher in knife cut animals in 16L:8D than in 6L:18D. By 30 days post-surgery, all groups showed similar levels of FSH. These findings indicate that knife cuts dorsal to the PVN cause a disinhibition of FSH that is attenuated by exposure to short days.

24.18

PARASAGITTAL KNIFE CUTS LATERAL TO THE PARAVENTRICULAR NUCLEI OF THE HYPOTHALAMUS BLOCK REPRODUCTIVE RESPONSES TO PHOTOPERIOD IN FEMALE GOLDEN HAMSTERS. K.K. Kelly*, L.L. Badura, and A.A. Nunez, Psychology Dept. and Neuroscience Prog., Michigan State University, E. Lansing, MI, 48824.

In female hamsters, interruption of the dorsally-projecting fibers of the hypothalamic paraventricular nuclei (PVN) is not sufficient to block short-day-induced estrous acyclicity and uterine regression. The purpose of the present study was to investigate the functional significance of the laterally-projecting fibers of the PVN in photoperiodic control of female reproductive physiology. Cycling female hamsters were maintained in a long-day (16L:8D) photoperiod. One group received bilateral parasagittal knife cuts aimed lateral to the PVN; the other group received sham surgery. After a two week recovery period, half the animals were moved to a short-day (6L:18D) photoperiod. Vaginal discharge was evaluated daily until all sham-operated animals in 6L:18D exhibited discharges charateristic of anestrus. The animals were then sacrificed, their uteri weighed, and the brains prepared for histological evaluation.

Animals with bilateral knife cuts placed through the lateral one-third of the PVN continued to show regular 4-day estrous cycles and to maintain stimulated uteri in both long and short days; thus, parasagittal cuts prevented the effects of short days on reproductive physiology. This finding suggests that the lateral efferent projections from the PVN represent an important component of the neural pathway that mediates photoperiodism in female hamsters.

PARAVENTRICULO-SPINAL PATHWAYS AND RESPONSES TO PHOTOPERIOD IN THE SYRIAN HAMSTER (*Mesocricetus auratus*). T.G. Youngstrom & A.A. Nunez. Psychology Dept. and Neuroscience Prog., Michigan State Univ., E. Lansing, MI. 48824.

An efferent paraventricular nucleus (PVN) projection to the spinal cord has been implicated in the control of seasonal reproductive cycles in the Syrian hamster. Horizontal knife cuts placed dorsal to the PVN in male, but not female, hamsters prevent short-day induced gonadal regression (Brain Res. Bull. *16*:705, '86; Brain Res. *370*:102, '86; Soc. Neurosci. Abstr. *13*:865 '87). To examine the course of PVN efferent fibers to the spinal cord, injections of Cholera toxin conjugated to horseradish peroxidase (CT-HRP) were aimed at the intermediolateral cell column and lateral spinal cord at the level of C7 to T2. Animals were perfused and the tissue processed using a previously published procedure (J. Histochem. Cytochem. *28*(11):1255, '80). Labeled neurons were present throughout the rostro-caudal extent of the PVN, but primarily in the parvocellular subdivisions of the nucleus. Labeled fibers that originated from these neurons formed two bundles, one immediately dorso-medial above the third ventricle and a second that exited the PVN laterally. The bundle projecting laterally divided into two components. A prominent ventro-lateral tract appeared to join the medial forebrain bundle, while a second smaller set of fibers turned dorso-laterally. While some horizontal knife cuts placed above the PVN may sever the dorsal bundle just above the PVN and third ventricle, knife cuts placed further dorsally (Brain Res. *370*:102, '86) should leave PVN-spinal connections intact; yet those dorsal cuts are also effective in preventing testicular regression. In males, knife cuts dorsal to the PVN result in elevated serum levels of follicle stimulating hormone (FSH) regardless of photoperiod (Badura *et al.*, Soc. Neurosci. Abstr. *14* '88). Thus, due to the increase in FSH, animals in short days may maintain large testicles even though the neural pathway that mediates photoperiodism is not damaged by the knife cuts. Supported in part by NIMH Grant MH 37877 to AAN.

24.20

EVIDENCE FOR RETINAL INPUT TO THE BASAL FOREBRAIN IN THE HAMSTER THAT MAY INFLUENCE RESPONSES TO PHOTOPERIOD. A.A. Nunez, T.G. Youngstrom & M.L. Weiss. (SPON: G. Richmond) Psychology Dept. and Neuroscience Prog., Michigan State Univ., E. Lansing, MI. 48824.

In this study, retinal projections to the brain of the Syrian hamster (*Mesocricetus auratus*) were examined using intraocular injections of Cholera toxin conjugated to horseradish peroxidase (CT-HRP). Following a 24-72 hour survival period, male and female Syrian hamsters were perfused and the tissue processed using a previously published procedure (J. Histochem. Cytochem. *28*(11):1255, '80). Areas previously reported to receive direct retinal input were labeled including the suprachiasmatic nucleus (SCN), the paraventricular nucleus (PVN), the sub-PVN area and the supraoptic nucleus (SON) (Soc. Neurosci. Abstr. *13*:211, '87). In addition labeled fibers were seen in the preoptic area where a diffuse bundle continued into the diagonal band of Broca. A distinct fiber tract was followed into the superficial layer of the piriform cortex where putative terminals were seen. Extra-geniculate input to the thalamus was primarily to the nucleus reuniens and dorsal thalamus. A portion of this projection appeared to terminate in either the caudal bed nucleus of the stria terminalis or rostral thalamus. Many areas of the basal forebrain that receive direct retinal input participate in the control of reproductive behavior or physiology and may play a role in photoperiodism. Supported in part by NIMH Grant MH 37877 to AAN and NRSA Postdoctoral Grant NS 08125 to MLW.

25.1

CHOLINERGIC AND CATECHOLAMINERGIC SUPPRESSION OF NERVUS TERMINALIS GANGLION CELL ACTIVITY IN THE ELASMOBRANCH. J. White* and M. Meredith. Dept. of Biol. Sci., Florida State Univ., Tallahassee, FL 32306-3050.

Our previous observations suggest that impulses from the brain suppress nervus terminalis (NT) ganglion cell activity in the bonnethead shark (Sphyrna tiburo), probably through inhibitory synaptic potentials. We are currently conducting in vitro pharmacological studies on the bonnethead NT to investigate the synaptic interactions responsible for this suppression. Multi-unit activity from NT ganglion cells was recorded extracellularly from central nerve trunks with suction electrodes. Electrical stimulation of central or peripheral nerve trunks suppresses this activity. Bath application of acetylcholine (ACh), norepinephrine (NE), dopamine, and epinephrine (EPI) at 1 to 100 uM also suppressed ganglion cell activity. These agonists were effective when applied under zero-calcium conditions to block synaptic transmitter release, suggesting that each was acting directly on the NT ganglion output cells and not through interneurons or presynaptic mechanisms. Experiments with neurotransmitter antagonists further suggest that ACh may be acting via muscarinic receptors and EPI via alpha-adrenergic receptors. Furthermore, ACh and NE suppression appeared to be due to different mechanisms: ACh prevented further suppression by electrical stimulation, while NE application did not. The functional significance of this difference is unknown and is currently under study.

25.2

HORN SHARKS POSSESS SEPARATE HOMOLOGUES OF NUCLEUS GENICULATUS LATERALIS AND NUCLEUS ROTUNDUS. E. Fiebig* and R. G. Northcutt (SPON: M. S. Northcutt). SIO Neurobiol. Unit & Dept. of Neurosci's., UCSD, La Jolla, CA 92093.

A dorsolateral optic complex is said to exist in sharks (Ebbesson, Brain Behav. Evol., 6:75, 1972) and to have given rise to a lateral geniculate nucleus and n. rotundus by parcellation (Ebbesson, Behav. Brain Sci's., 7:321, 1984). Injections of WGA or WGA-HRP into the eye in horn sharks, Heterodontus francisci, revealed no retinal projections to the dorsal posterior thalamic nucleus. However, injections of PHAL into the optic tectum (4 cases) revealed extensive tectofugal projections to this nucleus. While the projections of this nucleus are not known in Heterodontus, only a few cells of the dorsal posterior thalamic nucleus project to the tectum following injections of WGA-HRP into the tectum (5 cases), and that in a related genus, Platyrhinoidis, the dorsal posterior nucleus and a more rostral retino- and tectorecipient thalamic nucleus (anterior nucleus) project to the telencephalon (E. Fiebig and H. Bleckmann, in press). The topography and connections of the dorsal posterior nucleus support the hypothesis that this nucleus is the homologue of n. rotundus. Therefore, at least some elasmobranchs have separate homologues of the geniculate and rotundal nuclei, and the condition in these species does not support a hypothesis of phylogenetic parcellation.

25.3

LOCUS COERULEUS AND SUBCOERULEUS IN AN ELASMOBRANCH: TELENCEPHALIC, CEREBELLAR AND SPINAL CORD CONNECTIVITIES AND IMMUNOHISTOCHEMISTRY. W.L.R. Cruce, E. Fiebig*, S.L. Stuesse, and H. Bleckmann*. NEOUCOM, Rootstown, OH, UCSD, La Jolla, CA, and U. of Bielefeld, FRG.

HRP or WGA-HRP was injected into spinal cord, cerebellum, or basal forebrain bundle of the thornback guitarfish, Platyrhinoidis triseriata. Mesencephalic cells showing retrograde label were compared to cells showing 5HT and tyrosine hydroxylase (TH) immunoreactivity. All cells are small (10x30u) and oval. Locus coeruleus (LC) cells are scattered along the ventricular border medial to the sulcus limitans for a short distance below the caudal pole of the trigeminal motor nucleus; some cells lie dorsolateral to the sulcus limitans as well. Major dendritic processes are parallel to the ventricular surface. Subcoeruleus pars alpha (SCA) is found at the same level as LC and merges with that nucleus in a dorsomedial direction. Ventrolaterally SCA merges with pars beta (SCB). SCA cells can be distinguished from cells of LC and SCB by their dorsomedial to ventrolateral dendritic orientation. SCB is a tight group of cells (probably homologous to the mammalian Kolliker-Fuse n.) found at the same level as LC but lying at the lateral edge of the brainstem between nucleus F dorsally and nucleus B ventrally. SCB merges medially with SCA but can be distinguished from it by the mediolateral major dendritic axis of SCB cells. All three nuclei have a predominantly ipsilateral projection to spinal cord and telencephalon. LC and SCA but not SCB project to cerebellum bilaterally. All three nuclei contain cells immunoreactive to TH but only LC contains 5HT immunoreactive cells.

LEUCINE-ENKEPHALIN-LIKE IMMUNOREACTIVITY IN THE FOREBRAIN OF THE THORNBACK GUITARFISH, WITH COMPARISONS TO A SQUALOMORPH SHARK. J.G. New, Neurobiology Unit, Scripps Inst. of Oceanography, UCSD, La Jolla, CA 92093.

The telencephalon of the thornback (Platyrhinoidis triseriata) represents an intermediate level of complexity between the primitive condition of squalomorph sharks and the large and complex telencephalon of galeomorph sharks and myliobatoids. The purpose of this study is to localize L-ENK+ neurons in the forebrain of Platyrhinoidis and to compare the distribution with that previously reported in Squalus acanthias (Northcutt, et al., 1988).

The fixed brains of 9 Platyrhinoidis specimens were sectioned at 30-35 um and incubated with a commercially obtained antibody to L-ENK. The antigen-antibody complex was visualized via PAP methods, using DAB as the chromogen.

The greatest concentration of L-ENK+ fibers and somata was observed in the dorsal pallium (DP). DP in Squalus is also rich in L-ENK+ cells, but in Platyrhinoidis DP has expanded greatly and extends over the rostrodorsal pole of the telencephalon. A number of discrete regions of high or low immunoreactivity were also discernible within DP.L-ENK+ somata and fibers were also observed in lesser concentration in the lateral and medial pallia, suprapeduncular nucleus, nucleus Q, the septal area, and the preoptic region. Weak staining of large somata, as well as fibers , was observed in the area superficialis basalis. L-ENK+ neurons were not observed in the APVL, a region of stong immunoreactivity in Squalus.

AN IMMUNOHISTOCHEMICAL STUDY OF THE TELENCEPHALON OF POLYPTERUS. A. Reiner and R.G. Northcutt. Dept. of Anatomy and Neurobiology, Univ. Tenn., Memphis, TN and Dept of Neurosciences, UCSD, La Jolla, CA.

In teleosts, the most advanced ray-finned fish, eversion of the pallial roof of the telencephalon together with neuronal proliferation and migration makes comparisons between cell groups of the teleost telencephalon with those of the telencephalon in other vertebrates extremely difficult. The telencephalon of polypterus, a primitive living ray-finned fish, however, is much simpler in cytoarchitecture than that of teleosts and is also everted. To aid in clarifying the evolution of the telencephalon in teleosts and aid in making comparisons between the telencephalon in ray-finned fish and other vertebrates, we have applied immunohistochemical techniques to the study of the telencephalon of polypterus.

Antisera specific for the following substances were used: 1) 5-HT; 2) tyrosine hydroxylase; 3) substance P; 4) leucine-enkephalin; 5) NPY; and 6) LANT6. The staining pattern for the various regions of the telencephalon of polypterus revealed similarities to specific regions of the telencephalon of other vertebrates: 1) the dorsal and ventral subdivisions of the area ventralis appear to include the homologues of the basal ganglia and septum; 2) the olfactory pallium (P1) appears comparable to olfactory cortex; and 3) the P2 (dorsal) and P3 (lateral) fields of the pallium appear to correspond largely to the dorsomedial and medial pallial walls, respectively, in lungfish, sharks, frogs and reptiles. These results thus suggest homologues in polypterus for some of the major parts of the telencephalon in tetrapods and non-ray-finned fish.

Supported by NIH grants NS19620 (AR) and NS11006 (RGN).

25.6

DISTRIBUTION OF GAP JUNCTION PROTEIN-IMMUNOREACTIVITY IN THE BRAIN OF THE WEAKLY ELECTRIC FISH. T. Yamamoto[1], L. Maler[2], E.L. Hertzberg*[3] and J.I. Nagy[1] [1]Dept. of Physiology, Univ. of Manitoba, Winnipeg, CANADA, [2]Dept. of Anat., Univ. of Ottawa, Ontario, CANADA, and [3]Dept. of Biochemistry, Baylor College of Med., Houston, TX.

Electrotonic coupling via gap junctions between neurons in the CNS of weakly electric fish represents an important mode of communication in certain structures associated with the electrosensory system. We have used an affinity-purified polyclonal antibody against a 27KD gap junction protein (GJP) to determine immunohistochemically the distribution of GJP-immunoreactivity (GJP-IR) in the brain of gymnotiform fish. GJP-IR consisted of individual punctate deposits of immunoreaction product and sequences of puncta which appeared to be varicosities along fibers. The density of both patterns was remarkably heterogeneous throughout the brain. Areas with very dnese GJP-IR included the nucleus electrosensorius, the inferior lobe, nucleus praeeminentialis dorsalis and the vagal sensory nucleus. Moderate to high densities were observed in the torus semicircularis dorsalis, the periglomerular nucleus and the descending trigeminal nucleus. In several areas, punctate or fibrous GJP-IR was associated with neuronal somas or initial segments of dendrites. Preliminary EM observations indicate that GJP-IR is localized, in part, to regions of cytoplasmic membranes forming gap junctions.

HEXOKINASE HISTOCHEMISTRY IN THE BRAIN OF GOLDFISH. J.G. Dulka,* T.L. Krukoff, J.I. Goldberg and N.E. Stacey*. (SPON: B. Calancie). Department of Zoology, University of Alberta, Edmonton, T6G 2E9, Department of Anatomy and Cell Biology, University of Alberta, Edmonton, Alberta, Canada T6G 2H7.

Histochemical demonstration of hexokinase (HK), the first enzyme in the glycolytic pathway, has been used as an indicator of metabolic activity in selected brain regions in rats (Krukoff et al., Am. J. Physiol. 251:R268, 1986). We are using HK histochemistry on male goldfish to ultimately identify brain regions that control the release of gonadotropin into the blood following exposure of males to a sex pheromone, 17o, 20B-dihydroxy-4-pregnen-3-one (Dulka et al., Nature, 325: 251, 1987).

In this preliminary report, the distribution of HK staining in the brains of normal, unstimulated males is described. Brain regions showing strong HK staining include the habenula, the ventral floor of the preoptic recess, periventricular hypothalamic nuclei, portions of nuclei associated with the lateral and posterior recesses, and neurohypophysial fibers in the pituitary. Distinct cells which stained strongly for HK were identified in the dorsal midbrain and throughout the medulla. The results suggest that these brain regions have high levels of glucose utilization. Interestingly, most areas staining strongly for HK overlap with regions known to contain biogenic amines. In support, HK staining in the nucleus recessus posterioris was found to overlap with immunocytochemical staining of serotonin on alternate sections. However, additional research is needed to determine if other aminergic systems also show high HK activity.

EIGENMANNIA POSSESSES AUTAPOMORPHIC RAMI OF THE ANTERIOR LATERAL LINE NERVES. R. G. Northcutt and H. A. Vischer (SPON: M. F. Wullimann), SIO Neurobiol. Unit & Dept. Neurosci's., UCSD, La Jolla, CA 92093

Examination of histological serial sections (Bodian stained) of entire heads, and Sudan Black preparations that render the head transparent while staining the cranial nerves, indicates that the anterior lateral line nerve complex of Eigenmannia consists of anterodorsal and anteroventral nerves. The anterodorsal nerve (ADN) consists of superficial ophthalmic and buccal rami that innervate the neuromasts of the supra- and infraorbital canals, respectively. The anteroventral nerve (AVN), as in other teleosts, exhibits an external mandibular ramus that innervates neuromasts of the preoperculomandibular canal as well as three additional rami not observed in non-gymnotid teleosts: supraorbital, infraorbial and recurrent. The supraorbital and infraorbital rami anastomose, respectively, with the superficial ophthalmic and buccal rami of the ADN distally, so that without experimental studies it is impossible to establish which lateral line organs these rami innervate. However, as siluroid teleosts are the sister group of gymnotid teleosts, and are electroreceptive but do not exhibit supraorbital and infraorbital rami of the AVN, or tuberous electroreceptors, we hypothesize that one or both classes of tuberous organs may be innervated only by the ADN and may thus arise or be induced in relation to the hyoid dorsolateral placode.

25.9

MAUTHNER-LIKE RETICULOSPINAL NEURONS IN THE ADULT GOLDFISH. **R.K.K. Lee, S.J. Zottoli and R.C. Eaton. Neuroscience Group, Campus Box 334, Univ. of Colorado, Boulder, CO 80309, & Dept. of Biol., Williams College, Williamstown, MA 01267.**

The Mauthner (M-) cells are a pair of prominent reticulospinal (RS) neurons that play a major role in the C-start escape responses but are not required for it to occur. This and other evidence suggests that the C-start must be mediated by a group of RS neurons. We are presently constructing a map of RS neurons for analysis of network interactions underlying the C-start. We report two new pairs of RS neurons whose morphology suggests a role in the C-start behavior.

We analyzed 17 brains retrogradely filled with HRP injected into various positions along the spinal cord. The identified cells are located together ventromedial and caudal to the M-cell somas at the level of the M-axon decussation. The coordinates of one of the pairs are at 274 ± 14 um (± SEM) posterior to the M-soma, 296 ± 16 um ventral to the M-axons and 243 ± 7 um lateral to the midline. This pair has a single, crossed, decussating axon in the MLF and a lateral and bifurcating ventral dendrite. These seem to receive afferents similar to the M-cell. Two pairs are distinguished because only one has an axon reaching the caudal end of the spinal cord.

DIENCEPHALIC NUCLEI THAT PROJECT TO THE PITUITARY IN GOLDFISH: AN IN VITRO HRP STUDY. H.E. Sloan and L.S. Demski, School of Biological Sciences, University of Kentucky. Lexington, KY 40506.

Neurons of the diencephalon were labeled following application of horseradish peroxidase (HRP) to the pituitary of the goldfish. Animals were anesthetized and perfused through the heart with teleost ringers. The pituitary was exposed and punctured with an HRP coated insect pin. The brain and pituitary were incubated in teleost ringers at 5-10°C for 1 or 2 days and then processed for HRP histochemistry. Nomenclature is from Braford and Northcutt or Peter and Fryer in Fish Neurobiology, vol. 2, 1983.

All labeled neuronal populations have bilateral projections to the pituitary. HRP-filled cells are found in the parvocellular, (PPa and PMp), magnocellular (PMm) and gigantocellular (PMg) regions of the preoptic area. HRP-labeled cells are present in the suprachiasmatic nucleus (SC), the lateral portion of the nucleus lateral tuberis (NLTl) and the lateral hypothalamic area (LH). Caudally, HRP-filled cells are found in the caudal hypothalamic area (Hc or NRP) and between Hc and the dorsal hypothalamic area (Hd or NRL). Labeled neuronal populations are similar to mammalian projections to the median eminence and pituitary. Supported in part by NIH Grant NS 19431.

25.11

BONY FISH PIT LINE NEUROMASTS ARE HOMOLOGOUS TO CANAL NEUROMASTS. J.F. Webb* and R.G. Northcutt. Neurobiol. Unit, SIO and Dep't Neurosciences, Univ. California, San Diego, La Jolla, CA 92093.

An examination of the distribution of lateral line canals and their homologues in major vertebrate taxa reveals frequent paedomorphic trends from a system composed exclusively of canals to a system characterized by the replacement of many of these canals by lines of superficial neuromasts (pit lines). If all pit lines have canal homologues in early vertebrates, then pit line neuromasts and canal neuromasts are components of a single mechanoreceptive lateral line system. As such, they should look fundamentally similar unless natural selection has resulted in their morphological differentiation. The pit line neuromasts in the lungfishes Lepidosiren and Protopterus and the bichir Polypterus were examined using scanning electron microscopy. Despite having quite long kinocilia, pit line neuromasts resemble canal neuromasts in shape, topography and hair cell orientation. This supports the hypothesis that they have a phylogenetic history as canal neuromasts and further suggests that pit line neuromast morphology is quite conservative having changed little since the late Devonian.

25.12

THE MORPHOLOGY OF THE BARBEL SENSORY SYSTEM IN A GOATFISH, PARUPENUS MULTIFASCIATUS. **M.A. Barry, C.S. Beeman*, and L.D. Savoy*, Dept. of Biostructure and Function, Univ. Conn. Health Ctr., Farmington, CT. 06032**

The paired mandibular barbels in goatfish are used for tactile and chemosensory exploration, and during intraspecific behaviors. Morphological studies of the barbel and on the central projections of the barbel nerve revealed a unique and complex organization of the brain. Numerous taste buds are located on the barbel. The barbel is innervated by the terminal and largest branch of the mandibular nerve. Barbel afferents enter the brain in the facial and trigeminal nerve roots. Trigeminal afferents course caudally in the descending tract of V. Facial afferents course in a fascicle dorsal to the IVth ventricle. Barbel afferents terminate in an enlarged region of the rhombencephalon composed of dorsal, intermediate, and ventral lobes. Facial afferents terminate primarily in the dorsal and intermediate lobes, whereas the ventral lobe receives trigeminal input. The ventral lobe contains numerous spheroidal glomeruli (100-200 μ in diameter). Each glomerulus is a cluster of small (5-8 μ) round cells surrounded by a molecular zone with scattered large and small cells. Clusters in the intermediate lobe are smaller and less well differentiated. The dorsal lobe is divided into 3-4 lobules extending rostro-caudally. Lobules consist of 4 layers: superficial cellular, molecular, cellular with multiple clusters of cells (like those in ventral lobe), and deep molecular with fiber tracts and scattered cells including 15-30 μ elongate cells. NIH-NS16993.

26.1

GABA NEURONS IN THE CORPUS STRIATUM OF THE SALAMANDER. Lorraine Dubé and Laurent Descarries. Centre de recherche en sciences neurologiques, Départements d'anatomie et de physiologie, Université de Montréal, Montréal, Québec, Canada H3C 3J7.

PAP-immunohistochemistry with an antiserum against GABA-BSA conjugate (Immunonuclear) was used to identify putative GABA-containing neurons in the brain of Necturus maculosus. Within the corpus striatum, 3 concentric layers of nerve cell bodies were distinguished on the basis of their immuno-reactivity. From the lateral ventricle outward, small immunonegative neurons formed a first layer, 1 to 3 cells thick, immediately beneath the ependyma. The second layer consisted of a single row of small, strongly positive somata, interlinked by long processes which were also intensely reactive. The third layer comprised several rows of larger neurons uniformly displaying a moderate GABA immunoreactivity and surrounded, individually or in small groups, by numerous GABA-positive punctate structures. Such punctae were also found in increasing number dorso-ventrally, within the neuropil layer at the base of the brain. This peculiar GABA distribution in the corpus striatum differed from that in the proeminentia ventralis, medially, where all cell layers were thicker and the strongly positive neurons exhibited processes which were mainly oriented vertically, reaching into the neuropil. Laterally, it contrasted sharply with the amygdalar pattern showing only a few immunoreactive nerve cell bodies interspersed among negative neurons. These data reveal the existence of a major contingent of GABA-containing neurons within the corpus striatum of the salamander and suggest that GABA could be strongly implicated in the striatal function of amphibians as well as higher vertebrates. (Supported by MRC grant MA-9847).

26.2

FUNICULAR PROJECTIONS OF BULBOSPINAL NUCLEI IN NOTOPHTHALMUS VIRIDESCENS. M.C. Anderson*, B.M. Davis, S.B. Simpson, Jr. (SPON: J Leonard). Dept. of Biological Science, Univ. of Illinois at Chicago, Chicago, IL 60680.

While numerous studies have determined the cells of origin of the bulbospinal projections in anurans (e.g., Corvaja and Grofova, 1972; Shapovolov, 1972; Fuller, 1974; Soller, 1977; Ten Donkelaar, 1981) little is known about these pathways in urodeles. To investigate the origin and funicular trajectories of the bublospinal nuclei HRP was injected into various spinal tracts at cervical and lumbar levels of adult salamanders.

Following injection of HRP, labeled nuclei were observed within the rhombencephalon in the nucleus reticularus isthmi, nucleus reticularus superiorus, nucleus reticularus medius, and nucleus reticularus raphe. These nuclei project bilaterally via the ventral and ventral lateral funiculi. Nucleus reticularus inferiorus courses bilaterally in the lateral funiculus. Vestibular projections appeared to be bilateral and were located in the ventral funiculus. The apparent bilaterality of this projection may be misleading. Descrete vestibular nuclei, which might project unilaterally, could not be identified. At the level of the vestibular nuclei two large contralaterally projecting Mauthner neurons were also present. Within the mesencephalon HRP filled cells are located in the presumed homologue of the red nucleus and the interstitial nucleus of the FLM. The red nucleus projection is located in the contralateral dorsolateral tract while the interstitial nucleus is located bilaterally in the ventral funiculus. In the diencephalon labeled nuclei include the preoptic and the periventricular (PVN) nuclei. The preoptic nucleus courses ipsilaterally in the lateral funiculus as far caudal as the thoracic spinal cord. PVN also projects ipsilaterally in the lateral funiculus, but appears to descend to the lumbar spinal cord. (Supported by NS 24162 to SBS).

CONNECTIONS OF THE MAIN AND ACCESSORY OLFACTORY BULBS IN RANID FROGS. T.J. Neary Anatomy Dept., Creighton Univ., Omaha, NE 68178.

The connections of the main and accessory olfactory bulbs (MOB & AOB) were examined following applications of the tracer wheat germ agglutinin/horseradish peroxidase (WGA-HRP). Fibers left the MOB to supply the ipsilateral dorsal and lateral pallia, the post-olfactory eminence, and nucleus of the diagonal band/olfactory tubercle (NDB/OT). Labelled fibers supplied the same structures in the opposite hemisphere by crossing directly to the contralateral MOB and by coursing through the habenular commissure. Labelled neurons were found in the medial pallium, the ventral dorsal pallium, and in the intermediate and ventral parts of the lateral pallium (LPi & LPv). In the subpallium, they were present in the NDB/OT, medial amygdala, and surrounding the rostral lateral forebrain bundle. Labelled cells were also found in the anterior thalamic nucleus. Most cells were found bilaterally, but were more numerous ipsilateral to the applications. AOB applications labelled fibers which projected to the ipsilateral caudal LPi and LPv, and lateral amygdala. A small projection to the ipsilateral anterior preoptic area was also present. Fibers to the contralateral lateral amygdala, LPi, and LPv crossed in the anterior commissure.

Supported by a BRSG grant to Creighton University.

MARGINAL NEURONS AND THE DENTICULATE LIGAMENT OF THE SPINAL CORD IN URODELE AMPHIBIANS. D. Schroeder and M. W. Egar*, Ind. Sch. of Med., Med. Sci. Prog., Bloomington, IN 47405 and Dept. of Anat., Indianapolis, IN 46223.

There has been a renewed interest in the marginal neurons of the spinal cord since they may be intrinisic mechanoreceptors (Grillner *et al.*, Science 223:500, 1984). They appear to be also structurally and functionally associated with the denticulate ligaments (Schroeder and Richardson, Somatosens. Res. 4:127, 1986). Marginal neurons have been described in several vertebrates but not amphibians. We examined the spinal cord of *Ambystoma mexicanum* and *Necturus maculosus* with light and electron microscopes. The spinal cord extends the length of the vertebral column and consists of about 50 pairs of spinal nerves: approximately 20 are associated with the trunk and 30 with the tail. The denticulate ligaments are prominent on each side and vary somewhat in shape and design with the two different urodeles. The teeth of the ligaments extend laterally from the spinal cord surface and are continous through the dura to a projection of bone on each side of the vertebral wall. The marginal neurons, approximately 30 u in diameter, are located in a scattered column just medial to the ligaments and at the lateral edge of the spinal cord. They are associated with neuropil that contains many boutons containing round, polymorphic or dense-cored vesicles, dendritic processes, axons, and a variety of glial processes. A more medially located neuropil is also present. In our preliminary examination of an anuran amphibian (*Rana pipiens*) spinal cord we have not found marginal neurons. Supported by PHS SO7 RR 53711.

SEROTONIN NEURONS IN THE BRAIN OF THE REPTILE CAIMAN CROCODILUS. S. E. Brauth, Department of Psychology, University of Maryland, College Park, Maryland 20742.

Immunohistochemical methods were used to map the distribution of serotonergic neurons in the caiman brain. Many serotonergic neurons were observed in the nuclei raphe magnus, raphe pontis and superior centralis. Serotonin neurons are also present in cell groups which contain catecholamine neurons including the nuclei subcoeruleus ventralis and dorsalis, the locus coeruleus and both the pars ventralis and pars compacta of the substantia nigra. The caudal portion of the area ventralis of Tsai contains a large number of serotonin neurons surrounding the interpeduncular nucleus on its dorsal and lateral margins.

Many subependymal and supraependymal CSF-contacting serotonin neurons are present in the caiman hypothalamus at tuberal levels. The paraventricular organ contains a large number of small, intensely staining serotonin immunoreactive neurons. Serotonergic fibers are present within both the lateral and medial hypothalamus and coarse immunoreactive puncta are prominent within the lateral hypothalamus and lateral external layer of the median eminence. Fine serotonin fibers and terminals are present in the dorsal thalamus including the lateral geniculate nucleus, nucleus dorsomedialis anterior and dorsolateralis anterior. The habenular and subhabenular nuclei also contain serotonergic fibers and terminals.

CEREBELLAR PROJECTING AND LOCAL CIRCUIT NEURONS OF REPTILIAN DORSAL COLUMN NUCLEUS. M.B. Pritz and M.E. Stritzel*. Div. Neurol. Surg., Univ. of California Irvine Medical Center, Orange, CA 92668.

The dorsal column nucleus (DCN) in reptiles, Caiman crocodilus, like its mammilian counterpart, is a heterogeneous area. The present experiments investigated the origin of cerebellar projecting neurons of the DCN as well as the presence of local circuit neurons (LCN).

The origin of cerebellar projecting DCN neurons was determined by horseradish peroxidase (HRP) injections into the cerebellum in 10 animals. Tissue was processed by standard neurohistochemical techniques using tetramethylbenzidine as the chromogen. Rostral and central cerebellar HRP injections, primarily labeled neurons in the rostral half of the DCN. However, injections of the most posterior cerebellum resulted in retrogradely labeled DCN cells that were located caudally as well as rostrally.

The presence of LCN was investigated by standard immunocytochemical techniques using a polyclonal antibody to GABA, a polyclonal antibody to GAD, and a monoclonal antibody to GAD (epitopes GAD-1 and GAD-2) both with and without colchicine pretreatment. Although reactive neurons were found in other brain regions, no GABA (+) or GAD (+) neurons were identified in the DCN.

These present results, and those of previous studies, indicate the following. First, relay cells of the DCN of Caiman that project to the spinal cord, midbrain, and cerebellum originate from separate populations in the DCN. Second, using GABA and GAD immunoreactivity as an indicator for the presence of LCN, the DCN of Caiman lacks these presumed intrinsic inhibitory cells. These data suggest that neuronal circuits and relay cells of the DCN that project to the spinal cord, midbrain, and cerebellum are phylogenetically ancient but that the presence of LCN may be a new feature in the evolution of the DCN.

GABA AND GLYCINE IMMUNOREACTIVITY IN THE TECTUM OF THE RATTLESNAKE. R.M. Meszler and L.B. McCleary*. Anatomy Dept., Dental School, Univ. of Maryland at Baltimore, Baltimore, Maryland 21201.

The optic tectum in the rattlesnake is known to be the site of integration of signals from the visual and infrared receptor systems. Retinal projections terminate in superficial layers including SGFS a,b,c (stratum griseum et fibrosum superficiale) and SGC (stratum griseum centrale) whereas infrared projections end in the deeper portion of SGC and SFC (stratum fibrosum centrale; Hartline et. al. Science 199:1225-1229, 1978). Golgi preparations of rattlesnake tectum reveal several morphological types of neurons with radial orientation and dendritic fields that straddle 2 or more tectal layers. Furthermore, the spectrum of morphological types of synapse varies significantly between the superficial and deeper layers. (Meszler, Anat.Rec.218(1):90A-91A,1987).

The localization of immunoreactivity to GABA and glycine in the rattlesnake tectum was investigated using antibodies kindly supplied by Dr. R. J. Wenthold (NINCDS-NIH). Vibratome sections of perfusion fixed brains (4% formaldehyde, 0.5% glutaraldehyde, 0.1M cacodylate buf. pH 7.4) were processed immunocytochemically, visualized using the Vectastain avidin-biotin-peroxidase complex method and prepared for light and electron microscopy.

Both antibodies produced strong staining of somata and dendrites. Staining for GABA reactivity appeared in: (1) occasional small somata and dendrites between the bundles of axons in SO (stratum opticum), (2) small somata in all three sublayers of SGFS including cells with tangentially running dendrites, (3) small, medium and large somata with radial dendrites in SGC and (4) scattered small somata in SFC. Glycine immunoreactivity was also present in somata in the same tectal layers, but mainly restricted to small neurons.

These observations are consistent with those of Hartline and Rockland (Soc.for Neurosci.Abstr.13(1):307,1987) for GAD reactivity and suggest that GABA and glycine, which are believed to be major inhibitory neurotransmitters, play an important role in the tectum, presumably in relation to integration of converging sensory signals. Supported by NIH Grant #1R01NS21989-01A1.

THE DISTRIBUTION OF GLUTAMATE, GABA, BENZODIAZEPINE, MUSCARINIC, AND OPIATE RECEPTORS IN THE AVIAN TECTUM R.L. Albin, E.K. Richfield, A. Reiner, A.B. Young, J.B. Penney. Dept. of Neurology, University of Michigan, Ann Arbor, MI 48109; and Dept. of Anatomy, University of Tennessee Health Science Center, Memphis, TN 38163.

A major visual center of vertebrates is the tectum. This structure achieves its greatest complexity in birds, where it possesses fifteen distinct laminae. Prior studies have provided data about the neurotransmitters of afferents and interneurons of the avian tectum. To complement these studies, we used standard techniques of receptor autoradiography to study the distribution of several neurotransmitter receptors in three White Carneaux pigeons (Columba livia). There was differential distribution of receptors with GABA-A and benzodiazepine receptors densest in layers 1-13 and 15; GABA-B receptors densest in layers 1-2 and 4; muscarinic receptors densest in layers 1-2, and 5; delta opiate receptors densest in layers 1-13, and 15; total glutamate binding densest in layers 1-2, 5, 7, and 15, NMDA subtype in layers 1-13, Quisqualate subtype in layers 1-2, 5, 15. The laminar distribution of receptors correlates well with previous knowledge about neurotransmitters of tectal afferents and interneurons. Supported by EY05298 and NS19620 to A. Reiner, and NS 19613 to A.B. Young.

CEREBELLAR CONNECTIONS OF THE TRIGEMINAL SYSTEM IN THE PIGEON. J.J.A. Arends and H. P. Zeigler, West Laboratory, American Museum of Natural History, NY 10024, and Biopsychology Program, Hunter College (CUNY), NY 10021.

WGA-HRP tracing methods were used to delineate trigemino-cerebellar projections in the pigeon and identify cerebellar connections with jaw premotor neurons.

The mossy fiber projection originates solely from subnucleus oralis of the nucleus of the descending trigeminal tract (nTTD) and terminates bilaterally (predominantly ipsilaterally) in cerebellar cortical lobules VIII and IXa. Trigeminal input to the climbing fiber system originates in the caudal part of the subnucleus interpolaris of nTTD and is almost completely contralateral. Interpolaris injections produce anterograde label in medial portions of both the ventral and dorsal lamellae of the inferior olive (OI), overlapping the areas retrogradely labelled from injections in lobules VIII and IXa. However, OI injections also retrogradely label a portion of the medullary lateral parvocellular reticular formation (Rpc) adjacent to nTTD and this region (Plexus of Horsley) also receives a projection from nTTD. Thus the existence of a second (trigemino-reticulo-cerebellar) pathway cannot be excluded.

The medial cerebellar cortical zone of lobules VIII and IXa receiving dense trigeminal projections connects exclusively with the caudal pole of the medial cerebellar nuclear complex (CbM). CbM projects upon a portion of Rpc containing jaw premotor neurons. Our results thus define a trigemino-cerebellar circuit, putatively involved in the sensorimotor control of the pigeon jaw.

LEARNING AND MEMORY: PHARMACOLOGY I

27.1

RECOVERY ON A REINFORCED ALTERNATION TASK WITH THA USING A SEQUENTIAL LESION MODEL FOR ALZHEIMER'S DISEASE. J.P. Kesslak, K. Kamali*, A. Korotzer*, A. Song*, & C.W. Cotman, Dept. of Psychobiol., Univ. of Calif., Irvine, CA 92717

The neuropathology of Alzheimer's disease (AD) is characterized by loss of neurons in the entorhinal cortex. This loss may contribute to memory impairment in AD. Entorhinal cell loss such as seen in AD can be simulated in rats by sequential lesions of the entorhinal cortex. The behavioral consequences of the lesions can be evaluated on a reinforced alternation task in a T-maze. Tetrahydro-aminoacridine (THA), a cholinesterase inhibitor, was administered to rats after entorhinal lesion to determine its effects on behavioral recovery. Rats were given unilateral entorhinal lesions and tested for 15 days. The lesions produced a transient deficit on the alternation task. THA (0.5 mg/kg) enhanced recovery while a higher dose of THA (5 mg/kg) impaired recovery. After this phase of testing, rats received lesions of the contralateral entorhinal cortex. Rats receiving a unilateral lesion after extensive training (i.e., undamaged in phase 1) did not show any impairment on the alternation task. Sequential bilateral lesions produced a long term deficit, making significantly more errors than undamaged controls during the 15 days of testing in phase 2. The 0.5 mg/kg THA group exhibited recovery intermediate between control and bilateral-lesion saline injected group. The group receiving 5 mg/kg THA after bilateral lesions did not differ from the bilateral lesion-saline group.

27.2

CHOLINESTERASE INHIBITION AFTER IN VIVO TACRINE IN RAT BRAIN AND BLOOD: DOSE-RESPONSE AND TIME COURSE. Kathleen A. Sherman and Erik Messamore*, Dept. Pharmacol., Southern IL Univ. Sch. Med., Springfield, IL 62794-9230

Tacrine (THA) is a cholinesterase (ChE) inhibitor which has stimulated considerable interest because of marked improvement reported in Alzheimer dementia after THA (Summers et al., NEJM 315:1241, 1986). THA has comparable potency to the carbamate inhibitor physostigmine (PHYSO) in vitro, but acts reversibly on an allosteric site rather than the catalytic site of ChE. Inhibition of acetyl-ChE (AChE) after THA in vivo, however, was modest compared to PHYSO in several studies, raising questions regarding the role of AChE inhibition in the mechanism of therapeutic concentrations. We report that AChE inhibition measured after THA in vivo decreases with increasing dilution of tissue for assay. We have characterized dose-response and time course functions for ChE inhibition after THA in various brain regions, plasma and red blood cells (RBC) using minimal tissue dilution for assay. Plasma ChE was inhibited near maximally by 5 min, but peak inhibition of brain or RBC did not occur until 30-60 min after 5 mg/kg THA, s.c. In brain and plasma, near maximal inhibition was maintained through 3 hr and then declined to control activity by 9 hr. AChE in cortex and hippocampus was inhibited 14-21% after 0.625-2.5 mg/kg THA, the dose range associated with improved retention in mice. Maximal inhibition occurred after 10-20 mg/kg THA and was 72-80% in hippocampus and cortex and 80% in plasma and RBC.

27.3

BEHAVIORAL AND NEUROCHEMICAL EFFECTS OF GALANTHAMINE IN MICE. J.E. Sweeney and J.T. Coyle. Departments of Environmental Health Science and Neuroscience. The Johns Hopkins University, Baltimore, MD 21205.

Previously, we have shown that galanthamine (Gal), a long-acting reversible central acetylcholinesterase (AChE) inhibitor, significantly improved performance on a water maze task of nucleus basalis magnocellularis (nBM)-lesioned mice and significantly impaired performance of controls (5.0 mg/kg, i.p. given 3.5 hours before testing). We now show that Gal improves performance of nBM-lesioned mice on a passive avoidance task by increasing latency to enter the dark compartment. Gal exhibits an inverted U-shaped dose-response curve characteristic of AChE inhibitors, with 3.0 mg/kg being the most effective dose at reversing the behavioral deficit. Further studies indicate that alterations in performance are not due primarily to changes in motor activity.

Using the Ellman method, *in vitro* analyses of AChE inhibition in cortical tissue have shown that Gal exhibits an IC_{50} of 17 μM. Analysis of brain homogenates *in vitro* 4 hrs after a Gal dose of 5.0 mg/kg i.p. (17 μmoles/kg) revealed significant inhibition of AChE activity. When extrapolated for the dilution of the tissue in the assay, this inhibition is equivalent to an 85% inhibition of AChE in cortical tissue *in vivo*. These data continue to support the hypothesis that Gal is a centrally active AChE inhibitor that reverses the behavioral deficits resulting from basal forebrain cholinergic lesions. Thus, Gal may have therapeutic utility in correcting the cholinergic deficits of Alzheimer's Disease.

27.4

HEMICHOLINIUM-3 (HC-3) PRETREATMENT ATTENUATES THE MEMORY IMPAIRMENTS AND PRESYNAPTIC CHOLINERGIC DEFICITS INDUCED BY ETHYLCHOLINE AZIRIDINIUM ION (AF64A). J.J. Chrobak, M. Spates*, T. Demetriou* & T.J. Walsh. Dept. of Psychology, Rutgers Univ., New Brunswick, NJ 08903.

Ethylcholine aziridinium ion (AF64A) is a neurotoxic analog of choline whose specificity is a consequence of an interaction with high affinity choline transport (HAChT) sites located on cholinergic nerve terminals. ICV administration of doses less than 3 nmol/side produces regionally select alterations of hippocampal cholinergic indices (Leventer et. al., Neuropharmacology, 26, 36,1, 1987). The loss of cholinergic markers induced by AF64A can be attenuated in vitro and in vivo by pretreatment with inhibitors of high affinity choline transport (HAChT) (Curti et. al., J. Membrane Biol., 82, 259, 1984; Potter et. al., Soc. Neurosci. Abst., 326.7, 1987). Previously, we have shown that icv administration of AF64A produces working memory impairments in the rat (Chrobak et. al., Brain Res., 414, 15, 1987; Chrobak et. al., Brain Res., in press). The present study examined whether pretreatment with HC-3, a more potent inhibitor of HAChT than AF64A, would attenuate the memory deficits and neurochemical alterations induced by icv administration of AF64A.

Male Sprague-Dawley rats were trained to perform a eight arm radial maze (RAM) task in which a one hour delay was imposed between the fourth and fifth arm choice. Following acquisition, rats were injected with AF64A (3nmol/side/icv)(AF group) or AF64A preceded by HC-3 (20 μg/ side/icv)(HA group). Control animals received either CSF or HC-3 (20 μg).

AF64A-treated rats were significantly impaired in their performance of the RAM task. This behavioral deficit was associated with a significant decrease (34%) in HAChT in the hippocampus. In contrast, no significant decreases in HAChT or RAM performance were observed in HA group. These findings support the hypotheses that the behavioral deficits associated with icv administration of AF64A are directly related to the compound's cholinotoxic properties and in particular its interaction with the HAChT carrier and further, that a select alteration of septohippocampal cholinergic activity is sufficient to produce an impairment in working memory processes.

SELECTIVE CENTRAL NICOTINIC RECEPTOR BLOCKADE INHIBITS PASSIVE, BUT NOT ACTIVE, AVOIDANCE LEARNING IN RATS. K. Elrod and J.J. Buccafusco. Dept. Pharmacology and Toxicology, Med. Col. GA and Vet. Admin. Med. Ctr., Augusta, GA 30912.

The influence of s.c. administration of the centrally-acting nicotinic antagonist mecamylamine (MEC) 20 min prior to active (AA) or passive (PA) avoidance training or testing was examined in male, Wistar rats. MEC (10mg/kg) prior to AA training failed to induce performance deficits compared with saline (SAL) controls. A higher dose of MEC (25mg/kg) did produce AA impairment, however, selective blockade of peripheral nicotinic receptors with 25mg/kg hexamethonium (HEX) produced a similar degree of impairment. MEC (0.5, 5 or 25mg/kg) prior to AA testing or testing in a standard 1 trial 24 hr PA paradigm failed to alter performance in either task. MEC (25mg/kg) however, impaired PA performance when administered prior to training as indicated by significantly lower testing step-through latencies compared with pretraining injection of SAL or HEX. Furthermore, MEC (25mg/kg) prior to training in a multi-trial acquisition version of PA failed to induce deficits in acquisition. The selective effect of MEC on PA performance, then, appears to be directed at processes mediating retention. Ongoing neurochemical studies are directed at elucidating the mechanism of action by which MEC exerts its cognitive effect. Suppt. by Smokeless Tobacco Research Council and the Vet. Admin. Med. Ctr.

27.6

PHYSOSTIGMINE ENHANCES SHORT-TERM MEMORY PROCESSES IN YOUNG RATS. C.A. Castro, R. Paylor, J.W. Rudy, and T.B. Moye*. Departments of Psychology, Uninversity of Colorado, Boulder, CO 80309 and San Jose State University, San Jose, CA.

Recently, we used a conditional-spatial alternation discrimination task to demonstrate that the rats' ability to use its short-term memory for recent events begins to emerge between 21 and 24 days after birth. Rats 21 days old are able to remember events that are seperated by 30 sec delays, but are unable to remember events sepeated by 60 sec. Since the cholinergic system is thought to contribute to performance in this task, we sought to determine whether the administration of the anticholinesterase, physostigmine, could enhance the 21 day olds' short-term memory capacity.

Twenty-one day old subjects were trained to solve a conditional-spatial discrimination problem. After solving the problem, subjects received an injection (s.c.) of either physostigmine (0.2, 0.02, 0.002 mg/kg), neostigmine (0.02 mg/kg), or a saline vehicle. The subjects were then tested for their ability to remember information over either a 30 or 60 sec interval. The results were dramatic. Saline and neostigmine treated animals could bridge the 30 sec delay, but their performance fell to chance when the delay was 60 sec. In contrast, there was no drop in the performance of physostigmine treated (.02) animals at either the 30 or 60 sec delay.

These results suggest that the maturation of the central cholinergic system contributes to the emergence of short-term memory processes in the developing animal.

27.7

EFFECTS OF COMBINED NICOTINIC AND MUSCARINIC BLOCKADE ON RADIAL-ARM MAZE PERFORMANCE. E. D. Levin, S. R. McGurk, D. South* and L. L. Butcher. Dept. of Psychology, Univ. of California, Los Angeles, CA 90024-1563.

Separate blockade of either nicotinic or muscarinic acetylcholine receptors has been found to impair choice accuracy in the radial-arm maze. We investigated the effects of combined nicotinic and muscarinic blockade. After being trained to run in an 8-arm radial maze for food rewards, female albino rats (N=18) were injected ip with saline, scopolamine (0.15 mg/kg), mecamylamine (10 mg/kg) or a combination of both drugs in a counterbalanced order 20 min before testing. With saline the rats made 6.89±0.23 (Mean±SEM) arm entries before repeating an entry. All three drug treatments caused significant ($p<.01$) decreases in choice accuracy. The entries to repeat scores were: scopolamine 4.50±0.58, mecamylamine 5.39±0.36 and scopolamine + mecamylamine 3.06±0.39. The combination treatment significantly ($p<.05$) decreased accuracy relative to either of the drugs alone. The scores after combination treatment were lowered to essentially random performance (3.19). These data show that nicotinic and muscarinic blockade have at least additive effects in producing a cognitive deficit. Given that both types of receptors have been found to be reduced in Alzheimer's disease, combination blockade may provide a good model for this disorder. 27.8

SND-5008 (AF102B), A NOVEL MUSCALINIC AGONIST, IMPROVES EXPERIMENTAL COGNITIVE DYSFUNCTIONS IN RODENTS. Y.Iga*, N.Nakahara*, F.Mizobe, N.Ohgane*, T.Sawai*, T.Nakajima* and G.Kawanishi*. Res.Inst.of Life Sci., Snow Brand Milk Products Co.,Ltd. Tochigi 329-05, Japan

Senile dementia of Alzheimer's type (SDAT) is characterized by central cholinergic dysfunctions, whereas post-synaptic M1 receptors on cholinoceptic neurons are found to be preserved. Therefore, M1 agonist is considered as a candidate drug for SDAT. In the present study we examined the effects of a novel M1 agonist SND-5008 on learning behavior in AF64A-injected (i.c.v.) rats, basal forebrain (BF) lesioned rats and scopolamine-induced amnesia mice.

AF64A-rats showed inferior performance in a radial-arm maze task. SND-5008 (1.0 and 5.0 mg/kg, p.o.) significantly decreased the number of incorrect response. BF lesions produced significant deficiency in two-way shuttle active avoidance performance. SND-5008(1.0 mg/kg, p.o.) significantly enhanced the avoidance rate without increace of unavailable response. Scopolamine impaired the retention latency in a passive avoidance task in mice. SND-5008 (1.0 and 5.0 mg/kg, p.o.) significantly extended the retention latency. Taken together with our earlier data (Soc.Neusci.Abstr.13 837,1987), the results strongly indicate that SND-5008 improves the learning and memory impairment associated with central cholinergic dysfunctions in rodents.

27.9

ASSOCIATIVE AND NONASSOCIATIVE CONTRIBUTIONS OF THE CHOLINERGIC SYSTEM TO PERFORMANCE IN THE MORRIS WATER TASK IN DEVELOPING RATS. R. Paylor and J.W. Rudy, Psychology Dept., Colorado University, Boulder, CO 80309.

Rat pups learn to navigate to a visible platform in the Morris water task when they are 17 days old, but are unable to learn the location of a platform until they are 21 days old. In adult rats, blockade of central cholinergic muscarinic receptors impairs place learning, without effecting cued navigation. In the present study we looked at the contributions the cholinergic system makes to place and cued learning in 17, 21, and 80 day-old rats using both a gray and white Morris water maze.

Consistent with the existing literature, cholinergic receptor blockade completely disrupted place learning. However, cued navigation was also impaired. The magnitude of the cued-navigation impairment was dependent upon age, context, and drug: (a) both 24- and 80-day-old scopolamine-treated rats were impaired in a gray tank compared to a white tank, but the younger pups were more impaired. (b) Saline-treated 24 day olds, but not adults were impaired in the gray tank. (c) The performance of 17-day-old scopolamine-treated pups on the cued task did not improve with training. In addition, the 17-day olds impaired performance on the cued-navigation task in the gray tank was attenuated by the cholinergic agonist, physostigmine.

The results suggest that the developing central cholinergic systems contribute to successful performance in the Morris water task by enabling the animal to (a) acquire spatial information and (b) inhibit interfering behaviors.

27.10

EFFECTS OF AF64A ON RADIAL-ARM MAZE MEMORY TASKS IN RATS. S.E. MacNeill, D.E. Walters, and R. C. Speth. Dept. of Psychology, Wash. State Univ., Pullman, WA 99164-4830.

ICV injections of mustard aziridinium (AF64A) have been shown to permanently damage cholinergic neurons of the hippocampus, while preserving the integrity of the cerebral cortex and straitum (Hanin, 1983). Because of this apparent long term cholinergic deficit, AF64A has been suggested in the study of Alzheimer's disease. Adult male Sprague-Dawley rats were given intracerebral bilateral injections of 8nmol AF64A, followed by testing for reference memory on a modified radial-arm maze; and choline acetyltransferase (ChAT) assays. Second, dipsogenic responses to carbachol were tested, and a third experiment tested recall of working memory, and delayed response on the radial-arm maze. Results indicate faster completion of the maze and increased frequency of errors in treated rats, accompanied by 50% decreases of ChAT activity.

	Average Time on Maze*	Average Errors*
Lesioned Rats	100.5±28	18.0±14.0
Control Rats	282.5±37	7.8± 2.9

*mean ± s.d.

The carbachol studies, and ensuing behavioral studies are currently in progress. These results should help assess the value of AF64A in studies of neurological disorders such as Alzheimer's disease.

27.11

EFFECTS OF PRAMIRACETAM AND PHOSPHATIDYL CHOLINE ON SPATIAL MEMORY DEFICITS IN MICE WITH LESIONS OF THE NUCLEUS BASALIS OF MEYNERT. N. M. Qashu* and A. E. Powell* (SPON: F. Volkmann). Department of Psychology, Smith College, Northampton, MA 01063.

This study investigated the role of pramiracetam as a cognitive adjuvant in an animal model of Alzheimer's Disease. The study examined the effects of nucleus basalis of Meynert (nbM) lesions and pharmacological agents on spatial memory as measured in a milk maze task. There were four groups: a control group receiving saline only, a control group receiving a diet of (86.4mg/kg) phosphatidyl choline (PC) and pramiracetam (10mg/kg), a lesion group (nbM) receiving saline, and a lesion group receiving pramiracetam and PC. Results showed that the interaction of lesion and day was marginally significant. There was no effect of day for lesioned animals, yet unlesioned animals did show such an effect. The drug by lesion effect was also significant. The unlesioned animals receiving saline performed significantly faster than the lesioned animals receiving saline. There was no significant difference in performance between control animals receiving drug/diet and lesioned animals receiving drug and diet. There was also no significant difference in performance between the unlesioned animals that received saline and the unlesioned animals receiving drug and diet. However, among lesioned animals, the animals receiving drug and diet performed significantly faster than those receiving saline. These results confirm the hypothesis that pramiracetam administered with phosphatidyl choline can reverse spatial memory deficits caused by lesions of the nucleus basalis of Meynert. THE EFFECTS OF GALANTHAMINE, AN ACETYLCHOLINESTERASE INHIBITOR, ON LEARNING AND MEMORY IN MICE AND MONKEYS. G.P. Vincent, N. Pietrusiak*, L. Rumennik* and J. Sepinwall. Neurobiology and Obesity Research, Hoffmann-La Roche Inc., Nutley, NJ 07110.

Galanthamine (Gal), claimed to be a long-acting acetylcholinesterase inhibitor, improved acquisition in a Morris water maze by C57BL/10 mice, i.e., it significantly decreased the latency to find the hidden platform. When given i.p. 30 min before testing, it was active from 0.1 to 1 mg/kg. When the pretreatment time (pt) was varied, Gal 0.1 mg/kg i.p. was active from 15 min to 3 hr, with peak effect occurring at 2 hr. When given i.p. with 2 hr pt, Gal was active from 0.1 to 3 mg/kg. When given p.o. 60 min before testing, Gal was active from 0.03 to 0.3 mg/kg. When the pt was varied, Gal was active 60 and 90 min after p.o. dosing. C57BL/10 mice are deficient in using distal room cues to locate the hidden platform and this deficit can be ameliorated with certain cognitive enhancing (CE) agents (Pietrusiak, et al., Soc. Neurosci. Abstr. 12:705, 1986). Gal (0.1 mg/kg, i.p., 2 hr pt.) tested using only distal room cues significantly decreased the latency to locate the hidden platform, thus reversing the behavioral deficit. In squirrel monkeys Gal improved the accuracy of retention on a delayed match-to-sample procedure by 6-21% (0.03-1.0 mg/kg, i.m.). Thus Gal has potent CE activity with a rapid onset and a long duration of action, especially after parenteral administration.

PRENATAL CHOLINE EXPOSURE PRODUCES LONG-TERM IMPROVEMENT IN TEMPORAL PROCESSING. W.H. Meck, A.G. Shapiro, and C.L. Williams. Department of Psychology Columbia University, New York, New York 10027.

Exposure to choline chloride supplementation during early development has been shown to have facilitative effects on spatial memory processes that extend well into adulthood (Meck et al., Dev. Psychobio. 21, 1988). We now report that a relatively brief period of prenatal choline supplementation is sufficient to modify temporal processing in adult male Sprague Dawley rats as indexed by the peak-interval (PI) timing procedure (Meck et al., J. Neurosci. 2:292, 1987). Using a 20-sec PI procedure with visual signals we demonstrated that in the course of 5 weeks of training prenatal choline exposure 1) alters the content of temporal in a dynamic fashion as a function of training and 2) significantly improves the differentiation between the response states involved in temporal regulation. These data support previous findings that modifications in cholinergic function alter the content and sensitivity of temporal memory by changing the speed of memory storage processes (Meck & Church, Behav. Neurosci. 101:457, 1987).

27.14

CHOLINE SUPPLEMENTATION DURING DEVELOPMENT: TIME FRAMES FOR SPATIAL MEMORY FACILITATION. A.G. Shapiro, C.L. Williams, and W.H. Meck. Department of Psychology Columbia University, New York, New York 10027.

Supplementation of choline chloride during early developmental periods has been reported to facilitate performance in spatial memory tasks such as the radial arm maze. This effect can be measured long after the initial treatments, suggesting that early doses produce organizational changes in cholinergic function. In the present study, six groups of male rats were exposed to choline at various periods of development in search of time frames where different organizational changes could occur. One pre- and 5 postnatal exposure periods were evaluated. Prenatally choline was administered through the drinking water (5 ml/L) of the pregnant dams. Postnatally choline was given by s.c. injections (300 mg/kg) on days 1-15, 16-30, 31-45, 46-60, and 61-75.

From 7-17 months of age treated and untreated rats were tested on a 12-arm radial maze with working and reference memory components. The results indicate a choline produced facilitation of spatial memory that varied as a function of exposure period in terms of susceptibility to disruption of memory processes.

27.15

EXPOSURE TO CHOLINE DURING DEVELOPMENT IMPROVES SPATIAL MEMORY CAPACITY OF MALE AND FEMALE RATS.

C.L. Williams, I. Tatsis*, and W.H. Meck
Department of Psychology
Barnard Col. & Columbia Univ., NY, NY 10027.

Previous work has shown: **1)** exposure to choline during development enhances spatial memory of male rats (Meck et al., Dev. Psychobiol. 21: 1988), **2)** females are less accurate than males during the acquisition of a spatial task, perhaps due to differential cue selection (Williams et al., Behav. Neurosci., in press). In the present study, we investigated the organizational effects of choline in both males and females. Pregnant dams received 0 or 5 ml choline chloride/L water. Pups (n=40, 10/condition) were raised by untreated foster dams and injected s.c. with saline or choline chloride (300 mg/kg) for 24 days. Subjects were gonadectomized at 60 days of age; testing began 20 days later. A radial maze with 8 baited and 4 unbaited arms was used for behavioral tests.

Results indicate that while early choline treatment significantly enhances memory capacity of both male and female rats, choline appears to improve choice accuracy of males more than females, and to influence choice latency in a sexually dimorphic manner. (NS 30671 to CLW)

27.16

RECEPTOR CHANGES ASSOCIATED WITH MEMORY DEFICITS FOLLOWING REPEATED ORGANOPHOSPHATE (DFP) EXPOSURE. K.C. Raffaele and D.S. Olton. The Johns Hopkins University, Baltimore, MD 21218.

The central cholinergic nervous system is important for performance of many learning and memory tasks. Organophosphates (OPs) interfere with the normal functioning of the cholinergic nervous system by irreversibly inhibiting the enzyme, acetylcholinesterase, which breaks down acetylcholine. Repeated exposure to OPs produces a down-regulation of muscarinic receptors. To investigate the relationship between sensitivity to scopolamine (a muscarinic receptor antagonist) and changes in muscarinic receptor levels, rat were tested in two different memory tasks before, during, and after repeated exposure to DFP, an organophosphate anticholinesterase. The rats were evaluated for changes in performance and changes in sensitivity to scopolamine, and changes in receptor levels and acetylcholinesterase activity were measured. The total number of muscarinic receptors (QNB binding) was reduced in both cortex and hippocampus at two time points after DFP treatment had ended. Acetylcholinesterase activity was also reduced at both time points. These changes in acetylcholinesterase activity and the number of muscarinic receptors were associated with the changes in sensitivity to scopolamine, which lasted throughout the period during which reductions were demonstrated.

ANTAGONISTIC EFFECTS OF ATROPINE, SCOPOLAMINE, AND APROPHEN AGAINST PHYSOSTIGMINE ON A REPEATED ACQUISITION RADIAL-ARM MAZE TASK IN RATS. J. R. Leu. Department of Medical Neurosciences, Division of Neuropsychiatry, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

Three anticholinergic drugs, atropine, scopolamine, and aprophen, were tested for efficacy in antagonizing the performance decrements induced by the cholinergic drug physostigmine. The task used was a repeated acquisition radial-maze task described elsewhere (1,2,3). This task requires the animal to search the various arms of a multi-arm radial maze to determine which arms are reinforced during a particular test session. The animal may then repeatedly procure food by alternating between these active arms. This procedure measures long-term memory of the task, the ability to form new associations and the ability to remember immediate past activities.

The range of effective antagonism of anticholinergic drugs, against the performance altering effects of physostigmine, was determined. All drugs provided effective antagonism at some dose. Aprophen was the most potent, and had the widest range of antagonism. Atropine and scopolamine were neither as potent nor as effective. Refs: (1)Popp & Leu (March, 1985). Proceedings and Abstracts: Eastern Psychological Association, 56. (2)Leu & Johnson (April, 1987). Proceedings & Abstracts: Southwestern Psychological Association, 33. THE EFFECTS OF SCOPOLAMINE ON DELAYED RESPONSE IN RHESUS MONKEYS. R. Lalonde and T.G. Aigner. Neurology Service, Hotel-Dieu Hospital, Montreal, Canada H2W 1T8 and Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892.

We have previously reported that the anticholinergic agent scopolamine (SCOP) impairs the performance of monkeys on a variety of object memory tests including recognition, recency, and recall. The results further indicated that SCOP acts at an early stage of memory, preventing information from entering even into an immediate store. To determine if these findings also apply to spatial memory, we administered SCOP to 2 monkeys trained in delayed response with 0 to 10-sec delay intervals. During the delays, an opaque screen was lowered to block the animal's view of the wells, except on half of the 0-sec delays when the screen was not lowered. The effects of SCOP (10.0, 17.8, 32.0, and 56.0 ug/kg, i.m. 20 min before testing) were then evaluated, first at the 10-sec interval and ending at the 0-sec intervals, with and without the screen. Although higher doses were required, SCOP had the same consequences on this task as on our previous ones, decreasing the percent correct choices in both monkeys in a dose-related manner on all conditions except the 0-sec delay without the screen, where it was ineffective. These results support and extend our previous conclusion that SCOP impairs the earliest stage of information storage.

PILOCARPINE DURING ACQUISITION DISRUPTS SUBSEQUENT REVERSAL IN N. BASALIS-LESIONED RATS: PRELIMINARY DATA. W. Jeffrey Wilson & Jennifer C. Hall*. Dept. of Psychological Sciences, Indiana-Purdue University, Fort Wayne, IN 46805

The n. basalis magnocellularis, source of cholinergic innervation of much of the cortex, has been implicated in normal memory functions, and in the impairments of memory that accompany Alzheimer's disease. Rats with lesions of the nbM have proven deficient in the acquisition and reversal of simple (i.e., learnable within a single session) discrimination problems. We report data from a preliminary study involving acquisition and reversal of a difficult visual discrimination problem, in which lesioned rats did not differ from sham-lesioned controls. However, exposure to the cholinergic agonist pilocarpine during a given reversal made the subsequent reversal more difficult. We suggest that this could have resulted from the development of supersensitive cortical cholinergic receptors as a result of the nbM lesion. The pilocarpine would thus have had a greater effect on the cholinergic receptors of the lesioned rats, resulting in a greater "stamping in" of the problem being learned, interfering with the later reversal of that discrimination.

After being shaped to press either lever in an automated T-maze, for a sweetened milk reward, rats received either electrolytic (n=8) or sham (n=8) lesions of the nbM. Following a 1 week recovery period, rats were again reduced to 80% of their free-feeding weight, then were trained in a 2-way visual discrimination requiring the choice of either the lighted or dark arm of the maze. Following Acquisition, rats received 6 consecutive Reversals. Sessions consisted of 150 trials, run daily until the criterion of 8 correct choices in a row was achieved. Reversal began at the start of the next session. 15 min prior to Reversals 3&4 rats received 3 mg/kg pilocarpine i.p., preceded by 1 mg/kg methyl scopolamine i.p. Saline was given on the other Reversals. As a result of post-op deaths and histology, n's were Sham = 7 and nbM = 3. Pilocarpine had no effect on performance during the session on which it was given; reversals of habits acquired under the influence of pilocarpine required more trials for nbM rats than for sham-lesioned controls. 27.20

NEUROCHEMICAL STUDIES OF E-2020, A NOVEL CENTRALLY ACTING ACETYLCHOLINESTERASE INHIBITOR. Y.Yamanishi*, S.Araki*T.Kosasa*H.Ogura*and K.Yamatsu*(SPON:Y.Sugiura). Eisai Tsukuba Res.Lab.,5-1-3 Tokodai,Tsukuba-city, Ibaraki, 300-26 Japan.

Novel piperidine derivatives, newly synthesized in our laboratory, showed potent inhibitory action on cholinesterase. In this study, we performed some neurochemical experiments to test E-2020, 1-benzyl-4-[(5,6-dimethoxy-1-indanon)-2-yl]methylpiperidine hydrochloride, one of the derivatives, compared with physostigmine(PHY) and tetrahydroaminoacridine(THA). IC50 of E-2020 in vitro on acetylcholinesterase(AChE) was 5.3nM. IC50 of THA and PHY were 52nM and 0.43nM, respectively. E-2020 inhibited AChE selectively 570 fold more than butyrylcholinesterase. The inhibition of AChE was reversible. In ex vivo experiment, E-2020 inhibited AChE in rats' brains dose-dependently at 1 to 30 mg/kg, p.o.. This inhibition lasted more than 4 hrs at 5 mg/kg. The inhibitory effect of E-2020 on AChE was more potent and longer than those of THA and PHY. E-2020 increased ACh content in rats' brains at 5 to 20 mg/kg, p.o.. At 2.5 mg/kg, p.o., it antagonized not only the decrease of ACh content in the frontal cortex induced by the lesion of nucleus basalis magnocellularis but also the depletion of ACh by scopolamine.

In conclusion, these data indicate that E-2020 is a potent centrally acting AChE inhibitor which may serve as a drug for Alzheimer's disease.

27.21

BEHAVIORAL STUDY OF E-2020, A NOVEL CENTRALLY ACTING ACETYLCHOLINESTERASE INHIBITOR. H.Ogura*,T.Kosasa*,S.Araki*, Y.Yamanishi* and K.Yamatsu*(SPON:Y.Arakawa). Eisai Tsukuba Res.Lab.,5-1-3 Tokodai,Tsukuba-city,Ibaraki,300-26 Japan.

E-2020 is a new piperidine derivative, which inhibits acetylcholinesterase potently in in vitro and ex vivo studies. We designed this study to evaluate its potency in behavioral tests compared with tetrahydroaminoacridine (THA). First, we studied effects on scopolamine-induced impairment in 8-arm radial maze. Male Wistar rats were thoroughly trained to get food chips. Scopolamine (0.5 mg/kg,i.p.) disrupted this behavior, i.e. increased errors and duration to complete the task. E-2020 antagonized these changes dose-dependently at 0.25 to 0.5 mg/kg, p.o., while THA at 1 to 2 mg/kg antagonized it. Secondly, E-2020 was tested in nucleus basalis magnocellularis (NBM) lesioned rats in a passive avoidance test. Male Wistar rats received ibotenate (5µg/0.5µl) bilaterally in NBM. Lesioned rats showed marked shortening of retention latency. E-2020 reversed the effect of the lesion at 0.125 to 1 mg/kg, p.o.. THA had a tendency to improve at 0.5 mg/kg. In the observation of general behavior after oral dosings, both E-2020 and THA produced fasciculation, a peripheral cholinergic sign, at the same dose of more than 2.5 mg/kg.

These results suggest that E-2020 has potent activity in behavioral tests and its safty margin is 4 times as wide as that of THA.

27.22

CHOLINERGIC RECEPTOR ACTIVATION AND ONE-TRIAL TASTE-AVOIDANCE LEARNING IN THE CHICK. M.R. Rosenzweig, T.A. Patterson, J. Lipton, & E.L.Bennett. Dept. of Psychology, University of California, Berkeley, CA 94720.

It has been shown that cholinergic receptor binding increases as a result of avoidance learning in the chick (Rose et al., 1980). However, involvement in a specific stage of memory formation was not determined. The present experiments were designed to examine the effects of muscarinic receptor antagonists on specific stages of memory formation (Patterson et al., 1986).

Experiment 1 determined the range of amnestic doses of scopolamine (SCOP). Chicks were given bilateral injections into the medial hyperstriatum ventrale (MHV; 10 µl per hemisphere) of either saline or different doses of SCOP, 5 min before training. Chicks were tested 24 hr after training. Results showed that 25mM - 100mM (millimolar) SCOP produced significant amnesia. In Experiment 2, the susceptibility gradient for SCOP was determined. SCOP (25mM) produced amnesia, tested 24 hr after training, when injected 10 or 5 min before training, but was not amnestic when injected earlier than 10 min before training, or at any time after training.

The time course of amnesia development following 5 min pretraining injection of SCOP was examined. SCOP (25 mM) produced amnesia that developed between 15 and 30 min posttraining; this amnesia was permanent. Further studies showed that this effect is similar to that produced by agents such as ouabain that interfere with the formation of intermediate-term memory (ITM), suggesting that cholinergic receptor activation is involved in formation of ITM.

The effects of antagonists to two cholinergic receptor-subtypes were examined. Pirenzepine (an M1 antagonist) produced amnesia in a dose-dependent manner (1.0-25 mM doses were amnestic). Gallamine (an M2 antagonist) was not amnestic, suggesting that M1 but not M2 cholinergic receptors are involved in formation of ITM in the chick.

27.23

THE EFFECT OF ATROPINE ON THE INTRACORTICAL PROFILE OF AUDITORY EVOKED POTENTIALS IN CLASSICAL AVERSIVE CONDITIONING. M. Molnár[x], G. Karmos[x], V. Csépe[x] and I. Winkler[x]. (SPON: European Brain and Behavior Society). Institute for Psychology of the Hungarian Academy of Sciences, Budapest, Hungary.

In a classical aversive conditioning paradigm intracortical auditory evoked potentials (EPs) were recorded simultaneously in six depths of the AI acoustic cortex of freely moving cats. 4 kHz meaningless background clicks given at 2/s rate were randomly interrupted by 3.6 kHz signal ones followed by an unavoidable electric shock. EPs evoked by the background and signal stimuli were averaged separately. As a result of conditioning the amplitude of a middle-latency (40-70 ms) negative component increased and its latency decreased. The observed waveform changes of the EPs were restricted to the upper layers of the auditory cortex.

Atropine (2 mg/kg i.p.) had no effect on this phenomenon. It was concluded that the observed EP changes accompanying aversive classical conditioning were probably the result of EPSPs summating in the upper cortical layers evoked by unspecific non-cholinergic afferent input.

27.24

ACTIVATION OF THE IMMUNE SYSTEM FACILITATES CONDITIONED EMOTIONAL RESPONSE LEARNING. D.T. Lysle*, B.J. Kucinski*, J.E. Cunnick*, H. Fowler*, & B.S. Rabin* (SPON: H. Barry). Departments of Pathology and Psychology, University of Pittsburgh, Pittsburgh, PA 15213-3417.

Activated lymphocytes produce many of the same hormonal factors found in the central nervous system (CNS). There is also evidence that the same hormones are involved in learning and memory processes. To assess the influence of immune activity on CNS function, the present research examined the acquisition and extinction of a conditioned emotional response during lymphocyte activation. An initial experiment showed that the learning of a conditioned fear response by Lewis rats was facilitated when the immune system was activated by sheep red blood cells (SRBC), a T-dependent antigen. However, there was no facilitation when TNP-Ficoll, a T-independent antigen, was employed. Likewise, the extinction of a conditioned fear response was facilitated by the response to SRBC, but not to TNP. Since a thermal-sensitivity test failed to show any analgesic effects of immunization, the present findings indicate that the facilitated conditioning effects were due, not to differences in unconditioned reactivity, but to differences in the rate of learning. These results imply that the immune system directly influences the CNS processes.

27.25

THE EFFECTS OF EXPERIENCE ON GAP INHIBTION OF THE ACOUSTIC STARTLE RESPONSE (ASR). K. M. Crofton, L. P. Sheets*, K. F. Dean*, and D. B. Peele, NTD, US EPA, RTP, NC 27711 and Northrop Services, Inc, RTP, NC 27709

The experiments reported here were designed to study the effects of experience on gap inhibition of the ASR. Two experiments were conducted with independent, naive groups of adult Long Evans hooded rats. They were tested using 20-msec gaps in white noise (ON 80dB/OFF 35dB) as the prestimulus (ISI = 190 msec) and a 120-dB, 40-msec white noise burst as the eliciting stimulus (ES). The first experiment was a test of associative conditioning. Three groups of rats were tested daily for 7 days under one of the following conditions: the gap and ES paired, ES only, or gap only. All groups then received both the Gap and ES for a further 7 days of testing. The second experiment studied the effects of scopolamine (SCOP) on the acquisition of gap inhibition. Animals were tested for 6 days under the following regimins: vehicle, 0.5 mg/kg SCOP 20 min prior to testing, or 0.5 mg/kg SCOP after testing. On day 7, vehicle and SCOP-after-testing groups recieved SCOP prior to testing. Results of these experiments indicate that 5-6 daily sessions are required to reach an asymptotic level of inhibition. The two stimuli must be paired for the inhibition to develop. SCOP blocks the development of this inhibition and also blocks the inhibition once it is achieved. These data suggest a learning component in the gap inhibition paradigm.

27.26

A COMPARISON OF DRUG-INDUCED EFFECTS ON ACQUISITION AND RETENTION IN THE SQUIRREL MONKEY. L. Rumennik*, G. P. Vincent, E. Schwam, and J. Sepinwall Neurobiology and Obesity Research, Hoffmann-La Roche Inc., Nutley, NJ 07110

The repeated acquisition procedure (RA) has been shown to be sensitive in identifying compounds which impair learning (Thompson, D.M. and Moerschbaecher, J.M., JEAB, 32: 433, 1979). Here a variation of the procedure was used to evaluate the learning-enhancing properties of five compounds in squirrel monkeys: d-amphetamine (0.003-0.03 mg/kg), physostigmine (0.003-0.03 mg/kg), TRH (0.01-1.0 mg/kg), piracetam (200-1600 mg/kg) and aniracetam (10-300 mg/kg). For comparison, these compounds were also tested at similar doses for their memory-enhancing effects using a delayed match-to-sample procedure (DMTS) (Schwam et al, Soc. Neurosci. Abstr., 8: 823, 1982) with retention intervals ranging from 0-195 sec. During the performance component of the RA procedure, the same well-established 4-response chain was repeated across days, while during the learning component a different 5-response chain was acquired each day. On RA, only piracetam at a single dose (800 mg/kg, ig) enhanced learning. On DMTS consistent memory-enhancing effects were obtained across retention intervals with several dose levels of aniracetam (10-100 mg/kg, ig). Less consistent memory-enhancing effects were obtained with the other compounds. The contrasting results between procedures suggest their usefulness for differentiating drug-induced enhancement of learning and memory.

27.27

HABITUATION AND RETENTION OF THE HEAD-SHAKE RESPONSE: LACK OF IMPAIRMENT BY NUCLEUS BASALIS MAGNOCELLULARIS LESIONS OR SCOPOLAMINE. C.P.J. Dokla[1], S.C. Parker*[1],& L.J. Thal[2]. [1]Dept.of Psychology,Fairfield Univ.,Fairfield,CT 06430 and [2]Neurology Service,VA Medical Center, La Jolla, CA 92161.

Pharmacological and anatomical studies have strongly implicated central cholinergic systems in learning and memory but are equivocal in regard to habituation. The present study examined the effects of cholinergic manipulation on habituation and retention of the head-shake response (HSR). HSR is a rapid, stereotyped rotation of the head about a front-to-rear axis which in the rat may be elicited by a stream of mildly pressurized air directed at the ear (Askew et al., J. Comp.Physiol.Psychol. ,67:497,1969). Fischer 344 rats received either bilateral ibotenic-acid lesions of the nucleus basalis magnocellularis (NBM) or sham-operations (SHAM). HSR training consisted of 40 stimulated trials followed by a 30-min retention test of 20 trials. Stimulus duration was 15 sec with a 15-sec inter-trial-interval. One group was given scopolamine (0.32 mg/kg,ip) 30 min prior to acquisition trials, while the NBM and SHAM groups received vehicle only. NBM lesions did not affect either habituation or retention of HSR. Although scopolamine decreased frequency and increased latency of HSR (ps $<.05$), habituation rate and retention were not significantly affected. The present results indicate that the cholinergic system may not be important in elicited types of habituation, such as HSR.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: POSTURE AND MOVEMENT I

28.1

PERCEPTION OF STIFFNESS: SENSORY THRESHOLDS L. A. Jones and I. W. Hunter. Faculty of Medicine, McGill University, Montreal, Canada H3G 1Y5

Classical psychophysical techniques have been used to determine sensory thresholds for a number of aspects of proprioception. With the exception of passively imposed movements, the stimuli detected in these experiments are generated by the subjects themselves and so it is only possible to measure difference thresholds. The sensitivity of subjects to changes in stiffness has not been systematically investigated; the objective of this experiment was to determine the difference thresholds for stiffness and to compare these values to those reported for force.

Subjects sat in an experimental rig with a linear motor connected to the wrist of each arm. Force and displacement were recorded on-line from transducers mounted on each motor and these signals were used for real-time servo-control of the stiffness of the motors. The procedure used to calculate the difference thresholds was the method of limits. On successive trials the stiffness of one motor (the comparison stimulus) was decreased or increased incrementally in the direction of the stiffness of the other motor (the standard stimulus).

The results indicate that the difference thresholds for stiffness are greater than those found for force (0.07), and that subjects can accurately detect changes in the stiffness of an external mechanical system.

A PSYCHOPHYSICAL MODEL OF KINESTHESIS: PERCEPTION OF FORCE, DISPLACEMENT AND EFFORT. C.L. Van Doren* and L.M. Javorsky* (SPON: M.W. Keith). Depts. of Biomedical Engineering and Orthopaedics, Case Western Reserve Univ., Cleveland, OH 44106.

To assist in the development of kinesthetic feedback for users of upper limb prostheses, a quantitative, psychophysical model of normal kinesthetic perception is developed. In the model, the total kinesthetic sensation is the weighted sum of three component sensations: force, displacement, and effort. The latter is proportional to the efferent command sent to the active muscles. The force and displacement sensations are power functions of their respective stimuli. The weighting given to each component depends on the instructions for a given task, such as "match a target force," or "match a target displacement." The model accounts for the interactions of force, displacement, and effort observed in previous investigations. In addition, by using a simple physiological model of motor unit recruitment, the efferent command can be expressed in terms of the fraction of MUs active in a muscle, and the probability density function for MU twitch strengths can be derived. The theoretical density function agrees well with existing measurements of MU twitch strengths in humans.

The results of a preliminary experiment are also compared to predictions of the model. Subjects matched the displacement or the force generated by MP flexion of their left and right index fingers, which were loaded by springs of different stiffnesses. The effects of spring stiffness and instructions on the matching errors are correctly predicted by the model.

28.3

FLEXION-EXTENSION DIFFERENCES IN SIMPLE REACTION TIME J.G. Anson and H.M. O'Connor*. Faculty of Physical Education and Neuroscience Research Centre, University of Otago, Dunedin, New Zealand.

Previous results (Anson & Wilson, Int. J. Neuroscience, 40, 1988) indicated no significant difference in simple reaction time (SRT) between flexion and extension for rapid initiation of movement of the index finger. However, significant ($p<.05$) differences for premotor time (PMT) were reported. Regardless of starting position, extensor PMT was shorter than flexor PMT. The present study sought to replicate the effect. In addition EMG was recorded from First Dorsal Interosseous (FDI), a possible flexor synergist though not, anatomically, an agonistic flexor of the index finger. Also subjects were asked to choose flexion and extension starting positions separately. (We had assumed in the previous study that the initially chosen starting position was equally appropriate for rapid iniation of either flexion or extension). In a second condition the agonist was put on stretch (index finger 10^{o} from self-selected start). Data from the self-selected start position support the previous result, PMT for FDI exaggerated the effect. Flexion took longer to initiate than extension but initiation from stretch reduced flexor PMT more than extensor PMT. While response conditions - limb segment, inertia and position are similar - the mechanisms underlying SRT seem different for flexion and extension.

28.4

IS 'YIELD TASK' SUPPRESSION OF PERTURBATION EVOKED M2-3 LATENCY EMG ACTIVITY DUE TO STRETCH TRIGGERED INHIBITION? J. S. Thomas, Dept. of Physiology, Meharry Medical College, Nashville, TN 37208

EMG response envelopes recorded from arm muscles of volunteer human subjects for both 'Resist' and 'Yield' TASK conditions reveal several features consistent with Yield TASK enabling of an anti-myotatically signed M3 (75-100 ms) latency response to agonist stretch. 1) Yield TASK EMG responses to muscle stretch drop below the pre-stimulus level of EMG activity (associated with resisting the pre-stimulus load offset) at 75 ms, and this suppression of agonist activity typically passes smoothly into a burst of antagonist activity. 2) The pattern of EMG inhibition evoked to an unloading torque, during a Resist TASK, is interrupted in the Yield TASK by a burst of agonist response which exceeds the pre-stimulus level of activity beginning at 75 ms. 3) A small 'neutral pulse' (+/- torque pulses) perturbation, which results in no net limb displacement and evokes no M2-3 latency activity when given alone, markedly enhances Yield TASK suppression of M2 (50-75 ms) latency activity evoked to a torque step when delivered 20-50 ms prior to a sustained loading torque stimulus. These results cannot be explained by Yield TASK 'gating' of myotatically signed M2-3 activity, but are consistent with a Yield/Assist TASK enabled, stimulus triggered, anti-myotatically signed response to load/stretch whose direct peripheral expression occurs at M3 (75 ms) latency. Stimulus triggered Yield/Assist inhibition of centrally conducted (i.e., trans-cortical?) myotatically signed transmission could occur earlier, accounting for Yield/Assist inhibition of M2 (50-75 ms) activity.

28.5

CHARACTERIZATION OF AN ARRAY OF SPINAL REFLEXES FROM THE COMMON PERONEAL NERVE TO THE VASTUS MEDIALIS MUSCLE IN HUMANS. P. Yoon, J.D. Brooke and W.E. McIlroy. Human Biology/Biophysics, Univ. of Guelph, Guelph, Ontario, CANADA N1G 2W1

To investigate translimb links, we evoked an array of spinal reflexes in tonically contracted vastus medialis muscle, from transcutaneous activation of common peroneal afferents at caput fibula in humans. Afferents were recruited by graded stimulation, and higher threshold interneurons were investigated with a pulse train (four pulses, interpulse interval = 3 ms). Four responses occurred: 1) early excitation at 25.8 ms, with one pulse at 50% of the stimulus for Mmax in tibialis anterior; 2) early inhibition at 39.5 ms, with four pulses at 50% Mmax; 3) second excitation at 58.5 ms with, four pulses at 50% Mmax; 4) later inhibition at 78.9 ms, with one pulse of 150% Mmax. Responses were powerful, statistically significant ($p < 0.05$) and attributed to afferent groups I through III. The findings show that movement interpretation of any single spinal reflex pathway in healthy humans should be constrained by the fact that the expression of spinal reflexes varies, dependent upon methodology.

MECHANISMS UNDERLYING MOTOR OUTPUT VARIABILITY STUDIED USING THE H-REFLEX TECHNIQUE. W.G. Darling and D. Rotella*, Dept. of Exercise Science, U. of Iowa, Iowa City, IA, 52242.

Studies of variability in motor output have shown that trial-to-trial variations in movement kinematics and muscle EMGs increase with increasing speed of movements. Such greater variability suggests that there are greater variations in centrally generated commands to muscles for fast movements. This hypothesis was studied using the H-reflex technique to examine variations in motor neuron excitability prior to initiation of muscle activity related to production of a controlled torque.

Volunteer human subjects produced increases in plantarflexion torque under two instructions: (1) increase torque smoothly and accurately to the target and (2) increase torque rapidly to the target. Subjects were cued with a verbal "ready" followed, after a variable time interval, by an auditory tone which served as the signal to initiate the contraction. H-reflexes (20% of maximum for soleus) were elicited in the triceps surae muscle group in about 1/2 of the trials by delivering rectangular pulses at various times after the ready and reaction signals. The results indicate that rapid increases in torque were associated with greater variability in the muscle EMG bursts, peak torques, peak rate of rise of torques and in the H-reflex amplitudes.

OPERANT CONDITIONING OF H-REFLEX IN UNRESTRAINED MONKEYS. P.A. Herchenroder* and J.R. Wolpaw (SPON: E.W. Wolpaw). Wadsworth Labs, NYS Dpt Hlth, Albany, NY 12201.

Monkeys can gradually increase or decrease the wholly spinal, largely monosynaptic stretch reflex or its electrical analog, the H-reflex, when reward depends on reflex amplitude (J Neurophysiol 50:1296-1311, 1983 & 57:443-458, 1987). Conditioning produces persistent spinal cord modifications, potentially accessible memory substrates (Wolpaw & Lee, this vol). The original experiment required animal restraint. This report describes a new design that achieves H-reflex conditioning in unrestrained animals.

Monkeys (Macaca nemestrina) are implanted under general anesthesia with chronic triceps surae (TS) fine-wire EMG electrodes and tibial nerve stimulating cuffs. Wires exit in mid-back into a pocket in a cloth harness. A 1 m flexible stainless steel cable anchored in the pocket conducts the wires through the cage top to a 24-lead electronic swivel. The swivel connects to amplifiers and stimulators that in turn connect to a minicomputer that interfaces with 6 animals 24 h/day. Animals move freely about their cages and readily adapt to the harnesses.

Each monkey learns a simple task. It places its mouth in front of the cage's water-delivery port and provides a given level of TS EMG in both legs for 1.2-1.8 s. Then, stimuli just above M response threshold elicit H-reflexes in both legs, and 200 ms later a solenoid-powered syringe delivers liquid reward to the animal's mouth. In control mode, reward always occurs. In HR↑ or HR↓ mode, reward occurs only if the H-reflex in one leg (the conditioned leg) is above (HR↑) or below (HR↓) a set criterion. Monkeys perform 3,000-6,000 trials/day.

Under HR↑ or HR↓ mode, H-reflex amplitude changes appropriately over weeks, just as it did with the original design. The new design provides precise reflex data and capacity for reflex modification in unrestrained animals.

ROLE OF SMALL DIAMETER AFFERENTS IN REFLEX INHIBITION DURING FATIGUE OF HUMAN SOLEUS MUSCLE. SJ Garland* and AJ McComas. Dept of Neurosciences, McMaster University, Hamilton, ON, Canada L8N 3Z5.

We have previously shown that H-reflex excitability of human soleus motoneurones is reduced during fatigue and is accompanied by an equivalent decrease in EMG activity during maximal voluntary contractions (MVC). These findings provide suggestive evidence for reflex inhibition of the alpha motoneuron pool during fatigue. To elucidate the contribution of different sized afferents in the reflex inhibition, compression of the sciatic nerve was used in an attempt to block large myelinated afferents. Fatigue of soleus muscle was then induced under ischemic conditions by intermittent electrical stimulation at 15 Hz in 5 healthy subjects. Subjects also participated in a control test in which the compression block was followed by ischemia without fatigue. Both mean EMG and MVC declined following nerve compression alone (by 10.9 $\pm$ 21.8% and 16.5 $\pm$ 12.3%, $p < .01$, respectively). Following fatigue, the mean MVC decreased by 43.8 $\pm$ 16.5% ($p < .01$) from the postblock value compared to a decrease of 6.4 $\pm$ 8.4% in the ischemia control. The mean EMG decreased from postblock values by 48.6 $\pm$ 12% ($p < .01$) following fatigue and by only 7.8 $\pm$ 6.6% following ischemia alone. The findings implicate smaller diameter muscle afferents in reflex inhibition of the alpha motoneuron pool during fatigue.

INTERACTIONS IN THE MODIFICATIONS INDUCED BY PROLONGED MUSCLE STRETCH ON REFLEX, VOLUNTARY AND SEMI-AUTOMATIC MUSCLE ACTIVATIONS. F. Malouin, C.L. Richards, F. Dumas* and F. Tremblay*. Physiotherapy Dept. and Neurobiology Lab., Fac. of Med., Laval Univ., Quebec, Canada.

Interactions in the effects induced by prolonged muscle stretch (PMS) were studied by comparing significant changes on ankle muscle activations during: reflex (passive movements), voluntary (isometric contractions) and semi-automatic (gait) types of activities. Ten spastic children (4-11 yrs) were tested before and after 30 min of stretch imposed on plantarflexor muscles (PF) by standing the child on a tilt-table. PMS-induced inhibitory effects in the triceps surae (TS) and the tibialis anterior (TA) during passive ankle movements were associated with increased TS ($p<0.08$) but not TA agonist activation during isometric contractions and higher TS activation ($p<0.05$) in early stance (0-15%) of the gait cycle. The higher TS activation during gait which was associated with a concomitant decrease in TA activation (0-15%) and an increased cadence is thus not likely due to hyperactive stretch reflexes. It is proposed that PMS-induced reflex inhibition resulted in improved supraspinal drive to the TS but not the TA during gait and isometric contractions and promoted reciprocal inhibition patterns in the TS and TA during gait.

PATTERNS OF IRRADIATION OF MOTOR UNIT ACTIVITY IN FATIGUE. M. R. Dimitrijevic, W. J. Eaton*, L. Emerich*, G. Vrbova* and W. B. McKay*. Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030

When a primary muscle fails to generate the intended force, progressive activation occurs in ipsilateral and contralateral muscles not directly involved in the force production. Increased levels of activity in response to demands for more force result in recruitment of more and more motor units within the motor pool. The activity spreads beyond the single motor pool when efforts to maintain the desired force begin to fail. In healthy subjects this recruitment pattern is stereotyped. Using surface EMG recordings over the lower extremities and trunk muscles, together with a force transducer to record ankle dorsiflexion force, healthy subjects were asked to make 3 repetitions of maximum voluntary contraction (MVC) levels, sustained until the subject could no longer maintain at least 50% of the initial effort, with an equal rest period between. Subjects then repeated a series of contractions at 20%, 40%, 60%, 80% and 100% of MVC for 6 seconds with 4 seconds rest between. Results of studies of these responses while seated and standing will be reported. Consistency of these patterns under varying conditions and across subjects suggest that these are indicative of the basic neurocontrol mechanisms operative under excessive loading conditions.

28.11

FUNCTIONAL ORGANIZATION OF MOTOR UNIT POOLS IN HUMAN DELTOID MUSCLE. S. Kane*, J. Hsieh* and K.C. Hayes. Dept. of Physical Medicine and Rehabilitation, The University of Western Ontario, London, Ontario, Canada.

We sought to characterize the activation of separate motor unit pools within the human deltoid muscle. Muscle fibers in the anterior head have force vector components 180° opposed to those of the posterior fibers. Different motor units within the same muscle therefore have the potential to serve agonistic or antagonistic functions within a given movement. Surface and intramuscular EMG recordings were made from the anterior and posterior fibers of the deltoid muscle in 5 healthy adult subjects while they performed rapid arm flexion or extension movements. EMG recordings consistently revealed bi- and tri- phasic patterns of motor unit activation within the deltoid muscle in the same manner as typically recorded from anatomically distinct agonist and antagonist muscles during ballistic movements. Suppression of background activity in the antagonist fibers often preceded activation of the agonist fibers (Hufschmidt phenomenon) by 30-50 milliseconds. This implies the presence of central descending influences; there also exists the possibility of peripheral inputs contributing to the later stages of inhibition. These results suggest that motor units within the anterior and posterior heads of deltoid are controlled similarly to motor units in anatomically defined antagonistic muscle pairs.

EMG COACTIVATION: THE REGULATORY ACTION OF THE MUSCLE ANTAGONIST. M. Solomonow, R. Baratta* and R. D'Ambrosia*. Bioengineering Laboratory, Louisiana State University Medical Center, New Orleans, LA 70112.

The EMG of the knee antagonist muscle group during maximal effort isometric and isokinetic contractions in flexion and extension over the full range of motion were studied. The simultaneously recorded EMG from the hamstrings and quadriceps, when acting as antagonists, were normalized with respect to their EMG during maximal effort when acting as agonist at each joint angle. The pooled data of 56 subjects was analyzed statistically to yield the following conclusions: athletes (volleyball and basketball) showed depressed activity probably due to increased joint efficiency resulting from frequent use of quadriceps; the antagonist compensated for the impact of gravity on the limb mass, increasing and decreasing activity during motion along and against the gravity vector, respectively; during contraction on the plane parallel to ground, the antagonist compensated for variations in its moment arm about the joint's center of rotation to generate nearly constant opposing torque, the antagonist allowed acceleration in the initial phase of motion, but increased opposition (dynamic braking) towards the terminal phase of the motion as velocity increased. The data points out that the role of the antagonist is to regulate the movement about the joint by compensating for various internal and external disturbances.

28.13

LOCAL CIRCUIT CONTROL OF LOAD COMPENSATORY REACTIONS IN LOCUSTS. S. N. Zill. Dept. of Anatomy, Marshall Univ. School of Medicine, Huntington, WV 25704.

In order to maintain an upright posture, many animals react to environmental perturbations with appropriate contractions of limb muscles. We have applied the paradigm of Nashner (Exp. Brain Res. 26:59, 1976) to the locust and have shown that these animals can respond with two discrete motor strategies when the substrate upon which they are standing is repetitively displaced: a resistance strategy, in which bursting occurs in motoneurons to tibial muscles to oppose imposed forces and a flexion strategy, in which the tibia is moved to full flexion and held in a locked position. We here report that resistance bursting is directional and occurs in a fixed range of phase (mean .49±.10) during the period when the animal is forced away from the substrate. In contrast, flexion responses show little rhythmicity and are non-directional. Simultaneous recordings of the activities of the tibial muscles of both hindlegs show that each leg can be used independently in either strategy. These findings imply that local circuit processing probably determines activities of tibial muscles in load compensation. We are presently examining whether the same or different interneurons mediate each of these discrete load compensatory reactions.

ACTIVITY OF LATERAL GASTROCNEMIUS COMPARTMENTS IN THE CAT DURING POSTURAL CORRECTIONS IN THE HORIZONTAL PLANE. D.C. Dunbar*, J.M. Macpherson, and J.T. Inglis* (SPON: H. Dinsdale). Depts. of Anatomy, Univ. of Puerto Rico Med. School, San Juan, PR 00936 (USA) and Queen's Univ., Kingston, Ontario K7L 3N6 (Canada)

This study investigated the activity patterns of the lateral gastrocnemius (LG) compartments in cats during postural corrections to support surface translations in the horizontal plane. Wire electrodes were surgically implanted into the four LG compartments (LG1, LG2, LG3, and LGm), plantaris, and soleus in the left hindlimb. The cats were trained to stand freely on a moveable platform. Quiet stance was disturbed by suddenly translating the cat in one of 16 different horizontal directions. Ground reaction forces and EMG activity were recorded on-line.

Each LG compartment and muscle responded over a range of directions and the amplitude of response varied with the direction platform movement. Maximum EMG responses for all four LG compartments, plantaris, and soleus occurred in the same region of translation where loading of the left hindlimb was maximum. Variation in LG compartment activity occurred at the boundaries of the response regions. Thus, LG compartmental activity patterns reflected the mechanical requirements, perhaps knee joint rotation, for postural correction. Supported by MRC of Canada.

THE ROLE OF THE CAT VESTIBULAR SYSTEM IN THE RESPONSE TO LINEAR ACCELERATION OF THE SUPPORT SURFACE J.T. Inglis* and J.M. Macpherson. Dept. of Anatomy, Queen's Univ., Kingston, Ont. Canada. K7L 3N6.

Linear acceleration (ramp displacement) of the supporting surface evokes fast, automatic postural responses in the cat. The latency of EMG activation is 30-40 ms following onset of platform movement. It is not clear for these perturbations when the acceleration of the support surface is transmitted to the head. In order for the vestibular apparatus to provide the triggering input for the postural response, there must be a change in the velocity of the head before the onset of the EMG response.

Quietly standing cats were subjected to horizontal plane, linear translation of the supporting surface. Acceleration of the cat's head was measured using an accelerometer mounted on the skull. The timing of head acceleration from onset of platform movement was variable, and often followed the onset of the evoked EMG. Only occasionally did head acceleration occur within 20 ms of the onset of platform movement. These data suggest that vestibular afferents are not the primary sensory inputs that trigger the postural responses. Preliminary results from a bilaterally labyrinthectomized cat support this conclusion since postural responses remain intact in the absence of the vestibular organs. Supported by the MRC of Canada.

GEOMETRICAL DETERMINANTS OF LIMB POSTURE IN CATS. C. Maioli*, F. Lacquaniti and L. Lopiano*. Istituto di Fisiologia dei Centri Nervosi, C.N.R., 20131 Milano, Italy.

We previously showed that the length and the orientation of the main axis of the limbs are actively controlled in cats standing on a platform statically tilted in the sagittal plane. We here address the question whether the redundant degree of freedom (which is inherent to this postural control of 3-jointed limbs) is constrained by geometrical factors or by cost criteria related to a preferred torque distribution. The former hypothesis is supported by the analysis of the overall pool of the data obtained at different inclinations (±20 deg) and interfeet distances, which reveals a strict planar covariation of the joint angles at both fore- and hindlimbs. The internal representation of postural geometry can thus be construed in terms of a simple linear compound of 2 independent parameters which establishes a unique mapping between the extrinsic space and the intrinsic space of 3 joint angles.

On the other hand, a weighted torque distribution between fore- and hindlimbs is effected via independent control of the contact shear forces.

28.17

MOTOR OUTPUT CAPABILITIES OF ADULT SPINAL CATS FOLLOWING POSTURAL TRAINING. R. J. Gregor, E. G. Fowler and R. R. Roy. Brain Research Institute and Department of Kinesiology, UCLA, LA, CA 90024

It has been demonstrated that the hindlimbs of cats spinalized (Sp) as adults are capable of full weight-bearing locomotion. In addition, Sp cats receiving regular treadmill training attain higher walking speeds than untrained Sp cats (*Exp. Neurol.*, 92:421–435, 1986). Weight support capability is requisite to locomotion and since postural training is often used in clinical settings, this study was designed to investigate the effect of postural training on the motor output of Sp cats. Three adult cats underwent spinal cord transection (T12–T13) and received daily care including range of motion therapy for six months. A postural training program (30 minutes daily, 5 days per week) for the hindlimbs was initiated one month post-transection. Medial gastrocnemius (MG) and soleus (Sol) were instrumented for force, EMG and muscle length measurements six months post-transection (*J. Biomech.* 17:685–694, 1984).

Despite postural training and daily range of motion exercises, none of the Sp cats were able to walk after the training period with the most notable decrement occurring during the flexion phase. Limited analysis during posture yielded forces ranging from 3.8 to 6.3N in the Sol and from 1.0 to 3.9N in the MG. When compared to locomotor performance by cats in untrained and treadmill exercise groups (*Exp. Neurol.* 92:421–435, 1986), postural training was detrimental. These findings have clinical relevance to rehabilitation programs following spinal cord trauma.

REAL-TIME PROCESSING OF CUTANEOUS NERVE ACTIVITY TO OBTAIN CONTACT FORCE INFORMATION. J.A. Hoffer and Thaddeus Li*. Depts. Clin. Neurosci. & Med. Physiol. and Electr. Engng., University of Calgary, Calgary, Alberta T2N 4N1, Canada.

Nerve cuff electrodes implanted on skin nerves may record signals suitable for closed-loop control of FES (functional electrical stimulation) of paralyzed muscles in tetra- or paraplegics (Hoffer & Sinkjaer, Soc NS Abst 12:1306, 1986). To test this hypothesis we implemented two real-time analog processors on tibial nerve data recorded from anesthetized cats. One signal processor was based on PID control theory, where proportional, integral and differential versions of the rectified electroneurogram were linearly combined. The other version involved also an exponential transformation.

With PID processing alone, the resultant signal revealed the basic shape and risetime of the vertical contact force applied to the footpads, but the fit appeared logarithmic (presumably reflecting the force/frequency relation typical of mechanoreceptors) and the off-response was sluggish when the force suddenly declined. The second processor included transistors placed in feedback loops to give an exponential transformation. With this approach the fit was effectively linearized over most of the physiological range of contact forces. The speed of the off-response was also improved by the exponential version. Thus, real-time analog processing of chronically recorded nerve activity can provide a useful and accurate replica of the contact force on glabrous skin.

USE OF LINEAR QUADRATIC CONTROL THEORY TO PREDICT OPTIMAL FEEDBACK FROM PROPRIOCEPTORS ONTO MOTONEURON POOLS OF THE CAT HINDLIMB. Jiping He*, W.S. Levine* and G.E. Loeb. Dept. Elect. Engng., Univ. Maryland, College Park, MD 20742, and Lab. Neural Control, NIH, Bethesda, MD 20892.

Spinal cord circuits from the various proprioceptors to the various muscles of the limbs are now known to be highly convergent and divergent, in a manner that seems inconsistent with servocontrol of individual muscles. A linear quadratic regulator is an alternative scheme (for small perturbations) that seems more suitable for such complex mechanical linkages having multiple, partially redundant actuators. Implementation has three main requirements: 1) Model of system dynamics - simplified musculoskeletal system with 3 segments (thigh, shank, and foot) moving parasaggitally and driven by 10 muscle groups, each with output dynamics dependent on activation kinetics, length & velocity. 2) Set of sensory signals - We have assumed receptors for muscle force (GTO), length & velocity (spindle primaries), and joint angle and velocity (optional; we are working on reconstructing kinesthesia from other sensory modalities). 3) Performance criteria to be optimized - We have examined the relative effects of control strategies that minimize muscle activation following a perturbation versus those that minimize deviations of a) muscle lengths, b) joint angles, and c) combined joint angles and muscle force levels (limb "stiffness").

So far, we have modeled regulators for stable standing and their responses to small horizontal perturbations of the feet. As is expected for this type of controller, feedback gain matrices tend to show a high degree of coupling, even among muscles acting on different joints. Homonymous feedback showed consistent inhibition from GTO's and excitation from spindles, but heteronymous feedback gains often switched sign depending on the control strategy employed and the relative importance of maintaining state vs. conserving activation. Another general pattern was that the sign of feedback from muscles crossing the adjacent joint was usually reversed from that of homonymous receptors. The most physiological responses to perturbation resulted from the limb stiffness controller operated fairly compliantly (emphasis on conserving activation).

We believe that these feedback matrices and their postural dependencies will improve our understanding of real motor control problems. They may also provide guidance for the design and interpretation of studies of reflexes, their gating during locomotion and their underlying spinal cord circuitry.

28.20

ANKLE PERFORMANCE PRE AND POST LATERAL COLUMN LESION IN THE BEHAVING MONKEY. M.H. Clare, S.A. Sahrmann, E.B. Montgomery, W.M. Landau, Dept of Neruology, Washington University School of Medicine, St. Louis, MO 63110

A macaque was trained to perform 4 mirror image isometric ankle tasks triggered and guided by light signals; 1. rest to large (L) plantarflexion (PL), hold for a random period, rapidly reverse into L dorsiflexion (DO) and return to rest; 2. the mirror image tasks; 3. small (S) PL with random hold, relax to rest; and 4. its mirror image S DO. After recording normative data daily for 3 months a complete right lateral column lesion was made at T10. Two days post lesion recording was resumed and continued daily for 3 more months. Force and EMG from tibialis anterior and gastrocnemius trial by trial and averaged records were used for data analysis. For all tasks the latency from the go signal in rest to onset of force change ranged from 210 - 250 msec. All DO related tasks were slower than PL tasks except for the return to rest following reversal. The most rapidly performed task, as measured from onset of force change to acceptable criterion was LPL (156 msec). LDO was 266 msec while the S tasks were 300 msec. Following the lesion the only timing deficits were slowed LPL reversal (pre 172, post 247) and prolonged return to rest following L DO reversal (pre 195, post 275) during the first 20 days. Prolonged TA activity was evident in both motions. In addition to slight weakness and difficulty maintaining force, there were increased errors for the S tasks (70 per day) not found in the L tasks (12 per day).

28.21

THE IMPORTANCE OF FOOT POSITION IN THE DEVELOPMENT OF WHOLE LIMB STRATEGIES FOR LOAD BEARING. W.E. McIlroy, P. Yoon and J.D. Brooke, Interdepartmental Biophysics and Human Biology, University of Guelph, Guelph, Ontario, CANADA. N1G 2W1.

Is the initial foot position a significant determinant of the pattern of muscular activity adopted for lower limb extensions? Subjects performed ballistic leg extensions, while seated, against a load which contacted the plantar surface of the foot. The ankle joint, which could be loaded independently, was set at different positions prior to the triggering of leg extensions. The initial activity in both tibialis anterior and soleus was directed towards re-aligning the foot. This re-alignment, which usually involved moving the foot to a dorsiflexed position, appeared to be a necessary precursor to peak knee and hip extension. The results confirm the importance of the distal segment in the organization of whole limb strategies for load bearing movements. It is also significant to note that this relationship appears to hold true for prevolitional responses when evoked by interruption of pedalling. Supported by NSERC Grant A0025.

29.1

PELVIC AND AXIAL MUSCLES. D. Filipini* & B. Dubrovsky. Neurophysiol. Lab, Royal Vic. Hosp., Montreal QC H3A 1A1.

EMG activity of external ani sphincter (EAS) and diaphragma pelvic (DP) muscles, both pelvic floor muscles, was studied in chloralose anesthetized cats using copper electrodes. Quantitative evaluation was carried out with the method of zero crossing. We will present evidence that the threshold for exteroceptive stimuli is lower for the EAS than for the DP muscles, in turn DP responds swiftly to interoceptive stimuli. EAS shares with epaxial muscles such as dorsal neck, lumbar dorsal and tail muscles, 1) absence of monosynaptic ventral root potentials in the presence of a muscle spindle apparatus, 2) strong dependence on suprasegmental stimuli and 3) large cutaneous input. Together with other evidence (Dubrovsky, Am. J. Physiol. 254: G100-107) the data suggests that the EAS is involved in continence by responding to threatening situations produced by distant events, e.g. coughing, postural changes, while DP muscles are involved both in continence and defecation by controlling expulsion of fecal mass. EAS and DP show different spinal connectivities, responsiveness to stimuli and segmental dependency. (Supported by NIH Grant IR01AM.34877-01.)

29.2

EFFECTS OF INDUCED SACCADIC FREQUENCIES ON POSTURAL SWAY IN CHILDREN AND ADULTS. J.L. Starkes and C.L. Riach. School of Physical Education, McMaster University, Hamilton, Ont., Canada, L8S 4K1.

Young children do not use visual information as an efficient means of reducing sway. In fact children 5-7 years are unable to fixate a target without spontaneous saccadic shifts. This study examined the effects of induced saccadic frequencies on postural sway in children and adults. Four groups of subjects (N=37) aged: 5-7, 8-9, 10-12 years and adults performed a series of 10 sec force platform (AMTI-OR6) trials. They stood in either a normal or Romberg stance and visually tracked two lights alternating in central vision at 0.5, 1, or 2 Hz. Eye movements were simultaneously recorded using corneal reflection. Dependent measures included: number of saccades made vs. required, and sd of centre of pressure in both AP and LAT planes. Children under 9 years made more saccadic shifts than adults at all frequencies. For AP sway, the Romberg condition was most difficult for children under 9 years regardless of induced saccadic frequency. Lateral sway during the Romberg stance was increased for young children only when saccadic frequency was low.

29.3

THE EFFECT OF PRACTICE ON THE STABILITY OF ANTICIPATORY POSTURAL PATTERNS DURING A BILATERAL ARM RAISING TASK. C.S. Layne. Dept. of Physical Education and Dept. of Physical Therapy Rehabilitation Research Laboratory, The University of Wisconsin-La Crosse, WI 54601

A number of investigators have assessed the effects of skill acquisition on a variety of electromyographic (EMG) variables. Efforts in this area have focused primarily on agonist and antagonist activity with the literature reflecting much inconsistency (Moore & Marteniuk), J. Mtr. Beh., 18: 4, 1986). However, there is a scarcity of studies designed to evaluate possible changes resulting from practice in the anticipatory postural patterns (APPs) observed during voluntary arm movement.

In order to assess the stability of APPs, five male subjects performed a total of 390 bilateral arm raises over three days. The subjects were instructed to move at a time of their choosing following activation of a light stimulus. Surface EMG was used to monitor the activity of the following muscles of the right side: gastrocnemius (G), biceps femoris (BF), erector spinae (ES) and anterior deltoid (AD). Trials 1-10 and 381-390 were analyzed in the following manner. EMG onset latencies were determined relative to movement onset. Movement onset was determined relative to the stimulus signal. With-in subject mean latencies were calculated and ratios were developed between the various muscle onsets and between muscle onsets and movement onset. With practice there were decreases in movement onset latencies and decreases in the muscle onset latencies. However, the variability of the latencies did not change with practice. In general, the ratios between the various muscle onset latencies did not vary despite the decreases in the latencies.

29.4

ABNORMAL POSTURAL COORDINATION IN PATIENTS WITH DISTORTED VESTIBULAR FUNCTION. Shupert, C., Horak, F., Black, F.O. Robert Dow Neurological Sciences Inst. and Dept. of Neurootology, Good Samaritan Hospital, Portland, OR 97210.

Normal subjects standing on narrow beams use a hip strategy to control posture. Some patients with peripheral vestibular disorders with abnormal ("distorted"), rather than absent, vestibular function also use hip sway even when standing on normal surfaces. We studied stance posture in 8 normals and 10 patients with vestibular pathology secondary to infection or head trauma to show whether hip sway is normally coordinated in these patients. All patients showed excessive hip sway and had positional nystagmus and/or vertigo, normal horizontal VOR gains, and no signs of CNS injury. Automatic postural responses to backward translation of the suport surface with eyes open and closed were compared. Ankle, knee, hip and neck angles; leg, trunk and neck EMGs; surface reactive forces; and head angular velocity were measured. Normals using hip strategy on a narrow beam activate trunk and neck flexors to coordinate trunk motion with good head stabilization. Patients showed two patterns of trunk muscle activation: 1) passive trunk collapse due to late or absent trunk muscle bursts, and 2) normal trunk flexor activation. However, all patients had angular head velocities about twice as large as normals, and none showed normal neck activation patterns. Thus, patients with vestibular distortions and excessive hip sway do not use a normal hip strategy to control postural sway. Supported by grants NS19222 and NS01094.

THE RELATIONSHIP OF AGE AND OTHER VARIABLES WITH UPRIGHT STANCE S. Bandinelli*, V.P. Panzer*, S.L. Thomas* and M. Hallett
NINCDS, NIH, Bethesda, MD USA 20892

The purpose of this study was to investigate the relationship of age, sex and visual condition with whole body and segmental measures of postural sway when standing. Thirteen normal volunteers (age 29-68; 7 female, 6 male) were evaluated. Three-dimensional kinematic data were collected (50 Hz) with a video based system (VICON) and kinetic data were obtained (200 Hz) from a force platform (AMTI) while subjects stood upright for 30 s with eyes open and eyes closed. The total excursion (TE) of the center-of-foot-pressure (COP), center-of-gravity (COG) and body segments (head-HD, shoulder-SH, hip-HP & knee-KN) and the variability (VAR) of these parameters about the mean, linear and quadratic fits to the respective displacement data sets were calculated in the vertical (V), anterior-posterior (A/P) and medial/lateral (M/L) planes. The relationship of subject variables with these measures was assessed using a stepwise regression procedure. Age was strongly related ($p < .05$) to increasing vertical VAR measures (COGV, HDV, SHV & HPV) and to a concurrent decrease in TE of HDA/P and HPV. These changes may characterize a strategy wherein the upper body segments are relatively fixed with gross postural adjustments. Sex was significantly ($p<.05$) related to M/L VAR and TE of COG & COP, which were greater in females, and accompanied by increased VAR of HPV and KNV. These differences are due to M/L weight shift apparently initiated by lower body segments. Vision was significantly related to TE COPA/P, probably reflecting an increase in ankle joint adjustments. In conclusion, there are identifiable differences in balance control associated with aging, and these are clearly distinct from those that are related to sex and vision.

AGE DEPENDENT DIFFERENCES IN PROGRAMMING LANDING FROM A JUMP IN HUMANS. L. Pelland* and P.A. McKinley. Sch Physical, Occupational Therapy, McGill, Montreal,Que., H3G 1Y5

Landing from a jump (45cm) was studied in children < 7 yrs, & 11-12 yrs under 4 conditions: Normal vision (*NV*), occluded vision (*OV*), stable visual field (*SV*), and disrupted vision (*DV*) using a strobe light at 3,5 and 8Hz. Surface EMG of the soleus (SOL), lateral gastrocnemious (LG), tibialis anterior (TA), rectus femorus (RF), vastus lateralis (VL) and biceps femorus (BF) was differentially amplified (1000x),bandpass filtered (10-1000Hz), and digitally stored on video tape. Take off and landing was monitored by use of footswitches. In children <7, for *NV*, EMG throughout flight was tonic in VL,BF,RF; SOL and LG were quiescent, while a burst of activity in the TA occurred 115-140ms before landing. *SV* increased the gain of the EMG but did not alter the pattern. *OV* resulted in pattern alteration but no gain change: TA was tonic while the BF,VL,RF became more burst-like. *DV* had little effect on the EMG activity. In contrast, all EMG was consistently burst-like in 11-12 yr-olds. With *NV*, prior to landing, co-contraction of the ankle muscles was followed by knee (VL) activity, but minimal activity at the hip (BF,RF). *SV* increased the gain only in the SOL, while *OV* and *DV* delayed the onset of activity, until post-landing, except in the SOL. It is concluded that visual perturbation responses varied in the 2 age groups and that children <7 used proximal joint control, while 11-12 yr-olds exercised distal to proximal joint control. Supported by NSERC.

EFFECT OF VISUAL PERTURBATIONS IN PROGRAMMING LANDING FROM A JUMP IN HUMANS. H.W.Thompson*, and P.A. McKinley. (SPON: D.. Rushmer) School of Physical & Occupational Therapy, McGill, Montreal, Que., H3G 1Y5

Surface EMG activity was analyzed during landing from a jump (45cm) in 6 normal adult subjects (Ss) with and without normal vision (*NV*). Visual perturbations included stable vision (*SV*), occluded vision (*OV*) & disrupted vision (*DV*) using the same methodology as described in an accompanying report. With *NV*, activity occurred prior to landing and was typically burst-like in all muscles, although 1 plantarflexor was often tonically active. There was usually co-contraction of the ankle musculature (TA,LG,SOL), followed by activity at the knee (VL) while activity at the hip (RF,BF) was minimal until post-landing. Strategies used during visual perturbation trials varied among Ss. Some Ss were largely unaffected by visual perturbations. In others, visual perturbations caused a delay in EMG onset and a decrease in peak pre-landing activity although the pattern of activation was unchanged. In some of these Ss the changes occurred only during *DV*, while in others, effects were seen under all conditions. In the latter group, when jumping with *DV*, the EMG was delayed until post-landing. It is concluded that musculature is activated in a distal to proximal sequence, and this pattern is not disrupted by visual perturbations. Onset and amplitude of EMG may be altered to varying degrees depending on the individual, and is most consistently affected during *DV*. Supported by NSERC.

29.8

EFFECT OF COMPLIANCE ON ANKLE, KNEE & HIP MOTION IN LANDING FROM A JUMP IN HUMANS. M.D. Bastien* and P.A. McKinley. (Spon: P. Gardiner). School of Physical & Occupational Therapy, McGill, Montreal, QUE. H3G 1Y5

Adaptive strategies for surface compliance were studied from kinematic analysis of human subjects landing from a jump (45cm) under 3 conditions: jumping from and landing onto a stiff surface(S-S); jumping from a stiff and landing onto a compliant surface (S-C); jumping from a compliant and landing onto a stiff surface (C-S). Typically, velocity and range of motion (ROM) for a given joint during take-off, flight and landing phases were similar within each condition. Across conditions, both ankle and knee adjustments were minimal and flexion & extension velocities were invariant. For ankle, ROM was unchanged except for increased oscillation post-landing during C-S. At the knee, ROM was invariant, except for the landing phase of S-C, where flexion was decreased. In contrast, hip-trunk motion was greatly affected by surface conditions: flexion & extension velocities were similar for C-S and S-C, and reduced for S-S. Most affected was ROM, which was minimal (30°) during S-S, and increased during S-C (65°) and C-S (85°). Hip and knee flexion was tightly coupled as were knee flexion/ankle dorsiflexion and knee extension/ankle plantar-flexion. It is concluded that adjustments for surface differences occur primarily at the hip-trunk, strategies differ in S-S when compared to S-C or C-S, but adjustments for incongruence in surfaces are minimal. Supported by NSERC.

BIOMECHANICAL ASSESSMENT OF THERAPEUTIC STRATEGIES IN PARKINSON'S DISEASE V.P. Panzer*, R.J. Plunkett*, S.L. Thomas* and M. Hallett; (SPON: M. Goldstein). NINCDS, NIH, BETHESDA, MD USA 20892

Upright posture is a major problem in patients with Parkinson's disease (PD), but no reliable assessment method has been established. There was some improvement in the ability to maintain upright stance in a 54 yo patient with PD after adrenal implant surgery. The patient stood upright for 30 s with eyes open & closed in the ON & OFF condition on 13 occasions, while three-dimensional kinematic (VICON-50 Hz) and kinetic data (AMTI force platform-200 Hz) were obtained. The total excursion (TE) of the center-of-foot-pressure (COP), center-of-gravity (COG) and body segments (head-HD, shoulder-SH, hip-HP, & knee-KN) and the variability (VAR) of these parameters about the mean, linear and quadratic fits to the respective displacement data sets were calculated in the vertical (V), anterior-posterior (A/P) and medial-lateral (M/L) planes. Individual contributions of vision, condition (COND), dosage, time since last dose (T/DO) and weeks post surgery (WPS) were evaluated with stepwise and multiple regression procedures. Highly significant ($p<.01$) relationships were obtained for these measurements with WPS, COND and T/DO. Differences related to COND generally accompanied changes due to T/DO; however, different parameters were associated with WPS. Sway measurements (A/P-COG, COP, KN, HP, SH, HD VAR and SH TE) were strongly related to COND and T/DO. Changes associated with WPS were primarily related to vertical displacement (V-HD, SH, KN VAR and COG, HD, HP, KN TE and A/P and M/L COP). These were characterized by reduction in VAR and TE such that mean values approached those of a normal population (age 29-68 yo). These measures are sensitive to subtle differences in condition and clinical change and may provide reliable measurements useful for clinical assessment of therapeutic strategies in the treatment of PD.

NEUROMUSCULAR RESPONSES UNDERLYING BALANCE IN THE CLUMSY CHILD. H Williams* and M.H. Woollacott. College of Human Development & Perf., U. of Oregon, Eugene, Oregon 97403

The purpose of the study was to examine the neural mechanisms underlying balance control in clumsy children and to explicate differences between clumsy and normal children in speed, consistency & organization of postural muscle responses activated by external threats to balance.

Twenty-six children of 2 ages and 2 motor development levels [6-7 yr normal (n=7); 9-10 yr normal (n=7); 6-7 yr clumsy (n=6); 9-10 yr clumsy (n=6)] were exposed to 18 randomly ordered trials of anterior and posterior movements of a hydraulically driven platform. Eight muscle groups were monitored (TA, Gas, Hams, Quads, Para, Abdms, Next, Nflx) using surface electrodes and muscle onset latencies were recorded. Latencies were analysed using a 2 (age) X 2 (motor dev. level) X 8 (muscle) MANOVA repeated measures. For anterior perturbations the main effect of age and interaction between motor dev. level and muscle group were significant. Onset latencies were shorter for older than younger children. For anterior perturbations Abdms were activated at shorter latencies in clumsy than normal children; no other latency differences were significant. For posterior perturbations, muscle responses of clumsy children were significantly more variable than those of normal children. In addition, normal children showed only the classic distal-proximal muscle response organization while clumsy children had a greater tendency to activate leg muscles in a proximal-distal direction.

PRESYNAPTIC MECHANISMS: TOXINS

30.1

OMEGA-CONOTOXIN GVIA (ωCgTx) REDUCES STIMULATED RELEASE OF ACETYLCHOLINE (ACh) FROM HUMAN AND MOUSE BRAIN SYNAPTOSOMES. C.L. Williams*, H.J. De Aizpurua*, T. Kryzer*, V.A. Lennon. Depts Neurol & Immunol, Mayo Clinic, Rochester, MN 55905.

It has been suggested that neuronal voltage-gated Ca^{2+} channels (VGCC) that are highly sensitive to blockade by ωCgTx are located presynaptically and mediate neurotransmitter release (Miller, Science 235:46, 1987). To investigate the role of ωCgTx-sensitive VGCC in regulating ACh release in the central nervous system (CNS), we isolated synaptosomes from biopsied human cerebral cortex and mouse cerebrum by Percoll density gradient centrifugation.

Synaptosomes were loaded with ^{3}H-choline, and thin layer chromatography was used to determine 3 min stimulated release (SR) of ^{3}H-ACh; SR = ([^{3}H-ACh released by 90 mM K^+] - [^{3}H-ACh released by 5 mM K^+]). In the absence of ωCgTx, SR from mouse synaptosomes was 198 ± 5.2 fmol ACh/min/mg protein, and from human synaptosomes was 41.7 ± 14.1 fmol ACh/min/mg. The lower human value may reflect hypoxia due to a 2-3 hr delay in processing surgical tissue. Incubation with 1, 5 and 10 μM ω-CgTx respectively reduced mouse SR by 0, 18 and 57% and human SR by 22, 60 and 58%; 10 μM control peptide had no effect. Cerebral cortical tissues from both species (solubilized in 2% CHAPS, w/v) specifically bound ^{125}I-ωCgTx. These data support the hypothesis that ωCgTx-sensitive VGCC mediate ACh release from nerve terminals in the CNS. Supported by NIH grant CA 37343.

30.2

ω-CONOTOXIN INHIBITION OF Ca^{2+}-EVOKED RELEASE OF [^{3}H]-DOPAMINE FROM SYNAPTOSOMES. J.F. Bowyer*, and N. Weiner. Dept. of Pharm. Univ. of Colo. Hlth Sci. Ctr 4200 E. 9th Ave. Denver CO 80262.

Unlike the K^+ depolarized release of ^{3}H-dopamine ([^{3}H]DA) from synaptosomes, [^{3}H]DA release by 1.25 mM Ca^{2+} (from synaptosomes previously superfused in Ca^{2+}-free media) can be modulated by DA(D2) agonists and antagonists. This "Ca^{2+}-evoked" release is dependent on tetrodotoxin sensitive Na^+ channels and regulated by K^+ channels (sensitive to tetraethylammonium and 4-aminopyridine). We now report that Ca^{2+}-evoked [^{3}H]DA release from synaptosomes is inhibited by ω-conotoxin GVIA (CON), an antagonist of brain Ca^{2+} channels. The maximally effective concentration (10 nM) of CON inhibited the Ca^{2+}-evoked [^{3}H]DA release from striatal synaptosomes to 49.8±5.2%, n=11, of control while release from olfactory tubercle (OT) was reduced to 53.0±7.5%, n=9, of control. Concentrations of 30 nM were no more effective than 10 nM CON at blocking release. The IC_{50} for CON inhibition of Ca^{2+}-evoked release was approximately 1.5 nM in both striatal and OT synaptosomes. The remaining Ca^{2+}-evoked release insensitive to CON could still be inhibited approximately 45% in either striatal or OT synaptosomes by the DA(D2) agonist LY-171555. Cobalt (1mM) also inhibited Ca^{2+}-evoked release to 21.1±2.9%, n=8 of control in striatal and 28.2±4.1%, n=6, in OT synaptosomes. However, the voltage-dependent "L" Ca^{2+} channel blockers verapamil and nifedipine did not affect Ca^{2+}-evoked [^{3}H]DA release at 10^{-7} to 10^{-6}M concentrations. The results of these experiments indicate that much of the Ca^{2+}-evoked release of [^{3}H]DA from synaptosomes is dependent on Ca^{2+} channels (CON sensitive) that have been previously characterized and associated with neurotransmitter release in brain. Supported by USPHS grants NS07927 and NS09199.

30.3

ω-CONOTOXIN GVIA BLOCKS SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS IN VITRO. H. Kamiya* (SPON: N. Miki). Dept. Physiol., Facul. Med., Kanazawa Univ., Kanazawa 920, Japan.

The effects of some subtype-selective Ca^{2+} channel blockers on synaptic transmission were examined in hippocampal slices from the guinea pig.

Mossy fibers were stimulated at 0.1 Hz and field potentials were recorded from pyramidal cell layer in the CA3 region, which reflect synaptic activation of CA3 neurons.

ω-Conotoxin GVIA (ω-CgTX), a novel peptide toxin which blocks N type and L type calcium channels, suppressed the evoked field potential at very low concentration (ED_{50} was about 30 nM). This effect was almost irreversible. On the other hand, 100 μM verapamil and 10 μM nifedipine (L type blockers) had little effect on the evoked field potential. Phenytoin (100 μM, T type blocker) was also ineffective to suppress the evoked field potential.

These results suggest that presynaptic calcium channels which cause transmitter release in the mammalian central nervous system have pharmacological sensitivities close to those of N type calcium channel.

30.4

TETANUS TOXIN INHIBITS VASOPRESSIN and OXYTOCIN SECRETION FROM ISOLATED NERVE ENDINGS OF THE POSTERIOR PITUITARY IN CULTURE. J. T. Russell*, W. H. Habig*, and A.B. Lynn* (SPON: S. Pocotte) LDN, NICHD, NIH, and CBER, FDA, Bethesda, MD 20892.

Nerve endings (neurosecretosomes) isolated from rat posterior pituitaries were maintained overnight under tissue culture conditions in media containing 10% fetal calf serum. These neurosecretosomes secrete vasopressin and oxytocin in response to a 10 min depolarization using veratridine (60 μM) in the perfusion medium. This secretion is strictly dependent on the presence of extracellular calcium.

It has been suggested that tetanus toxin, like botulinum toxin, blocks transmitter release at nerve terminals. When neurosecretosomes were exposed to tetanus toxin, the depolarization-induced secretion of both hormones was inhibited by more than 95%. Half-maximal inhibition of secretion was observed on incubations for 18 hrs with 2.7 nM tetanus holotoxin. The blockade of secretion was also dependent on time of exposure to the toxin. At a concentration of 67 nM, half-maximal inhibition was observed when the neurosecretosomes were incubated in toxin for 2.5 hrs. These experiments suggest that the neurohypophysial nerve terminals possess receptors for tetanus toxin to gain entry into the terminals, and block depolarization-induced secretion of hormones. This isolated nerve terminal preparation provides an unique model to study toxin-induced reactions that uncouple stimulus from secretion.

30.5

CALCIUM - DEPENDENT INACTIVATION OF VERATRIDINE-INDUCED VASOPRESSIN SECRETION IN NERVE ENDINGS OF THE RAT POSTERIOR PITUITARY. K. Payza and J. T. Russell*, LDN, NICHD, Building 36, Room 4A-18, NIH, Bethesda, MD 20892.

Nerve endings (neurosecretosomes), isolated from rat posterior pituitaries and maintained overnight in culture, respond to a depolarizing stimulus of 60 μM veratridine with a strictly calcium-dependent secretion of vasopressin. During the exposure to veratridine, the rate of vasopressin secretion rapidly peaks within two minutes, but then decreases to basal level even in the presence of depolarization, with a half-time of 5 minutes. Simple depletion of the hormone does not account for this decline, since the total secretion is less than 10% of the total amount in the neurosecretosomes.

We tested the hypothesis that the inactivation of secretion was dependent upon membrane depolarization, but independent of external calcium. We perfused a preparation of neurosecretosomes for 25 minutes with 60 μM veratridine and 100 μM EGTA in the absence of calcium. During this pretreatment, vasopressin release remained at basal level. If depolarization were solely responsible for inactivation, then, even in the absence of calcium, the prolonged pretreatment with veratridine should render the neurosecretosomes incapable of secretion. On the contrary, when 2 mM calcium was returned to the veratridine perfusate, the resulting secretion of vasopressin was the same as in the control preparation. Thus, in the absence of calcium, prolonged depolarization with veratridine did not cause inactivation of secretion.

30.6

BOMBESIN INHIBITION OF ^{3}H-SEROTONIN RELEASE: EFFECTS OF PHOSPHORAMIDON AND ENALAPRILAT. M. S. Saporito and R. O. Warwick, Jr. Philadelphia College of Pharmacy and Science, Phila. PA. 19104.

We have reported that bombesin (BN) inhibits K^+ evoked ^{3}H-serotonin (^{3}H-5-HT) release from hypothalamic (HYP) slices. The present study demonstrates the effects of the endopeptidase 24.11 inhibitor phosphoramidon (PAN) and the peptidyl dipeptidase A inhibitor enalaprilat (ENP) on this BN activity. The effects of neuromedin-C (NM-C) and neuromedin-B (NM-B) on ^{3}H-5-HT release were also examined. HYP slices, preloaded with ^{3}H-5-HT, were superfused with Krebs-Henseleit buffer and release stimulated twice with 25 mM KCl. Peptides (1 uM) and/or peptidase inhibitors (10 uM) were included for the second stimulation period. Release is expressed as the ratio of the second to the first peak (S2/S1 ratio). Control S2/S1 ratios were 0.86 ± 0.02. BN and NM-C decreased ($p < 0.05$) S2/S1 ratios by 27% and 28%, respectively. NM-B had no effect. PAN abolished the inhibitory activity of BN while ENP ($p < 0.05$) enhanced the inhibitory activity of BN by 50%. These data support the hypothesis that BN-like peptides function as presynaptic modulators of 5-HT neurotransmission in the HYP and suggest that BN is enzymatically hydrolyzed prior to eliciting this effect.

30.7

BINDING TO BOVINE CHROMAFFIN CELLS IN CULTURE AND POTENCY OF BOTULINUM A NEUROTOXIN ARE INCREASED BY LOW IONIC STRENGTH MEDIUM. H.Bigalke*, P.Marxen* (SPON: European Neuroscience Association). Department of Pharmacology and Toxicology, Medical School of Hannover, 3000 Hannover 61, West Germany.

Botulinum A neurotoxin (BoNtx) produced in cultured chromaffin cells a concentration dependent blockade of ^{3}H-noradrenaline secretion. The inhibition could be enhanced when the cells were exposed to the toxin after a preincubation with a mixture of gangliosides including GD1a, the putative receptor for BoNtx. A further increase in efficacy could be achieved when the toxin was offered to the cells in a solution in which sodiumchloride was replaced by sucrose. Digestion of the cell attached gangliosides with neuraminidase abolished the inhibitory action of BoNtx. To check whether the efficacy of BoNtx correlates with its binding we measured the fixation and distribution of ^{125}I-BoNtx. The radioactivity bound to the cells was increased by gangliosides and low ionic strength medium. Neuraminidase prevented the binding of ^{125}I-BoNtx to chromaffin cells. In a further series of experiments we determined the pattern of gangliosides synthetized by the cells. The quantity of polysialogangliosides extracted from chromaffine cells in culture and determined by chromatography correlated well with the binding and efficacy of BoNtx. Offered externally, polysialogangliosides were incorporated into the cell membrane and enhanced the susceptibility of chromaffin cells to BoNtx. In contrast, neuraminidase treatment decreased the amount of polysialogangliosides, the binding and the efficacy of BoNtx. Our results indicate that polysialogangliosides may be important for the action of this Clostridial toxin.

AUTOANTIBODIES OF LAMBERT-EATON SYNDROME BLOCK PRESYNAPTIC CALCIUM CURRENTS IN THE MOUSE MOTOR NERVE TERMINALS. M.P. Viglione*, R. Penner* and Yong I. Kim. (SPON: F.E. Dreifuss). Depts. of Neurology & Biomed. Eng., U.Va. Sch. of Med., Charlottesville, VA 22908 and Max-Planck-Institut für biophysik. Chemie, Göttingen, FRG.

Lambert-Eaton syndrome (LES) IgG blocks voltage-dependent calcium channels in bovine adrenal chromaffin cells (Kim and Neher, Science 239:405, 1988). We used subendothelial recording technique (Penner and Dreyer, Pflügers Arch. 406:190, 1986) to evaluate the integrity of presynaptic Ca^{2+} channels in the mouse passive transfer model of LES. Mice were injected with IgG from three patients with LES and healthy control subjects. In the majority of LES IgG recipients, there was a distinctive alteration in the time course of the presynaptic Ca^{2+} currents, recorded from the motor nerve endings in M. triangularis sterni muscles. Quantitative analysis indicated that the Ca^{2+} currents in six mice receiving patient 1's IgG were reduced by 21% to 72% (mean 47%) compared to the control. Of four mice receiving IgG of patients 2 and 3, two exhibited 35% and 47% reductions, respectively. We conclude that LES IgG blocks voltage-dependent Ca^{2+} channels in the motor nerve terminal, which accounts for the pathophysiology of this disease characterized by a deficiency in the neurally-evoked release of acetylcholine (Supported by NIH grant NS18607 and an MDA research grant).

30.9

EFFECTS OF CLOSTRIDIAL NEUROTOXINS ON CATECHOLAMINE RELEASE FROM DIGITONIN-PERMEABILIZED CHROMAFFIN CELLS. M.A. Bittner*, R.W. Holz and B.R. DasGupta* Dept. of Pharmacol., Univ. of Mich. Med. Sch., Ann Arbor, MI 48109; Food Res. Inst., Univ. of Wis., Madison WI 53706

Clostridial neurotoxins are 150 kDa proteins which consist of heavy (100 kDa) and light (50 kDa) chains joined by a disulfide bond. Tetanus exotoxin inhibited Ca^{2+}-dependent catecholamine secretion in a dose-dependent manner in digitonin-permeabilized bovine chromaffin cells. The inhibition was specific for tetanus exotoxin and the B proteolytic fragment; the C fragment had no effect. The light chain of tetanus toxin was fully active. Inhibition was not seen when intact cells were preincubated with the toxin or toxin fragments. Botulinum toxins A, B, and E also inhibited secretion in a dose-dependent manner. Again, the light chain of the molecule possesed activity, while the heavy chain had no effect. There appeared to be differences in the mechanism of action among the different toxins. In summary, clostridial neurotoxins can enter digitonin-permeabilized cells to interact with one or more components of the Ca^{2+}-dependent exocytotic pathway to inhibit secretion.

30.10

PERTUSSIS TOXIN-SENSITIVE G-PROTEINS ARE ASSOCIATED WITH *APLYSIA* SYNAPTIC PLASMA MEMBRANES AND VESICLES. S. S. Vogel, G. J. Chin and J. H. Schwartz, H.H.M.I., Columbia University, New York, NY 10032

We previously identified a Mr 41,000 pertussis toxin (PTX) substrate as *Aplysia* Gαo. Synaptosomes are enriched in this protein (42 pmol ^{32}P-ADP-ribose/mg protein) 3-fold over the homogenate. When synaptosomes are fractionated into plasma membranes and vesicles (for characterization see Chin *et al.*, These Abstracts) both fractions have the same concentration (77 and 72 pmol ^{32}P-ADP-ribose/mg) which is 5 times more than in homogenate. The G-protein labeled in the vesicle fraction represents 5.8% of total PTX-substrate in synaptosomes while that found in the plasma membrane fraction accounts for 84%. Although it is clear from these results that PTX-sensitive G-proteins are more plentiful in plasma membrane, both the high specific activity and the substantial percent recovered in the vesicle fraction argue that a sizable portion of Go in synaptic terminals actually is in synaptic vesicles. Two plausible explanations for the presence of Go in synaptic vesicles are that vesicles carry G-proteins to terminals by axonal transport and that G-proteins play a direct role in vesicular release. Consistent with transport, we find a 6-h ligature of *Aplysia* pleuro-abdominal connectives at 22°C results in a 2.5-fold increase in PTX substrate in the 1 mm segment containing the knot as compared to untied connectives, versus a 3-fold increase in adjoining segments. In squid axolemma we find Mr 41,000 and Mr 42,000 PTX substrates. In extruded axoplasm, however, we detect only the smaller protein, which is associated with internal membranes. These results suggest that a specific PTX-sensitive G-protein is transported to terminals by fast transport. Recently we reported that a PTX-sensitive G-protein mediates presynaptic inhibition by modulating ionic currents; at present we are investigating if G-proteins are directly involved in synaptic release.

S.S.V. is a trainee on NIH grant MH15174 and conducted some of this work in the Neurobiology Course at Woods Hole MBL in 1987.

PRESYNAPTIC MECHANISMS: IONS

31.1

OSCILLATION PERIOD OF mEPP FREQUENCY AT FROG NEUROMUSCULAR JUNCTIONS IS INVERSELY CORRELATED WITH RELEASE EFFICACY AND INDEPENDENT OF ACUTE CA^{++}-LOADING. A.D. Grinnell and P.A. Pawson, Jerry Lewis Neuromuscular Research Center, UCLA, Los Angeles, CA 90024.

We and others (Rahamimoff et al, Ann. N.Y. Acad. Sci., 307: 583-599, 1978) have noted periodic oscillations in mEPP frequency which presumably reflect corresponding changes in intraterminal free Ca^{++}. In an analysis of data related to post-tetanic changes in mEPP frequency, we find that most junctions show such oscillations, and the differences in the period of oscillation are consistently correlated with differences in synaptic release efficacy (quanta released/unit terminal length). The period is inversely proportional to release efficacy. Moreover, the oscillation period for any given junction is independent of short-term changes in Ca^{++} loading. It is essentially the same during resting mEPP release, or following tetani of different intensity in either zero Ca^{++}/EGTA or Ca^{++}-containing Ringer.

These data suggest that different junctions, as they develop differing mean mEPP frequency, release efficacy, and activity levels, acquire Ca^{++}-handling enzyme systems of a capacity and cycling rate that are appropriate to the long-term Ca^{++} handling needs applied to each, but independent of acute changes in Ca^{++} loading.
Supported by grants from NIH and the MDA.

31.2

INTRACELLULAR Ca^{2+} CHANGES IN PRE- AND POSTSYNAPTIC REGIONS OF APLYSIA NEURONS IN CULTURE MONITORED WITH FURA-2. E. Shapiro, S. Schacher and J. Connor. Howard Hughes Med. Inst., Columbia Univ. Col. of Phys. & Surg., New York, NY 10032 and AT&T Bell Laboratories, Murray Hill, NJ 07974.

Identified Aplysia neurons L10 and RB form synaptic connections in vitro. Stimulation of presynaptic cell L10 evokes a dual-action synaptic potential in RB. When L10 is fired from hyperpolarized resting potentials (-70 to -60 mV), PSP amplitude in RB is small. As L10 resting potential is depolarized (to -50 to -40 mV) the resting $[Ca^{2+}]_i$ as monitored by fura is increased and with stimulation the size of the PSP is increased in RB by 50-100%. During tetanic stimulation (5-10 Hz; 5 sec) the RB PSP was facilitated. Post-tetanic PSPs recovered to control levels very rapidly, usually within 10 sec. $[Ca^{2+}]_i$ in RB cells is also sensitive to resting potential. When RB cells were filled with fura (n=9), we sometimes could observe postsynaptic changes in $[Ca^{2+}]_i$ caused by L10 stimulation (n=4). In RB, depolarizing PSPs increased $[Ca^{2+}]_i$ and hyperpolarizing PSP trains decreased $[Ca^{2+}]_i$. These changes were greatest at localized areas of RB--good candidate regions for release sites. We are now examining changes in presynaptic fura signals in these localized regions during synaptic release and modulation.

31.3

RECORDINGS OF SINGLE CALCIUM CHANNELS FROM PRESYNAPTIC MOSSY FIBER TERMINALS IN ADULT GUINEA PIG HIPPOCAMPUS. *R. Gray and D. Johnston.* Program in Neuroscience, Baylor College of Medicine, Houston, TX 77030.

There is considerable interest in the identification and characterization of the type(s) of calcium channels responsible for neurotransmitter release at presynaptic terminals. We have used a fluorescent dye and Timm stain to identify presynaptic mossy fiber terminals (MFTs) in adult hippocampus and to record single calcium channel activity from cell-attached patches on these MFTs. A variety of fluorescent dyes (Magrassi et al., *J. Neurosci.* 7:1207, 1987) were tested for their ability to stain MFTs in slices of guinea pig hippocampus. Most of the dyes were relatively nonselective with considerable staining of putative smooth muscle cell nuclei, which are of similar size to MFTs (4-8 μm). One of the dyes (3,3'-diethyloxadicarbocyanine iodide), however, produced intense fluorescence of the mossy fiber synaptic fields with little or no staining of other, similarly-sized, structures. A modification of the acutely-exposed neuron preparation (Gray and Johnston, *Nature* 327:620, 1987) was used to dissociate the CA3 subfield from stained slices. Putative MFTs isolated from such slices were stained for zinc using the Timm method. We found that the intensely fluorescent objects 3-5 μm in diameter also stained positively for zinc, suggesting that they were indeed isolated MFTs. Cell-attached patch recordings were made from these isolated MFTs using a normal saline bath and pipettes containing isotonic $BaCl_2$, 1 μM TTX, and 0.1 mM 3,4-diaminopyridine. Channel openings were recorded in only about 25% of the patches, suggesting a relatively low channel density, although more than one channel was usually observed in these patches. Channel activity was also very transient in that it disappeared from most of the patches within several minutes. Channels with at least 3 distinct slope conductances were observed, however. The conductance levels averaged 9, 13, and 23 pS with multiple levels often being observed in the same patch. Ensemble averages from several patches suggested that there was little inactivation during 50-100 ms commands. This preparation should prove useful for investigating the function of presynaptic ion channels. (Supported by NIH grants NS11535 & HL31164 and AFOSR 85-0178).

31.4

CALCIUM CURRENTS IN FROG MOTOR NERVE TERMINALS. A. Arnon*, G. David*, E. Hevron* and Y. Yaari. (SPON: R. Rahamimoff). Dept. of Physiol., Hebrew Univ., Jerusalem 91010, Israel.

Local circuit currents flowing between motor nerve terminals and their parent axons were recorded from the perineurium of single motor axons or small nerve bundles in the frog (Rana ridibunda) cutaneous pectoris nerve-muscle preparation. Suppression of presynaptic K conductances, unmasked a current component during spike depolarization which was (i) abolished by cutting the motor axons distal to the recording site; (ii) positively related in amplitude to extracelular [Ca]; (iii) reversibly reduced by Mn (5 mM) and Cd (100 uM); and (iv) maintained when Ca was replaced by Sr. Therefore, we identified this current as an inward Ca current (ICa) at the motor nerve terminals.

ICa was markedly reduced by omega-conotoxin (5 uM) but not affected by nifedipine (1-100 uM). Omega-conotoxin, but not nifedipine, also blocked presynaptic Ca-activated K current and the endplate potential. Phenytoin and nickel (100 uM) did not affect ICa.

The pharmacological profile of ICa in frog motor nerve terminals is consistent with a high voltage-activated ICa, which mediates neurally evoked transmitter release.

MODULATION OF NEUROTRANSMITTER RELEASE BY INTRACELLULAR CALCIUM CHELATORS AT THE SQUID GIANT SYNAPSE. E.M. Adler*, G.J. Augustine, S.N. Duffy*, M.P. Charlton M.B.L., Woods Hole, MA 02543.

To further characterize the calcium milieu of the presynaptic calcium-receptor/transmitter release trigger, we injected calcium chelators into the presynaptic terminal of the squid giant synapse. Release was assayed by measuring the postsynaptic response to presynaptic stimulation.

BAPTA-family buffers with estimated calcium Kds ranging from 160 to 6250 nM in squid cytoplasm, caused similar reductions in transmitter release at similar intracellular concentrations. Dinitro-BAPTA, a derivative with a Kd in the millimolar range (Payne and Jaffe) was far less effective. Arsenazo III was also effective.

Chelators did not affect presynaptic action potentials. Prolonged stimulation did not reverse buffer effects. Transmission did recover as buffer diffused out of the terminal.

EGTA, which has a similar Kd but slower binding kinetics than BAPTA, was ineffective at reducing transmitter release at concentrations several times the effective concentration of BAPTA. The results suggest that the efficacy of calcium buffers in modulating transmitter release depends on both calcium binding kinetics and Kd.

31.6

SYNAPTOSOMAL CYTOSOLIC FREE CALCIUM DURING HYPOXIA WITH VARYING EXTERNAL CALCIUM

G. E. Gibson and L. Toral-Barza*, Cornell Univ. Med. Coll., Burke Rehab. Ctr. White Plains, NY 10605

Hypoxia selectively alters neurotransmitter release and this appears to be related to changes in nerve terminal calcium homeostasis. Cytosolic free calcium (Ca_i) was estimated in purified synaptosomes (Dunkley) with fura-2 and corrected for non-hydrolyzed dye. K^+ (31 mM) depolarization increased Ca_i from 101 $\pm$ 3 nM to 202 $\pm$ 9 nM. Histotoxic hypoxia (i.e. KCN addition), in the presence of 1.3 mM external Ca, increased Ca_i in resting (100%) and depolarized (58%) synaptosomes. If the Na/Ca exchanger was blocked by replacing most of the sodium in the media with choline, basal values increased by 74% and depolarized levels were elevated by 95%. In the absence of the Na/Ca exchanger, the hypoxic-induced elevation was still apparent under resting conditions but not during depolarization. Without external calcium, hypoxia did not alter Ca_i in the presence or absence of the Na/Ca exchanger. These data suggest that KCN treatment of synaptosomes does not release calcium from internal stores but reduces the ability to buffer the influx of Ca^{2+}. We hypothesis that this impairment elevates Ca_i, reduces further calcium uptake and alters the dependence of neurotransmitter release on external calcium.

31.7

MODULATION OF CALCIUM CURRENTS IN MAMMALIAN MOTOR NERVE TERMINALS. B.R. Hamilton, Z. Lu* and D.O. Smith. Department of Physiology, University of Wisconsin, Madison, WI 53706.

Nerve terminal currents were recorded from the rat EDL nerve-muscle preparation using a loose-patch technique. Initial recordings are characterized by an outward Na^+ capacitative current followed by an inward K^+ ionic current. Blockage of this terminal K^+ current with 10 mM TEA exposes the underlying terminal Ca^{2+} current. High-frequency (20 Hz) stimulation of the nerve decreased the magnitude of the inward Ca^{2+} current. This does not appear to be explained completely by either submembrane Ca^{2+} accumulation or channel inactivation as demonstrated in twin-pulse experiments. Instead, a major component in the frequency induced reduction in Ca^{2+} inward current may come from feedback modulation at the nerve terminal. ATP released during stimulation is quickly broken down to adenosine, which has been found to reduce the inward Ca^{2+} current. Intracellular recordings corroborate these findings. End-plate potentials are reduced by ATP and adenosine, but this effect is reversed by the adenosine-receptor blocker theophylline. Furthermore, ATP's effect is antagonized by α,β-methylene ADP, which prevents its breakdown to adenosine. Presynaptic muscarinic ACh autoreceptors may also be involved. Supported by NIH (NS13600) and M.D.A.

POTASSIUM-EVOKED $[Ca^{2+}]_i$ CHANGES IN A HIGHLY PURIFIED PREPARATION OF MOUSE BRAIN SYNAPTOSOMES LOADED WITH FURA 2. J. A. Bitran*, H. B. Pollard and E. Rojas*. LCB & G, NIDDK, NIH. Bethesda, MD 20892

Secretion from presynaptic terminals occurs by a very fast process. To determine the temporal relationship between secretion and $[Ca^{2+}]_i$ we measured high K^+-evoked ATP secretion and $[Ca^{2+}]_i$ transients. $[Ca^{2+}]_i$ changes were measured using Fura 2. The dye was incorporated into the synaptosomes either (1) by exposing the synaptosomes to Fura 2 AM or (2) by loading the salt form of the dye during the preparation of the synaptosomes ([Fura-2] = 100 uM). High $[K^+]_o$ causes the synaptosomes to secrete ATP. The secretion time course was measured using a luciferin-luciferase mixture. Depending on whether depolarization occurred in the presence or absence of external calcium two different modes of secretion were observed. In the presence of Ca^{2+}, secretion was fast and the signal could be fit to a single exponential (Tau ~ 1 sec). In the absence of Ca^{2+} secretion was much slower (Tau ~ 8 sec). In the presence of $[Ca^{2+}]_o$, synaptosomes loaded by protocol 1 showed that increasing $[K^+]_o$ induced a rapid rise in $[Ca^{2+}]_i$ and the size of the change depended on $[Ca^{2+}]_o$. The increase in $[Ca^{2+}]_i$ was blocked by La^{3+}. Synaptosomes loaded by protocol (2), showed clear increases in $[Ca^{2+}]_i$ upon application of high $[K^+]_o$ in the absence of Ca^{2+}. The data show that the $[Ca^{2+}]_i$ signal preceeds the ATP release and suggests that there is another mechanism of secretion that mobilizes calcium from intracellular stores.

31.9

PHYSIOLOGICAL EVIDENCE THAT EXCITATORY AMINO ACID RELEASE FROM HIPPOCAMPAL NEURONS IS MODULATED BY CALCIUM CHANNELS SENSITIVE TO BAY K 8644. D.M. Finch and M.B. Jackson. Departments of Neurology and Biology and Brain Research Institute, University of California, Los Angeles, CA 90024.

Whole cell patch clamp recordings from cultured embryonic mouse hippocampus show small, fast spontaneous inward currents (SICs). The currents are blocked by the broad spectrum glutamate antagonist gamma-D-Glutamylglycine, but not by 5-APV, a specific blocker of the NMDA glutamate receptor subtype. Therefore, SICs appear to be miniature excitatory synaptic currents that reflect vesicular release of excitatory amino acids and subsequent binding to a non-NMDA glutamate receptor. Increasing the bath concentration of K^+ from 4 mM to 16 mM produced a sustained, reversible, Ca^{++}-dependent increase in SIC frequency, coincident with a depolarization from about -60 mV at rest to -36 mV. The increased SIC frequency with high K^+ was blocked or substantially reduced by 50 µM Cd^{++}. At this concentration Cd^{++} has been shown to block almost completely Ca^{++} currents carried by "N" and "L" type channels, but to block the "T" type channel to a much lesser extent [Nowycky et al., *Nature*, 316 (1985) 440-443]. Further, both N and T type channels have been shown to rapidly inactivate upon depolarization (Nowycky et al., op. cit.), a property inconsistent with their mediation of a sustained effect. Addition of 1 µM of the L type Ca^{++} channel agonist BAY K 8644 to the high K^+ bath solution produced a significant further increase in SIC frequency. This suggests that L type Ca^{++} channels are present in glutamatergic synaptic terminals of hippocampal neurons, and are important in regulating transmitter release. Supported by NIH Grant NS 21908.

A CHARYBDOTOXIN-SENSITIVE CALCIUM-ACTIVATED POTASSIUM CONDUCTANCE AT THE CRAYFISH NEUROMUSCULAR JUNCTION: IMPLICATIONS FOR TRANSMITTER RELEASE AND FACILITATION. S. Sivaramakrishnan†, G. D. Bittner† & M. S. Brodwick*††. †Dept. of Zoology & Institute for Neurological Sciences, University of Texas, Austin, Texas 78712 & †† Dept. of Physiology & Biophysics, UTMB, Galveston, Texas 77550.

We have evidence for a calcium-activated potassium conductance [gK(Ca)] in the presynaptic terminal of the excitor axon that innervates opener muscle fibers in the crayfish walking leg. We record from the presynaptic terminal with two intracellular electrodes and from a muscle fiber with one intracellular electrode. Depolarization of the terminal by 60 mV or greater causes the membrane to begin repolarizing 0.5 ms after the start of a 5-10 ms current pulse. This repolarization is both calcium and voltage dependent. It is not blocked by 3,4-diaminopyridine, but is blocked by 0.5 mM cadmium, 13.5 mM barium, 20 mM tetraethylammonium and 50 nM charybdotoxin. This suggests that the repolarization is due to the turning on of high-conductance calcium-activated potassium channels in the presynaptic terminal membrane during the depolarizing pulse. The steady state presynaptic current-voltage relationship is linear only when gK(Ca) is blocked. The gK(Ca) has no significant effect on transmitter release though release begins at lower depolarizations when gK(Ca) is blocked. The gK(Ca) does have a dramatic effect on the growth and decay of twin pulse facilitation, primarily because of its effect on the membrane potential of the presynaptic terminal. gK(Ca) accounts for the first component of facilitation and the 'hump' in the decay curve of facilitation. gK(Ca) also accounts for the apparent decrease in facilitation at higher membrane depolarizations first reported by I. Parnas et al (Pflugers Arch., 1983, 399: 1-10). Supported by NIAAA grant #AA07746.

31.11

LIZARD MOTOR NERVE TERMINALS HAVE TWO CALCIUM-DEPENDENT POTASSIUM CONDUCTANCES. K. Morita and E.F. Barrett (SPON: K.L. Magleby). Dept. of Physiology & Biophysics, Univ. of Miami Sch. of Med., Miami, FL 33101.

Intra-axonal recordings were made from lizard motor axons impaled within a few mm of their motor terminals. In the presence of 4-aminopyridine (4-AP, 1 mM) the falling phase of the action potential is prolonged by these treatments: Ca-free solutions, 1 mM Mn, 10 nM charybdotoxin (CTx), or intra-axonal application of the Ca buffer BAPTA. In the presence of tetraethylammonium (TEA, 10 mM) and 1 mM 4-AP axons show prominent depolarizing afterpotentials followed by a small, slow hyperpolarizing afterpotential (h.a.p.) lasting several sec. These afterpotentials appear to originate in the motor terminals, and disappear in Ca-free solutions or following addition of 1 μM Cd. The slow h.a.p. is selectively blocked by 100 nM apamin, but not by CTx.

These data suggest that lizard motor nerve terminals express two kinetically and pharmacologically distinct Ca-dependent K conductances. The faster conductance, previously noted in extracellular recordings from lizard and mouse motor terminals, is sensitive to TEA and blocked by charybdotoxin. The slow, apamin-sensitive h.a.p. appears to be produced by a Ca-sensitive K conductance similar to that which underlies the afterhyperpolarization recorded in motoneuron cell bodies. Supported by NIH grant NS 12404.

EFFECTS OF DEPOLARIZATION AND Ca^{2+} INFLUX ON PROSTAGLANDIN PRODUCTION IN ISOLATED, CEREBELLAR GLOMERULI. R.V. DORMAN*. (SPON: D.M. Terrian). Dept. Biological Sciences, Kent State Univ., Kent, OH 44242.

Exogenous prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) has been shown to stimulate the release of preloaded D-[^{3}H]aspartate from isolated mossy fiber terminals. Cerebellar glomeruli, including mossy fiber terminals, were isolated and used to assess the effects of membrane depolarization and Ca^{2+} influx on the production of $PGF_{2\alpha}$ and prostaglandin E_2 (PGE_2). Glomerular particles were incubated in Krebs-Ringer buffer for 0 and 5 min, in the presence and absence of Ca^{2+}, prior to quantitation of the prostanoids by RIA. Depolarization with 45 mM K^+ caused a 32% increase in $PGF_{2\alpha}$ during 5 min of incubation, when compared to unstimulated controls. This increase was not observed in the absence of external Ca^{2+}. The presence of 25 μM diltiazem (Ca^{2+} channel blocker) or 1 mM EGTA prevented the depolarization-induced increase in $PGF_{2\alpha}$. The Ca^{2+} ionophore A23187 (5 μM) induced a 30% increase in $PGF_{2\alpha}$ in the absence of 45 mM K^+. There was no apparent effect of 45 mM K^+ on PGE_2 concentrations, but A23187 did induce a 47% increase during 5 min of incubation and diltiazem did inhibit incubation-dependent synthesis. It appears that depolarization-induced Ca^{2+} influx stimulated $PGF_{2\alpha}$, but not PGE_2 production in isolated cerebellar glomeruli.

SPINAL CORD AND BRAINSTEM: LESION STUDIES

32.1

RECIPROCAL INHIBITION FOLLOWING SPINAL LESIONS IN MAN. E. Ashby and M. Wiens*. Playfair Neuroscience Unit, Toronto Western Hospital, Toronto, Ont. M5T 2S8

Reciprocal inhibition was studied in normal subjects and patients with spinal cord lesions by stimulating the posterior tibial nerve below the threshold of the soleus alpha motoneuron axons and recording the changes in firing probability of tibialis anterior motor units activated by voluntary contraction. The strength of this inhibition was estimated from the number of displaced counts in post-stimulus time histograms (PSTH) of voluntarily activated motor units. For a given stimulus intensity this inhibition was greater in patients with spinal lesions than in normal subjects. In the patients with spinal lesions the Ia inhibitory interneurons had a lower threshold than soleus motoneurons, whereas in normal subjects the thresholds were approximately equal. These findings indicate that reciprocal inhibition of flexor muscles is enhanced following spinal lesions in man. A second period of inhibition was observed with a latency of approximately 50 ms. This was less prominent in the patients with spinal cord lesions.

32.2

THE ROLE OF INHIBITION IN RECOVERY FROM SUBTOTAL SPINAL CORD LESIONS IN A RAT MODEL. R. M. Harris and J. W. Little. Depts. of Biological Structure and Rehabilitation Medicine, University of Washington Sch. of Medicine, Seattle, WA 98195.

Spinal cord injury, in both humans and experimental animals, results in loss of muscle strength, but if the lesion is incomplete there is often considerable return of locomotor function. The neuronal mechanisms underlying this improvement, in particular the role played by inhibition in the cord, is unclear. On the one hand, inhibition is beneficial in damping hyperactive reflexes such as spasticity which act to hinder voluntary function. On the other hand, inhibition may act to block mechanisms which could be responsible for recovery of function. In order to study the role of inhibition in recovery from spinal cord injury, we injected spinal cord injured rats with either an agonist, baclofen, or an antagonist, bicuculline, to GABA, a major inhibitory neurotransmitter in the cord. Each rat had received a three-quarter cord lesion in the midthoracic region, sparing only the left lateral funiculus. For the next 4 weeks, daily intraperitoneal injections were given, and observations were made of the locomotor function of the hind legs. Our observations so far have not shown any significant differences in the rate or final level of locomotor recovery, between either baclofen- or bicuculline-treated animals and saline treated controls. We are thus unable to assign a role in the recovery process to GABAergic inhibitory effects.

32.3

OBSERVATIONS ON THE FIBER TYPE TRANSFORMATION IN SOLEUS MUSCLE AFTER SPINAL CORD TRANSECTION. E.Eidelberg, L.C. Maxwell*, R.Polich*, M.Moody*, and L.H. Nguyen*. Veterans Administration Hospital and the University of Texas Health Sciences Center, San Antonio, TX 78284.

In rats, complete transection of the spinal cord results in transformation of the slow twitch-oxidative (I) fibers that make up most of soleus muscle, to fibers with the histochemical and contractile properties of type 2A (fast-twitch, oxidative).This change takes place gradually beginning around the 10th day post transection, reaches maximum at 4-6 weeks post transection, and does not reverse afterwards.

Alpha-motoneurones innervating slow-twitch muscles, such as soleus, tend to be smaller than those innervating fast-twitch muscle.We asked whether the histochemical changes in muscle were paralled by changes in the size of the motoneurones.We compared the area of the soma, and the calculated dendritic surface area, of alpha motoneurones labeled by injection of WGA-HRP into the soleus muscles. The control rats were intact, and the test group were spinalized at L1 6 weeks prior to labeling.The soleus motoneurones from the spinal rats (N=29) had significantly (p=0.001) larger somata(mean:1230μm^2±352S.D.)than the controls(N=31)(mean:962μm^2 ±143S.D.).Perhaps this difference arises from increased motor unit innervation ratios due to collateral sprouting. 32.4

PHOTOCHEMICALLY INDUCED CYSTIC CAVITY FORMATION IN RAT SPINAL CORD T. Cameron, V.R. Holets, B.D. Watson, R. Prado, P. Tarjan*. Departments of Biomedical Engineering, Neurological Surgery and Neurology, University of Miami, Miami, FL 33136.

Cystic cavity (syrinx) formation in injured spinal cord is a well-known complication of spinal cord injury. Determining the origins of cyst formation and possible ameliorative strategies have been difficult owing to its unpredictable appearance following experimental impact injury in laminectomized animals. Cystic cavities can be created reproducibly in the rat spinal cord by modification of the recently developed photochemical method of spinal cord injury in non-laminectomized rats (Prado et al., J. Neurosurg. 67:745-753).

Sprague Dawley rats (85-120g) were anesthetized and their spinal vertebra exposed by blunt dissection. The 514.5 nm beam of an argon ion laser was focused as a sharp transverse line onto the spinal column at the level of T8 vertebra. The photosensitive dye, erythrosin B (FD & C Red No. 3) was injected intravenously to an initial blood concentration of 650 uM, and the translucent spinal column irradiated through a beam chopper operating at 10% duty cycle for 10 min, with a peak intensity of 60 W/cm^2. Animals evaluated for functional deficit by the modified system of Gale et al. (Exp. Neurol. 88:123-134, 1985) exhibited 35.3 ± 2% paralysis after 11 days which remained constant.

Immunohistochemical analysis of the resultant lesion, revealed cyst formation in the gray and white matter, but some fiber tracts in the dorsal and ventral columns were spared. At 3 weeks post-lesion the cyst had expanded to a length of 7 mm. This model is ideal for studying cyst formation and functional recovery following spinal cord injury.

BEHAVIORAL EFFECTS OF CAT SACROCAUDAL SPINAL CORD HEMISECTION OR TRANSECTION. E. L. Rhoton*, C. J. Vierck Jr., G. W. Sypert and L. A. Ritz. (SPON: H. Hirata). Univ of Florida Coll of Med, Depts. of Neurosurgery and Neuroscience, Gainesville, FL 32610.

In the cat, spinal cord segments caudal to the lumbosacral enlargement innervate the tail. These segments are designated the sacrocaudal spinal cord and extend from S3 to Ca8 (Ca = caudal). Hemisection or transection was carried out in the sacrocaudal spinal cord to study the behavioral effects of such lesions on hindlimb and tail function. Our long term goal is to develop a unique model for spinal cord injury. Under combined Ketamine and Halothane general anesthesia, cats were transected (N = 4) or hemisected (N = 6) at Ca1-Ca2. Behavior and reflexes of tail and hindlimb were observed from 3 to 7 months postoperatively.

None of the cats had evidence of bowel or bladder dysfunction. Hindlimb reflexes and gait were normal. In animals with hemisections the tail assumed a curved configuration towards the lesioned side, and tail tone increased during the first two weeks postoperatively. The duration of these effects extended at least 105 to 200 days. All animals with transections developed, after a period of hypotonia, persisting hypertonia. An exaggerated cutaneous flexion reflex was seen in the distal tail. Spontaneous side to side distal tail movements, termed spinal wagging, were also observed in 3 of 4 cats with transections.

Following sacrocaudal spinal cord hemisection or transection, no hindlimb or parasympathetic dysfunction was seen. With hemisection, tail hypertonia developed and with transection tail hypertonia and spinal wagging were seen. This model introduces an alternative location for studying spinal cord injury. (Research supported by NS23683 and the Veterans Administration Medical Research service.)

32.6

CONTRALATERAL INFLUENCES ON CAT SACROCAUDAL MOTONEURONS. L.A. Ritz, E.L. Rhoton* and G.W. Sypert, Univ of Florida Coll of Medicine, Depts of Neurosurgery and Neuroscience, Gainesville, FL 32610.

Anatomical studies in cat sacrocaudal spinal cord, from our laboratory, have shown that: 1) Ia primary afferent fibers can project into the contralateral ventral horn; 2) motoneuron dendritic trees extend into the contralateral ventral horn; and 3) commissural motoneurons are associated with tail musculature. We recorded ventral root potentials (VRPs) from sacrocaudal ventral roots to ascertain the physiological effects of contralateral dorsal root stimulation.

Adult cats, while deeply anesthetized with Halothane, were decerebrated by precollicular transection of the brainstem. The sacrocaudal spinal cord was exposed. For a given segment (S3 - Ca4) the dorsal roots (DRs) were placed on stimulating electrodes. Ventral roots potentials (VRPs) were recorded from the ipsilateral ventral roots. The efficacy and strength of dorsal root stimulation was assessed by cord dorsum responses.

Ipsilateral DR stimulation alone evoked monosynaptic and polysynaptic components of the VRPs. Contralateral DR stimulation alone produced a late polysynaptic response. When the ipsilateral and contralateral DRs were simultaneously stimulated, there was an enhancement or a diminution of the monosynaptic response. When the contralateral DR stimulation preceded the ipsilateral by 0.4 - 5 msec, the monosynaptic component was usually enhanced. When the contralateral DR stimulation preceded the ipsilateral by 6 - 30 msec, the monosynaptic and polysynaptic components were strongly inhibited and delayed.

These data indicate that, within cat sacrocaudal spinal cord, contralateral primary afferent input can have considerable influence on the output of ipsilateral ventral roots. The decreased monosynaptic response, sometimes seen, may be due to presynaptic inhibition. Of particular interest are the observations of enhancement of the monosynaptic response with simultaneous bilateral DR stimulation. This enhancement appears to be the physiological correlate of the crossed circuitry demonstrated by our anatomical studies.

32.7

ALTERATION OF MOTONEURON PROPERTIES BY PARTIAL SPINAL LESION IN THE DECEREBRATE CAT. J.S. Carp, R.K. Powers and W.Z. Rymer. Wadsworth Labs, NYSDOH, Albany, NY 12201, Dept. Physiol. & Biophys., U. Wash. Med. Sch., Seattle, WA 98195 and Dept. Physiol., Northwestern U., Chicago, IL 60611.

Interruption of pathways descending in the dorsolateral funiculi of the spinal cord of the decerebrate cat reduces the minimum repetitive discharge rate of motoneurons during physiological activation. The present study was designed to assess if the lesion-induced reduction in minimum discharge rate could be attributed to a change in intrinsic motoneuron properties or in synaptic input to the motoneuron.

Intracellular recordings from lumbar spinal motoneurons were performed in 14 paralyzed decerebrate cats before (n=48) or after (n=43) midthoracic dorsal hemisection. The two populations had similar distributions of resting membrane potentials, axonal conduction velocities and action potential characteristics. Repetitive discharge was elicited by 2 sec depolarizing current pulses in 37 cells. Minimum rate was estimated by adjusting the current magnitude until a sustained train of at least 6 spikes was elicited. Minimum rates were higher in the post- than in the pre-lesion group. The duration of the afterhyperpolarization (AHP) following a single spike elicited by a brief current pulse was shorter in the post- than in the pre-lesion group.

These data have two implications. First, the increase in minimum rate after lesion seen with current injection is probably due to the decrease in AHP duration. This suggests that an intrinsic motoneuron property which is an important determinant of repetitive discharge behavior may be under the influence of descending pathways. Second, the lesion-induced reduction in minimum rate seen during physiological activation is not due to changes in intrinsic motoneuron properties, but rather to changes in the pattern of afferent input or the efficacy of synaptic transmission. 32.8

CONTRIBUTIONS OF REGENERATION AND MECHANOSENSORY INPUTS TO BEHAVIORAL RECOVERY IN SPINAL-TRANSECTED LAMPREYS. A.D. McClellan, Dept. of Physiol. & Biophysics, Univ. of Iowa, Iowa City, IA 52242

Larval lampreys recover locomotor function 3-6 wks after receiving complete spinal transections. Descending brainstem command neurons functionally regenerate and can directly activate spinal locomotor networks below a healed transection site (McClellan, **Brain Res. 448**: 339, 1988). In the present study, the extent of this regeneration was examined using *in vitro* brain/spinal cord preparations. A short section of the spinal cord just below the healed lesion was bathed in a low-calcium Ringer's solution to block synaptic transmission at the terminals of descending axons that had possibly regenerated for short distances. Under these conditions, brainstem-evoked locomotor activity was reduced or sometimes abolished in the spinal cord below the blockade. Thus, many of the descending brainstem command axons appear to regenerate for short distances (less than 15 segments) before making synaptic connections. However, stimulation of the spinal cord above a healed transection site in low-calcium Ringer's solution could evoke action potentials more than 15 segments below the lesion site. Since locomotor activity can be initiated many segments below a healed transection site, propriospinal systems and perhaps mechanosensory inputs presumably aid in relaying the descending drive to more caudal parts of the spinal motor networks below the lesion area.

Mechanosensory inputs by themselves generally do not initiate locomotor activity below a spinal lesion but can couple motor activity across a transection site, since i.p. injection of NMDA (50 mg/kg) in animals with acute, mid-body transections evoked locomotor activity above and below the lesion that was often coupled 1:1. Since regenerated propriospinal neurons by themselves result in coupling of locomotor activity across the lesion site that is more variable than observed in recovered whole animals (McClellan, **Brain Res. 448**: 339, 1988), mechanosensory inputs appear to contribute significantly to the normal coupling of locomotor patterns across a healed transection.

32.9

THE EFFECT OF HIGH PRESSURE ON SYNAPTIC POTENTIATION IN ISOLATED BRAINSTEM-SPINAL CORD OF NEWBORN RATS. A. Tarasiuk and Y. Grossman. Unit of Physiology, Faculty of Health Sciences, Ben-Gurion Univ. of the Negev, Beer Sheva 84105, Israel.

High pressure (HP) induces hyperexcitability and convulsions in intact animals by mechanisms that are not understood. In the present experiments we examined the effects of HP on cranial reflexes and synaptic interactions in isolated brainstem-spinal cord of newborn rats. The preparation was isolated, placed in a pressure chamber and constantly superfused with oxygenated Krebbs solution (pH 7.3) at 27°C. Reflex activity was recorded extracellulary from the cut ventral roots of the 1st cervical nerves; the 5th (V) and 10th (X) cranial nerves were stimulated. Stimuli were delivered to one cranial nerve at 0.5 Hz before and after a short train of 100 stimuli at 10 Hz delivered to the same nerve to test post tetanic potentiation (PTP), or to the other nerve to test heterosynaptic potentiation (HSP). After control measurements under normal conditions, the pressure was raised to 10.1 MPa with compressed helium. Exposure to HP 1) increased the amplitude (26±10%, Mean±SE), duration (13.7±6%) and half rise time of individual reflex responses, 2) inhibited PTP from 165±25% to 138±18% with V stimulation and from 155±35% to 130±22% with X stimulation and reduced recovery time from PTP by 50-70%, and 3) decreased the marked HSP caused by V stimulation on the X reflex from 242±25% to 156±36%. X stimulation caused less HSP of the V reflex (122±15%) and was not affected by HP. In contrast to crustacean neuromuscular junction, HP in the mammalian CNS enhanced single polysynaptic responses but depressed frequency-dependent potentiation of cranial nerve reflexes.

33.1

REGULATION OF SOMATOSTATIN GENE EXPRESSION IN THE PERIVENTRICULAR NUCLEUS OF THE RAT HYPOTHALAMUS. J.A. Breed*, R.A. Steiner, and D.K. Clifton*. Ob & Gyn and Physiol & Biophys, Univ of Wash, Seattle, WA 98195.

Somatostatin (SS) has an important inhibitory role in the control of GH secretion. Sex steroids influence GH secretory patterns. This effect could be mediated by hypothalamic factors (e.g. SS) involved in the regulation of GH secretion. Castration of male rats results in an increase in baseline GH levels, and testosterone (T) replacement reverses this effect. These observations suggest that T stimulates hypothalamic SS synthesis. We tested the hypothesis that testosterone (T) stimulates SS gene expression in neurons of the periventricular nucleus (PeN) by measuring cellular SS messenger RNA (mRNA) using *in situ* hybridization. Male rats were castrated and implanted with either a Silastic capsule (30mm) containing T (n=3) or a sham implant (n=3). Animals were sacrificed 4 days after castration with a control group of intact animals (n=3). Coronal sections (20um) were prepared for *in situ* hybridization with an ^{35}S-labeled RNA probe complementary to the pre-pro-SS message. Sections were anatomically matched (10/animal) and read blindly. Signal levels for pre-pro-SS mRNA were measured in individual cells (approx. 100 cells/animal) in the PeN with a computerized image processing system. The results are shown with grains/cell as an index of SS mRNA content. The signal level of SS mRNA in cells of the PeN was significantly reduced

Group	Mean ± SE (grains/cell)	n
Intact	195 ± 3	3
Castrate	159 ± 6	3
T-replaced	182 ± 4	3

($p<0.006$) in castrate-sham implanted males compared with intact males. T replacement returned SS mRNA content to a level not significantly different from that of the intact animals. We conclude that T stimulates SS gene expression in neurons of the PeN and that this may, in part, account for the effect of T on GH secretory patterns.

33.2

REGULATION OF IGF-1 AND IGF-2 mRNAs IN THE MALE RAT HYPOTHALAMUS AFTER HYPOPHYSECTOMY. T.L.Wood, M.Berelowitz and J.F.McKelvy, Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, N.Y., 11794

Insulin-like growth factors (IGF-1, IGF-2) and their receptors are found throughout the brain, including the hypothalamus. Although peripheral IGFs may function as mediators of growth hormone (GH) action, their role in the CNS is unknown. IGF-1 has been shown to directly inhibit pituitary GH synthesis and secretion and to stimulate hypothalamic somatostatin (SRIF) secretion. Thus, hypothalamic IGFs may be involved in GH regulation in addition to the classical GH modulators SRIF and GH- releasing factor, GRF. If these peptides are involved in GH regulation then they should be influenced by GH removal.

We isolated total RNA from individual sham and hypox rat hypothalami 8, 15, and 27 days post op. IGF-1 and GRF RNA levels were determined by nuclease protection assays; IGF-2 and SRIF RNA levels were determined by Northern blot hybridizations. Hypothalamic IGF-1 and IGF-2 mRNAs decreased markedly 8 days after hypox and progressively declined over the course of the study. Confirming previous results, GRF mRNA increased over the same time course. Hypothalamic SRIF mRNA did not change significantly.

The novel demonstration of decreases in hypothalamic IGF-1 and IGF-2 mRNAs following hypox suggests a role for these peptides in hypothalamic-pituitary GH regulation. Studies using pituitary hormone replacement therapy in hypox rats are currently underway to determine GH specificity of the IGF-1 and IGF-2 mRNA regulation.

PERINATAL CHANGES IN THE GROWTH HORMONE (GH) RESPONSE OF CULTURED PITUITARY CELLS TO ISOBUTYLMETHYLXANTHINE (IBMX) AND FORSKOLIN (FSK). L. Cuttler, B. Collins* and M. Szabo*
Depts. Pediatrics/Medicine, Univ. of Chicago, Chicago IL

We have demonstrated that pituitary GH release in response to GH-releasing factor (GRF) and $(Bu)_2$cAMP in vitro is greater in newborn rats than in adults (Endocrinology 118:69). To determine the mechanism(s) underlying this developmental pattern, we tested the effects of 0.001-1.0 mM IBMX and 0.01-10.0 uM FSK, agents that increase intracellular cAMP content independent of the GRF receptor, on GH release from cultured pituitary cells of 2-day(d)-old, 15-d-old, and young adult male rats (n=3/group). The magnitude of GH release in response to IBMX and FSK was highly age-dependent, the fractional increase in GH release being greatest in newborn pituitaries and least in those of adults (ANCOVA: F=19.3 and 9.9 for age effects of IBMX and FSK, respectively; P <0.001 for both). GH release in response to a maximally stimulatory dose of IBMX (1 mM), was 376+45, 238+38, and 220+26% (mean ± SE) of controls by pituitary cultures of 2-d, 15-d, and adult rats respectively (ANOVA: F=4.5, P <0.05). Similarly, GH release with 10 uM FSK was 557+78, 264+25, and 226+51% of controls in 2-d, 15-d, and adults respectively (ANOVA: F=10.6, P<0.005). Conclusions: In the rat, pituitary GH responses to IBMX and FSK are highest in the newborn and decline with advancing age after birth. The findings suggest the existence of maturational changes within the somatotroph distal to both the GRF receptor and cAMP formation.

FORSKOLIN-STIMULATED GROWTH HORMONE (GH) SECRETION BY INDIVIDUAL SOMATOTROPHS FROM MALE, FEMALE AND TESTICULAR FEMINIZED (TFM) RATS. P. Martha, Jr.*, R. Krieg, Jr., A. Rogol* and W. Evans*. Univ. of VA, Charlottesville, VA 22908 and Medical College of VA, Richmond, VA 23298.

The quantity of GH released by individual somatotrophs from normal female and Tfm rats in response to GH-releasing hormone (GHRH) is similar, although significantly diminished compared to normal males. To define further the mechanisms subserving these differences we used a reverse hemolytic plaque assay to evaluate GH secretion by somatotrophs from male, female and Tfm rats following 90 min exposure to the adenylate cyclase activator, forskolin (3μM). The number of recovered somatotrophs ($x10^6$) responding to forskolin (as the percent plaque-forming x total dispersed pituitary cells) was greater from Tfm rats (1.05 ± 0.19) than males (0.51 ± 0.07; p=0.01), but no different than females (0.67 ± 0.11) although a strong trend was present (p=0.06). GH secretion, as assessed by the logarithmic mean GH plaque areas (μm^2 x 10^3; ± SE), was greater by somatotrophs from male rats both basally [5.8 ± 1.0 vs 2.7 ± 0.4 (female; p=0.006) and 3.3 ± 0.6 (Tfm; p=0.021)] and following forskolin stimulation [47.1 ± 8.9 vs 14.8 ± 1.9 (female; p=0.0008) and 16.2 ± 2.7 (Tfm; p=0.001)]. Plaque areas were not different between female and Tfm cells. The similarity between these and our previous results using GHRH as the GH secretagogue indicates that, compared to males, the reduced GH secretory capacity of female and Tfm somatotrophs is primarily determined by differences that occur distal to the GHRH receptor.

ONTOGENIC STUDY OF rGRF (1-29) NH2-INDUCED GH RESPONSE IN MALE OBESE ZUCKER RATS. P. Gaudreau, G. Renier*, N. Deslauriers* and P. Brazeau*. Neuroendocrinology Laboratory, Notre-Dame Hospital Research Center, Montreal, Canada, H2L 4M1.

To determine the onset of GH alterations in obese Zucker rats, we evaluated the in vitro and in vivo rGRF(1-29)NH_2-induced secretion (net area under the curve), at 60 and 90 days of age. The basal GH level in perifused dispersed pituitary cells of lean animals was significantly higher than that of their obese littermates. No significant deficit in stimulated GH secretion of 60-day-old rats was seen with increasing concentrations of rGRF (1.56 to 50 pM), although a trend was observed; however, in 90-day-old rats, a marked reduction of GH secretion was seen at all rGRF concentrations tested. The in vivo basal GH levels were similar in all animals, GH responsiveness was not altered after i.v. administration of 0.8 µg/kg b.w. rGRF, in 60-day-old obese rats, but was significantly diminished in 90-day-old rats. Moreover, a dose of 4.0 µg/kg b.w. rGRF significantly lowered GH secretion in obese animals of both ages. Altogether, these results indicate that the reduced sensitivity of somatotroph cells, observed in obese Zucker rats, is not primary in the development of the GH hyporesponse associated with obesity. Specific factors that influence in vivo somatotroph secretion and that represent important markers in the development of obesity, still remain to be found.

THREE DIMENSIONAL ORGANIZATION OF MICROTUBULES IN LACTOTROPHS.

A. Pollack*, C. Padula*, P.C. Goldsmith and R. Weiner. Reproductive Endocrinology Center, Univ. of Calif., San Francisco, CA 94143.

Recent evidence supports a role for cytoskeletal elements in intracellular transport of organelles and vesicles. To study the role of microtubules (MTs) in regulated prolactin (PRL) secretion, we established optimal conditions to stabilize MTs and retain cell ultrastructure during immunostaining of cultured lactotrophs. To characterize the inhibited state, we studied cells maintained under tonic dopamine (DA) control. Anterior pituitaries from ovex rats treated with estradiol-17B for 2 weeks were enzymatically dispersed. Cells were cultured on ECM-coated plastic coverslips in the presence of 500nM DA. After 2 days in culture, the cells were incubated in a stabilization + extraction buffer containing 500nM DA, fixed, and double immunolabeled for PRL and tubulin using 5 nm and 15 nm colloidal gold. Sections were viewed with bright field microscopy (LM) and both transmission (TEM, 60kV) and high voltage (HVEM, 300 kV) electron microscopy. At the LM level, the configuration of MTs in secretory cells was easily distinguished from stress fibers in fibroblasts. Polarized arrays of MTs radiated from a dense area around the nucleus. Patterns of MTs appeared as an intertwined cytoplasmic web or as a dense network embracing the Golgi apparatus and extending towards the plasma membrane (PM). In the TEM, the presence of long MTs subjacent to and following the contours of the PM was confirmed. Close associations between PRL granules and MTs were observed, and often seemed to involve an unlabeled connecting substance. In the HVEM, thick sections viewed at incremental angles gave stereoscopic images of 3-dimensional arrangements, displaying MT nucleating sites and granule-MT associations. These results demonstrate a highly organized MT network in lactotrophs which is closely associated with the secretory apparatus, and suggest a role for these cytoskeletal elements in PRL secretion. Supported by NIH grants HD08924 and HD11979.

DOPAMINE EFFECTS ON POTASSIUM CURRENTS OF IDENTIFIED RAT LACTOTROPH CELLS. PM LLEDO*, P LEGENDRE*, J ZHANG*, JM ISRAEL*, JD VINCENT (SPON : B. Bioulac). INSERM U.176, rue Camille Saint-Saëns, 33077 Bordeaux Cédex, France.

We have previously proposed that dopamine (DA) could inhibit prolactin release by changing the membrane potential of rat lactotrophs in primary culture (ISRAEL et al,1987). The present work was undertaken to study the effects of DA on identified K^+ currents using the "whole cell" patch clamp technique applied to enriched population of rat lactotrophs in primary culture. Each cell under recording was characterized by the reverse hemolytic plaque assay. In presence of Co^{2+} (2.5 mM), two K^+ currents were observed: a fast activated and inactivated current (IKt) and a sustained current (IKs). IKt had a range of activation from -40mV to +10mV and an inactivation range from -90mV to -30mV. It was slightly inhibited by 4AP (2mM). IKs had a range of activation from -20 mV to +40 mV, was not inactivated during long voltage step (up to 25 seconds), and was blocked by TEA (10 mM). DA added in bath (10nM) increased both potassium currents, with a major action on IKt without changing its steady state activation. These effects were mimicked by bromocriptine and blocked by the D2 antagonist sulpiride. We conclude that DA may control PRL release by increasing mainly transient outward K^+ current, thus decreasing excitability of the lactotrophs.

D_2 DOPAMINERGIC ATTENUATION OF PHOSPHOINOSITIDE PHOSPHORYLTRANSFERASES I AND II (PPT-I, PPT-II). W.D. Jarvis, A.M. Judd*, and R.M. MacLeod. Depts. of Medicine and Neuroscience, University of Virginia Medical Ctr., Charlottesville, VA 22908.

We have previously demonstrated that D_2 dopamine receptor activity attenuates the activities of PPT-I and PPT-II, thereby reducing the basal levels of PtdIns(4)P and PtdIns(4,5)P_2, but not of PtdIns, in the normal rat anterior pituitary gland. The concentration-response characteristics of this effect were recently examined as was the possibility that the somatostatin receptor may exert a similar influence.

Primary cultures of normal female rat anterior pituitary cells were incubated for 48 hrs with [^{3}H]Ins in the absence or presence of bromocriptine or SMS 201-995 (BRC, SMS), respective agonists of D_2 dopamine and somatostatin receptors. Following organic extraction, radiolabeled phosphoinositides were deacylated under alkaline conditions and assayed by conventional anion-exchange resin chromatography and liquid scintillation counting.

BRC (.001-10 μM) exerted profound, concentration-dependent reductions in the formation of [^{3}H]PtdIns(4)P (EC_{50}=.725 μM) and [^{3}H]PtdIns(4,5)P_2 (EC_{50}=.5 μM), but had no effect on the formation of [^{3}H]PtdIns; inhibition of prolactin release was also concentration-dependent (EC_{50}=.01 μM). In contrast, SMS produced dramatic inhibitions of both prolactin and growth hormone release, but failed to modify any aspect of phosphoinositide metabolism.

These data provide further evidence that PPT-I and PPT-II are the components of phosphoinositide metabolism that are sensitive to dopaminergic tone. We suggest that this capacity is unique to the D_2 dopamine receptor. (Supported by NIH grant CA-07535-24.)

ROLE OF VIP IMMUNOREACTIVE (VIP-IR) NEURONS WITHIN THE INFUNDIBULAR NUCLEAR COMPLEX (INF) IN REGULATION OF PROLACTIN (PRL) RELEASE IN THE DOMESTIC TURKEY L. J. Mauro , M. E. El Halawani*, and R. P. Elde. U of Minnesota, Dept. of Animal Science, St. Paul, MN 55108 and Dept. of Cell Biology and Neuroanatomy, Minneapolis, MN 55414.

During the reproductive cycle of the turkey, an initial elevation in plasma PRL occurs after photostimulation followed by a second rise during egg laying, culminating in the hyperprolactinemic state of incubation. Changes in PRL releasing factors such as VIP may account for these alterations. Using immunocytochemical techniques, we examined changes in hypothalamic VIP-IR expression in hens during different reproductive states. Birds were transcardially perfused with fixative,10μm cryostat sections of hypothalamus were incubated with rabbit VIP antisera followed by FITC-labeled goat anti-rabbit antisera. Marked differences in VIP-IR in the INF were noted in comparisons of non-photostimulated hypoprolactinemic (NP) and incubating hyperprolactinemic (HYP) hens. Numerous VIP-IR cells are present in the anterior (aINF=28±2 cells/section) and posterior (pINF=56±3) INF of HYP bird whereas 0-2 cells appear in the INF of the NP bird. The transition from the NP state to photostimulated (2 wks., 16L:8D) results in the appearance of VIP-IR cells (aINF=13±1; pINF=11±1) as well as increases in fibers in INF and median eminence. A second, greater increase in VIP-IR expression occurs in laying hens (aINF=30±5; pINF=39±3). These changes in VIP-IR in the INF coincide with alterations in plasma PRL and suggest that fluctuation in VIP expression by INF neurons may regulate PRL release during reproduction in this species.

CSF PROLACTIN CONCENTRATIONS IN FEMALE RATS CHANGE WITH ENDOCRINE STATE. B.S. Rubin, P.M. Ronsheim* and R.S. Bridges. LHRRB, Harvard Medical School, Boston, MA 02115.

Push pull-perfusion was used to estimate prolactin (PRL) levels in the CSF of female rats in various endocrine conditions. Cannulae were implanted in the lateral ventricle, and 10 minute perfusates were collected on ice and stored at -20°C until PRL content was measured by RIA. PRL was not detectable in perfusates collected from ovariectomized females. However, 4 days after sc implantation of a 5 mm estradiol-filled Silastic capsule, measurable levels of PRL were present in CSF samples from these same animals. Another group of animals was sampled on days 18 and 22 of pregnancy and again on day 8 of lactation. Levels of PRL in perfusates from pregnant animals were below the detectability of the RIA. On day 8 of lactation, pups were removed at 1000 h, CSF sampling began 2 hours later, and pups were returned to their mothers 4 hours after separation. Four of the 7 mothers showed a dramatic rise in CSF PRL levels after pups were returned and nursing resumed. These data suggest that when serum PRL levels are high, significant levels of PRL are present in the CSF and may therefore gain access to neural tissues that influence neuroendocrine and behavioral processes. Given that the lateral ventricles were sampled, it seems likely, that the major source of CSF PRL in the present study is the pituitary gland rather than the recently identified brain PRL system localized primarily in the basal hypothalamus. (HD 19789)

CHRONIC COCAINE (C) ALTERS THE RELEASE OF PROLACTIN (PRL) IN MALE RATS. N.S. Pilotte & L.G. Sharpe. Addiction Res. Ctr., Nat'l. Inst. on Drug Abuse, Baltimore, MD 21224.

A single exposure to C can alter the release of dopamine (DA; Pharmacol Biochem Beh 27:533). Such an alteration may be apparent in vivo as a change in the DA-controlled release of adenohypophysial PRL. We used the release of PRL as an index of hypothalamic DA activity in male Lewis rats that were passively injected with C for the first time or after 4 consecutive days of short-term exposure to the drug or its vehicle (V). A catheter was inserted into the right jugular vein of each rat. Three days later, blood was removed at 30, 15 and 0 min before and at 5, 10, 30, 45 and 60 min after the administration of C (1 mg/kg, iv) or V (0.15 M NaCl). Similar stable basal levels of PRL were observed both prior to and after the first administration of C or V on that day. However, when [PRL] was assessed similarly in the same rats after 4 consecutive days of short-term exposure to C, the basal [PRL] was 50% higher in rats exposed to C than to either their own previous levels or that of the V-injected rats. Furthermore, exposure to C, but not to V, resulted in a rapid and marked decrease (66%) in the peripheral PRL which was sustained throughout the sampling period. These results suggest that chronic exposure to C may decrease the amount of DA available tonically without necessarily interfering with the mechanisms of its release.

SEROTONIN (5HT) INFLUENCE ON ANTERIOR PITUITARY PROLACTIN (PRL) SECRETION: NOVEL SITES AND MECHANISMS OF ACTION. C.A. Johnston, F. Lopez*, G. Wisniewski* and A. Negro-Vilar. Lab of Molecular and Integrative Neuroscience, NIEHS, NIH, Research Triangle Park, NC 27709.

The site(s) and mechanisms by which 5HT stimulates PRL secretion from the anterior pituitary (AP) are poorly understood. We examined the effects of 5HT synthesis inhibition [using p-chlorophenylalanine (PCPA)] on basal, TRH or 5-hydroxytryptophan (5HTP) stimulated PRL release in vivo. We also examined the effects of in vivo 5HT synthesis inhibition or stimulation [tryptophan (TRYPT)] on basal or TRH-stimulated PRL secretion from dispersed AP cells as well as on the ability of neurointermediate pituitary (NIL) extracts obtained from the three treatment groups to stimulate PRL release in vitro.

PCPA treatment decreased basal PRL secretion in vitro and in vivo but did not diminish the PRL response to TRH either in vivo or in vitro, or to 5HTP administration in vivo. AP cells from PCPA-treated animals released less PRL than those from vehicle- or TRYPT-treated rats. NIL extracts from TRYPT-treated rats elicited a PRL response from AP cells at a concentration which did not affect PRL secretion when NIL extracts from control or PCPA-treated animals were used. In conclusion, changes in 5HT synthesis seemed to affect the ability of lactotrophs to release PRL under basal conditions, without impairing the response to known PRL secretagogues.

33.13

CORRELATIVE EVIDENCE FOR A ROLE OF HYPOTHALAMIC OXYTOCIN (OT) AND B-ENDORPHIN (B-EP) IN SUCKLING-INDUCED PROLACTIN (PRL) RELEASE. S.A. Frautschy* and D.K. Sarkar. (SPON: K. Heidenreich). Repro. Med. Univ. Calif. San Diego. La Jolla, CA. 92093. The role of OT and β-EP in the suckling-induced PRL release was investigated in urethane-anesthetized lactating rats. Unlike in control animals, PRL rose in response to suckling by 45 min. By 135 minutes levels reached 16-fold higher than controls. Suckled mothers displayed 1.6-fold higher pituitary portal levels of OT and 4.5-fold higher levels of β-EP between 0 and 45 minutes than control mothers. β-EP but not OT levels were 2.6-fold higher between 46-135 min during suckling than during control periods. Suckled mothers with intact pituitaries exhibited hypothalamic concentrations of OT and β-EP 24.5- and 2.7-fold lower respectively than in controls, and hypophysectomized-suckled mothers showed hypothalamic concentrations of OT and β-EP 1.4- and 1.6-fold lower respectively than in unsuckled/hypophysectomized mothers. In suckling mothers, the prolonged increase in β-EP in pituitary portal blood which coincided with a release of PRL and a decrease in hypothalamic concentrations of β-EP suggests that β-EP may modulate PRL secretion during lactation. The brief increase in pituitary portal plasma levels of OT coinciding with the suckling-induced PRL release and a decrease in hypothalamic OT concentrations would also support a role for OT in PRL secretion during lactation. The decrease in hypothalamic concentration of OT and β-EP, which was more accentuated in animals with intact pituitaries, is perhaps indicative that the pituitary plays a facilitory role in the suckling-induced surge of PRL. (supported by NIH grants # AG05453, HD20498).

33.14

SMALL DOSE OF DOMPERIDONE (DOMP) POTENTIATED THE EFFECTS OF TRH AND SEROTONIN (5-HT) ON PROLACTIN (PRL) SECRETION IN ESTROGEN-TREATED, OVARIECTOMIZED RATS. J.-T. Pan, K.-L. Teo* and C.-W. Chen*. Inst. Physiol., Nat. Yang-Ming Med. Coll., Taipei, Taiwan, Republic of China

A pharmacological regimen using Domp, a peripheral dopamine (DA) antagonist, plus CB154, a DA agonist, was developed by Haisenleder et al. and has been shown to enhance the effect of TRH on PRL release. However, the dose of Domp used (10 µg/rat) seems to be non-physiological since it induced a much higher PRL release and in order to reverse its effect, the use of CB154 which is dissolved in 50% ethanol solution further complicates the system. We found in this study that a smaller dose of Domp (1 µg/rat) without the accompanying CB154 induced a small but significant PRL release which lasted for over an hour. Giving TRH (1 µg/rat, iv) or 5-HT (0.3 mg/rat, iv) an hour later resulted in a significant rise of PRL which was much higher than that induced by TRH or 5-HT alone. The potentiating effect of Domp was even larger in the 5-HT- than in the TRH-stimulated PRL release. Pretreatment of vasoactive intestinal polypeptide (VIP, 10 µg/rat) or 5-HT, however, did not have any potentiating effect on the action of TRH. In conclusion, antagonizing the DA action on the anterior pituitary appears to potentiate the stimulatory effects of TRH and 5-HT on PRL secretion. (Supported in part by NSC77-0412-B010-11)

33.15

ROLE OF DOPAMINE AND VASOACTIVE INTESTINAL PEPTIDE (VIP) ON PULSATILE PROLACTIN SECRETION IN THE MALE RAT. F. López*, J.R. Dominguez*, F. Sanchez-Franco*, and A. Negro-Vilar. Reprod. Neuroend. Sect., LMIN, NIEHS, NIH, Research Triangle Park, NC 27709.

Pulsatile prolactin (PRL) secretion was analyzed by taking frequent blood samples (every 3 minutes for 2.5 hours) in undisturbed male rats. Animals were treated with a dopaminergic antagonist, domperidone (DOM, 0.1 mg/kg i.v.), a VIP antiserum (VIP-AS), the combination of both treatments or their respective vehicles. Samples were assayed for PRL by RIA, and data were submitted to the program "Detect" to analyze PRL pulsatile patterns. DOM treatment increased PRL pulse frequency as well as all quantitative parameters of pulsatile PRL secretion (peak and trough values, pulse amplitude, area under the pulses and mean secretion). Treatment with VIP-AS partially blocked the domperidone-induced increase in the quantitative parameters of pulsatile PRL secretion. By itself, however, VIP-AS did not alter pulsatile PRL secretion. The results suggest that in the presence of the tonic dopaminergic inhibition of PRL secretion, VIP is not able to elicit its stimulatory effects. On the other hand, in the absence of dopaminergic inhibition, VIP seems to participate in the genesis of dopamine-independent PRL pulses.

33.16

EFFECT OF HYPERPROLACTINEMIA ON 3H-NALOXONE BINDING IN SPECIFIC HYPOTHALAMIC NUCLEI OF OVARIECTOMIZED RATS. P.M. Wise and N.G. Weiland. Department of Physiology, University of Maryland, Baltimore, MD 21201

Hyperprolactinemia (hyperPRL) produced by administration of ovine prolactin (oPRL), suppresses plasma LH and PRL levels in ovariectomized rats. To test the hypothesis that hyperPRL influences LH or PRL through an opiatergic mechanism, we quantitated naloxone binding sites in the arcuate nucleus (AN), median eminence (ME), medial preoptic nucleus (MPN) and suprachiasmatic nucleus (SCN).

Young female rats were ovariectomized (day 0). Rats were treated with oPRL (4 mg/kg, sc, every 8h) or vehicle on days 4-6. Rats were decapitated on day 6; brains were removed and 20µ frozen sections were mounted onto slides and incubated in the presence of 2.5nM [3H]-naloxone in 50mM Tris buffer containing 100mM NaCl. Opiate receptor densities were quantitated in the rostral, middle and caudal AN and ME and rostral and caudal MPN and SCN. The densities of opiate receptors were significantly lower (17-25%) in all aspects of the AN of hyperPRL compared to control rats. In contrast, receptor densities were unaffected by hyperPRL in any other brain area examined. We speculate that the decrease in opiate receptor densities in the AN suppresses responsiveness to opiates and thereby mediates the PRL-induced suppression of PRL secretion. CORTICAL INPUTS IN THE RAT STRIATO-STRIATAL GRAFTS: ELECTRON MICROSCOPIC ANALYSIS WITH THE PHA-L METHOD. Z. C. Xu, C. J. Wilson, P. C. Emson. Department of Anatomy and Neurobiology, University of Tennessee, Memphis. Memphis, TN 38163, and Institute of Animal Physiology, Babraham, Cambridge, U.K.

We have previously shown that stimulation of the cerebral cortex evokes monosynaptic EPSP's in neurons located within grafts of fetal striatal tissue placed in the striatum of an adult host. We now report the direct anatomical observation of restored corticostriatal connection in neostriatal grafts.

Three to five days after creation of unilateral kainic acid lesions in the neostriata of Sprague-Dawley rats, a cell suspension prepared from striatal primodia collected from embryonic rats of 15-18 day gestation was implanted into the lesioned site. After a survival period of 2-4 months, PHA-L was iontophoretically injected unilaterally into the medial agranular region of the frontal cortex of the host rats. One to two weeks later, the brains of these rats were fixed and sections through the forebrain were prepared for light and electron microscopic studies using PHA-L immunohistochemistry.

Corticostriatal fibers labeled by medial agranular cortex injections arborized densely in the host striatum surrounding the grafts. Although the density of labeled fibers within the grafts was much lower than in the surrounding host tissue, many fibers could be seen to enter the graft and form terminal arboriztions within it. Electron microscopic examination of labeled terminals within the grafts revealed that they contained small round synaptic vesicles and formed asymmetric synaptic contacts with somata, dendritic shafts and dendritic spines. These synapses were similar in morphology to contacts formed by labeled fibers in the host neostriatum. The identity of the postsynaptic elements was different in the grafts from that of the hosts, however. In the host neostriatum, 90% of the labeled fibers contacted dendritic spines. In the grafts, only 47% of the corticostriatal contacts were axospinous. Most of the remaining synapses were on dendritic shafts. Supported by NIH grant NS20743.

INTRACELLULAR RECORDING OF PATCH AND MATRIX CELLS IN RAT STRIATAL SLICE PRESERVING CORTICAL INPUTS. Y. Kawaguchi, C.J. Wilson, P.C. Emson, Department of Anatomy and Neurobiology, University of Tennessee, Memphis, TN 38163 and Institute of Animal Physiology, Babraham, Cambridge, CB2 4AT, UK.

Spiny neostriatal projection neurons of the patch and matrix compartments are known to have somewhat different cytochemical staining characteristics, to have different efferent connections and to receive afferent fibers from topographically different regions of the cerebral cortex, but they are often supposed to be identical in their synaptic organization and electrical properties. The aim of this work is to compare their electrophysiological properties and responses to afferent input in vitro. We prepared rat brain slices which contained striatum and neocortex and preserved corticostriatal pathways. Extracellular stimuli were delivered through bipolar electrodes situated in both the medial agranular and prelimbic cortex. After physiological investigation, biocytin was injected intracellularly. Striatum slices with biocytin-injected cells were immersion-fixed, cut and incubated in the avidin-biotin-HRP complex and reacted with DAB. To identify whether the recorded cells belonged to the patch or matrix, calbindin immunohistochemistry was used to label the matrix in the same sections.

Calbindin staining clearly revealed patch and matrix in the immersion-fixed striatal slices and could be used for patch-matrix identification of recorded cells. Both patch and matrix cells extended their dendrites and local axonal collaterals only in their respective compartments. Both patch and matrix cells showed ramp depolarizing responses to depolarizing current steps, prominent anomalous rectification, and similar repetetive firing characteristics. Medial agranular cortex stimulation evoked three types of EPSP differing in latency and threshold. These EPSPs could elicit a depolarizing plateau potential, which was terminated by a resulting of action potential. Supported by NIH grant NS20743 (to CJW) and by a grant from the Japanese Ministry of Education (to YK).

34.3

MORPHOLOGICAL DIFFERENCES BETWEEN CORTICOSTRIATAL FIBERS TERMINATING IN THE PATCH AND MATRIX COMPARTMENTS OF RAT NEOSTRIATUM. C.J. Wilson and Z.C. Xu. Department of Anatomy and Neurobiology, University of Tennessee, Memphis, Memphis, TN 38163.

We have examined the corticostriatal connections formed by fibers arising from the medial agranular frontal cortical field and the medial prelimbic cortical field in the rat using orthograde labelling with PHA-L. These two cortical areas are known to project into the same general area in the neostriatum, but to different tissue compartments within that area. The medial agranular cortex projects to the matrix, while the medial prelimbic area has connections with the neostriatal patches. The PHA-L labelled fibers were examined using (1) light microscopy to determine the overall patterns of axonal arborization, (2) high voltage electron microscopy using thick (3-5μm) sections to quantitatively analyse the distances between boutons and to measure axonal diameters, and (3) conventional electron microscopy to determine the nature of the postsynaptic targets of each fiber type.

In both compartments, corticostriatal synaptic contacts are made primarily upon dendritic spines. Their convergence patterns are very different, however. Corticostriatal fibers terminating in the matrix have very extended arborizations that cover large areas in the neostriatum. Individual fibers can be followed for several millimeters. They make synapses almost exclusively *en passant*, and synaptic boutons from individual fibers are spaced so far apart that no fiber could possibly make more than a few contacts on each spiny neuron it encounters. Fibers terminating in the patches show a very different pattern. Individual fibers branch extensively and arborize within a region comparable to the dendritic field of a single spiny neuron. This pattern makes it possible for a single fiber to make many contacts with an individual neuron.

These observations suggest that the convergence ratio of corticostriatal connections may differ dramatically in the patch and matrix compartments. Supported by NIH grant NS20743.

REGULATION OF SODIUM AND CALCIUM SPIKES IN IMMUNOCYTOCHEMICALLY IDENTIFIED RAT DOPAMINE NEURONS RECORDED IN VITRO. AA Grace & SP Onn, Dept. Behav. Neurosci. & Psychiat., CNUP, Univ. Pittsburgh, Pittsburgh, PA 15260.

In vitro intracellular recordings were made from dopamine (DA) neurons identified by combined intracellular staining and tyrosine hydroxylase immunocytochemistry. DA neurons could be reliably identified by the slow depolarizing current (I_{SD}) and pacemaker firing pattern. DA neuron action potentials were long in duration (>2 msec) and exhibited comparatively depolarized spike thresholds (approx. -35 to -45 mV) which varied with membrane potential. The action potential was composed of two distinct components, a fast (1-1.5 msec duration) initial segment (IS) spike triggering a slow (1.5-3 msec duration) somatodendritic (SD) component. Cobalt application (4 mM:2 mM calcium) blocked the calcium-dependent SD spike component without blocking the IS spike, causing subsequent depolarizations to trigger a series of IS spikes at short (15-20 msec) interspike intervals. The IS spike could also be triggered alone in untreated slices by the rebound of strong hyperpolarizing pulses, with the threshold and amplitude of the IS spike strongly dependent on the initial membrane potential. The threshold for activating the rebound IS spike decreased with 4-aminopyridine (4-AP) application, but was unaltered by tetraethylammonium (TEA). When the IS spike is blocked by TTX, depolarization triggered high threshold calcium spikes after TEA but not after 4-AP. This evidence suggests that dendritic and axonal spiking regions exist in different functional subcompartments of the DA neuron, and can be independently modulated by pharmacologically distinct potassium currents. ANALYSIS OF FUNCTIONALLY DEFINED STRIATAL NEURONS BY COMBINED IN VIVO INTRACELLULAR RECORDING AND IMMUNOCHEMISTRY. SP Onn, TW Berger & AA Grace, Dept. Behav. Neurosci. & Psychiat., Univ. Pittsburgh, Pittsburgh, PA 15260.

In previous studies, we have identified two subtypes of striatal neurons based on their differential response to paired pulse stimulation of frontal cortex. However, it is unclear whether these neurons represent different histological types of striatal neurons. Using in vivo intracellular recording techniques, we have begun to examine the synaptic activity underlying these physiological responses, in addition to characterizing the cells recorded in terms of their morphology and neurotransmitter content.

Responses to the second pulse of paired cortical stimulation was characterized as facilitation, inhibition, or no change with respect to the amplitude of the response to the first stimulus. Using interstimulus intervals ranging from 10 to 100 msec, three different response patterns were observed: 1) inhibition followed by facilitation, 2) facilitation followed by inhibition, or 3) facilitation at all intervals. In each case examined, neurons showing the first response pattern, after labelling with Lucifer yellow, were shown to be of the medium or large spiny neuron type. We are currently classifying these neurons further by combining this with immunocytochemical localization of GABA, substance P and enkephalin. Another type of neuron showing primarily burst-type phasic firing patterns was found, after labelling, to resemble the large aspiny neuron of the striatum. Through this type of analysis, we hope to provide further information concerning the structural and functional organization of the basal ganglia. RESPONSES OF STRIATAL NEURONS TO PAIRED IMPULSE STIMULATION IN A CORTICOSTRIATAL SLICE PREPARATION. ES Nisenbaum, AA Grace and TW Berger. Depts. Behavioral Neuroscience & Psychiatry, U. of Pittsburgh, Pittsburgh, PA 15260.

Striatal neurons recorded in vivo can be segregated into two functionally distinct subpopulations, Type I and Type II, based on their inversely related probabilities of spike discharge to paired impulse stimulation of the corticostriatal pathway. We investigated whether or not the same two cell classes could be identified using an in vitro corticostriatal slice preparation.

Paired impulse stimulation of cortical fibers in vitro produced a facilitation of striatal cell discharge to the second impulse at interstimulus intervals (ISIs) of 10-400 ms. This paralleled a similar facilitation displayed by Type II neurons in vivo. Type II neurons also exhibit inhibition at ISIs of 10-30 ms, which was not observed in vitro. Consistent with previous reports of a GABA-mediated inhibition of striatal cells, addition of GABAergic agonists, pentobarbitol (50-100 uM) or pregnanolone (5-10 uM), produced a dose-dependent increase in short ISI inhibition, but did not affect the facilitation at longer ISIs. Direct stimulation of adjacent striatal tissue in vitro produced a similar selective enhancement of short ISI inhibition. Both drug- and stimulation-induced inhibitory effects could be blocked with bicuculline (20 uM). These results define conditions under which Type II-like neurons can be identified in vitro, and indicate that the magnitude of short ISI inhibition induced by selective activation of cortical afferents is reduced in vitro, but can be enhanced by GABAergic agonists or direct stimulation of striatal tissue. NONLINEAR RESPONSE CHARACTERISTICS OF STRIATAL NEURONS TO RANDOM IMPULSE TRAIN STIMULATION OF CORTICAL AFFERENTS. T.W. Berger, J.P. Sidney, E.S. Nisenbaum, and R.J. Sclabassi. Depts. of Behavioral Neuroscience, Psychiatry & Neurological Surgery, U. of Pittsburgh, Pittsburgh, PA 15260

Striatal neurons modulate excitatory input from the cortex through a substantial feedback network consisting of voltage-dependent membrane conductances, recurrent axon collaterals, and reciprocal connections with the substantia nigra. We quantitatively characterized the transformational properties of this network using nonlinear systems analytic procedures.

Unit activity of Type II striatal neurons was recorded in response to a train of 4064 impulses with a Poisson interval distribution (mean: 500 ms; range: 1-5000 ms) applied to the corticostriatal pathway. The relationship between inter-impulse intervals of the train and probability of spike output was represented as the first four kernels of a functional power series; the kernels were computed using cross correlation methods. Results showed that the probability of striatal cell discharge varied by as much as 40-50% depending on the interval since a prior impulse, with as many as four different ranges of intervals resulting in such nonlinearites. These second order nonlinear response properties were significantly different from those observed using paired impulse stimulation. Spike output also varied markedly depending on the intervals since two preceding impulses, with spike probability varying by 10-40% in response to several discrete input patterns. SINGLE UNIT ACTIVITY IN LATERAL STRIATUM OF FREELY MOVING RATS CORRELATES WITH SPECIFIC LIMB MOVEMENTS DURING LEVER PRESSING. R.M. Carelli* and M.O. West. (SPON: A. Tomie) Dept. of Psychology, Rutgers University, New Brunswick, NJ 08903.

We have previously demonstrated that units in the lateral striatum exhibit robust, short duration (50-150 msec) bursts of activity highly correlated with discrete limb movements (Neurosci. Abstr. 13:979, 1987). Units increased activity during the swing phase of forward treadmill locomotion, passive manipulation and cutaneous tapping of a particular limb. The objective of the present study was to further evaluate striatal involvement in sensorimotor integration via a more stringent behavioral measure, the force lever task. Long-Evans rats, aged 90-120 days, were prepared for chronic recording via a detachable microdrive positioned above the lateral striatum. Stereotaxic coordinates were referenced to bregma, using a level skull (A-P 0.8 to 1.7, M-L 3.2 to 4.0, D-V 3.0 to 6.0 mm). A mechanically operated force lever was electronically controlled by a computer which simultaneously recorded neural events. Rats were water deprived to 82% body weight and trained to depress the lever with the contralateral forepaw using a specified amount of force (10-15 grams) for durations ranging from 0-1.5 sec. This response produced an audio feedback cue and resulted in water reinforcement. In preliminary studies, striatal units correlated with locomotor movements and passive manipulation of the forelimb showed a pattern of activity consisting of maximal firing during extension of the forelimb as the subject reached for the lever. This was followed by a marked decrease in firing rate during actual contact with and depression of the lever. The significance of these studies is that they allow for an analysis of striatal function 1) in terms of quantifiable variables such as force, trajectory and timing of movement 2) in the context of unrestrained movement previously confined to studies in primates during head restraint, and 3) with respect to more global variables such as contextual cues. SOMATIC REPRESENTATIONS IN SINGLE UNIT RECORDINGS FROM THE DORSOLATERAL STRIATUM OF FREELY MOVING RATS. S.M. Cohen*, M. Pomerantz*, R.M. Carelli*, and M.O. West. Dept. Psychology, Rutgers Univ., New Brunswick, NJ.

A long-standing issue that is beginning to be resolved is whether the striatum is functionally compartmentalized. We have shown that robust single unit discharges correlated with specific locomotor limb movements were observed only in the most lateral and dorsal portion of the striatum (Neurosci. Abstr. 13:979, 1987). We now report that other neurons in the same subregion exhibit short-latency (<20 msec) responses to sensory stimuli applied contralaterally to circumscribed parts of the body. Long-Evans male rats (300g) were chronically implanted with a detachable microdrive positioned above the lateral striatum (0.0-1.7mm A-P, 3.5-4.5mm M-L and 3.0-6.0mm D-V from Bregma). Videotape recordings of the animal were synchronized by a computer, which simultaneously recorded each neural discharge. Frame by frame analysis (60 frames/sec) allowed the construction of peri-event histograms showing correlations between neural and behavioral events. As previously reported, over 70% of the units related to active movement of a particular limb also responded to passive manipulation and/or cutaneous tapping of the same limb. Further studies have revealed that, although individual forelimb and hindlimb representations could be found throughout the entire A-P range studied, the mean A-P coordinate for forelimb representations (0.92mm±.07 SEM) was significantly anterior to that for the hindlimb (0.61mm±.09) ($t = 2.73$; $p.01$). Specific sensory responses involving no apparent motor component were demonstrated consistently across animals during light stroking of the vibrissae, or light tapping of the neck, chin, and snout, throughout the entire A-P range studied. Sensory responses to light tapping of a restricted area of the trunk were observed in one animal at 1.0mm A-P. None of these responses could be obtained using a variety of anesthetics. It appears that all body parts are represented diffusely throughout a longitudinal strip in the dorsolateral striatum, the distribution of forelimb representations, on the average, somewhat anterior to that of the hindlimb. SINGLE DOPAMINERGIC NIGROSTRIATAL CELLS FORM TWO SYNAPTIC TYPES. T. Hattori, M. Takada and D. van der Kooy. Dept. of Anatomy, University of Toronto, Toronto, Ontario M5S 1A8, Canada

The characterization of the dopaminergic nigrostriatal neuron of the mammalian brain remains controversial, both in terms of structure (does it make symmetrical or asymmetrical striatal synapses) and of function (are its post-synaptic effects excitatory or inhibitory). Our data suggest that all of these seemingly contradictory characteristics may be possessed by single dopaminergic nigrostriatal cells. In single ultrathin sections through the rat striatum, ^{3}H-proteins anterogradely transported from the substantia nigra over short survival times (1 day) labeled primarily asymmetrical synapses "en terminaux", whereas antibodies to tyrosine hydrxylase(TH) marked almost exclusively symmetrical synapses "en passant". However, radiolabeled unmyelinated axons were usually double-labeled with TH. Employing longer survival times (10 days after the nigral isotope injections) in order to enhance the ratio of "en passant" to "en terminaux" labeling resulted in a large increase in the radiolabeling of striatal axonal varicosities and especially of symmetrical synapses "en passant" double-labeled with both the autoradiographic and immunohistochemical markers. We conclude that both the asymmetrical "en terminaux" and symmetrical "en passant" synapses take origin from nigrostriatal neurons.

EXTENSIVE CO-OCCURRENCE OF SUBSTANCE P AND DYNORPHIN IN STRIATAL PROJECTION NEURONS IN RATS. K.D. Anderson and A. Reiner. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, TN

Recent immunohistochemical studies have shown that substance P (SP) and dynorphin (DYN) co-occur extensively in striatal projection neurons in two non-mammalian amniote species and one mammalian species. Whether this is a typical feature of basal ganglia organization among other mammalian and non-mammalian amniotes is unknown. Since much work on the regulation of SP and DYN levels in striatal neurons has been done in rats, it is important to know the extent of SP/DYN co-occurrence in striatal projection neurons in this species. We therefore used the simultaneous immunofluorescence technique to examine the co-occurrence of SP and DYN in striatal projection neurons in rats (pretreated with colchicine). The studies were performed using antisera against different DYN peptides, each blocked by leu-enkephalin (LENK), to rule out possible spurious crossreactivity of anti-DYN antisera with LENK. Results consistently showed that the majority of SP+ or DYN+ neurons observed in the striatum were positive for both peptides. In contrast, SP and ENK co-occurrence was rare. Similarly, SP/DYN double-labeling of fibers and terminals of striatal projection neurons, both in the striatum itself and in striatal projection targets (i.e. substantia nigra and entopeduncular nucleus), was extensive, whereas SP/ENK double-labeling was rare. These results support the view that SP/DYN co-occurrence in specific populations of striatonigral and striatopallidal projection neurons is a widespread feature among amniotes and thus of fundamental importance to basal ganglia function. THE STRUCTURE OF NEURONS AND AFFERENT AXONS IN THE THALAMIC RETICULAR NUCLEUS: OBSERVATIONS WITH INTRACELLULAR LUCIFER YELLOW INJECTIONS AND PHA-L LABELING. by C. Asanuma. Laboratory of Neurophysiology, National Inst. of Mental Health, Poolesville, MD 20837.

The structure of neurons in the thalamic reticular nucleus (TRN) was investigated in lightly fixed slices of rat thalami by injecting the fluorescent dye, Lucifer Yellow (LY), under direct microscopic control, into individual TRN neurons. TRN neurons are large multipolar neurons, usually with elongated somata (range: 25-50 μm in longer diam.), whose dendritic arborizations are quite distinctive. The dendrites of each neuron radiate extensively in one or two tiers of restricted thickness (<10 μm) within the sheet-like plane of the TRN (approx. 200 μm in thickness). Each cell body has 3-5 primary dendrites, which rapidly give rise to 2-4 secondary dendrites. The primary dendrites are smooth, while secondary and tertiary dendrites are beaded; filamentous spine-like appendages are rarely seen. Many dendritic processes extend over 250 μm in length.

Retrograde tracer injections (FB,WGA-HRP,or FG) into the region of the TRN label neurons predominantly ipsilaterally in the parabrachial nucleus, the pedunculopontine nucleus, and in the magnocellular nucleus basalis, in addition to neurons in the locus coeruleus, raphé, dorsal thalamus, and cortex. However, anterograde tracer injections (WGA-HRP or PHA-L) into the parabrachial nucleus or the pedunculopontine nucleus label axonal arbors within the closely adjacent zona incerta, but not, to any significant extent, within the TRN. PHA-L injections into the nucleus basalis show widespread terminal arbors within the TRN; thin, varicose axons extend tortuously for considerable distances. The details of the relationship between these potentially cholinergic axons and the dendrites of TRN neurons remain to be investigated.

LAMINAR ORIGIN OF PATCH- AND MATRIX-DIRECTED CORTICOSTRIATAL PROJECTIONS IN THE RAT. C.R. Gerfen and A. Rutherford*. Lab of Cell Biology, National Institute of Mental Health, Bethesda, MD and MRC Brain Metabolism Unit, Edinburgh, Scotland.

Corticostriatal projections of medial frontal cortical areas in the rat are examined with the *Phaseolus vulgaris*-leucoagglutinin (PHA-L) anterograde axonal tracing method. Previous studies have suggested that corticostriatal inputs to the striatal patch and matrix compartments are determined by the cortical area of origin; i.e. the prelimbic cortex projects to the striatal patches whereas the anterior cingulate and medial agranular cortices project to the striatal matrix (Gerfen, 1984; Donoghue and Herkenham, 1986). The present more detailed analysis suggests a variation on this scheme. PHA-L labeled corticostriatal efferents of the infralimbic, prelimbic, anterior cingulate and medial agranular motor cortices each provide inputs to both the striatal patch and matrix compartments that are related to the laminar origin of the projection neurons. PHA-L injections into each of these cortical areas that label the efferents of cortical layer VI and deep layer V neurons, which provide a relatively restricted input to the deeper layers of the contralateral homotypic cortex, project relatively specifically to the striatal patch compartment. Conversely, injections that label efferents of more superficial cortical layers, which label a robust input to superficial layers of the contralateral homotypic cortex, label inputs to the striatal matrix. Also, qualitative observations suggest that inputs to the patch compartment are denser from the infralimbic and prelimbic cortices, whereas matrix directed projections are denser from anterior cingulate and medial agranular motor cortical areas. Thus the relative density of patch- and matrix-directed corticostriatal neurons may vary among cortical areas.

34.14

STRIATAL COMPARTMENTALIZATION IS PRECISELY PRESERVED ACROSS THE MAMMALIAN ORDER. **J. G. Johnston[1], C. R. Gerfen[2], K. Andruschak*[3], S. Haber[3] and D. van der Kooy[1], [1]Dept. of Anatomy, University of Toronto, Toronto, Canada, M5S 1A8, [2]Lab. Cell Biology, NIMH, Bethesda, Maryland, [3]Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, New York.**

The mammalian striatum is a compartmentalized structure that can be subdivided on the basis of different neurotransmitters, receptors and connections. Calcium-binding protein staining marks the matrix compartment, while enkephalin staining and opiate receptor binding mark the patch compartment, which is embedded in the matrix. Measurements of the patch compartment were made at rostral, mid and caudal striatal levels using opiate receptor binding in rat, enkephalin immunostaining in rhesus monkey and neurologically normal human and calcium-binding protein immunostaining in rhesus monkey sections. Although the human striatum is approximately 20 times larger than the rat striatum, the patch compartment still comprises 10-15% of the area of the striatum in the rat (10.6%), monkey (13.0%) and human (14.6%). The relative maintenance of the size of the patch compartment over a large increase in absolute striatal area could be achieved either by 1) increasing the number of patches, 2) increasing the area of individual patches, or 3) a combination of both strategies. We found that the area of the average patch enlarges along with increases in striatal area, while the average number of striatal patches does not vary in transverse sections of rat, monkey and human striatum. We suggest that lineage mechanisms (eg. equal increases in the number of patch stem cells and matrix stem cells) may underlie the maintenance of a specific ratio of total patch area to total matrix area across different mammalian species. However, epigenetic factors, such as adhesion and the establishment of afferent and efferent striatal connections, may play a role in the preservation of the absolute number of striatal patches across species.

PHARMACOLOGICAL AND MORPHOLOGICAL EVIDENCE FOR THE FORMATION OF CONNECTIONS BETWEEN TRANSPLANTED NEOSTRIATAL NEURONS AND SURROUNDING HOST NERVOUS TISSUE. N. Lee*, J.P. Walsh, C.D. Hull and M.S. Levine. MRRC, UCLA, Los Angeles, CA 90024.

Previous work from our laboratory demonstrated that transplanted striatal neurons (TSNs) possess normal, although immature, biophysical and morphological properties. TSNs also receive both excitatory and inhibitory synaptic inputs in response to stimulation of host striatal tissue. In the present study, neostriatal tissue from E14 fetuses was grafted into the intact host neostriatum. Recipient animals were sacrificed 4 to 10 weeks after transplantation and slices of their brains were studied in in vitro intracellular neurophysiological experiments. Excitatory postsynaptic potentials (EPSPs) elicited by stimulation of adjacent host tissue were blocked by the excitatory amino acid antagonist kynurenic acid. Since it is generally agreed that extrinsic neurons are the primary source of excitatory inputs to the neostriatum, these data indicate that the EPSPs resulted from an activation of synaptic contacts formed by the ingrowth into the transplant of extrinsic elements. Inhibitory postsynaptic potentials elicited by the same stimulus were blocked by the GABA antagonist biccuculine methiodide. Lucifer yellow injections into single TSNs demonstrated the outgrowth of processes from the transplant into the surrounding host tissue. Taken together these findings indicate that direct synaptic contacts may be formed between host and transplanted nervous tissue. Supported by USPHS Grant HD 05958.

COMPARATIVE FETAL DEVELOPMENT OF TYROSINE HYDROXYLASE AND SUBSTANCE P IN THE NEOSTRIATUM AND SUBSTANTIA NIGRA OF THE CAT. M.K. Boylan*, R. Gayek*, and R.S. Fisher. (SPON: D.L. Birt). MRRC and Dept. of Anatomy, UCLA, Los Angeles, CA 90024.

Dopamine is thought to play an organizational role in the fetal development of the neostriatum (NS), caudate (Cd) and putamen (Put). Tyrosine hydroxylase (TH), the rate-limiting enzyme of catecholamine synthesis and substance P (SP) develop early within the nigrostriatal and striatonigral pathways, respectively. In order to test the hypothesis that dopamine may influence the fetal developmental time course of SP in the NS, we compared the development of TH and SP immunohistochemistry in 16 fetal kittens from F30 through F60 in the NS and substantia nigra (SN) (gestation period in the cat is 65 days). The development of TH immunohistochemistry in the nigrostriatal pathway shortly preceeds the development of SP in the striatonigral pathway. At F45, TH undergoes its most dramatic increase in the number of cells and fibers in the SN and in TH innervation of the NS. At F50, SP undergoes its most noticeable developmental change in the NS; there is a large increase in the number of SP-positive cells, fibers and patches in the head of the Cd. At F55, SP fibers in the SN become significantly more dense. Also, the distribution of SP fibers growing into the SN closely matches the distribution of TH cells present in the SN. Thus, TH in the NS may influence the subsequent development of SP in NS cells, and may influence or guide the distribution of SP fibers growing into the SN. Supported by USPHS Grants NS 24596 and HD 05958.

NEUROPHYSIOLOGICAL DEVELOPMENT OF FELINE BASAL GANGLIA NEURONS IN VITRO: SUBSTANTIA NIGRA. M.S. Levine, J.P. Walsh, N.A. Buchwald, and C.D. Hull. MRRC, UCLA, Los Angeles, CA 90024.

Intracellular recordings were obtained from substantia nigra neurons in an in vitro slice preparation. To date, the ages of animals studied ranged from late fetal (E56) to postnatal day 39. Responses of individual neurons to intracellular injection of current and extracellular stimulation of local afferents were determined. Input resistance values obtained from current injection showed a gradual decline with age. In contrast to the large developmental changes in input resistance observed in other mammalian systems (i.e. caudate nucleus), values obtained from the youngest neurons examined were only slightly larger than those of the oldest neurons. The predominant form of synaptic input observed in the oldest neurons, an excitatory-inhibitory postsynaptic potential complex, was present in all neurons tested. Lucifer yellow (LY) was injected into neurons to study the development of single cell morphology. A variety of cell types were labelled by LY at each age. Dendrites and axons generally become more elongated and more highly branched with increasing age. The physiological and morphological information obtained indicates that substantia nigra neurons in the cat may mature earlier than neurons in the striatum. Supported by USPHS Grant HD 05958.

34.18

DYE-COUPLING BETWEEEN NEOSTRIATAL NEURONS: DEVELOPMENTAL REGULATION. J.P. Walsh, C. Cepeda*, R. Fisher, C.D. Hull and M.S. Levine. MRRC, UCLA, Los Angeles, CA 90024.

Intercellular communication via gap junctions has been shown to be developmentally regulated in the neocortex of rats and guinea pigs. The present study utilized Lucifer yellow (LY) injections and intracellular recording to determine if neuronal coupling among neostriatal neurons is under developmental control. Striatal slices were obtained by standard techniques from rats of 1 day postnatal age to adult (>35 days). Dye-coupling was found to be highest in the youngest neurons examined (1-5 day =70%). As age increased the incidence of dye-coupling declined. Six-ten day old neurons showed 60% coupling; 11-15 day old neurons showed 46% coupling; 15-20 day old neurons showed 36% coupling; 20-30 day old neurons showed 20% coupling and >30 day old neurons showed 2% coupling. In addition, the number of neurons labelled by each injection decreased with age. Single injections labelled large aggregates of neurons in slices obtained from 1-2 day old rat pups. After 5 days of age only 2-3 neurons were labelled per injection. Dye-coupled neurons also displayed fast-pre potentials or coupling potentials in response to orthodromic stimulation. These results indicate that striatal neurons in the immature rat are dye-coupled and can display electrotonic interactions. Coupling may function in the immature striatum to aid in the formation of neuronal connectivity by facilitating developmentally crucial electrical or chemical events. Supported by USPHS Grant HD 05958.

DYE-COUPLING BETWEEN NEOSTRIATAL NEURONS: MODULATION BY DOPAMINE. C. Cepeda*, J.P. Walsh, N.A. Buchwald, C.D. Hull and M.S. Levine (SPON: C.S. Bailey). MRRC, UCLA, Los Angeles, CA 90024.

Recent work in the retina suggests dopamine (DA) modulates the permeabilility of gap junctions. The present study determined if DA has a similar role in the mammalian neostriatum. Ten adult rats received unilateral electrolytic lesions in the substantia nigra (SN). After 3-5 weeks the animals were injected with ketamine (35 mg/kg i.p.). Six rats displayed turning to the side of the lesion. Neostriatal slices were prepared using standard techniques. Recording electrodes were filled with Lucifer yellow. Intracellular recordings were obtained from neurons in the striata ipsilateral and contralateral to the lesion in 23 slices. In the group with histologically verified SN lesions, 23 cells were filled in the ipsilateral neostriatum. Dye-coupling occurred in 43% of the injections. In the contralateral neostriata and in the striata ipsilateral to lesions that missed the SD, 31 cells were filled. Only 3% displayed coupling. Although no major electrophysiological differences were found between recorded cells on sides ipsilateral or contralateral to the lesions some cells in the ipsilateral striata displayed low-amplitude spontaneous depolarizing potentials. All animals that had SN lesions and a high incidence of dye-coupling displayed turning when injected with ketamine. This study suggests that DA may function in the neostriatum to uncouple gap junctions. Supported by USPHS Grants HD 05958 and AG 7462.

34.20

DEVELOPMENT OF CORTICOSTRIATAL CONNECTIONS IN THE CAT. R.S. Fisher and R. Gayek*. MRRC and Dept. of Anatomy, UCLA, Los Angeles, CA 90024.

The objective of these experiments was to determine the relationships between developing corticostriatal inputs and their target neurons. In fetal cats, retrograde and anterograde axonal markers (WGA-HRP) showed the initial ingrowth of corticostriatal axons at fetal age 55 (feline gestation = 65 days). As shown by electron microscopy and Golgi staining, this event coincided with the initiation of synaptogenesis in the neostriatum and began a period of dendritic outgrowth and elaboration. Immunochemistry also demonstrated that a massive increase in the expression of glutamatergic and GABAergic markers in the neocortex and neostriatum started at this time. Based on these data, it is reasonable to infer that the ingrowing corticostriatal axons exert an inductive effect on neostriatal target neurons. This influence may direct the morphogenesis of dendritic arbors in the neostriatum while coupling the expression of glutamatergic (neocortex) and GABAergic (neostriatum) fast amino acid neurotransmitters. Supported by USPHS Grants HD 05958 and NS 24596.

34.21

NEUROPHYSIOLOGICAL DEVELOPMENT OF FELINE BASAL GANGLIA NEURONS IN VITRO: CAUDATE NUCLEUS. *N.A. Buchwald, C. Cepeda*, J.P. Walsh, C.D. Hull and M.S. Levine. MRRC, UCLA, Los Angeles, CA 90024.*

Intracellular recordings were obtained from feline caudate nucleus neurons maintained in an in vitro slice preparation in 33 kittens ranging in age from fetal day 56 to postnatal day 64. Slices (400μm) from the caudate nucleus were obtained and incubated in Ringer's solution. Intracellular electrodes (50-120 mΩ) were filled with K-acetate. Some electrodes contained Lucifer yellow to identify the recorded cells. The passive and active membrane properties of 130 cells were studied. In very young neurons, spike amplitude was smaller than in older neurons. Caudate neurons recorded in slices from young animals showed high input resistances which progressively diminished with age. Excitatory postsynaptic potentials could be evoked in the youngest neurons tested (fetal day 56). Except for one large aspiny neuron all labelled cells were medium-sized spiny neurons. In cells obtained from prenatal slices and during the first postnatal week few dendritic spines occurred. A marked increase in spine density occurred during the second postnatal week. Caudate neurons showed dye-coupling more frequently in younger animals. These results in conjunction with our previously published in vivo studies demonstrate that both passive and active membrane properties of caudate neurons change during prenatal and postnatal periods. Supported by USPHS Grants HD 05958 and DA 3017.

Non-coupling Between D_1 Dopamine Receptors and Adenylate Cyclase in the Amygdaloid Nuclear Complex. C. Kilts*, C. Anderson*, J. Lackowicz* and R. Mailman (SPON:R. Erickson). Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

Accumulated evidence indicates that amygdaloid dopamine (DA) receptors are not coupled to the stimulation of adenylate cyclase (AC) activity. Fenoldopam and DA produced a concentration-dependent (SCH23390-inhibited) stimulation of AC activity in homogenates of the micropunch dissected caudate nucleus, olfactory tubercle, nucleus accumbens and substantia nigra-pars reticulata. With the exception of the intercalated cell groups, neither DA nor fenoldopam significantly increased cyclic AMP synthesis in the component nuclei of the amygdaloid complex. AC activity in the central amygdaloid nucleus (CAN) was stimulated by GTP and Ca^{2+}/calmodulin in a concentration-dependent manner. The addition of Mg^{2+} and GTP to a partially purified membrane preparation of the microdissected caudate nucleus restored both basal and DA-stimulated AC activity. Similar attempts restored basal enzyme activity but failed to constitute a DA-stimulated system in the CAN. These findings indicate a mismatch between functional and radioligand binding site (Boyson et al., J. neurosci. 6:3177, 1986) markers of D_1 receptors in the amygdaloid complex. The results of on-going studies of the DA receptor regulation of G protein function and cyclic AMP efflux from slices of the amygdaloid complex will be presented. (NIMH MH-39967).

EFFECTS OF PERTUSSIS TOXIN ON DOPAMINERGIC MECHANISMS IN CAUDATE. P.C. Bickford-Wimer, C.L. Boyajian, M. Kim*, D. Cooper*, and R. Freedman. Depts. of Pharmacology and Psychiatry, UCHSC, and the VAMC, Denver, CO 80220

Differences in the transduction mechanisms for D1 and D2 receptors were exploited to study their electrophysiology in the caudate nucleus. Unilateral injections of pertussis toxin (PT) were made into the caudate nucleus of Sprague-Dawley rats. 12 to 24 hours later there was a significant attenuation of in vitro PT-induced incorporation of ^{32}P-NAD$^+$ into 39 and 41 k-Da substrates. Additionally, this treatment prevented the inhibition of adenylate cyclase activity by N-n-propyl-norapomorphine. Previous work has indicated that spontaneous discharge of caudate neurons is dependent on endogenous DA neurotransmission; therefore rats were prepared for electrophysiological recording under urethane anesthesia. Single barrel micropipettes filled with 3M saline were stereotaxically placed in caudate nucleus. Mean discharge rate increased from 4.1 ± 0.4 (SEM, 29 cells, 4 rats) to 8.7 ± 1.4 Hz (49 cells 6 rats). In addition, a higher percentage of interspike intervals less than 50 msec was observed in PT-treated rats. These electrophysiological changes were consistent with decreased dopaminergic neurotransmission. The data suggest that D2 mechanisms may underlie dopaminergic regulation of caudate neuron spontaneous rate. Work supported by USPHS grant NS-09199 and the VAMRS.

DOPAMINE-INDUCED INHIBITION OF SUBSTANTIA NIGRA NEURONS IS NOT DEPENDENT UPON ADENYLATE CYCLASE INHIBITION: AN IN VITRO ELECTROPHYSIOLOGICAL STUDY. A.L. Mueller and M.S. Brodie, Neurosci.Res.Div., Pharmaceutical Discovery, Depts. 47H & 47W, Abbott Labs., Abbott Park, IL 60064.

Dopamine (DA)-containing neurons within the substantia nigra zona compacta (SNC) are inhibited by DA via D-2 autoreceptors. D-2 receptors are known to be either negatively linked or unlinked to adenylate cyclase (AC). Previous reports have suggested the involvement of a pertussis toxin-sensitive G-protein in the mediation of DA-induced inhibition; however, the role of AC was not investigated. The aim of the present study was to determine the involvement of AC inhibition in DA-induced inhibition of DA neurons within the SNC. Submerged rat brain slices containing the SNC were superfused (2 ml/min), and presumed DA-containing neurons were recorded extracellularly. DA (1-30 μM) produced a dose-dependent reduction in spontaneous firing rate. Three treatments were used to increase intracellular levels of cyclic AMP (cAMP) in the slice: the AC activator, forskolin, and two membrane permeable analogs of cAMP, dibutyryl cAMP and 8(4-chlorophenylthio)-cAMP (cpt-cAMP). Pretreatment of slices with forskolin (1-10 μM), dibutyryl cAMP (100 μM), or cpt-cAMP (100 μM) typically resulted in an increase in the spontaneous firing rate (range 0-89%). This excitation was preceded occasionally by a transient reduction in firing. In all cases, DA-induced inhibition was not altered in the presence of these agents, i.e., elevation of intracellular cAMP levels did not prevent DA-induced reduction in firing. These results strongly suggest that AC inhibition with a resulting reduction in intracellular cAMP levels is not involved in DA-induced inhibition of neurons in the SNC.

8-BROMO-cAMP MIMICS THE EFFECTS OF NEUROTENSIN IN MIDBRAIN DOPAMINE NEURONS: A STUDY IN BRAIN SLICE. W.-X. Shi* and B.S. Bunney. Depts. Pharmacol. & Psychiat., Yale Univ. Sch. Med., New Haven, CT.

We have previously reported that neurotensin (NT) selectively attenuates the inhibition of midbrain dopamine (DA) neurons induced by microiontophoretically applied DA in vivo. In the present study, the effect of NT on DA neurons and the possible mechanism of its action are further studied using a brain slice preparation. The slices containing the ventral tegmental area and substantia nigra were submerged beneath a continuously superfusing medium. Extracellular signals were recorded from DA neurons based on established criteria. The activity of DA neurons was usually totally inhibited by 10 uM DA or less. Confirming our previous finding, NT (100 pM-5nM) significantly attenuated DA-induced inhibition of DA neurons with no or small increase in basal firing rate. Significant excitation was observed when higher concentrations of NT (>5 nM) were used. Application of the membrane permeable analogue of cAMP, 8-Br-cAMP (50 uM-1 mM) was found to mimic the effects of NT. Forskolin (0.1-1 uM), a direct activator of adenylate cyclase, produced the same effects as those of NT and 8-Br-cAMP. These results raise the possibility that the attenuation of DA-produced inhibition by NT may be mediated by intracellularly produced cyclic AMP. Preliminary results with IBMX, a phosphodiesterase inhibitor seem to support this hypothesis.

TUBULIN MODIFIES SYNAPTIC MEMBRANE ADENYLATE CYCLASE VIA NUCLEOTIDE EXCHANGE. Nan Wang* & Mark M. Rasenick
Dept. of Physiology & Biophysics & the Committee on Neuroscience, Univ. of Illinois College of Medicine Chicago, IL 60680 USA.

Tubulin, the primary constituent of microtubules, is a GTP-binding protein with structural similarities to other GTP-binding proteins. Whereas, microtubules have been implicated as modulators of the adenylate cyclase system, the mechanism of this regulation has been elusive. Tubulin, polymerized with the hydrolysis-resistant GTP analog, GppNHp, can promote inhibition of synaptic membrane adenylate cyclase which persists subsequent to washing. When tubulin is polymerized with the hydrolysis-resistant photoaffinity GTP analog, [^{32}P] AAGTP, and this protein is added to synaptic membranes, AAGTP is transferred from tubulin to the inhibitory GTP-binding protein, Gi. This transfer is blocked by prior incubation of the membranes with GppNHp or covalent binding of AAGTP to tubulin prior to exposure of that tubulin to membranes. Incubation of membranes with GppNHp subsequent to incubation with tubulin-AAGTP results in a decrease in AAGTP bound to Gi and a compensatory increase in AAGTP bound to the stimulatory GTP-binding protein, Gs. These data are consistent with synaptic membrane tubulin regulating neuronal adenylate cyclase by transferring GTP to Gi and, subsequently, to Gs. Further, domains on tubulin required for polymerization appear to be required for the transfer of nucleotide to Gi. This and other physical evidence suggest that tubulin forms complexes with G proteins and, in doing so, may alter neuronal adenylate cyclase.

MODIFICATION OF G_s-STIMULATED ADENYLATE CYCLASE IN BRAIN MEMBRANES BY LOW pH TREATMENT: CORRELATION WITH ALTERED GUANINE NUCLEOTIDE EXCHANGE. M.M. Rasenick and S.R. Childers (SPON.: H. Hamm). Dept. of Physiology, Univ. Illinois Coll. Med., Chicago, IL 60680 and Dept. of Pharmacology, Univ. Florida Coll. Med., Gainesville, FL 32610.

Pretreatment of rat brain membranes at pH 4.5 modifies function of G-proteins by eliminating G_s-stimulated adenylate cyclase (AC) while increasing opiate-inhibited AC (Childers & LaRiviere, J. Neurosci. 4, 2764 [1984]). To help characterize the molecular nature of the low pH effect, we labeled G_i and G_s alpha subunits in both control and low pH pretreated membranes with the GTP photoaffinity analog [32P]P3(4-azidoanilido)-P1-5'-GTP (AAGTP). Crude synaptosomal membranes were prepared from 21 day-old rats and preincubated at 0° for 10 min in either Tris buffer, pH 7.4 (control) or sodium acetate buffer, pH 4.5 (low pH pretreated). Membranes were first preincubated with unlabeled AAGTP after pH treatment and assayed for AC activity. Preincubation with unlabeled AAGTP produced a persistent inhibitory state of AC which was overcome in untreated membranes with high (>1 µM) concentrations of Gpp(NH)p. In low pH pretreated membranes, this inhibition could not be overcome, and stimulation by Gpp(NH)p was eliminated. Maximum inhibition of AC achieved by incubation with AAGTP was not altered by low pH pretreatment.

Stimulation of AC has been associated with a transfer of guanine nucleotides from $G_{i/o}$ to G_s alpha subunits (Hatta et al, PNAS 83, 265 [1986]). To determine the effect of low pH pretreatment on guanine nucleotide labeling and transfer, labeling with [32P]AAGTP was accomplished in control and low pH pretreated membranes. Incorporation of [32P]AAGTP into G_s (42 kDa) or $G_{i/o}$ (40 kDa) was unaffected by low pH pretreatment; however, transfer of [32P] from $G_{i/o}$ to G_s, which occured with low (10 nM) concentrations of Gpp(NH)p in untreated membranes, was severely retarded in low pH pretreated membranes. Both the potency and efficacy of Gpp(NH)p in producing exchange of [32P]AAGTP from $G_{i/o}$ to G_s was markedly reduced by low pH pretreatment. These results correlate the loss of G_s-stimulated AC with a loss of transfer of nucleotide from $G_{i/o}$ to G_s alpha subunits, and suggest that the nucleotide exchange participates in the modulation of neuronal AC.

NOVEL MECHANISM OF REGULATION OF CYCLIC AMP ACCUMULATION IN A NEUROBLASTOMA CELL LINE. B. Baron and B.W. Siegel. Merrell Dow Research Institute, Cincinnati, OH 45215.

Muscarinic cholinergic (mAChR) and α_2-adrenergic receptors (α_2AR) share the ability to attenuate adenylate cyclase (AC) in diverse cell types, but are shown in the present study to exert opposite effects on AC in intact SK-N-SH (ATCC-HTB-11, passage 45-65) neuroblastoma cells.

The selective α_2 agonist, UK14304 (UK) reduced the level of forskolin (FORSK, 1 µM) stimulated cAMP formation by 36-56% (EC_{50} = 100 nM). The effect of 10 µM UK was antagonized by yohimbine, idazoxan, and phentolamine (IC_{50} = 0.25, 2.5, and 2 µM, respectively). In contrast, the α_1 adrenergic antagonist, prazosin (1 µM) was without effect. Carbamylcholine (CCh) increased both basal and FORSK-stimulated cAMP accumulation by 60% (EC_{50} = 10µM). The effect of CCh was sensitive to atropine and pirenzepine (IC_{50} = 0.03 and 20 µM, respectively).

Pretreatment of SK-N-SH cells with pertussis toxin (18h) led to a concentration-dependent loss of the ability of UK to attenuate cAMP accumulation (EC_{50} = 3ng/ml) while having no effect on the CCh facilitated response. Cyclic AMP formation elicited by the combination of CCh + FORSK was not reduced by 10 µM UK.

The presence of functional α_2ARs on SK-N-SH cells suggests that the biochemical requirements for receptor-mediated attenuation of AC activity are present. However, mAChRs in these cells do not utilize this signalling system. SK-N-SH cells may therefore provide a useful neuronal model system to study these receptor types.

CHOLINERGIC-LINKED, SECOND-MESSENGER INTERACTIONS BIMODALLY REGULATE ADRENAL OPIATE PEPTIDES. J.D. DeCristofaro and E.F. La Gamma. Dept. of Pediatrics and Neurobiology, SUNY @ Stony Brook, NY 11794-8111.

Physiologic stressors increase transsynaptic impulses to augment adrenal catecholamine release and synthesis. To determine the effects of stress on co-localized opiate peptides, we housed groups of 8 rats individually at 4°C. Cold stress (2 or 4d) slightly decreased enkephalin levels (ENK). More severe stress (wetting + cold) increased ENK levels by 95%; wetting alone (21°C) had no effect. To examine cholinergic mechanisms, rats were treated with nicotine (5 mg/kg sc BID or QID x 4d) or muscarinic agonist, carbechol (8.2 uM/kg sc BID or QID x 4d). ENK levels did not change. When given together ENK levels rose 3-fold. To examine cellular mechanisms, medullae were explanted in the presence of increased nicotinic or muscarinic receptor-linked, second-messengers, cAMP or cGMP, respectively. Increased cAMP prevented the rise in ENK levels relative to 4d control; db-cGMP (5 mM) had no effect. However, in the presence of both forskolin (10 uM) + db-cGMP (5 mM), ENK content rose 3-fold. Pertussis toxin blocked this increase. These data suggest that distinct from catecholamines, ENK pathways can be positively or negatively regulated by the severity of a stressful stimulus or by selective activation of cyclic nucleotide second-messenger pathways. Transmitter regulation may involve an interaction of multiple converging transsynaptic mechanisms. Sponsored by the Amer. Heart Assoc.

NEUROPEPTIDES INHIBIT cAMP PRODUCTION THROUGH A PERTUSSIS TOXIN-INSENSITIVE G PROTEIN IN THE NEUROBLASTOMA N1E115 CELL LINE. P. Kitabgi*, J.C. Bozou* and F. de Nadai* (SPON: A. Enjalbert). Centre de Biochimie du CNRS, Faculté des Sciences, 06034 Nice Cédex, France.

Neurotensin (NT), bradykinin (BK), somatostatin and Met-enkephalin all inhibited in a time- and concentration-dependent manner PGE_1- or forskolin-stimulated cAMP production in the neuroblastoma N1E115 cell line. Cell treatment with pertussis toxin (PT) for 6 hours partly reversed the inhibition elicited by peptides after short incubation periods (< 2 min) but, in contrast, had no effect after longer peptide incubations (> 3 min). Fluoroaluminate, a known activator of G proteins, also inhibited PGE_1-stimulated cAMP production in N1E115 cells, and this effect was not reversed by PT. The 6 hour treatment with PT was sufficient to ADP-ribosylate virtually all of the 41 kD substrate corresponding to the α-subunit of G_i. The peptides did not modify the rate of disappearance of cAMP in PGE_1-stimulated cells, indicating that the inhibition of cAMP production was not due to phosphodiesterase activation. Finally, protein kinase C which is activated by NT and BK in N1E115 cells did not interact with the cAMP-generating system, as shown by the lack of effect of phorbol ester on cAMP production. Altogether, these data point to the existence of a PT insensitive G protein that mediates neuropeptide-induced inhibition of adenylate cyclase in the neuronal N1E115 cell line.

ALUMINUM ALTERS CYCLIC AMP METABOLISM AND PROTEIN PHOSPHORYLATION IN RAT BRAIN. G.V.W. Johnson and R.S. Jope. Dept. of Pharmacology, Neurology, and Neuropsychiatry Res. Program, Univ. of Alabama, Birmingham, AL 35294.

The effects of aluminum (Al) on cyclic AMP metabolism and protein phosphorylation in rat brain were studied both in vivo and in vitro. Previously we demonstrated that chronic oral administration of Al to rats significantly elevates in vivo cyclic AMP levels in various brain regions. In our present studies we have demonstrated that the stimulation of cyclic AMP production in rat brain slices by 2-chloroadenosine was significantly potentiated when the slices were preincubated with 100µM $AlCl_3$. Al had no effect on basal or forskolin-stimulated cyclic AMP production.

The phosphorylation of certain proteins in rat brain is altered by Al. Previously, we demonstrated that orally administered Al significantly increased the in vivo phosphorylation of MAP2 and the 200-kD neurofilament protein. In our most recent study we measured protein phosphorylation in membrane and soluble fractions from the cortex and brainstem of control and Al-treated rats. In vitro endogenous protein phosphorylation was measured in the presence of cyclic AMP, Ca^{++}/calmodulin, Ca^{++}/phosphatidylserine or without additions. Al-induced alterations in phosphorylation were evident under several of these conditions. Supported by Fellowship #AG05382.

THE THALAMIC MIDLINE STRUCTURES PROJECTING TO THE AMYGDALA DISPLAY HIGH IMMUNOREACTIVITY FOR THE cAMP-RECEPTOR PROTEIN RII IN THE RAT

M. Bentivoglio+, M.A. Cenci*++, H.-S. Su*+, Institutes of Human Anatomy+ and Neurology++, University of Verona, Medical Faculty, Verona, Italy.°°

The cAMP-receptor protein RII is the regulatory subunit of type II cAMP-dependent protein kinase. RII immunoreactivity is not homogeneous in the rat's CNS. In the thalamus, the positivity to anti-RII serum appeared concentrated in the midline. In particular, high RII immunoreactivity was evident in the neuropil of the paraventricular nucleus, and part of the rhomboid and reuniens nuclei. In order to further characterize this territory, a combined immunohistochemical and retrograde labeling procedure was here adopted. Fluorescent tracers were injected in two main targets of thalamic midline efferents, the amygdala and the hippocampus. It was thus evidenced that the distribution of cells retrogradely labeled from the amygdala largely overlapped the RII-immunoreactive territory. The latter appeared, instead, mainly segregated from the thalamic territory retrogradely labeled from the ventral hippocampus.

°°The authors are greatly indebted to Drs. S. Lohmann, U. Walter and P. De Camilli for the supply of anti-RII serum.

MODULATION OF THE SECRETORY RESPONSE IN CAROTID BODY CHEMORECEPTOR CELLS BY ADENYLATE CYCLASE ACTIVATING AGENTS.

T. Perez García*, L. Almaraz* and C. Gonzalez (SPON: F. Reinoso Suarez). Depto. Bioq. Biol. Mol. y Fisiol. Fac. Med. Universidad de Valladolid, 47005-Valladolid. Spain

The carotid body (c.b.) chemoreceptors responds to pO_2 decreases. On hypoxic stimulation the chemoreceptor cells release dopamine (DA) in a Ca^{++}_O dependent fashion, being the release proportional to the O_2 decrease. It is known that B-agonists increase the electrical activity and cAMP levels in the organ. We explore the possibility that cAMP modulation of the transmitter release from type I cells is the nexus between both actions of the B-agonists.

Rabbit c.b. were loaded with ^{3}H-DA by incubation with ^{3}H-tyrosine and thereafter syperfused with salines equilibrated with either 100% or 5% O_2 in the presence or absence of forskolin, isobutyl-methyl-xantine (IBMX) and isoproterenol (Iso). We found: 1) Forskolin potenciates the hypoxic ^{3}H-DA release in a dose dependent maner (0.5 to 10 uM). 2) IBMX at 0.5 mM moderatly increases the hypoxic release. 3) Iso at 50 uM is equipotent to 5 uM forskolin. These findings support our working hypothesis.

ELECTROCONVULSIVE SHOCK INCREASES [^{3}H]-FORSKOLIN BINDING IN SUBSTANTIA NIGRA IN THE RAT.

L.J. Fochtmann, J.S. Gutkind, W.Z. Potter*. SCP,LCS,NIMH, Bethesda, MD 20892.

Electroconvulsive shock (ECS) affects a variety of neurotransmitter receptors, some of which are adenylate cyclase (AC) linked. In particular, cortical β receptors are decreased in number after chronic ECS with parallel decreases in forskolin and norepinephrine stimulated cAMP. Though brain homogenate studies have not revealed ECS-induced changes in dopamine receptors, we previously found increases in D1 receptor binding in the substantia nigra via quantitative autoradiography (QAR). We now report on QAR studies using [^{3}H]-forskolin to assess the catalytic subunit of AC after chronic ECS.

Chronic ECS consistently produced increases (30%-150%) in [^{3}H]-forskolin binding in the substantia nigra pars reticulata. In contrast, no consistent changes in the binding of [^{3}H]-forskolin were seen in other regions such as caudate and hippocampus. This parallels our finding of increased D1 receptor binding in the substantia nigra consistent with an upregulation of both the D1 receptor and the presumably D1-linked AC. Like the increase in D1 receptors, the increase in dopamine linked second messenger function may be relevant to the antiparkinsonian effects of clinically administered electroconvulsive therapy.

STIMULATION OF CATECHOLAMINE AND MET-ENKEPHALIN SECRETION FROM ADRENAL CHROMAFFIN CELLS BY ANGIOTENSIN: ROLE OF SECOND MESSENGERS.

A.M. Poisner*, H.K. Jiang*, M.K. Stachowiak, P. Hudson*, V. Owyang* and J.S. Hong (SPON: L. Lazarus). LMIN, NIEHS, Res. Triangle Pk., NC 27709.

To study long term regulation of the adrenal medulla, cultured chromaffin cells were exposed to Sar^1-angiotensin II (ANG) for 24 hrs. This caused a dose-dependent increase in the concentration of catecholamines (CAT) and met-enkephalin (MET) in the extracellular medium (ED_{50} 1 nM). Secretion was partially inhibited by nifedipine (calcium channel blocker), by TMB8 and dantrolene (inhibitors of calcium mobilization), by calmidazolium (calmodulin inhibitor) and by H7 (protein kinase C inhibitor). Phorbol ester (TPA) stimulated secretion. Forskolin (adenyl cyclase activator) potentiated the secretory effect of ANG. The results suggest that ANG effects are mediated by both extra- and intracellular calcium and may be modified by the level of cellular cAMP. Calcium may act in part by interacting with protein kinase C and calmodulin. These findings parallel our results on the effects of ANG on mRNAs for proenkephalin, tyrosine hydroxylase and PNMT (Stachowiak et al., 1988, this volume).

35.15

ROLE OF PHOSPHOINOSITIDE METABOLISM, CALCIUM AND ARACHIDONATE IN CYCLIC GMP SYNTHESIS IN N1E-115 CELLS.

W. Surichamorn, C. Forray and E.E. El-Fakahany. Dept. of Pharmacology and Toxicology, Univ. of Maryland. Sch. of Pharmacy, Baltimore, MD 21201.

Addition of phospholipase C (PLC) from B. Cereus to neuroblastoma N1E-115 cells markedly stimulated polyphosphoinositide (PI) hydrolysis and also increased intracellular free Ca^{2+} concentration ($[Ca^{2+}]_i$), cyclic GMP levels and arachidonate liberation in a time- and dose-dependent manner. The time profiles and dose-response relationships between the first three responses of PLC were well correlated, consistent with an inositol trisphosphate-mediated mobilization of intracellular Ca^{2+}. Ionomycin also stimulated intracellular cyclic GMP formation, in parallel to elevated $[Ca^{2+}]_i$, whereas it failed to induce arachidonate release. On the other hand, phospholipase A_2 markedly induced increased arachidonate formation in a time- and dose-dependent fashion (time-to-peak ~2-4 min) but only slightly elevated $[Ca^{2+}]_i$ and cyclic GMP levels. These results indicate that Ca^{2+} might play a more important role than arachidonate release in cyclic GMP synthesis in these cells. (Supported in part by NIH grants NS-24158, AG-07118 and AG-00344.)

35.16

MODULATION OF ATP RELEASE FROM ADRENAL CHROMAFFIN CELLS WITH CYCLIC GMP ANALOGS.

E. Forsberg*, E. Rojas* and H. Pollard (SPON: K. Kelner). NIDDK, NIH, Bethesda, MD 20892.

Acetylcholine (ACh)-evoked catecholamine (CA) and ATP release from bovine adrenal chromaffin cells is initiated by the influx of Ca^{2+} into the cells through both voltage- and nicotinic receptor-gated Ca^{2+} channels. ACh acting on muscarinic receptors also stimulates the production of cGMP, but no clear function for cGMP has been described. We have found that 1 min preincubations with an analog of cGMP, 8-Br-cGMP (1 mM), approximately doubles the amount of ATP release stimulated by nicotine, ACh, elevated K^+, and Ba^{2+} while having no effect on basal release. ATP release was measured using an on-line luciferin/luciferase assay. In contrast, 1 mM 8-Br-cGMP produced no consistent enhancement of total CA release from chromaffin cells. Since total medullary CA reflects primarily epinephrine (E), a preferential enhancement of norepinephrine (NE) release by 8-Br-cGMP may explain this difference. Since NE secretory granules have been shown to have a two-fold higher ATP to CA ratio than epinephrine granules, an enhanced release of NE granules by 8-Br-cGMP would result in a greater relative increase in ATP release than total CA release.

35.17

IMMUNOCYTOCHEMICAL LOCALIZATION OF THE 180 kD MEMBRANE GUANYLATE CYCLASE IN THE RAT BRAIN. A.A. Fedinec*, N.G.F. Cooper and R.K. [1]Sharma* (Spons: J.B. Schweitzer). Dept. of Anatomy and Neurobiology, [1]The University of Tennessee, Memphis, TN 38163, and [1]Section of Regulatory Biology Dept. of Brain and Vascular Research, Cleveland, OH.

A 180 kD protein which apparently contains atrial natriuretic factor (ANF) receptor coupled with membrane guanylate cyclase has been purified and biochemically characterized from rat adrenocortical carcinoma cells. Rabbit monospecific polyclonal antibodies to the 180 kD protein blocked up to 90% of the guanylate cyclase activity of the purified enzyme (Paul, A.K., Marala, R.B., Jaiswal, A.K., and Sharma, R.K. Science., 235:1224-1226, 1987). The distribution of the 180 kD guanylate cyclase was studied with a light microscope in vibratome sections of aldehyde fixed rat brains using a peroxidase immunocytochemical method. Controls for nonspecific binding were negative. Immunoreactivity of 180 kD guanylate cyclase in cerebellum was atributable to Purkinje cells. In these cells the dendrites, perykarya and axons demonstrated high concentration of immunoreactivity apparently associated with membranes. Deep cerebellar nuclei and cells in the brain stem, hippocampus, and cortex showed immunoreactivity. Supported by NIH:NEI EY02708 (NGFC) and NSF grant 8609867 and NIH grant NS23744 (RKS).

REGULATION OF CYCLIC GMP RESPONSE TO RAT ATRIAL NATRIURETIC FACTOR (99-126) DURING DEHYDRATION AND SALT-LOADING IN THE RAT SUBFORNICAL ORGAN. A. Israel, M.R. Garrido* and I. Becemberg*.(SPON: G. Viana) Universidad Central de Venezuela, Caracas-Venezuela.

Atrial natriuretic factor (ANF) is present in brain neurones. Binding sites for ANF are highly localized in the subfornical organ (SFO)(Brain Res. 408:31). ANF receptors are positively coupled to the guanylate cyclase system (GC) and they undergo regulatory changes with alterations in ANF plasma levels (PSEBM 182:559). We examined therefore the presence of functional- coupled to GC- brain binding sites for ANF by measuring the ANF-induced formation of cGMP in the rat SFO. In addition, the effect of water deprivation (WD)(reduced ANF plasma levels) and salt-loading (SL)(increased ANF plasma levels) on rANF-induced cGMP response was investigated. Male S-D rats (220-280g) were divided in the following groups: WS: water satiated, food and water provided; WD: water deprived for 4 days: SL: drinking water substituted for a 1% NaCl solution during one week. All animals were killed by decapitation and the brains were immediately removed. After removal, the SFO was homogenized and centrifuged. The supernatant assayed for GC activity. cGMP was determined with a radioimmuno-antibody procedure. ANF activated GC in crude homogenates of rat SFO (In pmol/5 min/mg protein: basal 97 $\pm$ 20 , ANF 100 nM: 166.3 $\pm$ 26). An elevated responsiveness to rANP-induced cGMP production was observed in crude homogenates of SFO after 4 days of water deprivation. WS: 83.4 $\pm$ 18 % and WD: 171.1 $\pm$ 43%. On the contrary, a reduced responsiveness to rANF-induced cGMP formation was observed in the SFO tissue from SL animals: 45.5 $\pm$ 17%. Our results suggest that cGMP mediates the central action of ANF and provide evidence suggesting that the receptors susceptible to the regulatory mechanism described in the SFO are the GC-coupled ANF binding sites. (Grants CDCH F.07.20.87).

PHORBOL ESTER AND dbcAMP REDUCE TAURINE CONTENT AND EFFLUX IN PRIMARY ASTROCYTE CULTURES. R.A. PHILIBERT AND G.R. DUTTON, Dept. of Pharmacology, College of Medicine, University of Iowa, Iowa City, IA 52242.

We have studied the effects of chronic treatment of cerebellar astrocyte cultures with a variety of hormones and second messenger analogues on intracellular taurine content and K^+-stimulated taurine release. Both dbcAMP (1 mM), and to a lesser extent PDBU (1 µM), produced marked conversion of astrocyte morphology to stellate forms which were maximal at about 6 hrs and reversed partially (dbcAMP) and almost completely (PDBU) after 2 to 3 days. Two day exposure to PDBU (1 µM) or dbcAMP (1 mM) reduced basal taurine efflux by 47% and 49%, respectively, reduced 50 mM K^+-evoked release by 35% and 64%, respectively and also reduced the cellular taurine content by 24% and 42%, respectively. However, neither cellular glutamate or protein was affected. Time course studies showed that these decreases in taurine content were time-dependent with effects plateauing after 1 day of treatment. FGF, EGF and dbcGMP had no effect on morphology, cellular amino acid content or taurine release any time tested.

The reduction of taurine efflux levels and intracellular content by PDBU and dbcAMP, in the face of somewhat transient morphological changes, show that PKC and adenylate cyclase may potentially regulate these phenomena in astrocytes. Supported by NS 20632 and MH 15172.

36.2

MUSCARINIC RECEPTOR-MEDIATED INCREASE IN cAMP LEVELS: EVIDENCE FOR CROSS-TALK BETWEEN TWO SIGNAL TRANSDUCTION PATHWAYS. J. Baumgold. Lab. of Molecular & Cellular Neurobiology, NINCDS, Bethesda, MD 20892.

In contrast to the well described inhibition of adenylate cyclase resulting from muscarinic receptor stimulation, activation of muscarinic receptors in SK-N-SH human neuroblastoma cells resulted in a 2-4 fold increase in cAMP levels. This increase was observed regardless of whether basal, PGE1-stimulated, or forskolin-stimulated levels were measured. It was dose-dependent (EC50 of 6 µM) and atropine-sensitive (IC50 of 20 nM). The EC50 of this cabachol effect was similar to that for carbachol stimulation of phosphoinositide turnover in these cells, suggesting that the former may be mediated by the latter. However, exogenous activation of protein kinase C by phorbol ester treatment did not mimick the carbachol-induced increase in cAMP levels. Furthermore, protein kinase C down regulation did not interfere with this carbachol effect indicating that this effect is not mediated by diacylglycerol activation of protein kinase C. On the other hand, treatment of these cells with the calcium ionophore A23187 resulted in increased cAMP levels. In addition, the calmodulin antagonists TFP, R24571, and W7 all inhibited the carbachol-mediated increase in cAMP levels. These data indicate that the carbachol-mediated increase in cAMP levels is mediated by a calcium-calmodulin dependent process resulting from increased intracellular calcium levels in turn resulting from inositol trisphosphate release.

36.3

cAMP MODULATES INOSITOL POLYPHOSPHATE PRODUCTION AND CALCIUM MOBILIZATION IN NG108-15 CELLS. M.D. Campbell*, S. Subramanian*, M.I. Kotlikoff*, J.R. Williamson* and S.J. Fluharty*. Dept. of Animal Biology and Biochemistry/ Biophysics, Univ. of Penna., Phila., PA 19104 (SPON: R.O. Davies)

In the neuroblastoma x glioma (NG108-15) hybrid cell line bradykinin (BK) receptor stimulation induced a rapid accumulation of inositol polyphosphates (InsPs). $InsP_3$ production was maximal at 15 sec and continued agonist exposure resulted in diminished $InsP_3$ production. BK stimulation of $InsP_3$ was also dose-related with an ED_{50} of 9nM, and was maximal at 1µM. HPLC analysis revealed that $Ins(1,4,5)P_3$ levels increased markedly after receptor activation, as did $Ins(1,3,4,5)P_3$, $Ins(1,3,4)P_3$ and $Ins(1,4)P_2$. BK induced InsPs production was attenuated by pretreatment with forskolin or dibutyryl cAMP. Forskolin also reduced InsPs production elicited by $GTP\gamma S$ or sodium fluoride in membranes. Dose response characteristics for calcium mobilization, as measured with fura-2, were similar to that observed for BK induced $InsP_3$ production, as were inhibitory effects of forskolin. These results suggest that cAMP may inhibit receptor mediated and post receptor stimulation of phospholipase C, as well as the mobilization of intracellular calcium in neuron like cells. Supported by NS 23986, and HL 36150 and Univ. of Penna. Research Foundation.

THE CHANGES IN THE INTRACELLULAR CALCIUM AND ION CHANNEL ACTIVITY IN THE MUSCARINIC RESPONSE OF SYMPATHETIC NEURON. T. Iijima* and G. Matsumoto*(SPON:T. Shiida.) Electrotechnical Laboratory, Tsukuba, Ibaraki, 305 Japan.

The acetylcholine (ACh) response in an isolated superior cervical ganglion of rabbit largely depends on the applied ACh dose. The versatile signal transduction in this neuron is based on the variety of the ACh receptor (muscarinic) types and of the intracellular signal pathways. Intracellular calcium, which is known to regulate the ion channel activity directly or indirectly, is a key factor in the second messenger system. We investigated the relation between the calcium ion and the ion channel activity with a simultaneous recording of the intracellular calcium concentration ($[Ca^{2+}]_i$) change with a calcium sensitive dye and of the membrane current with whole cell clamping. The low dose of ACh (3 µM) caused 10 - 20 nM increase in $[Ca^{2+}]_i$ and an outward current in the membrane clamped at -60 mV. The high dose of ACh (30 -100 µM) caused a large inward current followed by an outward current and more than 50nM increase in $[Ca^{2+}]_i$. In the absense of Ca^{2+} in the external medium, the inward current and the calcium change were decreased, while the outward current remained. We may explain the results as follows: The low dose of ACh interacts with M1 type receptors and causes the Ca^{2+} release from the intracellular Ca^{2+} store, resulting in the activation of calcium dependent K^+ channel. The high dose of ACh further interacts with M2 type receptors and activates the cation selective channels.

CALCIUM LOCALIZATION ASSOCIATED WITH *c-fos* INDUCTION IN ACUTELY ISOLATED CA1 NEURONS. J.A. Connor, W.J. Wadman, and H.-Y. Tseng. AT&T Bell Labs., Murray Hill, N.J. 07974.

Acutely isolated CA1 neurons from hippocampus of mature guinea pigs, loaded with the indicator fura-2 in its membrane permeable form, showed a distribution of Ca^{2+} in which levels in the nuclear region were considerably higher than elsewhere in the cell following prolonged stimulation. This gradient developed after a prolonged period (5 to 10 min) in which dendritic Ca^{2+} levels were higher than those in the soma. Ca iontophore, ionomycin, in low Ca saline, abolished the nucleus-zone gradient and brought Ca^{2+} down to low uniform levels (<50 nM). Cells injected with ionic fura-2 did not show the nucleus-zone gradient after stimulation but did show the high dendrite, low soma gradient. Apparently the membrane permeable form of fura-2 is able to enter some cellular compartment near the nucleus and report Ca^{2+} changes there, but the ionic form does not. Loaded by either method, indicator entered and left the nucleus itself freely. Recent reports have demonstrated expression of the *c-fos* protooncogene following periods of intense electrical discharge in neurons of the mammalian CNS (c.f. Morgan, *et al.*, Science, 237:192, 1987). Reasoning that the *in vivo* electrical discharge might be producing similar Ca^{2+} loads to our *in vitro* experiments, and that the nucleus-zone Ca^{2+} elevation might be a signalling event, we examined, by immunostaining for *c-fos* product, individual CA1 neurons that showed the nucleus-zone gradient and compared them with neurons that had low uniform Ca^{2+} levels (<200 nM). Of the cells with high nucleus-zone Ca^{2+}, more that 90% showed nucleus specific staining for *c-fos* product. Low Ca^{2+} cells on the same coverslips remained unstained or else showed weak, diffuse staining. We thank T. Curran of the Roche Inst. for antibodies. Supported in part by F49620 from the AFOSR.

A CALCIUM-DEPENDENT, SHORT-LIVED, POST-RECEPTOR EVENT MEDIATES PROSTAGLANDIN E_2 (PGE) ACTION ON LHRH (LH- releasing hormone) NEURONS. K.R.Bhasker* and A.Barnea (SPON: R.M. Lebovitz). Depts. OB/GYN & Physiol., Univ. Tx. Southwestern Med. Ctr., Dallas Tx. 75235, U.S.A.

PGE is known to stimulate LHRH release from explants of the median eminence (ME) and copper (Cu) amplifies PGE action. To define the kinetics of Ca requirement for PGE action, ME of female rats were incubated with 150 μM Cu for 5 min in the absence of Ca and then with 10 μM PGE and 1.8 mM Ca for 10 min. LHRH release was 3.6±0.4 pg/5'/ME without PGE and 12±1.2 pg with PGE; this stimulated rate of release was attained within the 1st 5 min of PGE exposure and persisted for another 5 min. That PGE exposure for 2 min sufficed to induce this maximal release response indicates that desensitization to additional PGE action occurred by 2 min. Omission of Ca from the medium during the first 2 min of PGE-exposure did not alter PGE stimulation of LHRH release regardless of whether PGE-exposure lasted for 2 or 7 min. However, omission of Ca for the first 5 min of PGE exposure almost completely inhibited PGE action. Thus, PGE interaction with the LHRH neuron is rapidly (<2 min) manifested and it leads to desensitization. PGE binding to its receptor and the initial post-receptor events do not require extracellular Ca, whereas the subsequent event(s) require Ca and involve a rapidly turning over component.

36.7

ROLE OF INTRACELLULAR CALCIUM AND CELL VOLUME IN HETEROLOGOUS DENERVATION SUPERSENSITIVITY OF MUSCARINIC, α ADRENERGIC AND SUBSTANCE P RESPONSES IN RAT PAROTID ACINAR CELLS. M.K. McMillian and B.R. Talamo, Neuroscience Labs, Tufts Med. Sch., Boston, MA 02111

Parasympathetic post-ganglionic denervation of rat parotid acinar cells produces heterologous supersensitivity to muscarinic, α-adrenergic and substance P agonists, even though the corresponding neurotransmitter is not lost for all (NE is not reduced). Receptor stimulation leads to fluid and electrolyte secretion via activation of phospholipase C (PLC) and mobilization of Ca_i. After denervation, several responses to receptor activation were tested. The concentration-response curve for PLC activation and (^{3}H)inositol phosphate(s) (IP_n) formation was unchanged. However, other agonist-stimulated responses were sensitized. These included Ca_i elevation (quin2 and Fura2) and ^{22}Na uptake, as well as muscarinic stimulation of amylase release, which is mediated via diacylglycerol and C kinase. Denervation also decreased cellular volume and lowered resting Ca_i. These changes, coupled with previous findings that muscarinic receptor levels are not increased, suggest that sensitivity is regulated down-stream from the receptor and receptor-activated PLC. A decrease in surface area and volume under conditions where the number of receptors is unchanged and where each agonist concentration mobilizes the same amount of second messenger (diacylglycerol, IP_n, and hence Ca^{++}), would contribute effectively to shift the stimulation-response curve for elevating second messenger concentrations and therefore sensitize Ca-dependent ion transport and C-kinase stimulated exocytosis. Supported by NIH grant 1F32 DE05489 and NSF grant BNS-8710238

REGIONAL DISTRIBUTION OF A NON-MITOCHONDRIAL, ATP+Mg^{2+} DEPENDENT CALCIUM-UPTAKE POOL IN RAT BRAIN AND PERIPHERAL TISSUES. S. Supattapone, A. Verma*, C. Ross and S.H. Snyder. The Johns Hopkins University Sch. of Med., Dept. of Neuroscience, Baltimore, MD 21205.

Many neural functions are controlled by the level of free Ca^{++} within neurons. While much work has been done in defining the subcellular distribution and pharmacologic specificity of Ca^{++} sequestering pools, little is known of the histological distribution of these pools in the brain.

We have performed energy dependent uptake of $^{45}Ca^{++}$ by 10 µm rat brain sections and visualized its regional distribution using autoradiography. This $^{45}Ca^{++}$ pool appeared to be non-mitochondrial as it was inhibited by vanadate but not by ruthenium red, rotenone and oligomycin.

Of the organs examined only neuronal and smooth muscle tissues sequestered significant amounts of $^{45}Ca^{++}$. Relatively high levels were observed in the frontal cerebral cortex, striatum, thalamus, substantia nigra, subiculum, and molecular layer of the cerebellum. Low levels of accumulated radioactivity were seen in the hypothalamus and brain stem.

STUDIES ON NEUROTRANSMITTER INTERACTIONS ON CULTURED HIPPOCAMPAL NEURONAL CELLS — FROM VIEWPOINTS OF INTRACELLULAR CA ION. S. Kito, R. Miyoshi and M. Shimizu*. Third Dept. of Internal Med., Hiroshima Univ. School of Med., Hiroshima 734, Japan.

We have been studing on interaction between muscarinic acetylcholine receptors and somatostatin (SS) in the rat hippocampus through radioreceptor assay and measurement of phosphatidylinositol turnover. In the present study, cytosolic free Ca^{2+} concentration ($[Ca^{2+}]i$) was examined by fura-2 fluorometry in cultured rat hippocampal neurons. Neurons were obtained from 18-day rat embryos and were cultured for 12 days. Changes of $[Ca^{2+}]i$ were monitored using a system in combination of fura-2, a fluorescence microscope, a video-camera and photometrical devices. Acetylcholine (ACh) of 10^{-5} M induced an increase of $[Ca^{2+}]i$, and heterogeneity in the responsiveness to ACh was observed in each cell. SS of 10^{-5} M also increased $[Ca^{2+}]i$. Addition of both ACh and SS induced an elevation more than the case of either ACh or SS alone. When 30 μM $LaCl_3$ was infused to block Ca^{2+} influx from extracellular fluids, the responses to ACh, SS and both were partially depressed with preservation of responses toward the same direction. Under this condition, an effect of KCl was abolished. These results suggest that the interaction between ACh and SS on $[Ca^{2+}]i$ occurs through both Ca^{2+} influx due to the opening of ion channels and mobilization of intracellularly stored Ca^{2+}.

PERTUSSIS TOXIN INDUCES ALTERATIONS IN SEPTO-HIPPOCAMPAL NEURONS PROPERTIES. P.Dutar, O.Rascol* and Y.Lamour. INSERM U.161, 2 rue d'Alésia, 75014, Paris, France.

The properties of septo-hippocampal neurons (SHNs) have been studied in vivo in rats pretreated with pertussis toxin (PTX)(n=12, urethane anesthesia). PTX (2µg) was injected bilaterally in cerebral ventricules 3 days prior to the experiment. Extracellular recordings coupled to iontophoresis were obtained from single neurons located in the medial septum, identified as projecting to the hippocampus by their antidromic response to the electrical stimulation of the fimbria-fornix. In PTX pretreated rats, the mean latency of the antidromic response was unchanged (1.4±1.3, n=121 vs 1.5±1.2ms, n=95). In contrast, the mean spontaneous activity was significantly higher (21.6±17.3, n=117 vs 13.2±11.6 spikes/sec., n=89) and the mean frequency of the rhythmic bursting activity was lower (2.7±0.4, n=42 vs 3.6±0.5Hz, n=40). The percentage of rhythmically bursting neurons was not different. Pharmacological properties of SHNs were differentially affected by PTX. Responses to acetylcholine (n=13), carbachol (n=51) and GABA (n=54) were unchanged. In contrast serotonin (n=28) and baclofen (n=83) -induced inhibitions were blocked.

In conclusion, these results provide evidence for a selective involvement of a PTX-sensitive G-protein in several physiological and pharmacological properties of septal neurons projecting to the hippocampus.

KAPPA OPIATE AGONISTS INHIBIT Ca^{2+} INFLUX AND INDUCE HETEROLOGOUS DESENSITIZATION IN RAT SPINAL CORD-DORSAL ROOT GANGLION COCULTURES: INVOLVEMENT OF G PROTEINS. Z. Vogel, D. Saya* and B. Attali*, Dept. of Neurobiology, Weizmann Institute of Science, Rehovot, Israel.

Basal $^{45}Ca^{2+}$ uptake in rat spinal cord-dorsal root ganglion (SC-DG) cocultures was potently stimulated (3.5-fold) by depolarization with 50 mM K^+ and the Ca^{2+} channel agonist Bay K8644. κ selective agonists such as U50488, tifluadom, dynorphin and MR2034 profoundly depressed the stimulated Ca^{2+} uptake, while μ (DAGO) and δ (DADL) agonists had no effect. κ agonist action was stereospecific and reversed by antagonists. Pertussis toxin pretreatment strongly affected the κ agonist inhibition of Ca^{2+} influx, suggesting that κ receptors are negatively coupled to voltage-dependent Ca^{2+} channels via a pertussis toxin-sensitive G protein. Chronic exposure of SC-DG to U50488 (10μM, 24h) desensitized the κ agonist inhibitory action. Moreover, this treatment desensitized the inhibition of Ca^{2+} influx observed with α2 adrenergic and muscarinic agonists (heterologous desensitization). The amount of a 41 kDa pertussis toxin substrate protein was decreased by 50 to 90% in U50488-treated cells, as compared to control. Using selective antibodies (kindly provided by Dr. A. Spiegel, NIH) we found a 30 to 80% down-regulation of the α subunit of Gi protein with no changes in Gαs, GαO and Gβ. Results suggest that the κ agonist-induced down-regulation of Gαi underlies the development of tolerance and cross-tolerance observed in spinal cord, following chronic exposure to opiates.

CALCIUM (Ca) AND GUANINE NUCLEOTIDE(G) REGULATION OF GABAb BINDING IN RAT CEREBRUM. R.H.Thalmann and M.I.Al-Dahan*
Baylor College of Medicine,Houston,TX77030

Using permeabilized(.05%Triton) thoroughly washed synaptic membranes, we confirmed that either Ca or G(GTPγs) controlled more than 90% of specific GABAb(^{3}H)--baclofen) binding. We then tested the hypothesis that the Ca effect might indeed depend upon a G protein. However: 1)Scatchard analysis indicated that Ca primarily affected Bmax while others had found that G primarily affected Kd; 2)Between postnatal day 1 and adulthood, the EC50 for Ca stimulation of binding remained constant at 1uM while that for the inhibition of binding by GTPγs declined from 1uM to 2.5nM; 3) Our permeabilized extensively washed membranes were probably unfavorable for phosphorylation by G protein dependent kinases, and 4) This Ca binding site does not so far behave as at least one Ca site that is known to be coupled to GABAb receptors via G proteins, namely the Ca channel.,e.g., 10uM nifedipine or 0.2uM w-conotoxin failed to antagonize the stimulation of GABAb binding by Ca. Although none of these experiments are themselves conclusive, none support the hypothesis. Thus Ca and G may regulate GABAb receptors by independent mechanisms and indeed we suggest that Ca may regulate the receptor directly, by a site on the receptor itself.

INTERACTION OF PYRETHROID TOXINS WITH GTP-BINDING PROTEINS. **D.P. Rossignol*. (spon: J.C. Kauer). E.I. du Pont de Nemours & Co., Experimental Station, Wilmington, DE 19898**

Insecticidal pyrethroid neurotoxins have been shown to alter a variety of membrane receptors and enzymes including sodium channels, calcium channels, GABA-b (baclofen) receptors, and Na^+/K^+ and Ca^{++} Mg^{++}ATPases. In order to study the mechanism of pyrethroid activity, I have synthesized [3H]DeCAF (decyanoazidofenvalerate), a photoactivatable arylazide derivative of fenvalerate. SDS-PAGE analysis of rat brain membranes indicated that [3H]DeCAF covalently labeled a 36kDa membrane-bound protein. Labeling was sensitive to GTPγS and other G-protein modifiers. To determine if pyrethroids bind to GTP-binding proteins, DeCAF binding was studied in the bovine retinal transduction system. In crude retinal homogenates, a 36kDa protein was specifically labeled. This labeling was enriched five-fold in rod outer segments (ROS) and was nearly quantitatively solubilized (>95%) by treatment of ROS with 40uM GTP. Labeling was 1700-fold higher in the GTP-solubilized proteins than the pellet. It is likely that [3H]DeCAF covalently labels the β subunit of transducin because SDS-PAGE showed the [3H]-labeled protein to be 36kDa, distinct from [32P]-ADP-ribosylated α subunit and [3H]DeCAF-labeled protein was specifically immunoprecipitated by antibodies directed against either the β subunit of transducin or a synthetic peptide of β subunit (Mumby et al. PNAS 83,265-269). These experiments indicate that DeCAF binds to the β subunit of retinal GTP-binding proteins.

THE INTERACTION OF Gp WITH GUANINE NUCLEOTIDES. A. Tamir*, A. B. Fawzi* and J. K. Northup* (SPON: S. Amara). Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510

Gp is a major GTP-binding protein of human placental membranes purified by Evans et al., (1986) J. Biol. Chem. 261,7052-7059. This protein was also purified from human platelets and bovine brain. High affinity guanine nucleotide (GN) binding is associated with a protein that has identical migration on SDS-PAGE to H-*ras*. We characterized the interaction of Gp with guanine nucleotides by studing the thermodynamics as well as the kinetics of GN binding to Gp. Using [^{3}H] GppNHp we determined an apparent K_d of 0.2 μM. Apparent K_d values for other GNs were derived from EC_{50} for displacement of [^{3}H] GppNHp. These were 4.2 nM for GTPγS, 0.9 μM for GDPβS, 0.1 μM for GTP and 0.1 μM for GDP. [^{3}H] GppNHp, [^{3}H] GTP, and [^{35}S] GTPγS all identified the same site. The rate of GN binding to the placental Gp is much faster than that of the protein purified from brain. The former occurred on ice as well as at 30 and 37 ^{0}c, but did not occur in the absence of magnesium. Gp hydrolyzed [^{3}H] GTP with [^{3}H] GDP remaining tightly bound. Apparent hydrolytic rate of 0.03 $min^{-1}$was observed. The protein from the placenta and from the brain but not from the platelets copurifies with the βγ- subunits common to the identified G-proteins. Initial data suggest a functional interaction of the α subunit of placental Gp with the βγ complex that regulates GN affinity. These biochemical criteria support the inclusion of Gp in a family of signal transducing GTP-binding proteins.

36.15

MODULATION OF G-PROTEIN mRNA LEVELS IN NEUROBLASTOMA X GLIOMA HYBRID NG108-15 CELLS BY ADP-RIBOSYLATING TOXINS. E. A. Thiele*, S. H. Snyder, & K. M. Braas. (Sponsor: S. M. Sato) Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Guanine nucleotide regulatory proteins (G-proteins) are important in signal transduction mechanisms. G-proteins are heterotrimers consisting of α, β, and γ subunits. Membrane receptors act through G_s to stimulate adenylate cyclase activity, and G_i to inhibit adenylate cyclase activity. Cholera toxin and pertussis toxin catalyze the ADP-ribosylation of the α_s and α_i subunits, respectively, and both result in the activation of adenylate cyclase activity. Using cDNA probes to the α_s, α_{i2}, and β_1 subunits (Jones and Reed, J. Biol. Chem. 262:14241, 1987) we have examined by Northern analysis the regulation of G protein mRNA levels in NG108-15 cells after toxin treatment. In NG108-15 cells, we identified single mRNA spiecies for α_s with an apparent size of 1.8 kb, and α_{i2} of 2.2 kb. Two mRNA species were observed with the cDNA probe to the β_1 subunit, with apparent sizes of 3.0 and 1.6 kb. Treatment of NG108-15 cells with cholera toxin or pertussis toxin resulted in a decrease in G protein subunit mRNA levels. The relationship of intracellular cAMP levels and G-protein subunit mRNA levels following toxin treatment for different times is being investigated.

36.16

GTPase ACTIVITY IN NORMAL HUMAN MYELIN. *Chi Kin Chan*J. Ramwani, and*M.A. Moscarello (SPON: F. Coceani) Dept. of Biochemistry, Research Institute, The Hospital for Sick Children, Toronto, Ontario M5G 1X8

Myelin, a multilamellar membrane surrounding the axon of both CNS and PNS of vertebrates, is considered to function as an insulator. In the past decade, studies have shown that it is metabolically active and perhaps involved in cellular regulation by extracellular hormones and/or neurotransmitters. Myelin has been shown to consist of the following transmembrane signalling components: phosphophatidylinositol phosphates, phospholipase C, protein kinase C, adenylate cyclase, and muscarinic cholinergic receptors. Recently, we have demonstrated that myelin basic protein (MBP) specifically binds to GTP (Chan et al BBRC in press). It can be ADP-ribosylated by cholera toxin and also can be covalently labelled by azido-GTP at Gln residue of the N-terminus of MBP. In this communication, data are presented to show a GTPase activity in myelin. This enzyme activity is specific for GTP and has been shown to be inhibited by cholera toxin. Hydrolysis of GTP to GDP is time dependent with very little GMP formation. Immunoprecipitation of MBP from detergent extract of myelin by a polyclonal antibody caused a 50% reduction in myelin GTPase activity. Isolation of myelin GTPase is in progress to establish the relationship, if any, between MBP and GTPase activity in myelin.
In conclusion, although the enzyme has not been identified and isolated, MBP could be a factor that interacts with myelin G protein(s) to regulate the enzyme activity.

APPARENT LOSS OF Gi PROTEIN ACTIVITY IN DIABETIC RETINOPATHY
M. Hadjiconstantinou, Z.-X. Qu,* S.E. Moroi-Fetters,* G.-Y. Le,* and N.H. Neff. Depts. Pharmacology and Pathology, The Ohio State Univ. Col. Med., Columbus, OH 43210.

Recently it was reported that Gi protein is deficient in the liver of streptozotocin (STZ)-induced diabetic rats and that insulin treatment partially restores Gi protein activity (Gawler et al., Nature 327:229, 1987). We have evaluated whether the loss of Gi protein is a more generalized phenomenon involving receptor Gi protein-mediated signal transduction in neuronal tissue. Retinopathy is a common feature of diabetes, therefore we chose the retina for our studies. Stimulation of retinal muscarinic (M1) receptors results in inhibition of adenylate cyclase activity. Intraocular administration of pertussis toxin prevents this response suggesting that this is a Gi protein mediated activity. Rats were treated with STZ (85 mg/kg, i.p.) or saline and 3 weeks later acetylcholine (ACh)-induced inhibition of cAMP accumulation in rat retina measured. In control animals, ACh induced about a 30% decrease of cAMP accumulation. In diabetic animals, basal cAMP accumulation was elevated and ACh was unable to reduce it. In another experiment, insulin treatment, NPH (porcine) 2 U/100 g, was initiated 3 days after the induction of diabetes and continue for 14 days. Insulin treatment restored the ability of ACh to inhibit the accumulation of cAMP in diabetic retina. Our studies suggest that loss of Gi protein activity in diabetes may be a universal response which might be related to the extensive pathologies associated with the disease.

SECOND MESSENGER PATHWAYS INVOLVED IN THE REGULATION OF SUBSTANCE P IN RAT SYMPATHETIC NEURONS.
N.E. Kremer and J.A. Kessler. Depts. of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

The expression of the preprotachykinin (PPT) gene and of substance P (SP) in sympathetic neurons is influenced by the neuronal microenvironment. We have investigated the role of second messenger pathways in the regulation of SP expression in cultured sympathetic neurons of the neonatal rat superior cervical ganglion. Pure neuronal cultures contained no detectable PPT mRNA or SP peptide. Coculture of neurons with ganglion non-neuronal cells, however, induced expression of substantial levels of both the mRNA and the peptide. Potassium- or veratridine-induced depolarization reduced SP and PPT mRNA in cocultures to barely detectable levels. The role of calcium as a second messenger was examined by using the calmodulin inhibitor R24571. Treatment of cocultures with R24571 elevated levels of SP. Further, addition of R24571 reversed the effects of depolarization by KCl; R24571 at 0.3 μM partially restored SP levels, while R24571 at 1 μM raised SP to above control levels.

The role of protein kinase C was evaluated by examining effects of treatment with phorbol myristate acetate (PMA). PMA treatment did not induce expression of PPT mRNA or SP in pure neuronal cultures. However, treatment of cocultures with PMA resulted in a dose-dependent increase in peptide and PPT mRNA levels. Simultaneous treatment with PMA and KCl reduced SP to negligible levels. Thus PMA, unlike R24571, could not reverse the effects of potassium-induced depolarization. None of these or other manipulations of second messenger pathways induced expression of SP in pure neuronal cultures, raising questions about which second messenger mediated effects of nonneuronal cells. Once SP expression was induced by nonneuronal cells, there appeared to be a hierarchy of second messenger signals which modulated peptide levels.

SECOND MESSENGERS III

CALCIUM AND SODIUM DEPENDENCY OF PHOSPHOINOSITIDE HYDROLYSIS IN RAT CEREBRAL CORTICAL SYNAPTONEUROSOMES.
L. J. Chandler* and F.T. Crews. (SPON: W.R. Kem). Dept of Pharmacology, Univ. of Florida College of Medicine, Gainesville, FL 32610.

To more fully understand the role of calcium and sodium in phosphoinositide hydrolysis in brain, we examined potasium and norepinephrine-stimulated phosphoinositide hydrolysis in rat cerebral cortical synaptoneurosomes in the presence and absence of sodium and in the presence of various concentrations of calcium or EGTA. In medium containing 1 mM calcium and 96 mM sodium, the addition of 30 mM KCl caused a large increase in the accumulation of [^{3}H]-inositol phosphates. The fastest rate of accumulation occurred within the first 5 min of depolarization and reached a maximum after 40 min. Norepinephrine-stimulated phosophoinositide hydrolysis showed a similar time-course of accumulation of [^{3}H]-inositol phosphates. Basal, potasium- and norepinephrine-stimulated accumulation of [^{3}H]-inositol phosphates decreased upon a decrease in extracellular calcium. Both basal and stimulated accumulation was almost completely eliminated by the addition of EGTA in concentrations as low as 50 μM. Isosmotically replacing sodium with choline chloride caused a large increase in the basal accumulation of [^{3}H]-inositol phosphates that was almost twice that caused by either KCl or norepinephrine in the presence of sodium. The removal of sodium completely eliminated potasium stimulated but not norepinephrine stimulated accumulation of [^{3}H]-inositol phosphates. Basal accumulation in the absence of sodium decreased with decreasing amounts of added calcium and by the addition of EGTA (0.025 to 1 mM), but remained quite large even in the presence of 1 mM EGTA. This data will be discussed in relation to the effects of sodium and calcium removal upon the intracellular free calcium concentration measured with the calcium sensitive fluorophore fura-2. It is hypothesis that removal of sodium causes an increase in intracellular calcium in the absence of sodium-calcium exchange and this elivation of intracellular calcium stimulates phosphoinositide hydrolysis. (Supported by NIAAA Grant # AA06060.)

37.2

INOSITOL PHOSPHATES, GTP AND CAFFEINE RELEASE CALCIUM FROM BRAIN MICROSOMES.
L.C. Daniell and R.A. Harris. Dept. Pharmacology and VA Med. Ctr., Univ. Colorado Health Sciences Center, Denver, CO. 80262.

The effects of various calcium releasing agents on intracellular calcium stores were studied in mouse whole brain microsomes. Calcium release was monitored by determination of the extra-microsomal calcium concentration using Indo 1, a fluorescent calcium indicator. Inositol 1-phosphate (1-30 uM) and inositol 1,4-bisphosphate (3 uM) did not release calcium from microsomes. Inositol 1,4,5-trisphosphate (IP_3)-induced calcium release exhibited two components. One component was dependent on prior ATP-stimulated calcium loading and had an EC_{50} of about 100 nM. A second component of IP_3-induced calcium release was detected in the absence of ATP-dependent calcium loading (EC_{50} approximately 30 uM). GTP (1-10 uM) released a small amount of calcium and caffeine (1-3 mM) released a larger amount of calcium. Work is currently in progress to identify and characterize calcium stores of brain microsomes. Supported by the VA administration and grants GM11905, AA06399 and AA03527.

37.3

STIMULATION OF Ca^{2+} REUPTAKE AFTER INOSITOL 1,4,5-TRISPHOSPHATE INDUCED Ca^{2+} RELEASE FROM RAT CEREBELLAR MICROSOMES.
K.A. Stauderman. Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, OH 45215.

The potential role of inositol 1,4,5-trisphosphate ($Ins(1,4,5)P_3$) to regulate intracellular Ca^{2+} fluxes in neuronal tissue was investigated with rat cerebellar microsomes as the model system. Using fura-2 fluorescence to monitor changes in extramicrosomal free Ca^{2+} concentration ($[Ca^{2+}]_e$), the microsomes accumulated Ca^{2+} in the presence of 500 µM ATP and an ATP-regenerating system. $Ins(1,4,5)P_3$ stimulated Ca^{2+} release in a concentration-dependent manner, producing half-maximal Ca^{2+} release at 60 nM after taking into account rapid metabolism of $Ins(1,4,5)P_3$. Following $Ins(1,4,5)P_3$-induced Ca^{2+} release there was a prompt reuptake of Ca^{2+} into the $Ins(1,4,5)P_3$-sensitive compartment, as judged by the lack of desensitization to subsequent additions of $Ins(1,4,5)P_3$. By measuring the rate of change of $[Ca^{2+}]_e$ as an index of Ca^{2+} uptake, the rate of Ca^{2+} reuptake after $Ins(1,4,5)P_3$-induced Ca^{2+} release was greater than after additions of Ca^{2+} standards, suggesting that Ca^{2+} reuptake was stimulated in the former case. The ability to detect this effect depends on whether $Ins(1,4,5)P_3$ can be metabolized faster than the rate of Ca^{2+} uptake into $Ins(1,4,5)P_3$-insensitive compartments. Ions other than Ca^{2+} may be involved in the process that stimulates Ca^{2+} reuptake.

37.4

PURIFICATION AND CHARACTERIZATION OF INOSITOL-1,4,5-TRIPHOSPHATE BINDING SITES IN RAT PERIPHERAL TISSUE.
R.J. Mourey*, S. Supattapone and S.H. Snyder. Dept. of Pharmacology and Molecular Sciences, Dept. of Neuroscience, Johns Hopkins University Sch. of Medicine, Baltimore, MD 21205.

An inositol-1,4,5-triphosphate (IP_3) receptor from rat cerebellum has recently been purified (Supattapone, S., et al., JBC, 263:1530, 1988). We were interested in identifying and characterizing IP_3 receptor from other rat tissues. In a screen of rat tissue, lymphoid organs and renal cortex provided the second most abundant source of [^{3}H]IP_3 binding.

We have purified the IP_3 binding site from rat spleen and thymus utilizing heparin-agarose and concanavalin A-sepharose affinity chromatography. The spleen and thymus IP_3 receptor are similar to the cerebellar IP_3 receptor, having high affinity for 1,4,5-IP_3 (K_d = 40 nM), and binding that can be inhibited by calcium, heparin and N-ethyl maleimide. However, the spleen and thymus IP_3 receptor differ from the cerebellar IP_3 receptor, both in molecular weight and cross-reactivity with anti-cerebellar IP_3 receptor antibodies. Interestingly, the kidney IP_3 receptor differs from the cerebellar receptor by having lower affinity for IP_3 (K_d = 400 nM), 1,3,4,5-IP_4 and IP_6 compete for IP_3 binding, it does not bind to concanavalin A-sepharose and it is resistant to N-ethyl maleimide.

STIMULATION OF DIACYLGLYCEROL FROM SOURCES OTHER THAN INOSITOL CONTAINING LIPIDS. M. S. Pessin* and D. M. Raben* (SPON: M. Steinmetz). Department of Physiology, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

α–Thrombin stimulates an increase in the mass of cellular diacylglycerol (DAG) in quiescent IIC9 fibroblasts. This generation is biphasic when stimulated by a high concentration of α–thrombin (500 ng/ml), with an early phase peaking at 15 seconds and a late phase peaking at 5 minutes. In addition, the DAG levels are sustained for at least 1 hour. We have analyzed the molecular species of DAGs generated 15 seconds, 5 minutes, and 1 hour after stimulation with α–thrombin and compared them to those contained in control, quiescent cultures. The data demonstrate that while the 15 second peak is temporally related with the hydrolysis of inositol lipids, these lipids contribute a small fraction of the total DAGs generated at this time. At later times the DAGs appear to be derived almost entirely from non-inositol containing lipids. (Supported by BRSG from JHU and GM0730 from NIH.)

37.6

EFFECTS OF PHENYLETHYLAMINE & NORADRENALINE ON POLYPHOSPHOINOSITIDE TURNOVER IN RAT CEREBRAL CORTEX. A.A.Boulton and L.E.Dyck (SPON: J.R.Doucette). Neuropsychiatric Research Unit, Dept. of Psychiatry, University of Saskatchewan, Saskatoon, Sask. Canada S7N 0W0

The trace amine, phenylethylamine,can excite or inhibit rat cortical neurons indirectly. In contrast, phenylethylamine can enhance the effects of noradrenaline (NE) directly, when it is applied simultaneously with NE. NE can alter neuronal excitability by stimulation of the α_1-adrenergic receptor which activates phospholipase C increasing polyphosphoinositide turnover (PIT) to produce the second messengers, inositol triphosphate and diacylglycerol. The ability of NE and phenylethylamine to stimulate PIT in slices of rat cerebral cortex was examined by using a direct assay which involves labelling with ^{3}H-inositol and assaying ^{3}H-inositol phosphates in the presence of lithium. 2.6 to 10 mM Phenylethylamine significantly stimulated the formation of ^{3}H-inositol phosphates (to 120 - 215 % of control), while 26 - 2600 μM PE dose-dependently inhibited (0.1 mM) NE-stimulated PIT. I mM NE was not inhibited by phenylethylamine. The effects of phenylethylamine & NE were inhibited by prazosin. Thus, phenylethylamine appears to stimulate basal formation of ^{3}H-inositol phosphates and to inhibit NE-induced formation of ^{3}H-inositol phosphates by acting as a partial α_1-agonist. (Supported by the M.R.C.)

CHANGES IN PHOSPHATIDYLINOSITAL CONCENTRATION AND MOTOR ACTIVITY ASSOCIATED WITH DENERVATION SUPERSENSITIVITY. C.A. Harrington and P.B. Silverman. Abbott Laboratories, Abbott Park, IL 60064 and Univ. of TX Ment. Sci. Inst., Houston, TX 77030.

The biochemical changes associated with post synaptic dopaminergic supersensitivity are poorly understood. Although receptor proliferation can be quantified after loss of presynaptic input, the time course increased receptor number and the behavior associated with denervation are significantly different. We have hypothesized that the changes in behavior may more closely parallel changes in inositol lipid metabolism. In order to test this hypothesis we injected intraventricularly two groups of mice with 6-hydroxydopamine (6 HDA) or vehicle. Mice were anesthesized with 400mg/kg chloral hydrate. Four days and eight days post injection motor activity was measured in both groups after administration of 5mg/kg apomorphine. The morning of the 10th day post lesion all animals were sacrificed and striata dissected from each brain and frozen on dry ice. Each pair of striata were divided at random, for catecholamine and phosphatidylinositol analysis.

Motor activity was increased 4 fold and 2.0 fold above control at 4 and 8 days respectively post lesion. Dopamine concentration was decreased to 40% of control values in animals given I.C.V. 6 HDA. The mass of phosphatidylinositol was increased 15% ($p < .05$) in the animals treated with 6 HDA. Therefore the time course of increases in motor activity, depletion of dopamine, and increased in phosphatidylinositol concentration may be related.

37.8

PHOSPHATIDYLINOSITOL TURNOVER IS PROPORTIONAL TO THE LEVEL OF EXPRESSION OF THE RAT M1 MUSCARINIC RECEPTOR GENE. D.T. Dudley*, C.R. Clark, F.Z. Chung*, C.M. Fraser* and J.C. Venter*, Parke-Davis Pharmaceutical Research, Ann Arbor, Mi 48105 and Section of Receptor Biochemistry and Molecular Biology, NINCDS, NIH, Bethesda, Md 20892.

To examine the second messenger coupling of muscarinic receptor subtypes, we have examined murine B82 cells transfected with, and expressing rat M1 muscarinic receptors (clone M1C2) and compared them with the previously characterized clones cTB9 and cTB10 (J. Lai *et al.* Life Sci., in press). As determined by [^{3}H](-)QNB binding to membranes, cTB9 cells expressed 64 fmol/mg protein and cTB10 cells expressed 170 fmol/mg protein (J. Lai, *et al.*), while M1C2 cells expressed 800 fmol/mg protein. The parent B82 cell exhibited no [^{3}H](-)QNB binding. In M1C2 cells labeled to equilibrium with [^{3}H]inositol and stimulated with 1 mM carbachol (CCh), there was a rapid increase in inositol trisphosphate as well as the tetrakis-, bis- and monophosphates. No effect of stimulation was seen on inositol pentakis- or hexakisphosphates. For routine studies, total [^{3}H]inositol phosphate (IP) accumulation in the presence of 10 mM Li^+ was monitored. CCh stimulated accumulation of IP in all three cell lines, with EC_{50} values of 42.3, 39.2 and 41.3 μM for M1C2, cTB9 and cTB10 cells, respectively. However, substantially more IP accumulated in M1C2 cells (10.1 fold) as compared to cTB9 (2.0 fold) and cTB10 cells (1.9 fold). These data indicate that expression of an appropriate foreign receptor protein in these cells can lead to the complete appearance of the phosphatidylinositol signaling pathway, and additionally suggest that the magnitude of the signal produced is proportional to the level of receptor present.

37.9

CARBACHOL STIMULATES INOSITOL-PHOSPHOLIPID METABOLISM IN PC12 CELLS BY MULTIPLE MECHANISMS. J. Horwitz* (SPON: N. Smalheiser). Pediatrics and Kennedy Mental Retardation Res. Ctr., The University of Chicago, Chicago, IL 60637

Muscarinic agonists are known to increase the hydrolysis of inositol containing phospholipids in PC12 pheochromocytoma cells. Here I report that activation of nicotinic receptors also increases inositol-phospholipid metabolism in these cells. The specific nicotinic agonist dimethylphenylpiperazinium and the mixed agonist carbachol both increased [^{3}H]inositol monophosphate ([^{3}H]IP_1) and diacylglycerol (DG) formation. The effect of carbachol was partly blocked by the muscarinic receptor antagonist N-methylscopolamine and was also partly blocked by the nicotinic receptor antagonist, mecamylamine. Activation of muscarinic receptors caused a two-fold greater increase in [^{3}H]IP_1 than did activation of nicotinic receptors. In contrast, nicotinic and muscarinic receptor stimulation had comparable effects on diacylglycerol formation. To understand the relationship between [^{3}H]inositol phosphate and DG formation I studied the time course of the effect of carbachol. [^{3}H]I-1,4,5-P_3, as measured by HPLC, was elevated at 15 sec and then began to slowly fall so that by 5 min levels had dropped by 50%. DG levels, in contrast, did not change for the first two minutes and then peaked at 5 min. In summary, the effect of carbachol on phospholipid metabolism is mediated by both nicotinic and muscarinic receptors. Phosphatidyl-inositol-4,5-bisphosphate is not the major source for the DG formed during carbachol stimulation. (Supported by NS-22694 and HD-04583)

37.10

CHARACTERIZATION OF RECEPTOR-STIMULATED TURNOVER OF INOSITOLPHOSPHATES IN THE RAT HIPPOCAMPUS AFTER COLCHICINE TREATMENT. P. Tandon, G.J. Harry, J. Peterson*, and H.A. Tilson. LMIN, NIEHS, P.O. Box 12233, Res. Tri. Pk., NC.

To study the effect of a neurochemical lesion on the muscarinic cholinergic system (mAch), colchicine was stereotaxically injected into the dorsal and ventral hippocampus of rats at a dose of 2.5 ug/site. The animals were sacrificed 1, 3 or 12 weeks after injection. Brains were removed and the hippocampus dissected out. Phosphoinositol (PI) hydrolysis was studied in hippocampal slices after the stimulation of mAch by carbachol. Colchicine was found to increase the sensitivity of the mAch to different concentrations of carbachol. Colchicine also produced an increase in the turnover of inositolphosphates (IPS) in hippocampal slices resulting in a significant increase in IPS released after receptor stimulation, together with an increase in ambient levels of IPS in the hippocampal slices. This effect was found to be time-dependent. The hyperstimulation of the IP metabolism was receptor mediated as mAch antagonists blocked the effect. The increased release of IPS was specific to mAch stimulation, as acetylcholine produced the same effect, while serotonin did not. These results suggest that colchicine alters the signal transduction process of the mAch and that these alterations are linked to the compensatory changes occurring after degeneration of the CNS.

37.11

CLONING, EXPRESSION AND DELETION ANALYSIS OF THE MOUSE M1 mAChR in Y1 ADRENAL CARCINOMA CELLS. R. A. Shapiro*, N. M. Scherer* and N. M. Nathanson. Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195.

We have cloned the gene encoding the mouse M1 muscarinic acetylcholine receptor and inserted it in an expression vector under the control of the zinc-inducible metallothionein promotor. When transfected into the Y1 adrenocarcinoma cell line, functional M1 receptor is produced in response to added zinc. The receptor is able to stimulate large increases in total inositol phosphate (InsP) production in response to the agonist carbachol but does not inhibit adenylate cyclase activity.

Mutations have been constructed that delete various portions of the putative third cytoplasmic loop, and the effects of these mutations on InsP metabolism and down regulation are being examined. 30% of the amino terminal portion of this loop can be deleted with no effect on agonist binding and minimal effect on coupling to InsP metabolism. Deletion of 75% of the loop results in substantial reduction in the ability of the receptor to stimulate InsP turnover. The deletions do not affect the affinity of the mutant receptors for agonist.

37.12

CNS RECEPTOR-COUPLED PHOSPHOINOSITIDE (PPI) HYDROLYSIS A.S. Chiu*, P.P. Li and J.J. Warsh. Clarke Institute of Psychiatry, Toronto, Ontario, CANADA M5T 1R8.

Understanding the mechanisms involved in brain receptor-coupled PPI hydrolysis is incomplete. We report here membrane preparation and incubation conditions combined with HPLC assay of inositol polyphosphates which permit more detailed characterization of receptor-PPI coupling mechanisms. Brain membranes were prepared from homogenates of rat cerebral cortical slices prelabelled with [^{3}H]myo-inositol. Carbachol (100 μM) induced a small increment in inositol bisphosphate (IP_2) (142% of control) formation in brain membranes without affecting insoitol monophosphate (IP) or inositol trisphosphates (IP_3). IP_2 accumulation was increased by 100 μM of GTP, GTPγS and GppNHp (142,520, and 220%, respectively). Carbachol-induced IP_2 accumulation was markedly potentiated by GTPγS and GppNHp (820 and 300%, respectively). Atropine (10 μM) inhibited the GTPγS potentiation of carbachol on IP_2 accumulation. IP and IP_3 did not show significant changes compared to controls for any of the above treatments. Rapid hydrolysis of exogenous [^{3}H]IP_3 to [^{3}H]IP_2 by the membrane preparation suggests IP_2 likely derives from metabolism of IP_3 and reflects agonist-induced hydrolysis of phosphatidylinositol 4,5-bisphosphate.

These data indicate that muscarinic receptor coupling to PPI hydrolysis remains intact in this cell-free preparation and provide evidence of GTP-dependent modulation of receptor-coupled PPI hydrolysis in CNS.

37.13

SIGMA RECEPTORS NEGATIVELY MODULATE AGONIST-STIMULATED PHOSPHOINOSITIDE METABOLISM IN BRAIN SYNAPTONEUROSOMES. B.N. Kirschner*[1], S.B. Hellewell*[1], A.H. Newman*[2], K.C. Rice*[2], and W.D. Bowen[1]. [1]Div. of Biology and Medicine, Brown University, Providence, RI 02912 and [2]NIDDK, Bethesda, MD 20892.

Several transmitters have been shown to mediate their effects by stimulating phosphoinositide (PI) turnover. We investigated whether effects of sigma ligands could be mediated by this system. Rat brain synaptoneurosomes were prepared and assayed for inositol-1-phosphate (IP_1) formation by the method of Gusovsky and Daly (Neuropharmacol. 27:95, 1988). (+)-Pentazocine, haloperidol, and DTG had no effect on PI turnover in the concentration range of 1-300 μM. However, above 300 μM, these ligands produced a slight (approximately 20%) inhibition of basal activity. This observation led to an investigation of the ability of sigma ligands to modulate stimulation of PI turnover by receptor agonists known to be coupled to this system. At 100 μM, the muscarinic cholinergic agonist carbachol produced a 2-fold increase in IP_1 formation. This value was set to 100% and the ability of various concentrations of sigma ligands to modulate this effect was determined. Sigma ligands produced a concentration-dependent attenuation in the ability of carbachol to stimulate PI turnover. The ED_{50} values correlated with binding affinities at sigma receptors (as determined in guinea pig brain). ED_{50} values (μM) were: (+)-pentazocine, 8.3; DTG, 25; dextrallorphan, 27; haloperidol, 35.4; and levallorphan, 155. (+)-Opiates lacking affinity for sigma receptors had no effect. Similar results have been obtained with norepinephrine-stimulated PI turnover. These results suggest that sigma receptors are coupled to an intracellular mechanism which negatively regulates some component(s) of the PI signalling system. Therefore, agonists at sigma receptors may play a neuromodulatory role in vivo by altering the efficacy of PI agonists. Effects of sigma ligands on the efficacy of other PI agonists will be discussed. (Supported by NIDA Grant #DA03776 and the Dystonia Medical Research Foundation.)

GLUTAMATE INHIBITS NOREPINEPHRINE-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS. X. Li* and R.S. Jope, Dept. of Pharmacology, Univ. of Alabama, Birmingham, AL 35294

Inhibition by excitatory amino acid agonists of norepinephrine (NE)-stimulated phosphoinositide hydrolysis was studied in rat brain slices. The distribution of ^{3}H-inositol and the production of ^{3}H-inositol phosphates in cortical slices were measured after 5 to 60 min of incubation, with some slices being exposed to NE, glutamate, NMDA, quisqualate, or to NE in the presence of each of the excitatory amino acid agonists.

Glutamate did not effect the slice content of free ^{3}H-inositol, but abolished NE-induced production of ^{3}H-inositol monophosphate, ^{3}H-inositol bisphosphate and ^{3}H-inositol trisphosphate. Quisqualate mimicked the effects of glutamate, whereas NMDA and kainate did not inhibit the response to NE, suggesting that only quisqualate-selective receptors affected α_1-adrenergic receptor-mediated phosphoinositide hydrolysis. Glutamate produced similar inhibitory effects in slices from hippocampus and striatum.

To test if the inhibitory effect of glutamate was the result of irreversible cell damage, cortical slices were incubated with glutamate for 60 min prior to exposure to ^{3}H-inositol and NE. Preincubation with glutamate did not inhibit NE-stimulated ^{3}H-inositol monophosphate production.

NMDA DOES NOT INHIBIT CARBACHOL-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS. G.C. Ormandy* and R.S. Jope. (SPON: L. Beani), Dept. of Pharmacology, Univ. of Alabama, Birmingham, AL 35294

The effect of NMDA on carbachol-stimulated phosphoinositide hydrolysis was studied in hippocampal and cerebral cortical slices of rat brain. NMDA was added either after 1 hour preincubation of slices with ^{3}H-inositol or simultaneously with ^{3}H-inositol. NMDA (50-1000 μM, 10 or 60 min) had no effect on the slice content of free ^{3}H-inositol or on carbachol-induced ^{3}H-inositol monophosphate production. Although NMDA produced a 15% inhibition of lipid labelling when added simultaneously with the ^{3}H-inositol it appears that these lipids are not in a pool associated with the cholinergic receptors. Even preincubation of slices with NMDA (60 min) prior to exposure to ^{3}H-inositol did not inhibit subsequent carbachol-stimulated ^{3}H-inositol monophosphate production. Thus, it is concluded that NMDA does not affect carbachol-stimulated phosphoinositide hydrolysis in either hippocampal or cerebral cortical slices of rat brain under these experimental conditions. Supported by NIH grant MH38752.

37.16

BIDIRECTIONAL REGULATION OF PHOSPHOINOSITIDE METABOLISM BY GLUTAMATE RECEPTORS: STIMULATION BY TWO CLASSES OF QA RECEPTORS AND INHIBITION BY NMDA RECEPTORS. Elizabeth Palmer*, Daniel T. Monaghan, Jennifer Kahle and Carl W. Cotman (SPON David R. Stevens) Dept. Psychobiology, Univ. California, Irvine, CA 92717.

Analysis of excitatory amino acid receptor regulation of phosphoinositide (PI) metabolism in rat neonatal hippocampal slices reveals two classes of quisqualic acid (QA) receptors. One class corresponds to the excitatory actions of the well described QA-agonist, AMPA (α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid), which is selectively blocked by the recently available QA antagonist CNQX (6-cyano-2,3-dihydroxy-7-nitro-quinoxaline). AMPA maximally elicits a 2-3 fold stimulation of PI metabolism which is readily blocked by CNQX. The second class of QA receptor is activated by 10 μM QA, resulting in a 15 fold stimulation of PI metabolism. The QA-induced PI metabolism is not antagonized by CNQX.

QA-induced stimulation of PI metabolism is inhibited by NMDA receptor activation NMDA (100 μM) inhibits the QA-induced stimulation by 75% and the inhibition is dependent on extracellular calcium. As expected, glutamate appears to be activating both QA and NMDA receptors since NMDA antagonists CPP (3-((±)2-carboxypiperazin-4-yl) propyl-1-phosphonic acid), AP5 (D-2-amino-5-phosphopentoate), and MK-801 enhance glutamate stimulation of PI turnover.

In the neonate and adult hippocampal slice it is the AMPA-sensitive QA receptor which mediates most of the Schaffer collateral electrically-evoked synaptic response. Therefore, if the CNQX-insensitive QA receptors are activated during synaptic transmission, at low stimulation frequencies the transmitter glutamate would activate both ion channels and PI metabolism via the two QA receptors. At high stimulation frequencies, NMDA receptors would become active and shut down PI metabolism, while promoting calcium entry. Thus the stimulation paradigm could be controlling the nature of the second messengers generated. During development such a mechanism would allow for synaptic activity to control two seperate second messenger pathways which could be exerting opposite regulation of synaptic stabilization as has been theorized by Bear and colleagues (Science 237: 42-48). Supported by ARO DAAL 03-86-K-0067.

INHIBITION OF INOSITOL PHOSPHATE PRODUCTION BY ADENOSINE IN GH3 CELL MEMBRANES. T.M. DELAHUNTY and J. LINDEN* Dept. of Neuroscience and Physiology, Univ. of Virginia, Charlott -esville, VA 22908

We have previously reported that adenosine and its analogues inhibit phosphoinositide hydrolysis and inositol phosphate (IPx) production in GH3 cells via a pertussis sensitive mechanism (FASEB J., 2:5, 1988). We now extend those findings to a cell free system. Both basal and TRH (thyrotropin releasing hormone) stimulated inositol phosphate production were inhibited and the potency order of adenosine analogues was similar to that observed in whole cells: N6-cyclopentyladenosine, phenylisopropyladenosine (R-PIA), 5'-N-ethylcarboxamidoadenosine, indicative of a response mediated by A_1 receptors. The selective adenosine receptor antagonists BW-A1433U and 8-phenylsulfyltheophylline blocked the response. The stable GTP analogue, GTP-gamma-S, stimulated IPx production in GH3 cell membranes and this response was reduced by R-PIA. These data rule out indirect regulation of phosphoinositide metabolism by adenosine receptor-stimulated second messenger production or ion channel modulation and suggest a more direct effect.

37.18

CHARACTERISTICS OF 5HT-MEDIATED PHOSPHOINOSITIDE (PI) TURNOVER IN RAT HIPPOCAMPUS: EFFECTS OF HIGH POTASSIUM. A.M. Mellow, D.L. Murphy,* J.M. Cossery,* and D.M. Chuang. NIMH/LCS and LPP; Bethesda, MD 20892 and Washington, DC 20032.

5HT-mediated activation of phospholipase C and promotion of PI turnover is an important mechanism of biochemical signal transduction in the brain and has not been well characterized in the hippocampus, where its properties differ from those in the cerebral cortex.

PI turnover (the production of inositol monophosphate (IP_1) in the presence of LiCl) was measured in 350-μm rat hippocampal slices prelabelled with [^{3}H]-myo-inositol. 5HT produced a biphasic increase in PI turnover, with a maximum (40% over control) occurring at a concentration of about 50 μM. At higher 5HT concentrations, PI turnover fell to near control levels. This phenomenon was not seen in the cortex. Treatment of slices with high potassium (15-25 mM) both potentiated the action of 5HT and abolished the biphasic nature of the dose-response curve. The selective receptor agonists m-CPP ($5HT_{1B}$), DOI ($5HT_2$), and 2-Me-5HT ($5HT_3$) all had weak activity. The $5HT_2$ antagonist, ketanserin, blocked the response poorly, and the $5HT_3$ antagonist, ICS-205-930, was ineffective, all suggesting possible involvement of both $5HT_2$ and $5HT_1$ receptor subtypes. These results indicate that 5HT-mediated PI turnover in the hippocampus is under complex modulatory control, possibly via opposing actions of 5HT at different concentrations and at different receptor sites, and can be further modified either by a direct effect of potassium ion or via the depolarization-induced release of an unknown modulator.

37.19

EFFECTS OF INDOLEAMINES ON POLYPHOSPHOINOSITIDE HYDROLYSIS IN RAT CEREBRAL CORTEX. L.E. Dyck Neuropsychiatric Research Unit, Dept. of Psychiatry, University of Saskatchewan, Saskatoon, Sask., Canada S7N 0W0

5-Hydroxytryptamine (5HT) increases polyphosphoinositide turnover (PIT) in rat cerebral cortex via stimulation of $5HT_2$ receptors. The effects of tryptamine (TRA) on PIT in rat cortex is less clear. Some groups report that it stimulates PIT in cortex, but others report that it is inactive. The ability of these compounds to stimulate PIT in slices of rat cerebral cortex was examined by using a direct assay which involves labelling with ^{3}H-inositol and assaying ^{3}H-inositol phosphates in the presence of lithium. 5HT increased the formation of ^{3}H-inositol phosphates by cortical slices significantly above control levels. Its effects were rather weak compared to noradrenaline (NE). 1 mM 5HT was inactive, and 10 mM increased PIT to 120±6 % of control activity. By comparison,the response to 1 μM NE was 162±17 % of control and 401±20 % to 1 mM NE. TRA (1-10 mM) stimulated the formation of ^{3}H-inositol phosphates(to 142- 234 % of control). In agreement with previous findings, ketanserin did not appear to block TRA. Interestingly, when TRA or 5HT (1mM) were incubated simultaneously with a submaximal amount of NE (0.1 mM), they inhibited NE-induced increases in PIT. TRA inhibited NE by 59%, while 5HT inhibited NE by 24%. The mechanism of this inhibition is under investigation.

NEUROETHOLOGY I

TEMPERATURE COUPLING IN CRICKET ACOUSTIC COMMUNICATION: LOCALIZATION OF TEMPERATURE EFFECTS ON THE FEMALE SONG-RECOGNITION NETWORK. A. Pires* and R.R. Hoy. (SPON: J.A. Doherty). Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

Temporal parameters of the song of the North American field cricket, Gryllus firmus, are strongly affected by environmental temperature. Chirp rate and pulse rate within the chirp both increase as linear functions of temperature. Female phonotactic preference is affected by temperature in a parallel manner, such that warmer females prefer faster songs. Thus this communication system is said to be temperature coupled.

Since male song is produced by a thoracic central pattern generator (CPG) and head ganglia are necessary for female song recognition, anatomical localization of the temperature effect on song recognition is a test of the hypothesis that neural elements homologous to the male song CPG are present in the female and are used as a template for song recognition.

We developed a technique for selectively manipulating and measuring temperatures in different body compartments while the animal walks on a spherical treadmill which records direction and velocity of movements in response to synthetic song.

An initial result of this study is that female phonotactic preference can be altered by raising the temperature of the whole animal but not by heating the head capsule alone, consistent with the CPG-template hypothesis.

38.2

SEXUAL DIMORPHISM IN THE AUDITORY SYSTEM OF THE PRAYING MANTIS. D. D. Yager* and R.R. Hoy (SPON. M. C. Nelson). Neurobiology & Behavior, Cornell University, Ithaca, NY 14853.

We have found physiological and anatomical sexual dimorphism in the metathoracic auditory systems of two mantis species, Stagmomantis carolina and Ameles heldreichi. In the latter, extracellular recordings from the connectives of males show ultrasonic tuning similar to that previously reported for M. religiosa, while we detect no auditory activity at all in the females. Male S. carolina have a W-shaped tuning curve with sensitivity at 2-4 kHz and at 25-45 kHz. The low frequency hearing is mediated by mesothoracic rather than metathoracic structures. The females of this species have low frequency curves identical to the males', but no detectable response to ultrasound.

Differences in the external anatomy of the ear region (the metathoracic groove) parallel the physiological findings. The males of both species have grooves of an anatomical type physiologically correlated with ultrasonic hearing in 10 of 11 species tested. The female grooves differ markedly from the males'. These groove structures correlate physiologically with absence or strong reduction of ultrasonic response in 10 of 10 species tested. The internal ear anatomy of S. carolina males and females is similar with respect to the tympanal organ, tympanal nerve, and auditory neuropile.

In museum collections we have examined the metathoracic groove (ear) anatomy in both sexes of species in 177 genera representing all major taxonomic groups in the suborder Mantodea and find sexual dimorphism in 66 cases. Further, the occurrence of dimorphism in groove anatomy is strongly correlated with dimorphism in wing length. The dominant pattern is that seen in both species discussed above: fully winged males have the ultrasound-correlated groove type while the short winged females of the same species have aberrant groove structures.

(Supported by NINCDS Grant NS11630 to R.R. Hoy and by the Eppley Foundation for Research.)

38.3

POSSIBLE ACTIVE SPACE OPTIMIZATION BY THE MALE CRICKET FROG, ACRIS CREPITANS, THROUGH ADJUSTMENT OF NEIGHBOR SPACING. J. H. Fox. Psychology Dept., University of Texas, Austin, TX 78712.

Computer models of hypothetical anuran choruses (Fox, J.H. and Wilczynski, W., Soc. Neuroscience Abst. 12:84.10, 1986) demonstrate that a male may increase the active space (AS) of its mating call by joining a chorus and optimize AS by spacing itself at an appropriate distance from neighboring males. Optimal neighbor spacing depends on chorus geometry type, approximate chorus population, call duty cycle (DC), the randomization factor (RF) for neighbor spacing, and the threshold distance (TD), over which the solitary male's mating call attenuates to the female's multiunit midbrain auditory threshold.

Acris crepitans choruses in the Austin area are usually linear but often planar and typically have less than 50 members. DC = .029, RF = .63, and TD= 18.4 M. Conflicting spacing optima exist, based on the above values, for the two chorus types. AS is optimized when neighbor spacing is .79 M in linear choruses and 8.15 M in planar choruses. Actual neighbor spacing is 4.8 M and does not seem to differ between chorus types. Perhaps 4.8 M represents a compromise between the conflicting linear and planar optima.

BEHAVIORAL AND NEURAL THRESHOLDS TO ADVERTISEMENT CALLS IN A NEOTROPICAL FROG. W. Wilczynski. Dept. of Psychology, Univ. of Texas, Austin, TX 78712.

Male Hyla microcephala produce a short, high frequency, advertisement call with two spectral peaks: the dominant frequency at ca. 5.8 kHz and a lower amplitude peak at ca. 3 kHz. Different call amplitudes characterize different male behaviors. The mean (±SD) threshold for antiphonal calling is 62.2 ± 2.99 dB SPL (fast RMS). Males maintain an intermale distance marked by neighbor call amplitudes of 75 ± 5.95 dB. At ca. 81 dB males switch to an aggressive call (estimated from Wells & Schwartz, Copeia, 1985: 27-38). Midbrain multiunit recordings reveal one broad area of auditory sensitivity below 1.2 kHz and a second marked by a V-shaped frequency-threshold curve with a mean best frequency of 5.3 kHz. Both peaks in the call fall within this upper sensitivity band, which presumably represents basilar papilla (BP) activity. BP thresholds at best frequency average 62.7 ± 10.8 dB, which is not significantly different from the mean threshold for antiphonal calling (t=0.51, p>0.25), but is different from the mean neighbor amplitude (t=10.0, p<0.001). In collaboration with W. S. Geisler, a computer model of sensory filtering is being applied to these data to investigate the relationship between behaviorally relevant call amplitudes and the intensity-dependent activity of BP neurons.

Supported by a Smithsonian Short Term Visitor Grant and NSF grant BNS 8606289.

TESTOSTERONE-INDUCED CHANGES IN HORMONE ACCUMULATION IN THE SONG SYSTEM OF FEMALE CANARIES. E.A. Brenowitz and A.P. Arnold. Depts. of Psych & Zool, Univ. Washington, Seattle, WA 98195 and Dept. Psych & Brain Res. Inst., UCLA, LA, CA 90024.

Adult female canaries (Serinus canarius) show extensive plasticity in the neural sytem that regulates song production. Normal females do not sing regularly, have smaller song control regions (SCRs) in their brains than do males (Nottebohm and Arnold 1976), and have smaller dendritic trees in one SCR than do males (DeVoogd and Nottebohm 1981). Treatment of females with testosterone (T) induces song and increases SCR volumes (Nottebohm 1980), neuron number (Bottjer and Dignan, submitted), and dendritic tree size (DeVoogd and Nottebohm 1981). In this study we asked whether such T-induced neural plasticity is accompanied by changes in the accumulation of T or its metabolites by SCR neurons.

Female canaries were implanted with silastic capsules containing either T (n = 5) or nothing (n = 3). Vocal behavior was monitored. One month later the pellets were removed, each bird was gonadectomized and then injected with tritiated testosterone for steroid autoradiography. In the caudal nucleus of the ventral hyperstriatum (HVc), we measured the proportion of cells that were labeled and the extent above background that cells were labeled (density ratio). Gross volume of HVc was also determined.

Song occurred in all T-treated but no control females. HVc volume was 75% greater in T birds. The proportion of HVc cells labeled by T or its metabolites did not differ between T-treated (X ± SD = 50.2 ± 7.8%) and control (50.3 ± 0.3%) groups. Density ratios of HVc cells, however, were greater for T females (6.5 ± 1.6) than for controls (5.5 ± 1.9; P<.01, t-test). The T-induced masculinization of vocal behavior is thus accompanied by an increase in the strength with which T/metabolites is accumulated by target cells but not in the frequency of such cells. Also, T target and non-target cells must be recruited at equal frequencies into HVc following T treatment.

NEUROCHEMICAL STUDIES OF THE NUCLEUS INTERCOLLICULARIS IN THE JAPANESE QUAIL. M. Gahr*, G.F. Ball, M. Schumacher*, & J. Balthazart. (SPON: J. Cohen). Univ. Kaiserslautern, FRG; Rockefeller Univ., New York, NY 10021 ; Univ. Liège, Liège, Belgium.

In the Japanese quail crowing and copulatory behavior are both suppressed by castration, but different steroid treatments reinstate these behaviors. Little is known about the reason for this difference. N. intercollicularis (ICo) has been identified as an important area mediating vocal behavior in the quail. We have therefore investigated neurochemical factors influencing steroid effects in ICo. Approximately 50% of the cells in the medial portion of the nucleus contain estrogen receptors (determined immunohistochemically), however, levels of the steroid converting enzyme aromatase are undetectable. Levels of the 5α reductase enzyme are high in ICo but do not appear to be regulated by testosterone (T). Steroid effects on crowing are presumeably mediated by the modulation of neurochemical activity in ICo. We have therefore studied the localization and modulation by steroids of two neurotransmitter systems in ICo. Dense α-2 adrenergic receptor binding ([^{3}H] Para-aminoclonidine [PAC]) and muscarinic cholinergic binding ([^{3}H]N-methyl scopolamine [NMS]) as determined by autoradiography is present in the nucleus. However, there are differences between the two ligands. For example, PAC shows a distinct sub-region of binding in medial ICo which resembles the dorso-medial region of ICo described in songbirds. PAC binding is sexually dimorphic although the density of receptors in the male is not affected by T treatment. In contrast, NMS binding is not sexually dimorphic but castration of the male seems to decrease the density of binding, especially in rostral ICo. The actions of steroids in ICo are different in several ways from those described for copulatory behavior in the medial pre-optic nucleus.

AUTORADIOGRAPHIC LOCALIZATION OF BRAIN PROLACTIN RECEPTORS IN A PARENTAL AND NON-PARENTAL SONGBIRD SPECIES. G.F. Ball, A.M. Dufty*, A.R. Goldsmith*, and J.D. Buntin. Rockefeller University, New York, NY 10021; Univ. of Bristol, Bristol, U.K. and Univ. of Wisconsin, Milwaukee, WI 53211

In several species of birds, such as the European starling (*Sturnus vulgaris*) plasma levels of prolactin are positively correlated with the onset and maintenance of incubation behavior. Brood-parasites such as the brown-headed cowbird (*Molothrus ater*) lay their eggs in other bird's nests and do not engage in any parental care. However, seasonal changes in prolactin secretion in this species show a pattern similar to that of parental birds. It has been hypothesized that cowbirds have evolved a central insensitivity to the action of prolactin. In order to test this idea we compared prolactin binding sites in the brains of male and female starlings and cowbirds using *in vitro* quantitative autoradiography. Sites were labeled using [^{125}I] ovine prolactin (55pM [^{125}I] oPRL ± 85nM oPRL). Sections were exposed to X-ray film and the autoradiograms were analyzed with an image analysis sytem. Plasma levels of prolactin were measured in all subjects. Specific [^{125}I]oPRL binding sites were observed in both species throughout the pre-optic area (POA) and in hypothalamic regions including such nuclei as the paraventricular nucleus and the infundibular nucleus. Extra-hypothalamic binding sites in both species include the n. intercollicularis and the n. taeniae. A sex difference in receptor density was identified in both species in the POA. The density of binding was similar between the two species in all hypothalamic regions but in the POA levels were significantly higher in starlings. This difference may be related to inter-specific differences in parental behavior.

CONNECTIONS AND FUNCTION OF AN "AROUSAL"-AREA OF THE CAUDAL FOREBRAIN OF ZEBRA FINCHES. H.-J. Bischof*, K. Herrmann*, J. Engelage*, J. Niemann*, E. Church* (SPON: European Brain and Behavior Society). University of Bielefeld, Dept. Ethology, POB 8640, D 4800 Bielefeld 1, FRG.

In previous studies (Bischof, H.-J., Herrmann, K.; Behav. Brain Res 21: 215, 1986; Behav. Neural Biol: in press), we demonstrated that four areas of the forebrain of zebra finch males are activated in situations which arouse the animal, e.g. if it is exposed to a female. We investigated the connections and responses to sensory stimuli of one of these areas, the archi/neostriatum caudale (ANC). In addition, we examined the effects of ANC lesions on courtship behaviour. Besides other afferents ANC receives input from the visual area pretectalis, locus coeruleus, and the reticular formation. Only one projection to the optic tectum could clearly be demonstrated. Evoked potentials within ANC occurred with visual and, very rarely, acoustical stimulation. The best responses were obtained with combined stimuli. Bilateral lesions to ANC reduce male song activity during courtship, but not courtship behavior in general. We propose that ANC may be involved in the regulation of song output according to the behavioral state of the animal. Supported by the DFG.

38.9

SEXUAL DIFFERENCES IN CONTROL OF THE ZEBRA FINCH DISTANCE CALL. H. B. Simpson and D. S. Vicario. The Rockefeller University, New York NY 10021.

Song production in birds has been extensively studied as a model for brain correlates of behavior and learning. The song control pathway includes central nuclei HVc and RA and the tracheosyringeal nerve. In addition to song, songbirds produce a variety of calls in different social contexts. In zebra finches, the distance (or contact) call is sexually dimorphic and learned in males (Zann, '84, '85). We wanted to know whether this call depends on the same central and peripheral pathway as that described for song in canaries.

In male zebra finches, cutting the tracheosyringeal nerves has a dramatic effect both on the distance call and on the song. However, in females, the distance call remains virtually intact after nerve section, suggesting that her call does not require active control of syringeal muscles. Lesioning either HVc or RA in males affects both his song and distance call. In contrast, the female's distance call remains virtually intact after HVc lesions. These data are consistent with anatomical work demonstrating that the connection between HVc and RA is present in males, but sparse or absent in females (Konishi and Akutagawa, '85).

Our data show that the male's song and distance call depend critically upon HVc, RA and the tracheo-syringeal path, whereas females can call without a significant contribution from these structures. We propose that there exists another system for vocalization used by female zebra finches that may play a role in male vocalizations as well.

38.10

CONTROL OF SYRINGEAL MUSCLES IN NUCLEUS RA OF ZEBRA FINCHES. D. S. Vicario, and H. B. Simpson. The Rockefeller University, New York NY 10021.

Telencephalic nuclei HVc and RA are critical for avian song behavior. HVc projects to RA, and RA projects to part of n. XII (nXIIts) that controls the vocal organ, or syrinx. We have recently shown that nXIIts is organized in control zones for syringeal muscles.

The present study mapped outputs from RA by injecting small amounts of retrograde tracers into physiologically identified subregions of nXIIts. In nXIIts, the control zones for the dorsalis and ventralis muscles (the two largest syringeal muscles) are located caudally and rostrally respectively. In RA, cells projecting to caudal nXIIts were located ventrally, whereas the projection to rostral nXIIts originated in mid RA. Dorsal RA contained almost no cells projecting to nXIIts; instead, the cells there project to DM of ICo, the other major output of RA. Anterograde tracers were injected into subregions of RA to confirm these projections. Thus, the overall pattern in RA consists of approximately horizontal slabs of cells with different targets.

The same methods did not show topographic organization in the projection from HVc to RA, so we made small injections of the anterograde tracer PHA-L in HVc. HVc axons arriving in the dorsal RA region (projecting to DM) bifurcate richly. In contrast, most axon trunks that enter mid and ventral RA run rostrally in the horizontal plane for long distances, giving off short branches. We suggest that the terminal field of each HVc axon within the nXIIts-projecting region of RA could select cells involved in the control of particular syringeal muscles.

38.11

'TIMBRE' CONTROL AND DISCRIMINATION IN ZEBRA FINCH SONG. H. Williams, J. Cynx*, F. Nottebohm. Rockefeller University Field Research Center, Millbrook, NY 12545.

Zebra finch song syllables include harmonically related frequency components which may be differentially suppressed or emphasized. We call these patterns of harmonic suppression `timbre'. A syllable's timbre is conserved over a period of at least 9 months, and young males imitate the patterns of harmonic suppression in a song model's syllables. Syringeal denervation dramatically alters the patterns of harmonic suppression in a manner suggesting that the vocal organ controls the relative amplitudes of harmonics within a syllable.

Zebra finches can also discriminate between two syllables differing only in timbre. In a go - no go operant paradigm, male and female finches rapidly acquired a discrimination between stimuli varying only in the amplitude of the harmonics. Discrimination performance was not affected by lesioning HVc, a forebrain nucleus that is essential for song production and possibly important for song perception.

The selective suppression of some harmonics creates a great number of possible timbre variants, which add signal diversity to the limited set of fundamental frequencies and frequency modulation patterns used in zebra finch syllables. Patterns of harmonic suppression and emphasis are also important in speech, and may previously have been overlooked in bird song. The neural mechanisms mediating the motor control and perception of 'timbre' in zebra finches may be of interest to all students of vocal communication.

38.12

A COMPARISON BETWEEN THE EFFECTS OF SYRINGEAL DENERVATION AND AIRFLOW OBSTRUCTION ON SONGBIRD PHONATION. S. Nowicki* (SPON: P. Marler). Rockefeller Univ., New York, NY 10021

The two sides of the songbird syrinx are thought to operate independently during phonation, providing a simple interpretation of peripheral function with respect to cerebral lateralization of vocal control in birds. In order to reassess this hypothesis, male swamp sparrows (Melospiza georgiana) were subjected to two different procedures, both intended to disable the syrinx unilaterally. One group of birds had either the right or left hypoglossal nerve sectioned. A second group had airflow to one or the other syringeal half blocked by insertion of a plug in the bronchus. Some birds were subjected to both procedures in series, receiving a nerve section ipsi- or contra-lateral to the side that was previously plugged.

Occluding airflow to one side of the syrinx produces qualitatively different phonological effects than those observed when that same side is disabled by nerve section. In general, unilateral blockage of airflow has remarkably little effect on song. Birds given nerve sections ipsilateral to a side that was previously plugged show vocal deficits comparable to those observed in the case of unilateral nerve sections alone. These data are inconsistent with previous interpretations of syringeal function. They suggest that mapping of lateralized central control onto the periphery is more complex than previously supposed.

CHANGES IN NEURON NUMBER DURING SENSORY LEARNING IN SWAMP SPARROWS. K.W. Nordeen, P. Marler, and E.J. Nordeen. Psychology, U. Rochester, Rochester, NY, 14627, and Rockefeller U. Field Res Ctr, Millbrook, N.Y. 12545.

During vocal learning in songbirds, neurons are added to some song nuclei and lost from others. Previous work has not distinquished whether these neural changes correlate with memorizing a song model (sensory learning) or practicing song-like vocalizations (sensorimotor learning). In this study we measured changes in neuron number within swamp sparrow song nuclei during sensory learning, but before the onset of sensorimotor learning.

Male swamp sparrows were tutored with taped songs from 20 days of age until they were sacrificed at 20, 40, or 60 days after hatching. Sparrows memorize about 60% of their song material during this period, but do not rehearse learned material until 6-7 months later. Brains were embedded in paraffin and serial sections (10um) were stained with thionin. Neuron number was determined for hyperstriatum ventralis pars caudalis (HVc), magnocellular nucleus of the anterior neostriatum (MAN), robust nucleus of the archistriatum (RA) and Area X.

Neuron number changed substantially during sensory learning in all areas examined except RA. In both HVc and Area X neuron number doubled between 20 and 60 days of age. In contrast, MAN lost about 30% of its' neurons between 40 and 60 days of age. If these patterns of neuronal addition and loss encourage learning, their timing may restrict the period of sensory learning.

NON-CLASSICAL AUDITORY PROJECTIONS TO SONGBIRD FOREBRAIN. A.J.Doupe and M. Konishi. Div. of Biology 216-76, Calif. Institute of Technology, Pasadena, CA 91125

Birdsong is a complex learned behavior which requires auditory experience and feedback during its development. The classical thalamo-telencephalic auditory projection in songbirds is from nucleus ovoidalis to Field L. In addition, projections from Field L to the vicinity of hyperstriatum ventrale, pars caudale (HVc) and the robust nucleus of the archistriatum (RA) are known.

Using single and multi-unit electrophysiological recordings, we have found a wide distribution of auditory responses in other areas of the forebrain of adult male bengalese finches. These units were located in anterior portions of all layers of the hyperstriatum, as well as in anterior neostriatum and lobus parolfactorius (LPO). In LPO some of the recording sites were within the song nucleus X. The auditory units had response latencies of 20-30 msec, preferred complex stimuli such as white and narrow band noise, and were broadly tuned to frequency. Preliminary results of horseradish peroxidase (HRP) injections into these auditory areas showed retrograde label in the posterior dorsal thalamus.

These results demonstrate a large area of auditory responsiveness in the songbird anterior forebrain, and raise the possibility of a separate thalamo-telencephalic auditory pathway, parallel to the classical pathway through nucleus ovoidalis and Field L.

38.15

AUDITORY EXPERIENCE OF MATURING BARN OWLS. T.A. Haresign* and A. Moiseff. Dept. of Physiology and Neurobiology, Univ. of Conn., Storrs, CT 06268.

We recorded short latency auditory evoked potentials (EPs) from the Barn Owl (Tyto alba) to study the changes in hearing during maturation. This non-invasive approach allowed us to follow the development of individual owls beginning about 1 week after hatching. Three electrodes were arranged with one located at the vertex and one at each ear canal. Stimuli consisted of click or click pips (2kHz - 12kHz), and responses were averaged over 50 or more repetitions.

Short latency EP components (less than 5 msec) were detected in response to free field stimuli in owls of all ages. The threshold of these components decreased as individuals matured. The ability to detect specific frequencies was independent of age, however, during maturation, sensitivity to particular frequency bands varied.

Longer latency (8-20 msec) components characteristic of adult owls' EPs were not apparent in very young individuals. As the animals aged these components gradually appeared. When the owls were about 4 months of age the EPs took their adult form.

MATING CALL CHARACTERISTICS AND LARYNGEAL MORPHOLOGY IN TWO POPULATIONS OF *ACRIS CREPITANS*. B.E. McClelland, W. Wilczynski and M.J. Ryan. Depts. of Psychology, Zoology, and Institute for Neurological Sciences Research, University of Texas, Austin, TX 78712.

Allopatric populations of cricket frogs (*Acris crepitans*) differ in average size and mating call characteristics such as dominant frequency and temporal pulse patterns. This study compares the anatomical components of the larynges with mating call characteristics in individuals representing two populations from Sabine (SA) and Lake Balmorhea (BA), Texas.

The dominant frequencies are lower (BA=2.78; SA=4.03 kHz), but the head widths (BA=.91; SA=.79 cm), arytenoid cartilages (BA=.881; SA=.665), vocal cords (BA=.065; SA=.048), constrictor (BA=1.077; SA=.767) and dilator muscles (BA=.27; SA=.178) are all larger in the BA population (laryngeal measurements in mm^3; all $p<.01$, Student's t-test). These size differences may account for dominant frequency differences between the two populations. However, within each population the relationship between morphology and call characteristics is more complex. Stepwise regression analysis using standardized data shows that the dilator muscle volumes were significantly correlated with the duration of the mating calls (SA=61.5 ms) ($r=.87$; $p<.03$) in the SA population, but not in BA. The number of pulses per call (BA=4.72) was negatively correlated ($r=-.66$; $p<.05$) with the constrictor muscle volume in the BA population. The volume of BA 's vocal cords was also related to the number of pulses per call ($r=.61$; $p<.04$). The only correlation involving the dominant frequency was a negative relationship ($r=-.75$; $p<.04$) with the arytenoid cartilages in BA. (Research supported by NSF grant BNS 8606289)

38.17

AUDITORY NEURONS SELECTIVE FOR COMBINATIONS OF BEHAVIORALLY RELEVANT SOUND PATTERNS. B. DIEKAMP* and H. C. GERHARDT* (SPON: F. vom Saal). Division of Biological Sciences, University of Missouri, Columbia, MO 65211.

We examined the temporal selectivity of single neurons in the torus semicircularis of two species of the gray treefrog complex (Hyla versicolor and H. chrysoscelis) to acoustic signals whose significance in intraspecific call recognition has been established. Two fine-temporal call properties underlying species recognition were changed parametrically: pulse repetition rate (PR) was varied from 10 to 70 pulses/s; pulse shape (PS) was varied from 35 to 95% rise time. The spectral characteristics and other temporal properties of the stimuli were held constant at species-typical values. A substantial proportion of neurons responded selectively to specific PRs; others were selective to particular PSs. A few neurons were tuned to a unique combination of these two parameters. That is, most of these neurons responded maximally to the conspecific PR only if the pulses of the stimuli also had the conspecific PS; they responded poorly to stimuli with a PS typical of the other species over the entire range of stimulus PRs. These data are consistent with the observed behavioral preferences for synthetic calls with a conspecific PR and PS. We propose that PR-, PS-selective and combination-selective neurons play a crucial role in intraspecific mate choice. PR is highly temperature-dependent, but both behavioral and neurophysiological studies indicate that the nervous system of the female compensates for her own temperature in selecting calls with an appropriate PR. Since PS is a temperature-independent parameter of the male's call, it should be a particularly reliable redundant parameter for species recognition.

38.18

CORTICAL NEURONS SENSITIVE TO THE HARMONIC STRUCTURE OF ECHOLOCATION SIGNALS EMITTED BY AN FM BAT. S.L. Shannon* and D. Wong. Department of Anatomy, Indiana University School of Medicine, Indianapolis, Indiana, 46223.

Neurons that are delay-sensitive to pulse-echo pairs, consisting of a constant frequency and FM sweep (CF-FM), are present in the auditory cortex of the FM bat, Myotis lucifugus. These neurons are interspersed with other neurons exhibiting delay-sensitivity to FM sound pairs. The cortical zone containing both CF-FM and FM-FM neurons overlaps extensively with the tonotopic zone.

Facilitative responses are elicited by CF-FM stimuli in which the constant frequencies of the pulse are centered near frequencies of 42 and 84 kHz. Sonograms of Myotis during the search phase display FM signals that sweep downward approximately an octave in about 4 msec. The second harmonic of the FM sweep starts with an average frequency of 83.7 kHz, with a corresponding fundamental of 42.3 kHz.

These data suggest a sensitivity of CF-FM neurons to harmonically related frequency components of the emitted sounds and echoes. The possible role of these cortical neurons in coding for target characteristics will be discussed.

Supported in part by BRSF RR 5371 from Indiana University.

TARGET DETECTION AND ACOUSTIC IMAGING IN ECHOLOCATING BATS. C.F. Moss and J.A. Simmons. Section of Neurobiology and Department of Psychology. Brown University, Providence, Rhode Island 02912

Echolocating bats emit ultrasonic sounds and use echoes of these sounds to detect and track flying insect prey. This experiment examined the manner in which small step changes in target distance (jitter) may influence target detectability.

Big brown bats (Eptesicus fuscus) were trained to detect electronically delayed echolocation sounds in a two-choice psychophysical procedure. These sounds simulated echoes from a target located either to the left or to the right of the bat's observing platform, and the bat learned to approach the side on which the target was presented. We measured detection performance for stationary targets located 57 cm from the bat (simulated by echoes returning at a fixed delay of 3.3 ms) and for jittering targets located at the same mean distance but changing by 1-7 mm from one sample to the next (simulated by echoes that underwent step changes in delay from 5-40 μs about a mean of 3.3 ms). The results indicate that target jitter improves detectability, particularly for values between 2.6 and 4.3 mm (echo jitter of 15-25 μs).

In the CNS of bats, neurons responsive to pulse-echo pairs are probably involved in the coding of target distance. These neurons show delay-tuning and are selectively activated by targets at particular distances (Suga & O'Neill, Science, 206: 351-353). If excitation of these cells is involved in target detection, then echo jitter may enhance target detectability by discretely activating subpopulations of delay-tuned neurons.

39.1

A MODEL FOR NEUROGENESIS IN THE MAMMALIAN NERVOUS SYSTEM: GENERATION OF AN OLFACTORY NEURONAL CELL LINE. Brian L. Largent, Ronald G. Sosnowski*, and Randall R. Reed, Johns Hopkins Medical School, Baltimore, MD

Among central neuronal systems, the vertebrate olfactory system is unique in that it contains a population of mature neurons constantly undergoing, even into adulthood, steady state turnover. This steady state process is accomplished by stem cells which differentiate and mature into primary olfactory neurons replenishing degenerated sensory neurons. Our approach to generate clonal cell lines has been to immortalize primary olfactory neurons through the introduction of a recombinant oncogene into the germline of mice. The recombinant oncogene was constructed to provide cell specific expression of the oncogene product within primary olfactory neurons, thereby selectively affecting those cells. Specifically, the hybrid gene consists of the early region of simian virus 40 (SV40) - encoding the oncogene product, large T-antigen - flanked 5' by the cell-specific regulatory elements (enhancers and promoters) of the rat gene for olfactory marker protein (OMP), a protein whose abundant expression is limited to mature olfactory sensory neurons. Cell immortalization and/or transformation can be induced by expression of SV40 large T-antigen. The regulatory elements of the OMP gene should target expression of T-antigen to primary olfactory neurons, thereby affecting those cells in a selective fashion within the transgenic mouse. Olfactory tissue-specific expression of T-antigen message has been demonstrated for each of the mouse lines. To date, one homozygous mouse (for wild type T-antigen) has developed a tumor apparently derived from olfactory tissue. We are currently establishing cell lines from this tumor.

39.2

CULTURES OF OLFACTORY EPITHELIUM: NEURONAL PROGENITORS? S.K. Pixley. Dept. of Anatomy and Cell Biology, University of Cincinnati, College of Medicine, Cincinnati, OH, 45267.

Basal cells of the rat olfactory epithelium can completely regenerate a damaged epithelium by differentiating into the primary receptor neurons and also, supposedly (currently debated), the sustentacular (supporting) cells. In order to study this remarkable neuronal regeneration, a culture system of putative olfactory basal cells has been developed.

Adult Spraque-Dawley rat nasal tissues, from areas containing predominantly olfactory epithelium, were dissociated and maintained in monolayer cell culture. Epithelioid and spindle shaped cells were present. The epithelioid cells were uniquely positive when immunostained with anti-keratin antiserum. In olfactory epithelium tissue sections, keratin was found only in basal cells and cells lining Bowman's gland ducts. Further characterization of cultured cells showed that subsets of the keratin-positive cells were positive for the monoclonal antibodies, A2B5 (a neuronal and glial progenitor cell marker) and 1D9.B9 (a novel cell marker for a subset of sustentacular cells). A subset was fibronectin-positive. The keratin-positive cells were negative for antibody markers of differentiated glial cells and mature neurons. The presence of keratin and the apparent multipotentiality suggest that these cultured cells are olfactory basal cells.

Optimal culture conditions were determined for enrichment of the putative basal cells. Pure populations of these cells could be obtained because the epithelioid and non-epithelioid cells were differentially adhesive.

These cultures will be used to identify factors which stimulate differentiation of a mature neuronal phenotype.

39.3

A SUBSET OF CENTRAL AND PERIPHERAL NEURONAL PRECURSORS EXPRESS AN INSULIN GENE CONSTRUCT PRIOR TO COMMITMENT IN TRANSGENIC MOUSE EMBRYOS. *S. Alpert*, D. Hanahan*, M. Moustakos*#, and G. Teitelman#.* (SPON: M. Ehrlich) Cold Spring Harbor Lab., Cold Spring Harbor, NY 11724 and #Neurobiology, Cornell Univ. Med. Sch. NY, NY 10021.

Transgenic mice harboring hybrid genes utilizing the insulin gene regulatory region express the transgene in β cells of the pancreas and in cells of the embryonic nervous system. In this study we used immunohistochemical procedures to examine the timetable of expression and distribution of labelled cells in the nervous system of one of these lines (RIP1-Tag-#2) during development. In the forebrain, cells expressing the transgene are first seen in the ventral region of the diencephalon at day 9.5 of development (e9.5, 18-24 somites), and persist until e16, the last stage examined. In the mesencephalon, stained cells are seen in the basal plate only at e9.5, while in the rhombencephalon, stained cells are seen in the basal plate from e9.5 to e12, and disappear at later stages. In the spinal cord labelled cells are first seen in the ventral plate of the apical region at e9.5, and appear in the posterior region at e12. These immunoreactive cells disappear from the spinal cord by e16. Neural crest cells expressing the transgene are first seen at e9.5, when the immunostained cells are distributed alongside the neural tube. At e10-e11 labelled neural crest cells are located in a segmented pattern between somites and ectoderm, and are also seen in clusters dorsolateral to the aorta. By e12, the neural crest cells no longer express the transgene. We conclude (1) the timing of expression of the insulin transgene is characteristic of each particular region of the central and peripheral nervous system and (2) the location of the immunoreactive cells suggests that the transgene is expressed by catecholaminergic precursors. Thus, the appearance of the transgene could signal the time of commitment of the different neuronal precursors to the specific pathways of differentiation.

39.4

CELL SIZES AND BIRTHDATES OF NEURONS IN THE OPOSSUM RETINAL GANGLION CELL LAYER. S.Allodi*, J.N.Hokoç and L.A.Cavalcante*. ICB and IBCCF Universidade Federal do Rio de Janeiro, 21941, Brazil.

The opossum retinal ganglion cell layer (GCL) contains large, medium and small ganglion cells plus homogeneously distributed displaced amacrine cells. We report here complex relationships between cell sizes and epochs of neuron production for GCL. Pouch young opossums received pulses of 3H-thymidine at ages from postnatal days 1 to 21 (PND1 to PND21) and were killed as adults. Soma sizes of heavily labeled (HLN) and adjacent unlabeled neurons (AUN) were measured in stained radioautographs of horizontal sections of the eye and histograms were plotted. The range of soma sizes of HLN was narrower than that of AUN in PND5 and PND21 with biases toward large and small diameters, respectively. Ranges of soma sizes of HLN and AUN were nearly overlapping and comparisions of median values revealed that HLN=AUN in PND14 and that HLN>AUN in PND1, PND3 and PND10. The results suggest that: 1) The peak of production of the largest ganglion cells is slightly delayed with respect to the onset of GCL genesis, 2) The production of amacrine cells persists to and, in fact, predominates in late stages of GCL genesis.

NEURAL DISRUPTED - A DROSOPHILA GENE REQUIRED FOR EMBRYONIC NEUROGENESIS. D.A. Wright, E.K. Neumann*, and A.P. Mahowald*. Genetics Dept., Sch. of Med., Case Western Reserve Univ., Cleveland, OH 44106

While some genes required for neural morphogenesis have been recognized on morphological grounds alone (e.g. neurogenic loci) other important genes may be overlooked in mutants screens. When abnormal neural development secondarily disrupts general morphogenesis, the primary defect is masked by a complex mutant phenotype. In Drosophila we can identify such loci directly from their stage- and tissue-specific gene expression. We report the characerization of l(2)nd by this approach.

The locus was detected by differential screening using cDNA probes from cultured embryonic nerve cells vs other tissues. Its chromosomal location (23A) is close to the decapentaplegic complex; W. Gelbart and colleagues provided a genomic walk and collection of lethals in the region. From these we have provisionally identified the l(2)nd complementation group. Normal expression of nd peaks in mid embryogenesis and again during pupation, with a separate maternal transcript in ovaries and young embryos. We are now using fusion proteins from a fly head cDNA expression library (P. Salvaterra) to generate antisera for mapping the tissues in which l(2)nd is normally expressed.

BIRTHDATE IS MORE IMPORTANT THAN TISSUE TYPE FOR THE *IN VITRO* REASSOCIATION OF EARLY POSTMITOTIC CORTICAL AND STRIATAL NEURONS. L.A. Krushel and D. van der Kooy, Department of Anatomy, University of Toronto, Toronto, Canada M5S 1A8.

Selective adhesion between early postmitotic neurons underlies pattern formation in the telencephalon. The earliest born cortical and striatal neurons form adhesive compartments *in vivo* in the face of the migration of later born (and not selectively adhesive) neurons. The earliest born cortical and striatal neurons (that form the deep cortical and striatal patch compartments, respectively) will selectively adhere together within their own tissue type, after being embryonically removed, dissociated, and reaggregated. Is this selective adhesion specific to neurons within their own tissue type or is a common adhesion molecule expressed on the surface of all early born neurons in the telencephalon? To examine this we cocultured dissociated embryonic cortex and striatum in a reaggregate suspension culture. Would early postmitotic cortical and striatal neurons reassociate according to tissue type or to birthdate? Timed pregnant Wistar rats were injected with 1 mCi ^{3}H-thymidine or 160mg/kg bromodeoxyuridine (BrdU) on embryonic day 13. These injectons label primarily the striatal patch and deep cortical layer cells. Two days later the striata and cortices were separately dissected and dissociated into single cells. Striata containing one label were cocultured with cortices containing the alternate label. After five days in a reaggregate suspension culture, the reaggregates which formed contained relatively small numbers of both cortical and striatal labeled cells. All the labeled cells appeared in clumps within the reaggregates. Within the labeled clumps, the BrdU and ^{3}H-thymidine labeled cells appeared randomly interdigitated. This suggests the existence of an adhesive factor common to early postmitotic telencephalic cells; a factor which may be more fundamental than tissue type preferences and instrumental in the compartmentalization of the forebrain.

MICROENVIRONMENTAL FACTORS IN NEURAL PATTERN FORMATION: ADDITION OF NEURONS TO DEVELOPING ENTERIC GANGLIA. H.M. Mackey and M.D. Gershon. Dept. of Anatomy & Cell Biology, Columbia Univ. P&S, New York, NY 10032

Neurons are added to the enteric nervous system (ENS), which grows as the bowel enlarges during postnatal life. The organization of the ENS is different from that of other regions of the PNS. The current experiments were undertaken in order to investigate the means by which new neurons are incorporated into enteric ganglia that have already begun to form, and also to test the hypothesis that the enteric microenvironment plays a critical role in determining the uniquely enteric pattern of neural organization. Neuraxial segments were dissected from the trunk region (which does not normally colonize the bowel) of quail embryos (16-20 somites) and co-cultured for 7-10 days with explants of chick gut that contained forming ganglia (ages 4-20 days) as chorio-allantoic membrane (CAM) grafts. Quail cells readily entered the developing ganglia of the gizzard and intestine until day E9. Quail cells also invaded the esophagus until day E12 but localized in the mesenchyme and muscle layers as well as in ganglia. Ultrastructural examination of chimeric ganglia revealed that the chimeric ganglia within the gut had adopted a typically enteric pattern of organization, while those that formed outside the bowel displayed a structure typical of extra-enteric peripheral nerve. Neurons and glia of quail origin were completely intermixed with chick cells in the chimeric ganglia. It is concluded that acquisition of the enteric pattern of organization is critically dependent on the enteric microenvironment, that new neural and glial cells can be added to enteric ganglia even after ganglion formation has begun, that preferential pathways exist within the gizzard and intestine that lead crest-derived cells to appropriate locations in the bowel where ganglia form, and that these pathways are less well developed within the esophagus than in the rest of the bowel. Supported by NIH grant NS 15547 and the Robert Wood Johnson Fdn.

EXTERNAL GERMINAL CELLS ALIGN ALONG SUBSTRATES IN DEVELOPING CEREBELLAR TRANSPLANTS. E.B. Ezerman. Dept. of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

During cerebellar (CB) development in the rat, external germinal (EGL) cells may migrate on axonal surfaces (Hynes et al., 1986) and/or be in contact with basal lamina (Hausmann & Sievers,1985). In intact and reaggregate CB transplants, EGL appears to align along penetrating blood vessels or pial membranes. We have investigated EGL orientation in CB primordia grown in culture prior to transplantation. If CB primordia are grown as explants in culture for 10-14 days prior to transplantation the EGL is less extensively aligned along penetrating blood vessels than in non-cultured transplants. This may result from absence of blood vessels in culture during the early migratory/proliferative period of EGL development. In reaggregated CB primordia grown on a collagen substrate in vitro for 10 days prior to transplantation neither ingrowing blood vessels nor extrinsic axonal surfaces are available as substrates for EGL migration or growth. When such explants + substrate are transplanted to cavities in rat CNS, EGL is observed primarily adjacent to the collagen. There are also laminin-stained glial end feet and processes along the collagen. Thus, EGL cells, initially interspersed throughout the reaggregate transplant, either proliferate along the surface/substrate, migrate to the surface/substrate, or both.

EVIDENCE OF A SIGNIFICANT ORGANIZING PATTERN FOR THE DEVELOPMENT OF LONGITUDINAL TRACTS IN THE NEURAL TUBE. M.-C. Bélanger*, L. Bertrand*, R. Marchand. Lab. Neurobiol., Hôp. Enfant-Jésus, 1401, 18e Rue, Québec G1J 1Z4 Canada.

In the past, several neuroanatomists perceived that the longitudinal arrangement of the nuclei of the cranial nerves represented a fundamental pattern of organization in the brain stem. Neuroembryologists have also described longitudinal columns in the neural tube. Since the advent of autoradiography, there has been very few studies of the rat brain stem histogenesis. The objectives of the present work are 1) to study the formation of such columns, 2) to identify by ^{3}H-thymidine autoradiography the earliest generated neurons that contribute to their formation, 3) to determine if brain stem nuclei other than the traditional somatic efferent or special visceral efferent nuclei also contribute to their formation, 4) to follow their histogenetic transformations through the different stages of development, 5) to evaluate the possibility that during the very early stages of development, these columns provide a substrate pathway (Katz) for the growth of axons and the setting of various longitudinal tracts.

Many of the earliest generated neurons ($E11_{15}$) are found in the different nuclei of the somatic and visceral efferent columns, and in the motor nucleus of the trigeminal nerve. Neurons of other nuclei like the interstitial (Cajal) and prepositus nuclei are generated simultaneously and are very closely related to the nearby somatic efferent column. During the early stages, all these neurons constitute a continuous column which is intimately related to the developing medial longitudinal fasciculus (mlf). We suggest that this primitive column of neurons might provide a substrate pathway for the setting of the mlf. The development of many other cell groups will also be presented and discussed. (In accordance with CCPA Guidelines). Supported by CRM and FRSQ.

PROCESS OUTGROWTH IN SITU IS NOT REQUIRED FOR THE ESTABLISHMENT OF POLARITY BY HIPPOCAMPAL NEURONS IN CULTURE. T.L. Fletcher and G.A. Banker. Department of Anatomy, Albany Medical College, Albany, NY 12208.

Hippocampal neurons were labeled at distinct stages of development by administering ^{3}H-thymidine to pregnant rats on either embryonic day 15 (E15) or E18.5. All of the fetuses were sacrificed on E19. Some of the fetal brains were sectioned and examined by autoradiography to determine the location of labeled cells in the hippocampus. The remaining brains were used to prepare hippocampal cell cultures.

Neurons labeled on E18.5 were still confined to the ventricular zone on E19; those labeled on E15 had completed their migration to the cortical plate. Other data suggest that the former cells had not begun process outgrowth, while the latter had begun to elaborate both axons and dendrites. The two populations of cells were equally able to establish axons and dendrites in culture, as judged by morphology and by immunostaining for MAP2, a dendritic marker. Cells that incorporated ^{3}H-thymidine in situ at E18.5 and underwent mitosis in culture also developed axons and dendrites appropriately. These results demonstrate that neurons can establish distinct axonal and dendritic domains in culture regardless of whether they have previously established processes in situ. Cells acquire this ability early in their development, perhaps shortly after their commitment to the neuronal lineage. (Supported by NIH grant NS17112.)

DEVELOPMENT AND CHARACTERIZATION OF HUMAN NEURONAL CELL CULTURE LINES. J. Nye(1)*, G. Ronnett(1,2), L. Hester(1) and S.H. Snyder(1). Depts. of Neuroscience(1) and Neurology(2), The Johns Hopkins University Sch. of Medicine, Baltimore, MD 21205.

Cell culture lines of human neurons have been established from tissue obtained at the time of hemispherectomies for intractable seizure disorders. Grey matter was dissected, dissociated and plated in wells containing minimal essential medium (MEM)-D-valine with 15% dialyzed fetal calf serum. Of 12 wells, 2 wells, EB1 and EB4, demonstrated spontaneous continued growth and have been passaged for over 6 months. Cells exhibit either bipolar or multipolar morphology; by immunocytochemistry, 100% of cells stain for neurofilament, neuron-specific enolase, tubulin, and are negative for keratin, vimentin, S-100, GFAP, and myelin basic protein. Treatment with several agents, including dibutyryl cAMP, isobutylmethylxanthine and dexamethasone causes cells to stop dividing and develop putative axons with varicosities and dendrites with spines. These lines should be useful to investigate neuronal differentiation.

39.12

DEVELOPMENT OF THE TURTLE CEREBRAL CORTEX IN VITRO. A.M.Wilson*, P.H.Desan and A.R.Kriegstein (SPON: S.Ryan). Neurology Dept., Stanford Med. Ctr., Stanford, CA 94305.

Dorsal telencephalic wall explants were dissected from embryos, anchored to the floor of a Primaria petri dish with a plasma-thrombin clot and maintained in 290 mOsm MEM with 10% horse serum for 0-20 days at 30°C. The explants survived and showed continued morphological and physiological development. Cultures taken at Yntema Stage 16, prior to the formation of the cortical plate (CP), showed abnormal morphological changes, such as continued proliferation of ventricular layer cells without formation of a CP, or formation of a convoluted, discontinuous CP. Cultures explanted at Stages 17 or 18/19, during formation of the CP, frequently showed continued maturation of the CP, although areas of deranged cytoarchitecture also occurred. Cultures from all three stages showed electrophysiological maturation, including the appearance of synchronized burst discharges following bicuculline application, which appears at Stage 21 in normal development. Similar electrophysiological development occurred even in cultures continuously exposed to bicuculline (10 μM) or APV (1 mM). Cultures from Stage 21 maintained normal anatomical and physiological organization for at least 20 days in culture. These observations suggest that both excitatory and inhibitory cortical circuits can develop and be maintained in vitro, and can form despite excitatory and inhibitory receptor blockade. Supported by NIH grants NS00887 and NS21223.

CEREBELLAR NEURONS GROW AND DIFFERENTIATE RAPIDLY AS INDEPENDENT CELLS IN THREE-DIMENSIONAL CULTURE. P.W. Coates & E.Dunn*. Cell Biol.& Anat.,TTUHSC Sch. Med.,Lubbock,TX 79430.

Monodispersed cerebellar cell suspensions from late gestation rat fetuses were plated at low density onto three-dimensional hydrated native collagen lattices and examined after each of 3 days in culture in order to determine whether cerebellar neurons could grow and differentiate as single neurons without direct cell-cell interactions similar to cerebral neurons (Coates, Dev.Br.Res.25:11,1986). Microscopy revealed cells that were widely dispersed and had distinct neuronal morphologies with long, thin thread-like processes identified as axons or dendrites which continued to lengthen and differentiate further over time. An image analysis system coupled to a phase contrast microscope and a microcomputer was used to measure indices of growth and differentiation. Only phase-bright, healthy neurons with at least one process more than 2 cell diameters long and not in contact with cells of any other kind were selected for measurment of axon and dendritic length alone and combined in μm per neuron, number of primary processes, branch points, segments and terminals per neuron. Data were analyzed by Duncan's analysis of variance. Mean axon length increased significantly on each day in culture. Mean length of the dendritic tree was significantly elevated by day 2. On average, single cerebellar neurons regenerated over 100% more new process growth within three days. Other indices of neuronal differentiation increased significantly on each day of the test period. Results support the hypothesis that in this culture system cerebellar neurons have an inherent capacity to grow quickly and express basic neuronal characteristics as single cells. The system should prove useful for examining intrinsic electrical (see Fermini et al., this volume) and other properties of cerebellar neurons that are not influenced by cell-cell communication. Support from NS20802.

EARLY MOLECULAR DIFFERENTIATION OF CELLS GIVING RISE TO PERIPHERAL AUDITORY AND OLFACTORY STRUCTURES. S.M. Prouty and P. Levitt. Dept. Anatomy, Med. Coll. Pa., Philadelphia, Pa. 19129.

The peripheral sensory structures of olfaction and audition are in part derived from surface ectodermal placodes. Through a series of morphogenetic and inductive events, specific segments of unspecialized surface ectoderm are committed to differentiate along various pathways. This committment is presumed to be determined by selective expression of gene products which affect cell-cell interaction. In the periphery, a monoclonal antibody generated against membranes from fetal brain cells cross-reacts specifically with these differentiated structures. Immunocytochemical analysis in rats from embryonic day (E) 9 to E18 determined the spatial organization of expression of the 3C2 antigen before and during the period of formation of the sensory organs. Immunoreactivity in all regions and at each age appears to be cell surface associated, with no apparent cytoplasmic staining. We found that the 3C2 antigen is expressed during neurulation in ectodermal regions that give rise to the auditory, olfactory, and hypophyseal placodes. Rathke's pouch and gut epithelium stain transiently during this early period of development. By E12, expression in the periphery is restricted to the otocyst and olfactory pits. Various parts of these epithelia and their derivatives are positive through E18. The lens placode is never immunoreactive. The data suggest that restricted regions of the ectodermal epithelium exhibit molecular specificity early in development, prior to the formation of the neural tube, which may relate to the ultimate fate of the cells in a specific segment. Supported by March of Dimes Research Grant 1-919.

RELATIONSHIP OF HYALURONIC ACID AND CHONDROITIN SULFATE PROTEOGLYCAN TO THE FAILURE OF NEURAL CREST-DERIVED CELLS TO COLONIZE THE TERMINAL COLON OF *ls/ls* MICE. V.M. Tennyson, R.F. Payette*, H.D. Pomeranz, T.P. Rothman, and M. D. Gershon. Depts. of Anat. & Cell Biol., and Pathol., Columbia Univ. P & S, N Y, N Y. 10032.

The enteric nervous system is derived from precursors that migrate to the gut from the neural crest. The precursors fail to colonize the terminal bowel of the *ls/ls* mouse. Laminin, collagen type IV, and glycosaminoglycans accumulate in the abnormal zone. The ultrastructural distribution of proteoglycans was studied with ruthenium red in the terminal colon of control and *ls/ls* fetuses. Extracellular matrix granules (g; 15-50 nm) and microfibrils (mf; 3-6 nm) were visualized. Digestion with testicular hyaluronidase removed g and mf, but chondroitinase ABC removed only g; therefore, g probably represent chondroitin sulfate (ChS-g), and mf hyaluronic acid (HA-mf). At day E11 ChS-g were juxtaposed to the surfaces of all cells and were also associated with HA-mf. The total number of ChS-g was the same in aganglionic and control gut; however, the ChS-g in apposition to cell membranes were increased 2.5-fold ($p< 0.001$), the packing density of HA-mf was higher, and the average length of HA-mf was 1.5 times as long in the *ls/ls* gut ($p< 0.001$). At day E13 the total number of ChS-g was similar in control and *ls/ls* mice; however, the pattern of distribution of ChS-g and HA-mf differed. In the control, the HA-mf decorated by ChS-g formed a regular intercellular array. In the *ls/ls* gut, HA-mf were much longer, and the microfibrils folded over and became redundant. The average number of ChS-g per μm length of HA microfibrils in the *ls/ls* mouse, moreover, was 3.5-fold greater than in control ($p<0.001$). At day E16 the innermost circular muscle cells were hypertrophic and the presumptive longitudinal muscle cells were separated by lakes containing abundant ChS-g and HA-mf in the aganglionic region. These observations indicate that HA-mf increase, and that the distribution, rather than the amount, of ChS is distorted in the path of migrating crest-derived cells in *ls/ls* mice. 39.16

IS THE PURKINJE CELL AN INTRINSIC SITE OF WEAVER GENE ACTION. R. Smeyne & D. Goldowitz. Dept. of Anatomy, Thomas Jefferson University, Philadelphia, PA. 19107.

Several cellular defects have been reported in the cerebellum of the homozygous weaver mutant mouse. These include a virtual absence of midline granule cells, abnormal Bergmann glia, and an approximately 50% decrease in the number of midline Purkinje cells (PCs). The loss of PCs has been reported as early as post-natal day 5. It is not known, however, if the PC number deficit is the result of a primary (i.e gene action intrinsic to the PC) or secondary (i.e. gene action extrinsic to the PC) site of mutant gene expression. This can be answered through the analysis of chimeric mice. In order to determine what is/are the primary site(s) of mutant gene action we constructed tetraparental chimeras from wv/wv and +/+ embryos. Cells from these two genotypes can be differentiated by the high (Gus^b, wv/wv) or low (Gus^a, +/+) expression of β-glucuronidase activity. Four chimeric animals, 2-4 months of age were perfused, the brains removed, embedded in wax, sectioned at 8 microns and stained for the presence of β-glucuronidase activity. Every 10th section was analyzed for number of Gus^b and Gus^a PCs. Controls were age matched +/+ and wv/wv mice. The phenotype of the each of the 4 chimeras analyzed suggested about a 90% contribution of wv/wv cells. Two formulas were used to assess the intrinsic (only wv/wv PC affected) or extrinsic (both wv/wv and +/+ cells equally affected) action of the weaver gene upon the PC. Newman-Keuls analysis of the 4 chimeric cerebella demonstrate no statistical differences from that predicted by either equation. The results, however, fit the extrinsic model better than the intrinsic model of weaver gene action. Further analysis of wv/wv<--->+/+ cerebella, containing a higher percentage of +/+ cells should better clarify whether the weaver gene intrinsically or extrinsically affects PCs to result in a reduced PC number.

39.17

FINE STRUCTURE OF SURVIVING +/+ CEREBELLAR PURKINJE CELLS IN LURCHER CHIMERIC MICE. K.W.T. Caddy and K. Herrup. University College London, London, England and E.K. Shriver Center, Waltham, MA.

Lurcher is an autosomal dominant mutation in the mouse that causes the cell autonomous degeneration of all +/*Lc* Purkinje cells (PCs). Lurcher ↔ wild type chimeras, therefore, contain only wild type PCs. Previous Golgi analysis of such chimeras revealed that these surviving +/+ PC have a grossly malformed dendritic tree (Caddy et al., *Neurosci Abst.* 12:1583). Electron microscopic examination has now been performed and shows both subtle differences in the organelles of the PC soma (compared to wild type mice or non-mutant chimeric mice) and also confirms our impressions from Golgi images that there is a deficit of PC dendrites in the upper part of the molecular layer. The organelle changes involve primarily the quantity of lysosomes and the organization of the rough endoplasmic reticulum. There are only a small number of lysosomal profiles in PCs from control animals (1 or 2 per section); in the lurcher chimeras, the number is usually greater than 10 per section. Further, rough ER, organized into Nissl bodies, is difficult to find in PCs from lurcher chimeric mice. The upper molecular layer contains a qualitatively normal density of parallel fiber profiles despite a clear reduction in the number of PC dendrites. Synaptic profiles are apparent, but preliminary analysis suggests that they are parallel fiber:stellate cell contacts. An ongoing analysis will quantitate the changes in the PC dendrites and further analyze the synaptic diversity in the cerebellar cortex of the lurcher chimera.

GLIAL ORGANIZATION IN THE DEVELOPING REELER NEOCORTEX. J.F. Gadisseux*, Ph. Evrard*, J.P. Misson*, V.S. Caviness,Jr. E.K.Shriver Center, Waltham, MA 02254.

Radial glial fibers(RGF) were identified in the reeler developing murine neocortex by immunostaining with RC2 antibody and, for EM study, preservation of glycogen content. Glial fiber organization within the cerebral wall at E14-15 is essentially identical in reeler and normal mice. The RGFs are mostly grouped in fascicles which ascend radially or slightly obliquely across the cerebral wall. The oblique transcortical axonal bundles and the malorientation of the cortical neurons are not associated with abnormalities of RGF orientation and grouping. Complete transformation of the glial fascicles to single fibers which occurs in the normal animal after E15, does not occur in reeler neocortex. As late as P0, many glial fibers remain grouped in fascicles across the reeler cortical plate(CP). This glial pattern in the CP of the reeler neocortex is similar to the pattern encountered in the subplate of the normal animal.Reduction in RGF density across the span from the ventricular to the pial surfaces occurs to a lesser degree and in a non-strata specific, more gradual way in the reeler mice. Thus many RGFs, like their counterparts in the normal animal, appear not to span the full width of the cerebral wall. Rather a substantial complement appear to extend no further than the upper zone of the CP. Selectively stained large growth cones at the tips of the transcortical glial fibers are abundant at this level of the mutant CP and superplate.

ELECTRON MICROSCOPIC ANALYSIS OF ECTOPIC GRANULE CELLS IN THE DENTATE GYRUS OF NZB/BINJ MOUSE. P.J. Costello,* M. Sekiguchi* and R.S. Nowakowski (SPON: N.L. Hayes). Dept. of Anatomy, UMDNJ-Robert Wood Johnson Medical School, and the Cell & Developmental Biology Program, Rutgers University, Piscataway, NJ 08854, and Dept. of Anatomy, Tokai University School of Medicine, Kanagawa, JAPAN.

In the molecular layer of the dentate gyrus of the NZB/BINJ mouse there are ectopic granule cells which occur singly or in clusters of two or more. In previous light microscopic studies we have demonstrated that in the clusters of ectopic granule cells the granule cells appear to be in direct contact with one another, and that glial cells are frequently found closely apposed to the granule cells. For this study, we have used electron microscopy to analyze the ectopic clusters. Electron micrographs showed that the plasma membranes of two ectopic granule cells are in direct contact with one another. The extent of granule cell to granule cell contact, however, seemed to be less than that which is found between normally positioned granule cells, presumably because of differences in the number of neighbors each granule cell has. In some places astrocytes extend processes which wrap around the peripheral aspects of the cluster, seemingly encasing it. Finally, our ultrastructural analysis reveals that on the surface of ectopic granule cells there are axosomatic synapses. Thus, we conclude: 1) that although the contacts of the ectopic granule cells in the molecular layer with each other and with astrocytes may be qualitatively normal it may not be quantitatively identical to those of normally positioned granule cells and 2) that the ectopic granule cells are contacted by synaptic inputs from, as yet, unidentified sources.

39.20

A QUANTITATIVE STUDY OF THE DISTRIBUTION OF ASTROCYTES IN THE MOLECULAR LAYER OF THE DENTATE GYRUS IN C57BL/6J AND NZB/BINJ MICE. P.R. Patrylo and R.S. Nowakowski, Department of Anatomy, UMDNJ-Robert Wood Johnson Medical School, and The Physiology/Neurobiology Program, Rutgers University, Piscataway, New Jersey 08854

In the molecular layer of the dentate gyrus of NZB/BINJ mice, ectopic granule cells occur either as single cells or as clusters. In contrast, ectopic granule cells occur rarely in the molecular layer of the dentate gyrus of C57BL/6J mice. Previously, we have shown that in the vicinity of ectopic granule cells in NZB/BINJ mice astrocytes display a non-stellate morphology and are seen to aggregate around the cluster. Here we show that the distribution of astrocytes in the molecular layer of NZB/BINJ and C57BL/6J mice is quantitatively different. For this study, the astrocytes were stained by the Cajal gold chloride-sublimate technique, and camera lucida drawings were made of the granule cell and molecular layers. The molecular layer was divided into thirds, and the astrocytes in each third were counted. In every C57BL/6J mouse studied the inner third of the molecular layer had fewer astrocytes than the mean of the outer and middle thirds, whereas in NZB/BINJ mice the inner third of the molecular layer, in general, had more astrocytes than the mean of the outer and middle thirds. A Mann-Whitney U test established that this difference in the distribution of astrocytes is significant (U=36, $p<0.003$). Experiments are currently being done to determine the developmental events which may lead to such a situation.

KAINIC ACID INCREASES INTRACELLULAR CALCIUM IN MOUSE STRIATAL NEURONS BY TWO MECHANISMS . Shawn N. Murphy* and Richard J. Miller, (SPON: D. U'Prichard) Univ. of Chicago, Chicago, IL 60637

$[Ca^{2+}]_i$ in single mouse striatal neurons grown 14-28 days was measured using the fura-2 technique. Changes in $[Ca^{2+}]_i$ during application of kainic acid (KA) were measured in the presence of 1 μM TTX and 10 μM MK-801 while the contents of the bath were rapidly exchanged. KA caused a rapid increase in $[Ca^{2+}]_i$ to >1 μM which decayed over the next 5-10 minutes to a sustained level. Part of this increase was due to voltage sensitive calcium channels (VSCC's) and could be substantially reduced by predepolarization (70 mM K^+) in Ca^{2+} free media in the presence of 10 μM nitrendipine. Increases in $[Ca^{2+}]_i$ due to the opening of VSCC's could also be prevented by maintaining the cell in 70 mM K^+ and allowing $[Ca^{2+}]_i$ to come to a new equilibrium prior to the application of the agonist. When either of these two methods were used to block VSCC's, KA still caused increases in $[Ca^{2+}]_i$ in these neurons. The increases in $[Ca^{2+}]_i$ caused by KA under these conditions had a slow onset and reversal (30-60 secs). They were dose dependent with an IC_{50} of 201 μM and a maximal $\Delta[Ca^{2+}]_i$ of 360 nM. They were increased when all Na^+ was replaced with N-methyl-D-glucamine. Sustained increases in $[Ca^{2+}]_i$ due to activation of KA receptors were at least as large as increases in $[Ca^{2+}]_i$ seen upon activation of NMDA receptors and could be involved in KA induced neurotoxicity.

40.2

A UNIQUE GLUTAMATE RECEPTOR REGULATES INTRACELLULAR CALCIUM MOBILIZATION IN HIPPOCAMPAL NEURONS. Richard J. Miller and Shawn N. Murphy*, (SPON: P.Huttenlocher) Univ. of Chicago, Chicago, IL 60637.

$[Ca^{2+}]_i$ in single mouse hippocampal neurons cultured 3-14 days was measured using the fura-2 technique. Activation of glutamate receptors with kainate (KA), N-methyl-D-aspartate (NMDA), or a-Amino-3-hydroxy-5-methylisoxazole propionate (AMPA) increased $[Ca^{2+}]_i$ in Ca^{2+} containing medium. However, on removal of Ca^{2+} and addition of EGTA (20 μM) these glutamate agonists were no longer effective in increasing $[Ca^{2+}]_i$. In contrast, transient (15-30 sec) increases in $[Ca^{2+}]_i$ (300±100 nM) could be obtained with quisqualate (QUIS) (EC_{50}=100 nM), ibotenate (EC_{50}=100 μM), and glutamate (EC_{50}=30 μM). Similar transients were produced by the a_1 agonist phenylephrine (PhE) in Ca^{2+} free medium. Following the production of a single response, subsequent additions of QUIS were ineffective in producing responses unless intracellular stores were refilled by loading cells with Ca^{2+} following depolarization in Ca^{2+} containing medium. Responses to QUIS showed no tendency to desensitize while responses to PhE did. Responses induced by 1 μM QUIS could not be antagonized by 1 mM AP4, GDEE, or GAMS; nor could they be attenuated by co-application of QUIS with NMDA or KA. The responses were not decreased in Na^+ free medium or sensitive to TTX. The responses did decrease to ≤10% of their original value when bathed in Ca^{2+} free medium for >9 minutes possibly reflecting the depletion of Ca^{2+} stores. Thus hippocampal neurons appear to possess a unique glutamate receptor which is linked to Ca^{2+} mobilization rather than an ion channel. It is likely that this is a consequence of glutamate stimulated synthesis of IP_3 previously described.

INTRACELLULAR HIGH-ENERGY PHOSPHATES PREVENT WASH OUT OF NMDA CURRENTS IN CULTURED HIPPOCAMPAL NEURONS. J.F. MacDonald, M.W. Salter & I. Mody. Playfair Neurosci. Unit, The Toronto Hosp.& Dept. Physiol., Univ. of Toronto, Toronto, Ont., M5T 2S8

Whole-cell recordings from cultured mouse hippocampal neurons were used to study changes during intracellular dialysis of currents evoked by NMDA receptor activation. Recording electrodes (3-5 MΩ) contained (in mM): 120 CsCl, 35 CsOH, 10 HEPES, 11 EGTA, ± 1 mM $CaCl_2$. Pressure applications of L-aspartate (ASP; 100-250 μM) were used to elicit NMDA responses. A *support system* [2 TEA, 2 $MgCl_2$, 4 Tris-ATP, 20 Creatine Phosphate and 50 U/ml Creatine Phosphokinase], found to retard the gradual decline ("wash out") of voltage-dependent Ca^{2+}-currents, was added to the recording electrode in some cases.

When the *support system* was omitted, ASP-currents washed out by about 50% to a steady state value within 20 min from the start of recording. This wash out was prevented or reversed by inclusion of the *support system*. In all cases, ASP-currents could be blocked by NMDA antagonists or channel blockers. Currents evoked by kainate were stable in the presence or absence of the *support system*.

Thus, NMDA currents likely have two components: one which requires the presence of intracellular high-energy phosphates and another which does not.

RELEASE OF INTRACELLULAR CALCIUM FOLLOWING ACTIVATION OF EXCITATORY AMINO ACID RECEPTORS IN CULTURED HIPPOCAMPAL NEURONS. I. Mody[1], J.F. MacDonald[1] & K.G. Baimbridge[2]. [1]Playfair Neurosci. Unit, The Toronto Hosp. & Dept. of Physiol., Univ. of Toronto, Toronto, Ont. and [2]Dept. of Physiol., Univ.of Brit. Columbia, Vancouver, B.C.

Intracellular calcium ($[Ca^{2+}]_i$) was measured using fura2 fluorescence in 7-12 day old cultured rat hippocampal neurons. After fura2-AM loading and a 30 min wash, neurons were placed in a small volume (<400 μl) rapid (2 ml/min) perfusion chamber at 22°C. The extracellular solution contained (in mM): Na-Isethionate or NaCl 144, KCl 5, D-Glucose 5.6, HEPES 10, $CaCl_2$ 1.8, TTX 0.5-1 μM and glycine 1 μM. Small volumes (25-50 μl) of excitatory amino acids (3-100 μM) dissolved in extracellular medium were rapidly injected into the chamber.

L-glutamic, L-aspartic, and N-methyl-D-aspartic acid caused rapid, reversible and concentration-dependent two- to ten-fold increases in $[Ca^{2+}]_i$. Perfusion of dantrolene-Na (15-20 μM) or 2,3-butane dione-monoxime (10-20 mM), drugs that antagonize release of Ca^{2+} from the sarcoplasmic reticulum, reversibly blocked the amino acid induced increases in $[Ca^{2+}]_i$. In voltage-clamp studies this effect could not be attributed to blockade of the receptor/channel. Thus, a significant portion of the rise in $[Ca^{2+}]_i$ produced by excitatory amino acids may be due to the release of Ca^{2+} from intracellular stores, possibly from the endoplasmic reticulum that has been known to function as a Ca^{2+} reservoir in neurons.

40.5

ACTIONS OF GLUTAMATE RECEPTOR AGONISTS ON INTRACELLULAR FREE CALCIUM $[Ca]_i$ IN CULTURED TURTLE CEREBELLAR NEURONS.

A.W. Krause, I.C. Haralabatos, and T.J. Sejnowski. Department of Biophysics, The Johns Hopkins University, Baltimore, MD 21218

Glutamate (GLU) receptor activation, particularly the N-methyl-D-aspartate (NMDA) subtype, is thought to affect long-term neuronal plasticity via modulation of ($[Ca]_i$). We have investigated this modulation using the $[Ca]_i$-sensitive fluorescent dye fura-2, in cerebellar cultures from the turtle.

Turtle cerebella were dissected from 2-6 week embryos, minced, then dissociated by trituration. Cells were incubated at 33° C in 3% CO_2 at pH 7.4-7.6 in a modified Basal Eagle's Medium supplemented with 10% fetal bovine serum on coverslips coated with polylysine and/or polyornithine. Cells at 2-25 days in culture were stained 1-2 hours with 5 μM fura-2AM, postincubated without dye at least 30 min and then observed on an inverted microscope at 22-24° C with continuous perfusion of turtle Ringer saturated with 95% O_2/5% CO_2. Koehler epifluorescence excitation (with 10 nm bandpasses) at 380 nm and either 345 or 350 nm was used with aperture-limited detection of fluorescence by a photon-counting PMT for maximum sensitivity.

Granule and Purkinje neurons and glia were studied as identified by morphology and parallel examination of cell-specific antibody staining. GLU, NMDA, kainate, and aspartate were applied from pressure micropipettes or by bath perfusion. In these neurons, GLU and NMDA frequently induced long-term $[Ca]_i$ elevation (>30 min) from resting levels (60-120 nM) to from 250 nM to >1 μM. Kainate and aspartate generally elicited fewer and more transient (10 sec - 5 min) $[Ca]_i$ increases. Surprisingly, 2-amino-5-phosphonovalerate (APV) also increased $[Ca]_i$, even in turtle Ringer without calcium (including 5 mM of the $[Ca]_i$ chelator EGTA), as did GLU and NMDA. Thus, these compounds can cause calcium release from intracellular stores. Glia rarely responded to these compounds and $[Ca]_i$ changes were usually slight (<50 nM). Oscillations in neuronal $[Ca]_i$ were sometimes observed with or without drug application. (Supported by NSF grant to TJS)

DEVELOPMENT OF EXCITATORY AMINO ACID AND SUBSTANCE P RECEPTORS IN RAT SPINAL CORD CELLS MONITORED BY CHANGES IN $[Ca^{2+}]_i$.

A.B. MacDermott, I. Schieren*, M. Womack*, and T.M. Jessell. Howard Hughes Medical Inst., Columbia U, CPS, New York, NY 10032.

Presumptive neurons in the rat spinal cord go through final cell division from embryonic day 10 (E10) to E15. As the neurons differentiate they begin to form synaptic connections with appropriate inputs and targets. We have studied the development of the response to excitatory amino acids (EAA) and substance P (SP) in populations of dissociated spinal cord cells from E13 to postnatal day 6 (P6) rats by following agonist-induced changes in $[Ca^{2+}]_i$. Voltage-gated calcium channels are an important route of calcium entry during agonist activation. The development of these channels was studied using high K^+ for activation. Measurements have been made by loading spinal cord cells, acutely dissociated by incubation in 0.06% trypsin, with the calcium indicator indo-1 and measuring responses in populations of cells using a flow cytometer.

At E13, there was no response to 72 mM KCl or to any agonist tested. By E15, >30% of the cells responded to K^+ while by E18, up to 65% responded. The development of the responses to kainate, quisqualate and glutamate shows a similar time course, although the increase in $[Ca^{2+}]_i$ elicited by kainate is much greater than that elicited by the other two agonists. 0.5 mM La^{3+} blocked the calcium response to K^+, kainate, quisqualate and l-glutamate. The response to NMDA/glycine was minimal at all ages suggesting that this class of receptors is trypsin sensitive, or selectively localized on the neurites or both. The number of cells responding to SP also increased from 0 to >35% of the population between E13 and birth. Thus, between E13 and P6, EAAs and SP caused elevation of $[Ca^{2+}]_i$ in an increasingly large subpopulation of spinal cord cells, with the response reaching a maximum near E18–E20.

DIFFERENTIAL DISTRIBUTION OF EXCITATORY AMINO ACID RECEPTORS ON EMBRYONIC RAT SPINAL CORD NEURONS IN CULTURE.

O. Arancio and A.B. MacDermott. Dept. of Physiology and Howard Hughes Med. Inst., Columbia U., CPS, New York, NY 10032.

The consequences of transmitter action depend not only on the properties of the receptor/channel, but also on the location of the receptor on the postsynaptic cell and its proximity to the presynaptic release site. To study the physiological localization of excitatory amino acid (EAA) receptors, we have measured the relative sensitivity to kainate, quisqualate and NMDA at the soma and along the neurites of rat spinal cord cells, plated at E14 and grown in culture for 8–18 days. Neurons were placed in a rapidly flowing bath (24°C) which kept the cells healthy for >8 hours. Recordings were made using whole cell patch recording under voltage clamp while drugs were applied through thin-tipped (<1μ id) puff pipettes. Two agonists were compared at each activation site, with each cell serving as its own control. Localization of drug application was confirmed with a fluorescent tracer dye.

All of the cells studied in culture responded to all three agonists when applied on the soma or on the neurites. As a rough indication of response decay over distance, we made local applications of 150 mM KCl along the neurite. The amplitude decreased >50% over 50 um from the soma. In contrast, responses to EAA agonists were often larger on the neurite than at the soma, even at 125 um distance. In 31% of the cells, the response to 1 mM NMDA was larger on the neurites than on the soma, and in 44% of the cells the response was larger at a more distant site on the neurite than closer to the soma. Similarly, with 100 uM kainate and 10 uM quisqualate, there were apparent hot spots on the neurites for each agonist. In addition, the variability of agonist sensitivity along the neurite was usually different for the two agonists tested on each neuron. These data support the notion that postsynaptic EAA receptors are differentially distributed on the surface of spinal cord neurons in culture.

CALCIUM CURRENT THROUGH CHANNELS GATED BY NMDA RECEPTORS.

J. E. Huettner. Dept. of Neurobiology, Harvard Med. School, 25 Shattuck St., Boston, MA 02115

Whole-cell and single channel currents activated by NMDA were recorded from rat neocortical neurons maintained in cell culture. Whole-cell: NMDA and glycine were dissolved in either (mM) 160 NaCl + 0-20 $CaCl_2$ or 160 *N*-methyl-D-glucamine-Cl + 0-20 $CaCl_2$. In 160 NaCl, increasing $[Ca^{2+}]_o$ reduced I at negative potentials. In 160 NMDG-Cl, which did not support current by itself, inward current increased with $[Ca^{2+}]_o$. Inward current carried by Ca^{2+} was best observed with electrodes containing NMDG-methane sulfonate (Fig.). When electrodes contained Cs-methane sulfonate, outward current at positive potentials was much larger in NMDG-Cl + Ca^{2+} than in NaCl + Ca^{2+}. Outward current was larger still in Ca^{2+}-free NMDG-Cl, which suggests that both external Ca^{2+} and Na^+ impede outward flow of Cs^+. Single channel openings of 5-10 pS were observed at negative potentials in outside-out patches exposed to NMDA in 110 Ca^{2+}; channel activity could not be resolved in NMDG-Cl + 2-10 Ca^{2+}. These results suggest that Ca^{2+} carries a small fraction (<10%) of the current recorded in physiological solutions. Supported by Harvard University Society of Fellows.

MULTIPLE ACTIONS OF CNQX ON EXCITATORY AMINO ACID RESPONSES IN HORIZONTAL CELLS ISOLATED FROM CATFISH RETINA. T.J. O'Dell* and B.N. Christensen. (SPON: B. Haber) Dept. of Physiology and Biophysics, Univ. of Texas Medical Branch, Galveston, TX, 77550.

The effects of 6-cyano-2,3,-dihydroxy-7-nitro-quinoxaline (CNQX) on voltage-clamped horizontal cell responses to kainate (KA), quisqualate (QA), and n-methyl-d-aspartate (NMDA) were examined. CNQX blocked responses to EC50 concentrations of QA (2 μM), KA (75 μM), and NMDA (40 μM) with IC50's of 0.39, 1.29, and 12.1 μM respectively. At QA concentrations ≥ 50 μM, CNQX (≥ 50 nM) both potentiated the peak response and slowed desensitization. CNQX (0.2 μM) enhanced the peak response elicited by 100 μM QA by 31 ± 9% (mean ± S.D., n=7). The time course of desensitization of 100 μM QA responses could be described by a single time constant of 12.48 ± 5.3 msec. (mean ± S.D., n=15). In the presence of 0.2 μM CNQX the current decay was best described by the sum of two time constants with values of 12.54 ± 3.5 and 85.04 ± 16 msec. (mean ± S.D., n=6). A hypothesis accounting for these multiple effects of CNQX on QA-induced currents will be discussed. Supported by grant EY-01897 from Dept. of Health and Human Services to B.N.C. We are grateful to Dr. Tage Honore for a gift of CNQX.

MECAMYLAMINE ANTAGONIZES THE N-METHYL-D-ASPARTATE ACTIVATED CHANNEL IN ISOLATED HORIZONTAL CELLS FROM THE CATFISH RETINA. B.N.Christensen and T.J. O'Dell* Dept. of Physiology and Biophysics, Univ. of Texas Medical Branch, Galveston, TX. 77550.

Mecamylamine, an ACh channel blocker, was applied under concentration clamp conditions to voltage clamped isolated horizontal cells. This drug completely abolished the inward NMDA or aspartate (ASP) evoked currents at micromolar concentrations. The block was voltage dependent and relieved when the membrane was stepped to positive potentials. The block was dependent on the channel being open by the agonist. MECA did not block membrane currents during application of kainate or quisqualate supporting the notion that the channel activated by these agonists are different from the NMDA receptor/channel complex. Concentration-response curves measured for ASP before and after 50 or 100 μM MECA showed a simple depression in the response indicative of a non-competitive interaction. The K_i calculated from data obtained from a double reciprocal plot gave a value of 38.5 μM. Supported by grant EY-01897 from Dept. of Health and Human Services to B.N.C.

DIFFERENTIAL EFFECTS OF KA/QA, NMDA and APB RECEPTOR ANTAGONISTS ON OPTIC AND TORAL AFFERENT-STIMULATED ACTIVITY OF GOLDFISH TECTAL NEURONS IN VITRO. E. B. van Deusen and R. L. Meyer, Developmental Biology Center, University of California, Irvine, CA 92717.

We have isolated single goldfish tecta with intact optic and toral marginal fiber tracts in a perfusion chamber where the effectiveness of excitatory amino acid antagonists on tectal field potential responses to stimulation of each afferent system could be tested.

Kynurenate (KYN, 1.0 mM), a mixed antagonist of the kainate (KA) and quisqualate (QA) receptor subtypes, only moderately blocked retinotectal synaptic activity represented by the optic field potential (FPO). 2-amino-5-phosphonovaleric acid (APV, 1.0 mM) which selectively binds the NMDA receptor had minimal effects on either its amplitude or time course. In contrast, 2-amino-4-phosphonobutyric acid (APB, 1.0 mM), an antagonist of the Cl-dependent APB receptor was most effective in blocking 90% of the FPO amplitude. This greater sensitivity to APB than to KYN or APV indicates that dominant retinotectal excitatory transmission may not be mediated by the classical GLU receptor subtypes KA, QA or NMDA.

The marginal fiber field potential (FPM) was more complex, having four major synaptic components. KYN (1.0 mM) selectively blocked the first (4 ms) and third (20 ms) components of the FPM. APV (0.1 mM) simultaneously potentiated the third (20 ms) and blocked the slowest 30 ms component. APB (1.0 mM) was ineffective in blocking the FPM. These results demonstrate that the absence of APB effects on the FPM as well as the incomplete effects of KYN on the FPO were not due to poor drug penetration of the tectum, and support the conclusions that GLU is a transmitter of the marginal fibers and that NMDA may be used by intrinsic tectal circuitry. N-METHYL-D-ASPARTATE RECEPTOR-MEDIATED COMPONENT OF FAST AND SLOW EXCITATORY SYNAPTIC TRANSMISSION IN THE RAT SPINAL DORSAL HORN. I. Kangrga, G. Gerber* and M. Randic, Dept. of Vet. Physiology and Pharmacology, Iowa State University, Ames, IA, 50011.

Synaptic transmitters released during activation of primary sensory neurons in the rat spinal dorsal horn may elicit both fast and slow excitatory responses in a single neuron (Urban and Randic, Brain Res., 290:336-341, 1984). Excitatory amino acids (EAA), are believed to be fast excitatory neurotransmitters released during low frequency stimulation of sensory afferents, whereas tachykinins were suggested to be slow excitatory transmitters released following the high frequency stimulation. However, the possible participation of EAA in the high-frequency evoked synaptic responses of individual dorsal horn neurons, that express receptors for EAA and peptides, has not been investigated.

Transverse spinal cord slices (300μm thick) with attached dorsal rootlets prepared from lower lumbar segments from 19day-old rats were used. Intracellular recordings were obtained from the dorsal horn cells using electrodes containing CH_3COOK (4M). The primary afferents were stimulated with single shocks at 1s intervals to elicit "low frequency" synaptic responses and for periods of 1s at 50ms intervals to evoke "high frequency" responses. L-glutamate and N-methyl-D-aspartate (NMDA) were locally ejected by positive pressures from micropipettes. Two antagonists of EAA, kynurenic acid and D-2-amino-5-phosphonovaleric acid (D,APV), were administered via the perfusion medium. In the presence of Mg^{2+} stimulation of the ipsilateral dorsal rootlet at low frequency (6-10V/0.04-0.2 ms) evoked a fast e.p.s.p. which was supressed by kynurenic acid ($2-5x10^{-4}$M) and APV ($0.5-1x10^{-4}$M). During high frequency stimulation the both EAA antagonists abolished the early component of the slow depolarizing potential. In the Mg^{2+}-free medium there was an increase in the peak amplitude, and especially the duration, of the low frequency-evoked e.p.s.p. and the early component of the high-frequency evoked depolarization.

These results indicate that the low-frequency excitatory synaptic transmission in the immature rat spinal dorsal horn is in part mediated by Mg^{2+}- and APV-sensitive NMDA receptors. In addition, tachykinin-mediated presynaptic release of EAA or postsynaptic activation of NMDA receptor system may participate in the high- frequency excitatory synaptic transmission. Supported by NSF and USDA.

40.13

PHORBOL ESTERS ENHANCE RESPONSIVENESS OF RAT DORSAL HORN NEURONS TO N-METHYL-D-ASPARTIC ACID. G. Gerber*, P. D. Ryu and M. Randic, Dept. of Vet. Physiol. and Pharmacol., Iowa State University, Ames, IA 50011.

Excitatory amino acids (EAA), L-glutamate and L-aspartate, appear to be the major excitatory neurotransmitters in the mammalian spinal cord. Since molecular mechanisms underlying the EAA-induced depolarization of the rat dorsal horn neurons are not presently understood, we analyzed possible involvement of protein kinase C in regulation of signal transduction at various subclasses of EAA receptors by using phorbol esters.

Transverse spinal cord slices from 16-20-days-old rats were used. We have recorded intracellularly from spinal dorsal horn neurons while L-glutamate, N-methyl-D-aspartate(NMDA), kainate and quisqualate were ejected extracellularly by positive pressure from microelectrodes. Two exogenous activators of PKC, 4-β-phorbol-12,13-dibutyrate (PDBu) and 4-β-phorbol-12,13-diacetate (PDAc), and an inactive phorbol analogue, 4-α-phorbol-12,13-didecanoate, were applied by bath perfusion. The bathing fluid contained tetrodotoxin (TTX) to block indirect synaptic interactions.

Dorsal horn neurons were effectively depolarized by all EAA used.PDBu and PDAc ($5x10^{-8}$ to 10^{-6}M for 3 min) produced a small, but prolonged membrane depolarization occasionally preceded or followed by a hyperpolarization. In the presence of TTX, the phorbol esters induced a persistent enhancement of the depolarizing responses of dorsal horn neurons to NMDA(in about 60% of tested cells, n=18), and L-glutamate(in about 25% of cells, n=8), but not to kainate and quisqualate. The enhanced responsiveness to NMDA is potentiated in Mg^{2+}-free solution. 4-α-phorbol-12,13-didecanoate did not modify the responsiveness of dorsal horn cells to either NMDA or kainate or quisqualate.

Our results suggest that the spinal transduction at NMDA receptors might be regulated through the C-kinase system and that this modulation may have physiological relevance. The molecular mechanism whereby phorbol esters enhance signal transduction at NMDA receptors remains to be elucidated. The postsynaptic mechanism, by an increase in receptor binding affinity or in receptor density or an action on the cationic channel associated with NMDA-sensitive receptors, might be considered. Supported by NSF and USDA.

ELECTROPHYSIOLOGICAL INTERACTIONS OF NMDA AND PCP/SIGMA RECEPTOR AGONIST AND ANTAGONIST IN THE RAT CEREBELLAR PURKINJE NEURONS. Y. Wang and H. K. Lee*. Dept. of Pharmacology, National Defense Medical Center, Taipei, Taiwan (10700), Republic of China

The purpose of this experiment was to study the electrophysiological interactions of PCP and NMDA receptors. Drugs were directly applied to a cerebellar Purkinje neuron of urethane-anethetized rats through a multibarreled pipette. Neuronal activity was recorded extracellularly. We found that NMDA majorly produced excitation in the Purkinje neurons although sometimes it caused inhibition or excitation followed by depression. NMDA-induced responses were blocked by (+)PCMP or dexoxadrol. Interestingly, quisqualate-induced excitation was also antagonized by (+)PCMP although quisqualate had a lower sensitivity to (+)PCMP than did NMDA. We previously found that metaphit irreversibly acylated and blocked PCP-induced reactions, at least, in the cerebellum. After the application of metaphit, we found that metaphit did not antagonize NMDA's reactions whilst PCP-induced depression was blocked. In conclusion, our findings suggested that PCP/sigma agonists antagonized NMDA and quisqualate reactions whereas the presence of intact PCP/sigma receptor was not essential for the NMDA-mediated response in the cerebellum.

THE NOVEL NEUROTOXIN H_{12}-HISTRIONICOTOXIN (H_{12}HTX) BLOCKS THE N-METHYL-d-ASPARTATE (NMDA) RECEPTOR OF CULTURED HIPPOCAMPUS OF THE RAT. M.T. Lima-Landman* & E.X. Albuquerque. Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201.

H_{12}HTX was initially described as a neurotoxin which noncompetitively blocks the nicotinic receptor, increases the affinity of ACh for its binding sites and causes desensitization (see Ion Channels Vol. 1, Ed. T. Narahashi, Plenum Press, 1988, pp. 95-162). Because some homology has been suggested among different receptors, the effects of H_{12}HTX were tested on NMDA receptors of CNS neurons. Using patch-clamp technique in the out-side-out configuration, it was observed that the amplitude of NMDA-activated currents was voltage-dependent, i.e. amplitude increased with membrane hyperpolarization. In the presence of NMDA (5-20 μM) plus H_{12}HTX (1-100 μM), alteration in the kinetics of the receptor-ion channel coupled with a significant decrease in the frequency and a reduction of about 50% of the mean channel open time were observed. Since H_{12}HTX was dissolved in ethanol, and this agent has well known effects on lipid membrane, the vehicle was tested alone, and a shortening of channel open time was observed at concentrations above 0.5%. Therefore, the final concentration of ethanol was kept below 0.1%. The results of this study suggest some homology between different types of receptor-ion channel macromolecules. (Support: NIH Grant NS25296)

EXCITATORY TRANSMITTER ACTION IN OLFACTORY BULB CULTURES. Paul Q. Trombley*,† and Gary L. Westbrook. †Dept. Biology, Univ. of Oregon, Eugene & Vollum Institute, Oregon Health Sciences Univ., Portland, OR 97201.

The identity of the excitatory transmitter(s) and postsynaptic receptor/channels in the olfactory system are not well defined. Although L-glutamate is the likely transmitter at afferent and efferent pathways of the olfactory bulb, several small peptides including carnosine and N-acetylaspartylglutamate have been considered as possible transmitters. Likewise although behavioral plasticity in odor-stimulated responses is well documented, the synaptic site and mechanisms mediating this plasticity are also unclear; e.g. both norepinephrine and L-glutamate (via NMDA receptors) have been implicated in olfactory plasticity within the bulb.

Pharmacological studies using extracellular recording have suggested that kainate/quisqualate receptors mediate excitatory transmission in the bulb since kynurenic acid (KYN), but not 2-amino-5-phosphonovalerate (AP5) blocked evoked synaptic responses. However, since NMDA receptors play a neuromodulatory role in hippocampus, it is conceivable that similar mechanisms exist in the olfactory system. To begin to examine this question, we have used dissociated neurons from olfactory bulb of neonatal rats.

Neurons were plated on confluent feeder layers of astrocytes which had been previously prepared from olfactory bulb. Standard methods of whole-cell recording were used to record agonist- and synaptically evoked responses. Extracellular saline contained Mg 0 or 1 mM, and glycine (1 μM). Under current clamp, spontaneous EPSPs were observed which were markedly reduced by KYN or 6-cyano-2,3-dihydroxy -7-nitro-quinoxaline (CNQX) whereas AP5 often reduced, but did not eliminate synaptic activity. In Mg-containing saline, application of NMDA evoked an inward current with a region of negative slope under voltage clamp. Carnosine or homocarnosine(100 μM) did not evoke a response. Supported in part by the McKnight Fdn.

B-N-OXALYLAMINO-L-ALANINE (BOAA) AND QUISQUALATE ACTIVATE SIMILAR IONIC CURRENTS [1]C.N. Allen, [2]P.S. Spencer and [1]D.O. Carpenter. [1]Wads. Ctr. for Labs & Res., NYS DOH & Sch. of Pub. Hlth., Albany, NY 12201 & [2]Dept. Neurosci., Albert Einstein Col. Med., Bronx, NY 10461.

B-N-oxalylamino-L-alanine (BOAA) is a potent neuroexcitatory amino acid found in the seed of the chickling pea Lathyrus sativus. Use of the chickling pea as a staple food is the etiologic al agent of a form of spastic paraparesis known as lathyrism. Experimental evidence suggest that BOAA's neurotoxic action is mediated by activation of quisqualate or kainiate type excitatory amino acid receptors. Whole cell voltage clamp recordings were made from cultured hippocampal neurons. Quisqualate (50 um), BOAA (50 um) and kainiate (20 um) activated inward currents. Kainate currents activated more slowly and remained at the peak value for as long as the agonist was being applied. The quisqualate current was characterized by rapid activation, decay to a steady state level then further slow decay to baseline following removal of agonist. BOAA had a two phase current similar to that of quisqualate, however the current decay much faster following termination of agonist application. (Supported by NIH Grant NS23087 to D.O.C.)

NMDA-MEDIATED SYNAPTIC TRANSMISSION IN THE CA1 PYRAMIDAL CELLS OF THE GUINEA-PIG HIPPOCAMPAL SLICE. Y. Sahara, A. Miwa* and N. Kawai*. Dept. Neurobiol., Tokyo Metropol. Inst. Neurosci., Fuchu-city, Tokyo 183, Japan.

Synaptic transmission between Shaffer collateral-commissural pathways and CA1 hippocampal pyramidal cells is considered to be mediated by non-NMDA receptors. Recent studies, however, on cultured hippocampal cells (Forsythe, I.D. & Westbrook, G.L., J. Physiol., 396:515, 1988) suggested that NMDA receptors can be activated during synaptic transmission. In this study, we have characterized NMDA-activated synaptic responses in the guinea-pig hippocampal slice by use of a spider toxin (JSTX), which preferentially blocks quisqualate receptors (Abe, T. et al., J. Physiol., 339:243, 1983), combined with NMDA-antagonists, APV and zinc. Excitatory postsynaptic currents (EPSCs) were recorded from CA1 pyramidal cells by employing a single electrode voltage-clamp. In the vast majority of pyramidal cells, the peak amplitude of the EPSCs increased with membrane hyperpolarization, with a linear current-voltage relationship. JSTX reduced a considerable portion of the EPSCs. The remaining EPSCs showed a marked non-linearity, and were suppressed by APV or zinc. In a small number of pyramidal cells, however, the EPSCs had a non-linear current-voltage relationship. APV or zinc effectively blocked these EPSCs. Our results demonstrate that APV-sensitive NMDA receptors, as well as non-NMDA receptors, are involved in the synaptic transmission of the hippocampus.

40.19

EFFECT OF (-)PHYSOSTIGMINE (PHY) AND NARCOTIC ANTAGONIST (+)BENZYLCARBAMOYLESEROLINE (BCE) ON NMDA AND QUISQUALATE RECEPTORS IN MAMMALIAN BRAIN. S.S. Deshpande* & E.X. Albuquerque. (SPON: P. Sokolove) Dept. Pharmacol. & Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

The beneficial effect of PHY in reducing convulsions and lethality has been suggested to result from blockade of peripheral AChR (*Ann. N.Y. Acad. Sci.* **505**:226, 1987). OPs and carbamates indeed have shown blockade of ion channels associated with glutamate receptors of insect muscles (*J. Pharmacol. Exp. Ther.* **239**:279, 1986). Hippocampal and brain stem pyramidal neurons (E18) in tissue culture were used to study single channel currents (under outside-out condition) activated by NMDA (5-10 μM) and quisqualate (20 μM). Single channel conductance and mean open times of these currents in brain stem neurons were similar to those observed in hippocampus. As in the hippocampus, NMDA channels in brain stem neurons were sensitive to block by Mg^{++} (0.1 mM) and PCP (5 μM). PHY and BCE (40 μM) apparently did not affect channel conductance or open time for both agonists tested but caused a reduction in frequency of openings of about 30% for NMDA. The low efficacy of these drugs on excitatory synapses in mammalian CNS suggests that blockade of glutamate receptors is not a primary mechanism responsible for protection from OP toxicity. Initial experiments suggest that PHY was able to alter the kinetic properties of the AChR in the CNS. (Supported by U.S. Army Med. Res. & Dev. Comm. Contract DAMD17-84-C-4219)

40.20

DISTINCT ACTIONS OF PHENCYCLIDINE (PCP) AND SOME OF ITS ANALOGUES ON NMDA-ACTIVATED SINGLE CHANNEL CURRENTS OF RAT HIPPOCAMPAL NEURONS. E.X. Albuquerque and A.S. Ramoa (SPON: J.E. Warnick) Dept. Pharmacol. Exp. Ther, Univ. MD Sch. Med, Baltimore, MD 21201 USA, & Lab. Mol. Pharmacol. II, Inst. Biophys. "Carlos Chagas Filho", Fed. Univ. of Rio de Janeiro, Brazil.

PCP is known to block the neuronal excitatory effect of N-methyl-D-aspartate (NMDA). We have examined the action of PCP and some of its analogues on the response properties of single NMDA receptors. Application of NMDA (2-40 μM) to outside-out patches (n=43) of membrane excised from neonatal rat hippocampal neurons in culture elicited ion channel openings which were markedly reduced in frequency and duration in the presence of PCP (2-20 μM) and its behaviorally active analogue m-amino-PCP (5-10 μM). These effects were relieved at positive potentials and were prevented by the simultaneous application of $MgCl_2$ (4-8 mM). MK-801 (PNAS **85**:1307, 1988) and SKF-10,047, which apparently compete for the same binding site as PCP, also showed such effects. In contrast, the behaviorally inactive analogue m-nitro-PCP displayed two distinct effects on NMDA receptors. At low concentration, m-nitro-PCP (5-20 μM) unexpectedly increased the frequency of NMDA-induced openings but had no effect on channel lifetime. At a higher concentration (100-300 μM) m-nitro-PCP reduced channel lifetime and frequency. This blocking effect was relieved at positive potentials. In conclusion, the binding sites for PCP and its analogues have a complex role in the regulation of NMDA receptor function, and their activation may lead either to enhanced or decreased NMDA response. HORMONAL CONTROL OF BEHAVIOR I

41.1

INDUCTION BY TESTOSTERONE OF THE AROMATASE IN THE SEXUALLY DIMORPHIC PREOPTIC MEDIAL NUCLEUS AND ACTIVATION OF COPULATORY BEHAVIOR IN QUAIL. J. Balthazart, C. Surlemont*, A. Foidart *and M. Schumacher*. (SPON: FNA), Lab. General and Comparative Biochemistry, Univ. of Liège Belgium.

In Japanese quail, the preoptic area (POA) contains a sexually dimorphic nucleus, the preoptic medial nucleus (POM; bigger in males than females) whose size, as observed in Nissl stain, is decreased by castration and increased by testosterone (T) treatments in adulthood. POM contains high levels of aromatase activity (AA). By the Palkovits punch technique combined with radioenzyme assays, we have shown that AA in the POM is controlled by T. It decreases after castration and is restored to intact levels by T treatments. The same effects are observed in other parts of POA but the magnitude of the changes and the absolute levels of enzyme activity are much smaller and do not always reach significance. The 5α- and 5β-reductases are not affected by these treatments. The AA induction by T in POA is dose and time dependent. Levels of AA seen in sexually mature males are restored in castrated birds by a treatment with 20 to 40 mm silastic T capsules which produce physiological levels of steroid in the plasma. Significant effects are observed within 8 hours of the implantation and the induction is maximal after 48 hours. Activation of copulatory behavior follows a similar time-course but occurs with a delay of 24-48 hours. If T-treated birds receive at the same time silastic implants filled with androstatrienedione, the activation of behavior and the increase of AA in POA are both suppressed. POM is probably implicated in the control of copulation because 27g stereotaxic implants of T in this nucleus but not elsewhere in the POA activate the behavior in castrated males. The increased Nissl staining (suggesting increased protein synthesis) and the induction of AA in POM following T treatment are probably critical steps mediating behavioral activation.

41.2

RELATION OF THE SEXUALLY DIMORPHIC DORSOMEDIAL NUCLEUS TO SEX BEHAVIOR IN MALE MICE. C.K. Wagner and L.G. Clemens. Neuroscience Program and Department of Zoology, Michigan State University, E. Lansing, MI 48824.

The sexually dimorphic dorsomedial nucleus (DM), located in L5-S1 of the mouse spinal cord, innervates the bulbocavernosus muscle (BC) of the perineal area. This muscle has been shown to be important in penile reflexes and successful reproduction in male rats. The present study examined the DM in male B6D2F1 mice, of which a subpopulation continue to exhibit the ejaculatory response (ER) long after castration, (continuers). The percent of males in each group exhibiting the ER 15 weeks after castration was: shams: 100% (n=4), continuers: 52% (n=4), non-continuers: 0% (n=4). Following the last test, lul of 1% CT-HRP was injected bilaterally into the BC. The total number of labeled cells did not differ significantly between groups: shams: 92.5 (8.34), continuers: 101.5 (19.6), non-continuers: 98.0 (20.0). In addition, no decrease in cell number was seen following long term castration, an outcome that differs from that obtained using thionin staining, (Wee & Clemens, Brain Res., 1987). It is suggested that the decrease in cell number seen with thionin stain may reflect a reduction in Nissl substance (i.e. cell activity), rather than degeneration of motoneurons. This study demonstrates that the number of cells in the region of the DM does not reflect the behavioral response to castration.

41.3

EFFECTS OF PREOPTIC AREA LESIONS ON THE SEXUAL BEHAVIOR OF MALE FERRETS. J.A. Cherry and M.J. Baum, Department of Biology, Boston University, Boston, MA 02215.

The effects of bilateral preoptic area (POA) lesions on masculine sexual behavior were examined in adult male ferrets. Males (N=40) were castrated, administered a high (5mg/kg) dose of testosterone propionate (TP) daily for 12 days, and pretested with a receptive female. Ten males then received large cathodal tungsten electrolytic lesions (LL, 2.5 mA for 1 minute) at the border of the POA and the anterior hypothalamus (AH), the site of a small sexually dimorphic nucleus (MN-POA/AH; Tobet *et al.*, Brain Res 364: 249, 1986). Three males were given sham lesions (SH), and 27 males received small lesions (SL, 1 mA for 15 seconds) aimed at the MN-POA/AH. For 9 LL males, the lesions destroyed most of the medial POA between the anterior commissure and optic chiasm including all of the MN-POA/AH, and portions of the AH and lateral POA. Sexual behavior was impaired in these males: mean durations of neck gripping, mounting, and thrusting were reduced significantly in post-lesion behavioral tests after 12 days of TP. These results confirm the effects of large POA lesions seen in many vertebrates. 12 SL males sustained some damage (9 bilateral, 3 unilateral) to the MN-POA/AH, while the rest of SL males had lesions scattered nearby. No lesions completely destroyed this nucleus bilaterally. No deficits in sexual behavior were observed in any SH and 24 SL males. However, in 3 males with bilateral MN-POA/AH damage, thrusting was substantially reduced despite high levels of mounting and neck gripping. Thus, large lesions including but not restricted to the MN-POA/AH impaired all aspects of mating; incomplete MN-POA/AH damage had limited effects.

41.4

CRUISING, AN INDEX OF SEXUALLY MOTIVATED SEARCH BEHAVIOR IN MALE RATS: ACQUISITION, EXTINCTION, AND DISRUPTION BY NEUROLPETIC DRUGS. J.G. Pfaus, S.D. Mendelson, and A.G. Phillips. Dept. Psychology, Univ. British Columbia, Vancouver, B.C. V6T 1Y7 Canada.

Sexual motivation in male rats is commonly inferred from measures of sexual behavior that are either confounded by the receptivity of the female (e.g., intromission latencies) or that preclude the full expression of copulatory behavior (e.g., maintenance of mounting behavior following penile anesthesia). In the present experiments, we characterized a form of sexually motivated search behavior, or cruising, that male rats exhibit by themselves during a 5 min habituation period prior to the introduction of a female in the bilevel testing chambers developed by Mendelson and Gorzalka (Physiol. Behav., 39:67, 1987). Cruising behavior consisted of regular bouts of level changes that developed in both sexually experienced and naive male rats only if sexually receptive females were presented after the 5 min habituation period. Once established, cruising behavior could be partially extinguished if nonreceptive females or no females were presented after the habituation period. Finally, cruising behavior was significantly attenuated by a dose of haloperidol (.1 mg/kg) that had no effect on intromission latencies. We conclude that cruising behavior represents a sensitive and unambiguous form of sexual motivation in male rats that depends, in part, on the functional integrity of brain dopamine systems.

41.5

Electromyographic activity of rat perineal muscles during sexual behavior. G. M. Holmes, B. D. Sachs, W. D. Chapple[1], R. E. Leipheimer. Depts of Psychology and [1]Physiology and Neurobiology, Univ of Connecticut, Storrs, CT 06268.

The bulbocavernosus muscle (mBC) augments erections of the glans penis, whereas the ischiocavernosus muscle (mIC) augments erection and anteroflexion of the penile body, which allows for intromission. The EMG signal from these muscles reveals that in mounts with intromission, mIC activity precedes the onset of mBC activity. Mounts without intromission are characterized by either strong activity in the mIC with minimal mBC activity, or strong mBC activity which precedes the onset of mIC activity. Rectified integrated signals demonstrate highly consistent mBC activity across different intromissions, whereas activity during mounts is quite variable in both the duration and the energy of the burst. Ejaculations are accompanied by consistently stronger mBC activity than are other copulatory events, and are followed by a series of post-ejaculatory bursts lasting for 10-20 sec. Comparisons are made between EMG activity during penile actions within and outside of the context of copulation.

41.6

Bulbocavernosus muscle activity during sexual behavior in estrogen-maintained castrated rats. B. D. Sachs, G. M. Holmes. Department of Psychology, University of Connecticut, Storrs, CT 06268.

Previous research has demonstrated that castrated male rats exhibit declining levels of copulatory activity, and their penises and perineal muscles atrophy. Administration of estradiol (E2) maintains the motor patterns of copulation. However, E2 does not prevent atrophy of the penis or the penile muscles, nor does it maintain reflexive erections tested outside the context of copulation. We analyzed EMG activity recorded from the bulbocavernosus muscle (mBC) in E2-maintained males that had been castrated 4-8 weeks earlier. This muscle displayed EMG activity during copulation, and peak amplitude and burst duration did not differ from those of intact males. In addition, mBC activity recorded during genital grooming bouts was accompanied by visually confirmed erection of the glans penis. These results suggest that E2-maintained males are capable of penile erection during copulation for at least several weeks after castration.

41.7

FACTOR ANALYSIS OF COPULATORY BEHAVIORS IN HAMSTER AND RAT. M. Miernicki, J.B. Powers and J.T. Clark. Dept. of Psychology, Vanderbilt Univ. and Dept. of Physiology, Meharry Med. Coll., Nashville, TN 37240

Male Syrian hamsters require olfactory stimulation to mate. This may be derived from their anogenital investigation (AGI) of females. The latter behavior may be controlled quite separately from copulation because specific hypothalamic lesions can abolish copulation without affecting chemoinvestigation. To further assess the relations between these 2 forms of reproductive behavior, we performed factor analyses on hamster data and on rat data for comparison.

Copulatory behavior (CB) of 209 hamsters and 653 rats was analyzed using BMDP principal components factor analysis with varimax rotation. Data were obtained from sexually experienced animals prior to any experimental intervention. Measures for analysis included ML,IL,MF,IF,EL,PEI,III and hitrate (HR). For hamsters, 3 chemoinvestigatory measures were also included: AGI rate (secs/min) during CB tests (AGR), the ratio of AGR to total body investigation (AGT), and the time spent investigating female hamster vaginal secretions (FHVS) in a separate test with no female present. Five factors were extracted from the hamster analysis. For 3 of these, CB measures loaded similarly to previous analyses of male rodent sexual behavior. These factors were Copulatory Rate (MF,HR,III,EL,IF), Initiation (ML,IL) and Intromission Count (IF,EL,PEI). Chemoinvestigatory measures loaded onto 2 additional factors; [a] (AGT,AGR) and [b] (FHVS,PEI). The rat analyses generated similar results except that 4 factors were extracted: Copulatory Rate (EL,III,PEI), Hit Rate (HR,MF), Initiation (ML,IL) and Intromission Count (IF,III,MF). These findings suggest, in contrast to our previous assumptions, that hamster chemoinvestigation does not reflect arousal or initiation.

41.8

AGE-RELATED DEFICITS IN MALE SEXUAL BEHAVIOR ARE ACCOMPANIED BY CHANGES IN ANDROGEN METABOLISM AND BINDING IN BRAIN. K.C. Chambers, J.E. Thornton, and C.E. Roselli. Dept. of Psychology, USC, Los Angeles, CA 90089 and Dept. of Physiology, OHSU, Portland, OR 97201.

Decreases in sexual behavior in aging male rats do not appear to be due to decreases in testosterone (T) levels as exogenous T cannot restore the behavior. To determine if these behavioral deficits are due to changes in neuronal sensitivity to T, androgen metabolism and binding were measured in the brains of 14 old (25 months) and 14 young (3 months) male Fischer 344 rats. Both groups were given 7 weekly tests of sexual behavior. Blood was then collected and brains and pituitaries were frozen on dry ice for subsequent simultaneous measurement of aromatase activity (AA) and cytosolic (ARc) and nuclear (ARn) androgen receptors in the preoptic area (POA), basal hypothalamus (BH) and amygdala (AMY). None of the old males mounted, intromitted or ejaculated in any of the tests whereas all of the young males ejaculated in at least 2 tests. T levels were significantly lower in old males ($p<.05$). AA was lower in POA ($p<.05$) but not BH or AMY of old versus young males. No age differences were observed in ARc levels in these brain areas, however old males had significantly lower levels of ARn in POA and BH ($p<.05$) than young males. To what extent the behavioral deficits in aged males are related to these changes in brain metabolism and binding is yet to be determined. HD 20970 and 23293

NEUROENDOCRINE CORRELATES OF AGGRESSIVE BEHAVIOR IN MALE GOLDEN HAMSTERS. K.M. Levy, B.N. Bunnell, E.H. Mougey, and J.L. Meyerhoff. Dept. Psychology, U. GA, Athens, GA 30602 and Dept. Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

In order to explore the neuroendocrine concomitants of various agonistic behaviors, two experiments were carried out. In the first, male hamsters were implanted with indwelling jugular catheters and paired with a dominant, ovariectomized female. Defeated males exhibited elevated plasma levels of adrenocorticotropin, cortisol, corticosterone, and beta-endorphin.

Several reports have suggested that pituitary-adrenocortical and opiate responses to defeat are greater in mice that are submissive than in those that are dominant. In Experiment 2, catheterized, male hamsters were paired, and the hormonal responses of the dominant and submissive animals were examined. The results did not support the hypothesis that losing is more "stressful" than winning in terms of pituitary-adrenocortical activation (using cortisol as an index). Cortisol was equally elevated in both dominant and submissive hamsters. The responses of various peptides are being explored to assess the extent of the difference between hamsters and mice and to characterize the correlates of both acute and chronic agonistic interactions in golden hamsters.

41.10

RETENTION OF COPULATORY BEHAVIOR AFTER CASTRATION AFFECTS THE EXPRESSION OF AGGRESSIVE BEHAVIOR IN THE MALE HYBRID B6D2F1 HOUSE MOUSE (Mus musculus). K.L. Sinchak*, B.E.F. Wee and L.G. Clemens (SPON: G. Lew). Dept. Zool., Mich. St. Univ. E. Lansing, MI 48224.

Male mice of the B6D2F1 hybrid strain retained the ejaculatory reflex up to one year after castration (McGill and Manning, An. Beh. 24:507-518, 1976; Clemens, et al. Phys. Beh. 42:69-76, 1987). In contrast, aggressive behavior in the B6D2F1 was nearly abolished 14 weeks after castration (Sinchak, Wee and Clemens Con. Repro. Beh. Abst., 1988). In the present study we investigated the influence of copulatory experience on the expression of aggression in castrated B6D2F1 males. When tested in a neutral arena, castrated males exhibited the ejaculatory reflex on 38% of the tests; when tested in their home cage, they achieved an ejaculatory reflex on 65% of the tests. Castrated males that copulated in the neutral arena were aggressive in 50% of the tests 23-28 weeks after castration. Those males that copulated only in the home-cage were aggressive in 28% of the tests. Males that exhibited minimal copulatory behavior in both the arena and the home cage were aggressive in only 12.5% of the tests. While these data indicate that continued copulation facilitates aggression, it is not clear whether these animals are responding to low levels of endogenous androgens or whether these behaviors are independent of hormone action.

41.11

THYROID STATUS AND THE ACQUISITION AND RETENTION OF AN IMMOBILE FLOATING RESPONSE. D. Jefferys and J.W. Funder, Medical Research Centre, Prince Henry's Hospital, Melbourne 3004, Victoria, Australia.

We have previously shown that adrenalectomized (ADX), hypophysectomized (HPX), or ADX/HPX rats show indistinguishable levels of progressive immobility over a 15 minute swimming test. In a 5 min retest 24 hours later, HPX rats show levels of immobility indistinguishable from intact controls (~70%); in contrast, ADX or ADX/HPX rats remain immobile for only ~30% of the time (Jefferys et al. Eur. J. Pharmacol., 92:99, 1983), an effect reversed by glucocorticoids or kappa-specific opioids around the time of test (Jefferys, D. & Funder, J.W. Endocrinol., 121:1006, 1987). In the present studies, rats were given PTU for 1-21 days before test. After 10+ days of PTU, the acquisition of immobility was significantly reduced, as was retention on retest; PTU for 1-5 days was without effect, as was thyroxine (T_4) given to intact rats. The effect of 21 days PTU was totally reversed by concurrent T_4 administration (15 µg/day), by a single 15 µg dose of T_4 1 hr before test, or by 1 mg SKF 94901 immediately before test. We interpret these data as evidence that thyroid hormone is required for both the acquisition and the incorporation of the response; whether the very rapid effect of T_4/SKF 94901 in restoring the response in hypothyroid rats is a central or peripheral effect remains to be systematically explored.

41.12

EFFECTS OF ESTRADIOL AND PROGESTERONE ON BODY WEIGHT AND FOOD INTAKE IN OVARIECTOMIZED (OVX) SYRIAN HAMSTERS. Anita J. Bhatia* and George N. Wade (SPON: W.G. Richards). Neuroscience and Behavior Program and Department of Psychology, Univ. of Massachusetts, Amherst, MA 01003.

The effects of estradiol benzoate (EB) and progesterone on body weight and food intake were examined in OVX Syrian hamsters (Mesocricetus auratus). Nine weeks following OVX, hamsters received subcutaneous injections of EB alone (5 ug/day), progesterone alone (1 or 5 mg/day) or EB (5 ug/day) in combination with progesterone (1 or 5 mg/day) for 44 days. Treatment with EB alone decreased both body weight and food intake. Differing from its effects in OVX rats, progesterone was found to increase body weight and food intake in the absence of exogenous estradiol. Both groups receiving EB and progesterone concurrently exhibited a similar initial increase in body weight without increasing food intake. This increase was followed by body weight losses and reductions in food intake until both of these groups stabilized at levels similar to that of hamsters receiving EB alone.

THYROID HORMONE REGULATION OF ALPHA-2 ADRENERGIC RECEPTOR SENSITIVITY AS MEASURED BEHAVIORALLY WITH THE ACOUSTIC STARTLE RESPONSE. D.A. Smith and J.V. Cassella. Neuroscience Program, Oberlin College, Oberlin, OH 44074

Stimulation of $alpha_2$-adrenergic receptors inhibits the acoustic startle response. Inhibition of adenylate cyclase (by the guanine nucleotide binding protein, G_i) may mediate this effect. Alterations in in vivo thyroid hormone levels produce changes in the sensitivity of cells to the action of other neuromodulators and neurotransmitters. It is possible that this effect of thyroid hormone is directly on the G_i protein. In this experiment, the effect of thyroid hormone on the $alpha_2$-mediated inhibition of startle was investigated.

The acoustic startle response was assessed in three groups of rats - controls, hypothyroid [treated with PTU for five weeks while fed an iodine-free diet], or hyperthyroid [thyroid hormone (T4) for three days].Animals were startled (30 white noise bursts at a 30 sec interval) before and after treatment with the $alpha_2$ agonist, clonidine (10ug/kg). PTU treatment slightly reduced baseline startle amplitude while thyroid hormone slightly increased startle but these changes were not significantly different from controls. The inhibitory effect of clonidine on startle was significantly enhanced in the PTU-treated animals compared to controls. The treatment with thyroid hormone did not significantly alter clonidine's effect.

41.14

DEFICITS IN MOTOR / REFLEX DEVELOPMENT AND SEXUAL BEHAVIOR IN THE MALE RAT FOLLOWING PRENATAL EXERCISE. S.K. Elliott* and J.L. Voogt. Dept. of Physiology , Univ. of Kansas Med. Center, Kansas City, KS 66103.

There is evidence that the developing brain is influenced morphologically (and functionally) by the gonadal hormone environment. Differentiation of sexual behaviors depends on the secretion of testosterone by the fetal testes, and prenatal stress alters the perinatal release of circulating testosterone with concomitant changes in adult male sexual behaviors. The goal of this research was to determine if strenuous maternal aerobic exercise induces the prenatal stress syndrome (PS-S) and its sequelae of impaired reproductive behaviors in male offspring. Changes in neurodevelopmental (motor/reflex) behaviors of offspring were evaluated, as alterations in these behaviors have been previously described in studies of CNS damage. Female rats were divided into 3 exercise groups with appropriate controls. Group I was pre-conditioned for 8 weeks prior to mating and continued to run during gestation at 75-80% of maximal aerobic capacity. Group II ran during pregnancy without pre-conditioning. Group III ran only during the last trimester, also without pre-conditioning. Acquisition delays were found in the following pre-weaning neurodevelopmental tests: surface righting, negative geotaxis, reflex suspension, and pole descent. Decreased exploratory behaviors, as evaluated with spatial maze and continuous corridor, persisted in adults. Copulatory behavior of adult male offspring was altered for mount, intromission, and ejaculation potentials, as well as for time to satiety. Severity of all behavior differences increased Group I II III. These results suggest that exercise during the prenatal period is sufficient to induce PS-S as well as cause other subtle neurodevelopmental impairments. Morphometric analysis of the SDN-POA is underway, as well as a search for other general cortical changes. (Supported by NIH Grant HD22340)

41.15

EFFECTS OF CYCLOHEXIMIDE ON MATERNAL EXPERIENCE EFFECTS IN POSTPARTUM FEMALE RATS. A.S. Fleming* and Una S. Cheung*. (SPON: G. Eskes). Dept. of Psychology, Erindale Campus, University of Toronto, Mississauga, Ontario, L5L 1C6.

Two hours of maternal experience with pups during the postpartum period in female rats results in heightened maternal behavior (reduced onset latencies to foster pups) 10 days later. This study investigated the effects of intraventricular cycloheximide, a protein synthesis inhibitor, on this maternal experience effect.

Eight groups of C-sectioned primiparous females were tested. Six groups of females were permitted to interact with neonatal foster pups for a two hour period thirty-six hours after C-section. Groups received intraventricular infusions of cycloheximide (100-400 ug) or saline immediately before, immediately after, and twenty-four hours after, the experience. Two groups of inexperienced animals had no post-C-section contact with pups and were injected with either cycloheximide or saline. All groups were tested for maternal onset latencies ten days after the C-section.

Experienced groups of females injected with cycloheximide immediately before and after the maternal experience, but not twenty-four hours after, had longer maternal onset latencies than experienced saline animals and similar to those of inexperienced groups. Cycloheximide did not, however, block the short-term retention of the behavior. These results suggest that maternal experiences are consolidated into long-term memory and that structural proteins are involved in this process.

41.16

EFFECTS OF ACUTE OR PROLONGED PROLACTIN ON LONG-TERM MATERNAL BEHAVIOR IN VIRGIN RATS. Gail Orpen[1], Jacquie Sarker*[2], and A.S. Fleming*[2]. St. Joseph's Hosp. Res. Inst., Hamilton, Ont.[1] and Dept. of Psychology, Univ. of Toronto, Mississauga, Ont.[2]

Female rats who give birth care for their pups immediately. If pups are removed by C-section, females continue to show a high level of responsiveness to foster pups for about a week. A rapid onset of maternal behavior can also be induced in virgin females with estradiol (E) and progesterone (P), but this responsiveness declines very rapidly. Attempts to prolong maternal responsiveness by brief exposure to prolactin (PRL) at the end of the E & P schedule were only partly successful (Orpen, et al. 1987). The first study investigated the possibility that prolonged PRL would be more effective. The second study investigated the long term effects on responsiveness of increasing levels of P or of E.

In the first study OVX female rats were implanted sc with a 1mm E capsule and 3 30mm P capsules in a 22 day schedule (Bridges, 1984) and received either SAL or PRL injections during the last 3 days (acute condition) or 12 days (prolonged condition) of the schedule. Groups of females were given maternal induction tests either 1, 4 or 7 days later. In the second study OVX females received either additional P (4 30mm capsules) or E (a 4mm capsule) in the same 22 day hormone schedule.

In study one neither acute nor prolonged exposure to PRL sustained maternal responsiveness for either 4 or 7 days. In study two, additional E sustained responsiveness for 4, but not for 7 days while additional P had no facilitatory effect.

41.17

ESTROGEN AND PROGESTERONE INFLUENCE ODOR STIMULATED HAMSTER FLANK MARKING. H.E. Albers and C.M. Rowland. Lab. of Neuroendocrinol. and Behav., Depts of Biol. and Psychol., Georgia State Univ., Atlanta, GA 30303.

Hamster flank marking is a form of communication stimulated by social encounters or the odors of other hamsters. Since the amount of flank marking in response to the odors of male hamsters varies over the 4 day ovulatory cycle, the present study examined how ovarian hormones influence odor stimulated flank marking. Ovariectomy (OVX), but not sham OVX, eliminated the 4 day cycle of flank marking and significantly reduced ($P<0.05$) the frequency of flank marking by over 50%. Implantation of Silastic capsules containing estradiol benzoate (E) restored preOVX flanking marking levels, whereas flank marking levels remained significantly reduced ($P<0.01$) in hamsters implanted with blank capsules (B). Injection of progesterone (P) into OVX+E treated hamsters 6 h before testing significantly reduced ($P<0.05$) flank marking when compared to OVX+E oil injected hamsters. The effects of P were only observed in E treated hamsters; no differences were observed in the amount of flank marking between OVX+B hamsters injected with oil or P 6 hrs prior to testing. These data demonstrate that estrogen and progesterone influence odor stimulated female flank marking and may underlie the variation in flank marking during the 4 day ovulatory cycle.

41.18

ESTROGEN'S INFLUENCE ON WHEEL RUNNING PATTERN IN FEMALE RATS. H. Looy & R. Eikelboom. Department of Psychology, Queen's University, Kingston, Canada, K7L 3N6.

Wheel running behavior occurs at night in episodes separated by nonrunning periods. For female rats with ad lib access wheel running declines over the night and is highest on the night of estrus. Running patterns were examined both over the night and the four-day estrous cycle, to see how changing estrogen levels affect running initiation and termination. In 8 intact females, duration of running episodes decreased over the night. On the night of estrus, episode duration was longer in the first three hours, but for the remainder of the night was comparable to that of nonestrous nights. The duration of nonrunning periods increased over the night, and were shorter on the night of estrus. In 8 ovariectomized rats total nightly running was reduced as duration of running episodes decreased, while length of nonrunning periods increased. No four-day cyclic pattern was evident. Injection of estradiol (20 µg/kg sc) every fourth day into ovariectomized rats (n=8) restored running by increasing episode duration and decreasing nonrunning periods, such that their running pattern was similar to that of intact females on nonestrous nights. In conclusion estrogen appears to increase the salience of wheel running in female rats.

41.19

EFFECT OF FLUID DEPRIVATION ON TESTOSTERONE LEVELS AND THE RATE OF EXTINCTION OF A CONDITIONED TASTE AVERSION IN MALE RATS. E.A. Brownson, C.B. Sengstake*, and K.C. Chambers. Departments of Neurobiology and Psychology, USC, Los Angeles, CA 90089 and Department of Psychology, PSU, Portland, OR 97207.

The rate of extinction of a conditioned taste aversion (CTA) is dependent on testosterone (T) levels; high levels slow extinction. Fluid deprivation increases the rate in male rats and this effect can be counteracted with exogenous T. In the present study, 48 male Sprague-Dawley rats were either fluid deprived (D, 1 hr/day access to fluid) or nondeprived (ND, 24 hr access to fluid); extinction rates and T levels were measured. Following the first presentation of a 10% sucrose solution, a CTA was induced by injection of LiCl (0.30 M, 20 ml/kg). Daily extinction trials began 2 days later and continued until criterion for extinction (100% of first day consumption) was reached. Half of the D and ND males were bled before the first extinction trial and the other half of each of these groups were bled after. Deprivation increased extinction rates [$F(1,43)=8.65$, $p<0.01$] and lowered T levels [$F(1,43)=25.87$, $p<0.01$]. The time of bleeding had no effect on T levels or on extinction rates and there were no significant interactions. These findings are consistent with the hypothesis that the increased rate of extinction exhibited by fluid deprived males is T dependent.

ROLE OF ANGIOTENSIN IN THE PRECIPITATION OF SEVERE SELF-INDUCED WATER INTOXICATION IN A PSYCHOTIC PATIENT. C.S. Sebastian and A.S. Bernardin*. Department of Psychiatry, LSU School of Medicine, Shreveport, La 71130.

Increased incidence of benign hyponatremia in psychiatric patients is well known. While moderate abnormalities in vasopressin secretion can explain mild basal hyponatremia in psychotic patients, they are inadequate to explain the more severe episodes of self-induced water intoxication (Goldman et al., N Engl J Med 1988; 318:397-403). The polydipsia is primary, rather than the consequence of a defect in renal concentration (Berl, N Engl Med 1988; 318:442).

Angiotensin II, a potent dipsogen that also increases sodium appetite may play a role in the development of water intoxication. It was hypothesized that central Angiotensin II is secreted in response to the mild hyponatremia in some psychotic patients. This results in increased water drinking and vasopressin secretion which aggravates the hyponatremia resulting in further release of Angiotensin II. An accelerating vicious circle is formed, until convulsions and following medical intervention with sodium supplementation interrupts it. A case of severe water intoxication was recently treated with Angiotensin Converting Enzyme (ACE) inhibitors on an "A-B-A" design. ACE-inhibitors have prophylactic value in the management of self-induced water intoxication.

A QUANTITATIVE STUDY OF INTRACRANIAL CALCIFICATION IN DEMENTIA OF THE ALZHEIMER TYPE. R.P.Friedland, J.Luxenberg*, E.Koss. Laboratory of Neurosciences, National Institute on Aging, N.I.H., Bethesda, Md. 20892.

Various lines of evidence from neurochemical, neuropathological and epidemiological investigations have suggested that calcium transport and binding are important processes in the normal cytoskeleton, and that these processes are disturbed in Alzheimer's disease (AD). In order to evaluate these hypotheses we analyzed the size of pineal and choroid plexus calcifications, using x-ray computed tomography, without contrast injection, in 23 subjects with probable AD (age 66.6±8.3 years) and 18 heathy aged controls (age 69.0±10.2 years). The area occupied by calcification was estimated directly from hard copies of the data by two independent observers who were blind to the diagnosis. There was good agreement between raters, with an ICC of 0.90 ($p < 0.0001$). Total calcifications occupied 130.8±89.8 mm2 and 170.9±79.6 mm2 in the AD and control groups, respectively. There were no differences in the area of calcification between the two groups. In the healthy aged group, but not in the AD group, there was a significant correlation ($r=0.69$, $p < 0.01$) between area of pineal calcification and lateral and third ventricular volume, as measured by volumetric x-ray CT. This relationship was also demonstrated using a partial correlation removing the effect of age ($r=0.75$, $p < 0.001$). These data suggest that AD is not accompanied by alterations in intracranial calcium deposition.

ANTIBODIES IN HUMAN SERUM AND CEREBROSPINAL FLUID RECOGNIZE NERVE GROWTH FACTOR. M.A. Downen, K. Wieties*, E.J. Moticka* and E. Giacobini, Dept. Pharmacol., Southern IL Univer. School of Medicine, Springfield, IL 62794-9230

Neurodegenerative disorders may involve a disruption of the trophic regulatory mechanisms in the nervous system. The presence of antibodies in human serum and CSF that recognize 7S nerve growth factor (NGF) from mouse submaxillary gland (Sigma) was determined. This was measured using an ELISA. 96 well plates (Dynatech) were coated with 1.25 µg NGF diluted in a carb-bicarb buffer, pH 9.6. Serum or CSF was applied to the wells. Goat anti-human IgG and anti-human IgA-alkaline phosphatase (Sigma) diluted 1/500 in PBS was applied and incubated overnight at 4°C. Immune complexes were visualized following incubation with p-nitrophenylphosphate. Absorbance was measured at 405 nm using the Titertek microplate reader (Flow Labs). The presence of antibodies was determined in serum samples diluted 1:30 from 32 Alzheimer's disease (AD) patients and 21 normal aged controls. No difference was seen between normals and AD patients when the mean absorbence was compared. Anti-NGF activity tended to increase with age in AD ($\bar{x}$=72.6) but not in normal controls ($\bar{x}$=71.1). An increase in antiNGF activity with age in CSF from 12 AD patients was seen. When serum anti-NGF activity as plotted versus CSF antiNGF activity, AD patients with higher CSF antibody activity also showed higher serum antibody activity. We have demonstrated the presence of antibodies in human serum and CSF which recognize 7S NGF.

42.3

A POSSIBLE NEUROPHYSIOLOGICAL MARKER FOR ALZHEIMER'S TYPE DEMENTIA AMONG SUBJECTS WITH A POSITIVE FAMILY HISTORY. J.A. Coffman, M. Torello, E. Burns, K. Travis,* N. Andreano,* H.A. Nasrallah. Department of Psychiatry, Ohio State University, 473 West 12th Avenue, Columbus, OH 43210

Early identification of individuals at risk for dementia of the Alzheimer type (DAT) is important for the establishment of early intervention strategies. There have been a number of reports documenting changes in long-latency evoked potentials in Alzheimer patients compared to controls (Pfefferbaum et al, EEG & Clin Neurophys 59:104, 1984). However, no data exists which show yearly evoked potential changes in an at-risk population. In this study, we have tested a group of individuals who have at least one parent or sibling with DAT and are therefore at-risk for the development of this disease (St. Clair DM et al, Br J Psychiat, 147:702, 1985).

Ten medication-free subjects with a family history of DAT and ten age, sex, and handedness matched controls were studied using an auditory "odd-ball" evoked potential task. Each subject was required to count the number of infrequently occurring (15%) high-pitched (1500 Hz) tones presented in a series of high and low-pitched (500 Hz) (85%) tones. The evoked potential to the high frequency tone was averaged from 40 artifact-free trials. The results showed a striking amplitude difference between groups ($p < .01$) during the post-stimulus interval of 100-150 ms specifically increased amplitude of the N100 waveform in the at-risk group (mean = 12.1 µV versus -6.8 µV) over the right centro-parietal area. Moreover, during the interval of 300-400 ms specifically decreased amplitude over the right fronto-temporal area there was a between-group difference ($p < .01$) in amplitude over the right fronto-temporal area. There were no differences in counting performance between groups.

These preliminary results represent to our knowledge a new finding and suggest the existence of an early neurophysiological marker of DAT in persons who may be at-risk for later developing Alzheimer.

42.4

GENETIC LINKAGE STUDIES IN AUTOSOMAL DOMINANT FAMILIAL ALZHEIMER'S DISEASE: AN ANALYSIS OF 30 FAD PEDIGREES. Peter St. George-Hyslop*, James F. Gusella*, Jonathan Haines*, Massachusetts General Hospital, Boston, Massachusetts 02114; John Hardy*, St. Mary's Hospital Medical School, London UK W21PG (Spon: S. Fink).

We previously reported that 2 anonymous DNA markers (D21S1/D21S11 and D21S16) on chromosome 21 showed evidence of genetic linkage to the Familial Alzheimer's Disease (FAD) gene. 29 additional small pedigrees with autosomal dominant FAD have now been examined. We confirm the prior report of linkage to chromosome 21 ($\hat{Z}$=3.30; $\hat{\theta}$ = 0.17 at D21S1/D21S11). Multipoint linkage analysis suggests that the FAD gene is located closer to the centromere, proximal to both D21S1/D21S11 and D21S16 ($\hat{Z}$=4.89). The current data do not permit the discovery of genetic heterogeneity ($P > 0.10$). The issue of genetic heterogeneity in FAD will be better resolved by the examination of highly informative markers closer to, or at the site of the FAD gene.

42.5

NEUROPSYCHOLOGICAL DIFFERENTIATION OF NEUROPATHOLOGICALLY DISTINCT DEMENTIAS WITH A BRIEF MENTAL STATUS EXAMINATION. D. Salmon, P. Kwo-On-Yuen, W. Heindel, N. Butters and L. Thal. San Diego VAMC and Depts. of Neurosciences and Psychiatry, UCSD, La Jolla, CA 92093.

Patients with Alzheimer's disease (AD) and Huntington's disease (HD) were administered the Dementia Rating Scale (DRS), a standardized mental status examination which provides a global dementia score and subscores for attention, initiation, construction, memory and conceptualization capacities. DRS scores were highly correlated with scores on two other widely used mental status examinations the Mini-Mental State (AD:r=.78; HD:r=.72) and the Blessed Dementia Scale (AD:r=-.79; HDr=-.80).

An analysis of DRS subscore patterns was conducted. Although the total DRS scores of 23 AD and 23 HD patients were precisely matched indicating equivalent levels of dementia, the patterns of subscores differed markedly. The AD patients' impaired memory subscore was significantly poorer than that of the HD patients. In contrast, the initiation and attention subscores were significantly lower for HD than for AD patients. These results are indicative of qualitative differences in the cognitive impairment associated with neuropathologically distinct dementias and demonstrate that such differences can be elucidated with brief mental status examinations.

42.6

CONTRIBUTION MADE BY INDIVIDUAL ITEMS OF THE MINI-MENTAL STATE EXAMINATION TO THE DIAGNOSIS OF ALZHEIMER'S DISEASE. [1,2]D. Galasko, [2]B.Lasker, [2]M.M.Pay, [2]D. Bauer, [1,2]L.J. Thal, (SPON: D. Jeste) [1]Dept. Neurol, VAMC, SD 92161, [2]Dept. Neurosci, UCSD, La Jolla, CA 92093

12 components of the Mini-Mental Status (MMS) examination were analysed for their contribution to the diagnosis of dementia in 97 patients with Alzheimer's disease (AD) and 85 elderly controls. A subgroup of the AD patients with mild dementia (MMS 24/30) was studied separately. AD was diagnosed clinically according to NINCDS-ADRDA criteria. The AD and control groups did not differ significantly with respect to age, sex or education. Mean MMS scores were 17.3 for AD, 25.2 for the mild AD subgroup, and 29.0 for controls. Total MMS score correlated well with the diagnosis of AD (r=.78). In the AD and mild AD groups respectively, delayed recall (r=.84 and .57), orientation for time (r=.79 and .58) and place (r=.75 and .64), construction (r=.59 and .35), and attention r=.53 and .40) correlated most strongly with the diagnosis of dementia. Stepwise logistic regression analysis produced an optimal model predicting the diagnosis of AD, using orientation for time and place, recall and construction.

42.7

SLEEP IS IMPAIRED IN EARLY ALZHEIMER'S DISEASE (AD)

DE Williams*, MV Vitiello*, PN Prinz & RK Ries* (Sponsor: C. Arnett). Dept. Psychiatry, U. Washington and American Lake VAMC, Seattle, WA 98195.

Sleep fragmentation is a common problem among AD patients. This change has been documented in polygraphic studies of mild to severe AD. The present study further documents this change in early stage AD. 46 healthy, early stage AD patients (possible or probable by NINCDS criteria; Mini Mental Status scores ≥21) were compared with 54 controls (matched on health and demographics). Polygraphic sleep/wake measures were averaged across the 2nd and 3rd consecutive nights of a 72 hour study during which napping was absent. Results: increased nighttime wakefulness (# awakenings; time awake) and decreased deep sleep (stages 3 + 4, when arousal thresholds are highest) was observed in early AD vs. controls.

	CONTROL	ALZHEIMER	
NUMBER OF WAKES	9.3±4.2	13.1±8.6#	
WAKE AFTER SLEEP ONSET (MIN)	50.5±39.3	78.9±47.5#	
% WAKE (TIB)	14.2±8.7	19.0±10.0#	
% 3 & 4 (TIB)	9.4±4.6	7.5±4.0#	
% REM (TIB)	19.2±5.2	17.7±6.0	#p<.05

These results suggest that neural pathways controlling sleep maintenance (thought to be predominately subcortical[1]) degenerate in early AD in parallel with the more commonly studied cortical and hippocampal areas.

COMPUTER AUTOMATED SLEEP EEG BIOMARKERS FOR EARLY ALZHEIMER'S DEMENTIA (AD)

PN Prinz, LH Larsen*, ML Akins* & MV Vitiello*. American Lake VAMC & Dept. Psychiatry, U. Washington, Seattle, WA 98195.

A growing literature suggests the clinical waking EEG is altered in AD such that lower (<8 hz) frequency activities increase at the expense of higher (>12 hz) frequencies(*). We report here the results of a computer automated procedure that examines this phenomenon in 3 states: REM sleep, slow wave sleep (SWS), & quiet waking (QW).

35 healthy aged control subjects, 35 early stage AD patients, and 23 major depression patients matched on health, age, education and other factors were studied over a 72 hour period. The all night EEG was digitized at 128 hz and analyzed using autoregressive and fourier transform techniques. ≥5 min of idealized, artifact-free QW, REM & SWS were automatically selected from 9+ hours of continuous EEG (C4 vs. A1).

Results: Beta activity (12-25 hz) was significantly decreased in the AD vs. non-AD groups regardless of state (QW, REM SWS). Delta and theta energy increased during REM and QW, and decreased during SWS in AD patients relative to the other two groups (all p<001, ANOVA). When the best of these variables (R12-16, R16-20, S12-16, W12-16, S6-8, ALPHA/ THETA) were employed in discriminant analyses they yielded correct overall classification rates of 90-92%. These results indicate that quantitative sleep EEG biomarkers may prove to be useful in early detection of AD. A prospective study to determine their usefulness is currently underway.

42.9

USE OF A SEMANTIC P300 TASK IN EARLY ALZHEIMER'S DISEASE DETECTION.

K.R. Erickson* (SPON: J. Hammerstad). Dept. of Neurology, Good Samaritan Hosp., and Depts. of Psychiatry and Physiology, Ore. Hlth. Sci. Univ., Portland, OR 97210.

Event-related potential (ERP) studies have demonstrated prolonged P300 latencies in a majority of subjects with dementia. However, most studies have not controlled for dementia etiology, nor confounding effects of nonspecific attentional or perceptual deficits. The classic auditory tone (be-boop) paradigm was employed, and failed to detect altered P300 in mild cases of Dementia of the Alzheimer Type (DAT). In young intact subjects, tasks that require semantic processing of words enhance later memory for the word as well as its associated P300 amplitude. This technique was adapted for 6 patients with mild DAT (meeting NINCDS-ADRDA task force criteria for Alzheimer's Disease, probable), with mean age of 71.7, and mean Mini-mental State Exam (MMSE) score of 22. Subjects sorted names by gender, and were asked to attend to randomly inserted target names occurring 20% of the time. Memory for the targets was tested on a probe recognition task after a 1-min. distraction. Compared to 6 control subjects (mean age 69.7, mean MMSE score 29.5), mild DAT subjects showed a significant reduction of N2-P3 amplitude difference (p<.005), prolongation of P300 latency (p<.05) to target words, and increase in probe errors (p<.005). This paradigm may be useful in the clinical evaluation of dementia to enhance detection of early DAT (supported by AG 05354).

42.10

THE P300 EVENT RELATED POTENTIAL (ERP) AND REGINAL CEREBRAL BLOOD FLOW (RCBF) IN THE ASSESSMENT OF PATIENTS WITH DISORDERS OF SHORT TERM MEMORY.

E. Gordon*, C. Kraiuhin*, Y. Zurynski*, A. Howson*, R. Meares*. (Spon: W. McEntee) Psychiatry Dept, Westmead Hosp. Sydney, AUSTRALIA

Studies in our laboratory suggest that an abnormal delay (2SD) in latency of the P300 ERP is found in 80% of patients in the moderate to severe stages of a dementing process. However, P300 latency does not appear to discriminate among patients with mild to moderate Alzheimer's (n=30), the elderly depressed (n=10) and healthy, normal subjects (n=100).

We propose that the P300 component elicited via the "oddball" paradigm does not reflect substantially those cognitive prccesses which are impaired in mild Alzheimer's. Our current research involves eliciting P300 during a specific test of verbal short-term memory. We hypothesize that the latency and amplitutde of the P300 component thus elicited will prove a means of distinguishing among the three groups noted above. To our knoweldge, we are the first group to record the P300 component from cognitively impaired patients performing a specific test of memory.

We have also examined Xe-133 RCBF in mild to moderately impaired Alzheimer patients (n=15), elderly depressed subjects (n=10) and normal controls (n=100). Seventy percent of the Alzheimer patients had abnormally low global cerebral flows. Moreover, global blood flow was abnormally low in some of the Alzheimer patients who had normal P300 latencies.

42.11

A STRESS TEST FOR MEMORY: DIFFERENTIAL EFFECTS OF MEMORY LOAD ON THE AMPLITUDE OF EVENT-RELATED POTENTIALS IN AGING AND ALZHEIMER'S DISEASE.

L. deToledo-Morrell, S.Evers*, T.J.Hoeppner, F.Morrell and D.C.Garron*. Depts. of Neurol. Sci. and Psychol., Rush Med. Coll., Chicago, IL 60612.

The amplitude and latency of event-related potentials (P300) were assessed during a modified Sternberg memory scanning task in patients with early Alzheimer's disease (AD, N = 5), age matched controls (N = 7) and young adults (N = 8). This report is based on P300 potentials recorded from a midline parietal electrode (P_Z) referred to linked ears. On a TV monitor, subjects were first shown a set of letters to be remembered, memory set size varying from 1 to 5 letters. After each study period for a given set size, single letters were presented one at a time and subjects were asked to press one key if the letter had been seen before, and a second key if it was any other letter of the alphabet. Previously memorized letters (target) were presented with a probability of 24%.

Although AD patients did not differ from age matched controls in P300 amplitude when a memory load of 1 letter was used, their P300 amplitude was dramatically and significantly reduced with increasing memory load. Aged controls did not differ from young adults on this measure. AD patients and aged controls did not differ from each other in P300 latency, but both showed delayed potentials compared to young adults. We conclude that electrophysiological abnormalities in early AD are best detected when functional demand is imposed on the memory system. In addition, amplitude measures seem to be more sensitive than latency measures in assessing memory dysfunction.

42.12

DIFFERENTIAL VULNERABILITY OF THE TWO HEMISPHERES DURING THE EARLY STAGES OF ALZHEIMER'S DISEASE: ELECTROPHYSIOLOGICAL EVIDENCE.

T.J. Hoeppner, L. deToledo-Morrell, F. Morrell and S. Evers.* Depts. of Neurol. Sci. and Psychol., Rush Med. Coll., Chicago, Il 60612.

Event related potentials (P300) were obtained from scalp electrodes (including P3-A1, P4-A2) in patients with early Alzheimers disease (AD, N=5) and in age matched controls (N=7) during two oddball procedures involving spatial and letter discriminations. The spatial task required Ss to press one response key when the upper of two box outlines was illuminated on a TV monitor and another key when the lower box was lit. The second task was a modified Sternberg procedure. On a TV monitor Ss were first shown a target letter to remember and then asked to press one key when the target was presented and a second key when any other letter was seen.

In the spatial task, AD patients exhibited a significant hemispheric asymmetry with P300 amplitude being markedly reduced at the P4 electrode compared to that at P3. Age-matched controls revealed no such asymmetry. In the letter discrimination task, the interhemispheric difference in AD patients was not as pronounced, although they still showed significantly lower amplitudes at P4 compared to age-matched controls. These results suggest that AD, unlike normal aging, may be associated with an early and selective impairment of right hemisphere function.

42.13

EFFECTS OF PHYSOSTIGMINE ON IMMEDIATE VERSUS DELAYED RECALL IN FOUR ALZHEIMER'S PATIENTS.
V.M. O'Donnell*, W.M. Pitts*, D.S. Friedman*, and W.E. Fann* (SPON: J. Fertig). Dept. Behavioral Biology, Walter Reed Army Inst. Rsch., Washington, D.C. 20307-5100 & VA Med Cen, Houston, TX 77211.

Four inpatients diagnosed as Alzheimer's dementia of mild to moderate severity were administered physostigmine (1.0 mg i.m.) accompanied by methscopolamine bromide (5 mg p.o.), and an intra-muscular placebo in a randomized double blind fashion, with forty-eight hours between drug and placebo treatments. Assessment began at 15 minutes after drug or placebo injection using digit span tasks, a semantic fluency task (recalling examples from a given category), and a Bushke list-learning task. Three of the four patients scored better on the digit span tasks following physostigmine as compared to the placebo. Three of the four patients also produced more correct responses and fewer incorrect responses on the Bushke task following physostigmine. However, far more reminders were necessary on the Bushke task after physostigmine so that the overall recall score (Correct responses - (incorrect responses + reminders)) was worse following physostigmine. Further, three out of the four patients did worse on the semantic retrieval task after physostigmine. These results suggest that while phyostigmine may improve memory on tests of immediate recall, the drug may actually impair performance on tests of delayed recall. Further, the similar results on the Bushke and semantic fluency tests suggest that retrieval rather than learning might be the focus of the drug-induced impairment.

42.14

EXTRAPYRAMIDAL SIGNS AND DEMENTIA PROGRESS INDEPENDENTLY IN ALZHEIMER'S DISEASE.
T.J. Rosen [1], J.H. Growdon [2], and S. Corkin [1], [1]Department of Brain and Cognitive Sciences, Mass. Institute Technology, Cambridge, MA 02139, and [2]Mass. General Hospital, Boston, MA 02114.

Dementia is the hallmark of Alzheimer's disease (AD), and extrapyramidal signs (EPS) are the hallmark of Parkinson's disease (PD). Many AD and PD patients display clinical and pathologic characteristics of both diseases, raising the question of whether mixed presentations reflect separate, co-occurring disease processes or the multifaceted expression of a single process. The former hypothesis predicts that EPS and dementia develop independently: the latter hypothesis predicts a correlated development. We investigated the independence of EPS and dementia in patients with probable AD: EPS scores equaled the number of signs observed (maximum = 12), and dementia scores were taken from the Memory-Information-Concentration section of the Blessed Dementia Scale. Longitudinal data ($N = 64$) showed that EPS and dementia significantly increased with time ($p < .01$). Cross-sectional data ($N = 137$) showed that the presence of EPS was not associated with the severity of dementia ($p > .5$): further, among patients with EPS, EPS scores were uncorrelated with dementia. The statistical independence of the progression of EPS and dementia supports the view that joint AD and PD symptomatology reflects the effects of multiple disease processes.

42.15

CHOLINERGIC MANIPULATION: EFFECTS ON REGIONAL CEREBRAL BLOOD FLOW AND COGNITIVE FUNCTION
G.S. Smith, S. Arnold, W.G. Honer, L. R.Lucas, I. Prohovnik. Brain Imaging Division, Department of Psychiatry, Columbia University and New York State Psychiatric Institute, New York, NY 10032

The effects of scopolamine were examined to elucidate interrelations between cholinergic manipulation, cerebral perfusion and neuropsychological function and to evaluate these findings relative to Alzheimer's disease (AD). Previous studies from this laboratory, conducted in young normal subjects, demonstrated that scopolamine produced dose and time dependent impairments in mnestic function and a global decline in regional cerebral blood flow (rCBF), maximal in frontal cortex (Honer et.al., 1988). However in AD, characterized by presynaptic cholinergic deficit, a global rCBF deficit is observed, with a temporo-parietal locus. The global rCBF deficit may reflect inhibition of diffusely distributed cortical cholinergic projections. The frontal lobe deficit may be attributable to an antagonism of dopaminergic projections, which have a greater distribution in frontal cortex. Interactions between acetylcholine and dopamine have been demonstrated *in vitro* and are mediated by high affinity muscarinic receptors, which are not impaired in AD (de Belleroche et.al., 1985).

Physostigmine (PHY, 0.02mg/kg,IV) and neostigmine (NEO, 0.01mg/kg or 0.007 mg/kg, IV) were administered to reverse the effects of scopolamine (0.007mg/kg,IV), to coincide with its maximal effects at 25 minutes after infusion. rCBF was measured by the 133-Xe inhalation technique, with 16 detectors over each cerebral hemisphere. The memory deficit (as measured by the Buschke Selective Reminding Test), produced by scopolamine was reversed by PHY, not NEO. Consistent word retrieval across trials was most impaired.This may be analogous to "representational memory", which is impaired by lesions ofthe prefrontal dopaminergic projection (Goldman-Rakic, 1987). PHY reversed the frontal rCBF deficit but NEO did not. These findings represent a divergence between the sequelae of muscarinic cholinergic blockade and AD. The rCBF deficits differ in the two conditions and, whereas physostigmine reversed scopolamine induced deficits, it is not consistently efficacious in the treatment of AD.

42.16

LANGUAGE PERFORMANCE AND RATE OF COGNITIVE DECLINE IN ALZHEIMER'S DISEASE (AD).
F. Boller*, A. Holland*, M. Forbes* and J.T. Becker (SPON: R.M. Dasheiff). Alzheimer Disease Research Center, Pittsburgh, PA 15213

Numerous reports have investigated the relationship between language function and the course of Alzheimer's disease. Some have found language disturbance to be an early prognostic sign of rate of cognitive decline. One recent study (Faber-Langendoen et al, Ann Neurol 23:365, 1988) found that early language dysfunction in AD subjects identifies a group with more rapid progression of dementia. In a recent study we conducted, however, we found that lexical-semantic impairment was unrelated to onset or progression of symptoms in 86 patients with probable AD (Becker et al, Arch Neurol 45:263, 1988).

In the present study, we further investigated this issue in 50 subjects with mild to moderate AD who where evaluated as part of a larger longitudinal study. We used more sensitive measures of language impairment, including a detailed analysis of a sample of spontaneous language. The language scores did not differ between those identified as "fast decliners" and "slow decliners" according to their change scores on the MMSE (Folstein et al, J Psychiatr Res 12:189, 1975). These findings suggest that the degree of initial language impairment in AD patients does not predict the rate of cognitive decline.

REGIONAL LOCALIZATION OF RECEPTORS AND TRANSMITTERS I

INSULIN RECEPTORS AND NEUROPEPTIDES IN LIMBIC-HYPOTHALAMIC AREAS OF THE RAT BRAIN.
J. Unger, T.H. McNeill, R.T. Moxley III* and J.N. Livington*, Dept. of Anatomy, Univ. of Munich, FRG; Depts. of Neurology and Endocrinology, Univ. of Rochester, N.Y., USA.

Although insulin receptors have been demonstrated in brain, little is known of their exact anatomical location and further characteristics of cells that express the receptors. Insulin receptor-like immunoreactivity (IR) was demonstrated by using a specific antibody against a unique peptide within the carboxy terminus of the receptor beta-subunit. IR was found in a widespread distribution on neuronal perikarya and processes throughout the rat forebrain. Among limbic areas, the highest density of IR was found in the CA1 and CA2 pyramidal cell layer of the hippocampus, followed by CA3, CA4, dentate gyrus and amygdaloid complex. In the hypothalamus, densest IR was present in the arcuate, periventricular, dorsomedial, suprachiasmatic and supraoptic (SON) nuclei; moderate dense IR was found in the ventromedial nucleus and posterior hypothalamic area. The median eminence showed a topographical distribution of IR with the highest density in the lateral part of the external zone. Double-labeling with antisera against somatostatin (SOM) and vasopressin (AVP) revealed a subpopulation of SOM neurons in the periventricular nucleus and a group of AVP neurons in the ventromedial SON that were colocalized with IR. Our findings suggest that insulin and its receptor may be involved in the regulation of neuronal activity including the release of neurotransmitters and peptides in the central nervous system. (Supported by PHS grants DK32884, AG05445, AG00300 and DFG, Un 59/1-2).

43.2

AUTORADIOGRAPHIC DISTRIBUTION OF 2-[^{125}I]-IODOHISTIDYL^{1}-NEUROKININ A BINDING SITES IN RAT BRAIN.
T.V. Dam, E. Escher* and R. Quirion. Douglas Hospital Res. Ctr. McGill Univ. Montréal, Québec and Dépt. de Pharmacol., Fac. de Méd. Univ. de Sherbrooke. Sherbrooke. Québec. CANADA.

Recent studies have suggested the existence of three neurokinin (NK) receptors in brain namely NK-1, NK-2 and NK-3. However, using [^{125}I]-Bolton-Hunter conjugates of neurokinin A ([^{125}I]-BH-NKA) and eledoisin ([^{125}I]-BH-ED), it was found that the distribution of [^{125}I]-BH-NKA and [^{125}I]-BH-ED binding sites were very similar. This casts some doubt over the existence of specific brain NK-2 sites. In this study, we use 2-[^{125}I]-iodohistidyl^{1}-NKA ([^{125}I]-NKA) as an alternate probe to characterize the autoradiographic distribution of putative NK-2 binding sites in rat brain. Rat brain sections were prepared and incubated with 50 pM [^{125}I]-NKA as described before (Quirion, R. and Dam, T.V., J. Neurosci., 6: 2187-2199, 1986). The results show that the distribution of [^{125}I]-NKA sites is different from those observed with other NK ligands including [^{125}I]-BH-ED. High densities of [^{125}I]-NKA binding sites are found in the external plexiform layer of the olfactory bulb, hippocampus, lateral septum, certain amygdaloid nuclei and locus coeruleus. The most striking difference between the localization of [^{125}I]-BH-ED and [^{125}I]-NKA binding sites is seen in the cortex. There is practically no specific [^{125}I]-NKA labelling in this region while very high densities of [^{125}I]-BH-ED binding sites are found in cortical laminae IV and V. These data suggest the presence of a distinct population of NK-2 binding sites in rat CNS. (Supported by Scottish Rite Foundation for Schizophrenia (U.S.A.).

43.3

DISTRIBUTION OF BINDING SITES FOR BASIC FIBROBLAST GROWTH FACTOR IN RAT BRAIN. W.F. Herblin, R.G. Krause* and J.S. Schwaber, Medical Products Department, E.I. duPont Nemours & Company, Wilmington, Delaware 19898

Basic fibroblast growth factor (FGF) has been shown to support proliferation of cell lines and survival of neurones in culture. Its local concentration has been reported to increase after injury in the brain. While these results imply the likelihood of FGF receptor mediation in brain, such receptors have not been demonstrated. In this study, we examined adult rat brain to determine whether binding sites for FGF were present.

Brains from male CD1 rats were cryostat sectioned at 20 microns and the sections melted onto gelatin coated slides. Sections were taken in the saggital and coronal planes at 90 and 150 micron intervals, respectively. The slides were dried overnight and covered with Dulbecco's modified Eagle medium with 0.15% gelatin and 20 mM HEPES (pH 7.5). Recombinant FGF supplied by Synergen, Inc. and iodinated by the lactoperoxidase method was added at 50 pM. Non-specific binding was determined with 5 μM unlabeled FGF. After two hours at 4° C., the slides were washed in PBS, 2M NaCl and PBS, followed by X-ray film and emulsion autoradiography.

Film autoradiography indicated an increased density of specific grains over the cerebellum, hippocampus, parietal cortex and the dorsal and pontine medullary regions. Emulsion autoradiography demonstrated that the grains in the more densely labeled regions were not associated with a particular cell type but were diffusely distributed throughout the tissues. When 2M NaCl was used to remove low affinity binding, much diffuse labeling was removed, but the hippocampus, cortex and the molecular layer of the cerebellum were still relatively more heavily labeled. This technique can be used to study the distribution of FGF receptors in other tissues as well as the response of receptor expression to injury.

EXPRESSION OF YES PROTO-ONCOGENE IN CEREBELLAR PURKINJE CELLS. M. Sudol*, and A. Alvarez-Buylla*. (SPON: C. Ouimet). The Rockefeller University, New York, NY 10021.

We have investigated the expression of the cellular-yes oncogene, the normal homolog of the Yamaguchi 73 virus-transforming gene, viral-yes. Using affinity-purified antibodies raised against the amino-terminal portion of the viral-yes protein, we have identified cellular-yes protein, pp62$^{c\text{-}yes}$, and analyzed its expression in various chicken tissues. Adult brain, retina, liver, and kidney express relatively high levels of pp62$^{c\text{-}yes}$ whereas muscle, spleen, and bone marrow contain low levels of the protein. Using an immune complex kinase assay and immune blot analysis we have shown that the adult cerebellum contains the highest level of pp62$^{c\text{-}yes}$ among all chicken tissues tested (Sudol et al., Oncogene Res., 1988, in press). Immuno-histochemical staining with anti-yes IgG localized pp62$^{c\text{-}yes}$ in denritic trees and cell bodies of Purkinje cells. Diffuse and less intense staining was also observed in the granular layer. It is possible that pp62$^{c\text{-}yes}$ is associated with a signal-transducing complex, expression of which is elevated in Purkinje cells.

43.5

LOCALIZATION OF CANNABINOID RECEPTORS IN BRAIN M. Herkenham, M. D. Little*, M. R. Johnson*, L. S. Melvin*, A. C. Howlett, R. B. Rothman, B. deCosta*, and K. C. Rice*. Unit on Functional Neuroanatomy, NIMH, Bethesda, MD 20892; Clinical Neurosci. Branch, NIMH; Lab Chemistry, NIDDK; St. Louis University Medical School, St. Louis, MO; and Pfizer Central Research, Groton, CT

A potent cannabinoid analog, CP-55,940, synthesized at Pfizer, shows high enantioselectivity and is pharmacologically similar to Δ^9-THC but with 5 to 80 times the potency in animal tests of adenylate cyclase inhibition *in vitro* and analgesia, catalepsy and spontaneous activity *in vivo*. Related compounds (levonantradol, nabilone) administered to humans produce psychoactive effects traditionally associated with the "marijuana high." CP-55,940 was tritiated (79 Ci/mmole) and used in section binding assays with 50 mM Tris-HCl buffer, pH 7.4 and BSA to minimize nonspecific binding. Optimized binding was 70% specific. Unfixed slide-mounted sections of rat and marmoset brains were incubated, washed, dried and exposed to LKB Ultrofilm. Resulting autoradiography showed great heterogeneity of binding in a unique and conserved pattern. Areas in both species showing strikingly high levels of binding sites were the globus pallidus, substantia nigra pars reticulata, and cerebellar molecular layer. Elevated and heterogeneous levels were also found in the olfactory bulb, cerebral cortex, hippocampus, and striatum. Low levels characterized most of the brainstem and spinal cord. These distributions suggest involvement of cannabinoids in motor and cognitive functions.

43.6

PHENCYCLIDINE AND σ RECEPTORS IN RAT SPINAL CORD: BINDING CHARACTERIZATION AND QUANTITATIVE AUTORADIOGRAPHY L. M. Aanonsen and V. S. Seybold Dept. of Cell Biol. and Neuroanatomy and Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

The biochemical characterization of PCP and σ receptor binding sites has been completed in slide-mounted tissue sections from rat brain and spinal cord. ^{3}H-N-(1-[2-thienyl]cyclohexyl)piperidine (^{3}H-TCP) and ^{3}H-(+)-3- (3-hydroxyphenyl)-N-(1-propyl)piperidine (^{3}H-3-PPP) were used as selective ligands for the PCP and σ binding sites, respectively. The dissociation constant (K_D) for ^{3}H-TCP was found to be 20.15 ± 4.56nM with a B_{max} of 296 ± 22 fmol/mg protein in rat brain tissue. The K_D for ^{3}H-3-PPP was 15.05 ± 3.31nM with a B_{max} of 29.94 ± 6.08 fmol/mg protein. K_D's for these ligands were not significantly different in spinal cord tissue. The order of potency of drugs inhibiting the binding of ^{3}H-TCP was MK-801>PCP>>haloperidol>3-PPP>> N-methyl-D-aspartate (NMDA) while the order of potency for ^{3}H-3-PPP was (±)pentazocine=haloperidol>>PCP>TCP>>NMDA.

Autoradiographic studies were performed on adjacent, identified spinal cord sections in order to compare the localization of PCP and σ receptors. ^{3}H-TCP receptors were found to be localized primarily in the superficial dorsal horn and were significantly decreased in caudal compared to rostral segments. ^{3}H-3-PPP binding sites were found to have the highest density over large dorsal root ganglion cells and over ventral motor neurons. The density of ^{3}H-3-PPP binding sites was also high in lamina X and in the intermediolateral area in thoracic segments. The differential distribution of PCP and σ binding sites in the rat spinal cord suggest that two binding sites exist for PCP and σ agonists.

REGIONAL DIFFERENCES IN PCP AND σ BINDING IN THE BRAINS OF SCHIZOPHRENICS. A.D. Weissman, M.F. Casanova*, J.B. Kleinman, E.D. London and E.B. De Souza. NIDA Addiction Research Center, Baltimore, MD 21224 and Clin. Brain Disorder Br., NIMH, Washington, DC 20032.

The psychotomimetic effects of certain cycloalkyls and benzomorphans that interact with PCP and/or σ receptors has led to the hypothesis that these sites may be important in the etiology of schizophrenia. To investigate this hypothesis, PCP and σ receptors were measured in homogenates of seven regions of postmortem brains of patients diagnosed as belonging to several subclasses of schizophrenia and age-matched controls. PCP receptors were measured with [^{3}H]TCP (5 nM), and specific binding was defined in the presence of 10 μM PCP. σ receptors were measured with [^{3}H]haloperidol (1 nM) in the presence of 50 nM spiperone to block D2 and S2 sites, and specific binding was defined by displacement with 1 mM d-NANM. Occipital and parietal cortices from schizophrenics had significantly lower (25 and 26%, respectively) specific PCP binding than controls. Specific σ binding also was significantly decreased compared to control in the parietal cortex (38%), temporal cortex (47%), and dentate nucleus (25%). In contrast, neither PCP nor σ receptors were altered in the cingulate and frontal cortices and putamen in schizophrenics. The data demonstrate selective and differential regional decreases in PCP and σ receptors in schizophrenia and suggest an involvement of both the PCP and σ systems in this disorder.

43.8

RECEPTOR PLASTICITY IN THE RAT VISUAL SYSTEM. D.T. Chalmers* & J. McCulloch, Wellcome Surgical Institute University of Glasgow, Glasgow G61 1QH.

The rat visual system provides an appropriate model in which to study neurotransmitter receptor plasticity. Using a fully quantitative autoradiographic technique, we have examined the responses of a number of receptors, implicated in visual neurotransmission, to reduced and prolonged functional deficit.

Black-hooded PVG rats (n=20) were unilaterally enucleated under 2% halothane anaesthesia. At 1,5,10 and 20 days post-enucleation, cerebral glucose use was measured using the (^{14}C)-2-deoxyglucose technique. (^{14}C)-2-deoxyglucose-6-phosphate was eluted from those sections required for receptor autoradiography and the binding of [^{3}H]-5HT (2nM), [^{3}H]-Ketanserin (2nM), [^{3}H]-QNB (2nM), [^{3}H]-Muscimol (10nM) and [^{3}H]-DHA (2nM) was measured.

Significant reductions in glucose use were evident in both primary and secondary visual structures in the visually deprived hemisphere at 24 hours. The responses in ligand binding levels were heterogeneous: [^{3}H]-QNB and [^{3}H]-Ketanserin unaltered throughout the time course; [^{3}H]-5HT and [^{3}H]-DHA reduced in primary visual areas at 5, 10 and 20 days and [^{3}H]-Muscimol levels reduced in primary and secondary structures only at 20 days.

The variation in receptor response may indicate the importance of the site in visual processing and/or susceptibility to altered neuronal activity.

43.9

EVIDENCE FOR A POSTSYNAPTIC COLOCALIZATION OF NMDA, GLYCINE AND PCP BINDING SITES IN THE CA1 REGION OF HIPPOCAMPUS. V.Crepel*, A.Represa*, M.Beaudoin-Kais * and Y. Ben-Ari, (spon:D.McKay) INSERM U29, 123 BD.Port Royal, 75014 Paris,France.

Recent studies suggest that NMDA receptors, a subtype of glutamate receptors, are subject to regulation by glycine and with a PCP site form a receptor channel complex. NMDA probably plays a critical role in epilepsy and ischaemic damage to the hippocampus. NMDA binding sites are widely distributed in the hippocampus, particularly in the CA1 region on the terminal field of CA3 pyramidal cell axons (the Schaffer collaterals). This zone is particularly vulnerable to ischaemic injury. We report here the long lasting changes that transient bilateral hemispheric ischaemia or kainic acid induced epilepsy produce in the distribution of these binding sites. The severity and the extent of the lesions were studied by Gallyas, Fink-Heimer and cresyl violet staining methods. The distribution of NMDA, glycine and PCP binding sites was studied by quantitative autoradiography.

After kainate treatement there was a selective destruction of CA3 pyramidal neurons and dentate polymorph cells. NMDA, glycine and PCP binding decreased in the lesioned zone but not in the terminal field of their axons (CA1). The ischaemically damaged hippocampus shows a clear destruction of CA1 pyramidal and dentate polymorph cells. The density of binding sites for the differents receptor markers was severly reduced in CA1(>70%) 10 days after transient ischaemia.

To conclude: 1/ our results strongly support the anatomical colocalization of NMDA, glycine and PCP binding sites on the pyramidal cells of CA1: 2/ there was no sign of presynaptic localization of NMDA receptors on Schaffer collaterals; 3/ we proposed that in CA1, 30% of NMDA binding sites must be located on interneurons.

43.10

GTP MODULATES MELATONIN BINDING AND ITS EFFECTS ON ADENYLATE CYLCASE IN HAMSTER BRAIN. L.P. Niles, F.S. Hashemi* and B.J. Mason*, Department of Neurosciences, McMaster University, Hamilton, Ontario, Canada L8N 3Z5.

We have reported that the pineal hormone, melatonin, causes a GTP-dependent inhibition of adenylate cyclase activity in the rat hypothalamus (1). We now report a similar GTP-dependent effect in the hamster hypothalamus where melatonin, in pico-nanomolar concentrations, inhibits forskolin-stimulated adenylate cyclase activity.

In view of GTP's importance in eliciting melatonin's effect on enzyme activity, we have examined the effects of this nucleotide on the binding of 2-[^{125}I]iodomelatonin ([^{125}I]MEL) (2) in the hamster brain. Brain homogenates were incubated in the absence or presence of GTP which caused a dose-dependent inhibition of [^{125}I]MEL binding with a maximal effect of 40-50% occurring at a nucleotide concentration of 10^{-3} M.

These findings suggest that hypothalamic [^{125}I]MEL binding sites are functionally relevant receptor sites coupled to adenylate cyclase via a GTP regulatory protein. (Supported by the Ontario Mental Health Foundation and MRC, Canada)

THE PHARMACOLOGY OF 2-[^{125}I]IODOMELATONIN BINDING SITES IN HAMSTER HYPOTHALAMUS. D.S. Pickering and L.P. Niles, Dept. of Neurosciences, McMaster University, Hamilton, Ontario, Canada L8N 3Z5

Recently the ligand 2-[^{125}I]iodomelatonin ([^{125}I]MEL) has been used to label putative melatonin receptor sites. Its high affinity and specific activity make it far superior to the previously used ligand, [^{3}H]melatonin. We report here on the site specificity of [^{125}I]MEL.

The pharmacological profile of the site labelled by [^{125}I]MEL was examined in detail in hamster hypothalamus. A high affinity site (K_d= 0.18 nM) was found, similar to that in cerebral cortex and hippocampus. The profiles in all three regions were qualitatively similar. Cold IMEL was the most potent inhibitor of [^{125}I]MEL binding (IC_{50}≈ 0.5 nM) while only other closely related indoles exhibited significant potency: 6-chloromelatonin > N-acetyl-serotonin (NAS) > melatonin > 6-hydroxymelatonin > 5-methoxytryptophol >> 5-methoxytryptamine (5-MT) >> serotonin (5-HT). Prazosin was found to be a potent inhibitor in all brain regions studied (IC_{50}≈ 10 nM); however, other α_1-adrenergic agents (e.g. WB-4101), serotonergic and dopaminergic compounds were poor inhibitors. The indole-like ring structure of prazosin and its 6,7-dimethoxy groups likely are responsible for its affinity at these sites. It is interesting that while 5-MT and 5-HT are poor inhibitors, NAS is a good inhibitor. This suggests that removal of the positive charge of the amino group (by acetylation) is important for directing the specificity of indoles towards the putative melatonin receptor and away from serotonin receptors.

In summary, a unique, non-serotonergic, non-dopaminergic and non-adrenergic binding site is labelled by [^{125}I]MEL in hamster brain and proposed to be a melatonin receptor site.

43.12

PROPERTIES OF ^{3}H-CARFENTANIL BINDING TO HUMAN AND RAT BRAIN OPIATE RECEPTORS IN VITRO. R.A. LYON, M. TITELER, L.T. RYDELEK*, A.E. BULLOCK*, J.J. FROST[1], R.F. DANNALS[1]*, and M.J. KUHAR[2]. Dept. Pharmacol. Toxicol., Albany Medical College, Albany, NY 12208. [1] Div. Nuclear Med., Johns Hopkins Med. Institutions, Baltimore, MD 21205, [2] NIDA Addiction Res. Ctr., Baltimore, MD 21224.

^{11}C-Carfentanil has been successfully used as a Positron Emission Tomography ligand in humans. Preliminary studies have shown that ^{11}C carfentanil interacts primarily with mu opiate receptors. Because the half-life of ^{11}C renders it difficult to use in in vitro binding studies, ^{3}H-carfentanil was synthesized (NEN) and its binding properties examined in rat and human brain membranes.

Preliminary saturation analyses indicate that ^{3}H carfentanil specific binding is saturable in rat diencephalon (105+/-5 fmol/mg protein) and whole cortex (82+/-4) and human thalamus (92+/-9) and pre-frontal cortex (43+/-8). Specific ^{3}H-carfentanil binding (determined in the presence of 1 uM naloxone) displays a K_D of 0.09 nM and is regulated by guanine nucleotides. Preliminary competition experiments indicate that the majority of specific binding is to mu opiate receptors. Data from completed saturation, kinetic and displacement studies in rat and human tissues will be presented. (Supported by USPHS NS150 80).

43.13

VALIDATION OF A POSITRON EMISSION PROBE FOR NEURO-RECEPTOR STUDIES IN HUMAN BRAIN K.J. Jeffries*, C.A. Tamminga, D.F. Wong*, H.H. Holcomb, K.H. Douglass*, J.M. Links*, R.F. Dannals*, H.N. Wagner* (SPON S. Presty). Maryland Psychiatric Research Center and Johns Hopkins Hospital, Balto., MD 21228

A dual detector positron emission probe developed by Bice et al. enables quantification without localization of positron emitter labeled tracers within an adjustable brain volume. This device consists of two sodium iodide scintillators which detect positron annihilation events by coincident detection of 511 keV gamma-ray pairs. The scintillators, placed on opposite sides of the head, provide a measure of activity in the delimited volume of tissue. Phantom studies demonstrate a linear response to increasing activity levels in the field-of-view. The radiation dose needed for a probe data acquisition is approximately 1/40 of that required for a PET scan, allowing for repeated studies to be performed over a short period of time. We have now developed a simple model based on geometry and attenuation in the field-of-view for interpretation of the probe signal to be used to calculate activity in a region-of-interest from probe raw data. This technique's most obvious application is in the study of CNS drug kinetics. A preliminary PET/Probe correlation study demonstrated a 46% displacement of C^{11}-NMSP by haloperidol in caudate/cerebellum as measured from PET scan data versus a 45% displacement measured from probe data. Multiple probe studies over 48 hrs demonstrated 25% and 21% displacement from baseline at 2 hrs and 48 hrs respectively after haloperidol. C^{11}-NMSP displacement by haloperidol at different dose levels and its correlation with plasma drug levels will be reported.

43.14

[3H]Ro5-4864 AND [3H]PK11195 LABEL FUNCTIONAL RECEPTORS IN MITOCHONDRIA. J.D. Hirsch, C.F. Beyer*, L. Malkowitz*, C. Loullis, B. Beer, and A.J. Blume. Molecular Neurobiology Group, CNS Res., Med. Res. Div., American Cyanamid Company, Pearl River, NY 10965.

By studying the distribution of enzyme markers, specific [3H]Ro5-4864 (Ro5) binding, and crosslinked [3H]-PK14105, we have determined that [3H]Ro5 and [3H]PK11195 (PK) receptors in rat kidney mitochondria (M) reside in the outer membrane. Ten receptor ligands (Ro5, PK, DZ, FLU, MPoIX, DPoIX, DiPy, DiBuPhth, CyA, CL 259,763; IC50's = 20-20000 nM) inhibited M respiratory control without altering ADP:O ratios and their potency correlated with their receptor binding affinity (r = 0.95). Receptors in kidney M photoaffinity labeled with [3H]PK14105 and analyzed by SDS-PAGE, showed specific labeling in only 1 (~17 kDa) or 2 (~17 + ~18 kDa) proteins depending on irradiation time. Specific labeling was reduced by prior treatment of M with diethylpyrocarbonate. Size exclusion HPLC of [3H]labeled proteins in SDS yielded 1 major component (~18 kDa) which was resolved on a reverse phase C8 column in the presence of SDS into several labeled peaks. These results indicate that the M receptor for Ro5 and PK is an outer membrane protein(s) that modulates organelle function. Work is in progress to purify it to homogeneity and establish its identity.

44.1

LOCALIZATION OF ATPase ACTIVITY IN DENDRITIC SPINES OF THE CEREBRAL CORTEX. Virginia Kriho* and Rochelle S. Cohen. Department of Anatomy and Cell Biology, Univ. of Illinois at Chicago, Chicago, IL 60612.

An ATPase activity has been demonstrated in dendritic spines of the adult rat cerebral cortex using cerium to capture inorganic phosphate that is liberated during the enzymatic hydrolysis of ATP. Small pieces of cerebral cortex tissue were fixed and processed according to the method described by Salama et al. (1987, J. Histochem. Cytochem. 35: 471-482). The tissue was then dehydrated and embedded in Epon or LR White. EM examination of the cerium phosphate reaction product showed an electron dense precipitate localized in the cytoplasm of the spine behind the postsynaptic density (PSD). Whereas the PSD, itself, is not reactive, dense reaction product is seen immediately underneath the PSD and extending into the subsynaptic web. The reaction product is seen to occur along filamentous material in this region. Reaction product is also associated with membranous cisternae within the dendritic spine. No reaction product is seen when the tissue was incubated in a substrate (ATP)-free medium. Similarly, virtually no reaction product is seen when the tissue was incubated in a medium devoid of Ca^{2+} and including 2mM EGTA, suggesting that the reaction depends on the presence of Ca^{2+}. Incubation of the tissue in a medium devoid of Mg^{2+} and containing 10mM EDTA or 10mM CDTA did not inhibit the reaction. Ouabain, a Na^{+}-K^{+}-ATPase inhibitor, and levamisole, an alkaline phosphatase inhibitor, had no effect on the reaction. The presence of an ATPase activity which is dependent on Ca^{2+} in dendritic spines where actin and actin-binding proteins have also been localized, suggests that this activity may be involved in the dynamics of cytoskeletal function leading to shape changes in dendritic spines and synapses, as seen with various behavioral and physiological paradigms.
Supported by NIH Grant NS 15889.

44.2

COLOCALIZATION OF ACTIN AND MAP2 IN DENDRITIC SPINES DEMONSTRATED BY DOUBLE LABELING WITH IMMUNOGOLD PROBE. M. Morales* and E. Fifkova (SPON: J. Werner). Dept. of Psychology, University of Colorado, Boulder, Colorado 80309.

Using immunogold cytochemistry in a postembedding procedure, we have studied localization of MAP2 in dendritic spines of the dentate molecular layer, CA_1 stratum radiatum, visual cortex and Purkinje neurons. We have used monoclonal anti-MAP2 antibody which was the generous gift of Dr. A. Frankfurter (University of Virginia). This antibody recognizes MAP2 in dendritic spines where it is prevailingly associated with actin filaments and endomembranes of the spine apparatus, and to a lesser extent with the postsynaptic density. In all sites MAP2 was colocalized with actin as evidenced by a double labeling procedure. In dendrites, MAP2 was associated with microtubules. However, there was no labeling with this antibody in axon terminals. So far the presence of MAP2 in dendritic spines has been a matter of controversy. While MAP2 in spines has been shown with light and electron microscopy using PAP immunocytochemistry (Binder et al., Ann. N.Y. Acad. Soc., 466:145; Caceres et al., J. Neurosci., 4:394), it was not observed by Burgoyne and Cumming (Eur. J. Cell Biol., 30:154) or by Bernhardt and Matus (J. Comp. Neurol., 226:203). The latter authors considered the spine labeling to be caused by diffusion of the reaction product from dendrites. Our results unequivocally demonstrate the presence of MAP2 in spines with a method that is not beset with the problem of diffusion. Moreover, this method allows for discrete localization of the antigen within the spine compartment and thus for inferences to the possible function. Although MAP2 induces gelation of actin in vitro, its affinity to actin filaments in the presence of microtubules is low (Griffith and Pollard, J. Cell Biol., 78:958). However, in the absence of microtubules, MAP2 will bind to actin filaments. Thus, MAP2 may be one of the actin associated proteins which endows the actin network in spines with the dynamic properties that are necessary for synaptic plasticity.

44.3

TAP-1 EXISTS IN TWO FORMS; AN INTEGRAL MEMBRANE PROTEOGLYCAN OF THE NERVE TERMINAL AND AN EXTRACELLULAR MATRIX PROTEOGLYCAN WHICH LACKS A MEMBRANE INTERCALATING REGION. M. Iwata*, A. Davis* and S.S.Carlson. Dept. of Physiology and Biophysics, University of Washington, Seattle, WA.

Terminal anchorage protein one (TAP-1) is a chondroitin sulfate proteoglycan which has all the properties of a protein that links the nerve terminal to the extracellular matrix (ECM) at the elasmobranch electric organ synapse: 1) It is located on the nerve terminal surface; 2) It behaves as an integral membrane protein; and 3) It is tightly bound to an electric organ ECM fraction (Carlson, et al., J. Cell Biol. 103:509,1986). The molecule purified under denaturing and reducing conditions is a large proteoglycan with $M_r \approx 10^6$. Visualized in the electron microscope it has the typical "bottlebrush" structure characteristic of proteoglycans with an average total length of 345 ±17nm, with about 20 side projections of about 110 nm in length (Carlson and Wight, J.Cell Biol. 105:3075, 1987). The large size of this molecule suggests that it could make a large structural contribution to the synaptic cleft.

Recently we have found that two forms of TAP-1 exist in electric organ. A portion of the isolated TAP-1 molecules behave like integral membrane proteins and the remainder do not. As expected for an integral membrane proteoglycan, about 30-40% have two properties: 1) low buoyant density (< 1.3 g/cc) when sedimented in CsCl density gradients containing 4M guanidine-HCl and non-denaturing detergent, and 2) the ability to be inserted into liposomes. The remainder have a high buoyant density (>1.50 g/cc) on these gradients and do not interact with liposomes. Presumably one form lacks a hydrophobic membrane intercalating domain.

In all other respects these two TAP-1 forms appear the same. They are both chondroitin sulfate proteoglycans of the about the same size which contain 4 disulfide linked subunits with molecule weights of 45Kd, 23Kd, 18Kd, and 12Kd. We recently found these subunits when TAP-1 was purified under denaturing, but non-reducing conditions.

One interesting hypothesis is that the integral membrane form of TAP-1 might be converted to the ECM form on the nerve terminal surface.

VESIPLEXIN: A PROMINENT PROTEIN COMPLEX ON MAMMALIAN SYNAPTIC VESICLES. E. Floor. Dept. of Anatomy, Univ. of Wisconsin Medical School, Madison, WI 53706.

Peripheral membrane proteins Q, S and V (*J. Neurochem.* **50**: in press, 1988) and the synaptic vesicle-specific, integral membrane protein p65 from rat or cow brain synaptic vesicles co-sediment as an ~10S complex on sucrose gradients after solubilization in the nonionic detergent, CHAPS. Proteins Q, S and V co-migrate as a complex of M_r ~200K during nondenaturing gel electrophoresis or column chromatography in nonionic detergents. These structural parameters are consistent with the presence of one copy each of proteins Q, S, V and p65 in a globular complex. Interaction of proteins S and V (*Ann. N.Y. Acad. Sci.* 493:62, 1987) and Q and S in intact synaptic vesicles was demonstrated by covalent crosslinking. Sensitivity to attack by proteases and reactivity with membrane-impermeant crosslinkers indicate that this protein complex is located on the cytoplasmic surface of synaptic vesicles. I have named this complex vesiplexin to connote its localization and multisubunit structure. Vesiplexin did not appear to contain synaptic vesicle proteins synaptophysin or SV2 or cytoskeletal proteins tubulin or neurofilament protein NF-L in Western immunoblot analyses. The abundance of vesiplexin in purified synaptic vesicles is comparable to that of synaptophysin as estimated from Coomassie Blue-stained SDS gels, which suggests that it is present in several copies per vesicle. The abundance and location of vesiplexin suggest a structural role, possibly in interactions of synaptic vesicles with the neuronal cytoskeleton or presynaptic membrane. The functions of vesiplexin are presumably related to the calcium-sensitive process mediated by p65, a calmodulin-binding protein. (Supported by NIH grant NS24890).

44.5

ACTIN ASSEMBLY and NEUROTRANSMITTER RELEASE. BW Bernstein and JR Bamburg*. Department of Biochemistry, Colorado State University, Fort Collins, Colorado 80523

Actin, the major cytoskeletal protein of nerve terminals, assembles, disassembles, and reassembles during a 30sec depolarization of whole mouse brain synaptosomes in a 75mM K^+/ 2mM Ca^{++} buffer. Synaptosomes, loaded with [^{3}H]-noradrenaline (1μCi/ml resting buffer), show rapid release during the first 1-2sec of depolarization (Drapeau, P and MP Blaustein, J. Neurosci.3:703-713, 1983); release recommences 20-30sec later, and after 60sec, total ^{3}H released is twice that of the first 2sec. The abrupt termination of release after the first 2sec occurs during the time of rapid assembly of actin previously described.

Membrane impermeable molecules can be entrapped in synaptosomes during brain homogenization (Akerman, K et al, Biochim. Biophys. Acta 858:275-285, 1986). We are testing whether cycles of actin assembly/disassembly are necessary for the cycles of release: cytoskeletal perturbing agents are entrapped and their effects on release are measured. One such agent, phalloidin (800 kD), binds filamentous actin and stabilizes it against depolymerization. We estimate that micromolar levels of phalloidin were incorporated in synaptosomes, assuming that phalloidin enters them with efficiency equal to that of a fluorescent dextran marker (9,000 kD average). The levels of entrapped phalloidin are sufficient to block 50-60% of radioactivity released during the first 2sec of depolarization.
Supported by NIH GM35126.

44.6

LOCALIZATION OF pp60c-src IN SYNAPTIC VESICLES. D. T. Pang, F. Valtorta*, M. E. DeMarco*(1), J. S. Brugge*(1), F. Benfenati*, P. Greengard. Lab. of Mol. & Cellu. Neurosci., Rockefeller U., New York, NY 10021 and (1) Dept. of Microbiol., SUNY, Stony Brook, NY 11794.

A possible regulatory role of tyrosine phosphorylation in neurotransmission is supported by the recent observations that synaptic vesicle proteins are phosphorylated by endogenous tyrosine kinases in intact vesicles and nerve terminals and that pp60c-src is present in nerve terminals and crude synaptic vesicle fractions. The present study examined pp60c-src in synaptic vesicles purified through the step of chromatography on controlled-pore glass beads. Immunoblot analysis showed that pp60c-src was enriched 4-5-fold in synaptic vesicles compared to the total particulate membrane fraction. To determine the contribution of pp60c-src to the total tyrosine kinase activity, subcellular fractions were solubilized in 1% Triton X-100 and immunoprecipitated with monoclonal antibody 327. With enolase as an exogenous substrate, immunoprecipitates and supernatants were assayed for tyrosine kinase activity. pp60c-src represented 70% and 14% of the tyrosine kinase activity in synaptic vesicles and brain homogenate respectively, indicating that pp60c-src is the major tyrosine kinase in synaptic vesicles. The presence of pp60c-src in synaptic vesicles suggests a possible regulatory role for this tyrosine kinase in neurotransmitter release. Gene regulation of pp60c-src in neurons may be involved in the long term modulation of neural transmission.

EFFECTS OF PHORBOL ESTER AND ACETYLCHOLINE ON PROTEIN PHOSPHORYLATION IN RAT NEURONS AND GLIAL CELLS. Y.F. Han* and L.A. Dokas (SPON: R.M. Kantner). Depts. of Biochem. and Neurol., Med. Col. of Ohio, Toledo, OH 43699.

Phorbol esters alter several synaptic responses in neurons. Since phorbol esters activate protein kinase C (PKC), it is important to characterize the phosphoproteins which mediate these effects and determine their functions. Hippocampus and cerebral cortex from 19 to 20-day-old rat fetuses or 1-day-old rats were dissociated and cultured to yield neurons or glial cells. Phosphorylation of cell proteins was initiated by addition of [^{32}P]-orthophosphoric acid followed by incubation with the phorbol ester 12-O-tetradecanoyl-phorbol-13-acetate (TPA) or other compounds. Phosphoproteins were characterized by SDS-PAGE, autoradiography and liquid scintillation counting. TPA (10^{-8}-10^{-6}M) stimulated, in a dose-dependent manner, the phosphorylation of a protein with an M_r of 84 kDa both in neurons and glial cells, and a protein with an M_r of 48 KDa in neurons only. 4α-Phorbol 12,13-didecanoate, an inactive derivative of TPA, showed no effects. Stimulatory effects of TPA could be significantly antagonized by 1-(5-isoquinolinyl sulfonyl)-2-methyl-piperazine (H-7), an inhibitor of PKC. Acetylcholine (10^{-3}M) enhanced phosphorylation of both the 84 and 48 kDa proteins. These studies suggest that these proteins may be involved in modulation of neuronal and glial functions. A Ca^{2+}-INDEPENDENT AUTOPHOSPHORYLATION SITE IN NEURONAL TYPE II CaM KINASE SUPPRESSES STIMULATION BY CALMODULIN. B.L. Patton*, S.G. Miller*, and M.B. Kennedy. Division of Biology 216-76, Caltech, Pasadena, CA 91125.

Rapid autophosphorylation of αThr-286/βThr-287 on the α and β subunits of type II Ca^{2+}/calmodulin (CaM)-dependent protein kinase is triggered in the presence of Ca^{2+}/CaM (see accompanying abstract). This produces a partially Ca^{2+}-independent kinase activity and we now find that it also permits the autophosphorylation of additional sites upon removal of Ca^{2+}. The Ca^{2+}-independent autophosphorylation does not reduce Ca^{2+}-independent activity, but is associated with a loss of further stimulation of activity by calmodulin (Hashimoto *et al.*, 1987, JBC 262, 8051; our own observations). We have identified two Ca^{2+}-independent autophosphorylation sites on each of the α and β subunits and have correlated the phosphorylation of one of them with loss of stimulation by calmodulin. The sites were identified following tryptic digestion of ^{32}P-labeled kinase that had been autophosphorylated first in the presence, then in the absence of Ca^{2+}. Tryptic phosphopeptides that appeared in the absence of Ca^{2+} were purified by HPLC and sequenced. Phosphate was found in peptides containing Ser-315 and Thr-306,-307 in the β subunit and in homologous peptides from the α subunit (containing sites Ser-314 and Thr-305,-306). These sites are located in the calmodulin-binding domain. Comparison of the time course of autophosphorylation of these sites with the loss of stimulation by calmodulin, as well as comparison of the rate of dephosphorylation with recovery of calmodulin stimulation, suggests that the threonine sites, rather than the serine sites, are responsible for inhibition of effective binding by calmodulin.

AN EARLY AUTOPHOSPHORYLATION SITE IN NEURONAL TYPE II CA^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE PRODUCES Ca^{2+}-INDEPENDENT ACTIVITY. S.G. Miller', B.L. Patton', and M.B. Kennedy (Spon: R. Bulleit) Division of Biology 216-76, Caltech, Pasadena, CA 91125.

It is now well-established that the enzymatic activity of neuronal type II Ca^{2+}/calmodulin-dependent protein kinase is regulated by autophosphorylation. Autophosphorylation in the presence of Ca^{2+}/calmodulin (CaM) leads to the generation of a partially Ca^{2+}-independent form of the kinase. This change in activity occurs after phosphorylation of only a few of the 12 subunits in a holoenzyme. We have identified the autophosphorylation sites that are involved in this change in activity using tryptic digestion, followed by reverse phase-HPLC and microsequencing. When autophosphorylation occurs in the presence of Ca^{2+}/CaM a common threonine residue (αThr-286/βThr-287) is rapidly phosphorylated in both the α and β subunits. It is located near the N-terminal boundary of the calmodulin binding domain. The β subunit contains a second rapidly phosphorylated threonine, βThr-382. It is in a region of the β subunit that is not present in the α subunit and that appears to be specifically deleted by mRNA splicing in the β' subunit (Bulleit *et al.* (1988) *Neuron* 1, 63-72).

Purified protein phosphatase 2A dephosphorylates βThr-382 at a higher rate than either αThr-286 or βThr-287. Partial dephosphorylation of the kinase with protein phosphatase 2A completely dephosphorylates βThr-382. The resulting kinase is phosphorylated only at αThr-286/βThr-287 and remains significantly Ca^{2+}-independent. These experiments indicate that βThr-382 is not *required* to maintain Ca^{2+}-independent kinase activity.

A POLYCLONAL ANTIBODY THAT SPECIFICALLY RECOGNIZES THE CALMODULIN (CaM) BINDING DOMAIN OF Ca^{++}/CaM-DEPENDENT PROTEIN KINASE II (CK-II). R.Weinberger*, J.Aronowski*, M.N. Waxham*, and P.Kelly. (SPON: M. Mauk). Dept. of Neurobiol. and Anat., and Neurol., Univ. of Tex. Med. Sch., Houston TX 77225.

CK-II is a major neuronal protein kinase in the CNS and has been shown to have both Ca^{++}/CaM -dependent and -independent kinase activity *in vitro*. Based on the primary sequence of the putative CaM binding region of CK-II, a peptide (CBP) has recently been synthesized and shown to display active site directed inhibitory properties (1). In the present study a rabbit polyclonal antibody was raised against CBP and its properties characterised. ELISA and immunoblot analyses indicated that anti-CBP was highly specific, recognizing both alpha and beta subunits of CK-II but sharing no cross reactivity with skeletal muscle myosin light chain kinase (Sk-MLCK), phosphorylase kinase, calcineurin, a 36 kDa CaM binding protein, Ca^{++}/CaM-dependent phosphodiesterase and two synthetic peptides modelled on the CaM binding region of Sk-MLCK. Minor cross reactivity with two unidentified protein bands was observed in crude fractions of rat brain. The only detectable phosphoproteins in brain subcellular fractions immunoprecipitated with anti-CBP were the alpha and beta subunits of CK-II. Anti-CBP inhibited the Ca^{++}/CaM stimulated activity of purified CK-II *in vitro* by 40-90%. This inhibition was dose- and time- dependent and was reversible in the presence of excess CaM. No inhibition of kinase activity was seen for the Ca^{++}/CaM -independent form of CK-II. These results indicate that anti-CBP is a potentially useful reagent with which to investigate the function of CK-II *in vivo* as well as demonstrate that the amino acid sequence contained in CBP is in fact the CaM binding domain of CK-II.

ACETYLCHOLINE RECEPTOR AGGREGATION IN CULTURED RAT MYOTUBES: ROLE OF A NEURAL FACTOR AND CA^{++}. E.K. Dutton and A.J. Olek*. Department of Zoology, The University of Maryland, College Park, MD 20742.

A soluble factor from embryonic brain (EBX) induces acetylcholine receptor (AChR) aggregation in cultured rat myotubes within 4 hours at 36° C (Olek et al., Cell, 34:255, 1983). This effect is dependent on extracellular Ca^{++} and increasing extracellular Ca^{++} from 1.8 to 3.6 mM greatly enhances the myotubes response to EBX. It appears that EBX and Ca^{++} are acting synergistically to promote AChR aggregation.

A larger increase in extracellular Ca^{++} to 7.2 mM can, by itself, induce AChR aggregation within 4 hours at 36° C. Increasing the extracellular concentration of other divalents cations does not induce AChR aggregation. Ca^{++}-induced AChR aggregation occurs to the same extent as EBX-induced AChR aggregation but with a clearly different pattern. Like EBX, Ca^{++}-induced AChR aggregation is sensitive to sodium azide and independent of protein synthesis. However, EBX can induce a detectable AChR aggregation response if applied for a 15 minute pulse while increased extracellular Ca^{++} requires a longer application time to induce a detectable AChR aggregation response.

IMMUNOELECTRON MICROSCOPY LOCALIZATION OF SYNAPTIC VESICLE-SPECIFIC PROTEINS AFTER INTENSE RELEASE OF NEUROTRANSMITTER. F.Torri-Tarelli*, A.Villa*, F.Valtorta*, P.De Camilli§, P.Greengard‡ and B.Ceccarelli* (Spon. L.Martini) Dept. of Medical Pharmacology, Univ. of Milan, Italy; § Yale Univ. School of Medicine and ‡ The Rockefeller Univ., New York

In order to follow the movements of the synaptic vesicle (SV) membrane during the exo-endocytotic cycle, we have applied immunogold labeling techniques to ultrathin frozen sections obtained from frog neuromuscular junctions stimulated with α-latrotoxin (α-LTx) using antibodies to an integral protein of the SV membrane, synaptophysin (p38). After one hour treatment with low doses of α-LTx in the presence of extracellular Ca (condition under which an active recycling of both quanta of neurotransmitter and SV occurs), the immunoreactivity pattern resembled that observed in resting preparations. Immunogold particles were found to be selectively associated with the membrane of SVs, whereas the axolemma was completely unlabeled, suggesting that the retrieval process is selective for the SV membrane and no extensive intermixing of membrane components occurs. When the same doses of α-LTx were applied in Ca-free solution (condition under which a block of recycling results in depletion of SVs and swelling of the nerve terminal), the gold particles were found to be uniformly distributed along the axolemma, indicating that SV membrane had been permanently incorporated into it. The same experimental procedures was applied to study the redistribution of synapsin I, a phosphoprotein associated with the cytoplasmic surface of the SV. Preliminary results show that after stimulation with α-LTx in the presence of Ca immunoreactivity for synapsin I is still localized around SVs, suggesting that either synapsin I remains associated with the vesicle membrane throughout the exo-endocytotic cycle, or that it reassociates with the vesicle after retrieval (MDA grant to B.C.).

QUANTAL RELEASE FROM IDENTIFIED SYNAPTIC BOUTONS IN SNAKE MUSCLE. R. S. Wilkinson. Dept. of Cell Biology and Physiology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Snake motor nerve terminals are comprised of discrete boutons, similar to CNS and autonomic terminals in mammals. In the thin transversus abdominis muscle of the garter snake, most tonic muscle fiber endplates are polyneuronally innervated; occassionally, one axon contributes only a few boutons. These small terminal projections have been utilized to investigate quantal release from single synaptic boutons.

Terminals of one tonic motor axon were supravitally labeled using the activity-dependent probe sulforhodamine 101 (200 μg/ml). Endplates having 1-4 boutons from the axon were selected. Spontaneous miniature (mepp's) and evoked endplate potentials (epp's) were recorded in normal or elevated Ca^{++} saline without paralysing agents. Mean mepp amplitudes were 2-10 mV at -80 to -90 mV resting potential. Low frequency stimulation (< 0.2 Hz) evoked epp's of fluctuating amplitudes indicating release of from 1 to 4 quanta/bouton, with mean quantal content, m, of 2-3 quanta/bouton. Higher stimulus frequencies reduced m but did not eliminate fluctuations. These data suggest that snake neuromuscular boutons contain more than one active zone. (Supported by NIH grant NS24752 and the Muscular Dystrophy Association).

IMMUNOCYTOCHEMICAL LOCALIZATION OF PHOSPHATIDYLINOSITOL-ANCHORED ACETYLCHOLINESTERASE IN EXCITABLE MEMBRANES OF TORPEDO. J. Eichler*, I. Silman*, M.K. Gentry* and L. Anglister. Anatomy Dept., Hebrew Univ. Med. Sch., Jerusalem 91010, Neurobiology Dept., Weizmann Inst., Rehovot 76100, ISRAEL and Walter Reed Army Inst. Res., Washington, DC 20307

In Torpedo electric organ much of the AChE is a hydrophobic dimer (G_2) which copurifies with synaptosomes, suggesting a presynaptic localization. G_2 AChE is anchored to the plasma membrane via covalently attached phosphatidylinositol (PI), and is selectively solubilized, in electric organ homogenates, by a bacterial PI-specific phospholipase C (PIPLC). This suggested use of PIPLC, coupled with immunocytochemistry, to localize G_2 AChE in Torpedo ocellata tissues.

Cryostat sections of electric organ, of electromotor nerve and of muscle were labelled with polyclonal antibodies to Torpedo AChE and then with fluorescein-tagged second antibody. Rhodamine-α-bungarotoxin was used to delineate synapses. Sections pretreated with PIPLC were compared with controls.

The antibodies bound selectively to innervated sites on electrocytes and myofibers. For both, pretreatment with PIPLC markedly reduced immunofluorescence. The strong binding to the electromotor axon surface was also diminished after PIPLC. MCAb 4E7, which binds preferentially to G_2 AChE, labelled both innervated and non-innervated faces of the electrocyte (Howland et al. Soc.Neurosci.Abstr.9:726, 1983) and strongly labelled muscle endplates. PIPLC decreased staining of the electrocyte's innervated face and of muscle endplates, and similarly reduced 4E7 staining of electromotor nerve.

The results support our previous assignment, based on biochemical evidence, for a neuronal and synaptic localization of the PI-linked AChE dimer in Torpedo. We are now using EM to precisely localize the dimer in the synaptic cleft. (Supported by grants from MDA to I.S., BSF to L.A. and Israel Acad.Sci. to L.A. and I.S.).

SKELETAL MUSCLE ACETYLCHOLINESTERASE A_I & A_{II} FORMS FOLLOWING ORGANOPHOSPHATE (DFP) INACTIVATION.
X. Busquets*, S. Rummel* and H.L. Fernandez. Neuroscience Lab., Veterans Administration Med. Ctr., Kansas City, MO 64128 and Dept. of Physiology, Univ. of Kansas Med. Ctr., Kansas City, KS 66103.

Mammalian skeletal muscles contain multiple molecular forms of AChE [acetylcholine acetylhydrolase, E.C. 3.1.1.7] which have been categorized as globular [low-salt soluble] and asymmetric [high-salt soluble]. The asymmetric [A_{12}] form, which is highly concentrated at the neuromuscular junction, has attracted much attention partly because of its acknowledged usefulness as a sensitive indicator of nerve-target cell interactions. Recently the existence of two pools of A_{12} AChE has been reported: A_I and A_{II}, extractable in high-salt buffer in the absence or presence of divalent cation chelators [e.g., EDTA], respectively. To further define these A_{12} subtypes we studied the time course of recovery of A_I & A_{II} activities following organophosphate [DFP] inactivation.

Anterior gracilis muscles [3 month old Fischer 344 rats] were treated "in situ" with 0.4 mM DFP for 5 min and at various times thereafter they were assayed, along with untreated muscles, for AChE molecular forms. Results showed that the activity of A_I AChE recovered approximately 48h earlier than that of A_{II} AChE. The recovery of A_I began shortly before 24h. In turn, the onset of A_{II} recovery occurred approximately after 72h of treatment. These and other results suggest a possible metabolic association between A_I and A_{II} AChE pools.

TETANIC AND POST-TETANIC POTENTIATION ARE DECREASED IN DEGENERATING NEUROMUSCULAR JUNCTIONS OF MANDUCA SEXTA.
I. M. Sonea*, C. A. Young* and M. B. Rheuben (SPON: A. E. Kammer), Dept. of Anatomy, Michigan State University, E. Lansing, MI 48824.

The electrophysiological properties of normal larval and degenerating day 1 pupal neuromuscular junctions (NMJ) were compared before, during and after a 6 min train of 20 stimuli/sec. Characteristic differences were observed between the 2 muscles studied, the mesothoracic AB and C muscles, which persisted in degenerating NMJ's. Tetanic potentiation, as measured by single test pulses during a brief interruption of tetanus, was present in normal larval EJP's, but reduced or absent in degenerating ones. Post-tetanic potentiation, measured by test pulses 2.5 sec apart, was also present in normal but not degenerating NMJ's. These alterations of relatively slow processes may reflect metabolic changes within the nerve terminal or secondarily the glial cells surrounding it. Up to 12 hours after pupation a portion of the junctions continued to release transmitter, as judged by intracellular recordings of EJP's. Failure to obtain EJP's was usually abrupt, occurred at high stimulus frequencies, and could be attributed to failure of the nerve to conduct. Morphologically, the glial sheath and the axons within it were undergoing dramatic changes at the same time. (Supported by N.I.H. Grant NS17132)

44.17

EJP PROPERTIES DURING NEUROMUSCULAR DEGENERATION MAY PARTLY BE RELATED TO DECREASING GLIAL FUNCTION. C. A. Young*, I. M. Sonea* and M. B. Rheuben, Dept. of Anatomy, Michigan State University, East Lansing, MI 48824.

The properties of the excitatory junction potential (EJP) and ultrastructural features of the larval and early pupal mesothoracic muscle fibers of Manduca sexta were compared during the neuromuscular degeneration associated with metamorphosis. Early in degeneration, lowered (Ca++) became less effective in decreasing EJP amplitudes in both salines with added nutrients (glutamine and sugars) and without. Beyond 4 hrs post-pupation, EJP's measured in added nutrient salines continued to have large amplitudes, while those in low nutrient salines declined. EJP's of pupal fibers in low nutrient saline were inconstantly lengthened (up to 400 msec) in total duration; those measured with nutrients present had statistically significant increases in times to 1/2 fall. Ultrastructurally, the glial cells were withdrawing their processes from the interstices of the neuromuscular junction, even though many nerve terminals continued to have apparently normal pre- and postsynaptic specializations. The observed physiological changes may reflect a decline of energy driven functions of both the nerve terminal and the glial cell, such as uptake and recycling of glutamate and regulation of ion concentrations within and around the nerve terminal. (Supported by N.I.H. Grant NS17132)

44.18

STRUCTURAL AND FUNCTIONAL DEVELOPMENT OF IDENTIFIED ELECTROTONIC SYNAPSES IN CRAYFISH. B. Leitch*, J.L.S. Cobb*, W.J. Heitler, and R.M. Pitman. Gatty Marine Lab., Univ. of St. Andrews, Scotland, KY16 8LB.

The post-embryonic development of the non-rectifying lateral giant septate synapse (LG-LG) and the rectifying giant fibre-motor giant synapse (GF-MoG) were investigated using ultrastructural and electrophysiological techniques.

In adults the LG-LG junction is characterised by windows of close membrane apposition with cross-bridging connexons. On either side of the junction are numerous, large (60-80nm) spherical vesicles. In newly hatched crayfish, vesicles are extremely sparse and much smaller (30-40nm). Occasional large vesicles become evident during the 2-month development period, however, vesicle number remains low. The LG-LG electrotonic junction is functional from day 0, as evidenced by Lucifer yellow dye coupling and the passage of current.

At the adult GF-MoG synapse, contact is made via narrow "bottle-necks". The gap junctional regions are similar to the adult LG-LG synapse except that large spherical vesicles are only present in the presynaptic giant fibre. In hatchlings, GF-MoG contact is made over extended areas of flat membrane apposition. Initially, the junctional region is morphologically indistinguishable from a chemical synapse. During development, gap junctional regions gradually appear bordered by chemical-like synapse areas. However, electrophysiological and dye coupling evidence indicates that these junctions too function as electrotonic synapses from day 0.

ORGANIZATION AND NEUROCYTOLOGY OF THE BRAIN OF A PARASITIC FLATWORM, *FASCIOLA HEPATICA*. S.C. Sukhdeo and M.V.K. Sukhdeo*. Dept. Zoology, University of Toronto, Toronto, Ontario M5S 1A1.

Flatworms (Platyhelminthes) are the most primitive animals to possess a central nervous system. The organization, architecture and neurocytology of the brain of *Fasciola hepatica* were examined in this study. Three-dimensional reconstructed models of the brain show that paired ganglia situated at the oral sucker/pharynx junction are connected by a dorsal transverse commissure. The ganglia are not surrounded by a capsule or glial sheath. The cell bodies in each ganglion are loosely organized around the periphery and are also found in the neuropile area; no clearly-defined cell rind is present. The neuropile is composed of tightly-packed unmyelinated nerve processes consisting of small nerve fibers (2 μm diameter) and large 'giant' nerve fibers (> 15 μm diameter).

The fine structure of the ganglion cell bodies are typical of cell bodies of higher invertebrates. Nerve processes contain four morphologically-distinct types of vesicles. Simple synapses and wedge-shaped or divergent diad synapses are present in the neuropile, commissure and nerve cords. The unique feature in the nervous system are the 'giant' nerve processes which have highly invaginated cell membranes. "Glial-like" cells interdigitate into the 'giant' processes and cytoplasmic organelles (mitochondria) are frequently found in the invaginations. These 'giant' processes are found in the neuropile and make up the bulk of nerve tissue in the commissure and nerve cords. The functions of these 'giant' nerve processes are unknown at this time but they may fulfill functions similar to those of trophospongium cells of insects.

SYNAPSES IN THE ANTEROVENTRAL COCHLEAR NUCLEUS PREPARED BY FREEZE-SUBSTITUTION. H.Tatsuoka* and T.S Reese. (SPON: P. Gallant) NINCDS, NIH, at MBL, Woods Hole, MA 02543.

The rostral anteroventral cochlear nucleus (AVCN) of the chinchilla has provided a preparation in which neuronal cell bodies and synapses in the CNS can be examined after direct freezing and freeze-substitution of rapidly excised brain stem slices. Cell bodies in the freeze-substituted AVCN differed from those in perfusion-fixed AVCN in several respects. In spite of these differences, four types of synaptic terminal were distinguished in freeze-substituted AVCN and correlated with the four types of terminals previously reported after chemical fixation. Since the transmitter for each of the four types of terminal is known, the structure of synaptic vesicles and junctions in the four chemical types of synapse could be compared. Synaptic vesicles were uniformly round, but their diameters and deployment near the synaptic junction as well as the detailed structure of the post synaptic density differed in each chemical type of synapse. In particular, the acetylcholine synapse had only a few vesicles clustered at its presynaptic junction-the rest were separated from the junction by a network of fine filaments. Characteristic of the post-synaptic density of glycine terminals were numerous fine filaments parallel to the plasmalemma and suspended between the postsynaptic projections. Thus, freeze-substitution revealed structural differences between chemically different types of synapses which may be related to differences in transmitter storage, release, and reception.

44.21

ULTRASTRUCTURAL CHARACTERISTICS OF THE SYNAPTIC JUNCTION: RELATIONSHIP TO SYNAPTIC SHAPE. E.J. Markus, T.L. Petit & J.B. LeBoutillier. Dept. of Psychology & Program in Neuroscience, Univ. of Toronto, Ont. M1C 1A4, Canada.

Recent research has indicated that synaptic structure & curvature are an important and potentially critical plastic feature of the synapse.

We have divided synapses into 4 types based on their shape: smile, flat, frown and irregular synapses. If one orients a photomicrograph with the presynaptic (axonal) terminal superior and postsynaptic (dendritic) terminal inferior then a protrusion of the presynaptic density into the postsynaptic terminal will form a "smile". Similarly, the protrusion of the postsynaptic density into the presynaptic terminal will form a "frown". Synapses with a parallel pre- and postsynaptic density are designated "flat" synapses, and synapses that are a combination of the above types are categorized as "irregular" synapses.

Alterations in synaptic shape is associated with synaptic function. Specifically, in the occipital cortex, an increase in the proportion of frown to smile synapses is related to maturation, and in adulthood, associated with the level of neuronal activity (see Markus & Petit, in press). The present study examined the ultrastructural characteristics of the different shaped synapses in a group of aged rats (25 month). Our findings indicate that:

1) Both the frown and irregular synapses are longer and have larger pre- and postsynaptic dense elements than smile or flat synapses.
2) Presynaptic dense projections are higher in the frown synapses than in the smile synapses.

A comparison will be made to hippocampal synapses, and functional implications will be discussed.

RECEPTOR MODULATION AND REGULATION I

45.1

THE EFFECTS OF GTP ON [^{3}H]CYCLOHEXYLADENOSINE BINDING TO A_1 ADENOSINE RECEPTORS IN MEMBRANES FROM RAT CORTEX AND HIPPOCAMPUS IN THE PRESENCE OF THEOPHYLLINE, 2-CHLOROADENOSINE, AND CARBAMAZEPINE. S.M. Anderson, R.L. Weir* and J.W. Daly. Dept of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307; Neurotoxicology Section, NINCDS, NIH, Bethesda, MD 20892 and Dept of Neurology, Howard U School of Medicine, Washington, D.C. 20060; Lab of Bioorganic Chemistry, NIDDKD, NIH, Bethesda, MD 20892

High affinity A_1 adenosine receptors mediating the inhibition of adenylate cyclase have been identified in the CNS. The binding of several adenosine agonists to A_1 adenosine receptors in rat brain has been shown to be decreased by guanine nucleotides. We have previously reported inhibition by 6.7 μM GTP of [^{3}H]CHA binding to membranes from rat cortex and cerebellum. In this report we present data showing an enhancement of 0.1 nM and 10 nM [^{3}H]CHA binding to cortical membranes by 0.05-0.80 μM GTP and inhibition of binding at higher GTP concentrations (1-10 μM). Unlike the biphasic actions of GTP on cortical membranes, we found no enhancement of [^{3}H]CHA binding to hippocampal membranes. The actions of GTP on the binding of [^{3}H]CHA in the presence of 2-chloroadenosine, a competitive agonist, theophylline, a competitive antagonist, and carbamazepine (an anticonvulsant which is a mixed competitive/noncompetitive inhibitor) parallel the pattern seen with GTP alone. These data suggest regional variation in GTP effects at A_1 adenosine brain receptors.

45.2

BIVALENT ANALOGS OF ADENOSINE: EVIDENCE FOR BINDING TO THE A1 ADENOSINE RECEPTOR. J.B. Wollack and J.B. Pennywell*. Dept. of Neurology, Div. of Pediatric Neurology, College of Physicians and Surgeons of Columbia University, N.Y., NY 10032

The adenosine receptor system is emerging as an important modulator of brain injury resulting from hypoxic, ischemic and epileptic insults. In seeking to develop new ligands for this receptor, we synthesized a series of bifunctional agents, containing two adenosyl moieties separated by an alkane bridge. This approach has been used previously (Portoghese et. al., J Med. Chem., 29:1855, 1986, Shimohigashi et. al., Molec. Pharmacol., 21:558, 1982) to develop useful agents for the opiate receptor system.

Ethylenediamine, 1,3-propanediamine, and 1,6 hexanediamine were reacted with an excess of 6-chloropurine riboside to produce the corresponding 1,2 bis(N^6-adenosyl)ethane (A-2-A), 1,3 bis (N^6-adenosyl)propane (A-3-A) and 1,6 bis(N^6-adenosyl)hexane (A-6-A), respectively. The affinity of these compounds for the A1 adenosine receptor in whole rat brain membranes was assayed utilizing [^{3}H]cyclohexyladenosine (CHA) as a radioligand. Comparisons were made with N^6 methyladenosine (meADO), a representative monovalent alkyladenosine; CHA, one of the most potent A1 agonists; and theophylline (theo), a commonly used antagonist. The order of binding was found to be CHA>A-6-A>A-2-A>meADO>theo. Limited solubility made evaluation of A-3-A difficult, however, it appeared less potent than A-2-A. These results suggest that bivalent adenosyl compounds represent a new class of compounds to be investigated as ligands for the adenosine receptor.

Supported by the Charles A. Dana Foundation and the Colleen Giblin Foundation.

PARTIAL PURIFICATION OF RAT BRAIN AND TESTICULAR A_1 ADENOSINE RECEPTOR BY AFFINITY CHROMATOGRAPHY. H. Nakata* (Sponsor: D.M. Jacobowitz), Laboratory of Clinical Science, NIMH, Bethesda, MD 20892.

Adenosine receptors have been classified into two major subclasses, A_1 and A_2. The A_1 receptor is linked to inhibition of adenylate cyclase whereas A_2 receptor is linked to activation of adenylate cyclase. In order to get more information about molecular properties of the A_1 receptor, purification of A_1 receptor by affinity chromatography was performed. The solubilized A_1 receptor from rat brain membranes was applied to a xanthine amine congener (XAC)-linked agarose column and eluted with 8-cyclopentyltheophylline (CPT). The adsorption of receptor to the affinity matrix was biospecific as preincubation of the solubilized preparation with A_1 agonists or antagonists blocked retention of receptor. Elution of the receptor was also biospecific as a potent A_1 agonist (CPA) or antagonists (CPT, XAC) were most effective in eluting the bound receptor. The affinity purification resulted in a recovery $\sim$ 30% of the solubilized A_1 receptor applied with a specific activity of $\sim_3$30 pmol/mg ($\sim$ 50-fold purification) as assayed with [^{3}H]DPCPX. This affinity purification was also applied successfully for the purification of rat testicular A_1 receptor. Chromatography of solubilized rat testes membrane preparations on XAC-agarose gel resulted $\sim$ 50-fold increase in the specific binding activity for [^{3}H]DPCPX. The affinity chromatography procedure described here should prove to be a key tool in the eventual purification of the A_1 receptor.

45.4

PROLACTIN UPTAKE BY THE CHOROID PLEXUS OF HYPERPROLACTINEMIC RATS. L.P. Mangurian*, R.J. Walsh and B.I. Posner*. Anatomy Department, The George Washington University Medical Center, Washington, D.C. 20037 and Department of Medicine, Royal Victoria Hospital, Montreal, Canada.

The choroid plexus (CP) contains prolactin receptors that are involved in transporting prolactin from blood to CSF. Since CSF concentrations of prolactin parallel blood concentrations, up regulation of prolactin receptors at the CP might facilitate transport into CSF during periods of elevated blood prolactin concentrations. In vivo autoradiography was used to assess the ability of the CP to uptake ^{125}I-prolactin during hyperprolactinemia. Ovariectomized rats were made hyperprolactinemic by treatment with haloperidol (2.5 mg/kg b.w./day for 3 consecutive days) and bromocriptine (10 mg/kg b.w., 4 hours prior to perfusion). In vivo administration of ^{125}I-prolactin was followed by vascular perfusion. Paraffin sections were coated with NTB-2 emulsion. Analysis of ^{125}I-prolactin accumulation in the CP was performed with a video grain counting program. A 133% increase in the accumulation of radioactivity was observed in the CP of hyperprolactinemic animals relative to untreated. Experiments are underway to determine whether the increase in ^{125}I-prolactin binding in the CP is due to up regulation of the receptor population or a variation in the occupancy of receptors due to the treatment. NSF Grant BNS-8604760. NIH 2-R01-DK19573-10A1.

BINDING OF DELTA-9-TETRAHYDROCANNABINOL (THC) TO GLUCOCORTICOID RECEPTORS IN RAT HIPPOCAMPUS. J.C. Eldridge*, D.G. Fleenor*, L.B. Cadwallader* and P.W. Landfield (SPON: M. Levitt), Dept. Physiol. & Pharmacol., Bowman Gray School Med., Winston-Salem, NC 27103

In recent studies (Landfield et al, 1988, Brain Res, vol. 443) chronic treatment of rats with THC, the major psychoactive component of marijuana, was found to induce structural changes in hippocampal neurons similar to normal aging or to the effects of glucocorticoids. Plasma corticosterone and ACTH were also increased by THC treatment. Due to similarities of THC and steroid molecular structure, it seems possible that THC a) binds to corticoid receptors and directly mimics hormonal actions or b) interferes with negative feedback of ACTH or otherwise activates the pituitary-adrenal axis, thereby enhancing endogenous hormonal effects on the hippocampus. To compare these possibilities, we studied competitive interactions of THC with hippocampal corticosteroid receptors (HCSR), and we also examined the functional ability of THC to down-regulate HCSR in adrenalectomized (ADX) rats.

Scatchard-type competition studies on hippocampal cytosol using [^{3}H]-dexamethasone (DEX) showed that 100-fold excess of THC displaced bound tracer in a lesser but parallel fashion to RU-28362 (a specific Type II agonist). Co-incubation of THC and RU failed to displace additional sites, indicating unlikely interaction of THC with Type I HCSR. Cannabadiol, a non-psychoactive cannabinoid, displaced DEX less than did THC. In another study, young ADX male rats were injected subcu. with 10 mg/kg THC daily for 14 days. Hippocampal tissue was analyzed for Type II HCSR by methods previously described (Eldridge et al, 1987, Soc Neurosci Abs). In comparison to controls given vehicle, a 28.3% down-regulation of Type II binding was seen in THC-treated rats ($p < .05$), with no change of K_d.

These results suggest that THC binds to HCSR with a lower affinity than natural corticosteroids, and that this binding can functionally regulate CSR density in hippocampus. (Supported by DA-03637)

TRANSIENT APPEARANCE OF $GABA_A$ AND BENZODIAZEPINE BINDING SITES IN BRAINSTEM NUCLEI DURING DEVELOPMENT. A. Frostholm, A. Neustadt and A. Rotter. Dept. of Pharmacol., Univ. of Calif., Irvine, CA 92717.

The embryonic and postnatal distribution of [^{3}H]muscimol and [^{3}H]flunitrazepam binding sites was studied autoradiographically in the brainstem of C57BL/6 mice. Although adult brainstem nuclei were almost devoid of [^{3}H]muscimol binding sites, high levels of grain density were distributed throughout the medulla in embryonic and early postnatal animals. The inferior olive and the nucleus of the sensory trigeminal tract were of particularly high grain density. Labeling over all medullary regions increased between embryonic day 18 and postnatal day 7, after which there was a gradual reduction in grain density throughout the brainstem. By postnatal days 14-16, the grain density over all medullary regions, including the inferior olivary and trigeminal nuclei, approached the low adult levels. As with [^{3}H]muscimol binding sites, a moderate to high level of [^{3}H]flunitrazepam labeling was uniformly distributed throughout the brainstem of neonatal mice; there was, however, no similar decrease in the overall grain density during development, but rather a steady increase to adult levels. Again, even higher grain density was observed over the trigeminal nucleus and inferior olive which was reduced to the level of other medullary regions by postnatal days 11-14.

N-ACETYL-5-METHOXYKYNURENAMINE AND MELATONIN INTERACTION WITH GABA AND DIAZEPAM RECEPTORS IN MAMMALIAN BRAIN. B.J. Mason and L.P. Niles (SPON: G.K. Smith), Department of Neurosciences, McMaster University, Hamilton, Ontario, Canada L8N 3Z5.

Pharmacological doses of melatonin enhance γ-aminobutyric acid (GABA) binding in rat brain (1,2). Melatonin's effects on GABA binding in vitro are blocked by the central benzodiazepine (BZ) receptor antagonist, Ro15-1788, indicating involvement of BZ binding sites.

Ring cleavage of melatonin by 2,3-dioxygenase in the CNS followed by the action of formamidase, produces N-acetyl-5-methoxykynurenamine (AMK). Since AMK (IC_{50} = 50-100 µM) is significantly more potent that melatonin (IC_{50} = 500 µM) in inhibiting [^{3}H]diazepam binding in synaptosomal membranes, we have examined this compound's effects on GABA binding in the rat cerebral cortex.

Binding experiments with [^{3}H]GABA ($\sim$1-750 nM) indicate that AMK (100 µM) enhances low-affinity $GABA_A$ binding with a concomitant decrease in binding affinity.

These preliminary findings support our hypothesis that the melatonin derivative, AMK, is a centrally active agent capable of modulating GABAergic activity.

TESTOSTERONE MODULATES OXYTOCIN RECEPTOR BINDING IN THE VMN OF CASTRATED MALE RATS. A.E.JOHNSON, H.COIRINI*, B.S.McEWEN AND T.R.INSEL. LCS/NIMH, Poolesville, MD 20837 and Department of Neuroendocrinology, Rockefeller University, N.Y., N.Y. 10021.

Oxytocin (OT) receptor binding is modulated by estradiol-17ß in several brain regions including the ventromedial hypothalamic nucleus (VMN) in both male and female rats (Coirini et al, in preparation). To further study steroid regulation of OT receptor binding, we examined the effect of androgen replacement in castrated male rats on OT binding with quantitative autoradiographic methods.

Adult male rats (300g) were castrated, treated one week later with either 250µg testosterone propionate (TP, N=4) or oil (N=3) for two days and killed 48hrs after the last injection. Cryostat cut brain slices (16µm) through the VMN were labeled with 5.0nM [^{3}H]OT± 5.0µM unlabeled OT or 1.0µM [Thr^4,Gly^7]-OT (a specific OT agonist) and apposed to tritium-sensitive film for two months along with plastic tritium standards. Autoradiograms were analyzed with a computer assisted densitometer (DUMAS) that converted gray levels to moles/mg tissue equivalents using the standard curve derived from tritium standards.

Results of this study show that TP increased [^{3}H]OT binding 3 to 5 fold in the ventrolateral VMN. In addition, [Thr^4,Gly^7]-OT completely displaced [^{3}H]OT binding in the VMN indicating that binding in this brain region was specific to OT receptors. Because E_2 also increases OT receptor binding in male rats (Coirini et al), it is possible that TP affects OT receptors after being converted by aromatase to E_2. Supported in part by grant numbers TW03617 (HC) and MH41256 (BMc).

EFFECTS OF DORSAL RHIZOTOMY ON NEUROKININ RECEPTOR DENSITIES IN THE RAT SPINAL CORD. K. Yashpal[1]*, T.V. Dam[1,2] and R. Quirion[1] (SPON: S. Gauthier) [1]Douglas Hospital Research Centre and Department of Psychiatry, McGill Univ., Verdun, Canada, [2]Dept. de Pharmacologie, Univ. Sherbrooke, Sherbrooke, Canada

Previous studies have indicated a loss of substance P/neurokinin 1 (NK-1) binding sites following chronic deafferentation (Brain Res. 343:268, 1985). This suggests that SP receptors are located on terminals of primary afferents in the spinal cord. However, it is not known if other NK receptor classes (NK-2, NK-3) are similarly located. In the present study, we determined the effects of unilateral dorsal rhizotomy on binding of ^{125}I-BH substance P, (2-(^{125}I)-iodohistidyl^{1})-neurokinin A and (^{125}I)-BH-eledoisin as respective radioligands for NK-1, NK-2 and NK-3 receptor subtypes. 7, 14, 21, and 28 days after a unilateral lumbosacral dorsal rhizotomy, receptor binding for the above neurokinins was evaluated using an autoradiographic method. Sections were prepared and incubated with 50pM of the different radioligands as described before (J. Neurosci. 6:2187, 1986). Preliminary results indicate a significant decrease of NK-1 sites at 7 and 14 days after rhizotomy. This is specifically seen in the dorsal horn of the spinal cord. This supports the hypothesis of a presynaptic location of certain NK receptor sites on primary afferents. (Supported by the Canadian Heart Foundation)

BINDING OF ^{125}I-SUBSTANCE P IN THE MEDIAL NUCLEUS OF THE AMYGDALA IS NOT AFFECTED BY GONADECTOMY. T.R. Akesson, P. Popper, and P. E Micevych. Dept. of Anatomy, Lab. of Neuroendocrinology, and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The medial nucleus of the amygdala (MeA) has a well established role in the processing of olfactory and endocrine information essential to reproductive function in the rat. This nucleus is a major target of gonadal steroids and contains a large population of substance P immunoreactive (sPir) cells as well as a dense plexus of sPir fiber terminals. Sex differences in the number of sPir fibers and, in males, a loss of sPir elements following castration suggest that gonadal steroids interact with sP in the MeA. The finding that this nucleus also contains a rich field of sP binding sites prompted us to test the possibility that gonadal steroids regulate sP binding. 30 µm sections through the MeA from intact and castrated males, ovariectomized females, and females receiving 50 µg estradiol benzoate 24 hours before death were used to generate autoradiographical images. Highest levels of ^{125}I-sP binding were found to be specifically localized in the posterior third of the MeA and ventral to the MeA. While the region that exhibited intense sP binding was slightly larger in males, gonadectomy in both males and females did not appear to affect either the extent or intensity of sP binding. Thus while immunohistochemical evidence suggests steroidal interaction with sP, in the MeA this interaction does not appear to involve modulation of sP binding. EVIDENCE FOR THE INVOLVEMENT OF PROTEIN KINASE C IN NEURONAL ANGIOTENSIN II RECEPTOR EXPRESSION. C.J. Kalberg*, M.K.Raizada* and C. Sumners. Dept. of Physiology, University of Florida, Gainesville, FL 32610.

Previously, we demonstrated that protein kinase C (PKC) activating phorbol esters increase [125I] Angiotensin II (Ang II) specific binding in neuronal cultures prepared from 1-day-old-rats (Sumners, C. et al., J. Neurochem. 48:1954-1961, 1987). This suggests PKC is involved in the expression of central Ang II receptors. However, phorbols have many nonspecific effects. Therefore, we used three distinct experimental approaches to substantiate the involvement of PKC in Ang II receptor expression in neuronal cultures. First, mezerein and teleocidin, two PKC activators that are chemically unrelated to phorbols, were shown to increase [125I] Ang II specific binding in a dose and time dependent manner. ED50 values for stimulation of [125I] Ang II specific binding by mezerein and teleocidin were 32 nM and 72 nM respectively. Second, the PKC antagonist H-7 was shown to significantly inhibit 0.8 uM phorbol-12-myristirate-13-acetate (TPA) stimulated increases in [125I] Ang II specific binding at doses of 50 uM, 75 uM, 100 uM, 150 uM, and 300 uM. The latter three doses of H-7 produced [125I] Ang II specific binding levels not significantly different from control levels (1% level Newman-Keuls). Thirdly, PKC downregulation by chronic phorbol ester incubations for 24 and 48 hrs prevented 0.8 uM TPA stimulation of [125I] Ang II specific binding. These results substantiate the involvement of PKC in Ang II receptor expression and suggest that certain neurotransmitters or hormones may affect central Ang II receptor numbers through modulation of PKC activity. (Supported by NIH grant NS-19441).

NEURONAL SPECIFIC SUBSTRATES FOR A GTP-PREFERRING PROTEIN-KINASE. A. Babinska*, R. McCullum* and Y.H. Ehrlich. Dept. of Psychiatry, Univ. of Vermont and The Ctr. Dev. Neurosci., CUNY/CSI, Staten Island, N.Y. 10301

GTP is a critical regulator of receptor function. Here we have characterized the endogenous substrates of a GTP-preferring protein kinase from rat brain membranes (BBRC 107:669-706). Using two-dimensional polyacrylamide gel electrophoresis it was found that in the M.W. range of 52Kd to 59Kd there are four distinct proteins (pI range 4.6-5.0) phosphorylated preferentially by GTP. Among them a protein with apparent M.W. of 53.1±0.6Kd and pI of 4.95 was phosphorylated almost exclusively by GTP (in the presence of Mn^{2+}). It was determined that this protein is not tubulin, it is enriched in synaptic plasma membranes, and present in brain but NOT in other tissues. This neuronal specific phosphoprotein was isolated from Triton-X-100 extract of brain membranes and characterized by phosphopeptide mapping. Using various concentrations of chymotrypsin, trypsin and V8-protease we identified three fragments of this protein (47.5K, 26.3K and 14.8K) that are phosphorylated by GTP greater than by ATP, and two fragments (21K and 32K) with preference for ATP. Raising antibodies which recognize specifically the sites phosphorylated preferentially by GTP will provide the tools for investigating their role in neuronal function.
Supported by NSF grant BNS85-07238.

REGULATION OF NEURONAL RECEPTOR EXPRESSION: THE TARGET CELL HYPOTHESIS. A. Rotter and A. Frostholm. Dept. of Pharmacol., Univ. of Calif., Irvine, CA 92717.

Cellular interactions regulating the expression of transmitter receptors are of considerable importance in the establishment of synaptic transmission. Based on results obtained on $GABA_A$/benzodiazepine receptors in the cerebellum of developing and neurologically mutant mice, we propose a hypothesis of neuronal receptor induction, stabilization and maintenance. We postulate that actively proliferating neuroblasts do not express transmitter receptors; these are acquired only after the cessation of cell division, during the period of cell migration. Since migrating neurons have not at this stage formed either afferent or efferent synapses, we propose that the initial induction of neurotransmitter receptor synthesis precedes, and is independent of, synaptogenesis. It is generally accepted that receptors actively turn over, thus, in order for them to be continuously expressed, the initial induction of neurotransmitter receptor synthesis must be stabilized.We suggest that the stabilization of receptor synthesis is dependent on the formation of efferent synaptic contacts with target neurons. If synapse formation with target cells fails to occur during development, the initial induction of neurotransmitter receptor synthesis is not stabilized, receptor expression remains labile and receptors are lost. Following receptor stabilization, continuous presence of the target cell is required for maintenance of receptor expression. In contrast to the role of the efferent connection, the afferent synaptic input plays no role in receptor induction, stabilization or maintenance; in most cases, in fact, it tends to down-regulate receptor number. The above hypothesis has features which may provide explanations for the phenomena of mismatches in receptor/neurotransmitter localizations and for the transient expression of receptors during CNS development. SYNERGISM BETWEEN ACTIVATED MEMBRANE RECEPTORS THAT TRIGGER THE SAME EFFECTOR MECHANISM. G.J. Christ[1,3]*, J. Goldfarb[2], A. Melman[3]*, R. Osman[4]*, and S. Maayani[1]. Departments of 1. Anesthesiology, 2. Pharmacology, 3. Physiology and Biophysics, Mount Sinai School of Medicine, CUNY, NY, NY 10029 and 4. Urology, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.

Simultaneous activation of distinct membrane receptors which are linked to the same physiological effect may result in either simple additivity, synergism, or antagonism. A steady-state model designed to predict simple additivity throughout the concentration-response curves for two agonists sharing the same effector systems was derived using the Black and Leff equations for operational agonism; equations which were originally utilized to predict the concentration-response relationship for agonists assuming a ternary (agonist-receptor-effector) complex model. Simultaneous activation of the 5-HT_2 receptor and alpha-1 adrenoceptor in the isolated rabbit aorta was assessed, and the observed dose response curves were compared to those predicted by the model for simple additivity. A robust synergism was detected at low occupancy levels. Supported by UPSH G5-34852.

A NON-LINEAR ONE-PARAMETER MODEL FOR RECEPTOR REGULATION: EQUILIBRIUM EQUATIONS AND COMPARISON WITH EXPERIMENTAL BINDING DATA. Eugene Somoza. Psychiatry Service, V.A. Medical Ctr, Cincinnati, Ohio 45220; and Lab. of Behavioral Neuroscience, Psychiatry Dept., Univ. of Cincinnati, OH 45267.

A simple non-linear one-parameter mathematical model is postulated which allows for receptor regulation. This is done by defining the association rate "constant" ka of receptor-ligand systems to be a monotonically decreasing function of receptor occupancy. The value of the parameter which governs the functional dependence of ka, to be called the regulation index, δ, is a characteristic property of a given receptor-ligand system. The value of δ can be calculated from experimental binding data along with the two classical parameters: the receptor density R and the dissociation constant K_D. Thus, according to the present model, three parameters (R, K_D, and δ) are always required to describe the interactions between receptors and their ligands. It will be shown that non-linear Scatchard plots can generally be fitted as well with this three-parameter model as they can be with the currently used model, which needs to invoke the ad hoc assumption that such non-linear plots represent the existence of several independent sites.

INTERACTIONS BETWEEN NEUROTRANSMITTERS I

46.1

STRIATAL DOPAMINE-ADENOSINE INTERACTIONS IN VIVO. P.J.Knott, D.M.Togasaki and K.L.Davis. Dept. of Psychiatry and Pharmacology, The Mount Sinai School of Medicine, New York, N.Y. 10029.

Previous work has revealed that L-DOPA increases uric acid in striatum and that there is a linear relationship between the induced striatal uric acid asymmetry and turning behavior in unilateral nigral-lesioned rats. We believe that uric acid may result from adenosine release in response to dopamine receptor interaction (Togasaki et al., Life Sci., 41, 1361, 1987).In the present study we find that uricase infusion close to the working electrode completely prevents the increase of Peak 2 in response to L-DOPA (25mg/Kg i.p.) administration. Evidence that striatal changes of uric acid result from increased adenosine release is suggested by the observation that local infusion of adenosine (1-10mM) also produced large increases in the uric acid peak. Our present data indicates that adenosine may indeed be released as a result of dopamine receptor interaction and may subserve a neuromodulatory role linked to regulation of dopaminergic activity. Accordingly, its production is greater in lesioned striatum where receptor numbers would be increased. (Supported by the Parkinson's Disease Foundation.)

MODIFIED SENSITIVITY OF RAT CORTICAL NEURONS TO BIOGENIC AMINES AFTER ABOLITION OF CORTICAL NORADRENERGIC TRANSMISSION. Jean Goyer and André Ferron. Centre de recherche en sciences neurologiques (Département de physiologie), Université de Montréal, Montréal, Canada.

We previously showed that 2 to 3 weeks following bilateral destruction of noradrenergic afferents with 6-hydroxydopamine (6-OHDA), the sensitivity of fronto-parietal neurons to microiontophoretic applications of the three biogenic amines (MA), noradrenaline (NA), dopamine (DA), and serotonin (5-HT), was increased in urethane-anesthetized rats (Soc. Neurosci. Abstr. 13: 1654, 1987). To verify whether these changes were due to the absence of NA or to other factors, we assessed the sensitivity of cortical neurons to iontophoretically applied MA after NA depletion with U-14,624 a dopamine-beta-hydroxylase inhibitor (200 mg/kg i.p. x 2 days). The responsiveness to MA was tested by measuring the charge (in nC) which induced a 50% decrease in the spontaneous firing rate. After U-14,624, neurons proved hypersensitive to both NA (1087 vs 1502 nC) and 5-HT (130 vs 974 nC), but not to DA (1197 vs 1265 nC). Thus, whereas NA and 5-HT hypersensitivities were probably due to the absence of NA, the DA hypersensitivity observed after 6-OHDA appeared imputable to other causes. In a second set of experiments, we sought to determine which types of receptors might be involved in the MA hypersensitivities. Preliminary results on NA receptors using amidephrine (AMI; α_1), clonidine (CLO; α_2) and isoproterenol (ISO; β) as specific agonists show increased responsiveness to α_1 agonist (1994 vs 2415 nC), while the responsiveness to α_2 and β receptors remains unchanged (1543 vs 1368 nC; and 661 vs 708 nC). These results suggest a synergism of action of the NA and 5-HT cortical systems that should be taken into account in the analysis of cortical monoaminergic function.

46.3

THE ROLE OF NOREPINEPHRINE IN THE SHORT-TERM DECREASE IN HIPPOCAMPAL TRYPTOPHAN HYDROXYLASE ACTIVITY INDUCED BY METHAMPHETAMINE. M. Johnson, G.R. Hanson and J.W.Gibb. Dept. Pharmacol. and Toxicol., University of Utah, Salt Lake City, UT 84112.

A single dose of methamphetamine (METH) induces a rapid and reversible decrease in brain tryptophan hydroxylase (TPH) activity. The diminution in neostriatal TPH activity can be prevented by depleting dopamine (DA) concentrations. Hippocampal TPH activity is as sensitive to the METH effect as the neostriatal enzyme although its DA content represents a fraction of the neostriatal concentration. In contrast, a significant amount of norepinephrine (NE) is stored in the hippocampus. The purpose of this study was to determine if NE participates in the short-term decline of hippocampal TPH activity induced by METH. Male Sprague-Dawley rats (200-240 g) received two doses of the dopamine-ß-hydroxylase inhibitor, U14,624 (200 mg/kg, i.p.), 18-h apart. The rats received METH (15 mg/kg, s.c.) 6 h after the second U14,624 injection, and killed 3 h later. TPH activity was determined using $^{14}CO_2$ release while NE concentrations were determined by HPLC-EC. The U14,624 treatment induced a 80% reduction in hippocampal NE concentration. Hippocampal TPH activity was unaffected by the decline in NE concentration while METH reduced the enzyme activity to 43% of control. The inhibition of NE synthesis did not alter the METH-induced decrease in TPH activity, thus suggesting that NE does not participate significantly to this decline. (Supported by USPHS DA 00869 and DA 04220)

46.4

RELEASE OF ENDOGENOUS ACETYLCHOLINE AND DOPAMINE FROM NEOSTRIATAL SLICES FROM SALINE- AND 6-HYDROXYDOPAMINE-TREATED RATS. L.M. Alcorn and M.H. Weiler. School of Pharmacy and Env. Tox. Center, Univ. of Wis., Madison, WI. 53706.

Neostriatal dopaminergic/cholinergic systems have been extensively studied (Lehmann and Langer, Neurosci., 10:1105,1983). For many of these studies, neostriatal neurotransmitter stores were prelabelled with radioisotope precursors and radioactive outflow subsequently monitored. In this study, release of endogenous acetylcholine (ACh) and dopamine (DA) was monitored in neostriatal slices from saline- and 6-hydroxydopamine (6-HDA)-treated rats. Each slice served as its own control by stimulating release of DA and ACh twice (K1 and K2) with 25mM potassium. Spontaneous release before each stimulation period and tissue content following K2 were also monitored.

ACh release (nmol/mg protein) during K1 was 0.79±0.14 and 0.84±0.15 and during K2 was 0.73±0.24 and 0.76±0.12 in control (n=5) and 6-HDA slices (n=5), respectively. ACh tissue content was also similar between both groups. In contrast, release of DA from slices of saline-treated rats was similar for both stimulation periods (K2/K1=0.95), but DA release during K1 from slices of 6-HDA-treated rats was 31% that of control, and during K2 was undetectable. The DA tissue content (n=4) was 2.35±0.62 and 0.12±0.09 nmol/mg protein (saline- and 6-HDA-treated slices, respectively). The data show that endogenous ACh release from neostriatal slice preparations is not affected by 6-HDA pretreatment. (Supported by NIH Grant AG05953).

46.5

OPPOSITE EFFECTS OF FORSKOLIN ON DOPAMINE VERSUS NOREPINEPHRINE RELEASE FROM RABBIT CAROTID BODY IN VITRO. G.-F. Cheng*, B. Dinger and S. Fidone, Dept. Physiol., Univ. of Utah, Salt Lake City, UT 84108

Previous experiments in our laboratory demonstrated that hypoxia preferentially releases dopamine (DA) over norepinephrine (NE) in the carotid body, and conversely, that nicotine preferentially releases NE over DA. The present study evaluated the effects of the adenylate cyclase activator forskolin on the stimulus evoked release (stimulus minus basal release in 100% O_2 media) of ^{3}H-DA and ^{3}H-NE (synthesized from ^{3}H-tyrosine) in superfusion media equilibrated with either 10% O_2 or media containing nicotine (50-100 uM). Evoked release was expressed as a fraction of the ^{3}H-DA or ^{3}H-NE content, respectively, and the data compared for carotid bodies incubated in the presence or absence of forskolin (10 uM). The basal release of ^{3}H-DA and ^{3}H-NE (in 100% O_2-media) was unaffected by forskolin, but the release of ^{3}H-DA evoked by 10% O_2-media was increased by 287% ($p<0.0025$). In contrast, forskolin depressed the nicotine evoked release of ^{3}H-NE by 91% ($p<0.005$). The data suggest that cyclic AMP has opposite effects on hypoxia vs. nicotine evoked release of DA and NE from the carotid body.

Supported by USPHS grants NS12636 and NS07938.

46.6

COEXISTENCE OF TYROSINE-HYDROXYLASE AND DOPAMINE-β-HYDROXYLASE IMMUNOREACTIVITIES IN TYPE I GLOMUS CELLS OF THE CAT CAROTID BODY. Z.-Z. Wang*, B. Dinger, S. Fidone and L.J. Stensaas (SPON: J.W. Woodbury), Dept. of Physiol., Univ. of Utah, Salt Lake City, UT 84108

We have recently shown that hypoxia evokes the preferential release of dopamine (DA) from rabbit carotid body and conversely, that nicotine primarily releases norepinephrine (NE), suggesting different storage sites of these substances in the chemosensory tissue. The present study was undertaken to determine whether DA and NE are synthesized (and stored) in different subpopulations of type I glomus cells. Double immunocytochemical staining was accomplished with a combination of a monoclonal antibody to tyrosine hydroxylase (TH; APAAP method; red stain) and a rabbit polyclonal antibody to dopamine-β-hydroxylase (DBH; PAP method; blue-black granules). The resulting sequence revealed red-stained cells containing blue-black granules. We observed that 98.9% of TH-stained glomus cells contained DBH, while 98.2% of DBH immunoreactive glomus cells contained TH. In view of the differential release of DA and NE, the data suggest that these two catecholamines may coexist in type I cells. Whether they are stored in different subcellular compartments (granular vesicles) will be addressed in future studies at the EM level (Supported by USPHS grants NS12636 and NS07938)

46.7

SPECIES-DEPENDENT AUGMENTATION OF RECEPTOR-MEDIATED cAMP PRODUCTION BY BACLOFEN. R.W. Scherer*, J.W. Ferkany and S.J. Enna, Nova Pharmaceutical Corp., Baltimore, Maryland 21224.

A neuromodulatory role for $GABA_B$ receptors has been suggested since the $GABA_B$ agonist baclofen (BAC) augments receptor-mediated cAMP production in rat brain slices but inhibits forskolin-stimulated second messenger production. The present study examined whether a similar role for $GABA_B$ receptors exists in other animal species.

For this study, the effects of BAC (100 μM) on cAMP production in the presence of isoproterenol (ISO; 10 μM), histamine (HIST; 100 μM), VIP (1 μM), 2-CADO (100 μM) or forskolin (5 μM) was examined in slices of guinea pig, rat and rabbit cortex. Whereas BAC alone had little or no effect on cAMP production in any of the species examined, it augmented cAMP production in response to ISO, HIST, VIP and 2-CADO in rat and rabbit but only to HIST and VIP in guinea pig. Forskolin-stimulated cAMP accumulation was inhibited in all species by BAC, although the extent of the inhibitory response varied among species from 20% for guinea pigs to 53% for rat.

These findings suggest that $GABA_B$ receptors regulate brain neurotransmitter activity in a variety of animal species. However, this interaction varies both quantitatively and qualitatively among species indicating phylogenetic differences in function of the $GABA_B$ receptor system.

46.8

PERTUSSIS TOXIN PRETREATMENT BLOCKS POSTSYNAPTIC BUT NOT PRESYNAPTIC EFFECTS OF ADENOSINE IN THE RAT HIPPOCAMPUS. Thomas V. Dunwiddie, William R. Proctor, and Bertil B. Fredholm, Dept. of Pharmacol., Univ. of Colo. Hlth. Sci. Cntr. and Veterans Administration Med. Center, Denver, CO, and Karolinska Institutet, Stockholm, Sweden

Adenosine has a variety of biological effects upon the rat hippocampus which are exerted via at least two distinct adenosine receptors. Adenosine can stimulate and inhibit adenylate cyclase activity via the A2 and A1 receptors respectively, but it has proven difficult to link either of these biochemical effects with electrophysiological responses to adenosine. In this study, we have compared the biochemical and electrophysiological responses in terms of their sensitivity to an A1 receptor selective antagonist (8-cyclopentyltheophylline; CPT), and to pertussis toxin (PTx), which can ADP-ribosylate (and inactivate) the GTP-binding protein that mediates the inhibition of adenylate cyclase activity by various receptors, including the adenosine A1 receptor.

Schild plots were used to estimate the affinity of CPT for the adenosine receptors mediating 1) inhibition of excitatory transmission in the CA1 region, 2) the inhibition of repetitive spiking following antidromic stimulation of the CA1 pyramidal neurons in low calcium medium, 3) inhibition of [^{3}H]-cAMP formation, and 4) increases in [^{3}H]-cAMP, all in the *in vitro* hippocampus. The pA_2 values were 42 nM, 45 nM, 60 nM, and 2200 nM respectively, suggesting that the first three responses are all mediated via A1 receptors, and accumulation of cAMP via an A2 receptor. Although both electrophysiological responses had A1-like pharmacology, only the effect of adenosine on low-calcium bursting (postsynaptic) response was blocked in animals pretreated with PTx. PTx pretreatment also reduced the adenosine-induced hyperpolarization of pyramidal neurons by about 95%, and depressed postsynaptic $GABA_B$-mediated responses to an equivalent extent. Since the inhibition of adenylate cyclase and the activation of a potassium conductance by adenosine are both inhibited by PTx, this suggests that the presynaptic modulatory effects of adenosine are exerted through another mechanism.

L-DOPA INDUCED CHANGES IN ENKEPHALIN AND SUBSTANCE P LEVEL IN RAT SUBJECTED TO NEONATAL DOPAMINERGIC DENERVATION. S. P. Sivam, Dept. Pharmacol. & Toxicol., Northwest Ctr. Med. Ed., Indiana Univ. Sch. Med., Gary IN 46408

Previous studies showed that lesion of dopaminergic neurons with 6-hydroxydopamine (6OHDA) during neonatal period led to an enhanced and a retarded development of Met-enkephalin (ME) and substance P (SP) systems in striatum respectively. Lesioned animals exhibited self mutilation behavior (SMB) when challenged with L-DOPA. The present study examined whether L-DOPA would modify the changes in SP and ME sytems established following neonatal lesion. Sprague-Dawley rat pups were lesioned with 6-OHDA and tested when they reached adulthood. One h after L-DOPA treatment, the animals were sacrificed; ME and SP levels were determined by radioimmunoassay. Lesioned group had an increase (+45%) in ME in striatum and a decrease (-22%) in SP level in striatum and substantia nigra. L-DOPA treatment to lesioned animals induced SMB; produced a greater decrease (-61%) in SP level than that observed with lesion alone; failed to modify the increased ME level. These results suggest that L-DOPA induced SMB is associated with a marked reduction of SP content; this has two components namely, a retarded development of SP system per se as a result of 6OHDA lesion and a depletion of remaining SP by L-DOPA presumably by enhanced release. DRAMATIC RESPONSES BY DYNORPHIN SYSTEMS OF THE BASAL GANGLIA TO COCAINE TREATMENT. G.R. Hanson, M. Johnson, L. Bush*, P. Smiley*, and J.W. Gibb. Dept. Pharmacology and Toxicology, University of Utah, Salt Lake City, Utah 84112

The effects of cocaine administration on neurochemical markers of the extrapyramidal monoaminergic systems are relatively small and of short duration. However, cocaine-induced changes in some neuropeptidergic pathways are dramatic, relatively long-lasting and likely mediated by dopaminergic mechanisms. This study reports the response of the dynorphin (Dyn) systems of the basal ganglia to multiple cocaine doses. Dyn is an opioid-related peptide associated with a striatal-nigral projection which is involved in regulation of locomotor activity. Five doses of cocaine (6-h interval) resulted in dose-dependent increases in striatal and nigral levels of Dyn A_{1-17}-like immunoreactivity (DLI). At 1 h following treatment, the maximum increases were 200-300% of control with 30 mg/kg-dose. The striatal effect was diminished by 8 h and no longer detectable by 24 h after cocaine administration. In contrast, nigral DLI levels increased to 500% of control by 8 h and were still elevated to 200% of control as long as 48 hr following treatment. The striatal effects were totally blocked by either D-1 or D-2 DA receptor blockade. In contrast, the cocaine-induced increases in nigral DLI concentration were only attenuated by either D-1 or D-2 antagonism. (This research was supported by USPHS Grant DA 00869).

RECEPTOR-SPECIFIC INTERACTIONS OF THE NIGRO-STRIATAL DOPAMINE PROJECTIONS WITH STRIATAL NEUROTENSIN SYSTEMS IN RAT BRAIN. K.M. Merchant, L. Bush, J.W. Gibb and G.R. Hanson, University of Utah, Salt Lake City, Utah 84112.

We have previously demonstrated that changes in dopaminergic activity causes dramatic alterations in the level of striatal neurotensin-like immunoreactivity (NTLI). In order to investigate the mechanisms underlying these observations, the nigro-striatal DA projections were lesioned with intra-striatal injections of 6-hydroxydopamine. Interestingly, when the pathway was destroyed by more than 85 to 90% (as judged by the residual tyrosine hydroxylase activity), the striatal NTLI level was significantly elevated. This suggests that basal activity of the nigro-striatal DA projections exerts chronic control over the activity of NT terminals in the striatum. Based on this and our earlier observations that blockade of D2 but not D1 receptors increase the striatal NTLI content, we propose that D2 receptors mediate the regulation of striatal NT systems by basal DA activity. To explore this role of D2 receptors, effects of treatments with LY 171555 (a D2-selective agonist) or SKF 38393 (a D1-selective agonist) on striatal NTLI concentrations were examined. Activation of D2 receptors decreased the striatal NTLI content whereas that of D1 receptors increased the same and when the two were combined their individual effects were nullified. Thus, D1 and D2 receptors regulate the striatal NT systems in an antagonistic manner with only the D2 receptors exerting basal control over them. (Supported by USPHS Grant 00869).

NEUROTENSIN COMPLEXES WITH DOPAMINE. D.K. Adachi*, P.W. Kalivas and J.O. Schenk (SPON: R. Abhold). Dept. of VCAPP, Wash. St. Univ., Pullman, WA 99164

The effects of neurotensin (NT) on mesolimbic dopamine (DA) transmission are paradoxical. NT appears to activate DA neurons at the level of the cell bodies, but blocks the behavioral effect of DA release in the accumbens, an axonal terminal field. Neuromedin N (NN), a peptide in the NT precursor, produced the activation of DA transmission in the cell bodies, but was ineffective at blocking the behavioral effect of DA in the accumbens. These data caused us to evaluate the possibility that a non-receptor mechanism may be responsible for the anti-dopaminergic effect of NT in the accumbens. Using molecular modeling designed to predict conformations of peptides in water, we found the structure of NT forms a highly basic pocket containing -Pro^8-Arg^9-Arg^9-Pro^{10}-, while NN did not. The basic -Arg-Arg- moiety of NT may be forming an acid-base complex with the hydroxyl groups in the catechol moiety of DA. Complexation of NT to DA in solution was measured using UV/visible spectroscopy and potential sweep voltammetry. Both techniques indicated that a complex was formed and from analysis of the shift in half-wave potential obtained from the voltammograms, the stoichiometry of complexation was 1: 1 (K_D = 3.7 X 10^{-7}). No complexation between NN and DA was observed. Thus, the complexation between DA and NT may partly underly the fact that NT has antidopaminergic qualities in vivo.

ANTICHOLINERGIC DRUGS DO NOT ALTER NEUROTENSIN CONCENTRATION IN THE NUCLEUS ACCUMBENS OR STRIATUM. B. Levant, C. Bissette, and C.B. Nemeroff, Depts. of Pharmacology and Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

Chronic treatment with typical antipsychotic drugs increases neurotensin (NT) concentration in the nucleus accumbens and striatum. In contrast, the atypical antipsychotic clozapine increases NT concentration only in the nucleus accumbens but not in the striatum. This study sought to determine whether the failure of clozapine to increase NT concentration in the striatum is due to its anticholinergic effects. Adult, male, Sprague-Dawley rats (175-200g) were injected (IP) daily for 21 days with haloperidol (1 mg/kg), atropine (20 mg/kg), atropine methyl bromide (20 mg/kg), scopolamine (2 mg/kg), or haloperidol (1 mg/kg) + atropine (20 mg/kg). NT concentrations in 7 brain regions were measured by a sensitive and specific radioimmunoassay. Haloperidol produced significant increases in NT concentration in the nucleus accumbens and anterior and posterior caudate. In contrast, atropine, atropine MeBr, and scopolamine failed to alter NT concentration in these regions. Concomitant administration of atropine with haloperidol attenuated but did not abolish the increases in NT concentration observed after haloperidol treatment. Because anticholinergic drugs alone do not alter NT concentrations, it is unlikely that the effects of clozapine on NT neurons are due to its anticholinergic properties. Supported by NIMH MH-39415.

NEUROTENSIN EVOKES THE PRODUCTION OF ENDOGENOUS DIHYDROXY PHENYLACETIC ACID (DOPAC) FROM SUPERFUSED RAT STRIATAL SLICES. L.P. Dwoskin. Dept. Pharmacol. Toxicol., Univ. Kentucky Col. Pharm., Lexington, KY 40536.

Neurotensin (NT) has been suggested to be an endogenous neuroleptic. Neuroleptics increase evoked dopamine (DA) release via blockade of D-2 DA receptors. Prior to determining if NT similarly modulates evoked DA release, it was necessary to examine the effect of NT itself. Single slices (6 mg) were superfused (1 ml/min) with Krebs' buffer. After 1 hr, 2 one-ml samples were taken to determine basal outflow. Then, NT (30 nM -10 uM) was added to the buffer and 15 samples collected. Samples received ascorbic acid oxidase and 50 ul was injected into the HPLC-EC. Detection limit was 10 pg/ml superfusate. NT, in a dose-related manner, increased the amount of DOPAC from 44 to 3800 pg/ml/mg tissue. DA was not detected. This response was not altered by adding nomifensine (10 uM), a DA uptake blocker, to the buffer from the start of superfusion. Pargyline (10 uM), a monoamine oxidase (MAO) inhibitor, included from start of superfusion decreased the basal outflow of DOPAC 86%, but surprisingly, enhanced the amount of DOPAC collected in response to NT by shifting the dose-response curve for NT to the left. One interpretation of these results is that NT releases DA from a (storage) pool which then is metabolized to DOPAC by extracellular MAO. Supported by NIMH Grant MH42934.

CHOLECYSTOKININ MODIFIES THE NEUROMODULATORY ACTION OF DOPAMINE IN NUCLEUS ACCUMBENS: ELECTROPHYSIOLOGICAL EVIDENCE. C.Y.Yim and G.J.Mogenson, Dept. of Physiology, Univ. of Western Ont., London, Ontario, Canada, N6A 5C1.

Dopamine (DA) has been shown to modulate responses of accumbens (NAcc) neurons to excitatory inputs from the amygdala (AMY). The present study investigates whether or not cholecystokinin (CCK-8), recently shown to co-exist and appears to be co-released with DA in the NAcc, modifies the modulatory action of DA in their sites of co-existence in the NAcc. Single unit recordings were made in the medial and caudal NAcc of urethan anesthetized male Wistar rats. These neurons were found to be strongly excited by AMY stimulation, as was observed before, and concurrent stimulation of the ventral tegmental area (VTA) at 10 Hz attenuated the responses, presumably due to DA release. Iontophoretic application of proglumide (PRG) at 30 nA enhanced the attenuating effect of VTA stimulation by 32-126% in 23 out of 37 neurons tested. Iontophoretic application of DA produced similar attenuation of responses to AMY stimulation in 12 NAcc neurons. The attenuation was, however, reduced by concurrent iontophoresis of CCK-8 at 20 nA (7 cells). CCK-8 by itself at 20 nA did not produce significant changes in the spontaneous activity of the neuron nor its response to AMY stimulation. These results demonstrate that exogenous as well as endogenous CCK-8 may modify the postsynaptic action of DA in the NAcc in addition to modulating its release shown in other studies. DOPAMINERGIC MODULATION OF IN VIVO GLUTAMATE RELEASE IN STRIATUM. B.K. Yamamoto and B.A. Donzanti. Dept. of Pharmacology, Northeastern Ohio Univs. Col. of Med., Rootstown, OH, 44272.

Previous in vitro evidence has shown that glutamatergic corticostriatal transmission is under presynaptic control by dopamine (DA). To further investigate the mechanism of this interaction, we have measured potassium-induced striatal glutamate release in vivo and the manner in which this is modulated by DA. Male Sprague Dawley rats (300-350 g) were anesthetized with urethane and implanted with microdialysis probes into the medial caudate. The probes were perfused with Krebs/Ringers bicarbonate buffer (pH 7.4) at a rate of 1.5 ul/min. The dialysates, containing extracellular glutamate and other amino acids, were collected at 20 min intervals and analyzed by pre-column derivatization and HPLC with electrochemical detection. After a 1 hr stable baseline period, rats were injected i.p. with the dopamine D2 agonist LY171555 (2 mg/kg) or saline and then perfused for 20 min with 80 mM KCl directly through the probe. Sampling continued for a 2 hr period. KCl increased glutamate release by 3024% above basal levels. This increase was maximal within 40 min and returned to baseline by 2 hr. Pre-treatment with LY171555 decreased KCl-induced glutamate release by 80%, i.e. to 595% above basal levels. This diminished glutamate response returned to baseline within 1 hr. Therefore, this study provides in vivo evidence that DA inhibits KCl-induced glutamate release in striatum and suggests that corticostriatal glutamate release is at least, in part, modulated by DA and the D2 receptor.

46.17

DOPAMINE MODULATION OF THE GABA PATHWAY BETWEEN THE NUCLEUS ACCUMBENS AND THE VENTRAL PALLIDUM. A.J. Bourdelais* and P.W. Kalivas (SPON: R.T. Kuczenski), Dept. of VCAPP, Washington State Univ., Pullman, WA 99164

It has been established that GABAergic neurons in the nucleus accumbens (NA) project to the ventral pallidum (VP). Also an increase in spontaneous motor activity produced by injection of dopamine (DA) agonists into the NA is prevented by pretreatment with a GABA agonist injection into the VP. This has led to the postulate that DA may be acting in the NA to inhibit GABA modulation of VP neurons. To investigate DA modulation of GABAergic pathway between the NA and VP, intracranial dialysis probes were used to simultaneously measure DA levels in the NA and GABA levels in the VP following amphetamine (AMP) administration. Rats were acutely implanted with dialysis probes, one in the NA and the other in the VP. Artificial CSF was used for dialysis. HPLC-EC was used to measure the neurotransmitter levels. By 60 min. a stable baseline was reached for both DA and GABA, 2 mg/kg AMP was then given. Samples were collected for another 120 min at 20 min intervals. The average baseline concentration of DA and GABA in the dialysate, based on four rats was 0.2 pg/ul DA in the NA and 0.06 pg/ul GABA in the VP. After AMP administration there was a maximal increase in DA, 1000% of baseline. GABA was found to be maximally decreased, 48% of baseline, by 40 min. The increase of DA in the NA and simultaneous decrease of GABA in the VP may indicate modulation of the GABA neurons in the NA by DA.

MULTIPLE EFFECTS OF DOPAMINE ON GABA EFFLUX FROM RAT STRIATUM: ROLE OF D1 AND D2 RECEPTORS AND GABA UPTAKE. S. Bernath,* D. Jackson and M. J. Zigmond, Dept. of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260

We have examined the effects of dopamine (DA) on the overflow of [^{3}H]GABA from rat striatal slices elicited by electrical field stimulation (2 Hz, 3 min). SCH 23390 (1 uM), sulpiride (1 uM), and nipecotic acid (100 uM) were used to examine the role of D1 and D2 receptors and the GABA transporter, respectively. We observed:

DA conc.	GABA overflow	blocked by
0.01 uM	+58%	SCH 23390
0.10	-28	sulpiride
10.0	+74	nipecotic acid

Amphetamine (100 uM) increased spontaneous GABA efflux (+30%); this was was not blocked by D1 or D2 antagonists, but was blocked by nipecotic acid. These results suggest that D1 and D2 receptors mediate opposing effects of DA on GABA release, that DA also can facilitate GABA release by a third mechanism, and that the high affinity GABA transport mechanism is involved in some of these processes. SELECTIVE DEPRESSION OF GABA-MEDIATED IPSPS BY SOMATOSTATIN IN AREA CA1 OF RABBIT HIPPOCAMPAL SLICES. **H.E. Scharfman and P.A. Schwartzkroin. Dept. Neurol. Surg., Univ. WA, Seattle, WA 98195.**

A subpopulation of interneurons in area CA1 of hippocampus, that contacts pyramidal cells (PCs), colocalizes the neuropeptide somatostatin(SS) and the inhibitory transmitter GABA. To investigate the significance of colocalized SS and GABA, we tested the effects of SS and GABA on 76 PCs recorded intracellularly.

SS had a potent effect on GABA-mediated IPSPs. GABAergic cells that synapse on PC somata were activated antidromically to elicit IPSPs in PCs. Pressure-ejection of SS(<1uM) at somatic synapses caused a large decrease in IPSPs (mean IPSP amplitude=41.8% of pre-SS amplitude; n=18). The effective dose of SS was less than that required to elicit changes in PC membrane potential(MP) and input resistance(R_{in}). Reversal potential of the IPSP did not change and vehicle had no effect. Stimulation of excitatory afferents that synapse on PC dendrites evoked an EPSP followed by a biphasic IPSP; when SS was ejected in the area of these dendritic synapses only the IPSP decreased(n=21). Coapplication of SS(1uM) and GABA(10mM) to PCs from double barrelled pipettes did not reveal any post-synaptic interactions of SS and GABA. The changes in MP and R_{in} produced by coapplication of SS and GABA appeared to reflect a summation of the effects elicited by separate application(n=23).

The results suggest that SS depresses release of GABA without affecting release of excitatory neurotransmitters. Since the dose required to elicit this effect is less than that necessary to change MP or R_{in} of PCs, the effect of SS on IPSPs may be more "physiologic" than direct actions of SS on PCs. Supported by NINCDS grant NS-07144.

46.20

COEXISTENCE OF GABA AND SOMATOSTATIN IN CULTURED RAT HIPPOCAMPAL NEURONS. A Legido*, J Buchhalter, S Reichlin^, M Dichter, Dept. Neurology, Graduate Hospital and the U of PA, Phila., PA 19146 and ^Dept. Medicine, Tufts Univ School of Medicine, Boston, MA.

We have examined the development of SOM in neurons in dissociated rat HC cultures and the degree with which SOM coexists with GABA. SOM was measured in culture media and cell extracts from 1 day to 8 weeks in culture. For SOM IHC, cultures were fixed with 4% paraformaldehyde (PF) and 5% DMSO, blocked with undiluted goat serum, treated with 0.2% Triton X-100, incubated with rabbit anti-SOM (1:200 in HBS) for 60 min, rinsed and incubated for 20 min with rhodamine-conjugated goat antirabbit IG (R-GARIG, 1:100 in HBS). For co-localization studies, cultures were fixed with 2% PF/0.1% glutaraldehyde, and then incubated with monoclonal mouse anti-SOM (1:100 in HBS) (MRC Regulatory Peptide Group of Canada) for 60 min, fluorescein-conjugated goat anti-mouse IG (1:100 in HBS) for 20 min, rabbit anti-GABA (1:50 in HBS) (Chemicon) for 60 min, and R-GARIG (1:100 in HBS) for 20 min. No staining occurred if the first antibody was omitted or adsorbed with antigen, or, during costaining, if the "opposite" second antibody was used. Staining patterns for SOM and GABA were quite different.

Levels of SOM progressively increased from undetectable to over 2000 pg per 35 mm dish in cells and media by 3-4 weeks in culture. At 3 weeks, approximately 11% of the neurons stained for SOM; staining was prominant in a perinuclear distribution, but could also be localized to processes with varicosities. After treatment with cochicine (100nM for 15 hours), the whole soma and proximal processes were stained. SOM was noted in pyramidal, bipolar and multipolar neurons. When neurons were stained for both SOM and GABA, 62 of 99 neurons staining for SOM also stained positively for GABA. These included bipolar, pyramidal, and multipolar neurons. Of 180 neurons staining for GABA, 62 (34%) were also positive for SOM.

Thus, a subpopulation of HC neurons in culture synthesize, store and secrete SOM and many of these also contain GABA. The coexistence of SOM and GABA suggests a functional relationship, but the nature of this has yet to be determined.

SPROUTING AND SPROUTING MECHANISMS I

47.1

NMDA PROMOTES BRANCHING, MK801 STIMULATES ELONGATION OF DENTATE GRANULE NEURONS. G.J. Brewer and C.W. Cotman†, Dept. of Med. Microbiology/Immunology, Southern Illinois Univ. Sch. of Med., Springfield, IL 62794-9230. †Dept. of Psychobiology, Univ. of California, Irvine, CA 92717.

During development in the central nervous system, recent data suggests a modulatory role of the NMDA receptor. The voltage-dependence of the NMDA receptor makes it activity dependent. As glutamate acts directly on this receptor, neuronal fiber elongation and synaptogenesis could both be regulated by synaptic transmission involving NMDA receptors. A direct test of these concepts is possible with the development of a serum-free defined culture medium that supports the growth of central neurons at low density. The dentate gyrus was dissected from 4 day old neonatal rats. Isolated cells were plated at low density (15,000 cells/cm^2) onto glass coverslips. In the continuous presence of 20 µM NMDA or 25 µM glutamate, abundant fine branches were apparent after 6 days in culture. Branching appeared to be specifically stimulated by the action of glutamate on the NMDA receptor because the high levels of branching were not observed upon depolarization with 25 mM KCl. The specific inhibitor of the NMDA receptor, MK801 dramatically reduced branch points almost 75%, and increased the longest neurite mean length to 350 µm, 2.5 times that for neurons treated with NMDA alone. Thus, neurite extension and branching appear to be reciprocally controlled by the NMDA receptor on dentate granule neurons in culture. This suggests that the NMDA receptor may provide the signal to induce localized branching, initiate synaptogenesis and thereby establish experience-dependent circuitries. Supported by NIH MH19691 to C.W.C. and Central Research Committee of SIUSM to G.J.B.

47.2

INTRAVENTRICULAR INFUSION OF NGF IN THE RAT RESULTS IN REDUCED SYMPATHOHIPPOCAMPAL SPROUTING. B.N. Saffran* and K.A. Crutcher. (SPON: G.C. Schoenwolf) Department of Neurosurgery, University of Cincinnati School of Medicine, Cincinnati, OH 45267

Intraventricular administration of NGF does not elicit sympathohippocampal sprouting, although it enhances the innervation of the extracerebral vasculature (Anat. Rec. 220:4, 1988). Since NGF increases the sympathetic innervation of normal targets, we asked whether the anomalous sympathetic projection to the hippocampus, which arises following septal denervation, would be similarly affected by intraventricular NGF infusions. Animals with a medial septal lesion received either ß NGF or cytochrome C in the right lateral ventricle through cannulae connected to an osmotic minipump. Solution was delivered at an approximate rate of 0.5 µl per hour for two weeks beginning two or four weeks after the lesion. NGF was measured using a two-site ELISA (reagents kindly provided by W.C. Mobley, UCSF), and the sprouting quantified by counting sympathetic axons between the blades of the dentate gyrus. The intensity of catecholamine fluorescence around the middle cerebral artery was quantified using a microspectrophotometer in 9 vehicle and 19 NGF-injected animals. The average fluorescence intensity in NGF-injected animals was twice that of vehicle-injected rats ($p<.01$); however, animals which received NGF for two weeks beginning two weeks after a septal lesion did not exhibit sympathetic ingrowth (7 of 7), whereas all vehicle-injected animals exhibited normal sprouting (6 of 6). Animals in which NGF was administered for two weeks, beginning four weeks after a septal lesion, did exhibit sprouting (7 of 7), albeit much less than controls. Interestingly, animals receiving NGF for two weeks, beginning four weeks after a septal lesion showed less sprouting than four-week controls suggesting that the sympathohippocampal fibers are retracting in response to NGF infusion. (Supported by NIH # NS 17131)

47.3

DEGENERATION AND REGENERATION IN THE OUTER MOLECULAR LAYER OF THE DENTATE GYRUS AFTER PERFORANT PATH LESIONS: ROLE OF ASTROCYTES, MICROGLIA AND INTERLEUKIN-1. A.M. Fagan*, R. Robertson* and F.H. Gage (SPON: A. MILLER). Dept. of Neurosciences, UCSD School of Medicine, La Jolla, CA 92093.

Damage to the perforant path (PP) results in sprouting of cholinergic fibers from the inner molecular zone of the dentate gyrus (DG) to replace those in the deafferented outer molecular zone. Concommitant with this sprouting is a dramatic astroglial response within this same region, suggesting a role of astrocytes in mediating the sprouting, perhaps via secretion of trophic factors. The present study is concerned with identifying the stimuli responsible for eliciting the astroglial response.

In vitro studies have shown that reactive microglia produce Interleukin-1 (IL-1), and that this molecule stimulates astrocyte proliferation. In the present experiment adult rats were sacrificed at various time points after PP lesions. Brain tissue was stained with antibodies recognizing astrocytes (GFAP), microglia (OX-42), and IL-1, as well as acetylcholinesterase (AChE) histochemistry. Cells immunoreactive with OX-42 and exhibiting the morphology of microglia are observed in the outer molecular zone of the DG within the first few days post-lesion. Cells similar in morphology and immunopositive for IL-1 are also seen in this same region at these times. However, GFAP immunoreactivity in the outer zone does not reach its maximum until a later time point. This time course of events supports the hypothesis that microglia and their ability to secrete IL-1 are important stimuli for the astroglial response observed in the DG after PP lesions.

INFLUENCE OF SUSPENSION HYPODYNAMIA ON THE FUNCTIONAL RESPONSES OF RAT PLANTARIS TO PARTIAL DENERVATION. R.N. Michel and P.F. Gardiner, Sciences de l'activité physique, Université de Montréal, Québec, Canada, H3C 3J7.

A functional index of neural adaptability is the capacity of motoneurons to extend and establish supernumerary contacts with neighbouring denervated muscle fibers. This study was conducted to gauge this response in rat plantaris muscles (P) subjected to decreased mechanical loading (suspension hypodynamia) resulting from hindlimb suspension. Three weeks of unweighting decreased P relative weight (26%), X-sectional area (19%), and absolute (32%) and relative (17%) tetanic tension (Po). In a separate group of animals which had undergone 2 weeks of unweighting, 3/4 of the P fibers were denervated by cutting radicular nerve L4. Contractile responses were obtained via sciatic nerve stimulation (sprouting motor units residing in L5) 7 days post-lesion, and the results compared to a weightbearing group which had undergone this same procedure. Partial denervation decreased P relative weight (15%), X-sectional area (19%), Pt (53%), and Po N/cm^2 (58%), in weightbearing (PD) and suspended (PDSUS) muscles to a similar extent. Decreases in Po as a result of partial denervation were smaller in PDSUS muscles. Our results suggest that neuromuscular adaptations occurring in response to mechanical unloading favor the functional recovery from a partial denervation lesion. This condition may be more conducive to optimal motoneuron sprouting. (Supported by NSERC Canada)

A SINGLE LOCUS MUTATION INCREASES CHOLINERGIC AXON TERMINALS INNERVATING MOUSE HIPPOCAMPAL DENTATE NEURONS. J.L. Noebels and N.W. Kowall[1] Developmental Neurogenetics Laboratory, Section of Neurophysiology, Dept. of Neurology and Inst. of Molecular Genetics, Baylor College of Medicine, Houston, Texas 77030, and [1]Dept. of Neurology, Massachusetts General Hospital, Boston, Massachusetts 02114.

Mutant mouse mocha (recessive, chr. 10) expresses an abnormally persistent synchronization of hippocampal and neocortical neurons, resulting in prolongation of the usual brief bursts of 6-7 Hz theta rhythms into virtually exclusive theta wave discharge in the behaving mouse. Electrogenesis of this specific frequency of atropine-sensitive hippocampal activity is modulated by a cholinergic synaptic projection to dentate granule cells and CA pyramidal neurons from the medial septal nucleus. We now find a gene-linked cholinergic hyperinnervation of the dentate granule cells in the mocha hippocampus that may directly account for the electrophysiological expression of the hypersynchronous mutant EEG phenotype.

Brains of 4 adult mh/mh mice stained for acetylcholinesterase were compared with 4 age-matched homozygous mice wild type at the mocha locus. Regional survey of major forebrain targets of limbic and ascending tegmental cholinesterase-positive pathways revealed uniformly increased laminar staining density of terminals bordering the dentate granule cell layer. No intensification of fiber tracts in the parent diagonal band and neurons of the medial septal nucleus was discerned. The potential of the septal Ach projection for reactive overgrowth following injury is known, however no pathology which might provoke an axonal sprouting reaction has yet been observed. This inherited structural error in hippocampal synaptic organization may represent a direct gene-linked action on cholinergic terminal neurogenesis.

Unilateral Hypothalamic Lesion Results in Changes in Size and Vasopressin Immunoreactivity in Rat Neural Lobe. J.A. Watt* and C.M. Paden, Dept. of Biology, Montana State University, Bozeman, Montana 59717.

Sprouting of vasopressinergic axons has been shown to occur following transection of the pituitary stalk or lesion of the paraventricular nucleus in adrenalectomized animals. In order to further investigate the plasticity of magnocellular neurosecretory efferents of both the supraoptic and paraventricular nuclei, we have induced partial denervation of the neural lobe (NL) using unilateral knife-cuts of the hypothalamo-neurohypophysial tract. Animals were sacrificed 10, 20 and 30 days post-surgery, and coronal sectons of NL were prepared for immunohistochemical localization of vasopressin. NL size and staining densities were measured by digital image analysis. A significant change in the size of the NL was observed, with the greatest reduction (47%) occurring in the 10 day post-surgical group. A trend toward recovery of NL cross-sectional area was apparent at later times, with the 20 and 30 day groups showing 30% and 17% reductions from control values, respectively. A decrease in the density of vasopressin immunoreactivity in the NL was also observed in all groups, but this was statistically significant only at 10 days post-surgery. Further immunocytochemical and ultrastructural studies are in progress. Rabbit anti-vasopressin sera was the generous gift of Dr. G. Nilaver. This work was supported by NIH grant NS23642.

CHANGES IN THE IMMUNOLOCALIZATION OF THE GROWTH-AND PLASTICITY-ASSOCIATED PROTEIN GAP-43 DURING LESION-INDUCED SPROUTING IN THE RAT DENTATE GYRUS. J.J. Norden, R. Woltjer* and O. Steward. Dept. of Cell Biology, Vanderbilt School of Medicine, Nashville, TN 37232, and Dept. of Neuroscience, U. of Virginia, Charlottesville, VA 22908.

Growth-associated protein-43 (GAP-43) is a fast-axonally transported phosphoprotein whose synthesis and transport appear to be selectively enhanced during periods of axon growth. The phosphorylation state of this protein has also been linked to axon growth and to synaptic plasticity during long-term potentiation in the hippocampus. In an effort to determine if GAP-43 is associated with other forms of synaptic plasticity, we have used LM immunocytochemical methods to examine any change in GAP-43 immunolabeling which occurs during lesion-induced sprouting in the dentate gyrus. To induce collateral sprouting, the entorhinal cortex on one side was lesioned electrolytically or by aspiration in adult male Sprague-Dawley rats, and the ABC immunoperoxidase method was used to localize GAP-43 antigenic sites. In normal animals, GAP-43 immunolabeling is laminar within the dentate molecular layer, with the inner one-third the most intensely immunoreactive and the outer two-thirds moderately immunoreactive. By 6-8 days following entorhinal cortex lesions, a dense band of GAP-43 immunoreactivity appears in the outer denervated zone, indicating that sprouting terminals, which are known to be proliferating at this time, are rich in GAP-43. This is the first identification of a specific presynaptic protein whose expression is correlated with collateral sprouting. Supported by Grant RR05424 to J.J.N.

PROGESTERONE INFLUENCES HIPPOCAMPAL PLASTICITY: Morse, J.K., Scheff, S.W., and DeKosky, S.T. Depts. Anatomy and Neurology, Lexington VA and Sanders-Brown Research Center on Aging, Univ. of Kentucky, Lexington, KY 40536

We have previously reported that there is a sexually dimorphic effect of glucocorticoids on Hippocampal lesion-induced fiber outgrowth. Ovariectomy leads to a decrease in fiber outgrowth while adrenalectomy leads to an increase in the reactive response in female rats. The present study has extended our research of steroid interaction with the mechanisms of reactive outgrowth.

Sixty day female Sprague-Dawely rats were ovariectomized and were exposed to replacement therapy of estrogen and/or progesterone via silastic capsule implants. Unilateral entorhinal cortex ablation was performed on all animals 7 days following surgery. Capsules were implanted on day of entorhinal cortex lesion. Hippocampal commissural-associational reactive outgrowtyh was assessed 15 days later.

The results suggest that progesterone was able to ameliorate the decrease in reactive fiber outgrowth seen following ovariectomy.

47.9

THE RELATIONSHIP OF BEHAVIOUR AND MORPHOLOGY FOLLOWING EARLY LESIONS IN RATS. R. L. Ladowsky, B. Kolb, and R. Gibb* University of Lethbridge, Alberta, Canada.

In infant rats neocortical lesions produce decreases in cortical thickness and changes in cell morphology that may be related to behaviour. It has previously been reported that recovery of function may be due to increased dendritic arborization. The present study supports these results and suggests that concomitant decreases in cortical thickness may also affect behaviour. Rats were given bilateral lesions of either temporal (T) or visual (V) cortex at 5 or 90 days. Several behaviours, including grooming and spatial navigation, were studied and after sacrifice the brains were processed for Golgi-Cox. The thickness of frontal and parietal cortex was measured and layer II/III pyramidal cells were drawn from these areas. Group V had significantly more basilar dendrites than group T ($p<.01$). Since group V showed recovery on a test of spatial navigation and group T did not, this recovery may be related to increased arborization of basilar dendrites. Both lesion groups showed significant reductions in the thickness of parietal cortex ($p<.05$), and many rats also showed reductions of frontal cortex. As the thickness of frontal cortex decreased, the length of grooming sequences decreased significantly in both group T ($r=.85$) and group V ($r=.83$). It therefore appears that both dendritic arborization and cortical thickness affect behaviour in rats with neonatal lesions.

47.10

PARACHLORAMPHETAMINE LESIONS OF THE DORSAL RAPHE PROJECTION TO THE AREA DENTATA DO NOT INDUCE SEROTONERGIC SPROUTING. J. Daugherty, B. Majidi* and J.H. Haring. Dept. of Anat. & Neurobiol., St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Dorsal (DRN) and median (MRN) raphe nuclei provide serotonergic (5HT) innervation to the molecular layer (ML) and hilar region (HR), respectively, of the area dentata (AD). We have reported (Soc. Neurosci. Abstr. 13:1595) that lesions of the MRN induce a proliferation and migration of remaining DRN axons from the ML to the HR. The present study asked whether selective lesions of DRN afferents to the ML would elicit sprouting by MRN fibers. Systemic injections of parachloroamphetamine (PCA; Soc. Neurosci. Abstr. 13:907) were used to selectively ablate DRN projections to the AD. Animals were studied using 5HT immunocytochemistry. Two wks after PCA treatment, the 5HT plexus of the ML appeared to be diminished. Hyperchromic, swollen 5HT axons were seen suggesting degeneration of 5HT fibers in the ML. The hilar 5HT plexus was essentially normal. Six wks after PCA injection, the 5HT plexus was unchanged except that presumptive degenerating 5HT axons were not present. Unlike the proliferation of 5HT fibers 6 wks after MRN lesion, the morphology of the remaining 5HT axons appeared normal. Thus removal of the 5HT projection to the ML was not sufficient to induce sprouting of the hilar 5HT plexus. Biochemical studies are being conducted to verify this result. Support: USPHS grant NS25752.

ASTROCYTIC RESPONSE TO A SMALL LOSS OF SYNAPSES. J. Wells, D.G. Wells*, and B.P. Vietje*. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

In response to extensive denervation astrocytes typically become reactive, change morphology, multiply and migrate into the area of degeneration. A different astrocytic response is described following lesions in the dorsal column nuclei (DCN) which led to a loss of only 3% of the total number of synapses in the ventral posterolateral nucleus (VPL). In order to describe the reaction of astrocytes over the time course of recovery, antibodies to the astrocytic proteins S-100 and glial fibrillary acidic protein (GFAP) were immunocytochemically localized in VPL. Since the projection of the DCN to VPL is entirely contralateral, the VPL containing the degeneration could be compared to the normal VPL on the opposite side in the same animal. When GFAP was present, it was colocalized with S-100. GFAP immunoreactivity began to increase in the first week after the lesion and was greatly increased by 10 days which is consistant with existing observations. However, there was no increase in the number of astrocytes containing S-100 at any time point, nor was there a change in astrocytic morphology. The increase in GFAP lasted for as long as 10 months even though the neuropil in VPL had recovered by 50 days indicating that the GFAP increase is not correlated in time with the re-establishment of synapses. We suggest that recovery after quantitatively small denervation may have different characteristics than those previously described.

47.12

AGE-RELATED REMODELING OF GAD-POSITIVE ELEMENTS IN DEAFFERENTED PIRIFORM CORTEX. N.A. Nousek-Goebl,* L.E. Westrum, and J.-Y. Wu[1] (SPON: A. Bunt-Milam). Depts. Neurol. Surg. and Biol. Struct., Univ. of Washington, Seattle, WA 98195; [1]Dept. Physiol., Penn State Univ., Hershey, PA 17033.

Olfactory bulb (OB) removal has been shown to result in plasticity in piriform cortex that is age-dependent. We are studying this phenomenon using immuno-electron microscopy of GAD reactivity at selected postnatal ages and in adults with emphasis here on short survival times. Normally GAD-labeled terminals form type II, symmetric contacts onto unlabeled dendrites and GAD labeled dendrites receive type I, asymmetric contacts from unlabeled terminals. The OB lesion results in degenerating terminals with type I contacts onto unlabeled and GAD-labeled dendrites. Type I postsynaptic sites are frequently seen partially or entirely devoid of degenerated terminals and may be apposed by normal unlabeled and GAD-positive terminals. GAD-labeled terminals now form asymmetric type I contacts with unlabeled and with GAD-labeled dendrites. The findings are most common in the younger subjects. The results provide new information about the connectivity of the GABA system in this area and also suggest a major role for this system in lesion-induced, age-related remodeling. ROBUST PROLIFERATION OF SYMPATHETIC INGROWTH AXONS IN DEVELOPING RAT HIPPOCAMPUS, R. M. Booze, Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27103.

The capacity of the developing CNS to exhibit axonal migration and growth is great in comparison to the mature CNS. A model of neural plasticity in the adult and aging hippocampus, sympathetic ingrowth, was studied to determine the extent of axonal growth in early development.

Five-day-old Long-Evans rat pups were anesthetized and the septal region removed by aspiration. At 30 days of age, the deafferented hippocampus was processed for identification of sympathetic axons and cholinergic markers to verify the extent of the lesion. Quantitation of sympathetic axons in the hippocampus revealed extensive axonal proliferation. The sympathetic axons were localized to the dentate hilus subgranular layer and in the mossy fiber layer of hippocampal area CA3.

These results indicate (1) sympathetic ingrowth is a robust phenomenon in early hippocampal development, (2) CNS maturation modulates sympathetic ingrowth, and (3) sympathetic ingrowth is a useful model for studying CNS maturation and neural plasticity.

ALTERED SLOW AXONAL TRANSPORT IN OPTIC NERVE OF SHIVERER MUTANT MICE. S. de Waegh* and S.T.Brady. Dept. of Cell Biol., Univ. of Texas Southwestern Med. Ctr.,Dallas, TX 75235.

Previous studies in slow axonal transport in the myelin deficient Trembler mouse revealed significant differences in the composition and rates of transport of the cytoskeleton proteins. In Trembler peripheral nerve, reduced axonal caliber and poor myelination correlates with a decrease in the rate of transport of neurofilament proteins and brain spectrin. The amount of tubulin transported as part of slow component b is increased by 40 % in the Trembler compared to the normal. Differences exist between myelination in the central and in the peripheral nervous system including the existence of two types of myelin producing cells, oligodendrocytes in the CNS and Schwann cells in the PNS and differences in the structure of the node of Ranvier. In light of these differences, we evaluated the effects of profound abnormalities in the myelin on slow axonal transport of cytoskeleton proteins in the CNS. In the Shiverer mutation the lack of myelin basic protein affects myelin compaction in the central nervous system but not in the peripheral nervous system, resulting in distinctive tremors, convulsions and early death. We analyzed slow axonal transport in the optic nerve of the Shiverer mice (provided by C.Readhead and L.Hood), by injecting 0.4 mCi of ^{35}S-methionine in the eye. Seven to 18 days after the injection, the transport was then analyzed by SDS-PAGE, fluorography and segmental analysis. Interestingly, our preliminary results indicated an increase in the rates of transport of neurofilament and tubulin when compared to the rates in control C57Bl/6N mice. It thus appears that a defect in the myelin producing cells affects slow axonal transport in the CNS in a different manner than in the PNS. The availability of transgenic Shiverer mice homozygous for MBP should permit us to analyze if restoring a normal compacted myelin in the CNS will reestablish normal rates for slow axonal transport of cytoskeleton proteins in the CNS.

PATCH-CLAMP STUDIES ON MYELIN-DEFICIENT SCHWANN CELLS FROM MUTANT TREMBLER MICE. S.Y. Chiu. Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

Recent studies in our laboratories have shown a relation between ion channels and myelinogenic behavior of Schwann cells in the normal adult mammalian PNS; neuronal-like ion channels are detectable only on the non-myelin type, but not on the myelinating type (Chiu, 1987, J. Physiol. 386, 181-203). We have now extended these studies to Schwann cells with genetically abnormal myelinogenic behavior. In the mutant Trembler mice, the myelinating Schwann cells fail to produce sufficient myelin in the presence of apparently normal axons. Axon-associated myelinating Schwann cells were acutely isolated from normal and Trembler mice (age 1-3 months) as described previously (Chiu, 1987). With KCl-filled pipettes, whole-cell recordings made at the cell body of Trembler Schwann cells revealed a large outward non-inactivating current (range 609-1781 pA at 105 mV depolarizations, mean 1157 $\pm$ 191 pA (n=13)) which resembled the delayed rectifying potassium current seen in excitable membranes. This outward current appeared to be normally "down-regulated"; whole-cell recordings in normal myelinating cells showed little or no outward currents. Cell-attached recordings in Trembler with KCl-filled pipettes revealed single *inward* current activities (single channel conductance about 34 pS, n=2) at potentials hyperpolarized relative to the resting potential.

The Trembler mice offer a unique system to examine dysregulation of ion channels and of myelinogenic behavior in genetically abnormal Schwann cells.

DO ASTROCYTES CAUSE THE MYELIN DEFICIENCY IN THE mdr MUTANT? J. Rosenbluth, M. Hasegawa* and R. Schiff*. Depts. of Physiology & Rehab. Medicine, N.Y.U. School of Medicine, New York, N.Y. 10016.

The CNS of myelin-deficient rats (mdr) contains small amounts of rudimentary myelin, which is often infiltrated by astrocyte processes. Immunocytochemical studies using monoclonal antibodies to GFAP show increased astrocyte staining in the lateral columns of the mdr spinal cord. These observations suggest the possibility of a defect in the astrocytes of this mutant that leads to their proliferation and also causes myelin deficiency by either inhibiting its formation or breaking it down after formation. To test this hypothesis, fragments of spinal cord from normal rat embryos (E15-E18) were transplanted into the dorsal columns of 7-13 d. mdr pups. 11 d. later, foci of thin, normal-looking myelin were found in host fiber tracts, in some cases remote from the transplant. At 16 d.,we found foci of thicker myelin (up to 19 layers) with no signs of breakdown or infiltration by astrocyte processes. These results show that normal myelin can form in the environment of the mdr CNS after transplantation of normal spinal cord fragments and do not support a primary role for astrocytes in the myelin deficiency. Supported by the NIH and NMSS.

A TRANSGENIC MOUSE WITH A MYELIN DEFECT. A. Privat*[1], M. Mondain*[1], F. Sandillon*[1] and M. Rassoulzadegan*[2] (SPON: M.C. Calvet) [1]Neurobiologie du Développement, LP8402 CNRS U.249 INSERM. Institut de Biologie, 34060 Montpellier France. [2]Centre de Biochimie, LP 7300 CNRS, 06034 Nice, France.

Transgenic mice were obtained by injection of the plasmid pP$_4$LT$_1$ coding for the polyoma T antigen (Nature 300, 713-18.1982). Upon clinical inspection, these mice appeared to develop a tremor during the first post-natal month. Microscopic analysis disclosed a paucity of myelin in the central nervous system, whereas the peripheral nervous system appeared normal. Electron microscopic examination of spinal cord, cerebellum and forebrain has shown in the white matter of adult animals a drastic reduction of the thickness of myelin sheaths, and even the absence of compact myelin around large axons, which are thus invested by one or two layers of oligodendrocyte cytoplasm. Oligodendrocytes appeared generally immature, with a low nuclear and cytoplasmic density, and a paucity of organelles. Conversely, myelinated tracts coursing in the grey matter appeared less affected. Myelin thickness was normal in dorsal and ventral roots of the spinal cord. Immunocytochemical detection of CNPase disclosed a marked increase of white matter immunoreactivity versus controls due to loose myelin, whereas IR oligodendrocytes of the grey matter appeared immature. GFAP immunocytochemistry detected an intense gliotic reaction in both white and grey matter of CNS. (supported by IRME)

DEVELOPMENT OF MYELIN AND OLIGODENDROCYTE ABNORMALITIES IN CAPRINE β-MANNOSIDOSIS. **K. L. Lovell. Dept. Pathology, Mich. State Univ., East Lansing, MI 48824.**

β-Mannosidosis, a genetic dysmyelinating disorder in goats, is associated with a deficiency of lysosomal β-mannosidase activity and tissue accumulation of oligosaccharides in lysosomal storage vacuoles. The myelin deficit shows substantial variation, consistent among all animals, throughout the nervous system. The present study compares the development of myelin and oligodendrocyte abnormalities in optic nerve and corpus callosum, regions which show different extents of deficits and which undergo myelination at different time periods. The diameters and density of myelinated axons and the density and appearance of glial cells were analyzed in affected and control animals at the following ages: 115/150 days gestation, 124/150 days gestation, 2-4 days postnatal and 3-4 weeks postnatal. In optic nerve, the density of myelinated axons in affected goats was 20-25% of that in control goats at all ages, while in corpus callosum, the myelinated axon density in affected animals was about 5% of the control value. In all postnatal animals in both regions, the mean diameter of myelinated axons in affected animals was substantially larger than the corresponding control value. The number of oligodendrocytes was decreased in affected animals, and dark vacuolated cytoplasm was common. These results help define the nature and timing of defects associated with myelin deficits in caprine β-mannosidosis. Supported by NS20254 to K.L.L. and by NS16886 to M.Z. Jones.

IMPAIRED EXPRESSION OF GLYCEROL PHOSPHATE DEHYDROGENASE AND OTHER OLIGODENDROCYTE MARKERS IN THE MYELIN DEFICIENT MUTANT RAT. M.N. Gordon, M.A. Espinosa de los Monteros*, S. Kumar* and J. de Vellis, Mental Retardation Research Center and Dept. of Anatomy, UCLA Medical School, Los Angeles, CA 90024-1759, USA

Oligodendrocyte differentiation and myelinogenesis are characterized by the sequential and coordinate expression of marker proteins. We have explored the temporal pattern of development of oligodendrocyte-specific marker proteins using immunohistochemistry in the sex-linked myelin deficient (md) rat mutant, which is characterized by a lack of CNS myelin. The number of oligodendrocytes containing glycerol phosphate dehydrogenase (GPDH)-like immunoreactivity is reduced in mutant rats, and in general these cells appear morphologically less complex with shorter processes. Reduced expression of transferrin, galactocerebroside, myelin basic protein and proteolipid protein are also observed. Expression of neuronal and astrocyte markers are largely unaffected. We have also observed reduced expression of these oligodendrocyte markers at the mRNA level by RNA blot hybridization (Kumar et. al., J Neurosci Res, in press). Although an abnormality in the PLP gene analogous to the mutation in the jimpy mouse is suspected in the md rat, these findings document profound deficits in many oligodendrocyte gene products. Supported by HD06576, HD07228, HD07032 and DOE Contract DE-FC03-87-ER60615.

DEVELOPMENT OF OLIGODENDROCYTE SPECIFIC MARKERS IN CELL CULTURES FROM THE MYELIN DEFICIENT MUTANT RAT. M.A. Espinosa de los Monteros*, M.N. Gordon, S. Kumar* and J. de Vellis, Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

Oligodendroglial cell development proceeds through distinct stages before myelin formation. The myelin deficient (md) rat mutant lacks myelin in the CNS and fails to express the developmental increase in galactocerebroside (GC), glycerol phosphate dehydrogenase (GPDH), myelin basic protein (MBP) and proteolipid protein (PLP) as previously detected by immunohistochemistry of tissue sections and by RNA blot hybridization. Newborn male rat brains from md carrier mothers were cultured individually on glass coverslips in Waymouth medium supplemented with 10% calf serum. Immunostaining of cultures prepared from affected md rats revealed a decreased number of oligodendroglial cells at all time points ranging from 5-19 days in vitro, compared to control cultures. However, the sequential pattern of marker appearance was preserved, resulting in delayed, but demonstrable, expression of oligodendrocyte markers, including transferrin, GC, MBP and PLP. These observations suggest that at early stages of oligodendrocyte differentiation in vivo, the progenitor cells or young oligodendrocytes are not able to survive, resulting in a diminished number of oligodendrocytes. In tissue culture, these cells are able to survive, giving rise to a new population of healthy oligodendrocytes which express several myelin markers. Supported by NICHD and DOE.

LOCALIZATION OF NILE GP AND MBP IN ADULT BRAIN OF NORMAL AND HYPOMYELINATING MOUSE MUTANTS.
E. Trenkner. Dept. of Pathology., Columbia University College of Physicians and Surgeons, New York, NY 10032.

Several glycoproteins have been attributed with the ability to modulate and regulate cell contacts during development of the nervous system. This study analyzes the expression of one of these molecules, the NILE GP/L1/Ng CAM epitope, in its relation to myelin basic protein (MBP) in normal and myelin deficient mutants.

The immunochemical localization of NILE-GP epitope in adult brain appears to vary with fixation and processing procedures and thus in its proposed functional roles. We demonstrate here, using immunochemical localization in Bouin's fixed paraffin sections of adult mouse brain and sciatic nerve of normal and myelin deficient mutants, that: 1. NILE GP is confined to presumptive myelinated fiber tracts in adult brain and sciatic nerve, but is expressed independently of MBP at early developmental stages; 2. NILE GP and MBP are coexpressed in normal mice and show the same abberant pattern in the myelin deficient mutants jimpy, quaking and shiverer (shi); 3. When the MBP gene is introduced into shi[1] (kindly provided by Dr. R.L. Sidman) not only MBP but also NILE GP is expressed in the normal pattern on myelinated axons, suggesting a coregulation of NILE GP and MBP and thus a role of NILE GP during myelination.

48.9

MYELIN CONTENT INCREASED IN TRANSGENIC MICE PRODUCING ELEVATED LEVELS OF INSULIN-LIKE GROWTH FACTOR-1 (IGF-1). M. J. Carson +*, R. R. Behringer §*, L. S. Mathews#*, R. D. Palmiter#*, R. L. Brinster §*, and F. A. McMorris+. +Wistar Institute, Phila.,PA 19104; §School of Vet. Med., U. of PA, Phila.,PA 19104; & #Dept Biochem. and Howard Hughes Inst, U. of WA, Seattle, WA 98195.

Transgenic (Tg) mice carrying a mouse metallothionein I promoter/human IGF-1 cDNA (MT/IGF-1) gene construct have higher levels of IGF-1 in serum and in brain than normal mice (1.5 and 2-fold respectively) (L.Mathews, ms. in prep). Because IGF-1 induces the development of oligodendrocytes *in vitro* (McMorris et al., PNAS *83* :822), we compared brain weight and myelin content of Tg mice with that of non-Tg littermate controls. Brain weights of Tg mice were 10-14% higher than their non-Tg littermates by postnatal day 15, and 55-65% higher by day 55. This increase in brain weight is due to both hypertrophy and hyperplasia. At day 15, the relative myelin content (mg myelin /g brain wt.)was not appreciably different from control; but by day 55, the relative myelin content was 25-30% higher in Tg mice than in non-Tg littermates, and the total myelin content of the Tg mice was 90-100% higher. These Tg mice were bred to a mouse line which was growth hormone (GH) deficient and hypomyelinated in the cerebrum. As GH regulates postnatal levels of IGF-1 in the brain, we examined if the observed hypomyelination could be reversed in GH-deficient mice carrying the MT/IGF-1 gene. The relative myelin content in the cerebrum of GH-deficient progeny carrying the MT/IGF-1 gene was 90% higher than their GH-deficient littermates. These data suggest that IGF-1 can enhance oligodendrocyte development and myelination *in vivo*. Supported by NMSS RG 1767-A-1, NSF BNS 85-18023, NIH NS11036, and NS 26119.

A 31.5kD PROTEIN UNIQUE TO CNS: EXPRESSION IN NORMAL AND JIMPY ANIMALS. D.M. Studzinski*, J.A. Benjamins, and R.P. Skoff, Depts. of Neurology and Anatomy & Cell Biology, Wayne State Univ. Sch. of Med., Detroit, MI 48201

We have identified a unique 31.5kD protein in mouse CNS, first detected in a rabbit antiserum raised against a synthetic peptide corresponding to amino acids 109-128 of PLP (Hudson et al., Am. Soc. Cell Biol., 101, 435a, 1985). The antibodies are not anti-PLP, as they are not absorbed by PLP. Palmitic acid labeling suggests that the protein is acylated in both normal and jp mice. It is present in brain and cord of normal mice from 2-200 days, and in jp mice until their death. It is not present in normal or jp sciatic nerve, liver, kidney, or muscle. Scanning of immunoblots shows the protein increases with age in brain and cord of both normal and jp and appears prior to PLP in normal brains. The level in jp increases from 8 to 14d and peaks at 17d, being 1.25 times normal levels. Myelin from 17d mice shows higher levels of the protein than that isolated at 200d. Levels are reduced in highly purified myelin, suggesting it is not a myelin component. Since the 31.5kD is present in jp mice, it is probably not related to PLP, which is absent in jp. The protein is slightly elevated in 17d jp but is not related to GFAP, which is increased at this age. Immunocytochemical and biochemical studies are in progress to determine its localization, function, and relationship to PLP.

GLIAL CELL DEATH IS NOT INCREASED IN FEMALE CARRIERS OF THE JIMPY GENE. P.E.Knapp, S.Dutta* and R.P.Skoff. Dept. of Anat. & Cell Biol., Wayne State Univ. School Med., Detroit MI 48201

Previous ultrastructural studies have shown extensive death of oligodendrocytes (OLs) in jimpy (jp) male mice. This OL death precludes the formation and maintenance of normal myelin sheaths in jp CNS. To clarify whether this defect is primary or if it is a secondary effect, glial death in female carriers (mosaics) of the jp gene was examined. Due to random X-chromosome inactivation, roughly half of the OLs in mosaic CNS should express the jp gene while the other half should express a normal phenotype. If OL death is a primary effect of the jp mutation, the jp OLs in the mosaic should die prematurely. Numbers of total and dying glia were counted in 1um plastic sections of spinal cords (white and gray matter) in 5 and 15D mosaics and controls. In 5D mosaics and controls the percentages of total glia which were dying were 0.56 and 0.40, respectively. At 15D, the percentages were 1.2 in both mosaics and controls. Thus, OLs in mosaic cords are not dying at greater rates than those in control cords of the same age. We conclude that OL death is not a primary effect of the jp mutation and that jp OLs are probably able to survive in the mosaic CNS. It is unknown if jp OLs in the mosaic are able to make and/or maintain myelin sheaths. It is unlikely that the defect in the PLP protein itself is the cause of OL death since jp OLs do not die in mosaic CNS. Supported by NS 18883.

THE S PHASE OF THE CELL CYCLE OF NEUROGLIA IS LENGTHENED IN THE MURINE MUTANT JIMPY. L.A. Furicchia* and R.P. Skoff. Dept. Anat. & Cell Biol., Wayne State Univ. School Med., Detroit MI 48201

Our previous study of the myelin deficient mutant jimpy (jp) revealed a defect in the cell cycle of neuroglia (Knapp & Skoff, Dev. Br. Res.,35:301, 1987). This defect was revealed by determining the ratio of the no. of {^{3}H} thymidine labelled cells to the no. of mitotic cells. The ratio was always 4:1 in normal mice regardless of the age or labelling index but the ratio was always 8:1 in jp mice. The cause for the different ratios was unknown but was most likely due to a shortened M phase or a lengthened S phase. To measure the cell cycle of glia, we utilized the "percent of labelled mitoses" method. 14 day old mice were injected with {^{3}H} thymidine, sacrificed at different time points ranging from 1 to 35 hrs and spinal cords processed for autoradiography. Between 50-100 meta- and anaphases at each time point were scored for the presence or absence of silver grains. We find the duration of the S phase to be about 6.5 hrs in normals and 9.5 hrs in jp. The length of the duration of the cell cycle is about 16 hrs in normals and about 19.5 hrs in jp. The 3.5 hr difference in the jp cell cycle length is attributed to the 3 hr increase in the S phase. Since the proliferating cells in jp are mostly oligodendrocytes (OL) at this time, this study shows the OL cell cycle is lengthened. This finding shows the differentiation of the jp OL is compromised in its earliest stage of development. SUPPORTED BY NS 15338.

MYELINATION IN VITRO: GLIA FROM ADULT CNS NEED UNKNOWN NUTRIENTS NOT REQUIRED BY IMMATURE GLIA. G.B. Stanhope*, W.J. Hendelman+, S. Billings-Gagliardi and M.K. Wolf, Dept. Cell Biol., U.Mass. Med. Sch., Worcester, MA 01655 and +Dept. Anat., U. Ottawa Fac. Hlth. Sci., Ottawa, Ont. K1H 8M5

In co-cultures, glia from both immature and adult mouse optic nerve will invade mouse cerebellum and myelinate its axons. We now find that the nutritional requirements for myelination are different for glia from immature and adult tissue. Cerebellar cultures were treated with cytosine arabinoside for 8 DIV to eliminate native myelinating glia, and then received fragments of immature (P8-9) or adult (P85-100) optic nerve in direct contact with cerebellum. Cultures were fed 25% each serum and embryo extract (SEE) or Hendelman's semisynthetic medium (HM). After 12 to 20 more DIV, myelination was estimated in living cultures or by counting myelin profiles in serial semithin sections. Abundant myelin (over 2000 profiles/culture) formed in over 50% of cultures with immature nerve (either SEE or HM) or with adult nerve fed SEE. However, no culture with adult nerve fed HM formed more than traces of myelin (70 profiles/culture). This suggests that glia from immature nerve can synthesize or store unknown nutrients, which glia from adult nerve must receive from SEE. The need for such nutrients may limit myelin regeneration in adult CNS. Grant support: NINCDS (Javits Award) and American Paralysis Association.

INCREASED MYELINATION IN HYPOMYELINATED MUTANT MOUSE CEREBELLUM CO-CULTURED WITH NORMAL RAT OPTIC NERVE. X.Y. Shen and S.C. Chang*, Dept. of Anatomy, Shanghai Medical University, Shanghai 200032, People's Republic of China.

When mouse optic nerve is co-cultured with hypomyelinated mouse cerebellum, the optic nerve glia invade the cerebellum and myelinate its axons. The experiment succeeds with genetically or chemically hypomyelinated cerebellum and with normal or mutant, immature or adult optic nerve. A similar experiment succeeds with rat glia and rat axons. We now find that rat glia can myelinate mutant mouse axons. Fragments of newborn shi^{mld}/shi^{mld} cerebellum were cultured on coverslips. On the 7th DIV, fragments of optic nerve from Wistar rats aged 7 to 82 D were placed in direct contact with the cerebellar explants. After 2 to 3 additional weeks in vitro, examination of living cultures showed that 11 of 24 cultures with added rat optic nerve had more myelin than any control, a success rate comparable to that obtained with mouse optic nerve. shi^{mld} myelin is not normally compacted, and is difficult to see in cultures. However, the additional myelin in successful cultures was concentrated near the optic nerve, and looked thicker and better defined than shi^{mld} myelin. Studies are underway to determine its ultrastructure and thus confirm its rat origin. This result suggests that at least part of the cell recognition system for CNS myelin formation is the same in closely related species.

PAIN PATHWAYS: CENTRAL MECHANISMS

NATURAL GROUPINGS OF SPINOCERVICAL TRACT CELLS BASED ON RESPONSES TO CUTANEOUS STIMULI, C.M. Owens, D. Zhang and W.D. Willis, Marine Biomed. Inst. and Dept. of Anat. & Neurosci., Univ. Texas Medical Br., Galveston, TX 77550.

Neurons with different degrees of convergence of noxious and innocuous inputs are often classified as low threshold, high threshold or wide dynamic range cells. A classification scheme that is sensitive to variations in responses to innocuous and graded noxious stimuli was applied to spinocervical (SCT) cells. Single units were recorded from the lumbar cord of nembutal and chloralose anesthetized cats. Antidromic activation of the unit from C_3 but not C_1 (or with a >50% reduction in conduction velocity), frequency following (333 Hz) and collision identified SCT cells. The receptive fields (r.f.) of isolated units were mapped and four mechanical stimuli were applied for 10 s to the center of the r.f. The 4 cutaneous stimuli included innocuous brushing and three graded reproducible noxious pressures. The activity evoked by each stimulus was quantified and the values expressed as a percentage of the sum of activity to all 4 responses. In a population of 88 SCT cells studied so far, there have been units which have responded to noxious and innocuous input from glabrous and non-glabrous skin. One unit had no cutaneous input and responded only to deep input. At this point there appear to be at least 4 major classes of cell types based on a k-means cluster analysis of the percent response to cutaneous stimuli. (Supported by NS 09743 and NS 11255.)

49.2

RESPONSE PROPERTIES OF CONTRALATERALLY PROJECTING SPINOTHALAMIC NEURONS IN THE SECOND CERVICAL SEGMENT OF CAT, M.V. Smith*, A.V. Apkarian and C.J.Hodge, Dept Neurosurg, SUNY Hlth. Sci. Ctr., Syracuse, NY 13210.

Anatomic studies have shown that the upper cervical spinal cord contains the highest density of spinothalamic tract (STT) cells. The purpose of this study was to investigate somatic response properties of contralateral STT cells in the second cervical segment (C2).

Single unit recordings were made in the gray matter of C2 in chloralose anesthetized cats. Cells projecting to the contralateral ventrobasal complex of the thalamus were identified by antidromic stimulation and collision techniques. The response properties of these cells to cutaneous stimuli were studied. Stimulation and recording sites were determined by electrolytic lesions.

Typical response properties of C2 STT units were: 1) large receptive fields (RFs), at times involving both trigeminal and hindlimb distributions; 2) bilateral RFs; 3) responses to a wide variety of stimuli including touch, pressure, tap, deep muscle squeeze, and at times noxious pinch; 4) relatively small areas responsive to noxious stimuli compared to the areas responsive to low threshold stimuli. Widespread inhibitory RFs were occasionally seen.

The properties of STT cells projecting to the contralateral lateral thalamus from C2 differ from those reported in the spinal cord enlargements.

49.3

THE LOCATION OF SPINOTHALAMIC AXONS WITHIN THE DORSOLATERAL FUNICULUS OF CAT, R.T.Stevens, A.V.Apkarian and C.J.Hodge, Dept Neurosurg., SUNY Hlth Sci Ctr., Syracuse, NY 13210

Previous studies in cat have shown that ascending axons of lamina I spinothalamic (STT) neurons are located in the contralateral DLF. The purpose of this study was to determine the location within the DLF of projecting DSTT fibers by direct visualization of HRP-filled axons.

In this study, a constricting ligature was placed on the spinal cord at the high lumbar level of cat. Injections of 4% WGA-HRP were then made into the thalamus and animals were then allowed to survive for 5 to 7 days before sacrifice. The ligature caused a backup within axons of retrogradely transported HRP resulting in the ability to visualize and localize HRP-labeled fibers of fine caliber.

Large numbers of very course HRP-filled axons were seen in the ventral and ventrolateral funiculi. The DLF contained a moderate number of very fine HRP-labeled fibers. The dorsal most aspect of the DLF contained the fewest labeled axons while the labeled axons in the ventral portion of the DLF were evenly distributed from the periphery to the border of the dorsal horn.

49.4

CERVICAL LAMINA I SPINOTHALAMIC PROJECTIONS IN THE CAT. A. D. Craig, Jr. Divisions of Neurobiology and Neurosurgery, Barrow Neurological Institute, Phoenix AZ 85013.

Lamina I neurons constitute half the spinothalamic tract in the cat and convey nociceptive- and thermoreceptive-specific activity in anatomically-selective projections. The PHA-L anterograde transport method is being used to identify the terminations and pathways of ascending spinal lamina I projections. One or more iontophoretic injections are made at recording sites in C5-7 in anesthetized, young (8-16 wks) cats and 3-4 wks later the PHA-L is immunohistochemically identified. Transport to the DCN by passing fibers is usually present but little labeling has been found in the LCN. Ascending axons of lamina I cells can be seen in the lateral funiculus in oblique C3-4 sections. Terminations are present in the parabrachial, Kolliker-Fuse, subcoeruleus, cuneiform and periaqueductal gray regions of the brainstem and in the dorsal hypothalamus. Thalamic targets include caudal PO, Pf, the ventral paralaminar periphery of VPLm, the ventral margin of VMb, and Sm. Comparison with trigeminal lamina I projections indicates that terminations in VP and VMb are coarsely topographic, whereas there is a point-to-point projection to Sm. The distinct morphological characteristics of terminations in each site support possible functional/neurochemical segregation within this distributed projection.

EFFECTS OF FRONTAL CORTEX STIMULATION ON NOCICEPTIVE NEURONS IN NUCLEUS SUBMEDIUS OF THE ANESTHETIZED RAT. J.O. Dostrovsky and K. Kawakita. Dept. of Physiology, Univ. of Toronto, Toronto, Ontario M5S 1A8, Canada.

We have recently reported the existence of many nociceptive neurons in nucleus submedius (Sm) of the rat thalamus (Dostrovsky & Guilbaud, Brain Res. 1988). Since Sm has reciprocal connections with the ventrolateral orbital cortex (VLO) we have now investigated the effects of electrical stimulation of VLO on Sm neurons. The majority (70%) of the 77 Sm neurons recorded in urethane-anesthetized rats responded only to noxious stimuli and these responses could be frequently (50%) evoked by stimuli applied to all body regions. No neurons responding to non-noxious mechanical stimuli were found. Most of the responsive neurons were located in the dorsal part of Sm and usually had larger responses than those located in ventral Sm. VLO stimulation induced long lasting inhibition of the spontaneous activity of most Sm neurons (lasting up to 200ms). However, when the rate of stimulation was increased to 10Hz excitation was also frequently observed. This wind-up phenomenon occurred in 69% of the nociceptive neurons; the mean minimum latency of this excitatory response was 7.3ms. Some short latency antidromic responses were also evoked. These results provide further support for the possible role of dorsal Sm in nociception and indicate the existence of complex interactions between Sm and frontal cortex. (supported by NIH DE05404).

DISTRIBUTION IN THE HYPOTHALAMUS AND TELENCEPHALON OF FIBERS ORIGINATING IN THE SPINAL CORD. K. D. Cliffer, R. Burstein and G. J. Giesler, Jr. Dept. of Cell Biology and Neuroanatomy, Univ. of Minnesota, Minneapolis, MN 55455.

We previously reported that cells in nociceptive areas of the spinal cord project to the hypothalamus and telencephalon. The present report provides a more complete description of the locations of the afferent fibers. PHA-L was applied iontophoretically with multiple injections into the spinal cord. After immunohistochemical processing, labeled fibers were found in medial hypothalamus and medial preoptic area, including the suprachiasmatic nuclei and the vicinity of the paraventricular nuclei. Fibers were also labeled in the lateral hypothalamus and lateral preoptic area. Labeled fibers were seen in the supraoptic decussation, crossing the midline in the most posterior portion of the optic chiasm. Further anteriorly, numerous labeled fibers were seen in ventral pallidum, nuclei of the diagonal band of Broca, bed nucleus of the stria terminalis and globus pallidus. Some labeled fibers were embedded in the internal capsule, in nucleus basalis of Meynert. Some of the labeled fibers approached the surface of the olfactory tubercle, presumably as part of a projection to ventral striatum. Fibers were labeled in both medial and lateral septal nuclei and nucleus accumbens, and extended to the cortex medial and dorsomedial to nucleus accumbens. The wide distribution of spinal afferents to these hypothalamic and telencephalic areas provides a direct route from the spinal cord for somatosensory information to reach areas involved in autonomic, neuroendocrine and emotional responses to somatosensory stimuli. Supported by DA03981 and BNS84187878.

49.7

PHYSIOLOGICAL CHARACTERIZATION OF SPINOHYPOTHALAMIC TRACT (SHT) NEURONS IN LUMBAR CORD OF THE RAT. R. Burstein, K. D. Cliffer, R. J. Dado and G. J. Giesler, Jr. Dept. of Cell Biol. and Neuroanat. Univ. of Minn., Minneapolis, MN 55455.

The hypothalamus participates in autonomic, neuroendocrine and emotional responses to somatosensory and nociceptive stimuli. Spinal projections to the hypothalamus have been thought to be multi-synaptic. Recently, we reported that in rats a large number of spinal cord neurons project directly to the hypothalamus. The present report describes our continuing studies of these projections. To date, we have recorded 33 neurons in lumbar cord that were antidromically activated (< 50 uA) from electrodes in the contralateral and ipsilateral hypothalamus of urethane- anesthetized rats. Recording points were found within the marginal zone (10 neurons), nucleus proprius (8), lateral reticulated area (4), ventromedial dorsal horn (2) and the lateral spinal nucleus (1). Approximately 60% of characterized SHT neurons responded to innocuous mechanical stimuli but responded at higher frequencies to noxious mechanical and thermal stimuli. Roughly 20% responded only to noxious stimuli. Other neurons responded to joint movements. In 11 cases, the SHT axon was found to be located in the upper cervical cord using systematic tracking with an additional stimulating microelectrode. Lesions marking the locations of these SHT axons were within the dorsal (5) or ventral (6) lateral funiculus contralateral to the recording point. The mean conduction velocity between the recording point and cervical cord was 28 M/S (range=10-38; n=17). Conduction in each axon slowed considerably between the cervical cord and the hypothalamus (mean=12 M/S; range=4-24; n=17). In 3 cases, SHT neurons were backfired from low-threshold points within the hypothalamus bilaterally. Using electrophysiological tracking techniques, the axons of these neurons were found to cross from contralateral to ipsilateral hypothalamus within the supraoptic decussation. These findings indicate that spinal cord neurons that project to the hypothalamus carry somatosensory and nociceptive information. Supported by DA03981 and BNS84187878.

49.8

SPINOTHALAMIC CELL RESPONSES TO RENAL PELVIC DISTENTION W.S. Ammons, Dept. of Physiology, Thomas Jefferson University, Philadelphia, PA 19107.

Twenty-seven spinothalamic tract (STT) neurons in the T_{11}-L_2 segments were studied in 15 anesthetized monkeys (Macaca fascicularis). All cells were antidromically activated from the VPL nucleus of the thalamus. Each cell was excited by renal nerve stimulation and was tested for responses to distention of the renal pelvis with saline or a balloon-tipped catheter. Pelvic distention to a pressure of 50 mm Hg excited 20 of 27 STT cells. Responses were characterized by an early dynamic phase followed by some degree of adaptation. Average activity increased from 11 $\pm$ 3 to 29 $\pm$ 9 spikes/s. The stimulus-response relation was determined for 9 cells. Response thresholds averaged 30 $\pm$ 4 mm Hg. Responses increased linearly up to 80 mm Hg. Greatest responses were observed from cells in the L_1 and T_{12} segments. All cells had somatic receptive fields located in the ipsilateral flank, abdomen, or upper hindlimb. One hundred percent of the wide dynamic range cells responded while 63% of high threshold cells responded. The results show that STT cells are excited by a noxious renal stimulus. Response characteristics and somatic receptive field location suggest that these cells are important in causing renal pain and its referral to somatic structures. Supported by NIH Grant HL-36378.

DIFFERENCES IN VISCEROSOMATIC INPUT TO SPINOTHALAMIC (ST) CELLS PROJECTING TO VPLc AND VPLo THALAMUS IN MONKEYS. **RD Foreman, SF Hobbs, MJ Chandler, and DC Bolser. Dept. Physiol., Univ. of Okla., HSC, Okla. City, OK 73190.**

VPLc and VPLo thalamic nuclei respond best to skin and muscle afferent input, respectively, and receive input from ST cells. Thus, we hypothesized that skin but not muscle input would excite VPLc-ST cells, and muscle but not skin would excite VPLo-ST cells. Also, since visceral pain is referred to muscle, we hypothesized that urinary bladder distension and electrical stimulation of hypogastric nerves would activate VPLo- and not VPLc-ST cells. In 7 anesthetized monkeys L_2 to S_3 segments were searched for ST cells that were antidromically activated from VPLc but not VPLo (n=26), and VPLo but not VPLc (n=13). VPLc- and VPLo-ST cells (n=29) with somatic fields that included thigh, abdomen, or tail received similar viscerosomatic input i.e. 60% of the cells were excited by both skin and muscle input, 23% by muscle only, 17% by skin only, and of those 40% received visceral input. In contrast, only VPLc-ST cells had somatic fields confined to foot and calf. Of 10 VPLc cells with distal somatic fields 6 (60%) were excited by skin only, 4 (40%) by skin and muscle, and 0 by visceral input. Thus, VPLc-ST and VPLo-ST cells with proximal/axial somatic fields were more likely to be excited by visceral input ($P<0.02$) or by both skin and muscle input ($P<0.04$) then were VPLc-ST cells with only distal somatic fields. (NIH grants HL22732, HL07930, NS08150, and HL07304)

49.10

SOMATO- AND VISCEROTOPIC ORGANIZATION OF SPINOTHALAMIC TRACT (STT) CELLS IN PRIMATE LUMBOSACRAL CORD. M.J. Chandler, S.F. Hobbs, D.C. Bolser, and R.D. Foreman. Univ. of Okla. HSC, Dept. of Physiol., Okla. City, OK 73190.

Visceral pain is referred to proximal body areas, and probably involves activation of the STT. Thus, we hypothesized that visceral afferent input would excite STT cells with somatic input from proximal body areas. Seventy lumbosacral STT cells from 31 chloralose-anesthetized monkeys (Macaca fascicularis) were identified by antidromic activation from lateral thalamus. The somatic field of each cell was mapped by brushing hair and pinching skin and muscle of the limb (foot, calf, thigh), and proximal areas (tail, groin, and abdomen). Urinary bladder distension and electrical stimulation of hypogastric nerves produced visceral afferent input. Each cell was lesioned and its spinal segmental and laminar location was identified. A somatotopic map was constructed from somatic fields and spinal locations of the cells. A viscerosomatic map was constructed from visceral and somatotopic data. STT cells with input from foot and calf were located in the medial dorsal horn in segments L_4-S_1. STT cells with input from the thigh, groin, abdomen, or tail were located in the medial and lateral parts of the L_3-L_4 and S_1-S_2 segments but only the lateral part of the L_5-L_7 segments. Visceral input excited only 1 of 23 STT cells with somatic fields confined to the limb but excited 12 (63%) of 19 STT cells with proximal somatic fields ($P<0.001$). These data can explain why visceral pain is referred to proximal and not distal somatic areas. (NIH grants HL22732, HL07930, NS08150, and HL07304)

49.11

A THERMAL SOMATOSENSORY EVOKED POTENTIAL STIMULATOR FOR ANALGESIA STUDIES. G.M. Strain, B.L. Tedford,* and S.G. Kamerling. Vet. Physiol., Pharmacol. and Toxicol., Sch. Vet. Med., Louisiana State Univ., Baton Rouge, LA 70803.

In analgesic drug assessment the rat hot plate and tail flick tests do not adequately assess drugs producing motor depressant effects and give poor evaluations of some drugs with proven analgesic effects. Somatosensory evoked potentials (SEPs) elicited by nociceptive stimuli have been used for drug assessment, but non-nociceptive fibers are also usually activated, resulting in a contaminated signal. A stimulator for SEP studies of analgesics has been designed that produces a pure thermal nociceptive stimulus with temporal characteristics adequate for EP averager activation. Thermal stimuli are produced by the ceramic elements of a thermal printhead; current to the printhead is controlled by a relay and multiplexing DIP switches. Timing control of stimulus frequency and duration may be provided by any lab stimulator, which also provides the EP averager trigger. The area of skin heated is determined by the number of elements activated through the DIP switches. Temperatures able to activate thermal nociceptors (> 45°C) are produced with durations below 100 ms, so that the stimulus has ended before pain perception can occur, minimizing pain and discomfort.

Calibration curves of temperature vs. duration at both the skin surface and intradermally are presented, and the typical thermal SEP produced over somatosensory cortex in the rat is characterized. Preliminary results of drug studies with prototype analgesics are reported.

PERCEPTION OF PAIN IN MAN AFTER TOTAL TRANSECTION OF THE CORPUS CALLOSUM. B.E. Stein, D.D. Price* and M.S.Gazzaniga, Depts. Physiology & Anesthesiology, Medical College of Virginia, Richmond, VA 23298 and Dept. Neurology, Cornell University School of Medicine, New York, NY 10021

Although theories emphasize that crossed pathways subserve pain, the role of uncrossed input is uncertain. We sought to determine the contributions of ascending ipsilateral inputs to pain, and the possibility that some dimensions of pain perception might be lateralized. This was possible in a patient with a total transection of the corpus callosum. Quantitative ratings of innocuous tactile, and noxious and innocuous thermal stimuli were accomplished using verbal (left hemisphere) and visual analogue scale (both hemispheres tested independently) methodologies. Surprisingly, noxious ipsilateral stimuli evoked all components of pain experience (sensory and affective) but only at intensities well above normal (49-51°C). Apparently, neural activity via inputs other than the classical crossed spinothalamic pathway (that synapses in VPLc and projects to somatosensory cortex) is sufficient to evoke the complex of responses associated with pain. These alternate pathways contribute to perceived pain intensity, unpleasantness, and location of the stimulus. However, they do not contribute much to these aspects of pain in the lower noxious ranges (<47°C), where they often fail to subserve detection and identification of stimuli, functions normally subserved by contralateral and interhemispheric (corpus callosum) pathways.

49.13

A PSYCHOPHYSICAL ANALYSIS OF SPATIAL SUMMATION MECHANISMS IN PAIN. D.D. Price, J.G. McHaffie & M.L. Larson, Depts. of Anesthesiology & Physiology, Medical College of Virginia, Richmond, VA 23298 and Dept. of Physical Therapy, Univ. Southern Calif., Los Angeles, CA 90033.

Psychophysical experiments were initiated to determine the influence of spatial summation on perceived pain intensity. Six trained human subjects (5 male, 1 female) made visual analogue scale ratings for sensory intensity and unpleasantness to noxious thermal heat stimuli (45° to 50°C) delivered by 1,2 or 3 contact thermodes (1 cm^2 each) applied within a single dermatome of the anterior median forearm. Stimulus size was varied from 1-3 cm^2 by varying the number of thermodes activated, and stimulus size and temperature were randomly interspersed. Spatial separation between thermodes was systematically varied (0, 5, 10 cm) across 3 experimental sessions. Considerable spatial summation occurred in both sensory intensity and unpleasantness dimensions. Unlike spatial summation of warmth (Stevens, J.C. & Marks, L.E., Percep. & Psychophys. 9:291, 1971), that of pain was not characterized by systematic changes in power function exponents but as parallel upward displacements in double logarithmic coordinates. Increasing thermode separation also significantly enhanced spatial summation. The results indicate that powerful spatial summation mechanisms exist for pain and that such mechanisms are likely to depend on numbers of neurons recruited at some central level. The spinal cord dorsal horn is a likely site of action.

49.14

DIFFERENTIAL EFFECTS OF HETEROTOPIC CONDITIONING STIMULI ON FIRST AND SECOND PAIN PERCEPTION IN HUMANS. J.G. McHaffie and D.D. Price, Depts. Physiol. & Anesthesiol., Medical College of Virginia, Richmond, VA 23298.

Psychophysical experiments were initiated to determine if experimentally produced first and second pain is reduced by concomitant heterotopic nociceptive stimuli, a form of pain modulation termed diffuse noxious inhibitory controls (DNIC- LeBars et al., Pain 6:283, 1979). The magnitude of electrically evoked first and second pain (9ms, 6-15mA pulses delivered subepithelially to the ankle) conditioned by 10 sec thermal heat pulses (43, 47, 50°C applied to either the contralateral foot or abdomen) was rated with visual analog scales by 7 male subjects. Frankly noxious thermal conditioning stimuli (47, 51°C), but not innocuous stimuli (43°C), applied to the contralateral foot or abdomen reliably inhibited both first and second pain. However, the degree of inhibition was not equal but was significantly greater for second pain. In addition, the inhibitory effects did not outlast the duration of conditioning stimuli. All of these results closely parallel electrophysiological observations about DNIC in primates. Since the magnitude of first pain reduction was relatively weak and the duration of inhibition brief, it is unlikely that DNIC subserves a major role in either relieving pain or providing a mechanism of coding pain. The spatial and temporal pattern of DNIC suggests that it may be a phenomenon more closely associated with the elaboration of withdrawal reflexes.

49.15

QUANTITATIVE EVALUATION OF NOCICEPTIVE NEURONS IN RAT TRIGEMINAL PARS CAUDALIS. M.A. Larson, J.G. McHaffie and B.E. Stein. Dept. Physical Therapy, USC., Los Angeles, CA. 90033 & Dept. Physiol., Med. Col. Va, Richmond, VA 23298.

Somatosensory neurons (n=135) were studied in pars caudalis of urethan anesthetized rats: 38% were low threshold (LT), 29% wide dynamic range (WDR), and 39% nociceptive specific (NS). WDR receptive fields (RFs) were restricted to the face but usually included 2 or 3 nerve divisions, had thermal thresholds of 42°-50°C, mechanical thresholds <100mg, and some responded to noxious cold. NS RFs were smaller and restricted to one nerve division. WDR and NS neurons had RFs on face, cornea, and in the oral cavity and rarely had responses outlasting the stimulus durations. They had positively accelerating power functions for thermal stimuli (3.9 WDR, 4.4 NS) but negatively accelerating power functions for LT mechanical stimuli (0.7). Superior colliculus (SC) nociceptive neurons with facial RFs reflect some of these properties (Larson et al. J. Neurosci. 7:547,1987) but lack oral and corneal representations, exhibit longlasting afterdischarges, lower thresholds (42-44°C), and lower exponents. This suggests that SC properties are derived from a select subpopulation of trigeminal nociceptive neurons: this finding is consistent with our anatomical studies (Bruce et al. J. Comp. Neurol. 262:315,1987) showing that trigeminotectal and other ascending trigeminofugal projections arise from two largely segregated populations. Supported by A.D. Williams Foundation and NIH grant EY05554.

PROJECTIONS OF LEMNISCAL AND SPINAL AFFERENTS TO RELAY AND LOCAL CIRCUIT NEURONS OF THE PRIMATE VENTROBASAL THALAMUS. H.J. Ralston, III, D.D. Ralston and P.T. Ohara. The Department of Anatomy, University of California, San Francisco, California 94143.

The dorsal column-medial lemniscal (ML) system carries information arising from nonnoxious mechanical stimuli, and terminates throughout VPLc - that portion of the ventrobasal complex (VB) which exhibits a somatotopic map of the contralateral body. The spinothalamic tract (STT) carries both nonnoxious and noxious mechanical and thermal information; its projections arborize as cylindrical arrays running rostrocaudally through VPLc, thus partially overlapping the ML distribution. Both the ML and STT axons project to thalamocortical relay (TCR) cells and to GABAergic local circuit neurons (LCN) of VB. The present study compares the synaptic organization of the ML and STT terminations, particularly in regard to the contacts made by these afferents with TCRs and LCNs, and whether the interactions are different in these two systems which mediate different types of information.

Macaque monkeys were anesthetized and, using sterile neurosurgical techniques, the ML or STT projections to VPLc were labeled by the orthograde axonal transport of WGA-HRP. After appropriate survival times, the animals were reanesthetized, perfused, and thalamic slices processed to demonstrate HRP reaction product in the ML or STT terminals. Serial thin sections of identified terminals were taken, examined by EM, and the images reconstructed by computer to permit a precise analysis of the synaptic interrelationships of ML or STT terminals with dendritic processes of TCRs and LCNs. Serial reconstruction reveals that a single ML or STT afferent axon contacts numerous branches of LCN presynaptic dendrites (PSDs), which have been shown to contain GABA, and that the afferent axon and the multiple PSDs also contact an extensive region of the dendritic arbor of a single TCR. Thus, the "triadic" relationship between afferent axons and VB neurons is extraordinarily complex, having a morphological organization which is far more elaborate than that shown by previous studies. These complex synaptic arrays serve both excitatory and feed-forward inhibitory synaptic functions in VB. (Supported by NS-23347 from NIH.)

50.2

SOMATOSENSORY RESPONSES OF PEDUNCULO-PONTINE NUCLEUS UNITS PROJECTING TO THE MEDIAL THALAMUS. B. Grunwerg*, J. Krol* and G. M. Krauthamer. Department of Anatomy, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

The parabrachial-pedunculopontine system is one of the major cholinergic cell groups in the brainstem. The pedunculopontine tegmental nucleus (PPTN) is located in the lateral aspect of the most rostral portions of this complex and projects to medial thalamic nuclei, subthalamus, hypothalamus and superior colliculus. Reciprocal projections link it with several extrapyramidal structures including the globus pallidus and substantia nigra pars reticulata. Extracellular recordings were made from single PPTN neurons in anesthetized hooded rats. Units activated antidromically from the medial thalamus responded to stroking, tapping and pinching. Small to large receptive fields were located on the contralateral paws, shoulder and neck. Other neurons in this area could not be activated antidromically from the medial thalamus but showed a similar receptive field organization. These findings suggest that the PPTN may be involved in the processing of sensory input to the medial thalamus.

50.3

COMPARISON OF THE MORPHOLOGY OF TRIGEMINOTHALAMIC AFFERENT TERMINATIONS IN THE VENTRAL POSTERIOR NUCLEUS OF THE RAT. H.P. Killackey, N.L. Chiaia and R.W. Rhoades. (SPON: M. Rayport) Dept. of Psychobio., Univ. of Calif., Irvine, CA 92717 and Dept. of Anat., Medical College of Ohio, Toledo OH 43699.

Both the principal sensory nucleus (PrV) and the subnucleus interpolaris (SpI) of the brainstem trigeminal complex project to the medial portion of the contralateral ventral posterior nucleus (VPM) in a topographic fashion. The functional correlates of these two projections differ greatly. In the present study, we examined the morphology of both PrV and SpI afferent terminations labeled with either phaseolous vulgaris leucoagglutinin (Phal) or intracellularly injected horseradish peroxidase (HRP).

A group of adult rats received iontophoretic injections of Phal (5 uA for 30 min) into either PrV or SpI. In a second group of rats trigeminal lemniscus fibers were isolated, functionally characterized and injected with HRP. Following appropriate histological procedures, labeled fibers in VPM were morphologically characterized.

Both procedures result in excellent labeling of trigeminothalamic terminations. The distribution of both PrV and SpI terminations in the medial to lateral dimension is quite restricted. The distribution of the SpI terminations along both the dorsoventral and rostrocaudal axis is more extensive than that of the PrV terminations. Qualitatively, PrV terminations appear denser than SpI terminations.

50.4

CHARACTERIZATION OF NEURONS IN THE VENTRAL POSTERIOR (VP) AND POSTERIOR (PO) NUCLEI OF THE RAT, USING PHYSIOLOGICAL, LIGHT AND ELECTRON MICROSCOPIC TECHNIQUES. G.R. Belford*, H.P.Killackey, N. L. Chiaia and R.W. Rhoades (SPON: M. Le Gare). Dept. of Psychobio., Univ. of Calif., Irvine, CA and Dept. of Anat., Medical College of Ohio, Toledo, OH.

Neurons in both VP and PO are responsive to vibrissae stimulation. We have used intracellular recording to physiologically characterize these neurons, combined with injection of horseradish peroxidase (HRP) for anatomical characterization with light and electron microscopes.

Neurons in VP were responsive to deflection of only one or two vibrissae, whereas PO neurons were typically responsive to 5 or more vibrissae. The cross-sectional areas of the dendritic fields of VP neurons did not overlap with those of PO neurons (VP range = 24,437-54,027 um^2; PO range = 58,832-110,381 um^2).

Examination with the electron microscope also showed differences. HRP-filled dendrites of VP neurons coursed through neuropil containing fewer profiles of myelinated axons than did dendrites of labelled PO neurons (8.5 per 100 um^2 for VP vs. 23.7 per 100 um^2 for PO). There were more profiles of large dendrites (cross-sectional area > 1 um^2) in VP than in PO (VP: 4.26 per 100 um^2; PO: 2.04 per 100 um^2). Finally, there were more large axonal terminals containing round vesicles in VP than in PO (VP: 1.64 per 100 um^2; PO: 0.41 per 100 um^2). This terminal type has been correlated with the ascending lemniscal input.

NEURONS IN THE DORSAL COLUMN NUCLEI OF RAT WHICH PROJECT TO THE IPSILATERAL THALAMUS. J.R. Norris and H.P. Killackey (Spon: R. Josephson) Dept. of Psychobiology, University of California, Irvine, CA. 92717

A recent study in cat reported that a small population of DCN neurons projected to the **ipsilateral** thalamus (Berkley, 1984). In the present study, retrograde tracing methods were used to determine if a similar population of cells exists in the DCN of rat.

Adult rats received large injections of 10% WGA-HRP into the lateral thalamus unilaterally, or thalamic injections of two fluorescent tracers into opposite sides of the thalamus. The animals were sacrificed and the tissue processed according to standard methods.

The rat DCN contains a small (<5%) but consistently labeled population of neurons which project to the ipsilateral thalamus. Labeled cells were observed in both the gracile and cuneate nuclei, though generally more gracile cells were labeled than cuneate cells. The cells occur singly and their positions within the cross-sections of the DCN are highly variable and follow no apparent pattern. Labeled neurons are most numerous in the middle and, especially, the caudal portions of both nuclei, although labeled cells are present throughout the entire rostral-caudal extent of the DCN. Based on the double labeling studies, the thalamic projection from these cells appears to be primarily, if not exclusively, ipsilateral.

Supported by BNS 87-19311.

AUDITORY INFLUENCES THROUGH THE COCHLEAR NUCLEUS ON CUNEATE NEURONS IN DECEREBRATE-DECEREBELLATE CATS. S.F. Atweh, Y. Bassim*, S.J. Jabbur and N.E. Saadé. Fac. of Med., American University of Beirut, Beirut, Lebanon.

In a previous study, we have demonstrated visual and auditory interactions in the cuneate nucleus (J. Physiol., 238:343, 1974). Recently, direct and reciprocal interconnections between the cuneate and cochlear nuclei have been anatomically demonstrated. We now report the effects of click and tone stimuli on cuneate nuclear activities in decerebellate cats with brainstem transected either below the inferior colliculi or at mid-collicular level with bilateral suction of the inferior colliculi. Conditioning clicks or tones produced negative and positive waves on the surface of the cuneate nuclei. The same conditioning stimuli modulated the activities of 15 cuneate neurons but had no influence on another 30 cuneate and 6 gracile neurons. One neuron was activated, 8 neurons were inhibited, 3 neurons were facilitated and the remaining 3 neurons showed cycling of facilitation-inhibition. Direct projection as well as interneurons were involved. Both gross potentials and effects on single neurons were more pronounced from the ipsilateral stimuli.

We have earlier demonstrated reciprocal intermodulatory loops involving the DC nuclei with trigeminal, raphe, periaqueductal and reticular nuclei. This study completes the description of another loop and illustrates heterosensory interactions between two primary sensory relays. (Supported from Lebanese N.R.C. and D.T. Sabbagh Fund).

A DORSAL COLUMN INPUT INTO COCHLEAR NEURONS IN DECEREBRATE-DECEREBELLATE CATS. S.J. Jabbur, A. Franjieh*, S.F. Atweh and N.E. Saadé. Fac. of Med., American University of Beirut, Beirut, Lebanon.

Direct projections from the dorsal column nuclei have been recently described in cats (Brain Res., 400:145, 1987). We now demonstrate that ascending activation of the dorsal columns (DCs) can modulate cochlear neuronal discharges evoked by sound clicks and tones. Seven cats were anesthetized, decerebrated (mid-collicular) and decerebellated. The C_1-C_4 dorsal roots were cut and the ventral and lateral funiculi were bilaterally lesioned at both C_1 and C_4 levels leaving the DCs intact. DCs were activated either directly through localized electrical stimulation or indirectly by stimulating the paws. The extracellular activity of 50 neurons in dorsal and ventral cochlear nuclei were recorded in response to peripheral clicks or tones. Conditioning activation of DCs modulated the activity of 23 neurons and had no influence on 27 others. Fourteen neurons were discharged from DC input with a latency of 4 to 10 ms. Conditioning DC activation produced weak facilitation in 3 neurons and inhibition in 6 neurons. The inhibition peaked at conditioning-testing interval of 10-25 ms and lasted for about 150 msec. DC effects were bilateral.

This report provides evidence for another extralemniscal output of the DC nuclei which plays a role in modulation auditory input at its entry nucleus in the brain.

SOMATOTOPIC ORGANIZATION OF FORELIMB AND HINDLIMB CUTANEOUS AFFERENTS TO THE DORSAL COLUMN NUCLEI (DCN) IN THE RAT. S. Maslany*, D.P. Crockett and M.D. Egger. Dept. of Anatomy, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ. 08854

Recent studies in the monkey and racoon have demonstrated that cutaneous afferents from specific digits of the hand project to discrete regions in the cuneate nucleus. We have now carried out a detailed analysis of projections from cutaneous afferents of the limbs to the DCN in the rat. A mixture of 25% free HRP and 2.5% WGA-HRP was intracutaneously injected into different limited regions of the forelimbs and hindlimbs. The rats were perfused transcardially after three days. Horizontal sections 60-µm thick were cut. The HRP was reacted using the TMB method. Data from 15 rats were analyzed. DCN labeling from different regions of the limbs was precisely restricted mediolaterally, with little or no overlap into adjacent areas. In the gracile nucleus (GN) more variability in labeling was found for the rostrocaudal direction than in the cuneate nucleus (CN). The detailed projection patterns demonstrated that primary cutaneous afferents from the limbs in the rat are strictly segregated within the CN and GN according to the origin of their peripheral fibers.

50.9

INTRA-AXONAL INJECTIONS OF HORSERADISH PEROXIDASE (HRP) INTO PRIMARY AFFERENTS TO THE MAIN (CN) AND EXTERNAL CUNEATE (ECN) NUCLEI IN THE RAT. D.P. Crockett, S.L. Harris* AND M.D. Egger. Dept. of Anatomy, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ. 08854

We have begun a structure-function analysis of the axonal arbors of primary afferents to the CN and ECN in the rat by intra-axonally injecting HRP into physiologically identified primary afferents. Two proprioceptive afferents (one responding to bending of the wrist and the other to movement of the elbow) were traced throughout much of the CN, ending in the ECN. Their arbors were simpler in the CN than in the ECN. Also, the density of boutons was greater in the ECN than in the CN. In the ECN, boutons were concentrated rostrocaudally within 400 µm. In contrast, within the CN, boutons were distributed rostrocaudally over 1.7 mm, extending from 1.6 mm caudal to the obex to 0.1 mm rostral to it. A rapidly adapting fiber with a receptive field on the second digit of the forepaw had a complex distribution of terminals confined to the CN, with boutons extending over 3.1 mm caudal to the obex. This distribution of rapidly adapting boutons agreed precisely with the overall distribution of transganglionically labelled primary afferent fibers we observed following intracutaneous injections of WGA-HRP into the forepaw (Maslany et al., 1988).

50.10

POSTSYNAPTIC DORSAL COLUMN (PSDC) AFFERENTS TO THE DORSAL COLUMN NUCLEI (DCN) OF RATS REVEALED BY *PHASEOLUS VULGARIS* LEUCOAGGLUTININ (PHA-L). M.D. Egger, S.L. Harris* and D.P. Crockett (SPON: S. Rosner). Dept. of Anatomy, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

The PSDC cells of the spinal dorsal horn provide an important source of ascending input to the DCN. Although the locations of many PSDC cell bodies have been described, the terminal projection patterns of PSDC cells are not well known. We have begun an examination of these terminal projections of PSDC cells in the DCN by injecting the anterograde tracer, PHA-L, at various segmental levels in the spinal cords of rats. Injections within the cervical (C5; n=1) and lumbar (L4; n=1) enlargements produced dense projections throughout much of the cuneate (CN) and gracile nuclei (GN), respectively, with the densest projections in the rostral and ventral regions of these nuclei. On the other hand, injections within the C8 (n=2) or the S1-S2 (n=1) segments labelled only a few fibers. The cervical injections produced no labelling in GN, confirming that the PHA-L is taken up only by cell bodies, but not by fibers of passage. The wide distribution of labelled afferents within CN or GN following an injection confined to a single segment suggests that the PSDC afferents may not provide detailed spatial information.

50.11

IMMUNOHISTOCHEMISTRY OF PUTATIVE NEUROTRANSMITTERS IN THE LATERAL CERVICAL NUCLEUS OF THE MONKEY. J. Broman* and A. Blomqvist (SPON: M. Bull). Dept. of Anatomy, Uppsala University, Box 571, S-751 23 Uppsala, Sweden.

The immunohistochemical localization of GABA in the lateral cervical nucleus (LCN) was investigated in cynomolgus monkeys. Light microscopy revealed the presence of a small population of GABA-positive neurons located within all parts of the LCN. Ultrstructural investigation showed that the labeled neurons were small and were contacted by few somatic boutons. GABA-positive terminals were numerous and scattered throughout the LCN. Most labeled terminals were presynaptic to dendrites, but axosomatic synapses were also seen.

The distribution of substance P (SP) and serotonin (5-HT) was investigated in owl monkeys. SP-like immunoreactivity was densest in the areas immediately surrounding the LCN, but densely labeled puncta were also seen within the nucleus. Electron microscopy showed that most labeled terminals were large and made synaptic contacts with dendrites and nerve cell bodies.

5-HT immunohistochemistry revealed the presence in the LCN of a dense network of thin fibers with bouton-like swellings. Most labeled profiles were identified as thin, unmyelinated fibers which often were surrounded by astroglial processes. Somewhat larger profiles containing densely packed synaptic vesicles were also seen, sometimes in apposition with dendrites or nerve cell bodies.

50.12

LIGHT AND ELECTRON MICROSCOPIC DEMONSTRATION OF SEROTONIN IMMUNOREACTIVITY IN THE DORSAL COLUMN NUCLEI OF CATS AND MONKEYS. A. Blomqvist and J. Broman*. Dept. of Anatomy, University of Uppsala, Box 571, S-751 23 Uppsala, Sweden.

The distribution of serotonin (5-HT) in the dorsal column nuclei (DCN) of cats and monkeys was studied by light and electron microscopic immunohistochemistry. A network of thin immunoreactive fibers with bouton-like swellings was seen throughout the DCN. However, in both species, regional differences in the density of the labeling was observed. In the cat, dense 5-HT immunoreactivity was seen in the rostral and middle-ventral "reticular" regions of the DCN, whereas the middle-dorsal "cell nest" regions were more sparsely labeled. In the monkey, the densest labeling was seen in the gracile nucleus and in the pars triangularis of the cuneate nucleus, with sparser labeling in the pars rotunda. In the neuropil of the DCN, electron microscopy showed the presence of thin, unmyelinated immunoreactive fibers as well as larger, labeled bouton-like swellings. The latter were often in contact with dendrites and nerve cell bodies.

The findings suggest that the 5-HT innervation of the DCN is related mainly to the regions of the nuclei that have been implicated in nociceptive and/or motor related functions.

50.13

THEORY OF IMPULSE PROPAGATION IN CAT CUNEATE NUCLEUS AXONS WITH SEROTONIN-LIKE IMMUNOREACTIVITY. M.D. Goldfinger, V.R. Roettger, & J.C. Pearson. Depts. of Physiology & Biophysics and Anatomy, Wright State University, Dayton, OH 45401-0927.

The cat Cuneate Nucleus is innervated by axons with serotonin-like immunoreactivity (5HT-LI: Pearson & Goldfinger, Neurosci. Lett. 74:125, 1987). The present work used 5HT-LI morphological data with cable theory to construct a model for impulse propagation in 5HT-LI axons. The assumptions were: (a) 1-dimensional unmyelinated core-conductor had uniform geometry-independent cable constants; (b) fiber varicosities [Diameter: D=2-3μm] and intervaricosities [D=1-2μm] differed only in diameter and length assessed from high-power sagittal photos of individual 5HT-LI axons; (c) both varicosity and intervaricosity membranes contained voltage-and-time dependent Na^+ and K^+ conductances represented by the Hodgkin-Huxley equations (J. Physiol. 117:500, 1952). The computational method [modified Euler integration; dT=0.1 us; dX/λ=0.0165; PDP-11/34] was tested for uniform-geometry axons [D=1-3μm] with no varicosities and gave CV (Conduction Velocity) =0.370*. Solutions were stable, requiring appr. 10 hr-cpu/4 ms-simulated, for 200 3μm-compartments; propagated impulse duration and amplitude were 2.0 ms and 100. mV, respectively.

Propagation (CV=0.37m/s) past a single varicosity [length = integr. step = 3μm] centered in a 1μm-D 600μm-length axon was unchanged by varicosity diameters [1-3μm] observed in stained axons. Incorporation of additional 3μm-long x 2μm-D varicosities to a 1μm-D 600μm-long axon (integr. step = 3μm) slightly increased CV towards that of a uniform 2μm-D axon. When varicosity number and spacing approximated those observed in stained axons: (i) doubling axial resistivity (110 to 220 ohm·cm) decreased CV from 0.39 to 0.29 m/s; (ii) speeding conductance kinetics (3X) increased CV (39%), shortened impulse duration (59%), and decreased impulse amplitude (11%).

These computations indicated that single impulse propagation: (a) is not compromised by varicosity-type geometrical inhomogeneities; (b) is influenced predictably by cable parameters; and (c) can occur at slow CVs (< 1 m/s) over long distances without failure.

RAT CUNEATE NUCLEUS CONTAINS GAMMA-AMINOBUTYRIC ACID-LIKE IMMUNOREACTIVE NEURONS. V.R. Roettger and J.C. Pearson. Depts. of Physiology and Biophysics and Anatomy, Wright State University, Dayton, Ohio 45401-0927

A neurotransmitter role for gamma-aminobutyric acid (GABA) in rat cuneate nucleus is supported experimentally. Immunohistochemistry reveals the presence of glutamic acid decarboxylase (GAD) in small cells within this nucleus [Barbaresi, et al., Brain Res. 382:305 1986]. Antiserum, raised against GABA-glutaraldehyde-keyhole limpet hemocyanin in guinea pigs, was specificity-tested by preabsorption with 100 or 500 μM concentrations of GABA-, glutamine (GLN)-, glutamate (GLU)-, or taurine (TAU)-glutaraldehyde conjugations. Cerebellar tissue staining was inhibited by 100μM GABA-glutaraldehyde whereas normal staining was seen with 500μM GLU-, GLN-, and Tau-glutaraldehyde. GABA-stained rats were intraventricularly colchicinized and transcardially perfused with 4% paraformaldehyde, 0.5% glutaraldehyde, 0.5% $K_2Cr_2O_7$ in 0.05M phosphate-buffered saline (pH=6.5). Visualization of cells was with avidin-biotin-peroxidase for GABA-LI staining and with cresyl violet acetate for Nissl staining. GABA-LI and Nissl-stained neurons from cuneate nucleus were compared in terms of cell body size, shape, and distribution using camera lucida tracings. GABA-LI cell bodies were distributed randomly throughout the cross-sectional area of the nucleus at all rostral-caudal levels except around the obex where they were limited to the peripheral border. GABA-LI cell bodies comprised 21.5% of the total population of cuneate neurons and had a mean cross-sectional area which was significantly smaller than that of the total neuronal population. These results closely approximate results obtained using anti-GAD antiserum [ibid.]. GABA-LI processes were seen throughout the cross-sectional area of the nucleus at all rostral-caudal levels, often surrounding empty spaces which appeared to be large, unstained neuronal cell bodies. Similarities between GABA-LI cells and previously reported GAD-LI cells suggest that GABA is synthesized and present within small cell-bodied rat cuneate neurons. These results are consistent with the hypothesis that GABA is a neurotransmitter involved in somatosensory information processing in this nucleus.

EFFECTS OF CHOLINERGIC AGONISTS ON THE VENTRO-BASAL COMPLEX OF THE RAT. G.A. Marks, A.M. Hoelscher*, H.P. Roffwarg, Dept. of Psychiatry, Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235-9070.

The influence of cholinergic agonists on thalamic relay cells was investigated by iontophoretic application to 71 identified ventro-basal neurons from 28 chloral hydrate anesthetized rats. Carb was applied to 63 cells eliciting either: no effect (64%), inhibition (8%), inhibition followed by facilitation (I/F) (3%), and facilitation (25%). Onset of facilitation was always later than onset of inhibition. Glutamate (glu) ejection produced a short latency facilitatory response in every cell. The simultaneous ejection of glu and carb to 36 cells was used to detect the short latency effects of carb ejection. Three response types detected were: no effect (8%), antagonism of glu (84%), and potentiation of glu (8%). Low-current continuous ejection of glu was also used to produce a single spike pattern in 24 cells. Ejections of carb now produced responses in every cell: inhibition (54%), I/F (33%), and facilitation (13%). The M_1 selective agonist McN-A-343 was applied to 27 cells. The major difference between McN and carb was McN inability to produce facilitation. Two response types were observed: no effect (74%) and inhibition (26%). Short-duration simultaneous ejections of McN and glu antagonized glu in all cases. Continuous application of glu lead to McN inhibition in 94% of cases. In cells receiving both carb and McN, it was observed that carb could facilitate and McN inhibit.

50.16

BRAINSTEM PROJECTIONS TO THALAMUS AND HYPOTHALAMUS. E. Carstens, J. Leah*, J. Lechner* and M. Zimmermann. II. Physiol. Inst., Univ. Heidelberg, D-69 Heidelberg (FRG).

A paucity of information on brainstem projections to medial thalamus and hypothalamus prompted us to map them using the retrograde transport of colloidal gold-WGA-HRP with silver intensification in the rat. Injections of <1 ul were restricted to centrum medianum (CM), centralis lateralis (CL), medialis dorsalis (MD), zona incerta (ZI), or medial or lateral hypothalamus (MH, LH).

Injection of CL/MD labeled numerous (>100/section) neurons bilaterally throughout the rostro-caudal extent of midbrain periaqueductal gray (PAG), dorsal raphe, reticular formation (RF) and substantia nigra, and in pontomedullary raphe (eg., raphe magnus), RF, locus coeruleus and dorsolateral pontine n., lateral reticular n. (LRN), n. of solitary tract (NST), and trigeminal n. caudalis (V). Many were labeled ipsilaterally in superior colliculus (SC) and ant. pretectal n. ZI similarly labeled numerous neurons except that there were many more in contralateral V and the dorsal column n. (DCN). CM or CL alone labeled relatively fewer midbrain neurons in a similar pattern, but with few or no pontomedullary cells. LH labeled numerous neurons in a distribution similar to CL/MD and ZI, but with fewer in SC or DCN and almost none in V. A small MH injection labeled scattered cells in midbrain PAG/LF, but revealed a strikingly dense bilateral projection from the ventral and laterodorsal tegmental n.

EXAMINATION OF RECEPTIVE FIELD SURROUNDS IN SOMATOSENSORY NEURONS IN CAT SUPERIOR COLLICULUS. H. R. Clemo and B. E. Stein. Dept. Physiol., MCV/VCU, Richmond, VA 23298.

Somatosensory receptive fields (RF) of superior colliculus (SC) neurons contain best areas where stimulation elicits the greatest response. As the distance from the best area increases, the number of spikes elicited and response probability decrease. We now examined RFs to determine the influence of surrounding regions. Two methods were used: a) some cells were studied by comparing the response to stimulation of the RF center to that evoked by simultaneously stimulating the RF center and (individually) sites outside the excitatory borders; b) in some cells, the response to a stimulus applied inside the RF border was compared to the response to a stimulus that was elongated and straddled the border. In most cells, stimulation at the majority of sites outside the RF had no significant effect on the within-field response. However, in almost one-half of the cells, the within-field response was influenced from at least one site outside the RF: 70% showed some response facilitation and 30% response inhibition. These results suggest that for many somatosensory SC cells the border defining the area within which impulses can be elicited does not define the extent of the excitatory region. Furthermore, in contrast to other sensory systems here, surround inhibition is of comparatively minor importance.

51.1

SIGNIFICANCE OF SPATIAL LOCATION DETERMINES THE FIRING CHARACTERISTICS OF RAT HIPPOCAMPAL PLACE CELLS. C.R.Breese*, R.E.Hampson, and S.A.Deadwyler. [*SPON: J.H. Ryu*], Dept. of Phys. and Pharm., Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27103.

Previous work from this laboratory demonstrated that control of hippocampal place cell firing was dependent upon several factors, including direction of travel, specific boundaries on the platform, off platform cues, distance from the center of the place field, and the significance of a spatial location (Breese *et al.*, Soc. Neurosci. Abstr. 13:173.6, 1987). We report here additional aspects of place cell plasticity determined by a comparison of firing before and after instituting a restrictive baiting procedure which was shown to alter the location of place cell firing. Place fields were defined as clusters of cell discharges within 0.75 cm of each other which constituted at least 20% of the total number of spikes. In control sessions, place fields emerged near regions of the platform where water was randomly available, but such fields could not be predicted on the basis of either traversal or time-in-location maps. Following a 20-30 min period in which baiting was restricted to only one location on the platform, a majority of the place fields (19 out of 21, X^2=20.5-225.2; $p<0.01$) shifted to that location. Analysis of variance showed no difference between control and restricted baiting fields in either total number of spikes, spike density, or total number of pixels containing at least one spike. Significant decreases were found in the distance of individual cell spikes from the region of highest firing density in the field ($F(41)=9.58$; $p<0.003$), total area included in the place field ($F(41)=11.503$; $p<.002$) and the number of fields meeting the field size criteria ($F(39)=6.896$; $p<.02$) in the baiting protocol. These results indicate that nonspatial attributes of the environment can change the location in which place cells fire and that such changes appear to affect all place cells regardless of field size, location, or density. *[Supported by NIDA grants DA 04441, DA 03502 and DA 00119 to S.A.D.]*

51.2

HIPPOCAMPAL PLACE CELL TO SILENT CELL RATIOS IN FREELY-BEHAVING RATS. L.T. Thompson & P.J. Best, Neuroscience Program and Department of Psychology, University of Virginia, Charlottesville, VA 22903.

A frequent criterion used for inclusion of units in both intra- and extracellular studies of neuronal function is spontaneous activity. In any given hippocampal electrode track, however, more neurons can be visualized proximal to the track than are recorded. Our interest in place cell activity led to the present study, which determines the relative proportions of place cells to silent cells in the dorsal CA1 area of rat hippocampus.

Well-isolated complex-spike cells were located using driveable chronic microwire electrodes in anesthetized rats. Unit activity was recorded under anesthesia, during exploration of a number of spatial environments consquent to place cell studies, and during later re-anesthetization. Only units demonstrating similar physiological characteristics during both periods of anesthetization were included in this study. Some units were also electrically driven by chronic stimulating electrodes in the conditions listed, to verify that anomolous changes in electrode position or other variables were not responsible for lack of detectable unit activity on many electrodes in waking rats.

Both barbiturate and benzodiazepine anesthetics increase the firing activity of hippocampal complex-spike neurons isolated in waking rats. Use of these agents during unit isolation therefore increases the likelihood that a unit is included in our sample. Over 60% of all units isolated in dorsal hippocampus under anesthesia have no detectable spontaneous activity, even when exposed to numerous spatial environments. Spontaneously active units in the waking rat generally exhibited place field activity, although the characteristics vary from cell to cell and from environment to environment. Within a given environment, such activity is extremely stable.

51.3

TWO FUNCTIONAL CATEGORIES OF HIPPOCAMPAL COMPLEX SPIKE CELLS. **S.I.Wiener & H.Eichenbaum. Dept. Biology, Wellesley College, Wellesley MA 02181.**

Several investigators have reported that most hippocampal complex spike cells fire in relation to significant behavioral events in learning tasks, but others have reported that most of these cells fire primarily in relation to the animal's location in its environment. To directly compare behavioral versus spatial correlates, we recorded from 100 neurons while rats performed an odor discrimination and a spatial navigation task in the same environment. In the odor task, 23 cells were characterized as cue-sampling (CS) cells that fire when the rat is investigating the odor cues, 22 as goal-approach (GA) cells that fire when the rat advances towards the odors or reward, and 55 as having no identifiable correlate (NC). In the spatial navigation task, 81 cells had a significant place field, that is, locus of elevated firing.

65% of CS cells had place fields in the spatial task compared to 86% of GA cells and 87% of NC cells. Place fields of CS and GA cells in the spatial task were not necessarily where odors or rewards were delivered, although more GA cells than CS or NC cells had fields encroaching on that locus. Directly comparing the correlates, 72% of CS cells increased firing more during odor sampling than when the rat was in the place field in the spatial task. Conversely, 74% of GA cells increased firing more when the rat was in the place field than when the rat was performing the approach behavior (X^2=8.35, p<.01). Hippocampal complex spike cells can have seemingly unrelated behavioral and place correlates in the same environment. However, there appear to be two functional subtypes: one type of cell that fires maximally during stimulus analysis and another that fires maximally during spatial navigation.

51.4

THE ORGANIZATION OF PLACE FIELDS IN THE HIPPOCAMPUS. **H.Eichenbaum, S.I. Wiener & N.J. Cohen. Dept. Biology, Wellesley College, Wellesley MA 02181.**

Since the discovery that most hippocampal cells have "place fields", that is, they fire selectively when a rat is in a particular locus in its environment, investigators have wondered how the representations of places are anatomically organized in the hippocampus. We recorded simultaneously from groups of neighboring (0.5mm radius) CA1 neurons in rats performing a spatial navigation task; over 80% of the cells had significant single place fields or multiple subfields. In this preliminary study, we asked whether neighboring cells represent a restricted part of space with close and overlapping place fields (like the organization of receptive fields in visual cortical column), represent all places (like the organization of trigger features in a column), or are not related. For each of 62 groups of 4-13 cells, the mean distance between nearest-neighbor subfields and field overlap were compared to similar measures on 1000 "simulated" groups with place fields matching those in the real group but located and oriented randomly. As a control, we made the same comparisons on groups of cells selected randomly from different animals.

Place fields of 76% of real groups were closer than the average for simulated groups (z=3.93, p<.001; 19% were above the 95th %ile) and 77% had more overlap (z=4.19, p<.001; 42% were above the 95th %ile). These signs of "clustering" were not seen in random-selection groups (real vs random-selection groups: X^2=5.13, p<.02 for closeness; X^2=8.93, p<.01 for overlap). Further analyses revealed that real groups usually have multiple clusters of place fields covering a total of up to 75% of the environment. Hence the mapping of space in the hippocampus involves a combination of overlapping place fields and representation of widespread loci.

51.5

EFFECTS OF ENVIRONMENTAL MANIPULATIONS ON THE DISCHARGE OF HEAD-DIRECTION CELLS IN THE POST-SUBICULUM. J.S. Taube, R.U. Muller*, J.B. Ranck, Jr. Dept. of Physiology, SUNY Health Sciences Center, Brooklyn, NY 11203.

Many neurons in the postsubiculum discharge as a function of a rat's head direction in the horizontal plane, independent of the rat's behavior and place in the environment. The present study examined the effects on head-direction cell firing of 1) removing the salient visual cue or 2) changing the shape of the environment. Recordings were made from head-direction cells while rats moved freely in a 76 cm diameter gray cylinder. The orienting visual cue was a white card taped to the inside wall of the cylinder. Following an initial session, an 8 min session was run with the cue card removed, followed by another control session. An 8 min session was then run with the rat in either a rectangular or square enclosure; each alternative enclosure contained a white cue card in a similar position as in the cylinder.

Results from both environmental manipulations were similar. The rate of cell firing remained unchanged, but the head direction for maximal firing rotated more than 36° in 9/15 cells when the cue card was removed, and in 9/11 and 3/8 cells in the rectangular or square enclosure, respectively. Some cells showed no change in the preferred head direction in one enclosure, but showed a change in the other. On 2 occasions, 2 head direction cells were recorded simultaneously. The effects of an environmental manipulation on the preferred head direction for one cell were nearly identical to the observed effects in the second cell. These results demonstrate that head-direction cell firing is not simply a sensory response to a visual cue. Furthermore, changes in the shape of the environment can influence the preferred head direction for maximal firing.

51.6

HIPPOCAMPAL PLACE CELLS CAN FIRE DIFFERENTLY IN TWO VISUALLY IDENTICAL LOCATIONS IN A SYMMETRICAL CHAMBER. P.E. Sharp, J.L. Kubie and R.U. Muller.* SUNY, Brooklyn, NY 11203.

The location-specific firing of hippocampal place cells can easily be brought under the control of experimenter-defined cues. Nevertheless, there is evidence that regions of intense firing (firing fields) are not determined just by immediate sensory input, but also by earlier states of the nervous system (O'Keefe & Speakman, 1987). Here, we report on the roles of visual cues and memory in determining the firing of place cells.

Single cell activity was recorded as rats chased food pellets in a gray cylinder with one or two identical cue cards on the wall; when two cards were used, they were placed 180° apart. If place cells are controlled only by sensory input, the firing pattern in the presence of two identical cards might consist of the field seen with one card, and a second field 180° away. Alternatively, since the rat moves freely in the cylinder, the information is available that pairs of visually identical places are not truly the same, and it is possible that the firing pattern will be different in two such places.

Most cells had just one field after the second card was introduced; the field was the same in the presence of either one or two cards. The field position could be flipped 180° by starting the rat out near one card or the other. Two cells showed paired firing fields 180° apart in the positions expected from sessions with a single card. Neither cell fired in a way consistent with exclusive control by cues. In one case, the second field disappeared with repeated exposures to two cards; in the other the second field persisted when only one card was used. We conclude that place cells are influenced both by the immediate sensory configuration and by internal neural states related to earlier experience in the environment.

51.7

THE EFFECTS OF HEAD ORIENTATION ON THE FIRING OF HIPPOCAMPAL PLACE CELLS. Elizabeth Bostock, Jeffrey Taube, and Robert U. Muller*, SUNY-HSCAB, Physiology Dept., Brooklyn, NY 11203.

Place cells are hippocampal complex-spike cells which fire rapidly only in a localized region of the rat's environment ("firing field"). Previous studies of the effect of direction on place cell firing measured direction from the rat's trajectory. For example, McNaughton, Barnes, & O'Keefe (1983) and Leonard, McNaughton, & Barnes (1987) found that place cell firing depends on the rat's movement direction within the firing field on an 8-arm maze, where both the reward location and the trajectories a rat may take are directionally restricted. We examined whether the firing of place cells is necessarily directional by recording from place cells when neither reward nor the set of possible trajectories were directionally restricted. A 2-diode video detection and recording system was used to track the rat's instantaneous head direction and position within a cylinder at 60 Hz. Hippocampal place cells were recorded while rats chased food pellets randomly thrown onto the floor of a cylinder. None of the 14 place cells recorded to date show strong variation of firing with head orientation. Thus, the firing of hippocampal place cells is not necessarily modulated by the rat's direction; directional modulation of place cell firing may be dependent on the structure of the space accessible to the rat, and the polarization of reward contingencies.

51.8

THE HIPPOCAMPUS AND SPATIAL LEARNING: A REAL-TIME ATTENTIONAL-ASSOCIATIVE MODEL. Nestor A. Schmajuk. Department of Psychology. Northwestern University. Evanston, IL 60201.

We applied the S-P-H model (Schmajuk, Soc. Neur. Abs 13: 1100) to the simulation of several spatial learning paradigms. We assumed that hippocampal lesions (HL) and long-term potentiation (LTP) induction affect computations of different variables in the model. In the normal case, the associability of stimulus CS_i with CS_k is given by: $\alpha_i^k = |\lambda^k - B^k|$, where B^k is the aggregate prediction of CS_k, and λ^k represents the intensity of CS_k. In the HL case, associability is given by $\alpha_i^{US} = |\lambda^{US} - \dot{V}_i^{US}|$, where $\dot{V}_i^k$ is the net associative value between CS_i and CS_k. In the LTP case, CS-CS associations are equal to 1. Computer simulations of normal and HL cases were carried out for: acquisition and reversal in a T-maze, acquisition in a water tank, acquisition in a radial-arm maze, and latent learning (cognitive mapping) in a multiple T-maze. Also computer simulations of normal and LTP cases were carried out for acquisition in a radial-arm maze.

51.9

MICROIONTOPHORETIC ATROPINE ELIMINATES FIRING OF HIPPOCAMPAL THETA CELLS. Mark Stewart and Steven E. Fox. SUNY Health Sci. Ctr., Brooklyn, NY 11203.

The medial septal nuclei are essential for the naturally occurring hippocampal theta rhythm. Evidence that the rhythmic activity of the septum is carried via *cholinergic* afferents to the hippocampus has been: a) the existence of a cholinergic septo-hippocampal projection and b) the sensitivity of one type of theta rhythm (type II) to antimuscarinic agents. The muscarinic action of ACh on pyramidal cells, however, is too slow to carry even a 4 Hz signal.

Eight extracellularly recorded hippocampal theta cells (3 CA1, 5 hilus) in urethanized rats were tested with iontophoretic application of atropine. The spontaneous firing of all theta cells tested could be temporarily *eliminated* by iontophoretic atropine (20-100 nA, 10-60 sec, 50 mg/ml in H_2O). At lower doses or during early recovery, the firing rates of the cells were greatly decreased. During this time, action potentials of phasic theta cells were still phase-locked to the ongoing theta rhythm.

This result is consistent with reports of a fast muscarinic excitation of hippocampal and cingulate interneurons, *in vitro* (Benardo & Prince, Brain Res 249: 315, 1982; McCormick & Prince, J Physiol 375: 169, 1986). It also suggests that: a) the cholinergic cells of the septum are, in fact, rhythmic and b) this connection with interneurons is the mechanism by which theta-frequency activity of the septum is transmitted to the hippocampus.

51.10

FUNCTIONAL CONNECTIVITY BETWEEN PAIRS OF MEDIAL SEPTAL NEURONS. L.V. Colom and B.H. Bland. University of Calgary, Department of Psychology, Calgary, Alberta T2N 1N4.

The medial septum/diagonal band nuclei are critical for the generation of hippocampal theta (θ) rhythm in vivo. The study of the discharge patterns of septal cells and their interactions during hippocampal EEG states will aid in the understanding of the mechanisms involved in the generation of θ activity. In order to examine the relationship between septal cells and the production of hippocampal θ, pairs of cells were recorded in the septum from the same microelectrode, during the spontaneous occurrence of θ and irregular activity (LIA) in the hippocampus, using urethane anaesthetized rats. Out of 25 pairs studied, 7 pairs showed a cross-correlation during both θ and LIA, 11 pairs showed a cross-correlation during θ, 1 pair was cross-correlated during LIA and 6 pairs showed no correlation in either state. Six out of the 7 pairs showing the strongest cross-correlations between both the θ and LIA states were comprised of rhythmic cells. Cell pairs maintaining a strong correlation of their spike trains during both synchronized and desynchronized EEG patterns have a stronger functional connectivity than pairs correlated in only one EEG state. We therefore conclude that pairs of rhythmic cells have a special functional connectivity allowing the recruitment and synchronization necessary to produce a strong rhythmic output to the hippocampus.

51.11

INTRINSIC THETA-FREQUENCY MEMBRANE POTENTIAL OSCILLATIONS IN HIPPOCAMPAL NEURONS IN VITRO INDUCED BY DEPOLARIZING CURRENT. L.S.Leung and C.Y.Yim, Depts. Clin. Neurol. Sci. and Physiology, Univ. of Western Ont., London, Canada.

Intracellular recordings were made in 40 CA3 and CA1 neurons in the in vitro hippocampal slice preparation. Sustained (> 10 s) depolarization of the neurons by current injection (0.1-0.5 nA) through the recording electrode produced an initial burst of action potentials at > 50 Hz, followed by rhythmic membrane potential oscillations (MPO) in the 3-11 Hz frequency range in all recorded CA3 and CA1 cells. The depolarized peak of the MPO was typically accompanied by a single action potential, although the MPO may continue for several cycles without action potential discharge. The MPO were larger and of higher frequency at a more depolarized membrane potential. At resting or hyperpolarized membrane potentials, theta-frequency MPO were less obvious. Tetrodotoxin (TTX, 3 μM) abolished the spiking and MPO in 4 cells; in all cells, membrane resistance decreased and spike threshold increased, although a broad, presumably Ca++ spike could still be evoked. Replacement of Ca++ by Mg++ abolished synaptic transmission and attenuated the MPO. It appears MPO arise when the membrane potential is at or near the spiking threshold, and requires (1) a somatic or dendritic sodium-mediated spike (blocked by TTX) and (2) Ca++, possibly Ca++ mediated K+ currents. 51.12

DISTRIBUTION OF COHERENCE OF MICRO-EEG IN THE HIPPOCAMPUS OF THE RAT ASLEEP AND AWAKE. T.H. Bullock, M.C. McClune*, G. Buzsaki, Dept. of Neurosciences, Univ. of Calif., San Diego, La Jolla, CA 92093

Recordings of ongoing, compound field potentials were made with 16 implanted semi-microelectrodes (A-P) in a row, 0.2 mm apart, either all in the same layer, stratum radiatum of CA1, or obliquely from str. oriens (A-F) to str. radiatum (I-P, H is just below the pyramids), in three behavioral states. Coherence, (COH) as a useful descriptor, was computed for each pair of electrodes in frequency bands from 1-40 Hz. (1) COH falls slightly with frequency in the 1-40 Hz range, but more consistently with distance between electrodes, most steeply at 20-40 Hz. The array in str. radiatum, parallel to the pyramids, shows decline of COH with distance is steeper than in isocortex (unpubl. data), except the widespread theta (8 Hz) band. Plots of COH vs time show stability of the 60s-mean over hours but in the domain of seconds, significant, nonrandom fluctuations, independent in the several bands. (2) The oblique array shows marked discontinuities across hippocampal laminae. Loci A-G within str. oriens and loci L-P in str. radiatum are each highly coherent among themselves. Locus H, just below the pyramidal layer is moderately and nearly uniformly coherent with A-K and less, yet significantly coherent with L-P. A-G have moderate COH with L-P, and less with I-K, the values depending on the frequency band but the above pattern is similar for all. These statements are true for all three conditions, slow wave sleep, paradoxical sleep (PS), and alert walking (W); PS shows the sharpest localization, whereas W in the theta band shows the least. (3) Delta (3 Hz) activity shows a narrow zone of phase lag of 125 deg below the pyramids (locus I) relative to the uniform phase of str. oriens, (A-H), dipping back to 14 deg lag (J) and then rising again over 0.6 mm to 188 deg lag by locus M, maintained through P deep in str. radiatum. Theta and up to 18 Hz shows only a broad zone at and below the pyramids slowly shifting to 120 deg phase lead of str. radiatum over str. oriens.

51.13

POWER SPECTRAL ANALYSIS OF RHYTHMIC FIELD POTENTIALS IN HIPPOCAMPAL SLICE: A MODEL OF THE EEG? J.H. Schneiderman
Univ. of Toronto., Toronto, Canada M4Y 1J3.

Power spectral analysis (PSA) was applied to spontaneous field potentials recorded from the CA3 distal apical dendritic region of 64 guinea pig hippocampal slices. Spectra distinguishable from those recorded from the bathing medium were obtained in 52 slices. The remaining slices were not viable since they did not respond to stimulation or burst in the presence of 3.4 mM Penicillin (PEN). Power was distributed in a diffuse band up to 15-20 Hz, however, in most of the slices was concentrated under 10 Hz. No consistent peaks were identified. Power was comparable to the 60 Hz peak indicating that the signal was largely buried in background noise. Distinct peaks around 6 Hz appeared in .085 to 0.17 mM PEN. Peak power increased and shifted to the left as PEN was raised to 0.51 mM. Spontaneous bursting was always heralded by non-stationary increases in rhythmic activity. Large peaks under 6 Hz developed in slices which burst spontaneously only after a few stimulations. In contrast, power increased in all frequencies in low Mg++ (0.1 to 0.5 mM) or shifted to the right. Concentrations of Mg++ interfering with synaptic transmission reduced the power both in normal medium and in low PEN. PSA revealed low level rhythmic activity responsive to pharmacologic and ionic manipulations which could provide a model for studying the mechanisms underlying the EEG.

51.14

APV, AN N-METHYL-D-ASPARTATE ANTAGONIST BLOCKS HIPPOCAMPAL THETA RHYTHM. D. J. Stewart, L. S. Leung and K. Desborough*. Depts. of Clin. Neuro. Sci. and Physiology, University of Western Ontario, London, Ontario, CANADA.

Recent work has suggested that excitatory amino acids, such as N-methyl-D-aspartate (NMDA), may be involved in normal hippocampal function. In freely behaving rats, intraventricular injection of the NMDA antagonist, 2-aminophosphonovaleric acid (APV; 10, 20, 40 ug) was associated with a dose-dependent ataxia and suppression of hippocampal theta rhythm. APV appeared to be capable of blocking both atropine-sensitive and atropine-resistant components of the theta rhythm. Theta rhythm following systemic atropine sulfate (i.p., 25 mg/kg) was suppressed by APV (20 ug). Similarly, the atropine-sensitive theta rhythm present under urethane anesthesia was also suppressed by APV (20 or 40 ug). However, the delta-frequency slow waves and hippocampal commissural evoked potentials were not affected by APV. The peak action of APV occurred at about 10 minutes after intraventricular infusion and theta rhythm was affected bilaterally after unilateral infusion of APV. The site of action of APV on the theta rhythm may be hippocampal, subcortical (septal) or some combination.

THE EFFECTS OF EARLY NEST ENVIRONMENT ON THE MATERNAL BEHAVIOR OF RATS WITH FORNIX TRANSECTIONS. B. Osborne, B.C. Woodside*, J.E. Jans* and K.E. Bjorn*. Department of Psychology, Middlebury College, Middlebury, VT 05753 and Department of Psychology, Concordia University, Montreal, Quebec, Canada H4B 1R6.

Total fornix transection results in marked deficits in pup retrieval, nest building and the pattern of mother-litter contact on Day 2 or 7 postpartum but only small and early (Day 0 or 1) effects on pup integrity (Osborne et al, Neurosci. Abst., 13, 1333). In the first experiment we looked at early postpartum maternal behavior following fornix transection. Fornix transected or sham operated nulliparous females were observed 6 hrs. in light and 6 hrs. in dark on Day 0 postpartum. Fornix transected dams exhibited marked differences in mother-litter contact but also severely reduced pup survival.

Since pup retrieval was severely reduced in comparison to our earlier work and the only changes were in early nest environment (dams in the earlier work were in small nest boxes for 48 hrs. postpartum), in the second experiment we manipulated nest environment. Groups received enclosed nest boxes inside observation cages (aided) or observation cages alone (unaided). Again fornix transection disrupted mother-litter contact but fornix transection decreased pup survival only in the unaided condition.

PHOSPHATIDYLINOSITOL METABOLISM DURING IN VITRO HYPOXIA. H-M. Huang* and G.Gibson (SPON:D. Levy). Cornell University Medical College at the Burke Rehabilitation Center. White Plains, NY 10605

The phosphatidylinositol (PI) cascade transduces numerous signals across cell membranes. Postdecapitative ischemia is known to activate PI metabolism. An in vitro model of these changes would help elucidate the molecular mechanism of these alterations. K^+-stimulated PI turnover was therefore examined in rat brain slices prelabelled with [^{3}H]-inositol. Depolarization (60 mM KCl) increased inositol phosphates (IP and IP_2) formation in a Ca^{2+} dependent manner. The effects of in vitro histotoxic hypoxia (i.e. 0.5 mM KCN) on the K^+ stimulated PI cascade were determined. At early times (10 sec and 1 min), hypoxia enhanced the cascade as shown by increased IP_2 formation. More prolonged hypoxia (10 min) reduced the cascade as shown by diminished formation of IP and IP_2. Hypoxia did not alter the PI cascade under basal conditions. The early stimulation of the cascade may be due to the hypoxic-induced increase in cytosolic free calcium that we previously demonstrated. Negative feedback regulation by protein kinase C may lead to the subsequent impairment of PI metabolism. An altered PI cascade may lead to neurotransmitter changes and tissue damage that accompany hypoxia-ischemia.

52.2

PROTEIN KINASE C FROM RAT BRAIN: CHARACTERIZATION AND INHIBITOR STUDIES. L.G. Mendelsohn, V.L. Lucaites and J.J. Howbert. Lilly Research Labs, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN 46285

The role of protein kinase C (PKC) in signal transduction in response to receptor stimulation and hydrolysis of phosphatidyl inositol (PI) is well established. Many neurotransmitters cause PI breakdown resulting in activation of PKC and reinforcement of the signal or negative feedback. Given the prevalence of PKC in the brain, the study of PKC inhibitors may allow for better understanding of the role of PKC in intercellular communication within the CNS. Partially purified PKC was prepared from soluble EDTA extracts of rat brain homogenate using DEAE-cellulose chromatography. Silver stained SDS-polyacrylamide gels of the enriched fractions show four major bands, the darkest staining of which is found at the molecular weight of PKC (M_r=80,000). The PKC-rich DEAE fraction was enriched about 90-fold; specific enzyme activity from the homogenate to the final fraction increased from 0.24 pmol ^{32}P incorporated/min/ug protein to 21.5 pmol/min/ug protein. A kinase assay using this fraction was adapted to microtiter plates using 20 mM tris-HCl pH 7.4, 750 ug/ml histone Type III, 5 mM magnesium acetate and 20 uM ATP containing ^{32}P-ATP. Phospholipid and Ca^{2+}-independent kinase activity (background) was measured in the presence of 1 mM EGTA. Phosphatidylserine (PS) and Ca^{2+} dependence of the enzyme was established; basal PKC activity was measured as phosphorylation in the presence of PS and Ca^{2+} minus the background activity. Maximum stimulation with phorbol 12,13-dibutyrate (PDBu) was seen with PS and Ca^{2+} concentrations of 2 ug/ml and 3 uM, respectively. Phorbol stimulation of PKC activity was assessed routinely at low PS, Ca^{2+} and PDBu (7.5 nM) levels, and yielded a maximally stimulated response of approximately 3-fold basal levels. The effects of four kinase inhibitors on PKC were examined at several concentrations. Inhibitors used were staurosporine, a microbial alkaloid, the isoquinolinesulfonamides H7 and W7, and the polypeptide Polymyxin B. All inhibitors showed a dose related effect, with staurosporine being the most potent with an IC_{50} of approximately 10 nM.

52.3

PROPERTIES OF A PROTEIN KINASE C ACTIVITY BOUND TO SYNAPTIC PLASMA MEMBRANE (SPM) AND POSTSYNAPTIC DENSITY (PSD) FRACTIONS FROM CANINE CEREBRAL CORTEX. T. Suzuki* and P. Siekevitz (SPON: J. A. Sechzer) Lab. Cell Biol., Rockefeller Univ., New York, NY 10021

Kinase C activity (phosphorylation dependent on Ca^{2+}/phosphatidylserine and Ca^{2+}/phosphatidylserine/phorbol ester) was detected in SPM with 87k Mr, 60k Mr, 50k Mr and 20k Mr as endogenous substrates and histone III-S as exogenous substrate. In PSD, only 20k Mr protein as substrate was detected, but this protein was also phosphorylated by the PSD Ca^{2+}/calmodulin-dependent kinase II. Both the phosphorylations of histone and of endogenous substrates were enhanced in SPM prepared after treatment of brain homogenate with phorbol 12-mysristate 13-acetate (TPA), but very little enhanced in PSD prepared after such TPA treatment. The phosphorylation of histone and endogenous substrates was inhibited by H-7 but not by calmidazolium in PSD and in SPM prepared with and without TPA treatment. A salient finding was that the SPM kinase C activity (both for endogenous proteins and for histone) enhanced by TPA treatment of brain homogenate was inhibited by calcium (IC_{50}, 3 x10^{-7} M). Others have found that TPA treatment causes a translocation of the kinase from the cytosol to a membrane-bound form. Our results suggest that this modified Kinase C may be under physiological control, dependent on the intracellular Ca^{2+} concentration.

52.4

COMPONENTS OF THE IP_3 SECOND MESSENGER SYSTEM IN RAT BRAIN DIFFER IN DEVELOPMENTAL REGULATION AND REGIONAL LOCALIZATION. A.M. Heacock, E.B. Seguin* and B.W. Agranoff. Neuroscience Lab, U of Michigan, Ann Arbor, MI 48104-1687.

In order to explore the mechanism of regulation of the phosphoinositide-linked second messenger system, we have examined the ontogeny and regional localization of three of its components: inositol 1,4,5-trisphosphate (IP_3) phosphatase, IP_3 kinase and IP_3 receptor. Developmental studies of IP_3 metabolism in rat cortex indicate that IP_3 phosphatase activity is relatively high at birth (50% of adult values) and increases to adult levels by 2 wk postnatal. In contrast, IP_3 kinase activity in cortex is low at birth (8% of adult values) and increases gradually, reaching adult levels by 4 wk postnatal. Cortical IP_3 receptor ontogeny appears to parallel that of the IP_3 kinase. In adult rat brain, IP_3 phosphatase activity in cortex, hippocampus, hypothalamus and pons/medulla was similar, whereas activity in the cerebellum was 8 to 10-fold higher. An enrichment of IP_3 receptor in the cerebellum has also been reported. The distribution of IP_3 kinase is markedly different, with similar activities present in cerebellum, cortex and hippocampus and very low activity in hypothalamus and pons. These results suggest that the principal route of IP_3 metabolism and the ability of IP_3 to release stored Ca^{2+} vary depending on both brain region and stage of development. (Supported by MH 42652 and NS 15413.)

52.5

Activation of Phospholipase D Phosphatidyl Transferase Activity by Protein Kinase C in Neural-derived NG108-15 Cells. M. Liscovitch* (SPON: Eli Hazum). Department of Hormone Research, The Weizmann Institute of Science, Rehovot 76100, Israel.

The activation of cellular phospholipase D by protein kinase C (PKC) was examined in NG108-15 cells by measuring the biosynthesis of the abnormal phospholipid phosphatidylethanol (PEt), produced by phospholipase D in the presence of ethanol by trans-phosphatidylation. PEt production depended on stimulation by 12-O-tetradecanoylphorbol-13-acetate (TPA), in a time- and concentration-dependent manner (EC_{50} = 18 nM). The levels of [^{3}H]PEt in TPA-treated cells were directly related to ethanol concentration in the physiologically attainable range (20-100 mM). The effect of TPA on PEt production could be mimicked by 1,2-dioctanoyl-sn-glycerol in a non-additive manner. The effect of TPA was inhibited by the PKC inhibitor H-7 (0.1 mM) by 70% and was abolished in cells in which PKC was down-regulated by pre-treatment of the cells with TPA. In contrast, TPA did not affect the levels of phosphatidic acid in NG108-15 cells. These results indicate that PEt biosynthesis depends largely on activation of PKC. It is proposed that PKC selectively activates the phosphatidyl transferase activity of phospholipase D, reflecting a signal termination mechanism which may be operative in phospholipase D-mediated signal transduction cascades.

52.6

IDENTIFICATION OF FOUR TYPES OF PROTEIN KINASE C IN RAT HIPPOCAMPUS. Bryan L. Roth#, James Hermiller*, David J. Jacobowitz° and Michael J. Iadarola**, #Department of Psychiatry, Stanford University Medical School, Stanford, CA 94305; °Lab Clinical Sciences, NIMH, Bethesda, MD; *Naval Medical Research Institute and **Lab Neurobiol and Anesthesiol, NIDR, Bethesda, MD.

Protein kinase C (PKC) is a calcium and phospholipid-dependent enzyme which is highly enriched in rat hippocampus. Many hormones and neurotransmitters may activate PKC via production of diacylglycerol from phosphoinositide hydrolysis. Activation of PKC induces a wide variety of biochemical actions including ion-channel opening and closing, long-term potentiation and alterations of PI metabolism. Recently several subtypes of PKC have been identified by cloning and sequencing cDNAs; we sought to determine whether 4 of these (γ, βI, βII, and ε) might be present in hippocampus. Northern blot analysis of total RNA from hippocampus disclosed distinct mRNAs for each PKC subtype and suggested preferential splicing of the β-PKC to the βII type. Antibodies directed against the β-PKC disclosed a heterogenous distribution in rat hippocampus with intense labelling of fibers in the s. oriens adjacent to the pyramidal cells as well as in s. radiata. Analysis of micropunches of rat hippocampus (300 µm each) by Western blots and visualization of PKC by antibodies labelled with [^{125}I]-protein A showed the β-PKC to be preferentially located in the CA1 region.

52.7

PHOSPHATIDYLINOSITOL 4-PHOSPHATE (PIP) AND MG^{2+} REGULATE THE ACTIVITY OF A SYNAPTOSOMAL PROTEIN KINASE. O.B. McDonald* and N. Sahyoun. (SPON: G. Pollard). The Wellcome Research Laboratories, 3030 Cornwallis Road, Research Triangle Park, NC 27709.

A synaptosomal protein kinase distinct from protein kinase C avidly phosphorylated a major endogenous M_r 87,000 polypeptide. Of a variety of lipid and lipid-derived potential regulators, PIP, PI and phosphatidylglycerol (PG) inhibited the phosphorylation of the M_r 87,000 substrate as well as ^{32}P-incorporation into two less prominent polypeptides with M_r values of 47,000 and 62,000. PIP was about threefold more potent than PI and PG with a K_i value of 0.3 µM at 1.5 mM $MgCl_2$. Unsaturated fatty acids mimicked the effect of PIP at concentrations above 10 µM. The inhibitory effect of PIP was investigated as a function of the concentrations of protein substrate, ATP and $MgCl_2$; the inhibitory mechanism featured a >fortyfold reduction in the affinity for $MgCl_2$ in the presence of 18 µM PIP. The PIP-sensitive protein kinase was released in synaptosomal hypotonic lysates from which the enzyme was purified by anion-exchange, hydroxylapatite and gel-permeation chromatography. The isolation and characterization of this protein kinase suggest a role for PIP and $MgCl_2$ in synaptosomal signalling.

52.8

PROTEIN KINASE C-MEDIATED PHOSPHORYLATON OF P_O IN PERIPHERAL NERVE FROM NORMAL AND DIABETIC RATS C.L. Rowe-Rendleman*, L.N. Berti-Mattera* and I. Eichberg, Dept. Biochem. Biophys. Sci., Univ. of Houston, Houston, TX 77004.

Previous studies from this laboratory have shown that the phosphorylation of the P_O glycoprotein as well as of myelin basic proteins, is increased in sciatic nerve from chronically diabetic rats. We have investigated whether protein kinase C (PKC) is responsible for this effect. As reported by others (Brunden and Poduslo, J. Neurochem. 49, 1863 (1987)), inclusion of phorbol 12,13-dibutyrate (PDB;100 nM) in incubations of desheathed nerve segments increased the phosphorylation of P_O as much as 500%. Phorbol-12-myristate 13-acetate (PMA) stimulated to a lesser extent and the biologically inactive phorbol ester, 4-a-phorbol, was without effect. Two antagonists of PKC, 1-(5-isoquinolinyl-sulfonyl)-2methylpiperazine (H-7) and staurosporine, depressed control phosphorylation levels and largely prevented PDB-mediated stimulation in a dose-dependent manner. Staurosporine (1 µM) also blocked the rise in P_O phosphorylation over basal levels in nerves from diabetic animals, In these nerves, PDB elicited a 50% greater rise in phosphorylation than in normal nerves. This stimulation was also prevented by H-7 (100 µM) and staurosporine. These results point to a role for PKC in the enhanced phosphorylation of P_O and suggest that additional phosphorylation sites on the protein may be available in diabetic nerve. (Supported by NIH grant DK30577 and NSF Fellowship RCD8758057).

52.9

Bradykinin (Bk)-induced activation of peripheral fibres in neonatal rat tail: receptors and second messenger systems.

M.Perkins*,J.Bettaney,*,P.Forster*and A.Dray. Sandoz Institute for Medical Research, Gower Place, London, England.

The mechanism by which Bk activates nociceptors may involve specific B1 or B2 receptors coupled to neural second messenger systems (Miller, 1987, TINS 10 226). The present study examines these possibilities in Bk induced activation of peripheral fibres of the neonatal rat.

Spinal ventral root depolarization evoked by activation of fibres in the tail was recorded in an in vitro preparation of the neonatal rat spinal cord/tail. Bk but not D-Arg9-Bk evoked a dose dependent response which was selectively antagonised by D-Arg0-Hyp3-Thi,5,8 D-Phe7-Bk. In low calcium perfusates of the tail 4--phorbol 12,13 dibutyrate (PDBu) also depolarized capsaicin sensitive fibres and the effect of PDBu and Bk was selectively antagonised by the protein kinase C inhibitor staurosporine. Neither nitroprusside, forskolin, dibutyryl cyclic AMP or GMP activated peripheral fibres.

These data suggest that protein kinase-C is involved in the stimulation of peripheral fibres by a phorbol ester or by Bk-B2 receptor activation.

52.10

C-KINASE & THE SLOW VOLTAGE DEPENDENT RESPONSE TO SEROTONIN IN A SEROTONERGIC NEURONE (GSN) OF THE SNAIL.

C.Hill-Venning* and G.A.Cottrell* (SPON: D.Kuterbach). Dept. Biology & Preclin. Med., University of St Andrews, Fife KY16 9TS, U.K.

In the GSN of Helix aspersa, serotonin (5-HT) modulates a slow voltage-dependent K+ current. This occurs via a second messenger system (Barnes, 1984). We used voltage-clamp to investigate the involvement of C-kinase. Effects of activators of C-kinase, down-regulation and an inhibitor were compared with the 5-HT response. Involvement of C-kinase is suggested by (1). OAG (1-oleoyl-2-acetyl-glycerol) (60nM) effected a similar reversible inward current (15-20nA at Vh=-15mV). (2). PDB (phorbol 12, 13-dibutyrate) also effected an inward current (200nM, 10-14nA at Vh= -15mV) which took 5-10 min. to reach maximum. 200nM PDB evoked a current with an average amplitude 67% (n=20) of the control 5-HT response and further application of 5-HT, with PDB, evoked a small response; 800nM PDB fully mimicked the 5-HT response. An additional second messenger is implicated because (1). Experiments to down-regulate the C-kinase by incubation with PDB for up to 24 hr. have failed to abolish completely the 5-HT response, but it was much reduced. (2). Incubation with the C-kinase inhibitor H-7 (1-(5-isoquinolinyl-sulphonyl)-2-methyl-piperazine) for up to 4 hr. (100uM) did not affect the 5-HT response. H-7 did, however, partially reverse the current evoked by PDB.

52.11

NORADRENERGIC POTENTIATION OF EXCITATORY TRANSMITTER ACTION IN CEREBROCORTICAL NEURONS: EVIDENCE FOR MEDIATION BY ALPHA RECEPTOR LINKED ACTIVATION OF PROTEIN KINASE C.

R. D. Mouradian, F. M. Sessler, and B. D. Waterhouse. Dept. of Physiol. and Biophys., Hahnemann Univ., Phila., PA. 19102-1192

Considerable evidence from intact, anesthetized preparations suggests that norepinephrine (NE) may play a modulatory role within local circuitry of the mammalian neocortex; i.e. iontophoretically applied NE or activation of the coeruleocortical pathway is capable of facilitating neuronal responses to synaptic inputs and putative transmitters. The goal of the present study was to further characterize the effects of NE on somatosensory cortical neuronal responses to putative excitatory transmitters using the in vitro tissue slice preparation. Five-barrel glass micropipets were used to record the extracellular activity of individual rat cortical neurons and to iontophoretically apply drug solutions. Somatosensory unit responses to iontophoretic pulses of acetylcholine (ACh) or glutamate (Glu) (10-60 nA; 5-25 sec. duration) were examined before, during, and after NE (1-35 nA) microiontophoresis. Quantitative analysis of peri-event histograms indicated that both Glu- and ACh-evoked excitatory discharges were routinely (Glu 94%, n = 54; ACh 67%, n = 9) potentiated above control levels during NE administration. In 8 cells, NE revealed robust excitatory discharges in response to otherwise subthreshold iontophoretic doses of Glu. The specific alpha antagonist, phentolamine, routinely blocked NE-induced potentiation of responses to threshold doses of Glu (n = 5). Moreover, activation of protein kinase C by iontophoretic application of phorbol 12,13-diacetate (PDA) (5-15 nA) mimicked the potentiating actions of NE on Glu-evoked excitation. In summary, these results demonstrate that NE can facilitate cortical neuronal responses to threshold and subthreshold levels of excitatory transmitter agents. Moreover, unlike noradrenergic augmentation of GABA-induced inhibition, which results from activation of the B-receptor linked cAMP system, these actions appear to be mediated by an alpha-adrenoceptor mechanism which may be linked to intracellular activation of protein kinase C. Overall, these findings reinforce the notion that noradrenergic modulatory actions on excitatory and inhibitory neuronal responses may involve the activation of separate receptor-linked second messenger systems. (Supported by AFOSR-87-0138, NINCDS 18081 to B.D.W.)

52.12

NORADRENERGIC POTENTIATION OF CEREBELLAR PURKINJE CELL RESPONSES TO GABA: PHARMACOLOGIC SPECIFICITY WITH RESPECT TO ADENOSINE ACTIONS AND GABA RECEPTOR SUBTYPES.

B.D. Waterhouse, F.M. Sessler and R.D. Mouradian. Dept. of Physiol. & Biophysics, Hahnemann Univ., PA, 19102-1192.

Previous in vivo studies from our laboratory have consistently shown that iontophoretically applied norepinephrine (NE) can potentiate GABA-induced depressant responses of cerebellar neurons. Other experiments have further suggested that this NE facilitating action is specific for GABA and results from activation of a beta type adrenoceptor which leads to increased intracellular levels of cAMP. The goal of the present studies was to further characterize this action in terms of GABA receptor subtypes and also determine the extent to which adenosine receptor activation might contribute to effects observed with application of 8-bromo 3',5'-cAMP (BcAMP). Extracellularly responses of both in vivo and in vitro cerebellar Purkinje (P) cells to iontophoretic pulses (5-55nA; 10-20 sec. duration) of GABA or baclofen were examined before, during and after NE, BcAMP or adenosine microiontophoresis. Perievent histograms were generated to assess the effects of NE, BcAMP and adenosine on GABA- and baclofen-induced inhibition of spontaneous firing rate. In contrast to results obtained with BcAMP, adenosine was ineffective (12 of 16 cells) in enhancing P-neuron inhibitory responses to GABA. Moreover, neither iontophoretically applied NE nor BcAMP were effective in augmenting baclofen-induced inhibition (5 of 6 cells), suggesting that GABA-B receptors are not directly involved in the potentiation of GABA by NE. However, baclofen was shown to enhance NE-induced potentiation of GABA inhibition (n = 1), suggesting a possible synergistic interaction between NE and GABA-B receptor stimulation in producing this facilitating effect. In summary, these findings suggest that noradrenergic potentiation of GABA-induced inhibition most likely involves changes which target GABA-A receptor mechanisms and that BcAMP-mediated potentiation of GABA does not directly depend upon interactions with the adenosine receptor system. Overall, these results further specify the receptor subtypes and intracellular mediators of NE's potentiating effect on GABAergic synaptic transmission. (Supported by grants AFOSR-87-0138 and NINCDS 18081 to B.D.W.).

52.13

COMPARISON OF MECHANISM OF N-METHYL-D-ASPARTATE AND PHORBOL ESTER INHIBITION OF CARBACHOL-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS IN RAT HIPPOCAMPAL SLICES.

C.C. Chow, R.A. Morrisett, J.O.McNamara. Duke/VA Med. Ctr., Durham, NC 27705

NMDA and phorbol esters have been demonstrated to inhibit PI hydrolysis stimulated by the muscarinic agonist, carbachol (Baudry et.al.,Nature, 319:329 (1986), Labarca et. al., Biochem. and Biophys. Res. Commun., 123:703 (1984)). The goal of this study was to determine whether NMDA and phorbol esters act through the same or different mechanisms.

PI hydrolysis was measured by determining the synthesis of radiolabelled IP1, using anion exchange chromatography in rat hippocampal slices. Preincubation in phorbol 12,13-diacetate (PDA), followed by rinsing was sufficient to inhibit PI hydrolysis stimulated by subsequent exposure to carbachol (1mM). The PKC activator, PDA, produced 42% inhibition of carbachol-stimulated PI hydrolysis in a dose (IC50=.6uM) and time dependent manner. Inactive phorbol, 4-phorbol, exhibited no significant inhibitory effects. Preincubation with NMDA(100uM) produced a 76% inhibition. H-7, a PKC inhibitor, reversed the inhibitory effects of PDA dose dependently(IC50=13uM). By contrast, H-7 did not block the NMDA inhibition of carbachol-stimulated PI hydrolysis.

The inhibition by active, but not inactive, phorbol ester confirms the work by Labarca et.al.and suggests that activation of PKC exerts a feedback inhibition of muscarinic receptor-activated phospholipase C activity. The reversal of the phorbol ester, but not NMDA, inhibition of H-7 suggests that NMDA acts through a mechanism independent of PKC.

52.14

N-METHYL-D-ASPARTATE RECEPTOR-COUPLED INHIBITION OF PHOSPHOINOSITIDE HYDROLYSIS IS DEPENDENT UPON CHANNEL ACTIVATION.

R.A.Morrisett, C.C.Chow, J.O.McNamara. Epilepsy Res. Ctr., Duke/VA Med. Ctr., Durham, N.C. 27705.

Kindled animals exhibit biochemical evidence of enhanced NMDA receptor function as shown by NMDA inhibition of carbachol-stimulated phosphoinositide hydrolysis; this led us to study the mechanism of the NMDA effect.

Hippocampal slices (400 u) were incubated with ^{3}H-inositol, washed, and treated with drugs; ^{3}H-inositol phosphates were isolated by nonpolar extraction and anion exchange chromatography. Preincubation with NMDA followed by rinsing was sufficient to inhibit PI hydrolysis stimulated by subsequent exposure to carbachol. The inhibitory effect of NMDA was dose-dependent (IC_{50}= 30 uM), maximal by 15 min, persisted unchanged for at least 3 hours, was inhibited by D-APV (100 uM) and the NMDA channel blockers, MK-801 (10 uM) and TCP (1 uM). Omission of Na^{+}, but not Ca^{++}, from the NMDA incubation prevented the inhibitory effect of NMDA.

These results demonstrate that NMDA receptor activation can produce a long-lasting inhibition of carbachol-stimulated PI hydrolysis by activation of the NMDA ion channel, an effect likely dependent upon influx of Na^{+} but not Ca^{++}. Control of muscarinic-receptor coupled PI hydrolysis by NMDA channel activation maybe one molecular means by which brief membrane events are translated into long-lasting modifications of neuronal function.

52.15

INHIBITION OF PROTEIN KINASE C BY MAST CELL DEGRANULATING PEPTIDE. H. Nakabayashi, P. Lazarovici and K.-P. Huang (SPON: W. Tsai) NICHD, NIH, Bethesda, MD 20892.

Mast cell degranulating peptide (MCD) is a polycationic bee venom toxin known to have a potent mast cell degranulating action and convulsion action for the central nervous system. In synaptic membranes, high affinity receptor site for MCD has been identified; however, the function of this receptor and its signaling mechanism is unknown. The effect of MCD on protein kinase C (PKC) isozymes (type I, II, and III) were investigated. Ca^{2+}/phosphatidylserine (PS) and diacylglycerol (DG)-dependent activities of these isozymes were inhibited to different degree by MCD, with an inhibitory response of type I>III>II. Apamin, analogous peptide of MCD, was less potent to inhibit these PKCs. MCD appears to be a specific inhibitor for PKC, it did not inhibit cAMP-dependent kinase, myosin light chain kinase (MLCK), nor casein kinase I and II. In comparison, mastoparan and melittin inhibited PKC as well as MLCK. The activity of PKC measured with protamine sulfate as substrate which is cofactor independent and that of the protease-activated PKC, M kinase, were not affected by MCD. The mechanism of inhibition of PKC by MCD appeared to be complex; the inhibitory response is biphasic and substrate dependent. Increasing concentrations of PS or DG counteracted the inhibition of type I and III kinase by MCD more effectively than that for the type II enzyme. MCD also inhibited the binding of [^{3}H]phorbol 12,13-dibutyrate (PDBu) to the kinase. Ca^{2+}/phospholipid-dependent protein phosphorylation of rat brain proteins in vitro were also inhibited by MCD. These results suggest the possibility that the neurotoxicity of MCD may be mediated by the inhibition of PKC.

MECHANISMS OF NEUROPEPTIDE INHIBITION OF PROTEIN KINASE C. V.J. Aloyo, M. A. Pullen* and R.F. Walker*. Dept. of Pharmacology, Medical College of PA, Philadelphia, PA 19129.

Several neuropeptides including ACTH, dynorphin and somatostatin are inhibitors of protein kinase C (PKC)-dependent phosphorylation of B-50 (also known as GAP43 and F1) in neuronal membranes. Furthermore, we have previously shown that ACTH-(1-24) is an inhibitor of partially purified PKC. However, the mechanism(s) by which these peptides effect PKC activity is unknown. Thus, we have investigated the kinetics of PKC inhibition by several peptides as well as the prototypical PKC inhibitor, H7. We have found that ACTH-(1-24) and dynorphin A are inhibitors of PKC independent of whether histone or myelin basic protein is used as the phosphate acceptor. However, the potent somatostatin analogue, [D-trp8]-somatostatin, did not inhibit PKC activity even at 100 uM, suggesting that this peptide inhibits neuronal B-50 phosphorylation by an indirect mechanism. Kinetic analysis demonstrated that although ACTH-(1-24) and H7 are equipotent inhibitors of PKC, they act by different mechanisms. We have confirmed that H7 is competitive with respect to ATP and noncompetitive with respect to phosphate acceptor. In contrast, ACTH-(1-24) is noncompetitive with respect to ATP but competitive with respect to phosphate acceptor. Although these results suggest that ACTH may be a phosphate acceptor for PKC, this was not the case under our assay conditions. Further insight into the mechanism of ACTH-induced inhibition of PKC was obtained from order of addition experiments. Preincubation of ACTH-(1-24) with the phospholipid cofactors before addition of histone resulted in significantly greater inhibition of PKC activity when compared to adding the peptide last. These results suggest that ACTH interacts with the phospholipids in order to affect PKC activity. These experiments lend further evidence to the hypothesis that neuropeptides may regulate the signal transducing activity of PKC.

GLUTAMATE INDUCES 12-HETE SYNTHESIS THROUGH NMDA RECEPTOR ACTIVATION IN RAT CEREBRAL CORTEX. L. Pellerin* and L.S. Wolfe. Donner Lab. of Exp. Neurochemistry, Montreal Neurological Institute, Montreal, Canada H3A 2B4.

Recent evidence (Piomelli et al., Nature, 328:38, 1987) suggests that 12-hydroxyeicosatetraenoic acid (12-HETE) or its hydroperoxy presursor (12-HPETE) act as a second messanger in Aplysia sensory neurons. Formed by receptor-mediated stimulation, they have been shown to activate a specific K^+ channel in these cells. We believe that in CNS of mammals, lipoxygenase metabolites might play a similar neuromodulatory role. We had previously found that rat cerebral cortex has the capacity to form at least four different hydroxyeicosatetraenoic acids, 5-, 11-, 12- and 15-HETE, with 12-HETE being the major one. However, only 12-HETE was found to be increased by raising intracellular Ca^{2+} concentration with the Ca^{2+} ionophore A23187 (10 M). Different neurotransmitters were then tested for their capacity to induce 12-HETE formation. Glutamate (100 M) and norepinephrine (100 M) induced a two-fold increase in 12-HETE level while other neurotransmitters were ineffective or even had a slightly inhibitory effect. Norepinephrine seemed to act through alpha receptors because isoproterenol, a beta adrenergic agonist, was found to be ineffective. N-methyl-d-aspartate (NMDA) and kainate, two glutamate receptor agonists, were assayed and only NMDA was found to induce 12-HETE synthesis. This points to a specific role for a 12-lipoxygenase metabolite in phenomenon linked to NMDA receptor activation, such as long term potentiation.

Supported by a grant from the MRC Council of Canada. L.Pellerin is a NSERC scholar.

53.2

POSSIBLE ROLES FOR ARACHIDONIC ACID METABOLISM IN THE PHYSIOLOGY AND PATHOPHYSIOLOGY OF CEREBELLAR GRANULE CELLS IN CULTURE.

K.S. Madden, A.E. Schaffner, P. Lysko* and J.L. Barker (SPON: M. Freed). Laboratory of Neurophysiology and *Laboratory of Molecular Biology, NINCDS, NIH, Bethesda, MD 20892.

Cerebellar granule cells from the neonatal rat are commonly raised as primary cultures and under conditions that promote the development of nearly homogeneous (>95%) populations. The advantages of this preparation have now been exploited in standard biochemical studies about the spontaneous and evoked conversion of 1-^{14}C-arachidonic acid (AA) to more polar derivatives. Tests of evoked conversion included exposure to saline that was unmodified or modified by the additions of extra sodium or potassium ions (20 mM) or by glutamate (3-500 µM). High doses of glutamate are neurotoxic and associated with conditions that also increase AA metabolism in the central nervous system, such as cerebral ischemia and epilepsy. As controls for cell death, preparations were also challenged with hypo-osmotic shock or mechanical stress. These last two treatments simulate the effects of positioning the glass microelectrodes needed from electrophysiological recordings from individual granule cells and the cell death that can occur during those studies. The results support a role for AA metabolism in the events of signal transduction in granule cells. This role appears to involve the release of di- and/or monoacylglycerols from cells, probably owing to the turnover of phosphatidylinositol. Since this release is not seen after the integrity of cell membranes is destroyed, it is likely to be a physiological, not a pathophysiological, response.

53.3

APLYSIA NERVOUS TISSUE CONTAINS PROTEINS THAT INHIBIT OR ACTIVATE PHOSPHOLIPASE A_2 (PLA_2). A. Calignano*, D. Piomelli, B. Wallner* and J.H. Schwartz, HHMI, Columbia Univ. Col. Phys. & Surg., New York, NY 10032 and Biogen, Cambridge, MA 02142.

Release of arachidonic acid from membrane phospholipids is the limiting step in the biosynthesis of eicosanoids, which may be second messengers in Aplysia neurons. We find that PLA_2, an enzyme that participates in arachidonate release, is modulated by proteins in homogenates of Aplysia nervous tissue which were fractionated by size-exclusion HPLC. We detect three heat-stable inhibitory components (M_r app 66,000, 40,000 and 15,000), suggesting the presence of lipocortin-like proteins. Preliminary Western blots with anti-human lipocortin antibodies reveal cross-reacting Aplysia proteins, and Northern blots, possible Aplysia lipocortin transcripts. We also find an M_r 29,000 component that stimulates PLA_2. This component did not contain intrinsic PLA_2; its stimulatory activity is destroyed by boiling and trypsin. Expression of proteins that modulate PLA_2 may be important for long-term regulation of synaptic plasticity in Aplysia.

53.4

SECOND MESSENGER SYSTEMS IN K^+-DEPOLARIZATION OF RAT BRAIN SYNAPTOSOMES. T-N Lin*, M Navidi*, RA MacQuarrie*[1], AY Sun and GY Sun. Sinclair Comp. Med. Res. Farm and Biochem, Dept., Univ. of MO, Columbia, MO 65203, and [1]School of Basic Life Sciences, Univ. of MO-KC, Kansas City, MO 64110.

To elucidate the role of second messenger production through phospholipases A_2 (PLA_2) and C (PLC) in the neurotransmitter release process, intracerebral injection, preincubation and incubation with exogenous substrates were employed for labeling phospholipids in synaptosomes. When synaptosomes were prelabeled with [^{14}C]arachidonic acid (AA) through the acyltransferase system, K^+-depolarization increased the release of labeled AA from phosphatidylcholines (PC) and phosphatidylinositols (PI). Under the same condition, there was an increase in transfer of labeled AA to PI and PC suggesting that the deacylation-reacylation mechanism mediated by PLA_2 and acyltransferases may be involved in the neurotransmitter release process. Attempts to test for K^+-stimulation of polyphosphoinositide breakdown by PLC, either by generating labeled substrate endogenously or adding labeled substrates exogenously, have produced mostly negative results which seem to indicate that the PLA_2 system may prevail over the PLC system. (Supported in part by NSF grant BNS8419063)

53.5

UNSATURATED FATTY ACIDS AND LYSOPHOSPHATIDYLINOSITOL (LYSO PI) ACTIVATE A CATIONIC RAT BRAIN PROTEIN KINASE.
M. Frangakis* and N. Sahyoun. (SPON: B. Cooper). The Wellcome Research Laboratories, 3030 Cornwallis Road, Research Triangle Park, NC 27709.

A search for a second messenger role of phospholipase A_2 hydrolytic products led to the isolation by CM-cellulose chromatography of an arachidonic-acid dependent protein kinase. The enzyme phosphorylated several endogenous substrates of which synapsin I was most prominent. The arachidonate effect was observed at concentrations above 6.6 μM with an apparent Km of 89 μM. Oleic acid had a similar effect but was inhibitory at higher concentrations. Lyso PI was also discovered to be an effective activator with peak stimulation at about 20 μM. The effects of unsaturated fatty acids or lyso PI were inhibited by 50 μM trifluoperazine. Interestingly, Ca^{2+}-calmodulin could partially replace the lipid activators, and this property was exploited to purify the protein kinase by calmodulin affinity chromatography. The purification and analysis of the activity of this protein kinase provide a regulatory target for unsaturated fatty acids, and lysophospholipids as well as Ca^{2+}-calmodulin. Elevated Ca^{2+} levels may activate this protein kinase by interaction with calmodulin and by phospholipase A_2 activation.

53.6

HEPOXILIN MAY BE A SECOND MESSENGER IN RAT HIPPOCAMPAL CA1 NEURONS: AN ELECTROPHYSIOLOGICAL STUDY.
N.Gurevich, P.H. Wu*, C.R. Pace-Asciak*, and P.L. Carlen, The Playfair Neurosciences Unit, Toronto Western Hospital, Addiction Research Foundation, Dept. Medicine, Physiology & Pharmacology, The Hospital for Sick Children, University of Toronto, Canada

Hepoxilin (HX) is a hydroxy epoxide derivative of arachidonic acid (AA) and is synthesized from 12-HPETE. It is formed in the rat brain. Hippocampal slices(400μm) from male Wistar rats(150-170g) were used for intracellular electrophysiological recordings by glass electrodes (3M KCl or 3M K-acetate; 60 to 150 Meg Ohm). HX(0.5 to 100μM),AA(5 to 100μM) and other AA metabolites were drop-applied or perfused onto the hippocampal CA1 neurons.

With HX perfusion, a hyperpolarization (< 4mV) developed gradually over a 7 min period. Drop application caused a small(<2mV) hyperpolarization within 10 to 20 sec, lasting up to 40 sec. The afterhyperpolarization (AHP), which is thought to be due to a Ca^{2+}-mediated K^+ conductance, was prolonged up to 50% by perfusion and up to 25% by drop application. EPSPs were not affected. However, a marked enhancement of the IPSP(up to 2-fold) was observed. This increase included both early chloride-dependent and the later K^+-dependent phase of the IPSP. These results suggest that HX may play a second messenger role in the mammalian CNS. Supported by MRC.

53.7

INCREASED MOUSE BRAIN FATTY ACID CYCLOOXYGENASE (CO) ACTIVITY FOLLOWING INCUBATION WITH PROTEIN KINASE (PK)-C.
Thomas W. Lysz and Philip E. Keeting, Dept. of Surgery, New Jersey Med. Sch. Newark, N.J. 07103 and East Orange Veteran's Administration, East Orange, N.J.,07109.

Recent evidence suggests that the brain CO activity is increased following drug induced convulsions (T.W. Lysz et al., Brain Res.408 (1987)6-12. To determine a biochemical mechanism underlying the increased CO activity, brain microsomes prepared from Swiss Webster mice were incubated under different phosphorylating conditions. Initial experiments indicated that microsomes prepared in 0.1M Tris buffer pH7.4 and incubated with 24 uM arachidonic acid (AA), 1 mM glutathione, and 1 mM epinephrine generated between 58 to 65% less PGE2 and PGF2 alpha (measured by RIA) then microsomes incubated in 0.1M phosphate buffer (N=6). The addition of 1 mM ATP,10 mM Mg,10 uM c-AMP and 10 ug c-AMP dependent PK-A to the CO in Tris increased prostaglandin (PG) production only 13%(n=6). However, microsomes incubated with purified rat brain PK-C, diolein, ATP,Ca, and phospatidylserine in Tris, increased total PG synthesis 50 %(N=2). These results suggest that a secondary control point may exist in the AA cascade at the CO level.Supported by a VA Merit Award and NIH grant 529621.

ION CHANNELS: CALCIUM CHANNELS I

54.1

MODULATION OF CALCIUM CURRENTS OF IDENTIFIED DORSAL HORN PROJECTION NEURONS BY GUANINE NUCLEOTIDES.
L.-Y. M. Huang. Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550.

Different types of calcium channels have been identified in acutely isolated, identified rat spinal dorsal horn projection neurons. They are low threshold transient, high threshold inactivating and non-inactivating Ca channels. The effects of intracellularly applied guanosine 5'-O-3-thiotriphosphate (GTP-γS) and guanosine 5'-O-2 thiodiphosphate (GDP-βS) on these Ca channels were studied in the projection neurons using whole cell patch clamp technique. GTP-γS markedly slowed the activation and inactivation of high threshold Ca current. The rate of activation was increased by about 10-fold, and the rate of inactivation was lengthened by about 15- to 20-fold. The effects of GTP-γS were abolished when the cells were treated with pertussis toxin. When GDP-βS was in the pipet solution, the rates of activation and inactivation of the Ca current were similar to those in the control cells. Cyclic AMP and forskolin did not mimic the effects of GTP-γS. These results suggest that guanine nucleotide binding protein modulates directly the activities of Ca channels in identified projection neurons. This work is supported by NS 23061 and NS 01050.

54.2

MECHANISM OF INHIBITION OF CA CURRENTS BY G-PROTEIN ACTIVATION
A.C.Dolphin, S.M. McGuirk* and R.H. Scott* Dept Pharmacology, St. Georges H. M. S., London SW17ORE, UK.

Activation of several receptors (including GABA-B) inhibits Ca currents in cultured rat dorsal root ganglion neurones, and this coupling occurs via a G-protein. The GTP analogue GTPγS also inhibits Ca currents, selectively abolishing the transient component. The remaining current is more slowly activating and sustained, and is distinguished from a control L-type Ca current activated from V_H -30mV by its much slower inactivation. The effect of GTPγS is seen using either Ba or Ca as the charge carrier, and is blocked by pertussis toxin. We have investigated whether a second messenger is involved in the response of Ca and Ba currents to GTPγS. Activation of adenylate cyclase by forskolin (10μM) or inclusion of 50μM cyclic AMP in the patch pipette had no effect on the response to GTP-γ-S. Three inhibitors of protein kinase C: polymixin B (20μM), H7 (50μM) and staurosporine (100nM) were also without effect. Bradykinin (0.1-1μM) stimulated inositol phosphate production in these cultures by 70±14% (mean± SEM,n=8)in 30s, whereas stimulation by the GABA-B agonist (-)-baclofen (100uM) was 22±2% (7). However, baclofen inhibited Ca and Ba currents by 40-70%, whereas bradykinin did not. Arachidonic acid (100μM), applied for up to 5 min., had no effect on Ba currents. These experiments provide no evidence for a second messenger coupling pertussis toxin sensitive G-proteins to Ca channels.

54.3

DIFFERENTIAL BLOCKING ACTIONS OF CHLORPROMAZINE ON SODIUM AND CALCIUM CHANNELS IN CULTURED NEUROBLASTOMA CELLS. Nobukuni Ogata* and Toshio Narahashi (SPON: J. Trubatch). Department of Pharmacology, Northwestern University Medical School, Chicago, IL 60611.

Chlorpromazine (CPZ), a major tranquilizer, affects the excitability of nerve membranes. However, little is known about the mechanism underlying this action. We investigated the effect of CPZ on voltage-gated sodium and calcium channels in cultured mouse neuroblastoma (N1E-115) cells using the whole cell patch clamp technique. CPZ in micromolar concentrations reduced both the sodium and calcium currents. The block was reversible, concentration-dependent, and enhanced by shifting the holding potential toward positive values. The block of sodium channels exhibited a marked use dependence during repetitive stimuli. On the contrary, the block of calcium channels did not appreciably accumulate during repetitive stimuli over a wide range of frequencies used. The lack of apparent use dependence of the calcium channel block was due to a slow onset of the block in the inactivated state and a rapid recovery from this block. This difference between calcium and sodium channels in frequency modulation of the CPZ block might be responsible for certain aspects of the therapeutic as well as the toxic actions of this drug (supported by NIH grant NS14144).

54.4

ROLE OF CALCIUM MODULATORS IN K^+ - STIMULATED NEUROTRANSMITTER RELEASE. V.C. Gandhi and D.J. Jones (Spon: S. Dalterio). Dept. of Anesth. Univ. Texas Health Sc. Cen., San Antonio, TX 78284.

Calcium channel modulators were investigated for their effects on K^+ - stimulated [^{3}H]5HT as well as [^{3}H]NE release in rat spinal cord preparations. Bay K 8644, at 1 uM augmented K^+ - stimulated release of both [^{3}H]5HT and [^{3}H]NE by about 50% without affecting basal release. Dihydropyridine Ca^{++} antagonist nimodipine at 1 uM had no independent effect on K^+ - stimulated release, but blocked the augmentation induced by Bay K 8644.

Quinacrine, a non-dihydropyridine compound produced differential effects on the K^+ - stimulated [^{3}H]NE and [^{3}H]5HT releases. It produced a dose - dependent inhibition (0.1um - 10um) of K^+ - stimulated [^{3}H]NE release with no change in basal release. At 1 uM it also completely antagonized the K^+ - stimulated elevation of [^{3}H]NE release produced by 1 uM Bay K 8644. A large dose-dependent increase in basal [^{3}H]5HT release was produced by quinacrine. This differential effect on the 5HT and NE release pathways may be due to differences in intracellular mediation caused by its other properties.

54.5

INTRACELLULAR AND EXTRACELLULAR MOBILIZATION OF Ca^{2+} IN GUINEA-PIG TRACHEA ARE AFFECTED BY DIHYDROPYRIDINES. **R.R.Ben-Harari*, B.Dalton*, J.Kaplan* and S.Maayani. (SPON: Yahr,M.D.).Department of Anesthesiology, Mt.Sinai Sch. Med.,CUNY, N.Y., N.Y.10029.**

Ca^{2+} blockers have relatively weak effects in the treatment of asthma compared with vascular disorders. This difference may be dependent on the source of Ca^{2+} for contraction. To test this hypothesis, effects of the Ca^{2+} channel activator, Bay K 8644(10uM) and blocker, nifedipine (1uM), were determined on the kinetics of the phasic (intracellular Ca^{2+}) and tonic (extracellular Ca^{2+}) components of the contractile responses to histamine (HA;10uM) and carbachol (Carb;1uM) in the isolated guinea-pig trachea. The experiments were performed in the presence of 1uM indomethacin otherwise basal tension was lost and no phasic response could be generated. Nifedipine eliminated the phasic response. Bay K 8644 increased peak tension but had no affect on the rate of decay of the phasic response. Nifedipine and Bay K 8644 had no affect on peak tension and nifedipine inhibited the rate of generation of the tonic response. Effects of Bay K 8644 and nifedipine were mutually antagonistic. The results suggest that in airway smooth muscle, contractions to HA and Carb mobilize both intracellular and extracellular sources of Ca^{2+}, and that dihydropyridines affect both. BLOCKADE OF DROSOPHILA NEURONAL CALCIUM CURRENT BY TOXINS PURIFIED FROM SPIDER VENOM Hung-Tat Leung*^, Dale Branton, Heidi Phillips*, Lily Jan, and Lou Byerly^. Howard Hughes Medical Institute, UCSF, San Francisco, CA 94143; ^Section of Neurobiology, USC, LA, CA 90089-0371.

The study of ion channels is greatly facilitated by the use of highly specific channel blockers. Dihydropyridines and ω-conotoxin, which are specific blockers for certain vertebrate calcium channels, do not appear to be effective against invertebrate calcium channels. In an effort to identify specific blockers for voltage-activated calcium channels in Drosophila, toxins were purified from Hololena and Plectreurys spider venoms (Bower at al., 1987 and Branton et al., 1987) which block synaptic transmission at the Drosophila larval neuromuscular junction (NMJ). We have now tested these toxins on the Ca current of cultured embryonic Drosophila neurons studied with the whole-cell patch clamp technique. Toxin fractions found to be both active and inactive in blocking the NMJ were tested. A blind study of three fractions from Hololena toxin found that the inactive fraction had no effect while the two active fractions blocked about 50% of the Ca current. A blind study of three fractions from Plectreurys toxin showed that the active fraction blocked 80% or more of the Ca current; the two inactive fractions had no effect in 15 out of 17 trials. These results show that the spider toxins act directly or indirectly to block Drosophila Ca channels.

AMINOGLYCOSIDE INHIBITION OF OMEGA CONOTOXIN BINDING AND THE ELECTRICALLY INDUCED VAS DEFERENS TWITCH RESPONSE ARE CORRELATED. B.A. Meiners, R. Keith*, R. Stumpo, D. LaMont‡ and A.I. Salama. Department of Pharmacology, ICI Pharmaceuticals Group, ICI Americas, Inc., Wilmington, DE 19897.

The peptide ω-conotoxin GVIA (WCT) inhibits N-type voltage-sensitive calcium channels (VSCC). Furthermore, it has recently been reported that some aminoglycoside antibiotics inhibit the binding of the [125I]WCT (Knaus et al., Naum-Schm. Arch. Pharmacol, 336, 583, 1987. We sought to further profile the effects of these antibiotics by comparing their potency in the electrically stimulated rat vas deferens preparation, an index of neuronal (presynaptic) N-channel function, with their inhibition of [125I]WCT binding. Surprisingly, at low concentrations (100 nM) neomycin caused an enhancement of [125I]WCT binding to levels 30 to 60% over control which appeared to be due to an increase in association rate. The rank order for inhibition of binding and of inhibition of the twitch response was the same for the compounds tested eg WCT > neomycin > gentamycin > kanamycin. The compounds were much more potent against the binding than against the twitch response. For example, the IC_{50} of neomycin in binding was 4 μM and in the twitch response was 300 μM. The observed correlation between the binding and the functional in vitro model supports the hypothesis that aminoglycoside antibiotics can interact with the N-type VSCC in a functionally relevant way.

54.8

DIFFERENTIAL SENSITIVITY OF SYNAPTOSOMAL CALCIUM ENTRY AND ENDOGENOUS DOPAMINE RELEASE TO OMEGA-CONOTOXIN. J.J. Woodward and S.W. Leslie. Division of Pharmacology, College of Pharmacy, University of Texas at Austin, Austin, TX 78712.

The presynaptic neurotoxin omega-conotoxin (w-CgTx) was tested for its ability to inhibit voltage-dependent calcium flux and transmitter release in rat brain synaptosomes. Synaptosomes were prepared from the striata of 2-3 month old Sprague-Dawley rats and were incubated in calcium-free medium with conotoxin (0.001-10 uM). Calcium uptake ($^{45}Ca^{2+}$) and endogenous dopamine release were measured during a three second period with either resting (5 mM KCl) or depolarization (60 mM KCl) medium (100 uM free calcium). Calcium influx was determined using liquid scintillation counting. Dopamine was measured using liquid chromatography with electrochemical detection. Conotoxin (0.001-10 uM) had no effect on calcium uptake or endogenous dopamine release from rat striatal synaptosomes under resting (5 mM KCl) conditions. Net potassium-stimulated calcium influx was partially (20-30%) inhibited by conotoxin at 10 uM. The net release of endogenous dopamine was inhibited by 25% at 0.01 uM and by 60% at 10 uM. These results suggest that a relatively small number of w-CgTx sensitive calcium channels may be linked to the release of synaptosomal dopamine. The majority of synaptosomal calcium influx and dopamine release appears to involve calcium channels insensitive to w-CgTx.

54.9

NIMODIPINE BLOCK OF L-TYPE CALCIUM CHANNELS IN FRESHLY DISPERSED RABBIT DRG NEURONS. H.K. FRY* AND R.T. MC CARTHY*. (SPON: A. Howard) Miles Institute for Preclinical Pharmacology, West Haven, CT 06516, USA

Nimodipine, a 1,4-dihydropyridine, is a potent cerebral vasodilator with beneficial therapeutic effects in aiding recovery from global and focal ischemia. The patch voltage clamp technique has been used to study nimodipine block of voltage-dependent calcium channels in dorsal root ganglion cells(DRG). In whole-cell recordings, a rapidly inactivating T-type channel current can be elicited with weakly depolarizing test pulses from hyperpolarized potentials. This current is almost completely inactivated at potentials positive to -55mV. A second whole-cell current (L-type) remains available at relatively depolarized holding potentials and features little inactivation during test depolarizations (200mS). In cell-attached patch, L-type channels display a slope conductance of 29pS and respond to BAY K 8644 (50nM) with prolonged single channel openings. Nimodipine (20, 200nM) reduces the whole-cell inward current from each of two different holding potentials (V_H=-90 & -55mV) with substantial resting state block ($K_D^H \cong$40nM). In cell-attached patches (V_H=-40mV), nimodipine (50 nM) increased (>3X) the number of null sweeps; hyperpolarization (V_H=-80mV) reversed this block. Direct action of nimodipine on neuronal L-type channels may account for some of its therapeutic effects.

BLOCKADE OF CALCIUM CHANNELS IN PC12 CELLS

Janigro D., Maccaferri G.*, Pandiella A.* and Meldolesi J.*

Dept. of Pharmacology, H San Raffaele, Milan Italy

The persistent depolarization induced by application of high potassium to undifferentiated PC12 cells is accompanied by a biphasic increase in cytosolic calcium as assessed by Fura-2 measurements. The early component of intracellular calcium concentration increase is blocked by -conotoxin whereas the later component is readily abolished by verapamil.

Patch clamp experiments using the whole cell mode, revealed a large (usually 300 pA) calcium current after strong cell depolarizatio from cell resting potential following blockade of potassium currents with intracellular CsCl. Multiple exponential fits of current decay revealed two different time constants. Verapamil (20 uM) was found to selectively abolish the longer lasting current decay.

Our results suggest the existence of at least two different calcium channels in undifferentiated PC12 cells.

54.11

NALOXONE ANTAGONISM OF THE ETHANOL INHIBITION OF CALCIUM CHANNELS IN NG108-15 CELLS. M.D. Herman*, D.A. Twombly*, C.H. Kye*, T. Narahashi. Dept. of Pharmacology, Northwestern Univ. Medical School, Chicago, IL 60611

The effects of ethanol on the nervous system have been studied for many years, yet the precise mechanism of action remains to be seen. Studies have suggested that the cellular activity of ethanol is mediated by the delta-opiate receptor, and that voltage-activated calcium channels are blocked by ethanol. Using the whole cell patch clamp technique, we tested the hypothesis that the delta-opiate receptor mediates the block of calcium channels by ethanol. Ethanol blocked two types of calcium channel currents in neuroblastoma-glioma hybrid cells (NG108-15). Both the transient (type I) component of the calcium channel current and the long-lasting (type II) component were blocked by ethanol. The degrees of block of type I channels at concentrations of 30 mM, 100 mM, and 300 mM were 3%, 19%, and 34%, respectively, and those of type II channels were 13%, 23%, and 32%, respectively. In the presence of 1μM naloxone, ethanol at a concentration of 100 mM had no effect on the type II calcium channels. In contrast to the type II channel effect, naloxone did not antagonize the type I calcium channel block by ethanol.

These results indicate that the block of type II calcium channels by ethanol appears to be mediated by the delta-opiate receptor. Although the inhibition of type I calcium channel currents by ethanol occurs at similar doses to type II calcium channel block, a different mechanism is indicated by the absence of antagonism by naloxone. The delta-opiate receptor mediated block of type II calcium channels may explain the inhibition of transmitter release by ethanol.

CALCIUM CURRENTS IN DENTATE GYRUS GRANULE CELLS AFTER KINDLING. J.N. Reynolds, I. Mody, M.W. Salter, P.L. Carlen & J.F. MacDonald. Playfair Neurosci. Unit, The Toronto Hosp.& Dept. Physiol., Univ. of Toronto, Toronto, Ont., M5T 2S8

We have investigated voltage-dependent Ca^{2+} currents in granule cells of the dentate gyrus in hippocampal slices obtained from control and commissurally kindled (stage 5) Wistar rats. Neurons were voltage-clamped using the single electrode switching clamp technique (Axoclamp 2A; 4-7 kHz). Electrodes (40-80 MΩ) were filled with 3-M-CsCl or 2-M-CsCl/0.5-M-CsOH/0.25-M-EGTA/10-mM-HEPES. The perfusion media included (in mM): 114 NaCl, 4.25 KCl, 26 $NaHCO_3$, 4 $CaCl_2$, 2 $MgCl_2$, 10 TEA, 5 4-AP, 3 CsCl, 10 d-glucose and 1 μM TTX.

Control granule cells displayed both a transient and a sustained Ca^{2+} current with distinct voltage-dependent properties. In contrast, in kindled granule cells the threshold for the transient Ca^{2+} current was lowered by 10 mV while the sustained Ca^{2+} current was significantly depressed. This depression was not due to an absence of Ca^{2+} channels since intracellular injections of EGTA revealed sustained Ca^{2+} currents in kindled neurons, while having little effect on control cells. Thus, granule cells of the dentate gyrus show marked changes in voltage-dependent Ca^{2+} currents following kindling. These changes may be a consequence of an altered intraneuronal Ca^{2+} homeostasis in kindled granule cells.

EFFECT OF IONIZING RADIATION ON CALCIUM CHANNELS IN RAT BRAIN SYNAPTOSOMES. S. B. Kandasamy and W. A. Hunt*. Behavioral Sciences Department, Armed Forces Radiobiology Research Institute, Bethesda, MD 20814-5145.

Exposure to ionizing radiation has been shown to reduce voltage-dependent sodium uptake in rat brain synaptosomes. Since sodium influx can be a stimulus for calcium influx needed for neurotransmitter release, the effect of ionizing radiation on voltage-dependent calcium influx was studied by measuring KCl-stimulated Ca-45 uptake into rat brain synaptosomes. Gamma irradiation (Co-60) (1-100 Gy) reduced calcium uptake after 3 sec in a dose-dependent manner. Non-stimulated calcium uptake was unaffected by radiation exposure. The time course (3, 10, 30 and 60 sec) of calcium uptake by irradiated (3 Gy) and non-irradiated synaptosomes was also measured as well as the effect of variable doses of KCl (15-65 mM). The fastest and highest rate of depolarization-dependent calcium uptake occurred at 3 sec and at 65 mM KCl. Irradiation reduced calcium uptake at all incubation times and KCl concentrations studied. Inositol-1,4,5-trisphosphate (1 nM-1 μM) and prostaglandin F2α (1 nM-1 μM) increased the entry of calcium in non-irradiated but had no effect on irradiated synaptosomes. Since researchers have linked protein kinase C to the opening or closing of ion channels, irradiation might have affected this enzyme, possibly through the lack of mobilization of calcium from intracellular stores.

54.14

EFFECT OF ELECTROCONVULSIVE SHOCK (ECS) ON THE L AND N TYPE CALCIUM CHANNEL IN DIFFERENT RAT BRAIN REGIONS. C.H. Gleiter, C. Cain* and P.J. Marangos. NIAAA/LCS, NIMH/BPB, Bethesda, MD 20892; Human Pharmacology Institute Ciba-Geigy, Tubingen, FRG.

Chronic ECS has been shown to change the number of [3H]nitrendipine binding sites in rat cerebral cortex and hippocampus (Pharmacol. Biochem. Behav. 27:217, 1987[1]). We examined the L-type Ca^{++}-channel using [3H]nimodipine (NI) and the N-type Ca^{++}-channel using [125I]omega-conotoxin GIVA (CO). Rats were sacrificed 30 min after a single ECS (A) or 24 h after 10 once-daily ECS (B). Binding of NI and CO to crude membrane preparations was examined at the respective Kd concentration in the same animals:

	[3H]nimodipine		[125I]omega-conotoxin GIVA	
(A)	CTRL	ECS	CTRL	ECS
Cortex	114 ± 6	99 ± 2*	300 ± 16	249 ± 6#
Cerebellum	33 ± 3	35 ± 2	141 ± 11	153 ± 12
Hippocampus	112 ± 5	116 ± 6	271 ± 5	275 ± 15
(B)	CTRL	ECS	CTRL	ECS
Cortex	98 ± 6	100 ± 3	218 ± 20	220 ± 13
Cerebellum	33 ± 1	33 ± 1	188 ± 20	168 ± 12
Hippocampus	128 ± 7	123 ± 5	289 ± 10	290 ± 15

(fmol/mg protein; mean±SEM; n = 8/group; * $p < 0.05$; # $p = 0.01$)

Conclusions: 1. Binding of the respective ligands to the L and N type Ca^{++}-channel shows a parallel decrease of Bmax (as confirmed by Scatchard analysis of pooled tissue) in cerebral cortex 30 min after a single ECS. 2. Distribution of densities of binding sites is similar for both ligands in the respective brain regions. 3. The earlier report[1] on changes of the L type channel following chronic ECS can not be confirmed.

VOLTAGE-DEPENDENT Ca^{++} UPTAKE IN CULTURED CEREBELLAR GRANULE CELLS. B.A. Armitage* and P.B. Molinoff (SPON: N.S. Thampi). Dept. of Pharmacology, Univ. of Pennsylvania, Sch. of Med., Philadelphia, PA 19104.

The biochemical properties of voltage-sensitive Ca^{++} channels (VSCC) were studied by measuring $^{45}Ca^{++}$ flux in cerebellar granule cells. Primary cultures were used because the activity of VSCC in neuronal cell lines may differ from that described for neurons *in vivo*. Dissociated cells from the cerebellum of 7 day old rats were plated on poly-D-lysine (PDL) in Basal Eagle's Medium (BME). In control assays the background contributed by PDL-coated plastic dishes was high and variable, whereas that of PDL-coated glass coverslips was negligible. Cells were plated at a density of 10^6 cells per 18mm coverslip. Cells were grown in BME supplemented with 25mM K^+ which is necessary to maintain cell viability. However, chronic depolarization was found to eliminate voltage-dependent Ca^{++} uptake. This activity returned after a 5 hr. incubation at 37°C in BME containing 5mM K^+. Uptake was measured in a balanced salt solution (BSS) containing $^{45}Ca^{++}$ and 5mM or 50mM K^+. Immersing the coverslips in a large volume of cold BSS containing 10mM EDTA for 10 sec. and draining off all excess liquid minimized background. In time course experiments voltage-dependent uptake reached a plateau after 2 min. ($t_{\frac{1}{2}} \approx 30$ sec.). VSCC activity was maximal after 10 days *in vitro*. Maximal voltage-induced uptake was found to be 4 times that of uptake in buffer containing 5mM K^+. Measuring $^{45}Ca^{++}$ uptake in cultured cerebellar granule cells represents a useful model system for studying the biochemistry and pharmacology of VSCC. (Supported by USPHS GM 34781).

Flow Cytometric Analysis of Calcium Levels in Rat Striatal Synaptosomes. Marina E. Wolf and Gregory Kapatos. Laboratory of Neurochemistry, Center for Cell Biology, Sinai Research Institute, Detroit, MI 48235.

Schieren and MacDermott (Soc. Neurosci. Abstr. 13: 1514, 1987) have previously used flow cytometry and the calcium (Ca^{++}) indicator INDO-1 to monitor receptor mediated changes in cellular Ca^{++} levels. We have used these methods to study the regulation of $[Ca^{++}]_i$ in striatal synaptosomes. While intrasynaptosomal $[Ca^{++}]$ has been previously measured fluorometrically, flow cytometry offers the advantage of enabling detection and separation of synaptosomal subpopulations exhibiting different responses. The ratio of INDO-1 fluorescence at 405 and 485 nm was measured using a Becton-Dickinson FACS 440 and used as an index of intrasynaptosomal $[Ca^{++}]$. Intrasynaptosomal $[Ca^{++}]$ was approximately 120nm under resting conditions and was increased to micromolar levels by the Ca^{++} ionophore ionomycin and by depolarization with 75uM veratridine. Glutamate (10uM) produced a much smaller increase. Nifedipine (10uM), a Ca^{++} channel blocker, produced a paradoxical increase in intrasynaptosomal $[Ca^{++}]$ when administered alone and failed to prevent veratridine-induced increases. Future studies will explore the effects of other Ca^{++} antagonists and neurotransmitters on intrasynaptosomal $[Ca^{++}]$.

55.3

FLOW CYTOMETRIC ANALYSIS OF CALCIUM LEVELS IN PC12 CELLS AND EMBRYONIC MESENCEPHALIC NEURONS. Gregory Kapatos and Marina E. Wolf. Laboratory of Neurochemistry, Center for Cell Biology, Sinai Research Institute, Detroit, MI 48235.

Schieren and MacDermott(Soc.Neurosci.Abstr.13:1514, 1987) have previously combined flow cytometric techniques with the fluorescent calcium (Ca^{++}) indicator, INDO-1, to monitor receptor mediated changes in intracellular Ca^{++} levels ($[Ca^{++}]_i$). The PC12 cell line offers an opportunity to use similar techniques in a homogeneous cell population which maintains multiple Ca^{++} channel subtypes (L and N) and responds to numerous neurotransmitters and growth factors with an increase in $[Ca^{++}]_i$. As expected, PC12 cells responded to ionomycin (10uM) or depolarization with K^+ (56mM) or veratridine (75uM) with a large increase in $[Ca^{++}]_i$ which was dependent on extracellular Ca^{++} ($[Ca^{++}]_o$). K^+ was substantially more effective than veratridine. The response to K^+ was completely blocked by the L-type antagonist nifedipine yet, surprisingly, was potentiated by cadmium (1mM). Incubation with carbacol increased $[Ca^{++}]_i$, but this response was unaltered by nifedipine and independent of $[Ca^{++}]_o$. Similar studies will be reported which examine the development, cell specificity and receptor mediation of changes in $[Ca^{++}]_i$ in embryonic and newborn mesencephalic neurons.

55.4

BLOCK OF ^{45}Ca UPTAKE INTO SYNAPTOSOMES BY METHYLMERCURY: REVERSIBILITY, STATE- AND Na^+-DEPENDENCE. T.J. Shafer* and W.D. Atchison (SPON: J.E. Thornburg). Dept. of Pharm./Tox., Michigan State Univ., E. Lansing, MI 48824.

Characteristics of blocking action of methylmercury (MeHg) on Ca^{2+} influx into isolated nerve terminals were assessed by measuring $^{45}Ca^{2+}$ content of rat forebrain synaptosomes following 1 ("fast phase") or 10s ("total") of depolarization induced by elevated K^+ (77.5 mM), or after 10s of depolarization of synaptosomes that had been predepolarized for 10s in solutions free from Ca^{2+} and MeHg ("slow phase"). Block of the "total" and "fast" phases by MeHg (50 μM) were not completely reversed by increasing $[Ca^{2+}]_e$ from 0.01 to 1.2 mM. However, for $[Ca^{2+}]_e \geq 0.30$ mM, "slow" $^{45}Ca^{2+}$ uptake returned to control levels. When dependence of block of $^{45}Ca^{2+}$ uptake on Na^+_e was tested, block of the "slow" phase of $^{45}Ca^{2+}$ uptake by MeHg (25 μM) was potentiated in the absence of Na^+_e. Furthermore, in the absence of Na^+_e, increasing $[Ca^{2+}]_e$ from 0.15 to 1.2 mM did not reverse block of the "slow" phase by MeHg. When the state dependence of block was tested, similar dose-dependent suppressions of $^{45}Ca^{2+}$ influx by MeHg during depolarization were observed in synaptosomes incubated for 10s in depolarizing or non-depolarizing media prior to measuring 1s of depolarization-induced $^{45}Ca^{2+}$ influx. Finally, MeHg reduced resting $^{45}Ca^{2+}$ uptake at concentrations >125 μM. Results of the present study indicate that 1) the reversibility of block of the "slow" phase of $^{45}Ca^{2+}$ uptake by MeHg is Na^+-dependent; and 2) block of $^{45}Ca^{2+}$ uptake by MeHg is not more pronounced during the inactivated state of the channel. (Supported by NIH grant ES03299.)

FURA-2 MEASUREMENT OF VOLTAGE-DEPENDENT CHANGES IN INTRACELLULAR CALCIUM CONCENTRATION IN GUINEA-PIG SUBMUCOUS NEURONS. K. Hirai*, Y. Katayama and K. Morita (SPON: E.F. Barrett), Dept. Autonom. Physiol., Med. Res. Inst., Tokyo Med. & Dent. Univ., Tokyo, 101 JAPAN

Voltage-dependent changes in intracellular calcium concentration ([Ca^{++}]i) were investigated by using fura-2 in single voltage-clamped neurons in the guinea-pig submucous plexus. Fura-2 staining of single cells was performed by ionophoretic injection of the dye through the recording microelectrodes.

The resting value of [Ca^{++}]i was about 100 nM. An action potential (AP) increased [Ca^{++}]i by about 80%. The recovery time courses of both the after-hyperpolarization (AHP) and [Ca^{++}]i were single exponentials with time constants of 6 s and 3 s, respectively. In neurons held at -70 mV, [Ca^{++}]i increased with a depolarizing command of 40 mV; the time constant of the increase and the maximum value of [Ca^{++}]i were about 0.5 s and 170% of control. These were almost linearly related to the command amplitude. The recovery time course of [Ca^{++}]i after the depolarization was similar to that after the AP. [Ca^{++}]i was decreased by a hyperpolarization even at the holding potential of -70 mV. This decrease was dependent on the amplitude of hyperpolarizing command. Supported in part by the Nakatani Electronic Measuring Technology Association of Japan.

FLOW CYTOMETRIC ANALYSIS OF CALCIUM FLUXES IN DISSOCIATED EMBRYONIC RAT HYPOTHALAMIC NEURONS. J. P. Grierson, R. E. Petroski, S. M. O'Connell* and H. M. Geller. Department of Pharmacology, U.M.D.N.J. - Robert Wood Johnson Medical School and The Graduate School, Rutgers University, 675 Hoes Lane, Piscataway, NJ 08854.

The fluorescent, calcium-sensitive dye, INDO-1, has been used in several previous studies to examine stimulus-induced changes in cytoplasmic free Ca^{++} in blood cells. However, calcium mobilization is also known to be important in certain neurons for neurotransmitter transduction and neurotransmitter release. We utilized INDO-1 to probe the expression of functional Ca^{++} channels in dissociated rat neurons obtained from the embryonic day 17 hypothalamus. Neurons were dissociated by enzymatic treatment followed by mechanical dispersion and the cells loaded with 1uM INDO-1 at a concentration of 10^6 cells/ml. Fluorescence was measured on a Coulter EPICS-753 dual laser flow cytometer. The calcium ionophore, ionomycin, induced a substantial increase in the concentration of cytoplasmic free calcium. A significant increase was also induced by the addition of 10-100mM KCl or 50 uM veratridine. The K^+- and veratridine-induced calcium influx was completely inhibited by 3 mM cobalt chloride. Verapamil inhibited the calcium influx and the L-channel antagonist, nifedipine, produced a greater than 50% inhibition of K^+-stimulated Ca^{++} influx. Parallel studies of stimulus-induced membrane depolarization with these cells is presented in one presentation (Grierson et al) and patch-clamp analysis of calcium channels in these cells in another (Petroski et al). Supported by NIH NS25168 and a grant from the UMDNJ Foundation.

INHIBITION OF THE K^+ STIMULATED RISE IN INTRACELLULAR FREE Ca^{++}, $^{45}Ca^{++}$ INFLUX AND ENDOGENOUS ACETYLCHOLINE RELEASE BY ω-CONOTOXIN GVIA. P.M. Lundy*, J.C. Goulet* M.G. Hamilton*, W. Lee*, R. Frew* and K.A. Stauderman[1] (SPON: J. Maas). Defence Research Establishment Suffield Ralston, Alberta, Canada TOJ 2NO and [1] Merrill Dow Research Institute 2110 E Galbraith Rd. Cincinnati, Ohio 45215, USA.

ω-Conotoxin GVIA (CgTX) is an inhibitor of neuronal N type voltage sensitive Ca^{++} channels (VSCC). We have performed various manipulations to elucidate the effects of CgTX, on K^+ stimulated $^{45}Ca^{++}$ influx, intracellular free Ca^{++} and endogenous acetylcholine (ACh) release using chicken brain synaptosomes and slices respectively. The initial phase of K^+ stimulated $^{45}Ca^{++}$ influx and the rise in intracellular free Ca^{++} measured with Fura-2 was accompanied by release of endogenous ACh as detected by chemiluminescence. ACh release was reduced by 90% in the absence of Ca^{++} ions, or by Cd^{++} (0.1mM). CgTX (1μM) completely blocked the fast phase of $^{45}Ca^{++}$ influx, markedly inhibited the rise in intracellular free Ca^{++} and greatly reduced ACh release. The dihydropyridine VSCC antagonist (-)202791 and agonist (+)202791, by contrast, were ineffective in significantly altering these events. The results are consistent with the suggestion that CgTX inhibits N type VSCC's and that these channels are intimately associated with endogenous ACh release.

55.8

ACTIVITY-DEPENDENT INTRACELLULAR CALCIUM DISTRIBUTION IN GUINEA PIG CEREBELLAR PURKINJE CELLS: AN *IN VITRO* STUDY. M. Sugimori, D.W. Tank, J. Connor, and R. Llinás. Dept. Physiol. & Biophys, NYU Med. Ctr. New York, N.Y. 10016 and Molec. Biophys. Res. Dept. AT&T Bell Labs, Murray Hill, N.J. 07974.

Intracellular Ca concentration ($[Ca]_i$) was measured in adult guinea pig Purkinje cells in cerebellar slices following intracellular fura-2 injections. The ratio of digital micro-fluorometric images at 340 and 380 nm excitation provided a high resolution spatial map of the Ca^{++} distribution in soma, axon and dendrites. Maps were measured at 2 sec intervals during spontaneous .05 Hz oscillatory activity characterized by periods of calcium spiking and silence (Llinas & Sugimori, J. Physiol 1981). Ca^{++} accumulation first peaked in the distal spiny branchlets. Subsequently, $[Ca]_i$ rose in the primary and secondary branches of the main dendritic tree but remained low at the soma. Nearly identical oscillating calcium maps could be repetitively measured for several hours. Following gK blockage by TEA, the dendritic $[Ca]_i$ increased sufficiently to increase slightly the somatic $[Ca]_i$ Bath addition of *Agelenopsis aperta* toxin, known to block calcium spikes in Purkinje cells (Sugimori and Llinas, Soc. Neuroscience 1987), blocked oscillatory activity and produced a spatially uniform very low $[Ca]_i$. These results indicate that calcium entry into Purkinje cells occurs intially at the peripheral dendritic tree, probably in the form of a plateau potential that may serve as a boosting mechanism for the parallel fiber Purkinje cell synapse. When the depolarization becomes high enough, calcium-dependent spikes occur at the main dendrite generating the second phase of calcium entry. Supported by NIH grant NS13742.

A CA CHANNEL PROBE FOR HUMAN BRAIN: SPECIFIC BINDING SITES FOR ω-CONOTOXIN. M. Litzinger, A. Azimi-Zoonoz* and S. Stensaas*. Depts. of Biology, Neurology and Pathology, University of Utah, Salt Lake City, UT 84112.

ω-Conotoxin GVIA (ω-CgTx), a 27 amino acid positively charged peptide purified from the venom of Conus geographus, a marine snail, is believed to bind to the voltage-sensitive Ca channel (Olivera et al., Science 230, 1338-1343, 1985; Nowcyky et al., Nature 316, 440-443, 1985). Binding with ^{125}I-ω-CgTx was carried out (Cruz and Olivera, J. Biol., 261, 6230-6233, 1986) using crude membranes from two freshly frozen pathology specimens (12-16 hr postmortem) of human forebrain and hippocampus. A ^{125}I-ω specific ω-conotoxin binding site was found in both forebrain and hippocampus. It was displaced by pre-incubation with $2.5x10^{-7}$ M ω-conotoxin GVIA or $1x10^{-4}$ M neomycin. It was not displaced by $2.5x10^{-7}$ M μ-conotoxin (muscle Na-channel specific) or by $5x10^{-6}$ M α-conotoxin GI (nicotinic acetylcholine receptor-specific). Assay conditions employing low ionic strength for binding (Cruz and Olivera, 1986) lead to "false-positive" specific sites when human brain tissue is used; assays carried out under physiologic ionic salt concentrations gave a more reliable estimate of specific binding. High ionic concentrations (> 0.3 M) abolished specific binding in human brain membranes. Further characterization of the human ω-conotoxin binding site is in progress. (Supported by a gift from Miles Laboratories)

1,4-DIHYDROPYRIDINE-DISPLACING FRACTION FROM BRAIN ACTING ON CALCIUM CHANNELS:ISOLATION AND PARTIAL CHARACTERIZATION A.V. Shrikhande*, D.E. Johnson*, A.D. Howard, R.T. McCarthy* and R.A. Janis* (SPON: R.J. Fanelli). Miles Inc., 400 Morgan Lane, West Haven, CT 06516 USA

The purpose of this study was to determine if a 1,4-dihydropyridine (DHP)-displacing substance that modulates calcium channels could be isolated from mammalian tissue. Bovine brain was subjected to acid extraction and several purification steps. A fraction from brain that eluted from C18 reverse phase columns at 32% acetonitrile inhibited [^{3}H]DHP binding to cardiac membranes. Electrophysiological studies were carried out on rat anterior pituitary cells (GH3) using the whole cell variation of the patch clamp. Addition of the fraction to the inside, but not the outside of the cells produced a block of the sustained, but not the transient calcium channel current (CCC). This inhibition resembled that produced by DHPs. It was time- and voltage-dependent, such that block of slowly-inactivating CCC is maximized by prolonged depolarization. Further purification of this fraction on a sizing column in the presence of 40% acetonitrile yielded a low molecular weight fraction (<1 kDa) and an 18 kDa fraction consisting of myelin basic protein. Both fractions inhibited DHP binding but only the former inhibited CCC. This low molecular weight substance was active when added extracellularly. The results suggest that this fraction contains an endogenous substance that may regulate slowly-inactivating calcium channels.

KINETIC STUDIES OF [^{3}H]-NITRENDIPINE BINDING IN NORMAL AND CARDIOMYOPATHIC HAMSTER HEARTS. S.E. Howlett & T. Gordon. Dept. of Pharmacology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2H7.

The characteristics of high affinity dihydropyridine binding sites were compared in normal and cardiomyopathic (CM) hamster hearts to probe for possible defects in the Ca channel which could lead to Ca overload and, in turn, muscle necrosis. Kinetic studies of the temperature dependence of [^{3}H]-nitrendipine ([^{3}H]-NTP) binding to ventricular homogenates from 60-day-old normal and CM hamsters showed that, in normals, the rate of dissociation (0.049±0.006 min $^{-1}$ @ 25°C) was highly temperature-dependent (Q_{10} = 4.40±0.69) and that neither the rate nor the temperature dependence were influenced by disease. The rate of association (1.12±0.11 min $^{-1}$ nM^{-1} @ 25°C) was weakly temperature dependent (Q_{10} =1.25±0.04) and similarly unaffected by disease. The rates of [^{3}H]-NTP dissociation were increased and decreased by the Ca antagonists verapamil and diltiazem, respectively with little effect on the association rates. Allosteric interactions were identical in normal and CM hearts and, together with the normal temperature sensitivity, show that there is no abnormality at the related binding sites for nitrendipine, verapamil and diltiazem in the Ca channel of the CM hamster heart. Supported by the AHF and the AHFMR.

APPEARANCE OF SLOW CALCIUM CHANNEL ACTIVITY IN THE MYOTUBES OF MUTANT MICE WITH MUSCULAR DYSGENESIS (*mdg*). R.Bournaud[1,*], T.Shimahara[1,*], L.Garcia[2,*] and F.Rieger[2]. (SPON: Y.Brunner). Lab. of Neurobiologie Cellulaire et Moléculaire, CNRS, 91198 Gif/Yvette cedex France. Groupe de Biologie et Pathologie Neuromusculaires INSERM U153, 17 rue du Fer à Moulin 75005 Paris France.

Skeletal muscles from *mdg/mdg* fetuses are characterized by an absence of excitation-contraction (E-C) coupling and a significant reduction in the number of binding sites for dihydropyridine (D.H.P.). In vitro the high threshold slow Ca current is totally absent and contractile activities could be restored when these myotubes are co-cultured with spinal cord cells from normal mice. We have studied : 1) the modifications of physiological phenotype of *mdg/mdg* myotubes cultured with or without spinal cord cells. 2) the role if any, of the functional synaptic transmission in the appearance of normal physiological activities. We establish that both slow calcium current and E-C coupling were restored only when mutant myotubes are co-cultured with spinal cord cells from normal mice. Such a restoration of physiological phenotype did not require functional synaptic transmission since it was also obtained when neuro-muscular transmission was chronically blocked with α-bungarotoxin. The restored slow Ca conductance was identical to that observed in normal myotubes. The spinal cord cells from *mdg/mdg* mice, however, failed to induce normal muscle activity in the mutant myotubes. Partial restoration of the slow calcium current was also observed in aged *mdg/mdg* myotubes cultured without spinal cord cells. Though, in our experimental condition we did not observe an E-C coupling establishment in aged *mdg/mdg* myotubes. We conclude that: 1) *mdg/mdg* myotubes are capable of expressing slow calcium channel activity. 2) spinal cord cells stimulates the synthesis of D.H.P. receptors which are supposed to control both slow calcium current and E-C coupling. 3) functional neuromuscular transmission is not involved in the reversion of the *mdg* phenotype.

CALCIUM CURENTS EXHIBIT ALTERED SENSITIVITY TO BAY K8644 IN PC12 CELLS DIFFERENTIATED WITH NGF AND V-*SRC*. D. Lewis, D. Rausch, L. Eiden, and J. Barker (SPON: J. Lechleiter). Neurophysiology, NINCDS, NIH and Cell Biology, NIMH, Bethesda, MD 20892.

Ca currents were recorded with the patch clamp technique in PC12 cells under normal growth conditions and following differentiation induced by NGF or v-*src* oncogene. Following infection with a recombinant retrovirus carring the gene for v-*src*, PC12 cells extended neuron-like processes similar to that seen following NGF (D. Rausch & L. Eiden, these abstracts; Alemá et al., *Nature* 316:557, 1985). Peak Ca current in control PC12 cells increased in the presence of (-)Bay K8644 by 50.2 ± 7.8% (n=18), but was unaffected in v-*src* and NGF differentiated cells.

It has been reported that secretion in NGF-treated PC12 cells is insensitive to Bay K8644 (Kongsamut,S. and Miller, R. *PNAS*., 83:2243, 1986) implying that NGF-induced differentiation results in secretion mediated via dihydropyridine insensitive Ca channels (Miller, R. *Science*, 235:46, 1986). Our results indicate that PC12 cells differentiated with NGF or v-*src* do indeed develop Ca currents which have altered sensitivity to Bay K8644. Our macroscopic current recordings did not indicate the appearance of dihydropyridine insensitive Ca currents similar to the T and N types (Nowycky, M. et al., *Nature*, 316:440, 1985). The Ca currents recorded here were of the high-threshold, slowly inactivating or L type. It is possible that dihydropyridine insensitive channel types are expressed which have macroscopic properties different from the N and T types. Single channel analysis must confirm the channel types and their dihydropyridine sensitivities with neuronal differentiation.

55.14

EFFECTS OF NERVE GROWTH FACTOR ON CALCIUM CURRENTS IN PC12 CELLS. J.Streit*, H.D.Lux (SPON:H.R.Lüscher). Department of Neurophysiology, MPI for Psychiatry, D-8033 Planegg-Martinsried, GFR.

In the rat pheochromocytoma cell line PC12 cell sprouting is activated by nerve growth factor (NGF). We investigated, whether NGF treatment alters calcium currents in these cells in a way which could be related to neurite outgrowth. Whole cell calcium currents were recorded in the somata of PC12 cells using the patch clamp method. Peak current amplitudes (I_*), times to peak (ttp) and the fraction of inactivated current after 200ms pulse duration [F_i=1-(I_{200}/I_*)] were sampled for various groups of cells with different NGF treatment protocols. All three parameters were increased in cells treated with NGF compared to untreated cells [I_*: 256 ±12pA (n=91) versus 69±6pA (n=35), ttp: 19.9±1.0ms (n=109) versus 11.9±0.8ms (n=39), F_i: 0.39±0.01 (n=104) versus 0.27±0.01 (n=39), all ±SEM]. The increase in ttp was stronger correlated to neurite bearing cells than to cells treated with NGF, indicating that it was due to the changed electrotonic properties of differentiated cells and not to a change of the activation kinetics of the calcium channels. The increase in I_* became prominent only after 5 days of NGF treatment, clearly after the sprouting of the cells had occurred. However, it persisted when the cells lost their neurites due to a subculturing procedure, thus showing that it was not a consequence of neurite outgrowth. The NGF-induced increase in F_i was most prominent in the first three days of NGF treatment, that is during neurite outgrowth. It was strongly correlated to the NGF treatment, much less to the existence of neurites and not to I_*. These findings were confirmed when NGF was applied directly to previously untreated PC12 cells during whole cell recordings. In periods up to 60 minutes no effect of NGF on ttp or I_* was observed, whereas F_i was increased after 10 to 20 minutes of NGF application. This effect was partially reversible after washout of NGF. Due to the lack of temporal correlation of the NGF effects on I_* and F_i we conclude, that these effects can not be explained by an NGF-induced synthesis of an altered calcium channel, which is inactivated to a greater extent. The results are, however, in good agreement with a hypothesis based on calcium current distribution measurements (Streit,J. and Lux,H.D., Pflügers Arch.,411(sup.):R143, 1988), where a NGF induced clustering of calcium channels leading to more current inactivation is proposed.

Monoclonal Antibodies to the Alpha1 Subunit of the Muscle Voltage-gated Calcium Channel Identify Related Proteins in Human Small Cell Carcinoma and Neuroblastoma Cell Lines. Mary E. Morton* and Stanley C. Froehner. Department of Biochemistry, Dartmouth Medical School, Hanover, N.H. 03756.

Lambert-Eaton Syndrome (LES) is a neuromuscular disorder characterized by defective transmitter release and thought to involve an autoimmune response to presynaptic calcium channels. LES is frequently associated with small cell carcinoma of the lung (SCCL). We have investigated the possibility that SCCL cells express calcium channels similar to those found on the nerve terminal. A monoclonal antibody, mAb 1A, that recognizes the alpha$_1$ subunit of the voltage-gated calcium channel from skeletal muscle identified a related component on SCCL cells. FACS analysis demonstrated the presence of mAb 1A-reactive molecules on the surface of cultured human SCCL cells. An alpha$_1$-like polypeptide immunoaffinity purified from these cells exhibits an M_r similar to that of alpha$_1$ from skeletal muscle and is recognized by two distinct anti-alpha$_1$ mAbs. In addition, similar experiments showed that an alpha$_1$-like protein was present on the surface of IMR-32 cells, a human neuroblastoma line. These results indicate that small cell carcinoma and a cell line derived from peripheral neurons share surface proteins related to calcium channels. The data support a model which proposes that cross-reactivity of anti-tumor cell antibodies with presynaptic calcium channels plays a role in the development of Lambert-Eaton Syndrome.

CHARACTERIZATION OF Ca^{2+} TRANSPORT SYSTEMS IN RAT BRAIN MICROSOMES. J. Shah*[1] and H.C. Pant[2]. [1]Biophys. Inst., Boston Univ. Sch. of Med., Boston, MA 02118 and [2] Lab. of Neurochem., NINCDS, NIH, Bethesda, MD 20892.

We have characterized the different Ca^{2+} transport systems existing in the microsomes isolated from rat brain. A Mg^{2+}-ATP-dependent Ca^{2+} uptake was observed in K^+ loaded microsomes which was inhibited by sodium ortho-vanadate. A maximal 34% of total sequestered Ca^{2+} was released by an inositol 1,4,5-trisphosphate (IP_3)-gated channel and this release was insensitive to various Ca^{2+} channel blockers e.g. dihydropyridines (nitrenedipine, nifidipine), ω-conotoxin, Co^{2+}, ruthenium red, verapamil or dantroline. However, this IP_3-induced Ca^{2+} release was blocked by tetraethyl ammonium chloride (TEA) and 9-TEA (potassium channel blockers). The addition of IP_3, also results in a K^+ influx, suggesting that IP_3-induced Ca^{2+} release requires an opposite flow of K^+ ions. However, coexistence of another kind of Ca^{2+} transport system was found in these microsomes which was activated by Cd^{2+}. Cd^{2+} produced a rapid, large release of Ca^{2+} in a concentration-dependent manner. Maximal release (80% of the total A23187 releasable Ca^{2+}) was noticed at 250 uM Cd^{2+}. The Cd^{2+} stimulated Ca^{2+} release was inhibited by cysteine. Similar effects were shown by $AgNO_3$, although Ca^{2+} release was less pronounced compared to Cd^{2+} stimulated release. Different Ca^{2+} channels may play different physiological roles.

55.17

RECONSTITUTION OF A CALCIUM CHANNEL FROM OF A HIGHLY PURIFIED PREPARATION OF MOUSE BRAIN SYNAPTOSOMES. R. Etcheberrigaray* and E. Rojas* (SPON: J. Rinzel) LMCN, NINCDS and LCB & G, NIDDK, NIH, Bethesda, MD 20892.

It is generally accepted that, regardless of the origin of the Ca^{2+} required for exocytotic release of neurotransmitters, intracellular Ca^{2+} stores play a fundamental role in secretion. Membrane channels provide the most efficient mechanism to furnish the Ca^{2+} required for release. However, the role of the endoplasmic reticulum (ER) Ca^{2+}-channels in nerve cells has not yet been elucidated. A highly purified synaptosome preparation was used to obtain intra-synaptosomal membranes. Application of the freeze and thaw method to the synaptosomes generated a membrane preparation rich in ER fragments. Ca^{2+}-channels were reconstitued into bilayers made with phosphatidylinositol (Avanti Polar Lipids). Membranes were formed at the tip of patch clamp pipets by the "double dip" method. A low [Ca^{2+}] solution (mM: 100 CsPipes, 1 CaHepes, pH = 6.4) was used in the chamber containing the membranes fragments (cis side) and a high [Ca^{2+}] solution in the pipet (mM: 100 CsPipes, 50 CaHepes, pH = 7.6). Under these conditions, we were able to incorporate Ca^{2+}-channels with the following properties: 1) Strong voltage sensitivity. Fractional open-time increased from 32.4 (measured at 20 mV) to 84.5% (at 60 mV). 2) Single Ca^{2+}-channel currents varied linearly with pipet potential to give a slope conductance of 20 pS. 3). The channel was activated by ATP (500 uM) and caffeine (10 mM) and was blocked by ruthenium red (10 uM). Nifedipine (10 uM) was without effect (drugs were added to the cis side). These pharmacological properties support the idea that the Ca^{2+}-channel originated from internal organelles such as the ER and emphasize its possible role in Ca^{2+} mobilization from internal stores.

56.1

DISTRIBUTION OF T,L AND D CHANNELS IN HIPPOCAMPAL GRANULE CELLS: SIMULATION OF VOLTAGE CLAMP DATA AND CALCIUM SPIKES.

G.L.F. Yuen and D. Durand Applied Neural Control Labaratory, Department of Biomedical Engineering, Case Western Reserve University, Cleveland, Ohio 44106.

Although hippocampal granule cells were previously supposed to possess weak calcium conductances, recent singlé-electrode voltage clamp studies (Blaxter et at, in press) have revealed the presence of three types of calcium channels (T,L and D) similar to the well known T, L and N channels found in other preparations (see Fox et al J Physiol 394:173,1987a). In this study, we have attempted to simulate the clamp voltage versus peak current relation (I-V curve) as well as the shape of the clamp current over time, using detailed descriptions for these channels derived from whole-cell patch-clamp data (Fox et al J Physiol 394:149,1987b). Steady-state gate opening curves were fitted to the data of Fox et al (1987b) for each of the calcium channels (each with m^2h kinetics). Special attention was paid to the relative positions of the activation and inactivation curves on the voltage axis and the ranges of the inactivation time constants. These channels were incorporated into a model of the electrical properties of granule cells (Yuen and Durand Soc Neuro Abs 13:1353 with gNa=gK=0) and their I-V curves and clamp currents were simulated as a function of the distribution, type and density of the channels.

The experimentally obtained I-V curve was essentially reproduced by a model with T and L at the soma and D in the proximal dendrites at properly adjusted conductance values. However, the appearance of the I-V curve is sensitive to a number of other factors such as the rate of intracellular calcium ion removal and the spatial location of the D channels on the dendrites. Whereas **the simulated clamp currents for T and L resembles the experimental data, the inactivating portion of the D-current (observing from soma) gives a different appearance from the data.** Introducing calcium dependence to the inactivation gate for D improves the fit but at the expense of a fairly large (6.5 mS/sq.cm.) channel density and a shifted I-V curve to positive voltages. This discrepency between the simulated and the observed D-current may therefore be due to the experimental difficulty of obtaining adequate space-clamp. This simplified model of the distribution of T, L and D (somatic T and L, dendritic D) is also capable of generating calcium spikes similar to those obtained experimentally under TTX and TEA treatments. Simulations to date confirms (see Blaxter et al) that **a dendritic D-current is probably involved in the calcium spike** as suggested by: (1) the failure to generate a proper rising phase for the calcium spike in the absence of dendritic D channels at various values of somatic T and L conductances (2) preferential localization of the D-channel to the dendritic tree as suggested by experimental studies and (3) failure to obtain calcium spike with somatic T, L and dendritic T.

56.2

CALCIUM-DEPENDENT INACTIVATION OF CALCIUM CURRENTS IN HIPPOCAMPAL NEURONS: EFFECTS OF TETRAETHYLAMMONIUM AND NIMODIPINE. L.W. Campbell*, S.Y. Hao*, and P.W. Landfield (Spon: J. Robinson) Dept. of Phys./Pharm., Bowman Gray Sch. of Med., Winston-Salem, NC 27103.

Recent studies have indicated that Ca conductance (G_{Ca}) in rat hippocampal neurons exhibits a form of apparent Ca-dependent feedback inactivation (Pitler, Landfield, *Brain Res.* 410: 1987) similar to that described for invertebrate neurons (Eckert, Tillotson, *J. Physiol.*, 1981). However, hippocampal neurons were also shown recently to exhibit a brief Ca-and voltage-dependent K current (I_C) (Storm, *J. Neurophysiol.*, 1987), that could confound measures of G_{Ca} inactivation. This I_C is blocked by TEA, and the present studies therefore compared Ca-dependent inactivation of G_{Ca} before and after TEA application.

Ca currents were measured in cesium-loaded, TTX-treated rat hippocampal slice CA1 cells, in which the slow K-mediated afterhyperpolarization was blocked. TEA was applied by pressure ejection, and TEA efficacy was assessed by a several-fold lengthening of the Ca spike in current-clamp. Single-electrode voltage-clamp methods were used to study Ca currents in response to depolarizing commands below Ca spike threshold. TEA administration did not alter the time course or percentage inactivation during 2- or 5- Hz trains of command steps, indicating that I_C is not a confounding factor in the apparent inactivation of Ca current. However, the application of nimodipine, a DHP Ca-channel antagonist, reduced baseline current amplitude and slowed the rate of inactivation. These studies further indicate that a Ca-sensitive negative feedback mechanism inactivates Ca currents and limits the influx of Ca into mammalian brain neurons. (Supported by AG04542).

56.3

IDENTIFICATION OF TWO CA-CURRENTS IN NEURONS FROM THE RAT LATERAL GENICULATE NUCLEUS. A. HERNANDEZ-CRUZ* and H.-Ch. PAPE* (SPON: ENA), Howard Hughes Institute at Stony Brook and Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

Ca-conductances have been proposed to crucially determine firing properties of thalamic neurons (Jahnsen & Llinás, J. Physiol., 349: 205, 1984). Here we characterize Ca-currents in acutely dissociated multipolar neurons of the lateral geniculate nucleus (LGN). Cells were obtained after papain incubation (14 u/ml) of LGN slices from rats at postnatal days 13 and 14. Bath // pipette solutions contained respectively (in mM): 5 $CaCl_2$, 15 TEA, 3 4-AP, 10 K-HEPES, 24 glucose, 5 KCl and 236 sucrose // 50 CsCl or CsAc, 50 CsF, 10 TEA, 10 Cs-HEPES, 5 Cs-EGTA or 10 Cs-BAPTA, 2 Na-ATP, 10 phosphocreatine and 50 u/ml creatine phosphokinase. Whole-cell recordings showed two components of the Ca-current similar to the "T" and "L" type currents found in other central neurons. 1) The low-threshold transient (T) component: a) Is best elicited from holding potentials <-80 mV. b) Peaks in 35 to 6 ms and decays with a time constant ranging from 30 to 22 ms in the activation range -50 to -25 mV. c) Its steady-state inactivation occurs in the range -80 to -30 mV with half-inactivation near -60 mV. d) Is relatively insensitive to 50 μM $Cd^{++}$and blocked by 50 μM Ni^{++}. e) Is less permeant to Ba^{++} than to Ca^{++}. 2) The high-threshold sustained (L) component: a) Is selectively activated from less negative holding potentials. b) Shows no decay over pulses 100 ms or longer. c) Its activation ranges between -22 and 3 mV. d) Is relatively insensitive to $Ni^{++}$and very sensitive to block by Cd^{++}. e) Is less permeant to Ca^{++} than to Ba^{++}. To assess the role of these two currents in normal firing behavior, relay cells from the same animals were recorded in the in vitro LGN slice preparation (Ca^{++} concentration 1.5-2.5 mM). Cells in the dorsal LGN showed characteristic thalamic responses, including low-threshold Ca-spikes (LTS). LTS were de-inactivated with hyperpolarization <-80 mV, readily blocked by Ni^{++}(0.2-2 mM), whereas block by Cd^{++}(1-1.5 mM) was slower and incomplete. We conclude that a "T" type current underlies LTS in thalamic neurons, being this current dominant in the near-threshold voltage range.

56.4

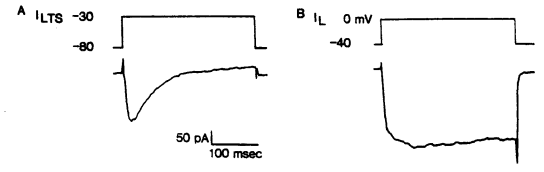
CALCIUM CHANNELS IN HYPOTHALAMIC NEURONS IN DISSOCIATED CELL CULTURE R. E. Petroski and H. M. Geller. Dept. of Pharmacology, UMDNJ - Robert Wood Johnson Medical School and The Graduate School, Rutgers University, Piscataway, NJ 08854.

We previously demonstrated that cultured embryonic hypothalamic express functional sodium and potassium channels as measured by whole cell patch clamp recordings. We now report that at least two kinds of calcium channels can be recorded from these neurons. Hypothalami are dissected from E17 rat brains and plated onto a confluent monolayer of cortical astrocytes. Whole cell recordings were made beginning 1 day in vitro. Input resistances range from 1000-5000 MΩ on these neurons which are 10-25 uM in diameter. Calcium currents are recorded with an electrode containing Cs+/TEA to block potassium currents. Choline was used in the bath to eliminate sodium currents and barium was utilized as the charge carrier. By 1 d.i.v., most neurons display an inactivating inward current carried by Ca^{++}/Ba^{++}. The time course of this current resembles that of the T-channel described in many neuronal preparations. At this time, little if any sustained inward current can be detected. As the neurons develop in vitro, a non-inactivating inward current develops. This is usually seen as a "notch" current with a variable lag period before activation. Additionally, prolonged "tail" currents are seen. The inadequate space clamp control suggests that the channels which carry this current are located in the processes of the neuron. This is temporally correlated with the appearance of long processes in the neurons. Parallel experiments with flow cytometric methods have also detected voltage-dependent calcium fluxes in freshly dissociated embryonic hypothalamic neurons (see Grierson et al, this meeting).

56.5

CHARACTERIZATION OF THE IONIC CURRENT UNDERLYING THE LOW-THRESHOLD CALCIUM SPIKE IN ENZYMATICALLY ISOLATED THALAMIC NEURONS. **Setsuo Suzuki* and Michael A. Rogawski, Medical Neurology Branch, NINCDS, NIH, Bethesda, MD 20892.**

Current clamp recordings in thalamic slices have demonstrated low-threshold (LT) Ca^{2+} spikes that are believed to mediate the shift from tonic to burst firing that occurs with hyperpolarization to -80 mV (Jahnsen & Llinas, *J. Physiol.* 349:205-247). We recorded similar LT spikes in neurons acutely isolated from the adult guinea pig dorsal lateral geniculate nucleus (LGNd), and, using whole cell voltage clamp recording techniques (140 mM *N*-methyl-D-glucamine internal solution), we characterized a novel Ca^{2+}current in these cells that may underlie the LT spike. Step depolarization to -30 mV and above from a holding potential of -80 mV activated an inward Ca^{2+} current (I_{LTS}) that rose to a peak within 25-35 msec and inactivated during the subsequent 100-200 msec; the current was reduced by Ba^{2+}. I_{LTS} was completely inactivated at -40 mV; depolarization from this potential elicited a slowly activating, minimally inactivating Ca^{2+}current (I_L) that was reduced by nimodipine. The characteristics of I_{LTS} are generally comparable to those of the N-type Ca^{2+} current of sensory neurons.



56.6

TWO TYPES OF SINGLE CALCIUM CHANNEL CURRENTS IN NG108-15 CELLS. H. Kojima* and T. Narahashi (SPON: A.B. Butler). Department of Pharmacology, Northwestern University Medical School, Chicago, IL 60611.

Single calcium channel currents were recorded from neuroblastoma-glioma hybrid cells (NG108-15) using the cell-attached patch clamp technique. The cells used were 5-6 days old in culture. The pipette solution contained 110 mM $BaCl_2$ and 10 mM HEPES (pH 7.5). The external solution contained 140 mM K-aspartate, 10 mM EGTA and 1 mM $MgCl_2$ (pH 7.3). Under this condition the membrane potential was maintained close to 0 mV. All experiments were performed at room temperature (22°C).

Two types of calcium channel currents were observed during step depolarizing pulses in the same membrane patch. One type of currents was generated during a depolarizing step to -20 mV from a holding potential of -80 mV, and had relatively short (1-3 msec) durations. This type of currents was observed frequently. The other type was generated during a depolarizing step to +20 mV from a holding potential of -20 mV, and had relatively long (2-8 msec) durations. This type of current was observed much less frequently than the former type. The short and long single calcium channel currents correspond to type I (T-type) and type II (L-type) whole cell calcium channel currents, respectively (supported by NIH grant NS14144).

56.7

CHARACTERIZATION OF VOLTAGE-DEPENDENT BARIUM CURRENT IN DORSAL ROOT GANGLIA x NEUROBLASTOMA HYBRID CELLS. L.M. Boland and R. Dingledine, Neurobiology Curr., Univ. North Carolina, Chapel Hill, NC, 27599.

The whole cell patch clamp technique was used to study voltage-dependent ionic currents in F-11 cells (see Dingledine and Boland, this meeting). F-11 cells expressed outward K and inward Na and Ca currents. The properties of the whole cell Ba current through voltage-dependent Ca channels were studied using 30 mM external Ba and an internal Cs solution that contained a nucleotide regenerating system to minimize washout. In most cells, the Ba current had a transient and a sustained component. The transient current was activated at -30 mV (peak at -10 mV) and exhibited voltage-dependent inactivation (half inactiv. at -30 mV). The sustained current was activated at -10 mV (peak at +20 mV) and could be isolated from the transient by holding the cell at -30 mV. Cadmium (20 μM) blocked 35$\pm$5% of the transient current and 95$\pm$3% of the sustained current (n=5-6). At a holding potential of -80 mV, 1 μM nimodipine blocked 18$\pm$5% of the transient current and 47$\pm$11% of the sustained current (n=5-6). Perfusion of F-11 cells with the opioid agonist DPDPE (30 nM) blocked 17$\pm$11% of the transient current and 16$\pm$6% of the sustained current (n=5-6). The percent block was not reduced further by increasing the concentration of DPDPE to up to 5 μM or by using other opioids (DAGO, Dynorphin A, U50,488). Thus, similar to DRG neurons from which this cell line is derived, a small fraction of the Ba current is blocked by opioids. (Supported by NS23804)

56.8

Possible existence of two types of Ca^{++} channels in bovine chromaffin cells. **R.Y.K. Pun and J. Picone* Dept. of Physiol. and Biophys., Coll. of Med., Univ. of Cincinnati, Cincinnati, OH 45267.**

There is ample evidence implicating the presence of multiple Ca^{++} channel subtypes. To determine whether release of catecholamines in chromaffin cells is mediated by a specific Ca^{++} channel, we studied the Ca^{++} currents in these cells using whole-cell "tight-seal" voltage clamp technique. Bath solutions contained (in mM): 5 Ca^{++}, 2 μM TTX, 100 TEA; and 110 Cs, 25 TEA, 2 ATP, 5 creatinine phosphate, 1.1 EGTA in the pipette solution. All drugs were applied from a perfusion pipette placed near the cell. At a holding potential (V_h) of -90 mV, depolarizing steps to between -30 and -10 mV evoked a sustained inward current. Depolarizing steps to between -10 and 0 mV evoked a large inward current which peaked within a few msec of the step and decayed slowly. This current was blocked by the addition of Mn^{++} (2 mM) or removal of Ca^{++} from the perfusion medium. In some cells, at a V_h of -90 mV, both nitrendipine (1 μM) and nifedipine (1-10 μM) enhanced the sustained inward current and slightly attenuated the slowly decaying current. When the V_h of the same cell was changed to -30 mV, the inward current evoked during depolarizing steps was greatly attenuated by the dihydropyridines. Peak current-voltage plots further showed that in the presence of Cd^{++} (5-20 μM), currents evoked positive to 0 mV from a V_h of -90 mV were blocked revealing an outward current. An inward current could still be recorded at negative potentials. Our results indicate that in chromaffin cells there may exist two types of Ca^{++} channels.

56.9

SPATIAL HETEROGENEITY OF NEURONAL CALCIUM CURRENTS. Man-Son-Hing, H.J. and Haydon, P.G. Department of Zoology, Iowa State University, Ames, IA 50011.

While neuronal somata are known to contain multiple types of calcium currents, it is unclear whether all types of calcium currents are distributed throughout the neuronal arbor, or whether they exist only in localized regions. To address this question, neurons were isolated from adult specimens of *Helisoma*, and plated in cell culture where the macroscopic calcium currents of the soma and growth cone were examined.

Acutely-isolated somata and somata which had extended neurites were found to contain three types of voltage-sensitive calcium currents. Using electrophysiological and pharmacological manipulations, the macroscopic current was separated into its three components: a low-voltage-activated decaying current, a high-voltage-activated decaying current, and a high-voltage-activated sustained current.

Cell bodies adjoined to their original axons were plated in culture. The first growth cone to arise from the axon was physically isolated and the local calcium current examined. Only a single type of calcium current was present in growth cone, a high-voltage-activated sustained current.

The high-voltage-activated sustained currents of the soma and the growth cone were both reduced by 10μM Cd^{++} and/10μM racemic Bay K8644. These data demonstrate that multiple types of calcium currents can be localized in the soma while the growth cone contains one specific type of current.

Ca CURRENT OF A PARASYMPATHETIC NEURON. R.B. Clark*, A. Tse and W.R. Giles (SPON: T.M. Dwyer). Dept. of Physiology, Faculty of Medicine, University of Calgary, Calgary, Canada.

Parasympathetic neurons from the interatrial septum of bullfrog (Rana catesbeiana) heart were isolated with an enzymatic dispersion procedure (Tse et al, Soc. Neurosci. Abst. 13,535) and maintained in short-term (1-6 d) tissue culture. Ca currents were recorded with whole-cell patch clamp methods. Na and K-dependent currents in these cells were blocked by replacing external Na and K by either n-methyl-d-glucamine or tetraethylammonium (TEA), and by an internal pipette saline containing Cs-aspartate, TEA Cl and 5 mM EGTA.

Ca current activated near -40 mV, and reached peak values at about +10 mV. The peak current density in 2.5 mM external Ca, was 34 $\pm$ 3 μA/μF (S.D.; n=10); the capacitance of the same sample of cells was 22.9 $\pm$ 9.1 pF. The Ca current appeared to be predominantly "L-type", and it inactivated by 19.1 $\pm$ 5% (n=12) during 200-300 ms depolarizations to about +10 mV. The amplitude of the Ca current was reduced by up to 30% by depolarizing prepulses of 0.5-0.9 sec in duration, but only for prepulse potentials more positive than about -10 mV, i.e. in the range where significant Ca current was activated. "T-type" currents could not be detected, even after holding at hyperpolarized potentials (-80 to -100 mV) for 1-3 min. The peak of the I-V relation was shifted negative by about 10 mV when Ca was replaced by a equimolar amount of Ba, but the peak current magnitudes were similar. After Ca replacement, the time course of inactivation of Ba current was essentially unchanged. These data suggest that inactivation of the Ca current in these neurons results from a small component of "N-type" Ca channels.

TRANSIENT CALCIUM CURRENT OF SOLITARY BIPOLAR CELLS FROM THE MOUSE. L. H. Pinto, A. Kaneko and M. Tachibana. Northwestern University, Evanston, IL 60201, and National Institute for Physiological Sciences, Okazaki 444, Japan.

We obtained solitary bipolar cells by enzymatic (papain) dissociation of the adult mouse (C57BL/6J) retina and measured the membrane currents of these cells by whole-cell patch clamp. Hyperpolarization from the holding voltage, V_h, of -40 mV evoked a slowly-activated, Cs-sensitive, inward current (probably an h-current), and depolarization evoked a TEA-sensitive, outward current (probably a combination of $I_{K(V)}$ and $I_{K(Ca)}$). Depolarization from more negative V_h (*e.g.*, -80 mV) evoked a transient inward current that had maximal amplitude between -40 and -20 mV. This current was identified as a Ca current: its amplitude was increased with elevated $[Ca^{2+}]_o$ and was decreased with reduced $[Ca^{2+}]_o$, and it was blocked by Co^{2+} (4 mM), but not by TTX (5 μM). The Ca current was insensitive to Cd^{2+} (50 μM) and ω-conotoxin (1 μM). The Ca conductance was activated by voltage steps to potentials >-60 mV and inactivated fully at potentials >-20 mV. This voltage range includes the presumed physiological range; thus, this current may participate in synaptic transmission. The transient character of the current may also help to shape transient responses of ganglion cells. (Supported by NEI R01EY01221, NSF INT8613447 and Japan Society for the Promotion of Science)

CALCIUM CURRENTS IN COCHLEAR HAIR CELLS OF THE DOMESTIC CHICK. P.A. Fuchs and M.G. Evans*, Dept. Physiology, C240 Univ. Colorado Med. School., Denver, CO 80262.

We have examined calcium currents (I_{Ca}) in hair cells isolated from apical and basal regions of the chick's cochlea. Solitary tall hair cells were voltage-clamped using whole-cell tight-seal recording methods. Large, non-inactivating, outward K currents (these are Ca-activated K currents (I_{Kc}) in basal cells) dominate the net current-voltage relationship. Therefore, inward currents were studied under a variety of experimental conditions designed to eliminate the larger outward currents. Inward currents were measured in some cells in the presence of 10-20 mM tetra-ethyl ammonium (TEA) or in solutions in which Ba substituted for Ca. In both of these conditions I_{Kc} was eliminated. Alternatively, substitution of internal K by Cs eliminated outward currents. This last procedure proved to be necessary for cells from the cochlear apex with large voltage-activated K currents that were insensitive to external TEA and barium. When outward currents were blocked the residual inward current required external Ca but also could be carried by Ba. I_{Ca} activated positive to -50 mV and reached maximum amplitudes of 75 pA (in 5.6 mM Ca) at 0 mV. When care was taken to block all outward current, no inactivation of I_{Ca} was evident for at least 200 msec. The activation time constant (derived from the fit of a squared exponential) decreased with depolarization and was approximately 0.4 msec at -10 mV (23 °C) in all cells examined. There appeared to be no significant differences in magnitude or kinetics of I_{Ca} in apical versus basal hair cells. Supported by grants NS21454 and NS01007 from NIH/NINCDS.

VERY SLOW, VOLTAGE-DEPENDENT INACTIVATION OF CA CURRENT IN INSULIN-SECRETING HIT CELLS. L.S. Satin* and D.L. Cook* (SPON: S. Fatherazi). Depts. of Physiol/Biophys and Medicine, Univ. of Wash. and VA Medical Ctr, Seattle, WA 98108.

The whole-cell patch clamp technique was used to voltage clamp single cultured HIT cells, a pancreatic β-cell line which secretes insulin in response to glucose. Na current was blocked by TTX (.5μM), outward currents by internal Cs (140mM), 4-AP (10mM), EGTA (1mM) and ATP (2mM) and external TEA (10mM). Depolarization-activated Ca currents inactivated in two phases: about 50% in <100 msec; the remaining in >10 seconds. The fast phase appears to depend on Ca influx since it was prolonged by replacing Ca with Ba and was proportional to Ca current but not depolarization. In contrast, the slow phase was voltage-dependent since long depolarizations inactivated the current in the absence of Ca influx (e.g. below the ICa threshold and above its reversal as well as in Ba). Recovery of inactivated Ca current was biphasic, consisting of rapid (<2 secs) and much slower (tens of seconds) components. Fast and slow inactivation may correspond to low and high-threshold Ca currents respectively (Satin and Cook, Pflugers Archiv, in press) since: 1) the rapid phase predominated at relatively low depolarizations and 2) 100 msec prepulses inactivated the rapid phase to reveal a slowly inactivating high threshold component. These properties may be useful for understanding the electrical activity observed in pancreatic β-cells in response to elevated glucose.

CALCIUM CURRENT IN PARASYMPATHETICALLY ANEURAL CHICK HEARTS. Tony L. Creazzo* (SPON: D. Stoney). Dept. of Anatomy, Medical College of Georgia, Augusta, GA 30912.

Chick hearts were made parasympathetically aneural by bilateral ablation of the nodose placodes and the neural crest which seeds pharyngeal arches 1-3 at H.H. stages 8 or 9 (Kirby M.L., J. Neurosci., in press). In conjunction with an absence of intracardiac ganglion cells the hearts from lesioned embryos suffer from failure of conal truncal septation (persistent truncus arteriosis; PTA). Therefore, hearts were used for these experiments only if diagnosed as having PTA. The atria and ventricles from 3 sham operated and 3 lesioned embryos were separated and enzymatically dissociated to yield single cells. A total of 33 cells from sham and experimental atria and ventricles were examined using the whole cell variation of the patch clamp. K+ currents were blocked by replacing K+ with Cs+. The extracellular solution contained 1.8 mM Ca++ and 3 μM TTX to block Na+ current. Inward Ca++ current (ICa) was elicited with 400 msec depolarizing pulses from Ehold = -80 mV to potentials ranging from -60 to 60 mV in 10 mV increments. Peak ICa was about 30% greater in experimental ventricles when compared to the sham at depolarizing potentials from -40 to 0 mV while not significantly different at positive potentials. At 0 mV the peak current density was 3.2 +0.7 pF/pA (SEM, n=7) and 2.1+0.4 pF/pA (n=8). Peak ICa in experimental atria was not significantly different from sham. Currently, experiments are underway to determine whether the increased ICa is due to the absence of innervation, the PTA or both.

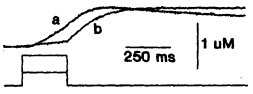
TUBULAR INWARD CALCIUM CURRENT CAN DIRECTLY CONTRIBUTE TO MYOPLASMIC CALCIUM TRANSIENTS. E. Stefani, M. Amador* & J. García*. Baylor College of Medicine, Dept. Physiology and Molecular Biophysics, One Baylor Plaza, Houston, TX, 77030.

To detect any contribution of inward Ca currents to the myoplasmic Ca transients, it becomes necessary to reduce Ca release and removal. Experiments were performed in cut single skeletal fibers isolated from the semitendinosus muscle of Rana pipiens by using the indicator dye Antipyrylazo III. The fiber was held at -90 mV with the vaseline gap voltage clamp technique; temperature= 16 °C. The intracellular solution contained 1.0 mM-EGTA. Ca transients progressively decreased and became slower after repetitive stimulation (0.02 to 0.03 Hz) with 250 ms pulses to 0 mV. As Ca transients became smaller, it was more evident their relation with the amplitude and the time integral of the inward Ca current. Ca transient amplitude followed the electromotive force for Ca; during a large pulse to +100 mV they were greatly reduced and became large after repolarization during the inward tail current. In agreement, with the addition of 2 μM-Bay K 8644, Ca transient increased parallel to the inward current. The figure shows the Ca transients obtained with Bay K to pulses delivered to a: 0 mV and b: +100 mV. Supported by NIH.



56.16

TWO TYPES OF CALCIUM CURRENTS IN MAMMALIAN SKELETAL MUSCLE. J. García*, R. Gamboa-Aldeco*+ and E. Stefani (Spon: E. R. Decker) Baylor College of Medicine, Dept. Physiology and Molecular Biophysics, One Baylor Plaza, Houston, TX, 77030.

Voltage clamp experiments were made in cut single fibers from extensor digitorum longus muscle from rats and rabbits using the vaseline gap technique. Holding potential was -90 mV. External solution contained 2 mM-Ca. Two populations of calcium channels were found according to their kinetics and voltage dependence (fig. a). A low threshold current was detected at -70 mV in 21 out of 31 fibers from rats, reached its maximum amplitude (-1.9 uA/uF) at about -30 mV, and the time constant of deactivation at -70 mV was 80 ms. A higher threshold current was detected at -20 mV, its maximum (-6 uA/uF) was at 0 mV (fig. b), and the time constant of deactivation at -70 mV was 10 ms. This current was DHP-sensitive: it was blocked by 10 uM-nifedipine and potentiated by (-)-Bay K 8644 (1 uM). Peak tail amplitudes showed two plateaus, at -40 mV and 10 mV, corresponding to each current (fig. c). In 4 out of 5 fibers from rabbits both currents with similar properties were found. Supported by NIH.

ION CHANNELS: MODULATION AND REGULATION I

57.1

EARLY APPEARANCE OF NEUROMODULATORY MECHANISMS IN THE EMBRYONIC CHICK CHOROID. D. Zelazny* & D.B. Gray. Dept. Physiol. & Neurobiol., Univ. Connecticut, 75 N. Eagleville Rd., Storrs, CT 06268.

Somatostatin (SS) and morphine have recently been shown to completely inhibit K+-evoked release of ^{3}H-ACh from isolated nerve terminals of the ciliary ganglion (CG) in the choroid layer of the chick eye (Gray, D. & G. Pilar, Soc. Neurosci. Abstr., 13: 790, 1987). To determine if this capacity for neuromodulation is present in immature synapses, ^{3}H-ACh release from CG terminals in St 40 (E 14) choroid was measured in normal and 55mM K+ Tyrodes. In these preparations, K+-evoked release per choroid was 5-10 fold lower than after hatching. Only 30% of ^{3}H-choline uptake (in 1μM choline) was sensitive to 0.5μM hemicholinium (a specific antagonist of Na+-dependent, high-affinity choline uptake) at St 40 as opposed to 85% at hatching. In spite of these differences, K+-evoked release of ^{3}H-ACh from CG terminals in the choroid at St 40 is abolished by both 100nM SS and 10μM morphine. As in the hatchling chick this inhibition of ACh release is sensitive to a 1-hr preincubation in pertussis toxin (200 units/ml). These studies suggest that even in immature synapses between CG neurons and vascular smooth muscle in the choroid, the membrane apparatus mediating neuromodulation is already in place.

THE TRANSIENT K+ OUTWARD CURRENT DEVELOPS LATER THAN THE DELAYED K+ CURRENT IN THE RAT PINEAL CELL. Luis G. Aguayo and Forrest F. Weight. Section of Electrophysiology, Laboratory of Physiologic and Pharmacologic Studies, NIAAA, Rockville, Md 20852.

The outward currents of pineal cells acutely dissociated from Sprague-Dawley rats aged 1 and 2 weeks were studied with the whole-cell variation of the patch-clamp technique and compared with those of adult rats. All adult cells displayed both a transient and a delayed voltage-activated K^+ outward current. The delayed current, which was activated from a holding potential of -50 mV, had an activation threshold of -20 mV. This current was activated in all the cells from 1-week-old rats and the amplitude was about 70% of the amplitude in adult cells. In young and adult cells no evidence for a Ca^{2+}-activated K^+ current was found.

The transient current was activated from a holding potential of -100 mV with commands potentials positive to -60 mV. With more positive holding potentials the transient current displayed voltage-dependent inactivation with 50% inactivation at -76 mV. The transient current was observed in only 40% of the cells dissociated from 1-week-old rats. The peak amplitude of the transient current measured in cells from rats up to 2 weeks of age was no more than 25% of the amplitude in adult rats. Comparison of the time course and voltage dependence of the delayed and transient currents in young and adult cells showed no significant differences. The appearance of the transient current was associated with a marked acceleration of the rate of decay of the voltage response produced by a depolarizing constant current pulse.

The results suggest that the K^+ channels carrying the transient current in pineal cells are expressed later than those carrying the delayed current.

57.3

LONG-TERM REGULATION OF POTASSIUM CHANNELS IN PC12 PHEOCHROMOCYTOMA CELLS BY NERVE GROWTH FACTOR. B. Rudy and J.D. Pollock. Dept. of Physiol & Biophys., NYU Med. Ctr., New York, NY 10016 and Division of Biology, Caltech, Pasadena, CA 91125

PC12 cells are a clonal cell line isolated from a rat pheochromocytoma (L.A. Greene and A.S. Tischler, PNAS, 73: 2424, 1976). In the presence of nerve growth factor (NGF) PC12 cells cease dividing and differentiate from chromaffin-like cells to sympathetic-like neurons. As PC12 cells differentiate the amount and types of sodium and calcium channels expressed changes (B. Rudy, J. Neurosci.2: 1405, and S. Kongsamut, PNAS 83: 2243, 1986). We have explored if the amount and types of potassium channels expressed in PC12 cells is altered after long term NGF treatment.

Ten day NGF treatment of PC12 cells increased the net outward current fourfold without changing the current density. However, a significant change in potassium current kinetics is observed after ten day treatment with NGF. Undifferentiated PC12 cells show a transient outward current that is elicited by commands to 0 mV or greater from a holding potential of -90 mV. The total current decays by 31.3 $\pm$ 1.02% n=30 at the end of a 400 ms step to 30 mv. The transient component is sensitive to 200 μM TEA. We have identified a 21 pS channel whose ensemble average resembles the macroscopic current observed in undifferentiated cells. The transient component is no longer apparent in PC12 cells treated with NGF for ten days and appears to be replaced or obfuscated by a more slowly inactivating current. In these cells the total potassium current decays by 12.9 $\pm$ 1.8% n=16 at the end of a 400 ms step to 30 mV. We have observed a 12.5 pS channel whose ensemble average resembles the macroscopic current in NGF differentiated cells.

57.4

HUMAN AND BOVINE bFGF BUT NOT cAMP INDUCE SODIUM CHANNELS IN PC12 PHEOCHROMOCYTOMA CELLS. J.D. Pollock, M. Krempin*, and B. Rudy (Caltech, Pasadena, Ca. and NYU School of Medicine, NY, NY)

Nerve growth factor (NGF) has been previously reported to induce neurite outgrowth and sodium-dependent action potentials in PC12 cells (L.A. Greene and A.S. Tischler. PNAS, 73: 2424, 1976 and B. Rudy, et al., J. Neurosci., 2:1405, 1982). The effect of NGF on neurite outgrowth can be mimicked with human and bovine basic fibroblast growth factor (bFGF) (R. Rydel and L.A. Greene, J. Neurosci., 7: 3639, 1987). Other substances such as EGF and cAMP lead to some of the early events elicited by NGF but not to later differentiating events (D.G.B. Leonard, et al., Mol. and Cell. Biol. 7: 3156, 1987). Since induction of sodium channels is a key feature of the late neuronal-like differentiation of PC12 cells by NGF we asked the question whether bFGF or cAMP also induces sodium channels in PC12 cells.

Ten day treatment of PC12 cells with either 50 ng/ml human bFGF or 10 ng/ml bovine bFGF caused neurite outgrowth and a significant increase in sodium current and sodium current density. The sodium current in bFGF cells starts to activate at -50mV and peaks at about -10 mV. The midpoint for steady-state inactivation of the sodium current is around -70 mV and can be completely blocked with 1 uM TTX. Single channel recording of sodium channel currents suggest a single channel conductance of 10-11 pS. On the other hand, 300 uM treatment with CPT-cAMP for ten days failed to induce sodium currents.

These results suggest that sodium channel is a final common pathway of late gene expression induced by bFGF and NGF but not cAMP. Moreover, any possible elevation of cAMP by NGF or bFGF is not by itself sufficient for the induction of sodium channels in PC12 cells.

57.5

REGULATION OF IONIC CURRENTS IN PC12 CELLS BY NERVE GROWTH FACTOR AND DEXAMETHASONE. S. S. Garber, T. H. Hoshi*, and R.W. Aldrich, Dept. of Neurobiology, Stanford Univ., Stanford, CA 94305-5401

Differentiation of pheochromocytoma (PC12) cells can be influenced by growth factors and hormones. On application of Nerve Growth Factor(NGF), PC12 cells extend neurites and become morphologically similar to sympathetic ganglion cells (SGCs), whereas incubation of PC12 cells with a steroid, dexamethasone (DEX), causes an increase in tyrosine hydroxylase activity suggesting that the cells become chromaffin cell-like. SGC's are known to express voltage-dependent Na^+ currents and more then one type of Ca^{++} current. Chromaffin cells express voltage-dependent Na^+ current and only "L-type" Ca^{++} current. We measured voltage-dependent Na^+ currents (23%) and transient "T-type" Ca^{++} currents (20%) were expressed by only a fraction of PC12 cells grown for up to 21 days in the absence of either NGF or DEX. In the presence of 200 ng/ml NGF, the percent of cells with Na^+ currents increased within 7 days to 94%, as has been previously documented. The fraction of cells with "T-type" Ca^{++} current increased to 46% after 7 days of exposure to NGF. Cells incubated with 1μM DEX become large and irregular in shape over 2-3 weeks. Cells grown up to 21 days in DEX, showed an increase over control cells in the expression of Na^+ current (75% over 23%) and a small but significant increase in "T-type" Ca^{++} current (40% over 20%). After 21 days, this difference declines because of a gradual increase in the fraction of control cells expressing Na^+ and "T-type" Ca^{++} current. Incubation of cells in both NGF and DEX prevented the rapid increase in the appearance of the currents observed with NGF alone. All cells (control, NGF and DEX) retained "L-type" Ca^{++} current and no changes in K^+ currents were observed. These results suggest that the temporal expression of ionic currents are differentially regulated by NGF and DEX. Supported by NS23294, NS07158, and a NIH postdoctoral fellowship to T.H.

HORMONAL CONTROL OF MEMBRANE CURRENTS IN SOMATOTROPHS. Stephen M. Sims* and Jacob Kraicer*. Dept of Physiology, Univ. of Western Ontario, London, Ontario, Canada. N6A 5C1 (SPON: P. Grigg)

Control of growth hormone secretion was studied with patch-clamp recording of freshly dispersed, normal rat somatotrophs. In whole-cell voltage-clamp mode, depolarization elicited a number of currents, including a transient inward Na^+ current, a slowly inactivating Ca^{++} current, and outward K^+ current. Inward Ca^{++} channel current was studied in isolation with Cs^+ in the recording pipette and 10 mM Ba^{++} in the bath. The inward current, which was fully blocked with 1 mM Cd^{++}, inactivated slowly during 100 ms test depolarizations and was partially blocked by nifedipine. Outward currents were studied with K^+ in the patch electrode, and evidence was consistent with K^+ being the charge carrier. The reversal potential for tail currents was close to the predicted K^+ equilibrium potential, and shifted 56 mV/10 fold change of $[K^+]_{out}$. Furthermore, TEA blocked the outward current. Cd^{++} reduced the K^+ current, suggesting the presence of Ca^{++}-activated K^+ current. In these respects normal rat somatotrophs resemble clonal growth hormone secreting cell lines,(eg. GH_5/GH_4). Growth Hormone Releasing Factor (GRF) (2-76 nM) reversibly suppressed outward K^+ current, an effect which could underlie the excitatory, depolarizing action of GRF, and trigger growth hormone release. (Supported by MRC Canada)

CIS-UNSATURATED FATTY ACIDS ATTENUATE VOLTAGE-DEPENDENT SODIUM CURRENT IN N1E-115 NEUROBLASTOMA CELLS. D.J. Linden* and A. Routtenberg. Cresap Neuroscience Laboratory, Northwestern University, Evanston, IL 60208.

Cis-unsaturated fatty acids such as oleic acid have been shown to modulate synaptic efficacy (J. Neurosci. 7:3783) and to activate purified protein kinase C (PKC) in vitro (J. Biol. Chem. 261:15424). We wished to determine the ionic basis of this modulation and its potential link to PKC in a simplified system and thus turned to the whole-cell voltage clamp preparation, using the N1E-115 neuroblastoma cell differentiated in medium containing 4% DMSO.

Oleic acid bath-applied at 5 uM produced no alteration of the resting potential (-45 mV) and only a slight decrease of the baseline input resistence (135 megohm). Analysis of families of currents evoked under voltage clamp by depolarizing steps from a holding potential of -85 mV during application of 5uM oleate showed a 40% reduction in the peak inward current with no appreciable shift in the I-V relation, and no detectable alteration of outward current. Na current was then isolated by application of external Mg, internal F and TEA and replacement of internal K with N-methylglucamine (Ikeda et al., J. Neurophys. 55:527). This isolated current was completely and reversibly abolished by TTX or removal of external Na. The cis-unsaturated fatty acids oleate, linolenate and linoleate were seen to attenuate isolated Na current with approximate ED_{50}'s of 5, 5, and 20 uM respectively. Elaidate (a trans-unsaturated isomer of oleate) and stearate (a saturated fatty acid), which do not activate PKC, had no effect on the isolated Na current when applied at concentrations of 1-50 uM. Since cis-unsaturated fatty acids are known to fluidize membranes as well as to activate PKC, we sought to dissociate these functions by applying compounds that fluidize membranes but do not activate PKC: methyloleate and lysophosphatidylcholine. Neither compound affected Na current when applied at concentrations of 1-50 uM, consistent with the view that the reduction of Na current by cis-unsaturated fatty acids is mediated by activation of PKC. (Supported by MH25281-13 and AFOSR87-0042 to A.R. and an Air Force Laboratory Graduate Fellowship to D.J.L.)

57.8

ALTERED MEMBRANE FATTY ACID COMPOSITION MODIFIES NA-CHANNEL INACTIVATION. C.C. Park* and Z. Ahmed. Dept. of Physiology, State Univ. of New York, Buffalo, NY 14214.

Dissociated embryonic neurons (E16) from rat diencephalon were grown in a defined medium. Membrane fatty acid composition was modified by supplementing culture media with either the n-3 or n-6 class of polyunsaturated fatty acid (PUFA). Lipid analysis showed that the ratio of PUFA to saturated fatty acid (SFA) was increased about 2 fold. This increase was due to a class-specific incorporation of PUFA.

Electrophysiological studies were performed on 5-10 days old cultures using the whole-cell voltage-clamp technique. Neurons grown in PUFA supplemented media showed an age-dependent increase in input capacitance and a decrease in input resistance. Control cultures showed no significant change. The peak-Na current-voltage relationships in the supplemented and control cultures were not significantly different. The inactivation time course of Na-currents can be described by a sum of two exponentials with a slow (tl) and a fast (t2) time constant. In PUFA supplemented cultures, tl was reduced 40% from that of the control while t2 was not significantly affected.

These effects are not due to the metabolites of the n-6 class of PUFA since they occurred with both classes. Rather they are probably due to the increased ratio of PUFA/SFA in the membrane. Supported by NSF Grant BNS 84-17003.

57.9

REGULATION OF MEMBRANE-MEDIATED CHRONIC MUSCLE DEGENERATION IN DYSTROPHIC HAMSTERS (DH) BY ATP-$MgCl_2$. Syamal K. Bhattacharya and Denise M. Riedel*. Surgical Research Laboratories, University of Tennessee, Memphis, TN 38163.

Membrane-mediated excessive intracellular Ca accumulation (EICA) appears to be a fundamental pathogenetic event associated with chronic muscle degeneration in humans and hamsters with hereditary muscular dystrophy (Muscle & Nerve, 10:168, 1987). Dystrophic muscle is deficient in ATP which stabilizes the membrane fluidity and fuels the intracellular Ca-pump in the regulation of excessive myoplasmic Ca^{2+}. Hypothesizing that ATP and $MgCl_2$ possess membrane stabilizing and Ca-antagonistic properties, we studied whether subcutaneous (sc) ATP-$MgCl_2$ could regulate EICA and improve the associated dystrophic lesions in the heart, diaphragm, and rectus femoris of CHF-146 strain DH. Equimolar ATP-$MgCl_2$ (100 micromoles/100 g BW/day) was administered sc to 8 DH and 8 CHF-148 strain normal hamsters (NH) for 87 days, beginning at the age of 20 days. Six DH and 5 NH served as vehicle controls. Muscle and plasma [Ca], [Mg], and [P_i] as well as plasma CK were determined. Histologic evaluation was also performed on the tissues. The ATP-$MgCl_2$ treated DH showed significant reduction in EICA, plasma CK activity and overall improvement in the muscle morphology and phosphate sequestration. We conclude that ATP-$MgCl_2$ lowers EICA and improves membrane-mediated dystrophic lesions in DH and thus, may have therapeutic applications in the regulation of dystrophic pathobiology in humans. (Supported by NIH grant #AR-38540)

57.10

EFFECT OF ALTERATIONS IN EXTRACELLULAR MAGNESIUM CONCENTRATION ON EXCITABILITY AND LTP IN THE RAT HIPPOCAMPAL SLICE. K.E. VanLandingham, J.M. Stringer, and E.W. Lothman. Dept. of Neurology, University of Virginia Medical Center, Charlottesville, VA 22908.

Extracellular magnesium ($[Mg^{++}]_o$) is known to regulate NMDA receptors and synaptic transmission in the central nervous system. In the hippocampal slice, removing $[Mg^{++}]_o$ causes epileptiform activity and high $[Mg^{++}]_o$ suppresses stimulus induced responses. However, intermediate variations in $[Mg^{++}]_o$ have not been studied systematically. We examined the effects of 0, 0.5, 1.0, 1.5(control), 2.5, and 3.5mM $[Mg^{++}]_o$ on input-output (I/O) curves, long-term potentiation (LTP), and epileptiform activity in the CA1 region of rat hippocampal slices. Extracellular calcium and potassium were kept at 1.5 and 3.1mM, respectively. $[Mg^{++}]_o$ below 1.5 mM always caused a left shift in the I/O curve and an increase in the maximal population spike (PS) amplitude. Raising $[Mg^{++}]_o$ above 1.5mM always caused a right shift of the I/O curve and a decrease in the maximal PS amplitude. LTP was completely blocked in 3.5mM $[Mg^{++}]_o$, suppressed in 2.5mM, but constant in $[Mg^{++}]_o \leq 1.5$mM. Spontaneous or stimulus-locked epileptiform bursts were present in $[Mg^{++}]_o$ lower than 1.5mM, but never in 1.5mM or higher. The percentage of slices showing spontaneous epileptiform discharges was: 79% (0mM), 40% (0.5mM), and 9% (1.0mM) and the percentage of slices showing only stimulus-locked bursts was: 7% (0mM), 50% (0.5mM), and 45% (1.0mM).

57.11

FAST AXONAL TRANSPORT SPEED AUGMENTATION BY Ca^{++} CHANNEL AGONISTS. M.B. Atkinson*, C.M. Ferrario and A.C. Breuer (SPON: D. Averill). Depts. of Neurology and Brain and Vascular Research, Cleveland Clinic Foundation, Cleveland, OH 44195.

The interruption of fast axonal transport (FAT) by Ca^{++} depletion (Ca^{++} free buffer or Ca^{++} channel antagonists) has been documented by several investigators (Ochs, S., *et al*, Nature, 270:748-750, 1977; Lavoie, P.A., *et al*, J. Neurochem, 32:1745-1751, 1979). We report here on the results of increased Ca^{++} flux into the axons to further modify FAT rates.

Axonal preparations from male Sprague-Dawley rats were treated with either 1 μM BAY k 8644 (a Ca^{++} channel agonist) or depolarized by 50 mM K^+ (to open Ca^{++} channels). Axonal transport was then video-recorded under DIC optics for later analysis by computer methods. BAY k treatment resulted in an anterograde (ANTERO) FAT speed increase of 9.9 ± 1.9% ($p < 0.05$) and a retrograde (RETRO) FAT increase of 9.5 ± 1.1% ($p < 0.001$). K^+ depolarization increased the ANTERO and RETRO FAT speed by 14.9 ± 1.9% ($p < 0.001$) and 10.6 ± 1.6% ($p < 0.001$) respectively. Pre-treatment of the axonal preparations with nitrendipine (a calcium channel antagonist) with subsequent exposure to either BAY k or K^+ depolarization completely eliminated the observed FAT speed increases (not significantly different from controls in either direction). These results substantiate a critical role for calcium in the modulation of fast axonal transport speeds.

DIFFERENT EFFECTS OF CAPSAICIN ON SUBTYPES OF DORSAL ROOT GANGLION NEURONS IN VITRO. M.J. McLean and S.E. Barron. Departments of Neurology and Pharmacology, Vanderbilt Univ. Med. Ctr., Nashville, TN 37212.

Subtypes of adult mouse dorsal root ganglion neurons (DRGn) in monolayer dissociated cell culture were recognized by comparison of action potential (AP) waveforms with those of DRGn in intact ganglia whose type was determined by conduction velocity and stimulus specificity (Lawson and Harper, J. Physiol., 1985; Rose et al., Neurosci. Lett., 1986). Neurons (SDn) which fired one or a few short-duration (2 msec), tetrodotoxin (TTX)-sensitive APs during depolarizing steps resembled mechanoceptors in situ. Neurons in cell culture (LDn) which sustained repetitive firing of long-duration (2-5 msec), TTX-resistant APs resembled nociceptors in situ. Action potentials of both SDn and LDn were sodium-dependent. Pressure ejection of capsaicin (CAP, 1 uM) onto quiescent LDn, but not SDn, caused depolarization and AP firing. Firing of depolarization-elicited APs by SDn was reversibly abolished by CAP applied in Ca^{++}-containing, but not Ca^{++}-free, solution. Depolarization of LDn was less when CAP was applied in Ca^{++}-free solution, but was not abolished. These findings suggest different mechanisms of action of CAP on functionally distinct DRGn.

EFFECTS OF LIDOCAINE AND SAXITOXIN ON THE TETRODOTOXIN-RESISTANT CURRENT OF MAMMALIAN DORSAL ROOT GANGLION NEURONS. S.E.Barron, P.B.Bennett* and M.J.McLean. Depts of Neurol. and Pharm., Vanderbilt Univ. Sch. Med., Nashville,TN 37212.

Freshly dispersed dorsal root ganglion neurons (DRGn) have tetrodotoxin (TTX)-resistant and sensitive sodium currents (I_{Na})in varying proportion (McLean et al.,1987). Neurons with a large proportion of TTX-resistant I_{Na} (I_{Na}-R) resemble nociceptor-like DRGn in cell culture which fire TTX-resistant action potentials. Effects on the I_{Na}-R may help determine cellular mechanisms of action of analgesic drugs such as lidocaine (LIDO). To characterize the I_{Na}-R further, whole cell currents were recorded from dispersed adult mouse DRGn. TTX(3uM), saxitoxin(STX,1uM) and LIDO(37uM) were added to the extracellular solution (in mM: NaCl 65;CsCl 65;$MgCl_2$ 2;$CaCl_2$ 1;dextrose 10;TEA-Cl 10;HEPES 10; and pH 7.35) at 15 to 18°C. Patch pipettes were filled with solution containing (in mM:CsF 110;NaF 10;CsCl 30;$MgCl_2$ 2;EGTA 2; HEPES 10; and pH 7.35). The I_{Na}-R was reduced tonically by STX and both tonically and in use-dependent manner by LIDO. Thus, LIDO produces use dependent block of a unique I_{Na}-R of DRGn,similar to its blockade of nerve TTX-sensitive I_{Na}. Supp: Mallinckrodt Fellowship and NIH Grant #NS01194.

INHIBITION OF THE Na^+-Ca^{++} EXCHANGE SYSTEM BY AMILORIDE ANALOGUES STIMULATES DOPAMINE RELEASE FROM TUBEROINFUNDIBULAR HYPOTHALAMIC NEURONS. L.Annunziato, L.M.T. Canzoniero*, S.Amoroso*, G.F.Di Renzo*, E.J.Cragoe*and M.Taglialatela* Inst. Pharmacology,Univ.Naples and Chieti,Italy,and Merck Sharp & Dohme,Res.Lab.,West Point,PA 19486,USA.

In the last years a great deal of attention has been pa to the membrane Na^+-Ca^{++} exchange system as an important regulator of Ca^{++} transport across the neuronal membrane. In the present study we investigated the effect of amiloride and of some of its derivatives, which are provided with different inhibitory potency in inhibiting the Na^+-Ca^{++} antiporter, on ^{3}H-dopamine (^{3}H-DA) release from superfused tuberoinfundibular hypothalamic (TIDA) neurons. Amiloride (0.3-1mM) and its 2',4'-dimethylbenzamyl derivative (2',4'-DMB)(30-300uM),which inhibited Na^+-dependent Ca^{++} uptake in synaptosomes obtained from TIDA neurons, dose-dependently stimulated ^{3}H-DA release from these neurons. Furthermore, 2',4'-DMB (50uM) was able to prevent the stimulatory effect on ^{3}H-DA release elicited by the cardioactive glycoside ouabain (0.5mM),which is known to promote neurotrasmitter release through the stimulation of Ca^{++} entrance into the neurons mediated by the Na^+-Ca^{++} antiporter. On the other hand, 5-N-methyl-N-(guanidinocarbonylmethyl)-amiloride, an amiloride derivative which lacks of inhibitory properties on the Na^+-Ca^{++} exchange activity, but displays high selectivity in inhibiting the Na^+-H^+ antiporter, failed to modify basal release of ^{3}H-DA from TIDA neurons. Collectively, these results for the first time demonstrate that the inhibition of the Na^+-Ca^{++} exchange system can modulate neurotrasmitter release from central synapses.

ANTIBODY TO THE 45 kD GAP-JUNCTIONAL PROTEIN BLOCKS DYE COUPLING BETWEEN CARDIAC MYOCYTES. R. Lal, S. B. Yancey*, J.-P. Revel*, Division of Biology, Caltech,Pasadena, CA 91125

Gap junctions mediate rapid intercellular transfer of electrical signals and synchronous activity of the excitable tissues. In heart, the major constituent of the gap junction is believed to be a 45 kD protein. Here we present evidence that site-specific antibodies raised to a synthetic peptide corresponding to the first 20 amino acids of the 45 kD heart gap junction protein blocks intercellular communication between pairs of neonatal rat myocardial cells in culture. All experiments were conducted at room temperature, between 3-6 days of culture. In isolated pairs, one cell was iontophoretically injected with 5% Lucifer Yellow CH (LY) or 0.2% Texas Red (TR) in 150 mM LiCl. Dye transfer to the other cell of the pairs indicated normal coupling between myocardial cells in culture. In one cell of a dye-coupled pair, antiserum diluted 1:4 in 150 mM LiCl buffered to pH 7.6 with 10 mM HEPES was iontophoretically injected by a large (~100 nA) hyperpolarizing pulse at 1 Hz for 5 sec. After 3-5 mins.,the other cell of the pair was injected with the second dye. In 27 of 30 cell pairs which showed an intercellular transfer of the first dye (LY or TR) the injection of antiserum showed unequivocal blockage of transfer of the second dye (TR or LY). The remaining instances were questionable for various reasons. In 22 of another 25 dye-coupled pairs an identical injection of pre-immune serum had unequivocally no effect on transfer of the second dye. Thus our results are consistent with the notion that the heart gap junctions mediating cell-cell communication are formed by 45 kD proteins. Further our finding that the intracellular injection of the antibody disrupts dye-coupling indicates that the amino terminus of the protein resides in the cytoplasm and that this portion of the molecule may play role in regulating channel functions.Supported by NIH grant LH37109.

MODULATION OF APLYSIA CELL MEMBRANE RESISTANCE BY A SINUSOIDAL ELECTRIC FIELD. A.R. Sheppard, M.R. Wacker,* S.M. Bawin and W.R. Adey. Research Service, J.L. Pettis VA Medical Center, and Departments of Physiology, Neurosurgery and Surgery, Loma Linda University, Loma Linda, CA 92350.

Membrane resistance of silent cells of the Aplysia abdominal ganglion was studied by hyperpolarizing current clamps during a 4 h period which included two 0.5 h exposures to a 10-Hz, 1 V/m rms electric field (produced by constant current between Ag-AgCl electrodes in artificial seawater perfusate, ~22 C). Resting membrane potential and single electrode clamp data were obtained regularly by a minicomputer interfaced to a digital 'scope and microelectrode amplifier via custom hardware and software. Delayed, gradual reductions of 5 to 30% in membrane resistance occurred with a mean latency of 20 min after start of exposure. Often, the first exposure had little or no effect, but larger changes occurred during the second exposure. Cell resting membrane potential also changed, but the magnitude and direction of changes were not tightly linked to resistance changes. These results suggest a modulation of one or more membrane channels as a result of changes in slowly responding intracellular biochemical pathways. PATCH CRAMMING: A NEW METHOD FOR DETECTING INTRACELLULAR MESSENGERS IN INTACT CELLS. Richard H. Kramer Graduate Dept. of Biochemistry, Brandeis University, Waltham, MA 02254.

Intracellular messengers are ubiquitous regulators of cellular processes. However, little is known about the intracellular concentrations, dynamics, and spatial distributions of most of these molecules. To address these questions I have been developing a method for detecting intracellular messengers in intact cells. The "patch cram" method utilizes ion channels sensitive to a messenger as probes for detecting that molecule inside a cell. The method is conceptually simple: A conventional patch pipette is used to obtain a patch of membrane housing the "detector" ion channel, and the pipette is then "crammed" into the cytoplasm of a recipient cell. The activity of the detector ion channel will then reflect the intracellular concentrations of the messengers to which it is sensitive. Ion channels directly sensitive to Ca, cAMP, cGMP, and IP_3 have been described; hence all of these should be detectable with the patch cramming technique.

I have obtained detector ion channels either by 1) patch clamping a cell known to contain the detector ion channels, and then excising the patch (inside-out patch configuration), or 2) reconstituting the ion channel in an artificial lipid bilayer formed at the tip of the patch pipette ("tip-dipping"). Patches containing the detector channels have succesfully been crammed into neurons from Aplysia and Helix. Even though these patches were forceably thrust through the membrane of the recipient cell, in more than 75% of cases the patch continued to exhibit a gigaohm seal, and channel gating activity continued unabated for up to 20 min. In addition, the recipient cell often quickly recovered from the impalement, exhibiting normal resting potential, action potentials, and complex spontaneous behavior, such as bursting pacemaker activity.

In initial experiments, I have used a Ca-activated K channel from Helix neurons to detect intracellular Ca. After cramming the patch into a recipient Helix neuron, the channel open probability decreases as calcium diffuses away from the patch. If the patch is depolarized, channel open probability increases, and then quickly returns to baseline after the depolarization. In contrast, depolarizing the cell, either with action potentials, or under voltage-clamp, results in a increase in channel opening which long outlasts the depolarization. I suggest that this change in gating activity is due to increase in intracellular calcium induced by opening voltage-dependent calcium channels in the recipient cell. Ongoing experiments are aimed at confirming this suggestion. Additional experiments are aimed at detecting cyclic GMP in Helix neurons and in other cells, utilizing cyclic GMP detector ion channels from vertebrate rods.

DISCERNING MULTIPLE CONDUCTANCES USING A NOVEL METHOD TO ANALYZE VOLTAGE RECORDS. S.D. Hocherman,* R. Werman* and Y. Yarom* (SPON: A.J. Susswein), Department of Neurobiology, Hebrew University, Jerusalem 91 904, Israel.

We have developed a procedure which enables us to calculate the time course of a conductance change as well as its reversal potential from voltage recordings by calculating the neuronal input resistance at different times during a voltage response. We used this procedure to study the kinetics of the long afterhyperpolarization (*AHP*) that follows a train of action potentials in the vagal motoneuron in guinea pig brainstem slices. The *AHP*'s were superimposed on long hyperpolarizing pulses of varying intensities. The voltage-current relation of each sampled point (digitized at 500 *Hz*) was plotted to give the instantaneous input resistance of the cell, while the intersection of each plot with the control voltage-current relation gives the reversal potential. This procedure reveals that the vagal *AHP* results from activation of at least two conductances that differ in their time course, amplitude and reversal potential. As these conductances overlap, we used a differential blocker, norepinephrine (*NE*), in order to resolve their kinetics. Application of 50-200 μM *NE* does not change the Ca^{2+} action potential but blocks the main component of the *AHP*, leaving a brief (decays with τ=200 msec) Ca^{2+}-dependent AHP. This *AHP* apparently involves at least two ions (from reversal potential measurements). The main component of the *AHP*, which is blocked by *NE*, is produced by a calcium-dependent K^+ conductance that rises monotonically, to peak in about 1 sec, and then decays slowly ($\tau \sim 1.5$ sec). The maximum amplitude of this conductance increases linearly with the number (1-10) of action potentials. The unusual, relatively simple tool introduced here is powerful in the detailed analysis possible with its use.

PEPTIDES: PHYSIOLOGICAL EFFECTS I

58.1

SOMATOSTATIN INCREASES THE HEIGHT OF ACTION POTENTIALS IN HIPPOCAMPAL PYRAMIDAL NEURONS. T.W.J. Watson and Q.J. Pittman. Neuroscience Research Group. University of Calgary, Calgary, Alberta, Canada T2N 4N1.

In addition to previously reported actions on various neural and endocrine cells, we have found that somatostatin (SS14) causes an increase in height of action potentials (AP) in CA_1 pyramidal neurons. Intracellular voltage records were obtained by conventional methods using transverse rat hippocampal slices that were submerged and perfused with oxygenated artificial CSF at 30-32 C. Drugs were applied through the perfusate. SS14 ($2x10^{-6}$M) consistently resulted in a 3-10 mV increase in the amplitude of evoked or spontaneously occuring AP and this action was associated with an increased rate of rise of the depolarizing phase of the AP. This was not related to a change in membrane potential and was not associated with any change in width of the AP. The effect persists in 0.5mM $CdCl_2$ thus it appears to be a direct action not involving a calcium conductance. The increase in AP height is seen with 2mM $BaCl_2$ in the extracellular fluid which suggests it is independent of the previously described action of SS14 on the m-current (Moore et al Science 239: 278-80). This action is not seen with somatostatin 1-12. The increase in amplitude of the AP is blocked by 10^{-6}M TTX and may represent an effect on the fast sodium current.

58.2

GALANIN DECREASES MEMBRANE EXCITABILITY OF MUDPUPPY PARASYMPATHETIC POSTGANGLIONIC NEURONS. R.L. Parsons and L.M. Konopka*. Department of Anatomy and Neurobiology, College of Medicine, University of Vermont, Burlington, VT 05405.

Galanin inhibited action potential firing in mudpuppy parasympathetic neurons which exhibited spontaneous activity. This effect remained after the membrane potential was returned electrotonically to pregalanin values. Quiescent parasympathetic postganglionic neurons produced a brief train of spikes during 400 msec depolarizing current pulses. Following application of galanin, the number of spikes in the train was decreased. This effect also occurred in cells in which the galanin-induced hyperpolarization was negated. Galanin shifted the value of the threshold for spike generation and decreased the MRR, amplitude and MRF of sodium spikes. The spike HAP was also significantly prolonged by galanin. Galanin decreased the amplitude and duration of TTX-insensitive spikes initiated in cells maintained in a solution containing 9mM calcium, 20mM TEA and 1.5uM TTX. These results demonstrated that galanin decreases excitability of individual neurons in the mudpuppy cardiac ganglion. The decrease in excitability is due to an action of this peptide on a number of membrane conductance components and occurs independently of the galanin-induced hyperpolarization. Supported by PHS RO1 23978 and NSF BNS 8605611.

58.3

CHARACTERISTICS OF THE GALANIN-INDUCED HYPERPOLARIZATION OF MUDPUPPY PARASYMPATHETIC POSTGANGLIONIC NEURONS. L.M. Konopka* and R.L. Parsons (SPON: I. Young). Department of Anatomy & Neurobiology, College of Medicine, University of Vermont, Burlington, Vermont 05405.

Many parasympathetic postganglionic neurons in the mudpuppy cardiac ganglion are hyperpolarized by local application of the 29 amino acid neuropeptide, galanin (Neel et al., Neuroscience Abstracts 13:739, 1987. The present study was undertaken to establish the properties of the galanin-induced hyperpolarization. Application of galanin produced a hyperpolarization which developed within a few seconds and persisted for tens of seconds after the galanin application was terminated. The galanin-induced hyperpolarization was present after pretreatment with either 1uM atropine, 50uM curare, or 1.5uM TTX. Desensitization of the galanin-induced hyperpolarization occurred in only a small percentage of cells. In nine cells maintained in 2.5mM extracellular potassium, the reversal potential for the galanin-induced hyperpolarization was -105.4 $\pm$ 2.7mV. In four cells the reversal was shifted by 38.7 $\pm$ 4.9mV with a fourfold elevation of the extracellular potassium concentration. The galanin-induced hyperpolarization exhibited rectification when the membrane potential was made more positive than E_K. The results of these studies suggest that the galanin-induced hyperpolarization results from the activation of a potassium conductance. Supported by PHS RO1 23978 and NSF BNS 8605611.

58.4

SOURCE OF GALANIN-LIKE PEPTIDE IN THE MUDPUPPY CARDIAC GANGLION. T.W. McKeon and R.L. Parsons. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

Galanin has been demonstrated to have inhibitory effects on parasympathetic postganglionic neurons in the mudpuppy cardiac ganglion. The present study was undertaken to determine the source of galanin-like peptide in this preparation. Using immunohistochemical techniques, galanin-immunoreactive fibers were seen to form complexes over many mudpuppy parasympathetic postganglionic neurons in the cardiac ganglion. These fibers remain two weeks following bilateral vagotomy and appear to be processes of postganglionic parasympathetic neurons and SIF-like cells. In many instances, processes from galanin-immunoreactive SIF-like cells were the origin of the pericellular immunoreactive complexes around the postganglionic neurons. We hypothesize that the SIF-like cells in the mudpuppy cardiac ganglion may function as inhibitory interneurons and that in many cases a galanin-like peptide may mediate this inhibition. Supported by PHS RO1 23978 and NSF BNS 8605611.

NPY STIMULATION OF LHRH RELEASE FROM RAT MEDIAN EMINENCE: EFFECTS OF ESTROGEN AND CALCIUM. F.D. Sabatino and J.K. McDonald. Dept. of Anatomy and Cell Biology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

NPY stimulates LHRH release from median eminence (ME) fragments in vitro from ovariectomized (OVX) rats treated with estrogen (E) (Sabatino & McDonald, Neurosci. Abstr. 13: 1310, 1987). We examined the effects of physiological doses of E on NPY stimulation of LHRH release and the role of extracellular Ca^{2+}. Sprague-Dawley rats were OVX and 2-4 weeks later implanted with silastic tubes containing vehicle or E (1E, 2E and 4E), which produced plasma E levels of 17, 30 or 73 pg/ml. MEs were incubated in medium before and after application of NPY (10^{-5} & 10^{-6} M). In other experiments, MEs from rats treated with the 2E dose were incubated in medium containing 2.5, 1.0 or 0.25 mM Ca^{2+} or in Ca^{2+} free medium containing 2.0 mM EGTA and in some cases 2.5 mM Co^{2+}.

NPY caused a dose-related stimulation of LHRH release which was enhanced by increasing plasma levels of E. No effects were observed in vehicle-treated OVX rats. Treatment with 2E and 4E increased ME concentration of LHRH, while NPY levels were significantly greater only with the 4E dose. KCl (56 mM) stimulation of LHRH release was reduced in a dose-dependent fashion by decreasing Ca^{2+} levels and absent in Ca^{2+} free medium. Reductions of Ca^{2+} or omission of Ca^{2+} $\pm$ inclusion of Co^{2+} had no effect on NPY (10^{-5} M) stimulation of LHRH release. The results show E-dependent modulation of NPY stimulation of LHRH release from the ME and suggest that extracellular Ca^{2+} may not be required for this effect. Supported by NIH HD19731, HD00727 and March of Dimes 5-524.

58.6

INHIBITION OF SMOOTH MUSCLE CELL CYCLIC AMP ACCUMULATION AND DISRUPTION OF LIPOSOME STRUCTURE BY NEUROPEPTIDE Y (NPY). S.H. Buck, B. Baron, J.L. Krstenansky* and L.R. McLean*. Merrell Dow Research Institute, Cincinnati, OH

The 36-amino acid peptide, NPY, and its receptors are found in the CNS and in the periphery. Recently, NPY was reported to inhibit forskolin- or agonist-induced adenylate cyclase activity in CNS and peripheral tissues with an EC_{50} of 10-100 nM. In the CNS, a second phase (nonreceptor mediated?) of inhibition was also observed at NPY concentrations above 5 µM. We have found similar complex inhibition by NPY of cyclic AMP accumulation stimulated by 10 µM isoproterenol (ISO) in cultured rat aortic smooth muscle cells. As NPY concentration is increased, there is an initial, small inhibition (30%, EC_{50} = 3 nM), a disappearance of inhibition (approximately 100 nM), and a subsequent second phase of intense inhibition (> 70%) commencing at NPY concentrations greater than 1 µM. Deletion of Ca^{2+} from the incubation medium abolished the disappearance phase resulting in continuous, dose-related inhibition by NPY at 1-1000 nM (EC_{50} = 24 nM). In dimyristoylphosphatidylcholine liposomes, addition of 12 µM NPY induced a rapid, nearly complete loss of turbidity monitored by absorbance at 400 nm. Thus, some of the inhibitory effects of NPY on adenylate cyclase may involve membrane perturbation due to the amphipathic helical conformation proposed for the unfolded peptide. It is not yet clear if similar structural requirements underlie the receptor-mediated physiological effects of the peptide.

BRADYKININ INDUCES AN INWARD CATION CURRENT AND AN INCREASED MEMBRANE CONDUCTANCE IN CULTURED RAT SENSORY NEURONS. D.S. McGehee* and G.S. Oxford. Dept. of Physiology, Univ. of North Carolina, Chapel Hill, NC 27599.

The excitatory effects of the nonapeptide bradykinin (BK) were examined on sensory neurons in primary culture. Whole cell patch clamp techniques were used to measure BK responses from rat DRG neurons 1-20 days in vitro. BK (10-1000nM) was applied directly to cells via U-tube perfusion. Concentration-dependent depolarizations and conductance increases were seen in BK responsive cells. Action potneitla frequency increased and many cells (20-30um diam.) fired in bursts. These effects lasted 1-3 min in the continued presence of agonist, and repeated applications gave attenuated responses. Responses to BK were attenuated or absent in 0mM external Ca^{++} or with internal EGTA. Under voltage clamp conditions, BK causes an inward current with a time course similar to the depolarizations. This inward current was potentiated by the inclusion of 100uM GTP in the patch electrode. Identical BK effects could be recorded from cells in young (1-2 day) cultures without obvious synaptic connections, indicating a postsynaptic effect. Gammon et al. (in press) have reported BK-induced increases in phosphatidylinositol metabolites in DRG cutlures with time courses which closely match those seen electrophysiologically. We are undertaking experiments to dtermine which portions of the PI second messenger cascade are involved in the excitatory response to BK. Supported by NIH grant NS23804.

58.8

BRADYKININ AGONIST AND ANTAGONIST RESPONSES IN SENSORY NEURONS AND SMOOTH MUSCLE ASSAYS. D.M. Rock, M.J. McLean, J.J. Geer*, L.W. Cooke* and C.P. Taylor. Parke-Davis Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105 and Dept. Neurol., Vanderbilt Univ., Nashville, TN 37212.

Bradykinin (BK) is a nonapeptide that causes pain and inflammation. BK depolarizes unmyelinated dorsal root ganglion neurons (DRGNs) releasing neurokinins peripherally[1]. We studied BK responses with intracellular recordings from cultured mouse DRGNs and with contractile responses of several in vitro preparations: isolated rabbit iris muscles[1] (contractions from activation of BK receptors on sensory neurons), rabbit jugular vein segments[2] and guinea pig ileum segments[2] (smooth muscle responses).

We appljed BK and peptide BK antagonists[3] [$Thi^{5,8}$,$DPhe^{7}$]-BK or $DArg^{0}$-[Hyp^{3},$Thi^{5,8}$,$DPhe^{7}$]-BK to cultured DRGNs from blunt micropipettes. The peptide antagonists did not depolarize DRGNs and appeared to block BK responses. The peptides were competitive antagonists of smooth muscle BK responses. Seven peptide derivatives of BK had similar relative potencies as agonists of neuronal (rabbit iris) and contractile responses.

These data are consistent with the existence of a single BK receptor type in sensory neurons and certain smooth muscle preparations.

58.9

IN VIVO ELECTROCHEMICAL STUDIES OF THE EFFECTS OF CHOLECYSTOKININ ON EVOKED OVERFLOW OF DOPAMINE (DA) IN THE CAUDATE NUCLEUS AND NUCLEUS ACCUMBENS OF THE ANESTHETIZED RAT. G.A. Gerhardt[1,2], M.S. Brodie[4], A.P. Gratton[2], T.W. Vickroy[4], G.M. Rose[2,3] and B.J. Hoffer[2] Depts. of Psychiatry[1] and Pharmacology[2], Univ. of Colorado & VAMC[3], Denver, CO 80262 and Neuroscience Research[3], Pharmaceutical Discovery, Abbott Laboratories, Abbott Park, IL.

Peptides related to cholecystokinin (CCK) have been reported to have both facilitory and inhibitory actions on transmitter release in DA pathways in the central nervous system. In order to further investigate this phenomenon, in vivo electrochemical studies of DA release were conducted in the striatum and nucleus accumbens of the urethane anesthetized rat. High-speed chronoamperometric measurements (5-25 Hz; IVEC-5 Instrument, Medical Systems Inc.) were performed using Nafion-coated recording electrodes fastened to double-barrel micropipettes containing solutions of potassium and cholecystokinin octapeptide (CCK-8). Potassium-induced overflow of DA was studied both before and after CCK-8 ejection. Locally applied CCK-8 consistently augmented potassium-evoked overflow in both brain areas. In addition, parenterally administered CCK-8 also augmented potassium-evoked overflow of DA. Thus, our data support that CCK-8 possesses a facilitory action on the presynaptic elements of the nigrostriatal and mesolimbic DA systems. (Supported by USPHS grants AG06434 and NS09199, NSERCC, and the VAMRC.)

58.10

EFFECTS OF CERULEIN ON THE IN VIVO RELEASE OF NEUROTRANSMITTERS FROM RAT STRIATUM. M.Shimoyama* and S. Kito. 3rd Dep. of Int. Med. Hiroshima Univ. Sch. of Med., 1-2-3, Kasumi, Minami-Ku, Hiroshima, 734, Japan.

In 1980, Hökfelt et al. showed that cholecystokinin(CCK)-immunoreactivity was co-localized with dopamine (DA) in some neurons in the rat ventral tegmental area which projected to various limbic structures. This finding has led to the suggestion that CCK-peptides may modulate the DA function in the brain. The present study examined the effects of cerulein, a decapeptide analog of CCK-8, on the in vivo release of DA and acetylcholine (Ach) from the rat striatum through intracerebral dialysis. A thin dialysis tube was inserted transversally through the rat caudate nuclei and the tube was perfused with the Ringer solution. The perfusion arrangement allowed the rats to move freely. The perfusates were assayed for DA, 3,4-dihydroxyphenylserine(DOPAC), homovanillic acid(HVA) and Ach by HPLC with electrochemical detection. Intraperitoneal and intrastriatal administrations of cerulein were without effect on the spontaneous release of both DA and Ach in striatal perfusates. Elevated K^+-induced DA release was inhibited by cerulein(100 µg/kg, i.p.). The inhibitory effect of cerulein on the high potassium-evoked DA release disappeared in bilateral vagotomized rats. This results suggested that the inhibitory effect of systemically administered cerulein on the rat striatal DA system was mediated by vagal CCK receptors.

58.11

INHIBITION OF POTASSIUM-EVOKED RELEASE OF CHOLECYSTOKININ (CCK) FROM RAT CAUDATO-PUTAMEN INCUBATED IN VITRO BY PHENCYCLIDINE (PCP) AND RELATED COMPOUNDS. L.R. Allard*, P.C. Contreras and M.C. Beinfeld* (SPON: S.E. Dryer). Department of Pharmacology, St. Louis University School of Medicine, St. Louis, MO 63104 and G.D. Searle/Monsanto Co., Chesterfield, MO 63198.

We have suggested that CCK release from rat caudato-putamen (cp) is under inhibitory control by another substance which is released from the cp along with CCK by a Ca^{+2}-dependent mechanism. Since we have found that glutamate inhibits CCK release, we examined whether PCP (which is known to interact with NMDA receptors) influences CCK release. PCP at 10^{-5}M produces a significant inhibition of CCK release, greater than that produced by 10^{-5}M glutamate. However, PCP and glutamate appear to be acting differently because while the inhibitory action of glutamate could be blocked by APB (amino-phosphono-butyric acid), the inhibitory action of PCP was increased by APB. Several other PCP-like drugs were also found to inhibit CCK release. These results suggest that it is possible that PCP may inhibit CCK release in vivo and that inhibition of CCK may be involved in PCP-induced psychosis.

CHOLECYSTOKININ (CCK) DEPOLARIZES RAT SUPRAOPTIC NUCLEUS (SON) NEUROSECRETORY NEURONS. C.R. Jarvis, C.W. Bourque and L.P. Renaud. McGill Univ. Centre for Research in Neuroscience, Montreal, Canada H3G 1A4.

The rat hypothalamic SON demonstrates CCK-like immunoreactive cells and fibers as well as high density CCK binding. Intracellular recordings obtained from 26 phasic and 17 non-phasic SON neurons in superfused explants revealed dose-dependent, reversible and TTX resistant membrane depolarizations (2-11 mV) during brief infusions of 0.05 - 2.0 µM CCK-8 (both sulfated and non-sulfated), CCK-4 and caerulein. A reversible inward current accompanied by a small increase in chord conductance were seen under voltage clamp. Proglumide (1 mM) reversibly blocked CCK but not glutamate-evoked depolarizations. These data suggest that activation of a postsynaptic CCK receptor can excite SON neurosecretory neurons.

Supported by FRSQ, FCAR and the MRC.

CALCITONIN GENE-RELATED PEPTIDE ENHANCES CALCIUM CURRENT OF THE RAT DORSAL ROOT GANGLION NEURONS AND SPINAL EXCITATORY SYNAPTIC TRANSMISSION. P. D. Ryu, G. Gerber*, K. Murase and M. Randic, Dept. of Vet. Physiology and Pharmacology, Iowa State University, Ames, IA, 50011.

Calcitonin gene-related peptide (CGRP) is a 37 amino acid peptide formed in neural tissue by alternative splicing of mRNA of the calcitonin gene. The presence of CGRP-like immunoreactivity in the rat dorsal root ganglion (DRG) neurons and spinal dorsal horn has been demonstrated. Our experiments were designed to examine the actions of CGRP on the Ca^{2+}-dependent action potentials and the voltage-dependent Ca^{2+} current in rat DRG neurons in vitro. In addition we tested the effect of CGRP on excitatory synaptic transmisison in the rat spinal dorsal horn.

Experiments were performed on the isolated preparations of lower lumbar (L4-L6) DRGs attached to a length of dorsal roots and horizontal spinal cord slices with attached dorsal roots and ganglia prepared from 14-28-day-old rats. Single-electrode voltage-clamp recordings were made from DRG neurons and intracellular current-clamp recordings from dorsal horn neurons. Synthetic rat CGRP was applied into the bath in known concentration.

CGRP (10^{-8} to 2 x 10^{-6}M for 1-3 min) evoked a slow, reversible dose-dependent hyperpolarization accompanied by an increase in neuronal input resistance in DRG cells. In addition, some large DRG neurons were depolarized by CGRP. CGRP produced a reversible increase in the amplitude and the duration of the Ca^{2+} spike of DRG neurons and directly increased the voltage-dependent Ca^{2+} current by enhancing both the transient and the sustained components of the current.

CGRP caused a pronounced and long-lasting increase in the amplitude of the fast e.p.s.p.s. recorded in dorsal horn neurons in response to high intensity electrical sitmulation of a lumbar dorsal root. In addition, CGRP increased the frequency and amplitude of presumptive spontaneous e.p.s.p.s.

The increase in the Ca^{2+} current is likely to be responsible for the increase in the Ca^{2+} spike and facilitation of excitatory synaptic transmission. These results are consistent with a neuromodulator role for CGRP in the rat spinal dorsal horn. Supported by NSF and USDA.

CHARACTERIZATION OF DIFFERENT FACTORS WITH FMRF-AMIDE-LIKE ACTIVITIES FROM NEUROHAEMAL ORGANS OF THE LOCUST. M. Schiebe*, R. Watts*, I. Orchard, A. Lange and H.L. Atwood. Dept. Physiology and Zoology, Univ. of Toronto, Ont. M5S 1A8

The extensor tibiae muscle of the locust Schistocerca gregaria is modulated by FMRF-NH2-like peptides. Immunohistological data suggested that a FMRF-NH2-like factor is concentrated in neurohaemal organs (NHO). Extracts of these organs were processed using reversed phase HPLC, and were split up on an acetonitrile gradient. The fractions were assayed by examination of their effects on muscle kinetics using muscle fiber bundles innervated by the slow motor axon in both Schistocerca and Locusta. Five different fractions with FMRF-NH2-like properties were identified. However, at the retention times of FLRF-NH2, YGGFMRF-NH2 and YGGFLRF-NH2, the known FMRF-NH2 agonists, no bioactive material was found. The peptides TNRNFLRF-NH2 and SDRNFLRF-NH2 from Homarus (Trimmer, B.A. et al., J. Comp. Neurol. 266:16, 1987) which are as potent as YGGFLRF-NH2/YGGFMRF-NH2, were eluted at the retention time of one bioactive NHO fraction. Part of the biological activity of NHO extracts may be provided by these peptides.

58.15

EFFECTS OF TACHYKININS AND OPIOID PEPTIDES ON NEUROTRANSMISSION IN THE AVIAN CILIARY GANGLION. L. Mossman, C.-H. Feng*, O.A. Ramirez* and V.A. Chiappinelli. Dept. of Pharmacol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

In addition to acetylcholine, some presynaptic terminals in the avian ciliary ganglion contain substance P-like and/or leucine-enkephalin-like immunoreactivity (Erichsen et al., J. Neurosci. 2:994, 1982). We have described the physiological effects of substance P on choroid neurons and presynaptic terminals within intact chick ciliary ganglia in an in vitro chamber (Dryer, S.E. and Chiappinelli, V.A., J. Neurosci. 5:2654, 1985 and Brain Res. 336:190, 1985). We now report the pharmacological profile of the tachykinin receptors present on choroid neurons. These receptors mediate a slow, depolarizing response which mimics a slow EPSP activated by brief 5-20 Hz preganglionic stimulation. A putative tachykinin antagonist, (D-Arg^{1},D-Pro^{2},D-Trp^{7,9}, Leu^{11})-substance P, acts either as a pure antagonist or as a mixed agonist/antagonist at these receptors.

Several opioid peptides, including leucine-enkephalin, DADL (Tyr-D-Ala-Gly-Phe-D-Leu) and DAGO (Tyr-D-Ala-Gly-N-Me-Phe-Gly-ol) reduce nicotinic transmission through the choroid neurons, an effect which may be due to presynaptically located delta- and mu-opioid receptors. The effects of the opioid peptides are blocked by naloxone.

PEPTIDES: PHYSIOLOGICAL EFFECTS II

59.1

BRAIN NATRIURETIC PEPTIDE AS A SYMPATHETIC PREGANGLIONIC NEUROTRANSMITTER. M.M. Moga, N.J. Dun, P. Needleman and C.B. Saper, Depts. of Pharm. & Physiol. Sci. and Neurol., Univ. of Chicago, Chicago, IL 60637, Dept. of Pharm., Loyola Univ., Maywood, IL 60153 and Dept. of Pharmacology, Wash. Univ. Sch. Med., St. Louis, MO 63110.

Brain natriuretic peptide (BNP) is a 25 amino acid peptide recently isolated from porcine brain that shares substantial sequence homology with atrial natriuretic peptide (ANP), as well as eliciting similar hypotensive and diuretic-natriuretic responses (Sudoh et al., Nature 332:78, 1988). Several studies suggest that ANP can influence the synthesis and release of norepinephrine by sympathetic ganglion cells. However, we have found no sympathetic preganglionic neurons that are ANP-like immunoreactive (ir). We now report that many neurons in the sympathetic preganglionic cell groups in the spinal cord, including the intermediolateral and intermediomedial columns and the dorsal commissural nucleus, are BNPir. BNPir fibers leaving these cell groups enter the ventral roots, and can be traced into sympathetic ganglia.

We further examined the responses of neurons in sympathetic ganglia to microapplication of BNP. In the inferior mesenteric ganglion of the guinea pig in vitro, BNP produced a depolarization and increase in membrane conductance, suggesting the opening of a cation channel. These results suggest that BNP may be an important modulator of sympathetic postganglionic neurons.

59.2

DOPAMINERGIC MEDIATION OF THE DIURETIC AND NATRIURETIC ACTION OF CENTRALLY ADMINISTERED RAT ATRIAL NATRIURETIC FACTOR (99-126). M. Torres*, Y. Barbella* and A. Israel. U.C.V. and U.C., Venezuela.

Atrial natriuretic factor (ANF) has actions on the brain. Central administration of ANF inhibits salt appetite, water intake, vasopressin and prolactin secretion and increases urinary volume and sodium excretion. The mechanism of central-rANF-induced diuresis and natriuresis (D&N) is unknown. The interaction of ANF with brain dopaminergic systems has been demonstrated (EJP 131:171). We examined therefore, the possible involvement of brain dopaminergic systems in the D&N produced by intracerebroventricular (IVT) administration or rANF. Male S-D rats (230-280 g) were implanted with a cannula in the left lateral cerebroventricle and were divided in the following groups: C= control; H= receiving a s.c. dose of haloperidol (2.5 and 1.25 mg/kg) or V= vehicle at 18 and 2 h before the experiment; 6OHDA= receiving a IVT dose of 250 ug/5ul of 6-OH-dopamine or V'= vehicle 72 and 48 hr before the experiment. Half of the rats receiving each treatment were IVT injected with saline (S) or rANF (5ug/5ul) (A) followed by 20 ml/kg p.o. water. Urine was collected at 1,3 and 6 h and samples were assayed for Na+ and K+ content. rANF-IVT to conscious hydrated rats resulted in an increase in urinary volume and sodium excretion at 1,3 and 6 h period collection. This effect was prevented by 6OHDA pretreatment and by the unselective dopamine antagonist haloperidol. Uri.Vol (ml/100g) at 3h= C-S: 1.5 $\pm$ .3; C-A: 2.8 $\pm$ .2*; 6OHDA-S: 1.8 $\pm$ .2; 6OHDA-A: 1.5 $\pm$ .1; H-S: 1.5 $\pm$.12; H-A: 1.8 $\pm$ .1. Na+ (uEq/100g) at 3h= C-S:67 $\pm$ 20; C-A: 203 $\pm$ 15*; 6OHDA-S: 63 $\pm$ 20; 6OHDA-A: 81 $\pm$ 16; H-S: 101 $\pm$ 13; H-A: 103 $\pm$ 14; *$p < 0.01$. Our findings strongly suggest that ANF exerts its centrally mediated effects on sodium and water metabolism, at least in part, via a dopaminergic mechanism.(Supported by grants CDCH F.07.20.878, UCV).

59.3

STIMULATORY EFFECTS OF ATRIAL NATRIURETIC PEPTIDE (ANP) AND ANGIOTENSIN II (AII) ON LUTEINIZING HORMONE (LH) RELEASE IN FEMALE RATS. M.K. Steele, Dept. of Physiology, University of California, San Francisco, CA 94143

Intracerebroventricular (ICV) ANP antagonizes the increase in blood pressure, fluid ingestion and vasopressin release due to ICV-AII. In addition, ICV-ANP inhibits the release of LH in male rats (Samson, et al, 1988), an animal model in which ICV-AII also inhibits LH secretion (Steele, Murakami and Ganong, unpubl.). The present experiment investigated the effects of ANP or ANP plus AII on LH release in ovariectomized rats treated with estradiol and progesterone, a model in which ICV-AII stimulates LH secretion (Steele, et al, 1985).

Conscious rats were bled from a jugular cannula prior to and following ICV injection of vehicle, AII (50 ng), ANP (1-28, 200 ng), or ANP plus AII. Blood LH levels and water intake were measured. Vehicle injection did not modify LH values or water intake. AII or ANP increased LH levels 100% at 10 min and 50% at 20 min postinjection. Coinjection of ANP plus AII resulted in increases in LH values of 200% at 10 min and 100% at 20 min. AII-induced water intake was attenuated by coadministration of ANP. These data show that low doses of ANP affect LH release in the same way as AII. The effects of ANP plus AII on LH are additive, whereas the effects on water intake are antagonistic.

INTERACTION OF METHYSERGIDE AND THYROTROPIN-RELEASING HORMONE ON SPINAL REFLEXES IN NEONATAL RATS. S.B. Deshpande and J.E. Warnick (SPON: S. Das Gupta). Dept. of Pharmacol. & Exp. Ther., U. of MD Sch. of Med., Baltimore, MD 21201.

Thyrotropin-releasing hormone (TRH) is known to enhance the excitability of motoneurons and potentiate the monosynaptic reflex (MSR) while methysergide (MeSG) was found to depress the MSR. This study was begun to examine the ability of TRH to reverse the depression of the MSR by MeSG and to elucidate the specificity of this action in the neonatal rat spinal cord. Spinal cords from male Wistar rats (8-9 days old) were hemisected, placed in an experimental chamber and superfused with oxygenated physiological solution. Stimulation of an L_{3-5} dorsal root evoked a MSR in the corresponding ventral root and a dorsal root reflex (DRR) in an adjacent dorsal root. MeSG produced a dose-dependent depression of the MSR with 50% depression at 7-9 nM, without affecting the DRR. TRH, which selectively increases the magnitude of the MSR without affecting the DRR, reversed the depression of the MSR by MeSG (30 nM) in a dose-dependent manner with 50% reversal at 40-50 nM TRH. The K-channel blocker 3,4-diaminopyridine (10 μM) reversed MeSG-induced depression of the MSR, but it evoked segmental polysynaptic discharges and also potentiated the DRR. The results suggest that TRH, unlike 3,4-diaminopyridine, selectively acts on α-motoneurons to reverse MeSG-induced depression of the MSR. (Supported by USPHS grant NS-21312.)

INTRACISTERNAL INJECTION OF TRH PRECURSOR TRH-GLY PRODUCED STIMULATION OF GASTRIC ACID SECRETION IN RATS.

R.L. Stephens*, A.E. Pekary*, Y. Taché. CURE, VA Wadsworth Medical Center, UCLA, Los Angeles, California 90073.

It has been established that TRH in the mammalian brain is formed by post-translational processing of a larger precursor molecule. Reports indicate that the prohormone contains five copies of the sequence pGlu-His-Pro-Gly, termed TRH-Gly. Intracisternal injection of TRH produces a marked stimulation of gastric acid secretion in rodents (Nature 1980; 287: 149-151). The effects of TRH-Gly on gastric acid secretion was investigated in urethane-anesthetized rats with gastric fistula. Intracisternal injection of TRH-Gly (1, 10 and 100 μg) produced a dose dependent stimulation of gastric acid secretion (μmol-/2h: 12 ± 5; 37 ± 12 and 162 ± 43; n = 4-15). In contrast, iv injection of 100 μg TRH-GLY produced no stimulation of gastric acid secretion (umol/2h: 2 ± 1; n = 5).Cerebrospinal fluid collection (20 μl) every 15 min and replacement by artificial CSF was performed to assess the rate of disappearance of TRH-Gly and the appearance of TRH (n = 9) using sensitive radioimmunoassay with no cross reactivity between TRH and TRH-Gly. Intracisternal injection of TRH-Gly (10 μg), induced a marked increase ($2x10^4$) in TRH-Gly and a 30 fold elevation in CSF levels of TRH 15 min post injection. These results demonstrate that intracisternal TRH-Gly like stimulates TRH gastric acid secretion, although doses required are 100 fold higher 2) TRH-Gly is rapidly converted to TRH in the CSF, with peak levels occurring at the first period (15 min). TRH-GLY bio-logical activity may result from its conversion into TRH, or direct activation of TRH receptors or its own specific receptor.

ω-CONOTOXIN "SHAKER" PEPTIDE CAUSES INCREASED GLUCOSE USE IN VESTIBULAR NUCLEI AND CEREBELLUM OF RATS AND MICE.

S.R. Nelson, G. Liang*, F.E. Samson, T.L. Pazdernik*, R.S. Cross* and B.M. Olivera*. Depts. of Anatomy, Pharmacology and the R.L. Smith Research Center Laboratories, Univ. of Kansas Sch. of Med., Kansas City, KS 66103, and Dept. of Biology, Univ. Utah, Salt Lake City, UT 84112.

The intraventricular injection of "shaker" peptide, ω-conotoxin GVIA, from venom of fish eating cone snails (Conus geographus), causes prolonged "shaking," characterized by a posture of spread limbs and rapid shaking of head, body and limbs. Local cerebral glucose use was determined during the shaking period in peptide-treated rodents (2 nmole into the lateral ventricle) by the [^{14}C]-2-deoxyglucose method. High glucose use occurred in vestibular nuclei and paraflocculus, flocculus, ventral vermis and cortex of the cerebellum. The findings suggest that "shaker" peptide activates vestibular nuclei in the floor of the 4th ventricle, and secondarily, the cerebellum. Disruption of normal interactions between vestibular nuclei and cerebellum may account for the characteristic posture and "shaking" induced by the peptide. The peptide is known to block voltage-activated Ca^{2+} channels; thus, blockade of ω-conotoxin sensitive Ca^{2+} channels in rat CNS may interfere with the normal inhibition/excitation balance in the vestibular system. Supported in part by DAMD17-86-G-6038 and NIH GM 22737.

59.7

EFFECT OF ANGIOTENSIN II (AII) AND AII RECEPTOR BLOCKERS ON PROLACTIN (PRL) SECRETION.

L.S. Myers* and M.K. Steele (SPON: D.N. Darlington). Department of Physiology, University of California, San Francisco, CA 94143.

Previous work has shown that a high dose of intracerebroventricular (ICV) AII suppresses levels of PRL in ovariectomized (OVX) rats (Steele et al., 1981). The present study investigated the sensitivity of this effect on PRL secretion by using varying doses of AII in OVX female and intact male rats. Additionally, AII receptor blockers, Saralasin (SAR) or Sarthran (SART) were given to OVX rats.

Blood samples were drawn from a jugular cannula from conscious rats prior to and following ICV injections of vehicle, AII (50 ng, 500 ng or 5000 ng), SAR (25 μg), or SART (10 μg). Water intake and plasma levels of PRL were measured. In males, AII significantly suppressed PRL levels up to 60 min. In OVX rats AII (50 ng) significantly suppressed PRL at 15 min, with levels returning to preinjection values at 60 min. Neither SAR nor SART were found to alter PRL levels compared to injection of vehicle in OVX rats.

These data show that low doses of AII can suppress basal PRL secretion in both male and OVX female rats. However, the lack of response when endogenous AII is blocked suggests that AII is not acting tonically to suppress PRL.

59.8

REGULATION OF STRIATAL TYROSINE HYDROXYLASE BY CRF.

M.C. Olianas and P. Onali. Dept. Neurosciences, University of Cagliari, Italy.

We investigated the effect on synaptosomal dopamine (DA) synthesis of corticotropin-releasing factor (CRF),a putative brain neuromodulator of stress-induced responses. DA synthesis was assayed in a synaptosomal preparation from rat or mouse striatum by measuring the release of $^{14}CO_2$ from L-[1-^{14}C] tyrosine. In rat striatum, CRF caused a 34% increase in DA synthesis with half-maximal and maximal stimulations at 40 and 300 nM, respectively. In mouse striatum CRF increased DA synthesis by 48%. The CRF effect was accompanied by a stable change in the activity of tyrosine hydroxylase (TH) assayed in extracts of lysed synaptosomes. The exposure of synaptosomes to CRF resulted in 30% and 64% increase of TH activity in rat and mouse striatum,respectively. The stimulatory effect of CRF on synaptosomal DA synthesis was significantly counteracted by the specific CRF receptor antagonist α-hel CRF 9-41 (1 μM). The effect of CRF was dependent on the concentration of Ca++ in the incubation medium and was antagonized by polymyxin B,an inhibitor of protein kinase C,with an IC50 value of about 30 μM. These results indicate that CRF can regulate striatal TH activity via presynaptic receptors which operate through a Ca++-dependent mechanism.

VIP EXCITATION OF LOCUS COERULEUS NEURONS: EVIDENCE FOR A G-PROTEIN-MEDIATED INWARD CURRENT.

Y.-Y. Wang and G.K. Aghajanian, Depts. Of Pharmacol. and Psychiat., Yale Univ. Sch. Med., New Haven, CT 06510.

VIP (vasoactive intestinal polypeptide) receptors and immunoreactive nerve terminals have been localized in the locus coeruleus (LC). The purpose of this study was to characterize the electrophysiological actions of VIP in the LC and the possible mediation of these actions by guanine nucleotide regulatory proteins (G proteins).

Brain slices containing the LC (male albino rats) were perfused with standard artificial CSF. Intracellular recordings and single-electrode voltage-clamping were performed using an Axoclamp-2; electrodes were filled with 2M KCl or 2M KCl with GTP*r*S (10 mM). Puffs of VIP (125-500 μM) were applied by pressure ejection.

VIP produced a reversible increase in the firing rate of LC neurons. Voltage-clamping at -60 mV revealed that VIP induced an inward current which slowly recovered within about 5-10 min. The inward current persisted in the presence of Ca channel blockers (e.g., 2 mM Co or Mn), suggesting a direct action of VIP at postsynaptic sites. Partial replacement of Na with choline (about 80%) reduced the VIP-induced inward current by about 60%. Current-voltage plots of VIP did not show any reversal at E_K. When electrodes containing GTP*r*S, a hydrolysis-resistant analog of GTP, were used, the VIP-induced inward current became irreversible (observed up to 2 hrs), implying that VIP receptors are coupled to G proteins. In contrast, the inward current generated by N-methyl-D-aspartic acid (NMDA, 50 μM) was not prolonged by GTP*r*S. After multiple applications, responses to VIP tended to become smaller, indicating the possibility of receptor desensitization.

In summary, our results indicate that VIP directly excites LC neurons by inducing a Na-dependent inward current; as this effect becomes irreversible in the presence of intracellular GTP*r*S, mediation through a G protein is suggested. Since VIP is known to activate adenylate cyclase in brain, we are investigating the possible involvement, if any, of cAMP in these actions.

ALTERED REGULATION OF GLYCOGEN METABOLISM BY VASOACTIVE INTESTINAL PEPTIDE (VIP) AND K^+ IN THE NEOCORTEX OF THE SPONTANEOUSLY EPILEPTIC MOUSE MUTANT QUAKING.

P.J. Magistretti and P.R. Hof, Département de Pharmacologie, CMU, 1211 Geneva 4, Switzerland.

K^+ at concentrations reached in the extracellular space during normal neuronal activity (i.e. 5-12 mM) promotes a concentration- and calcium-dependent hydrolysis of ^{3}H-glycogen newly synthesized by mouse cerebral cortical slices. The quaking mutant (qk) is characterized by a severe myelin deficiency in the CNS due to an impaired differentiation of oligodendrocytes. We have observed a supersensitive response to the glycogenolytic effect of low concentrations of K^+ in cerebral cortical slices prepared from homozygous (qk/qk) mutants. This supersensitive response to K^+ was only observed in qk/qk older than 8 weeks, with differences between qk/qk and controls of 28 % at 10 weeks, 50 % at 16 weeks and 17 % at 30 weeks for 8 mM K^+. VIP induces glycogen hydrolysis in neocortical slices with an EC50 of 26 nM. We have recently observed a new effect of VIP on cortical glycogen levels. VIP at non-glycogenolytic concentrations, i.e. pM, strongly inhibits the K^+-evoked ^{3}H-glycogen hydrolysis in normal mice. Thus, VIP 10 pM inhibits by 75 % the glycogenolysis elicited by 8 mM K^+. This novel action of VIP is not observed in qk/qk mutants, suggesting the presence of an impaired function of the VIP intracortical neuronal system in the cerebral cortex of the qk mutant. Supported by FNRS Grant No 3.357-0.86.

59.11

VASOPRESSIN AND OXYTOCIN CONTENT IN HYPOTHALAMIC NUCLEI: RELATION TO FOOD DEPRIVATION AND SUBSEQUENT REFEEDING. M. Jhanwar-Uniyal, M. L. Chapleur*, A. J. Burlet* and S. F. Leibowitz. The Rockefeller Univ. New York, NY 10021 and Laboratoire de Biologie Cellulaire, Faculte de Medecine, INSERM U 308, 54000 Nancy, France.

The peptide hormones, vasopressin (AVP) and oxytocin (OT), appear to play a role in the control of food intake. Recent evidence suggests that norepinephrine (NE), in the hypothalamic paraventricular (PVN) and supraoptic (SON) nuclei, is involved in controlling the release of these hormones, as well as in controlling eating behavior. An increase in NE turnover in the PVN was demonstrated in 48 hrs food deprived (FD) rats. The present study examined the effect of FD (48 hrs), or food intake (FI, 6 hrs) following 42 hrs FD, on the content of AVP and OT in 7 discrete hypothalamic sites and the neurohypophysis.

Eight hypothalamic areas, namely, PVN (M; magnocellular), PVN (P; parvocellular), dorsomedial nucleus (DMN), median eminence (ME), perifornical lateral hypothalamus (PLH), SON, suprachiasmatic nucleus (SCN), and ventromedial nucleus (VMN), were micropunched and assayed for AVP and OT content via RIA. The results demonstrate that: 1) after 48 hrs. FD, AVP and OT levels in the hypothalamic nuclei remain stable, except in the VMN where AVP is reliably increased ($p<0.05$); 2) after 6 hrs of refeeding, AVP levels are significantly reduced in the PVN-P ($p<0.05$), ME ($p<0.05$), SON ($p<0.01$), and VMN ($p<0.05$) and unaffected in other hypothalamic areas and neurohypophysis; and 3) after 48 hrs FD, a small decline in OT levels in the PVN and ME ($p<0.05$) occurs. No change is seen after refeeding. These studies demonstrate that hypothalamic AVP, and to a lesser extent OT, may vary in relation to feeding behavior.

59.12

ARGININE-VASOPRESSIN; A RELEASING FACTOR FOR POMC PEPTIDES IN THE BRAIN. V.M. Wiegant*, C.G.J. Sweep*, I. Barna* and D. De Wied*. Rudolf Magnus Institute of Pharmacology, University of Utrecht, Vondellaan 6, 3521 GD Utrecht, The Netherlands.

Arginine-vasopressin (AVP) is well established as a hypothalamic neurohormone involved in the regulation of the activity of pro-opiomelanocortin (POMC) cells in the anterior pituitary gland. We have obtained evidence that AVP may also function as a releasing factor for brain POMC activity. Intracerebroventricular (icv) treatment of rats with AVP (pg-ng) resulted in a rapid, dose dependent increase in the concentration of β-endorphin immunoreactivity (βEIR) in cerebrospinal fluid (CSF). This effect could not be obtained with several fragments of AVP, nor with structurally related peptides such as oxytocin and N^{α}-acetyl-AVP. In addition, pretreatment (icv) with a specific vasopressin pressor antagonist completely prevented the effect of AVP. This suggests the involvement of vasopressin receptors in the brain, possibly of the V1 type. A possible site of action for this effect of AVP may be located in the mediobasal hypothalamus, as AVP (10^{-7} - 10^{-9} M) stimulated the in vitro release of βEIR from slices prepared from this brain region. Indeed, it has been reported that the arcuate nucleus, which contains cell bodies of POMC neurons, is rich in putative vasopressin receptors as evidenced by high binding of the vasopressin pressor antagonist (Van Leeuwen, F.W. et al., Neurosci. Lett., 80: 121, 1987).

59.13

MAINTENANCE OF LONG-TERM POTENTIATION IN THE LATERAL SEPTUM REQUIRES VASOPRESSIN.
P. van den Hooff,* I.J.A. Urban* and D. De Wied.* Rudolf Magnus Institute for Pharmacology, University of Utrecht, Vondellaan 6, 3521 GD Utrecht, The Netherlands.(SPON: EBBS)

Excitatory postsynaptic potentials (EPSPs) and field-potentials (FPs), evoked by stimulation of the fimbrial (Fi) afferents, were recorded in rat brain slices of the lateral septum (LS) in order to examine long-term potentiation or LTP of synaptic efficacy following brief high frequency stimulation of the Fi fibers. We observed that the amplitude of the EPSPs and the amplitude of the negative wave (N-wave) in the FPs of Wistar (WI) rats were long lasting increased following tetanic stimulation of the Fi fibers. Slices prepared from vasopressin (VP) deficient Brattleboro rats consistently failed to maintain a tetanus induced increase in the N-wave amplitude. This could be restored by VP supplementation to these rats and also by VP or picrotoxin administration to slices from these rats. In addition, the V1 vasopressor antagonist, $d(CH_2)_5Tyr(Me)AVP$, prevented the maintenance of a tetanus induced increase in the N-wave amplitude in control Long-Evans (LE) and WI slices.

It is concluded that VP is important for maintenance of LTP in excitatory transmission in the LS. It is postulated that the effect of VP on memory could originate from increased synaptic efficacy similar to the LTP phenomenon.

59.14

A PROBABLE MECHANISM FOR VASOPRESSIN ACTION IN THE HIPPOCAMPUS. D. Albeck* and T. Smock (SPON: S. Calisher). Behavioral Neuroscience Program, Dept. of Psychology, Univ. Colorado, Boulder, CO 80309.

Arginine vasopressin (AVP) is contained in fibers that project to the hippocampus and is released from neural terminals upon stimulation. Receptors for the peptide exist in the hippocampus and the effect of the AVP on various hippocampal cell types can be blocked by a selective pressor (V_1) antagonist.

Nevertheless, confusion as to the actual mechanism of AVP action impedes evaluation of the peptide as a central neurotransmitter candidate. At first, single unit recording in the slice preparation suggested a direct excitatory action on CA1 neurons (Mühlethaler et al., 1982, Nature 296:749), but subsequent studies implicated direct, excitatory action on inhibitory interneurons and secondary inhibition of pyramidal cells (Mühlethaler et al., 1984, Brain Res. 308:97). Intracellular recording from pyramidal cells revealed an excitatory action, but constriction of slice microvessels was also observed, suggesting that the excitation may have been a byproduct of direct vascular activation (Smock et al., 1987, Exp. Brain Res., 66:401).

Here we report results from field potential recordings from the slice that reconcile these seemingly disparate findings. Male Sprague-Dawley rats (150-250 g) were used to prepare hippocampal slices with standard techniques. Monopolar DC pulses of 75 µsec duration (submaximal voltage) were applied to stratum radiatum and composite postsynaptic potentials and population spikes were recorded from the pyramidal cell body region of CA1. AVP, bath applied at 1 µM, had negligible action on the rising phase of the synaptic potential and a slight inhibitory effect on the falling phase. However, the population spike due to pyramidal cell discharge was profoundly inhibited, falling from an average of 1.67 mv (± .35) to .41 mv (± .22) in thirty minutes postapplication (n = 11). The inhibition produced by AVP was completely blocked in the presence of a specific V_1 pressor antagonist for the peptide (also 1µM, n = 9).

These data imply inhibition of pyramidal cell somata with little effect on presynaptic excitability or dendritic mechanisms. The results are consistent with a model that posits direct AVP action on inhibitory interneurons and slice microvessels and reveal pyramidal cell inhibition and excitation to be secondary consequences of the two direct effects.

VASOPRESSIN MEDIATION OF MICROVASCULAR SPASM IN THE RAT BRAIN. R. Cach*, C. Durboraw*, T. Smock and D. Albeck. School of Medicine and Behavioral Neuroscience Program, University of Colorado, Boulder, Colorado 80309.

The coagulation reaction produces a substance that elicits regional constriction of penetrating microvessels in the rat hippocampal slice (Cach et al., 1987, Brain Res. 414:1). The spasmogen, probably related to an eicosanoid of the thromboxane series, employs neural mechanisms to bring about the vasoconstriction (Cach et al., 1987, Brain Res. 421:370). Here we show that this neural mechanism probably involves a subpopulation of vasomotor neurons that secrete the polypeptide, arginine vasopressin (AVP).

In the first series of experiments, spasmogenic serum and candidate spasmogens were applied to the slice and the evoked perforant path-to-granule cell field synaptic potential and population spike were recorded. In contrast to control serum (n=7), dilute spasmogenic serum obtained by incubating coagulated blood inhibited the evoked neural responses in each case (n=8). Thus, the spasmogen, which employs neural mechanisms for its action, does not do so by generally enhancing the neural excitability of the slice. A subpopulation of vasomotor neurons must be involved.

Alone among several candidate vasomotor transmitters tested, AVP consistently duplicated the constricting response to spasmogenic serum (Smock et al., 1987, Exp. Brain Res. 66:401). We therefore used a specific AVP antagonist to block the action of spasmogenic serum. The vascular response evoked by spasmogenic serum (62 ±4 microns of blood movement, n=5) was completely absent in the presence of 1µM antagonist (2±0.5 microns, n=6).

Taken together, these data implicate AVP in the etiology of the acute phase of cerebral microvascular spasm and present the intriguing possibility that structural AVP antagonists might prove to be valuable probes in future studies of this condition.

DIFFERENTIAL AFFECTS OF DOPAMINE AND NOREPINEPHRINE ON GONADOTROPIN-RELEASING HORMONE NEURONS HARVESTED FROM ADULT MALE RATS[1]. P. A. Melrose. Dept. Vet. Anatomy, LSU School Vet. Med., Baton Rouge, LA 70803.

The gonadotropin-releasing hormone (GnRH) neurons of 40 adult male Sprague-Dawley rats were harvested to determine if dopamine (DA) or norepinephrine (NE)produced acute, in vitro, affects on the neurosecretion of GnRH or on cellular GnRH concentrations. Cell fractions were recovered as previously described (Melrose et al., Endo.121 1987). Neurons from each rat were then plated in an individual culture dish; the cells were incubated for 5 days. On day 6, cultures were treated with vehicle, 1000 ng DA, 2500ng DA, 500ng NE, or 1000ng NE (8/group). Media samples for GnRH RIA were collected at 2 min intervals for 30 min during the pretreatment period(P) and for 60 min during the treatment P. The cellular GnRH concentrations were determined 24 hrs after the initiation of treatment.

Neuropeptide release from cultures, during both the pre- and post-treatment P, was pulsatile. There was no treatment affect ($P>0.05$) on mean media GnRH concentrations or on the overall mean post-treatment frequency and amplitude of GnRH pulses. Significant treatment affects which were observed are summarized in Table 1. The 2500ng DA treatment lengthened the interval to, and increased the amplitude of, the first post-treatment GnRH pulse. In contrast, NE treatments reduced cellular GnRH concentrations at 24 hours of treatment. Results from this experiment suggest dopamine and norepinephrine may produce differential short-term affects on GnRH neurons of adult male rats. Further, these results suggest that unprimed GnRH neurons rapidly become refractory to the direct affects of dopamine.

TABLE 1: AFFECTS OF CATECHOLAMINES ON GNRH NEURONS[2]

group	cellular GnRH pg/culture)	interval to 1st post-treat. pulse (min.)	amplitude 1st post-treatment pulse (as % pre-treatment)
control	12905 ± 72.8	7.0 ± 2.0	100.4 ± 5.1
1000ng DA	11700 ± 57.4	10.0 ± 0.0	91.5 ± 4.0
2500ng DA	12681 ± 59.4	23.6 ± 6.2*	162.2 ± 9.0*
500ng DA	6825 ± 18.7*	11.6 ± 3.8	110.0 ± 7.5
1000ng NE	6431 ± 34.8*	14.0 ± 3.6	103.6 ± 8.8

CONTRASTING EFFECTS OF ENALAPRILAT AND PHOSPHORAMIDON ON BOMBESIN INDUCED HYPOTHERMIA IN THE RAT. R. T. Layer and R. O. Warwick, Jr. Dept. of Pharmacology and Toxicology, Philadelphia College of Pharmacy and Science, Philadelphia, PA 19104.

Bombesin (BN) is a potent hypothermic neuropeptide with slow onset and long duration of action when given intracerebroventricularly (i.c.v.) to cold exposed rats. Little is known of the in vivo inactivation of BN, although BN-degrading enzymes are present in rat brain synapses. We studied the effects of enalaprilat (ENP), a peptidyl dipeptidase inhibitor, and phosphoramidon (PAN), a endopeptidase 24.11 inhibitor, on BN hypothermia. All agents were administered into the right lateral ventricle of rats at 6° C ambient temperature. BN (0.01 ug) hypothermia (33.5° C ± 1; n = 6) was potentiated ($p < 0.05$) 10% by simultaneous administration of PAN (50 ug i.c.v.), and was abolished ($p < 0.05$) by simultaneous administration of ENP (100 ug i.c.v.). The results suggest that BN administered i.c.v. is inactivated by endopeptidase 24.11 and activated by peptidyl dipeptidase. Additionally, these data support in vitro evidence that these peptidase inhibitors differentially modulate BN-induced inhibition of serotonin release.

60.2

INDOMETHACIN-INDUCED ANTIPYRESIS IN THE RAT. D.M. Fyda, K.E. Cooper and W.L. Veale. Department of Medical Physiology, University of Calgary, Calgary, Alberta T2N 4N1.

These experiments were undertaken to determine whether indomethacin given into the ventral septal area (VSA) could suppress a prostaglandin E_1 (PGE_1) hyperthermia and, if so, to assess whether the antipyresis was evoked by means of vasopressin receptors. Thirty-two male, Long Evans rats had cannulae stereotaxically implanted which were aimed at the lateral cerebral ventricle (LCV) and bilaterally at the VSA. The rats were fitted with indwelling radio-transmitters which allowed for the remote monitoring of core temperature. During control infusions of artificial cerebrospinal fluid into the VSA, PGE_1 (30 ng/µl) into the LCV evoked a 1.0°C increase in core temperature; whereas during indomethacin infusions (15 µg/µl/hr) the PGE_1-induced hyperthermia was reduced to 0.3°C. When a V_2-receptor blocker was injected into the VSA the temperature response to PGE_1 was not altered. Conversely, when a V_1-receptor blocker was administered into the VSA the hyperthermic effect of PGE_1 was abolished; whereas the antipyretic effect of indomethacin was maintained. Neither indomethacin nor the two receptor blockers affected core temperature when administered individually. The results suggest that although indomethacin is an effective antipyretic against PGE_1-induced fever, its mode of action does not involve V_2-receptors and may not involve V_1-receptors.

MICRODIALYSIS EVALUATION OF BRAIN ANTIPYRETIC CONCENTRATIONS OF AVP FOLLOWING ICV INJECTION. N.W. Kasting and M.F. Wilkinson*, Dept. of Physiology, Univ. of British Columbia, Vancouver, B.C., Canada.

Microdialysis is an adaptation of the push-pull technique that keeps the perfusate separated from the ECF by a dialysis membrane to allow exchange of only small molecules. Microdialysis tubing (MWCO 9000) was fastened between two stainless steel cannula so that a length of 1 mm of membrane was exposed. The cannula was stereotaxically implanted into the Ventral Septal Area (VSA) of the anesthetized rat brain along with an icv cannula. In vitro experiments utilizing labelled AVP determined that the exchange rate between external fluid and perfusate was 0.04%. During in vivo experiments, rats were injected with 10 ng of AVP icv and the perfusate collected at 5 min intervals and assayed for AVP by RIA. Peak levels were typically obtained in the perfusate 10 to 15 min after icv injections. The peak levels also indicated that levels of AVP in the VSA reached values of 10.7 ± 0.5 nM after 10 ng icv injections. The threshold response for antipyretic effects is 1 ng icv, which would indicate that the threshold AVP concentration in the ECF of the VSA would be 1.07 nM. According to recent receptor binding analysis of AVP receptors from the VSA, the K_D for AVP is 1.06 nM. Thus, we conclude that icv injections of AVP reach the receptors in the VSA at physiologically relevant levels. Supported by MRC of Canada.

CENTRAL NERVOUS SYSTEM EFFECTS OF LIPOPHILIC ACE-INHIBITORS IN RODENTS: BEHAVIORAL AND BIOCHEMICAL EVIDENCE. H.J.Gerhards*, F.J.Hock, U.Leven*, J.Stechl* and G.Wiemer*. Hoechst AG., 6230 Frankfurt/M.-80, FRG.

Inhibitors of Dipeptidyl-peptidase A (ACE) have been described to possess distinct psychotropic effects in the clinic. Since these compounds are not easily crossing the blood brain barrier, we tested some more lipophilic ACE-Inhibitors and their prodrugs for CNS effects in behavioral and biochemical models in mice and rats.

From a series of derivatives of the ACE-inhibitor Hoe 498 (Ramipril) the compounds S84 8882 and S86 4065A were selected for a comparison of their antagonism against scopolamine amnesia in a passive avoidance model and their inhibition of brain ACE (in vitro and ex vivo in vitro autoradiography using 125J-MK3251A as ligand).

The potency of these compounds to displace 125J-MK351A from its binding sites in brain (in vitro and ex vivo in vitro) was Hoe 498 > S84 8882 > S86 4065A whereas the ranking according to their antiamnestic activity was S86 4065A > S84 8882 > Hoe 498. Thus, the central ACE-inhibitory effects of these compounds did not correlate with their antiamnestic properties.

THE NEUROPEPTIDE α-MSH ANTAGONIZES IL-1 INDUCED INCREASES IN CAPILLARY PERMEABILITY. J. M. Lipton, L. B. Deeter* and L. W. Martin*. Dept. of Physiol., The Univ. Tex. Southwestern Med. Ctr. at Dallas, Dallas, TX 75235.

α-MSH, an endogenous peptide, is a potent antipyretic when administered i.v., i.c.v., intragastrically or into CNS sites. Recent research suggests that the peptide can antagonize neutrophilia and other acute phase responses elicited by IL-1. To test the idea that the peptide can antagonize localized cutaneous inflammation caused by IL-1 injections, 30 rabbits with shorn backs were given the peptide (2.5 µg/kg, i.v.) or saline, followed by pontamine sky blue dye (30 mg/kg, i.v.) and intradermal injections of IL-1 (.10 ml, 6-8 sites). One hour later the animals were killed via an overdose of anesthetic and the skins were removed. The intensity and dimensions of subcutaneous staining, an estimate of capillary permeability, were judged by independent observers. α-MSH inhibited the increase in capillary permeability caused by IL-1 ($p = .019$, sign test). Although it is not clear whether the inhibition by α-MSH occurred via peripheral or central actions, the results indicate that the neuropeptide has the capacity to antagonize yet another action of crude IL-1. CENTRAL INFUSION OF AMINOPEPTIDASE AND CARBOXYPEPTIDASE INHIBITORS INCREASES BLOOD PRESSURE IN NORMOTENSIVE AND SPONTANEOUSLY HYPERTENSIVE RATS. L.L. Jensen, J.W. Harding, J.M. Hanesworth*, L.L. Cushing* and J.W. Wright. Dept. of Psychology, Wash. State Univ. WA.99164-4830.

Acute intracerebroventricular (icv) infusion of a cocktail consisting of the aminopeptidase inhibitors, amastatin and bestatin, as well as a carboxypeptidase inhibitor, plummer's maximally elevated blood pressure (BP) in the anesthetized Wistar-Kyoto (WKY: from 100 to 180 mm Hg) and to a greater degree in Spontaneously Hypertensive rat (SHR: from 120 to 274 mm Hg). BP elevations were concomitant with increases in cerebrospinal fluid (CSF) levels of angiotensin in both strains of rat. These increases in BP were blocked by icv infusion with the specific angiotensin receptor antagonist Sar^1,Thr^8-AII (sarthran), suggesting that these inhibitors are acting via the central angiotensinergic system. Icv infusion with leucine aminopeptidase M (LAPM) induced significant drops in BP as well as in CSF levels of angiotensin in both strains (WKY and SHR) of rat.

Cocktail Mean elevations			Sarthran Mean drops			LAP-M		
Strain	n	BP(mm Hg)	Strain	n	BP(mm Hg)	Strain	n	BP(mm Hg)
SHR	8	127→242	SHR	8	185→75	SHR	8	190→116
WKY	8	94→169	WKY	8	143→77	WKY	6	151→104

These data support the notion of a dysfunction of central angiotensinases in the SHR (Wright et al., 1985) contributing to the hypertension in this genetic rat model.

60.7

DSIP MODIFIED THE LEVELS OF BLOOD PRESSURE, HEART RATE, BODY T°, AND PAIN THRESHOLD BEFORE SLEEP ONSET IN RATS. S. Yehuda and R. L. Carasso*. Dept. of Psychol., Bar-Ilan Univ., Ramat-Gan, Israel.

Previous studies showed that the effects of Delta-Sleep-Inducing-Peptide (DSIP) on the levels of blood pressure, heart rate, body T°, and pain threshold are circadian cycle-dependent (Yehuda, S., and Carasso, R.L., Peptides, 1987, submitted). Another study (Yehuda, S. et al., Intern. J. Neurosci., 32, 185-197, 1987,) showed a treatment with DSIP (at 18:00 hr) results in significant changes in the lymphokine system. These changes were found even 10 min after treatment, before the sleep onset (at about 25 min).

In this experiment, groups of male albino rats received a dose of 0.1 mg/kg DSIP at 18:00 hr. In one group, the levels of blood pressure and heart rate were measured 10, 20 and 30 min after treatment. An increase in blood pressure was found after 10 min ($p<.05$) & after 20 & 30 min ($p<.01$) only among DSIP-treated rats which exhibited EEG sleep signs (n=22). Among non-responder rats (n=8) the blood pressure level was the same as in control rats (n=10). A significant decrease in heart rate ($p<.01$) was found even after 10 min only among responder rats. In the 2nd group, DSIP induced significant hyperthermia ($p<.01$) among DSIP responders and non-responders. In the third group, the level of pain threshold was increased in non-responders (n=12) ($p<.05$) & in responders (n=18) ($p<.01$).

60.8

EFFECTS OF NEUROTENSIN AND SOME ANALOGS ON BLOOD PRESSURE IN RAT. E. Donato Di Paola*, D. McCormick*, and E. Richelson. Mayo Foundation, Rochester, MN 55095.

Neurotensin (NT) a tridecapeptide, first found in the CNS, induces hypotension in anaesthetized rats[1]. The effects of NT, NT(8-13), and [D-Lys^8]NT(8-13) (NT2) on DBP are reported below. All three peptides evoked a dose-related decrease in DBP.

Change in Diastolic Blood Pressure (mm Hg)

dose(nmol/kg)	0.1	0.3	1	3	10	30
NT	-5±5	-22±3	-33±1	-44±4		
NT(8-13)		-2±1	-8±2	-18±4	-30±2	-41±2
NT2	-2±1	-12±6	-17±6	-27±4	-42±5	-48±4

These results demostrate that neurotensin was more potent than its analogs in producing hypotension. However, the rank order of potency of these peptides in reducing blood pressure was the opposite of that found in binding studies in human brain or in assays measuring peptide stimulation of cyclic GMP formation in a murine neuroblastoma cell line[2]. These data suggest that subtypes of the neurotensin receptor exist.

ALTERATIONS IN THE EVOKED RELEASE OF NE AND PERIPHERAL VASCULAR RESISTANCE FOLLOWING INTRATHECAL NPY. X. Chen*, M.M. Knuepfer and T.C. Westfall (SPON: J. Farah). Dept. Pharmacol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

Previous studies from our laboratory have shown that the intrathecal injection of neuropeptide Y (NPY) has a depressor effect in anesthetized and unanesthetized rats. We have observed that the depressor effect of NPY involves alpha$_2$ and beta adrenoceptors. The purpose of this study was to further probe the mechanism of action of intrathecal NPY. In the present study, a catheter (PE10) was inserted 10 cm down the spinal subarachnoid space and another catheter (PE20) was placed 0.5-1.0 mm into the cisterna magna in urethane-anesthetized rats. Artificial cerebrospinal fluid (CSF) was infused (100 µl/min) into the lumbar spinal cord and withdrawn from the cistern. We observed that high K^+ CSF (30 mM) increased NE release about twofold. NPY (10^{-7}M) had no effect on basal release of NE, but significantly inhibited high K^+ CSF-evoked NE release. Hindquarter and mesenteric blood flows were measured using miniaturized pulsed Doppler flow probes. Intrathecal injection of 1 nmol of NPY significantly increased hindquarter resistance concomitantly with depressor and bradycardic responses and a small decrease in mesenteric resistance. Our results are consistent with NPY exerting an inhibitory effect on evoked NE release in the spinal cord as well as producing a differential effect on regional vascular blood flow. (Supported by HL26319, HL35202 and HL39299.)

60.10

SUBSTANCE P(SP) ANTAGONISTS CAUSE SPINAL CORD VASOCONSTRICTION THAT IS NOT PREVENTED BY SP OR THYROTROPIN-RELEASING HORMONE (TRH) AGONISTS. C.J. Helke and E.T. Phillips*. Uniformed Services Univ. of the Health Sci., Bethesda, MD.

Intrathecal (i.t.) administration of SP antagonists caused neuropathological changes that were prevented by i.v. pretreatment with TRH (Freedman etal., 1986). We found that SP antagonists, including [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]-SP([D-Arg]-SP), reduced spinal cord blood flow and increased vascular resistance at the i.t. injection site, whereas TRH (i.v.) and a stable TRH analog (MK-771 i.t.) increased thoracic cord blood flow. Thus, the ability of pretreatment with TRH (i.v.) and MK-771 (i.t.) to prevent the [D-Arg]-SP-induced spinal cord vasoconstriction in anesthetized rats was assessed. [D-Arg]-SP (3.3 nmol i.t.) decreased thoracic cord blood flow within 15 min. Neither i.v. TRH (5mg/kg 1 hour, & 2 mg/kg just prior to [D-Arg]-SP) nor i.t. MK-771 (1 ug 8-10 min prior to [D-Arg]-SP) pretreatment prevented the [D-Arg]-SP-induced increase in thoracic vascular resistance. However, TRH (i.v.) but not MK-771 (i.t.) pretreatment partially opposed [D-Arg]-SP-induced reductions in blood pressure and thoracic cord blood flow. Thus, the prevention of SP antagonist-induced neuropathological changes by TRH is not due to prevention of the local spinal cord vasoconstrictor actions of the SP antagonist. In addition, the vasoconstriction is probably not a SP receptor-mediated effect as pretreatment with a SP agonist did not alter the thoracic cord vasoconstriction caused by [D-Arg]-SP.

60.11

DIRECT EVIDENCE FOR AN INVOLVEMENT OF CALCITONIN GENE-RELATED PEPTIDE(CGRP) IN NOCICEPTION AT THE SPINAL DORSAL HORN. M. Satoh, Y. Kuraishi*, R. Oku*, T. Nanayama*. Dept. of Pharmacol., Fac. of Pharm. Sci., Kyoto Univ., Kyoto 606, Japan.

We have reported that CGRP pharmacologically promotes nociceptive transmission at the spinal dorsal horn by potentiating substance P release from the primary afferents. In this study, the role of endogenous CGRP in hyperalgesia of adjuvant arthritic rats was investigated. a)An intrathecal injection of the anti-CGRP antiserum, but not the antiserum absorbed with synthetic CGRP, in arthritic rats significantly elevated nociceptive threshold in the paw-pressure test. b)The content of immunoreactive CGRP (iCGRP) was significantly increased in the dorsal root ganglia (DRG; L4-6), but not in the lumbar dorsal horn. c) An intrathecal injection of colchicine augmented the increase in iCGRP content of the DRG and reduced that of the dorsal horn, only in arthritic rats. d)The amount of capsaicin-evoked release of iCGRP from the lumbar dorsal horn slices was significantly larger in arthritic rats than in control rats. These results provide the direct evidence for the involvement of endogenous CGRP in the primary afferents in nociception at the spinal dorsal horn.

60.12

DIFFERENTIAL EFFECTS OF INTRATHECAL ADMINISTRATION OF SUBSTANCE P, GALANIN AND VIP IN MECHANICAL VS THERMAL STIMULATION TESTS IN THE RAT. Cridland, R.A.* and J.L. Henry (SPON: R.B. Malmo) Depts. Physiol. & Psychiat., McGill Univ., Montreal, H3G 1Y6

Substance P, galanin and VIP have been implicated in thermal and/or mechanical nociception. The present study compares the effects of intrathecal administration of these peptides to the L5 spinal level in a thermal stimulation test (tail withdrawal from a noxious radiant heat source, measured at 5 min intervals) and in a mechanical stimulation test (vocalization in response to application of von Frey hairs at 30 s intervals). In the tail-flick test, VIP (0.65-6.5 nmoles) produced a dose-dependent decrease in reaction time which peaked at 1 min and lasted 6-16 min; 6.5 nmoles decreased reaction time to 37.4 ± 3.8 % (mean ± S.E.M.; n=7) of control values at 1 min. Galanin (.65-6.5 nmoles) produced a dose-dependent increased reaction time at 1 and 6 min; 6.5 nmoles of galanin increased reaction time to 80 ± 10.7 % of the M.P.E. at 1 min (n=9). Adminstratation of CSF was without effect on reaction time (n=5). In the mechanical test, vocalization in response to a previously innocuous pressure stimulus was observed at 30 s in all 5 of the rats given galanin and 1 of the 5 rats given substance P (6.5 nmoles); the effect lasted 4-8 min. VIP and CSF had no effect. These results suggest unique roles of these peptides in the mediation or modulation of nociception at the spinal level. (Supported by MRC Grant MA-5891 to JLH)

60.13

DYNORPHIN AND SOMATOSTATIN INDUCE SPINAL CORD INJURY: NEUROANATOMICAL FINDINGS IN THE RAT. J.M. Petras* and J.B. Long (SPON: C.B.G. Campbell). Walter Reed Army Institute of Research, Washington D.C. 20307-5100.

Dynorphin-A (1-13) and somatostatin (3.1-50 nmoles) induce spinal cord injury in rats when injected, without physical trauma, into the lumbosacral subarachnoid space. Spinal cords of clinically impaired and unimpaired rats show evidence of neuropathology. Paraplegics have widespread bilateral loss of appendicular and axial motor neurons and interneurons, pronounced vascular proliferation and areas of necrosis dispersed in the gray matter. Ischemic or chromatolytic interneurons are plentiful and "surviving" motor neurons may be similarly affected. Axon degeneration is widespread and massive in the gray and white matter. Tracts to the tegmentum, cerebellum and thalamus are degenerated. Neurologically unimpaired low dose rats reveal evidence of less severe injury. Spinal cord interneurons and motoneurons appear to be unaffected when studied by light microscopy, whereas axonal degeneration is clearly evident in the same cases. On the basis of their apparent analgesic effects in mice, rats and human cancer and surgical patients (Chrubasik, J. et al., Lancet, 2: 1208,1984; Han, J-S. and Xie, C-W., Life Sci., 31: 1781, 1984; Nakazawa, T. et al., Peptides 6: 75, 1985; Wen, H.L. et al., Peptides 8: 191, 1987), both peptides have been proposed as potent spinal analgesics at the doses which we have observed to induce injury. More research is required before dynorphin or somatostatin can be considered potent clinical analgesic agents without deleterious effects.

60.14

CONUS PEPTIDES WHICH INDUCE SLEEP IN YOUNG MICE AND HYPERACTIVITY IN ADULT MICE. J. Haack, L. J. Cruz, R. Galyean*, J. Rivier* and B. M. Olivera. Dept. of Biology, University of Utah, Salt Lake City, UT 84112 and Clayton Foundation Laboratories for Peptide Biology, Salk Institute, San Diego, CA 92138.

An unusual heptadecapeptide purified from the venom of the fish-hunting snail Conus geographus induces a sleep-like state in mice under two weeks of age, and a hyperactive state in older mice upon i.c. injection. The unusual change in physiological effects of this peptide are matched by its biochemical properties; out of 17 amino acids, 5 residues are the unusual modified amino acid γ-carboxyglutamate (GLA). We report the isolation and characterization of a homologous sleep-inducing peptide from the venom of Conus tulipa, another fish-hunting cone. This peptide shows the same remarkable developmental switch in physiological effects as the sleep-inducing peptide from Conus geographus. However, the Conus tulipa peptide has 21 amino acids instead of 17; 4 out of the 5 Gla positions are conserved, but only 4 of 12 non-Gla residues. The high degree of conservation of Gla residues suggests that this modification may be important in producing the physiological activity of these peptides, but that there is considerable flexibility in other sequence features. Both sleep-inducing peptides have been synthesized. (Supported by GM22737 and AM26741).

NEUROTENSIN (NT) APPLIED ON VENTRAL SURFACE OF MEDULLA (VMS) ENHANCES THE PHRENIC NERVE (Ph) RESPONSES TO HYPERCAPNIA AND HYPOXIA. M.A. Haxhiu, E. van Lunteren, E.C. Deal, N.S. Cherniack. Dept. of Medicine, Case Western Reserve University, Cleveland, OH 44106.

NT, a tridecapeptide, fulfills many of the criteria required for a neurotransmitter or a neuromodulator, and NT-like immunoreactive fibers have been described just beneath the surface of the ventral medulla. We determined whether NT applied topically to the intermedio-caudal area of VMS affects Ph activity and its responses to steady state hypercapnia and isocapnic hypoxia. In 16 chloralose anesthetized, paralyzed, artificially ventilated cats application of pledgets containing NT (10^{-5} to 10^{-3}M) to VMS increased phrenic nerve activity, and potentiated the response to hypercapnia and hypoxia. The increases after combination of ventilation with 3% CO_2 in O_2 and VMS application of NT (n=6) were significantly greater ($p<0.05$) than with either one alone (3% CO_2:9.3 ± 1.6; NT:8.2 ± 3; NT + 3% CO_2:24.8 ± 4.5; a.u.). NT also enhanced the response to 7% CO_2, but less than when the animals were ventilated with 3% CO_2. The combination of hypoxia and NT also had significantly greater effects ($p<0.05$) than either stimulus alone (12% O_2:2 ± 1.6; NT:3 ± 2; NT + 12% O_2:12.3 ± 4.1; a.u.). The results suggest that NT excites medullary inspiratory-related neurons possibly by allowing them to fire with less input from central and peripheral chemoreceptors.

MOLECULAR BIOLOGICAL APPROACHES TO STUDY NEUROPEPTIDE BIOSYNTHESIS. **L.Fricker, Albert Einstein College; S.Watson, Univ. of Michigan; R.Scheller, Stanford Univ., L.Devi, New York Univ., I.Lindberg, Louisiana State Univ.**

This session will focus on the expression, regulation, and proteolytic processing of neuropeptides; with emphasis on both techniques and results. Stanley Watson will discuss the use of in situ hybridization and Northern blot analysis to measure neuropeptide mRNA levels, as an indication of cellular biosynthetic ability. Gene transcription studies will be addressed, with a major focus on the integrated physiology of several endocrine and CNS peptide systems. Richard Scheller will discuss the application of novel approaches to study processing of egg laying hormone in the Bag cells of Aplysia. Lakshmi Devi will discuss the use of gene transfer techniques to introduce foreign neuropeptide genes into heterologous hormonal cell lines in order to study the specificity of the processing enzymes. Iris Lindberg will discuss the use of eukaryotic expression systems as a means to generate neuropeptide precursors, and the use of these precursors to study the substrate specificity of an enkephalin-generating endopeptidase isolated from adrenal chromaffin granules. Lloyd Fricker will present the cloning and sequence analysis of cDNA encoding carboxypeptidase E, a carboxypeptidase B-like enzyme associated with the biosynthesis of numerous neuropeptides. Regulation of carboxypeptidase E mRNA and enzyme activity will also be discussed.

63

WORKSHOP: AFFERENT REGULATION OF THE LOCUS COERULEUS, G. Aston-Jones (Chairman), New York Univ., M.T. Shipley, Univ. Cincinnati College of Medicine, V.A. Pieribone, New York Univ., J.T. Williams, Oregon Hlth. Sci. Cntr., T.H. Svensson, Karolinska Inst., and D.J. Reis, Cornell Univ. Medical School.

Knowledge of afferent mechaisms regulating LC neurons has increased dramatically in the last few years. This workshop will integrate results of experiments in several subdisciplines that converge to yield a markedly revised but coherent view of mechanisms important in controlling this ubiquitous noradrenergic system.

M. Shipley will describe a recent anatomical reinvestigation of afferents to LC revealing that major inputs beyond the LC region are limited to 2 rostral medullary areas, the paragigantocellularis (PGi) and the prepositus hypoglossi (PrH). He will also describe several autonomic and visceral brain areas that send converging projections to PGi areas afferent to LC. **V. Pieribone** will describe double labeling studies revealing that PGi and PrH are sources for several neurotransmitters that innervate LC (incl. epinephrine, 5-HT and GABA). **G. Aston-Jones** will describe physiologic experiments *in vivo* revealing that (i) PGi and PrH have potent effects on LC discharge (ii) PGi uses glutamate and epinephrine, and PrH uses GABA, in projections to LC, (iii) LC sensory responses may be mediated by glutamate inputs from PGi, and (iv) 5-HT has potent modulatory effects on glutamate-evoked responses of LC neurons. **J. Williams** will describe recent *in vitro* intracellular studies revealing that stimulation-evoked synaptic potentials in LC neurons are also mediated largely by glutamate (which is modulated by 5-HT), GABA, and epinephrine. **T. Svensson** will review evidence that many visceral and autonomic stimuli influence LC discharge, and recent studies by G. Engberg indicating that certain drug effects on LC activity may be initiated in the periphery and transmitted to the LC via an excitatory amino acid pathway. These results are consistent with above findings that PGi, a key autonomic and vegetative region, provides prominent glutamate inputs to LC. Finally, **D. Reis** will discuss anatomic and physiologic characteristics of the rostral ventrolateral medulla (PGi area), its role in autonomic control, and functional implications of this area being a major afferent to LC. A general discussion among the speakers and audience will follow.

PROGESTERONE INDUCES THE DEVELOPMENT OF CALCIUM CURRENTS IN MYOMETRIAL CELLS ISOLATED FROM IMMATURE RAT UTERUS. J. Rendt* and S. D. Erulkar. Departments of Pharmacology and Physiology, University of Pennsylvania, School of Medicine Philadelphia, PA.

We have examined the role of ovarian steroids in modulating the ionic currents of single immature rat myometrial cells in primary tissue culture.

Myometrial cells were isolated from uteri of 23 day old Sprague-Dawley rats as described by McCormick and Glasser (Endocrinology, 106:1634,1980). Steroid treated animals were injected with either progesterone (500 μg/animal/day), or estrogen (1 μg/animal/day) or both for 3 days prior to cell isolation. Treated cells were grown in DMEM with the steroid. Currents were recorded by the whole cell patch-clamp method.

Cells from untreated immature rats show outward K^+ currents, but little or no inward current. Cells from rats injected with either progesterone or progesterone plus estrogen have significantly larger inward currents. Treatment with estrogen alone does not elicit similar inward currents.

The inward current displays time and voltage-dependent inactivation. It is blocked by Co^{++}, Mn^{++}, Cd^{++}, and nifedipine; it is enhanced by Bay-K8644. Total replacement of external Na^+ by Cs^+ does not reduce the inward tail current suggesting that the inward current is carried exclusively by Ca^{++}.Supported by NS-12211

DEVELOPMENT OF Ca, Na AND K CURRENTS FROM OOCYTE TO NEURULA IN ASCIDIAN EMBRYOS. W.J. Moody, L. Simoncini* and M.I. Block, Dept. of Zoology, Univ. Washington, Seattle, WA

We have studied the ontogeny of voltage-dependent currents in embryos of the ascidian B. villosa using the whole-cell clamp on blastomeres isolated from various embryonic stages from oocyte to neurula. Muscle-lineage blastomeres in this species have an orange pigment that enables them to be identified at any stage. The unfertilized oocyte has three voltage-dependent currents: Na and Ca currents activated by depolarization and an inwardly rectifying K current activated by hyperpolarization. These three currents disappear from all blastomeres during early development, each at a characteristic stage: the Na current by the 2-cell stage, the Ca current by gastrulation, and the inward rectifier by mid-neurula. Just as the inward rectifier disappears, the Ca current reappears, but only in muscle-lineage cells. This is the first stage of development at which cells of different developmental fates have different electrical properties. The appearance of Ca currents in muscle-lineage cells precedes morphological changes, contractility and innervation in these cells. The time between gastrula, when all blastomeres are electrically equivalent, having only inwardly rectifying K currents, and neurula, when muscle-lineage cells, but not other cells, have developed large inward Ca currents, is only about 3 hours. This short time period and cell specificity of the appearance of Ca currents should allow us to study their ontogeny in detail.

64.3

CYCLIC CHANGES IN CHLORIDE CURRENT DENSITY WITH CELL DIVISION IN EARLY BLASTOMERES FROM THE ASCIDIAN BOLTENIA VILLOSA. M. L. Block and W.J. Moody, Dept. of Zoology, U. of Washington, Seattle, WA 98195

The unfertilized eggs and quiescent blastomeres through 3 cell divisions of the ascidian Boltenia villosa have 3 main voltage dependent ionic currents (Block & Moody, 1987, J. Physiol. 393, 619). These are transient inward Na and Ca currents upon depolarization from rest (-70mV) and an inwardly rectifying K current upon hyperpolarization. The Ca and K current densities through the 8-cell stage remain approximately equal to those of the unfertilized oocyte. The Na current density, on the other hand, decays rapidly and steadily after fertilization until the current is no longer detected at the 8-cell stage. This is a report of a 4th current with a completely different behavior in the developing embryo. There is seen in quiescent cells after fertilization a very small inward current with very slow kinetics compared with those of the inward K current when 10Ba-ASW is used to completely block the K inward rectifier. Over the course of about 15-20 min., as the cell prepares for division, this current increases in size, sometimes by a factor of 1000, to a peak just before cell division and then drops rapidly back to its origional level as soon as cell division is complete. Cyclic changes in this current can be seen in the transitions between 1 to 2, 2 to 4 and 4 to 8 cells. This cyclic change can also be observed over at least 3 cycles as a change during nuclear division in cytochalasin B treated embryos (no cell division takes place). Tail current measurements were made in Na free, K free ASW (choline sub.) with varying Cl concentrations (gluconate sub.). The reversal potential of this current follows the Cl concentration. Supported by HD17486 and Research Career Development Award to WJM.

EFFECTS OF MITOGENS ON SCHWANN CELL ION CHANNELS. G.F.Wilson* and S.Y.Chiu. (SPON: D. Oertel) NeuroScience Program & Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

Previously, our lab has shown that increases in potassium current accompany the avid Schwann cell proliferation induced by nerve transection. Since, in Wallerian Degeneration the mitogens initiating proliferation remain enigmatic, we examine the effects of known mitogens on outward current in purified Schwann cell populations from newborn rat sciatic nerve. Primary cultures were stimulated for 12-40 hours using either crude myelin (MF, 150 μg/ml) or axonal fractions (AF, 150 μg/ml), bovine pituitary extract (BPE, 500 μg/ml, Sigma P1167), or a combination of BPE and 2μM forskolin (F, Sigma F6886). Whole cell recordings from unstimulated cells (n=61) revealed a variable outward current averaging 148 ± 14 pA. Mitogen enhancement of this current ranged from 4.8 to 1.0 times control per experiment for MF(n=14), 2.9 to 0.9 for AF(n=17), 2.4 to 1.0 for BPE(n=19), and 1.2 to 1.0 for BPE+F(n=20) when treated and control cells from one culture were compared on the same day. It appears that mitogen induces the largest relative increase in cells having a low pretreatment basal current. These results roughly parallel those observed for mitogen induced Schwann cell proliferation, as measured by scintillation counts of ^{3}H-thymidine incorporation. Preliminary data also suggest 4AP, TEA, and quinine block MF-induced mitosis, functionally linking current to proliferation in developing, as well as adult Schwann cells.

CONCANAVALIN A INCREASES THE ACTIVITY OF A POTASSIUM CHANNEL IN CULTURED APLYSIA NEURONS VIA AN INTRACELLULAR SECOND MESSENGER. S.S. Lin*, D. Dagan, and I.B. Levitan. Graduate Department of Biochemistry, Brandeis University, Waltham, MA 02254

The lectin Concanavalin A (Con A) has been shown to affect a number of properties of *Aplysia* neurons. It alters their response to glutamate (Kehoe, *Nature* 274 (1978) 866-869), and enhances neurite outgrowth and changes the type of synapses formed between cultured neurons (Lin and Levitan, *Science*, 237 (1987) 648-650). The mechanism(s) by which Con A induces these various types of neuronal plasticity is not known. We report here that, in cell-attached membrane patches on cultured medial neurons, the activity of a 100 pS potassium channel increases when the cell is exposed to Con A. This increase in activity is due to a large decrease in the mean closed time between bursts of channel openings with little if any change in the mean open time. Since the lectin is applied in the bathing medium outside the patch electrode and has no direct access to the channel in the patch, it must affect the channel's activity through a second messenger. Preliminary results suggest this effect of Con A is not mediated by voltage or Ca^{2+}. Work is currently under way to determine which intracellular messenger is involved in altering channel activity. Supported by NIH grant NS25366 to I.B.L.

FMRFamide ANTAGONIZES S CURRENT MODULATION AND PROTEIN PHOSPHORYLATION PRODUCED BY 5-HT and cAMP. A. Volterra, S.A. Siegelbaum, E.R. Kandel and J.D. Sweatt*. HHMI, Ctr. for Neurobiol. & Behavior, Columbia Univ., New York, NY 10032.

5-HT closes the S K^+ channel in Aplysia sensory neurons through cAMP-dependent protein phosphorylation while FMRF-amide increases S channel opening through lipoxygenase metabolites of arachidonic acid. FMRFamide also antagonizes the effects of 5-HT (or cAMP) by reopening S channels closed by 5-HT (or cAMP). At what level in the cAMP cascade does this antagonism occur? Voltage-clamp experiments show that FMRFamide produces a 300 pA increase in S current while cAMP alone produces a 200 pA decrease in S current. However, when FMRFamide is applied on top of cAMP, there is a net increase in S current of 400 pA, confirming a partial reversal of the effects of cAMP. 5-HT or a cAMP analog increase the phosphorylation of 17 spots (by 50-700%) as measured by ^{32}P autoradiography of 2-D gels. By contrast, FMRFamide decreases basal phosphorylation levels in 10 of the 17 spots (40-90% decrease). When FMRFamide is applied 1 min after either 5-HT or cAMP, the normal increase in phosphorylation in all 17 spots is now reversed. In 7 spots, the level of phosphorylation is at control levels. In the 10 spots whose phosphorylation is decreased by FMRFamide alone, the level of phosphorylation is reduced below control values. Since FMRFamide reverses S channel modulation and phosphorylation with cAMP or 5-HT, the antagonism must work either through kinase inhibition or phosphatase activation.

64.7

PROCTOLIN MODULATES K^+ AND Cl^- CURRENTS IN THE CRAB STG. J. Golowasch and E. Marder. Biol. Dept., Brandeis Univ., Waltham, MA 02254.

The peptide proctolin excites the pyloric network of the Stomatogastric Ganglion (STG) of the crab, Cancer borealis. The Lateral Pyloric (LP) neuron is one of the direct targets of proctolin, and its proctolin response is qualitatively the same in the intact ganglion as that seen when it is isolated from presynaptic inputs. Thus LP neurons were studied in minimal isolation conditions (TTX-picrotoxin) in two-electrode current and voltage clamp to determine the currents modulated by proctolin. At hyperpolarized membrane potentials proctolin action is associated with a net conductance decrease, while at depolarized potentials proctolin action is associated with a conductance increase. At least two components can be distinguished in the total current modulated by proctolin: 1) A voltage independent K^+ current that is turned off (or decreased) 2) A voltage dependent Cl^- current that is turned on (or increased) at membrane potentials around and more positive than resting potential. These currents are sufficient to account for most or all of the properties of proctolin's actions on the LP neuron observed in current clamp. Supported by NS 17183.

FORSKOLIN REDUCES THE POTASSIUM CURRENT I_A BY A cAMP-INDEPENDENT ACTION IN LOBSTER NEURONS. R.M. Harris-Warrick. Section of Neurobiology and Behavior, Cornell University, Ithaca, N.Y. 14853.

Forskolin directly activates adenylate cyclase and is frequently used as a tool to analyze the effects of cAMP in neurons. However, Watanabe and Gola (Neurosci. Lett. 78:211,1987) demonstrated that forskolin can reduce voltage-dependent potassium currents in snail neurons by a cAMP-independent mechanism. Here I show that forskolin reduces I_A in neurons of the stomatogastric ganglion of the spiny lobster, *Panulirus interruptus*. Using a 2-electrode voltage clamp, the somata of these cells have little or no detectable inward currents. Three voltage-dependent outward currents have been described by Graubard, Hartline and colleagues (Neurosci. Abst. 10:1073,1984; 11:1023,1985): I_A, a transient potassium current activated from hyperpolarized holding potentials; $I_{K(Ca)}$, a calcium-dependent inactivating current; and $I_{K(V)}$, a slowly activating, non-inactivating potassium current. Forskolin (50 μM) reduced I_A, decreasing the peak outward current and accelerating the rate of inactivation. Forskolin had little or no effect on $I_{K(Ca)}$ or $I_{K(V)}$ (seen with measurements from V_{hold} of -50 mV, where I_A is inactivated). Forskolin had strong effects on identified cells with prominent I_A (PD,AB,PY), but very little effect on cells which have small I_A (LP,VD,IC). Several other compounds that enhance cAMP-dependent effects in these cells (8-bromo-cAMP, N,N-dibutyryl cAMP, IBMX: Flamm et al, J. Neurophysiol. 58:1370,1987) had no detectable effect on I_A in any cells tested. Finally, 1,9-dideoxyforskolin, an analog that does not activate adenylate cyclase, mimicked forskolin's reduction of I_A. In conclusion, forskolin reduces I_A in lobster neuronal somata by a mechanism that is independent of cAMP synthesis. Supported by NIH NS17323.

64.9

REDUCTION OF VOLTAGE-ACTIVATED K^+ CURRENTS BY FORSKOLIN IS NOT MEDIATED BY cAMP IN PLEURAL SENSORY NEURONS OF *APLYSIA*. D.A. Baxter & J.H. Byrne Dept., of Neurobiol. & Anat., Univ. of Tex. Med. Sch., Houston, TX 77225.

Forskolin (FSK) is often used in studies of the modulation of ion channels to specifically activate adenylate cyclase. Previously, we found that application of FSK reduced the transient ($I_{K,A}$) and voltage-dependent ($I_{K,V}$) K^+ currents in sensory neurons isolated from pleural ganglia of *Aplysia* (Baxter & Byrne, *Soc Neurosci Abstr* 11:787, 1985). However, we also found that application of cAMP analogues reduced only the serotonin-sensitive ($I_{K,S}$) K^+ current (Baxter & Byrne, *Soc Neurosci Abstr* 13:1440, 1987); suggesting that FSK has actions unrelated to elevation of cAMP. The present study confirms that FSK reduces the amplitudes of $I_{K,A}$ and $I_{K,V}$ in a dose-dependent manner (10-300 μM); apparently without altering the kinetics of the currents. This action of FSK is not mimicked by cAMP, which reduces only $I_{K,S}$. Furthermore, 1,9-dideoxyforskolin, an analogue which does not stimulate the cyclase, also reduces voltage-activated K^+ currents. In contrast, Modified-FSK (Calbiochem), an analogue which stimulates the cyclase, reduces only $I_{K,S}$. While the nature of interaction between FSK and ion channels is not known, the simplest interpretation of these results is that FSK can act as a K^+ channel blocker. These results and those from several other recent studies support the conclusion that, in addition to activating adenylate cyclase, FSK may have a direct affect on ion channels that is not mediated via cAMP (Hoshi *et al.*, *Biophys J* 53:144*a*, 1988; Coombs & Thompson, *J Neurosci* 7:443, 1987; Watanabe & Gola, *Neurosci Let* 78:211, 1987). Supported by grant AFOSR 87-020.

64.10

MODULATION OF A CALCIUM-ACTIVATED POTASSIUM CURRENT BY CYCLIC-AMP. M.D. Womble and W.O. Wickelgren. Dept. of Physiology, Univ. Colorado Health Sci. Ctr., Denver, CO, 80262.

In the presence of Na^+ (TTX) and K^+ (TEA and 3,4 DAP) channel blockers, sensory neurons (dorsal cells) of the isolated lamprey (*Lampetra lamottenii*) spinal cord produce Ca^{+2}-dependent action potentials (Ca AP's). Their duration is prolonged by γ-aminobutyric acid (GABA) which reduces a Ca^{+2}-activated K^+ conductance ($G_{K(Ca)}$) (Leonard and Wickelgren, J. Physiol. 375: 481, 1986). Ca AP's are also broadened by forskolin, an activator of adenylate cyclase (Womble and Wickelgren, Soc. Neurosci. Abstr. 13: 790, 1987). Here, we confirm that forskolin also inhibits a $G_{K(Ca)}$, via activation of adenylate cyclase.

Ca AP's were prolonged by forskolin in a dose-dependent manner, with an EC50 of 55 μM and maximum effective dose of approximately 250 μM. This action is inhibited by dideoxy-adenosine, an inhibitor of adenylate cyclase. Further, Ca AP's are not prolonged by the inactive analogue 1,9-dideoxyfoskolin. We conclude that forskolin is activating adenylate cyclase and does not act by blocking $G_{K(Ca)}$ directly.

In voltage clamp, dorsal cells show a sustained outward current which is decreased by Ba^{+2} or forskolin application and is correlated with an increase in Ca AP duration. We conclude that activation of adenylate cyclase by forskolin results in a prolonged Ca AP by decreasing the size of a repolarizing $G_{K(Ca)}$. Thus, the broadening action of GABA on Ca AP's of lamprey dorsal cells may also be mediated by cyclic AMP.

64.11

ACTIVITY OF PROTEIN KINASE C (PKC)-INDUCED CA^{++} CHANNEL PERSISTS AFTER INHIBITION OF THE KINASE. P.J. Conn, J.S. Strong, and L.K. Kaczmarek. Depts. of Pharmacol. & Cell. Molec. Physiol. Yale Univ. Sch. of Med., New Haven, CT 06510.

Following brief stimulation of an afferent pathway, the bag cell neurons of Aplysia generate a prolonged afterdischarge during which action potentials become enhanced in height and width. In isolated bag cell neurons, PKC activators, such as TPA, enhance the amplitude of action potentials by unmasking a previously covert species of voltage-dependent Ca^{++} channel. We have now shown that PKC inhibitors prevent TPA-induced expression of the covert Ca^{++} channel when added prior to TPA addition, but do not reverse the effects of TPA when added after action potentials have already become enhanced by TPA. This suggests that transient activation of PKC may act as a "trigger" for the appearance of the covert Ca^{++} channels but that continued activation of the enzyme is not required for the maintenance of active channels. We have also shown that, in intact ganglia, PKC inhibitors do not prevent initiation of the afterdischarge but inhibit the enhancement of action potentials during the afterdischarge. These data suggest that the PKC-induced unmasking of the covert Ca^{++} channel contributes to the enhancement of action potentials during the afterdischarge.

64.12

MODULATION OF NEURONAL Ca CHANNELS BY cAMP AND PHORBOL ESTERS. D. Lipscombe, K. Bley & R.W. Tsien. Department of Cellular and Molecular Physiology, Yale University School of Medicine, New Haven, CT 06510.

Norepinephrine (NE) has dual actions on whole cell Ca channel currents in frog sympathetic neurons. L-type Ca current is enhanced through ß-adrenergic stimulation while N-type Ca current is inhibited via α-adrenergic stimulation. Inclusion of GTP (0.2-0.3 mM) in the pipette solution is required to see both effects repeatedly. In cell-attached patches, unitary activity of L-type Ca channels is stimulated by NE, isoproterenol or 8-bromo-cAMP added to the bath. The increase in L channel activity is dominated by enhanced opening probability and a clearcut increase in open time. However, the activity of single N-type Ca channels is not increased by ß-adrenergic stimulation. Thus, L and N-type Ca channels can be distinguished by their very different responsiveness to the second messenger cAMP.

α-adrenoceptor mediated inhibition of N-type channel activity is not mediated by a widely diffusible messenger since it is not observed in cell-attached patch recordings when NE is added to the bath. Stimulation of protein kinase C (PKC) has been shown to inhibit Ca channel activity in chick DRG neurons (Rane & Dunlap, *PNAS*, 83:184, 1986). However, in frog sympathetic neurons, PKC activation by either phorbol diacetate or phorbol dibutyrate (0.1-1 μM) does not mimic the α-effect on N-type Ca channels. Stimulation of PKC produces little change in whole cell Ca channel current. In cell-attached patches, L and N-type Ca channel activity both increase within 1-3 min following application of phorbol ester due to a marked enhancement of single channel open probability. This increase of Ca current differs in mechanism from that reported in *Aplysia* bag cell neurons (Strong et al, Nature, 325:714, 1987).

64.13

ROLE OF C KINASE AND cGMP IN REGULATING GUINEA PIG OR RAT HIPPOCAMPAL CA CURRENT: STUDIES WITH KINASE INHIBITORS. D. Doerner, M.P. Walsh* and B.E. Alger, Univ. MD. Sch. Med., Balto, MD 21201; *U. Calgary, Calgary, Alberta T2N 4N1.

We have shown that phorbol esters suppress voltage-dependent Ca currents in hippocampal neurons recorded with Cs filled electrodes under whole cell clamp. To test whether this effect is mediated by C kinase, we used the kinase inhibitors H-7, H-8, a 17 kD peptide (PKCI, McDonald and Walsh, BBRC, 129:603, 1985), and sphingosine, before and after application of phorbol esters.

At $\leq$ 20 μM, H-7 reversed the phorbol-ester-induced suppression of I_{Ba}, but had no direct effects. Other inhibitors, sphingosine and PKCI also blocked phorbol ester effects suggesting these effects are due to C kinase. At $\geq$ 40 μM H-7 directly enhanced I_{Ba}, an effect probably not mediated by inhibition of baseline C kinase activity since other C kinase inhibitors produced no enhancement. Involvement of A kinase in the direct effects of H-7 was excluded as 8-Br-cAMP did not suppress I_{Ba}.

We report for the first time that 8-Br-cGMP reversibly reduces I_{Ba}. Interestingly, this effect was not blocked by H-8, a potent G kinase antagonist, or the other kinase inhibitors, suggesting cGMP effects may be independent of C or G kinase. We also conclude that high dose H-7 does not enhance I_{Ba} by inhibiting ongoing C, A or G (since H-8 did not mimic H-7) kinase activity and may represent a direct effect on the calcium channel.

ALZHEIMER'S DISEASE II

65.1

CALBINDIN D28 NEURONS IN THE HIPPOCAMPAL FORMATION ARE RESISTANT TO DEGENERATION AND DO NOT DEVELOP REGENERATIVE FEATURES IN ALZHEIMER'S DISEASE. S.R. Hoffman*, N.W. Kowall, and A.C. McKee (SPON:Valerie Knowlton) Neurology Service and Dept. Neuropath., Mass. General Hospital, Boston MA 02114.

CA1 neurons in the hippocampal formation are sensitive to ischemic, hypoglycemic and seizure induced insults as well as neurofibrillary tangle (NFT) formation in Alzheimer's disease. The resistance of neurons to seizure induced injury may be related to their enrichment with Calbindin D28 (CaBP). We used an antibody against CaBP (courtesy of C.R. Gerfen) to examine the hippocampus in 6 patients with AD and 6 age-matched controls. In normal dentate gyrus CaBP is prominent in granule cells and scattered stellate cells.A dense band representing mossy fiber terminals is seen in CA 4 and CA 3. Scattered non-pyramidal neurons with extensive dendritic and axonal branches are found in CA 1. In AD dentate stellate cells are more intensely reactive while granule cells are unchanged. Enhanced terminal staining is seen in the outer part of the molecular layer and senile plaques are evident. Non-pyramidal neurons show perikaryal swelling but their dendritic trees are largely unchanged, in stark contrast to changes evident with MAP 2 histochemistry in the same regions. CaBP neurons are less severely affected by degenerative and regenerative responses than pyramidal neurons possibly due to their enhanced calcium buffering capacity.

65.2

THE CALCIUM PUMP AS A POSSIBLE DIAGNOSTIC MARKER FOR ALZHEIMER'S DISEASE. E. RIZOPOULOS, M.J. WAYNER, J.P. CHAMBERS. SPON: (F.C. BARONE). The Brain Research Laboratory of Biochemistry, University of Texas at San Antonio, TX 78285.

Increased intracellular calcium has been correlated with neuronal degeneration. Fibroblasts from SDAT patients have been shown to exhibit high calcium levels suggesting a problem with extrusion of calcium. In an attempt to establish a diagnostic assay for SDAT, we investigated the hydrolytic properties of the calcium pump from SDAT fibroblasts (cell lines AG0364B and AG4402) and their age-matched controls (AG4440A and AG4058). Control homogenates exhibited the well established property of inhibition of ATP hydrolysis at high free calcium (360 uM); whereas SDAT fibroblasts retained at least 50% ATP hydrolytic activity. As assayed, this activity corresponds to ATP hydrolysis by the plasma membrane, calcium pump. Although more SDAT cell lines must be examined, these data suggest that an abnormality in the calcium pump from SDAT patients may be the basis for noninvasive, diagnostic assay. Such abnormalities related to calcium homeostasis could provide insight into the etiology of this memory related neuronal disease. (Supported by the American Health Assistance Foundation)

CHEMICAL PATHOLOGY OF CEREBRAL VESSELS IN ALZHEIMER'S DISEASE. R.N. Kalaria, M.J. Mitchell* and S.I. Harik Dept. of Neurology, CWRU, Cleveland, Ohio 44106

Increasing evidence suggests there is breakdown of blood-brain barrier (BBB) function in Alzheimer's disease (AD). Cerebral amyloid angiopathy is common in AD and plaques are observed to evolve around brain capillaries. We studied the biochemical and pharmacological properties of cerebral microvessels isolated from the brains of AD subjects and age-matched controls. Microvessels isolated from frontal and occipital lobes were checked for purity by light microscopy and biochemically. Fractions of vessels were also stained with thioflavin-S to assess amyloid deposition. We also assayed several marker enzymes for subcellular fractions of brain endothelium. The activities of γ-glutamyl transpeptidase, alkaline phosphatase, monoamine oxidase, glucose-6 phosphatase, and Na+,K+-ATPase (ouabain binding) were not significantly altered in AD. However, there was a decreased activity of the angiotensin converting enzyme in vessels from AD subjects. Also, BuChE was reduced by ~ 50% in AD. Hydroxyproline levels to assess basement membrane were significantly increased in vessels from AD subjects. These changes along with other alterations in transport proteins such as the glucose transporter suggest functional impairment of the BBB in AD.
Supported by a grant from ADRDA and by grant HL-35617.

65.4

ABNORMAL PROTEIN KINASE C IN ALZHEIMER FIBROBLASTS. T. Saitoh, G. Cole*, T. Huynh*, R. Katzman and M. Sundsmo*. U.C.S.D., Sch. of Med., Neuroscience Dept., M-024, La Jolla, CA 92093.

Protein kinase C (PK-C) cascade is altered in brain of Alzheimer's disease (AD) patients detected as 1) reduced PK-C activity in the particulate fraction (PF), 2) reduced phorbol ester binding in PF and 3) reduced in vitro P86 phosphorylation in the cytosol fraction (CF) (Cole et al., Brain Res. 1988). To further understand the biological meaning of this finding, we asked if these alterations are secondary effects of neuronal degeneration or primary changes involved in AD pathogenesis. If altered PK-C cascade is found in AD fibroblasts which are not involved in the degeneration, the latter possibility is more likely. Upper-arm skin biopsies of AD patients and age-matched controls were trypsinized and dissociated fibroblasts incubated in DMEM. Cells were harvested when 80% confluent, washed, homogenized and fractionated into PF and CF. When PK-C activity was assayed with histone as substrate, AD and control samples were equally active. However, quantification of PK-C with anti-(PK-C) antibody revealed a lower level of enzyme in AD samples in both PF and CF. When AD samples were subdivided into two groups, i.e. sporadic and familial AD, the reduction in the concentration of PK-C was greater in familial cases. In vitro phosphorylation of a major PK-C substrate, P79, in Alzheimer CF was also decreased relative to control. The reduction in the P79 phosphorylation was more pronounced in familial cases than in sporadic cases. From these studies, we conclude that abnormal PK-C cascade reactions that we observed in the brain tissue of AD patients are not the mere consequence of neuronal degeneration but are involved, possibly causally, in the pathogenesis of Alzheimer's disease.

α_1-ANTICHYMOTRYPSIN IN BRAIN AGING AND DISEASE. H. Potter, D.J. Selkoe[1], D.L. Price[2], L. Cork*[2] and C.R. Abraham. Dept. Neurobiology, Harvard Medical School, Boston, MA 02115; Brigham and Women's Hospital, Boston, MA 02115[1]; Johns Hopkins Medical School, Baltimore, MD 21205[2].

The recent finding (Abraham et al., 1988, Cell 52:487) that the serine protease inhibitor, α_1-antichymotrypsin (ACT), is tightly associated with the amyloid deposits of normal aged and Alzheimer's disease (AD) brains, suggests a role for this inhibitor in the amyloid deposition. We used immunocytochemistry to analyze the presence of ACT in brain amyloid of aging monkeys. The earliest ACT immunoreactivity was found in cortical perivascular cells. The cortical amyloid, both in senile plaques and vasculature, was seen only several years later, and could be stained for both β-protein and ACT. In addition, we examined the distribution of the inhibitor in various human neuropathological states in order to identify cells that contain this protein during brain degeneration. ACT immunoreactivity was found in astrocytes near areas of neuronal or tissue loss, in pericytes and in a few neurons. Lastly, we analyzed the association of ACT with the other types of amyloidoses. ACT antibodies labeled only amyloid deposits that have as their major component the β-protein: normal aging, AD, Down's syndrome and in the hereditary cerebral hemorrhage of Dutch origin. In Familial Amyloidotic Neuropathy, primary amyloidosis and secondary amyloidosis, the ACT staining was not associated with amyloid fibers. In summary, ACT is found in the brain in three cell types. In amyloid deposits it is found only in association with the β-protein, further strengthening its possible role in the processing of the β-protein precursor.

TAURINE IMMUNOREACTIVE PYRAMIDAL NEURONS DEGENERATE IN ALZHEIMER'S DISEASE HIPPOCAMPAL FORMATION. N.W. Kowall A.C. McKee and M.F. Beal, Neurology Service and Dept. of Neuropathology, Mass. General Hospital, Boston MA 02114.

Taurine is a putative inhibitory neurotransmitter found in high concentrations in animal and human brain. A subset of hippocampal pyramidal and granule cells in rat hippocampus are taurine immunoreactive. Taurine concentrations are not depleted in Alzheimer's disease (AD) cortex, but histochemical studies have not been performed to determine the state of immunoreactive neurons in human brain. An antibody to taurine was raised using colloidal gold adsorbed taurine as the antigen to elicit antibodies in rabbits. Antiserum was characterized with absorption controls for taurine and related amino acids and by its characteristic staining pattern in the brain. Four AD brains and 4 age-matched controls were examined after immersion fixation in neutral buffered formalin or periodate-lysine-paraformaldehyde. Purkinje cell bodies and dendrites were intensely immunoreactive, consistent with reports in other species. In the hippocampal formation a subset of pyramidal neurons were immunoreactive. In AD these neurons degenerated and developed neurofibrillary tangles, as shown with silver and thioflavine S counterstains. Therefore, a second neurotransmitter defined subset of pyramidal neurons, in addition to glutamatergic neurons, is predisposed to neurofibrillary tangle formation in the hippocampus.

MICROTUBULE DISORGANIZATION AND GROWTH CONE FORMATION CHARACTERIZE DEGENERATION AND REGENERATION IN ALZHEIMER'S DISEASE. A.C. McKee, N.W. Kowall, and K.S. Kosik, Dept. Neuropath. and Neurol., Harvard Med Sch, Boston, Ma 02114

In Alzheimer's disease (AD) widespread neuritic proliferation is associated with cytoskeletal disruption, reorganization of microtubule proteins, and extensive neuronal degeneration. To further define these sequential changes, we examined the hippocampus of 12 AD patients and 10 age-matched controls using immunoperoxidase methods with antibodies against tau (5E2), MAP2 (5F9), ubiquitin and tubulin. Initially, tau and tubulin form granular deposits in normal appearing perikarya. As further tau is deposited, tubulin reactivity diminishes and neurofibrillary tangles (NFT) develop. Mature NFT are ubiquitin positive. MAP2 histochemistry shows distortion and dissolution of apical dendrites. In regions severely affected by NFT, remaining neurons exhibit rampant proliferation of basal dendrites. Fibrillar tau can extend into these MAP2 positive dendrites that demonstrate other features reminiscent of regenerating neurons in culture including lamellipodia and filopodia of growth cone structures. Proliferative tau reactive dystrophic neurites (DN) are evident even in regions with little or no NFT formation. A subset of DN are reactive for tubulin and ubiquitin. The distribution of tau DN suggests a dendritic origin and the presence of filopodia implies a regenerative process. In AD, regeneration is aberrant and largely unsuccessful. Chaotic misconnections may be as important as disconnections in the pathogenesis of cognitive dysfunction in AD

Enzymatic Properties of Cholinesterases in Normal Human Brain and Alzheimer's Disease. Changiz Geula and Marsel Mesulam, Harvard University and Beth Israel Hospital, Boston, MA.

In the cerebral cortex of the normal human brain, cholinesterase staining is localized primarily within cell bodies and axons and is predominantly of the acetylcholinesterase (AChE) type. This neuronal and axonal AChE is severely depleted in Alzheimer's disease (AD). An analysis of cortical cholinesterase activity in AD reveals 4 additional deviations from the normal pattern: 1) The cerebral cortex in AD does contain considerable AChE activity but much of this is localized within neuritic plaques (NP) and neurofibrillary tangles (NFT). 2) In addition to AChE, many NPs and NFTs also display intense butyrylcholinesterase (BChE) activity while the normal cerebral cortex contains very little BChE in neurons or fibers. 3) Using a modified Karnovsky-Roots procedure, the AChE within normal cells and fibers is stained optimally at pH 8.0. The optimum staining of the NP- and NFT-bound AChE, however, occurs at pH 6.8. 4). In general, the normal AChE activity in cells and fibers is inhibited by 10^{-7}-10^{-6}M of the specific AChE inhibitor BW284C51. The AChE in NPs and NFTs, however, is inhibited at the higher concentration of 10^{-5}-10^{-4}M of BW284C51.

These enzymatic differences may reflect transformations that the premorbid AChE molecule undergoes during NP and NFT formation in AD. The possibility also exists that the cholinesterase activity observed in NP and NFT might reflect the synthesis or accumulation of a novel cholinesterase or perhaps a proteolytic enzyme that also hydrolyzes choline esters.

NEUROTENSIN AND PHENYL-N-METHYLTRANSFERASE (PNMT) IMMUNOREACTIVITY IN LOCUS COERULEUS OF ALZHEIMER'S DISEASED (AD) BRAINS. H.D. Chung*, W.J.Burke and D.S. Zahm. (SPON: J. Gibbons) VA Med. Ctr., Dept. of Neurol. and Dept. of Anat.& Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104

Sequential retrograde degeneration involving cortex, locus coeruleus (LC) and the C1-C2 group of medullary epinephrine-containing neurons, in that order, has been proposed as one component in the progression of AD (Burke et al., Ann. Neurol.22:278-80, '87). The C1-C2 group, however, does not appear to degenerate or have reduced PNMT levels (Burke et al., Geriatric Clin. Pharmacol., Raven, '87). Because neurotensin (NT) has been reported to coexist within LC-projecting PNMT neurons (Hokfelt et al., JCN 222:543-59, '84), we examined AD brainstems with the intent of exploiting NT immunoreactivity (IR) as another marker of AD-affected axon terminals originating in C1-C2 and projecting to LC. Four AD brainstems were removed between 1 and 3 hours post-mortem, fixed, exposed to antisera against neurotensin (INCstar) or PNMT (Eugene Tech) and processed for light and electron microscopic immunohistochemistry. PNMT-IR, restricted to the central tegmental tract (CTT) in fine fibers, involved LC minimally. NT-IR colocalized with PNMT-IR in the CTT, but was distributed widely, in coarse fibers, throughout other brainstem regions, including the LC, where the plexus was quite dense. NT may accompany PNMT in the C1-C2 projection to LC, but it must originate elsewhere too and therefore is an unacceptable marker for that pathway. Supported by the VA.

CENTRAL METABOLISM OF SOMATOSTATIN 14 AND 28 IS ALTERED IN ALZHEIMER'S DISEASE. T. P. Davis, P. Davies, A. J. Culling-Berglund*, E. Malek* and T. Gillespie*. Dept. of Pharmacology, Univ. of Arizona Coll. of Med., Tucson, AZ 85724 & Dept. of Neuroscience, Albert Einstein Coll. of Med., The Bronx, New York, 10461.

Senile dementia of the Alzheimer type (SDAT) is a progressive dementia characterized neuropathologically by the presence of neurofibrillary tangles and neuritic plaques in the cerebral cortex. It has been reported that somatostatin (SS) is contained in 20% of all neuritic plaques and RIA-SS is decreased in several brain regions of SDAT patients. The present study was designed to compare the time-course metabolism of SS-14 and SS-28 in specific regions of post mortem brain materials from sex and age matched controls versus SDAT patients and to compare the carboxypeptidase E (CPE) like activity. In vitro SS 14 and 28 metabolism was studied in twice-washed membrane homogenates of hippocampus and temporal cortex (Broadman Area 22). The CPE assay of STACK et al.(Life Science [1984] 34) was performed in the presence and absence of 10mM GEMSA. Previous reports have shown a significant decrease in RIA-SS in SDAT temporal cortex, but little change in hippocampus. Our study resulted in a SS-14 and SS-28 half-life of 140 and 267 min. respectively in SDAT temporal cortex versus 181 and 440 min. in controls. SS-14 and SS-28 half-life in the hippocampus showed no significant difference between SDAT and controls. CPE-like activity was higher in SDAT temporal cortex versus controls (120 vs. 101 pmoles/mg pr.). The order of activity was reversed in the hippocampus with controls greater than SDAT (93.5 vs. 61.5 pmoles/mg pr.). Our data support the hypothesis that alterations in the enzymatic metabolism/processing of SS-14 and 28 is a mechanism leading to decreases in RIA levels in specific SDAT brain regions.

POSTMORTEM VENTRICULAR FLUID (PVF) GALANIN (GAL) NEUROPEPTIDE Y (NPY) and SOMATOSTATIN (SOM) LEVELS: ALZHEIMER (AD), HUNTINGTON (HD), PARKINSON (PD) DISEASES and CONTROLS (C). N.R. Cutler, W.H. Barrettini, D.M. de Luna and W.W. Tourtellotte. Center for Aging & Alzheimer's, Beverly Hills, CA 90211. GAL, NPY, and SOM have been found to co-exist in hippocampal and cortical cholinergic neurons. In lieu of these associations, we evaluated PVF GAL, NPY, and SOM levels in autopsy-proven AD, HD and PD patients and C. METHODS: Aliquots were withdrawn immediately following death and stored at -70°C. GAL, NPY and SOM levels were measured in duplicate and in a blinded fashion by RIA assay. The subjects were as follows: 14 AD ($\bar{x}$ age=79±6); 5 PD ($\bar{x}$ age=74±9); 5 HD ($\bar{x}$ age=64±6); and 10 C ($\bar{x}$ age=62±16). RESULTS: NPY (pg/ml)--AD ($\bar{x}$=454±294), HD ($\bar{x}$=873±310), PD ($\bar{x}$=606±113) were greater than C ($\bar{x}$=225±113), ($p<0.05$). GAL-HD ($\bar{x}$=42±8) were found greater than C ($\bar{x}$=23.0±18), ($p<0.05$). SOM-PD ($\bar{x}$=202±111) levels were found increased as compared to C ($\bar{x}$=70±40), ($p<0.05$). There was a relationship found between AD SOM and NPY ($r=0.84$; $p<0.01$), but not between GAL and NPY levels ($p>0.05$). CONCLUSIONS: Elevated PVF NPY levels in AD, HD, PD, GAL-HD and SOM-PD will be discussed in relation to postmortem brain tissue, in vivo CSF levels and other neuropeptides.

65.12

THE EFFECTS OF NICOTINE ON ATTENTION, INFORMATION PROCESSING, AND SHORT-TERM MEMORY IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE. G. M. M. Jones*, B. J. Sahakian, R. Levy*, J. A. Gray* and D. Warburton*. Section of Old Age Psychiatry and Dept. of Psychology, Institute of Psychiatry, London SE5 8AF and Department of Psychology, Univ. of Reading, Reading, U.K.

Nicotine (s.c.) in patients with dementia of the Alzheimer type (DAT) produced a significant and marked improvement in performance, as measured by discriminative sensitivity, and faster reaction times on a computerized test of attention and information processing. Nicotine also improved the ability of DAT patients to detect a flickering light in a critical flicker fusion test. These results suggest that nicotine may be acting on cortical mechanisms involved in visual perception and attention and support the hypothesis that acetylcholine transmission modulates vigilance and discrimination. Nicotine may therefore be of some value in treating deficits in attention and information processing in DAT patients.

HETEROGENEOUS STRIATAL AFFERENT CONNECTIONS FROM DISTINCT REGIONS OF THE DOPAMINE-CONTAINING MIDBRAIN OF THE PRIMATE.
L. A. Feigenbaum and A. M. Graybiel. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

The mesostriatal projections labeled by 35S-methionine injections placed in different parts of the A8-A9-A10 cell complex of the midbrain were analyzed by autoradiography in 4 squirrel monkeys. The locations of injection sites were plotted in relation to subdivisions of the A8-A9-A10 cell complex visible in sections immunostained for tyrosine hydroxylase. Anterograde labeling in the striatum was charted with respect to histochemically identified compartments revealed in serial sections immunostained for met-enkephalin or stained for acetylcholinesterase or butyrylcholinesterase. In all cases labeling appeared from anterior to posterior poles of the striatum, and distinct regional patterns of labeling were also observed. In addition, two strikingly different compartmental patterns of mesostriatal projection were found. There was dense labeling of the matrix compartment in both the caudate nucleus and the putamen with minimal labeling of striosomes in three cases: one with a caudal injection in A8, and two with more rostral injections in A8 involving also A10 and the pars mixta of Francois et. al. (85). By contrast, in the fourth monkey, there was vivid labeling of striosomes in the caudate nucleus and putamen with much weaker labeling of the matrix. The injection site in this monkey was centered in the main horizontal band of the substantia nigra pars compacta. These findings demonstrate that in the A8-A9-A10 cell complex of the primate, there are distinct subdivisions with preferential projections to striosomes and other subdivisions with preferential projections to the matrix. *Supported by The Whitaker Health Sciences Fund, The Seaver Institute, and The McKnight Foundation.*

66.2

ORGANIZATION OF THE EFFERENT PROJECTIONS FROM THE PRIMATE VENTROMEDIAL STRIATUM. E. Lynd, C. Klein, H.J. Groenewegen, and S.N. Haber (SPON: T. Pasternak). Dept. of Neurobiology and Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642.

The n. accumbens is considered to be the limbic-related portion of the striatum by virtue of its afferent connections from allocortical and mesolimbic areas as well as from the amygdala. However inputs from these regions are not unique to the n. accumbens and project to more rostral and dorsal striatal areas as well. We undertook a study to compare the efferent projections from the n. accumbens with more rostral and dorsal regions of the striatum to determine whether the n. accumbens should be considered a unique striatal region by virtue of its efferent fiber pathways.

Injections of 3H amino acids, WGA-HRP, or PHaL were placed in various striatal regions including, the medial n. accumbens, the lateral n. accumbens, the ventromedial rostral pole of the caudate n., and the centromedial caudate n. Results indicate that regardless of the injection site, terminals were observed in the ventral palidum and in the rostral pole of the external segment of the globus pallidus (GP) and in the inner portion of the rostral internal segment. At this point, fiber bundles head caudalward to the substantia nigra (SN) and are no longer observed in the GP.

In contrast, the entire rostral-caudal extent of the SN receives input from these striatal regions. Rostrally the labeling is concentrated primarily in the medial portion of the SN. In more caudal regions dense terminal labeling was observed more laterally. In all cases terminals to the substantia nigra were not limited to the pars reticulata, but some overlap with the pars compacta was observed. These studies suggest that there is not a significant difference between the efferent projections from the n. accumbens compared to the rostral and medial caudate n. in the monkey.

66.3

COMPARTMENTAL ORIGINS OF THE STRIATOPALLIDAL PROJECTION IN THE PRIMATE. J. M. Gimenez-Amaya* and A. M. Graybiel (SPON: J. Jimenez-Castellanos). Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

In the squirrel monkey we injected horseradish peroxidase-wheatgerm agglutinin (HRP-WGA; 15 cases) or HRP-WGA and fluorescent latex microspheres (FBS; 2 cases) into the globus pallidus (GP). The distribution of retrogradely labeled striatal neurons was studied in relation to striosomal architecture demonstrated histochemically. Deposits involving both pallidal segments (GPe and GPi) and smaller deposits in GPi labeled medium-sized neurons in different parts of the putamen and, often, in the lateral and rostral caudate nucleus. Circumscribed fields of striatal labeling appeared always; in some cases there were also far-flung patches of labeled matrix cells (0.2-0.5mm wide, ca. 1mm apart). The main fields of label were interrupted by pockets of sparse labeling corresponding to striosomes where these could be identified as such. These zones almost always contained some labeled cells: these cells were usually weakly labeled and varied in number from a few to 1/4-1/2 the number per area in the matrix. With FBS in GPe and HRP-WGA in GPi, striatal neurons labeled with each tracer were partly intermingled but FBS cells were striking in some striosomes. Only 1 doubly labeled cell was found of 507 FBS cells checked. Because of variable fibers-of-passage contamination we cannot be sure whether a projection from some striosomal cells to pallidum exists. We can conclude that in the primate (1) a massive striatopallidal projection originates in the extrastriosomal matrix, (2) heterogeneous distributions of these matrix projection cells occur, and (3) GPe and GPi probably receive inputs from different sets of matrix neurons. *Supported by The Seaver Institute and FISSS.*

66.4

PATTERNS OF COEXISTENCE OF NEUROPEPTIDES AND GLUTAMIC ACID DECARBOXYLASE IN NEURONS OF THE FELINE STRIATUM M.-J. Besson*, A. M. Graybiel and B. Quinn. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139; INSERM U114, Paris, FRANCE.

In the striatum of colchicine-treated cats, substance P (SP)-like and dynorphin B (DYN)-like immunoreactivities coexist in ca. 90% of neurons in striosomes (where the SP/DYN cells are concentrated) and neurons in the extrastriosomal matrix (where SP/DYN cells are more sparse). In untreated cats met-enkephalin (mENK)-positive neurons appear mainly in the matrix, but after colchicine many also appear in striosomes, suggesting SP/DYN/mENK coexistence. We report here on the coexistence of these peptides and glutamic acid decarboxylase (GAD) in striatal neurons of colchicine-pretreated cats with methods and controls as previously described. In striosomes we confirm ca. 90% SP/DYN colocalization. In these SP/DYN neurons, mENK was colocalized in 80% and GAD in 60%. Of striosomal mENK neurons, ca. 70% were SP/DYN-positive. In the matrix, mENK cells were more numerous but only 35% expessed SP or DYN. Levels of colocalization of SP and DYN were 85%. About 75% of these SP/DYN neurons expressed mENK. Fully 90% of mENK cells coexpressed GAD, but these mENK cells represented only ca. 60% of GAD-positive neurons. We conclude that (1) there are different populations of peptidergic neurons in striosomes, many expressing GAD and including many SP/DYN cells expressing mENK and fewer SP/DYN-negative mENK cells; (2) in the matrix, GAD neurons expressing SP, DYN, and mENK make up a minority population, mENK/GAD neurons a larger group, and GAD-positive without these peptides a third group. *For antisera we thank Dr. Elde (mENK) and Dr. Wu (GAD). Supported by NSF BNS83-19547 & BNS87-20475 and The Seaver Institute.*

66.5

COMPARTMENTATION OF VENTRAL PALLIDAL EFFERENTS IS REFLECTED IN THE DENSITY OF AFFERENT INPUTS TO PERIKARYA AND PROXIMAL DENDRITES. D.S. Zahm and S.N. Johnson* Dept. of Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

We reported last year that ventral pallidal efferents projecting to the ventral tegmental area are restricted to a ventromedial part of ventral pallidum (VP) that is rich in neurotensin (NT) immunoreactivity (IR) and that nigropetal axons originate with neurons in dorsolateral, NT-IR-poor parts of VP. Our present results, also generated following small injections of WGA-HRP into the brainstems of rats, indicate that fibers enroute from VP to the subthalamic nucleus also originate from dorsolaterally positioned cells. EM examination of retrogradely labeled cells, which carried the TMB reaction product stabilized with DAB and cobalt, indicated that the cell bodies and proximal dendrites of neurons in the dorsolateral division of VP are contacted by significantly more boutons which exhibit more synapses than are neurons in the ventromedial pallidal division. In ventromedial VP, thin laminae of glia frequently intervene to prevent contact of neurons and afferent boutons. Such glial blockade was not observed in the dorsolateral district of VP. In other respects the projection neurons in the ventromedial and dorsolateral districts of VP are similar, all having fusiform perikarya at the large end of the medium sized range (18-25 µm), with electron lucent cytoplasm and heterochromatic, deeply indented nuclei. Supported by NIH NS-23805 and the American Parkinson Disease Association.

66.6

LIMBIC AND NON-LIMBIC RAT STRIATAL REGIONS DIFFER MARKEDLY IN THEIR HIGH-AFFINITY DOPAMINE TRANSPORT. J.F. Marshall, Dept. of Psychobiology, Univ. Calif. Irvine, CA 92717.

Although the rodent nucleus accumbens septi (NAS) and dorsal striatum (caudate-putamen, CPu) share a common development, architecture, and connectivity, the present experiments reveal large differences in their dopamine (DA) transport systems. The DA content of cylindrical punches from NAS and CPu were similar (102 and 119 ug/mg), whereas the desipramine- resistant, benztropine-inhibited transport of [^{3}H]DA (0.5 uM) into microsomal fractions prepared from these punches differed markedly (0.89 and and 3.38 pmol/mg P, respectively). Saturation analysis of 0.02-1.0 uM [^{3}H]DA transport revealed these regional differences were due to V_{max}, not Km, variations. Compared with CPu, the NAS also had markedly less binding of [^{3}H] mazindol (15 nM) to the recognition site associated with the high-affinity DA transport. In punched tissue samples, the specific binding of this radioligand was three fold lower in NAS relative to CPu (1.12 pmol/mg P vs 3.41 pmol/mg P), which by Scatchard analysis reflected fewer binding sites in NAS. Quantitative autoradiography of [^{3}H]mazindol binding revealed a similar 2.5-3.0 greater ligand binding in dorsal CPu relative to NAS. The relative paucity of high-affinity dopamine transport sites in the NAS may contribute to (i) the observation that in vivo biosynthesis of dopamine in the NAS is higher than that in CPu, and (ii) the tendency for NAS to be spared from neurotoxin-induced DA terminal injury.

66.7

INTERACTION BETWEEN D1 AND D2 DOPAMINE (DA) RECEPTORS REVEALED BY DISCRETE INJECTIONS OF SELECTIVE AGONISTS INTO THE BASAL GANGLIA OF DA-DENERVATED RATS. G.J. LaHoste, J.F. Marshall and R. Navarrete*, *Dept. of Psychobiology, Univ. of California, Irvine 92717.*

Recent studies of dopamine (DA) D1 and D2 receptors have revealed an interaction between the two in intact but not DA-denervated rats. This interaction may vary with neural locus as autoradiographic studies have revealed distinct anatomical distributions of D1 and D2 receptors in rat brain. Using quantitative receptor autoradiography, we confirmed the anatomical distinction between D1 and D2 binding patterns in rats whose ascending DA projections had been unilaterally destroyed by 6-OHDA. In addition, such rats rotated vigorously contralateral to the lesion when 5 ug apomorphine (APO) was injected into the brain at either the substantia nigra pars reticulata (SNr), a site rich in D1 receptors, or the caudate-putamen (CPu). The selective D2 agonist quinpirole (5 ug) induced contralateral rotation when injected into the CPu but was ineffective in the SNr. By contrast, the selective D1 agonist SKF 38393 (15 ug) induced rotation equivalent to APO when injected into the SNr but not the CPu. The effect of SKF 38393 in the SNr was apparently not mediated via the D1 receptor, however, since it was not antagonized by SCH 23390 and since S(-)-SKF 38393, which is inactive at the D1 site, also induced rotation when injected into the SNr. Although these data seem to indicate an exclusive D2 effect in the CPu and a possible D1 effect in the SNr, neither SCH 23390 nor eticlopride, a selective D2 antagonist, could block rotation elicited by APO in either brain site; both antagonists together, however, blocked rotation. Furthermore, a subthreshold dose of quinpirole (1 ug) injected into the CPu in combination with SKF 38393 (15 ug) produced vigorous rotation while neither treatment alone caused rotation. In addition, a subthreshold dose of SKF 38393 (2 ug) injected into the SNr in combination with quinpirole (15 ug) caused rotation while neither treatment alone caused rotation. These data provide evidence for distinct types of D1/D2 synergism that vary as a function of neural locus.

66.8

THE DIFFERENTIAL ROLE OF THE DORSAL AND VENTRAL STRIATUM IN THE REGULATION OF FORELIMB AND HINDLIMB MUSCLE TONE. B.A. Ellenbroek and A.R. Cools, Univ. of Nijmegen, Psychoneuropharmacol. Res. Unit, P.O. Box 9101, 6500 HB Nijmegen, the Netherlands.

Whereas it has become increasingly clear that the dorsal and ventral striatum differ in certain anatomical connections, relatively little is yet known on the functional differences between these two areas.

In the past we have found that the dorsal but not the ventral part of the striatum plays an important role in the regulation of the hindlimb extensor muscle tone (Ellenbroek et al, Brain Res, 345: 132, 1985). Thus, injections of haloperidol (250-750 ng/ 0.5 µl) into the dorsal striatum led to a dose-dependent increase in the tonic EMG activity of the gastrocnemius soleus muscle. Since this haloperidol effect could be antagonised by apomorphine, dopaminergic receptors appear to play a prominent role.

We now report that the ventral but not the dorsal part of the striatum plays an important role in the regulation of the forelimb extensor muscle tone. Thus, injections of haloperidol (500-1000 ng/ 0.5 µl) into the ventral striatum led to a dose-dependent increase in the tonic EMG activity of the triceps muscle. The finding that this effect of haloperidol was insensitive to apomorphine but could be antagonised by phenylephrine suggests that α_1-adrenoceptors might play an important role in these effects of haloperidol.

66.9

REGIONAL DISSOCIATION OF BEHAVIORAL FUNCTIONS IN THE RAT STRIATUM: SPATIAL ALTERNATION, REACHING AND HOARDING. M. Pisa, J.A. Schranz, A. Brooks and S. Shastri. Dept. Neurosciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Male Wistar rats with histologically verified, ibotenate-induced lesions of either the medial region or the lateral region of the rostral striatum were compared with vehicle control rats for learning of T maze spatial alternation, forepaw reaching of food pellets inside a tube, and hoarding of food from an alley connected to their home cages. Lesions of the medial striatum produced a statistically significant impairment of spatial alternation performance only. Lesions of the lateral striatum produced a statistically significant impairment of food reaching only. Neither medial nor lateral striatal lesions significantly altered hoarding performance. These results agree with, and extend, previous findings demonstrating distinctive roles of the medial and the lateral striatum in visuospatial cognitive functions and segmental motor control, respectively (Pisa, Neurosci. Abstr., 1987, 13: 980). A role of the rostral striatum in hoarding behavior, reported by other investigators, was not confirmed, however. (Supported by MRC operating grant and Scholarship of the Ontario Mental Health Foundation to M.P., and MRC Studentship to J.A.S.).

DOPAMINE-MEDIATED CIRCLING BEHAVIOR PRODUCED BY SIGMA LIGANDS. J.M Walker, S.R. Goldstein*, R.L. Patrick and R.R. Matsumoto, Department of Psychology, Brown University, Providence, RI 02912.

Haloperidol-sensitive sigma receptors densely populate many brainstem motor regulatory areas including the facial, hypoglossal and motor trigeminal nuclei, the red nucleus, cerebellum and the substantia nigra pars compacta. Behavioral studies from this laboratory further suggested a role of sigma receptors in the regulation of posture and movement.

Two selective sigma ligands, 1,3-Di-o-tolyl-guanidine (DTG) and (+)-pentazocine, were unilaterally microinjected into the substantia nigra of rats and circling behavior was assessed. Both DTG and (+)-pentazocine (0.7 to 18.6 nmol) produced dose-dependent contralateral rotational behavior; DTG was significantly more potent than (+)-pentazocine.

The role of the ascending nigrostriatal dopamine pathway in these effects was assessed by testing the compounds in animals with unilateral 6-OHDA lesions of the medial forebrain bundle. Lesioned animals showed markedly attenuated circling in response to both DTG and (+)-pentazocine. These data suggest that sigma receptors influence dopamine release from the striatum. Furthermore, it would appear that some dopaminergic effects of neuroleptic drugs may occur indirectly through sigma receptors.

NEURONAL ACTIVITY IN THE MONKEY STRIATUM PRECEDING SELF-INITIATED ARM MOVEMENTS. W. Schultz* and R. Romo* (SPON: European Neuroscience Association). Institut de Physiologie, Univ. Fribourg, CH-1700 Fribourg, Switzerland.

The inputs from frontal cortex and midbrain dopamine neurons to the striatum (caudate nucleus and putamen) suggest that this structure may be engaged in neuronal processes related to movement initiation.

We recorded the electrical activity of single neurons in the striatum of 2 Macaca fascicularis monkeys conditioned to perform self-initiated arm reaching movements into a covered food box at irregular, self-chosen intervals and without phasic external cues. Electromyograms collected from the arm, shoulder, trunk and leg of both sides during all neuronal recordings served to control for untimely muscle activity.

Neurons in both parts of the striatum were activated 700-3000 ms in advance of self-initiated arm movements (39 of 215 neurons in caudate, 18%, and 38 of 167 neurons in putamen, 23%). Premovement activity clearly began before earliest EMG activity and either ended immediately before the movement or continued during its execution. It only occurred when animals performed a self-initiated reaching movement from the well-defined resting position on an immovable key, and not in advance of occasional postural adjustments.

These data provide evidence for neuronal mechanisms in the striatum related to the initiation of purposive voluntary movements in the absence of phasic external stimuli. The premovement activity may reflect the excitatory input from frontal cortex in which comparable activity in advance of self-initiated movements is found. Alternatively, this activity could be built up by interactions in cortico-basal ganglia-cortical loops.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: CORTEX I

67.1

SPATIO-TEMPORAL ACTIVATION OF CORTICAL CIRCUITS: VISUALIZATION WITH MTV/2

D.M. Senseman, P. Muljadi*, P.L. Nash* and M.J. Wayner,
Brain Research Laboratory, Division of Life Sciences
The University of Texas at San Antonio

In order to understand better the integrative synaptic mechanisms used by cortical neurons to extract information from afferent inputs, it might be useful to visualize directly the spatio-temporal pattern of stimulus-evoked neuronal activity. To this end we have developed a second generation data acquisition system for multiple site optical recording of transmembrane voltage from intact brains stained with potentiometric probes. Using this MTV/2 system, we have been able to observe the spread of electrical activity in the salamander olfactory bulb following electrical stimulation of the transected olfactory nerve with a temporal resolution better than 1 ms/frame.

The system uses a silicon photodiode array to monitor optically the electrical activity in up to 124 contiguous cortical regions. The optical data is later processed and used to generate Pseudocolor Activity Maps (PAM's) in which the instantaneous amplitude of each diode signal is represented using a 16-level color scale. To correlate changes in activity with specific anatomical regions, the PAM is displayed superpositioned on a computer enhanced video image of the preparation. Animation of the evoked response is achieved through the rapid display of sequentially recorded PAM's. Examples of typical activation patterns observed in the salamander olfactory bulb will be presented in a short movie.

VISUAL AND NON-VISUAL MECHANISMS UNDERLYING DISCRIMINATION OF SELF-GENERATED RETINAL SLIP. R.G. Erickson and P. Thier
MIT, USA and University of Tubingen, West Germany.

Visuo-spatial stability requires suppression of retinal image motion caused entirely by voluntary eye movements. To determine if such suppression is evident in the responses of macaque monkey cortical neurons we compared the responses of visual neurons to actively and passively generated stimulus motion. Stimulation consisted of ramp movement of a stimulus during fixation (passive), and pursuit of a target moving in the opposite direction past a stationary stimulus (active). Compilation of an index used to quantify the active/passive comparison showed that many directional visual neurons in the superior temporal sulcus (STS) responded at least twice as well to passive as compared to active stimulation. No non-directional passive-only neurons were found, and few passive-only cells were found outside the STS.

Specific controls verified that at least three separate mechanisms work synergistically to produce this response property. Directional center-surround antagonism accounted for the passive-only responses of some cells. In others, which summed retinal slip across quadrant-sized fields that included the fovea, target retinal slip during tracking suppressed responses to stimulus retinal slip. Finally, some passive-only cells lacking center-surround interactions did not respond to target retinal slip. The responses of these cells to actively induced retinal slip may be suppressed by non-visual mechanisms.

The results imply that conscious perception of movement may be derived primarily from the responses of motion-sensitive cells in the STS, and that visual mechanisms largely supplant the need for oculomotor efference copy.

67.3

INFERIOR PARIETAL CORTEX ACTIVITY DURING PREPARATION OF VISUALLY-CUED ARM MOVEMENTS IN MONKEYS. M. Godschalk.
Dept. of Anatomy, Erasmus Univ., Rotterdam, The Netherlands

Macaque premotor cortex (PM) contains neurons that modulate their activity during preparation for specific movements in a detour reaching task. PM receives inputs from the anterolateral part of the inferior parietal lobule (IPL) and projects into the primary motor cortex (MI). IPL receives input from non-primary visual areas, thus providing access for visual information to the motor system. The present experiment was designed to compare neuronal activity in IPL with that in PM.

Two macaque monkeys were trained to perform a detour reaching task containing a "Visible-phase" of variable length (1.0-2.5 s) during which the direction of the subsequent movement was cued to the animal by the target becoming visible, but the actual movement had to be withheld until a Go-signal occurred. Single unit activity in IPL was recorded on tape and analyzed off-line.

A total of 128 task related units were recorded. Of those, 86 showed cue-related modulation. Most of these units were found in IPL. In 68 units cue-related modulation was related to target position.

Neurons in this area have been reported to be responsive to visual stimuli, and to be involved in visual attention. This reinforces the hypothesis that some neurons in IPL play a role in the preparation for visually-cued arm movements. It is possible that an IPL-PM-MI pathway processes visual information used for these arm movements.

67.4

ACTIVATION OF DIFFERENT NEURONAL ELEMENTS IN CORTEX BY DIFFERENT TYPES OF TRANSCRANIAL ELECTRICAL AND MAGNETIC STIMULATION IN MAN. J.C. Rothwell*, D. Dressler*, B.L. Day*, P.D. Thompson* and C.D. Marsden* (SPON: A. Chapman). Institute of Neurology, London WC1N 3BG, U.K.

Electrical or magnetic stimulation over central areas of scalp can produce short-latency EMG responses in muscles. Here we compare responses in the first dorsal interosseous muscle to anodal and cathodal electrical stimulation and to different orientations of the magnetic stimulator. The latter was achieved with a 10cm diameter coil centered on the vertex, held either so that coil current flowed clockwise or anticlockwise as viewed from above. The latency and form of surface EMG responses depended on the type of stimulation. The shortest latency was observed using anodal or cathodal stimuli, although cathodal shocks had a higher threshold and generally produced more complex, polyphasic responses. Clockwise magnetic stimulation usually evoked responses 1-2ms later, and anticlockwise stimulation often gave responses which began 1-2ms later still. These latency differences were most evident at just-suprathreshold intensities and disappeared at higher intensities. The same latency differences were observed when single motor units were studied using the post-stimulus time histogram technique. This indicates that excitation arrives at the spinal cord at different latencies depending upon the form of stimulation applied at the scalp.

A SENSE OF MOVEMENT IS ELICITED IN ISCHEMICALLY PARALYZED DISTAL ARM BY FOCAL MAGNETIC COIL STIMULATION OF HUMAN MOTOR CORTEX. V.E. Amassian, R.Q. Cracco and P.J. Maccabee*. Depts. of Physiology and Neurology, SUNY Health Sci. Ctr. at Brooklyn, New York 11203.

Using ourselves as subjects, Cadwell magnetic coils (MCs) of special design were used to stimulate motor cortex transcranially so as to elicit reproduceably movements only of contralateral digits or hand. Movements were tracked with a Videcon-computer system and EMGs were recorded with surface disc electrodes. The arm was made ischemic by a cuff inflated to 180-280 mmHg on the upper arm. After 25-35 min of ischemia, MC elicited movements and EMG responses to stimulation of a given site were abolished, but a clear sense of movement persisted, which was projected even to a single digit. The sensation could be changed in intensity and projected elsewhere if the MC stimulus intensity and location, respectively, were altered. Alternatively, the subject's arm was first ischemically paralyzed. The sensations of distal movement subsequently elicited by MC stimulation at various sites could then be compared with those elicited after the circulation had been restored (they were not necessarily identical).

Our findings probably did not result from fusimotor activation of muscle afferent receptors, because large afferent axons were blocked as evidenced by loss of position sense. Possibly, MC stimulation of motor cortex elicits a "corollary discharge".

67.6

FOCAL MAGNETIC COIL STIMULATION OF HUMAN FRONTAL CORTEX ELICITS SPEECH RELATED MOTOR ACTIVITY. P.J. Maccabee*, V.E. Amassian, R.Q. Cracco, J.B. Cracco* and B.J. Anziska* (SPON: J.B. Ranck jr). Depts. of Neurology and Physiology, SUNY Health Sci. Ctr. at Brooklyn, New York 11203.

Using ourselves as subjects, various sites over left and right frontal cortex were transcranially stimulated with a Cadwell magnetic coil(MC). An X-Y coordinate system measured from the external auditory meatus was used in positioning the MC, which was orientated such that only the edge contacted the scalp, thus enhancing focal activation. Either compound motor action potentials or individual motor units were recorded with bipolar surface electrodes placed paramedianly and contralaterally between thyroid cartilage and sternum. The EMG activity increased markedly during utterances, but insignificantly with head turning. Triggering the MC by voice enhanced the laryngeal EMG response and therefore was routinely used. Latencies of laryngeal muscle responses were: 1) 6-8 ms, often associated with contralateral arm movement. The MC position was consistent with stimulation of precentral gyrus. 2) 13-20 ms, best obtained at more anterior and more medial sites, consistent with stimulation of Broca's area and the supplementary motor area, respectively. 3) 40-60 ms, highly variable in latency and amplitude and often terminating a silent period. Stimulating Broca's area elicited repetitive discharge by some motor units. No clear differences were seen when stimulating the right hemisphere, suggesting the importance of Wernicke's area for left hemisphere dominance.

67.7

NEURONAL ACTIVITY PRECEDING DIRECTIONAL AND NONDIRECTIONAL CUES IN THE PREMOTOR CORTEX OF RHESUS MONKEYS. Steven P. Wise, Kiyoshi Kurata, and Eilon Vaadia*. Lab. of Neurophysiology, N.I.M.H., P. O. Box 289, Poolesville, MD 20837.

Pre-cue activity, a change in neuronal discharge preceding a predictable stimulus, was studied in the premotor cortex of three rhesus monkeys. Two behavioral conditions served as the focus of investigation. In one condition, a directional cue dictated the timing and target of a forelimb movement. In another condition, a nondirectional cue provided only timing information. Of 501 task-related neurons recorded in the premotor cortex, 168 showed pre-cue activity. The onset time of pre-cue activity varied markedly from trial to trial and cell to cell, ranging from trial initiation to 4.8 s later. No pre-cue activity reflected the direction of limb movement; thus, the data argue against a previous suggestion that pre-cue activity reflects the preparation of specific limb movements. A small number of cells showed greater pre-cue activity before directional cues than before nondirectional cues, and this difference may reflect anticipation of the cue's specific directional information. However, the vast majority of units (84%) lacked significant activity differences between the two conditions. We therefore hypothesize that most pre-cue activity reflects or contributes to the main aspect common to the two conditions: anticipation of the time and/or nature of events. The results of the present study indicate supramotor or nonmotor roles for the premotor cortex and serve to undermine the rigid distinction traditionally drawn between the functions of the caudal, "motor" areas of the frontal cortex and the rostral, prefrontal areas.

67.8

CONNECTIONS OF THE PHYSIOLOGICALLY DEFINED SUPPLEMENTARY EYE FIELD. M.F. Huerta and J.H. Kaas. Department of BioStructure and Function, Univ. of Conn. Health Ctr., Farmington, CT 06032, and Department of Psychology, Vanderbilt Univ., Nashville, TN 37240.

In macaque monkeys, cortex medial to the arcuate sulcus has been implicated in oculomotor function, and has been called the Supplementary Eye Field (SEF). In the present study, the connections of the SEF in four M. fascicularis monkeys were determined by: defining the borders of the SEF with intracortical microstimulation, marking these borders with electrolytic lesions, injecting HRP-WGA within the SEF, and subsequently processing the tissue with TMB.

The present data reveal that the SEF has bilateral cortical connections with the SEF, Frontal Eye Field, Supplementary Motor Area, Postarcuate Premotor Cortex, and Frontal Ventral Field. Ipsilateral cortical connections are also made with lateral orbital and periprincipal regions, as well as with cortex in the depths of the intraparietal, lateral and superior temporal sulci. The numerous thalamic connections of the SEF include those made with VA, VAmc, VLp, X, CSL, CL, Pf, Sg-Li nuclei, and all parts of the MD nucleus. The SEF also innervates the subthalamic nucleus, parvocellular red nucleus, central mesencephalic reticular formation, layer VI of the superior colliculus, and several pontine nuclei. 67.9

SACCADE LATENCY AND PREPARATORY NEURONAL ACTIVITY IN THE SUPPLEMENTARY AND FRONTAL EYE FIELDS. **J.D. Schall. Department of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139**

The relationship between preparatory neuronal activity in the supplementary and frontal eye fields and saccade latency was investigated in rhesus monkeys performing a delayed response, go/nogo visual tracking task. The go/nogo cue was given after the target appeared by changing the color of a fixated spot. Saccade latency was negatively correlated with the duration of the delay. After delays over 300-400 msec saccades with latencies under 100 msec were common. Such short latency saccades were observed even though monkeys were required to fixate and attend to the cue spot to successfully withhold saccades on nogo trials. Single units were recorded in rostral supplementary motor area and frontal eye field. Many units were specifically active during the period after the target appeared until the go/nogo cue or the saccade. A prediction of the hypothesis that this neuronal activity is involved in preparing movements is that the level of activity is correlated with reaction time. This prediction was not supported by the results. These results contribute to our understanding of visual attention and motor set.

ABLATION OF MI DIGIT AREA ALTERS MOVEMENT RELATION OF MONKEY SUPPLEMENTARY MOTOR AREA. J.TANJI, M.INASE* and H.MUSHIAKE*. Lab. of Neurophysiology, Tohoku Univ. Sch. of Med., Sendai, 980, JAPAN.

In order to study neuronal activity in supplementary motor area (SMA) after localized lesion in primary motor cortex (MI), monkeys were trained to press two small keys with their right or left digits. After a waiting period of 2-5 sec, either a right or left LED in a front panel came on and triggered the right or left digit movement. Microelectrodes were inserted into the anterior and posterior banks of the left central sulcus in order to make detailed receptive field maps and ICMS maps of the digit area of sensory and motor cortex. Subsequently, electrolytic lesions were made in a portion of MI covering most part of digit area. This was achieved by repeatedly passing DC currents of 100-200 uA through the microelectrodes used for neuron recording. About 4 weeks after the lesion, the reaction time and movement time of the key press movement returned to prelesion values. At this stage, premovement activity of SMA ipsilateral to the lesioned MI was analyzed. Both the frequency of occurrence of movement-related neuron and their magnitudes of activity changes were much reduced. In SMA of the opposite hemisphere, in contrast, the occurrences of neurons related to ipsilateral movement and related to ipsi- as well as contralateral movements were greater.

EFFECTS OF COOLING PARIETAL OR PREFRONTAL CORTEX ON SPATIAL AND NONSPATIAL VISUO-MOTOR TASKS. J. Quintana* and J. M. Fuster (SPON: M. Chase). Department of Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The purpose of this study is to ascertain the importance of spatial and temporal factors in the sensory-motor integrative functions of parietal and prefrontal areas of the primate cortex. Monkeys are trained in color discrimination tasks with delayed and non-delayed motor responses. The stimuli are randomly presented by rear projection on three translucent buttons--one central, for the trial cue, and two lateral, for the discriminanda (choice stimuli) and responses. Some color cues call only for a positional choice (right or left), others call for either a positional choice or a color match. Thus the cue by itself may either connote position or not. Blocks of trials with simultaneous presentation of cue and choice alternate with others with 5-sec or 12-sec delays between the two. In one animal, cooling probes were implanted bilaterally over posterior parietal and dorsolateral prefrontal cortex. Parietal cooling (15° C) induced a reversible impairment of spatial-task performance with delay when the cues connoted exclusively spatial choices; parietal cooling did not impair delayed nonspatial performance or performance guided by cues with ambiguous connotation (spatial and nonspatial). Prefrontal cooling (15° C), on the other hand, induced a reversible deficit in both spatial and nonspatial performance with delay. Neither parietal nor prefrontal cooling impaired tasks without delay. These results suggest that the functional integrity of prefrontal cortex is essential for spatial and nonspatial tasks if they contain temporal discontiguities between cues and responses. The parietal cortex appears important for tasks that depend on the retention of spatial information. These tentative conclusions agree with the concept of a role of both posterior parietal and prefrontal cortex in spatial information processing and a supraordinate role of prefrontal cortex in temporal integration.

NEURONAL ACTIVITY IN THE FRONTAL CORTEX DURING ALTERED VISUAL FEEDBACK CONTROL OF MOVEMENT. D.K. Onstott, S.-K. Park and T.J. Ebner. Depts. Neurosurgery and Physiology, Neuroscience Grad. Prog., Univ. of MN, Mpls., MN 55455.

Activity of frontal cortical cells during a visually-guided, voluntary arm movement under conditions of normal and altered feedback was examined. Rhesus monkeys were trained to move a cursor coupled to a manipulandum from a start box to a target box displayed in one of four positions on a video screen. The position of the target box and the gain between the movement of manipulandum (hand) and cursor were randomly varied from trial to trial. Extracellular recordings from single cells in the frontal cortex revealed modulation of activity that included increased discharge rates during or at the end of the movement. The amplitude and/or duration of a large portion of these responses was scaled to the amplitude of the movement gain between hand and cursor. This activity reflected the altered duration of the movement and the direction of corrective movements required by the change in gain. Cells exhibiting increased activity with movement to one target often showed end-of-movement activity or no response to the orthogonal target. For gains > 1.0, which require reversal of movement direction to attain the target, this directional or position sensitivity resulted in an abrupt reduction of activity upon reversal of hand movement direction. EFFECT OF PHOSPHODIESTERASE INHIBITORS ON RODS L. Cervetto*, L. Colombaioni* and G.M. Ratto* (SPON: European Brain & Behavior Society). Ist. Neurofisiol., CNR, 56100 Pisa, ITALY.

Activation of phosphodiesterase (PDE) causes a fall in cytosolic cGMP which in turn close ionic channels and generates the light responses in retinal rods (Stryer,L. Ann.Rev. Neurosci.9:87-119,1986).

We have analyzed the effect of two well known PDE inhibitors (IBMX and zaprinast) on both membrane current and photoresponse of salamander rods.

Application of IBMX (5÷20μM) caused dose-dependent increases in the dark current and a small desensitization to light. By contrast similar amounts of zaprinast had small effect on the dark current and produced large, long lasting, desensitization to light.

These results suggest the existence of two fractions of PDE, one active in darkness and more sensitive to IBMX, the other, activated by light and strongly inhibited by zaprinast.

L-CIS-DILTIAZEM BLOCKS THE cGMP-GATED CHANNEL IN CONES. L.W. Haynes and K.-W. Yau. Howard Hughes Medical Institute and Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

cGMP-gated channels isolated and reconstituted from retinal photoreceptors by others have not been consistent in their responses to the blocker l-cis-diltiazem, raising the possibility that the unresponsive channels may come from cones[1]. This possibility is ruled out by our experiments. Patches of plasma membrane were excised from catfish cone outer segments and voltage clamped[2]. In isotonic NaCl and low divalent cations, application of diltiazem to the cytoplasmic face of inside-out patches blocked the cGMP-gated channel. The block was enhanced by depolarization, with the resulting current-voltage relation showing inward rectification instead of being nearly linear as in the absence of block. With the channels fully activated, the concentration of diltiazem necessary to reduce the current by half varied from near 10 μM at +30 mV to about 75 μM at -30 mV. These values are in the range found by others for the cGMP-gated channel of the rod outer segment.

CALCIUM AND LIGHT ADAPTATION IN RETINAL RODS AND CONES. K.-W. Yau and K. Nakatani* (SPON: J.M. Baraban). Howard Hughes Med. Inst. and Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The role of Ca^{++} in phototransduction as presently conceived is that it provides negative feedback between the light-regulated conductance and cGMP metabolism, consequently down-regulating a cell's sensitivity to light and leading to light adaptation. The question remains, however, as to how much of the light adaptation exhibited by photoreceptors is actually attributed to this Ca^{++} feedback. We have studied this question by recording from a single amphibian (salamander) rod or cone with a suction pipet while exposing its outer segment to a test solution containing low Ca^{++} and with all Na^{+} replaced by guanidinium. This solution essentially removed the Ca^{++} feedback in the cell[1,2]. In normal Ringer, the response of a rod or cone to a step of light rose transiently to a peak but rapidly relaxed to a lower level, indicative of light adaptation. In the test solution, however, the response relaxation was absent, and the steady response levels at different light step intensities could be well predicted by a statistical superposition of invariant single photon responses each assumed to consist of a regional, complete closure of the light-regulated conductance. We therefore conclude that the Ca^{++} feedback basically underlies all light adaptation in rods and cones.

NONLINEAR PHOTORECEPTOR PROPERTIES INFLUENCE FLICKER SENSITIVITY: INTRACELLULAR AND PSYCHOPHYSICAL ANALYSIS. T. E. Frumkes, M. Sliwinski*, N. Denny*, and T. Eysteinsson, Dept. Psychol., Queens College CUNY, Flushing, NY 11367

Psychophysical sensitivity to rod-mediated flicker of different waveforms suggests 2 types of nonlinearities. Sensitivity to negative sawteeth (rapid on, slow off) is about 0.3 $\log_{10}$ units less than to sine waves. For frequencies <6 hz, sensitivity to positive and negative sawteeth is equal. For higher frequencies (circa 10 hz), sensitivity to positive sawteeth (rapid off, slow on) is further reduced about 1 $\log_{10}$ unit. No similar phenomenon occurs for cone-flicker. We observe similar nonlinear properties by intracellular recording from rods and horizontal cells in Xenopus and mudpuppy. Responses to relatively high intensity positive sawteeth is often interfered with by the rod-after potential. At most frequencies, sensitivity to sinewaves is generally greater than to either sawtooth. To slow frequencies, the slow ramp of both positive and negative sawteeth elicit a response characterized by two straight line segments: an earlier shorter segment with shallow slope, and a subsequent longer segment with steeper slope.

68.5

CELLULAR MECHANISMS OF SURROUND ANTAGONISM IN TURTLE CONES. Wallace B. Thoreson and Dwight A. Burkhardt. Depts. of Physiology and Psychology, Neuroscience Program, Univ. of Minnesota, Mpls., MN 55455.

Illumination of the receptive field surround of a cone evokes two distinct depolarizing responses: 1) an early, graded depolarization presumably mediated by a reduced release of GABA from horizontal cells and 2) a prolonged depolarization of many seconds in duration which can also be evoked by injecting a brief pulse of depolarizing current.

Both responses, along with the light-evoked response of horizontal cells, are abolished by adding kynurenic acid (1-5 mM) or d-O-phosphoserine (5 mM) to the superfusate but the prolonged depolarization can still be evoked by current injection. These results support the view that the graded depolarization is mediated by synaptic input from horizontal cells and that the prolonged depolarization is normally triggered by the graded depolarization.

The following results indicate that the prolonged depolarization depends on an increased Ca^{++} conductance: 1) The cone's input resistance decreases during the prolonged depolarization. 2) In the presence of 10 mM $CoCl_2$, the light-evoked prolonged depolarization, graded depolarization, and horizontal cell response are all abolished, and the prolonged depolarization cannot be evoked by current. 3) In the presence of 5 mM $CoCl_2$, the light-evoked cone depolarizations and horizontal cell response are abolished, but current can now evoke the prolonged depolarization. 4) The prolonged depolarization is facilitated by 5-10 mM $SrCl_2$ and its duration is increased.

GABA (5-20 mM) and its antagonists, bicuculline (1 mM) and picrotoxin (0.5-2 mM), have little effect on the graded depolarization. This lack of effect suggests that either GABA does not play a role in the surround antagonism of turtle cones or that these agents are denied access to the GABA receptors on cones.

EFFECTS OF GABA AND GLYCINE ON THE HORIZONTAL CELL RESPONSE RISE TIME IN THE TIGER SALAMANDER RETINA **Samuel M. Wu and Xiong-Li Yang. Cullen Eye Institute, Baylor College of Medicine, Houston, Texas 77030**

Our previous studies (Yang and Wu, Neuroscience abstract 12:8, 1987; Wu and Yang, ARVO abstract 102, 1988) have shown that the horizontal cell response rise time (HCRRT) in the tiger salamander retina can be modulated either by background illumination (short-term modulation, STM) or by prolonged light exposure (long-term modulation, LTM). Application of GABA and glycine to the retina blocks the LTM, but not the STM. 100 uM GABA mimicks prolonged darkness and lengthens the time to peak of the HC response. 100 uM bicuculline mimicks prolonged light exposure and expedites the HCRRT. 3mM glycine exerts action on the HCRRT similar to those of the 100 uM GABA, and the glycine action can be reversed by strychnine. In the presence of bicuculline, the glycine action on HCRRT disappears. GABA, glycine and their antagonists do not affect the time course of the photoreceptor light responses. It is possible that GABA regulates the kinetics of the post-synaptic receptors for the photoreceptor transmitters in the HC, and glycine acts either like an agonist of GABA and/or increases GABA release through synapses made perhaps by the interplexiform cells. LOW IONIC CHANNEL DENSITY OF THE AXON TERMINAL OF TELEOST RETINAL HORIZONTAL CELLS. T. YAGI* and A. KANEKO. Natl. Inst. Physiol. Sci., Okazaki, Aichi 444, Japan.

In the teleost fish horizontal cells light-evoked responses conduct from the soma to the axon terminal (AT) without much decrement through a slender long axon (*ca.* 500 μm long and <1μm thick). To understand the electrotonic conduction through such structure, we studied membrane properties of AT and soma enzymatically dissociated from the goldfish using whole-cell patch-clamp method. Cells were superfused with a solution containing (in mM) NaCl 79, KCl 10, $MgCl_2$ 1, $CaCl_2$ 2.5, Choline-Cl 37, glucose 16 and HEPES 2 (pH 7.4). Pipettes were filled with a solution containing KCl 120, EGTA 5, and HEPES 10 (pH 7.3). Steady state current-voltage relation of most (80 %) ATs was nearly linear in a voltage range of -60 ~ 10 mV, where the slope conductance was *ca.* 5 $\mu S/cm^2$. The sodium current (I_{Na}) was activated by depolarization from a holding potential of -90 mV to more positive than -50 mV, and was maximal (*ca.* 60 pA) at about -20 mV. I_{Na} of AT was <10 % of that of the soma. I_{Ca} was isolated in a small proportion of ATs, with its amplitude being about 5 % of that of the soma. I_K through the anomalous rectifier was induced in AT when the membrane potential was less negative than -60 mV. Its conductance was 15 ~ 20 $\mu S/cm^2$ (*ca.* 1/20 of I_K of the soma). Other types of I_K were not detected. The present results indicate that low conductance of AT minimizes the leakage of signals arriving electorically through the thin connecting axon.

CALCIUM CHANNEL CURRENTS OF BIPOLAR CELL AXON TERMINALS ARE MODULATED VIA $GABA_B$ RECEPTORS. G. Maguire, B. Maple, P. Lukasiewicz and F. Werblin. Neurobiology Group, University of California at Berkeley. Berkeley, CA 94720.

Calcium channel currents of bipolar cells were recorded under whole cell patch clamp in retinal slices of the tiger salamander. Bipolar cell types were identified with Lucifer yellow staining during the recording. By the criteria of Fox, Nowycky and Tsien J. Physiol. (1987) **394**:173-200, two classes of calcium current were identified:

1) An L-current with slow activation and inactivation when stepped from -50 to 0 mV, that was enhanced by barium substituted for calcium, blocked by nifedipine and cadmium, and was found only in cells with synaptic terminals. Cells with ripped off axon terminals were completely devoid of the L-current.

2) A T-current that was more transient, inactivated at holding potentials more postive than -50 mV, was sensitive to nickel but not cadmium or nifedipine, and was found in most bipolar cells.

The L-type current in barium ringer was reduced by about 50% with 50uM baclofen, a $GABA_B$ receptor agonist, in the bath. When 50 to 500 uM GTP-gamma-S was included in the pipette, bathed baclofen completely eliminated the L-current. This modulation of L-current is limited to classes of bipolar cells with terminals that ramify near the center of the inner plexiform layer (IPL); bipolar cells that ramify near the peripheral margins of the IPL are unaffected by baclofen. The T-current located in the bipolar cell soma, and present in most bipolar cells, is unaffected by baclofen.

Thus, the modulation of calcium channel currents by $GABA_B$ receptors in bipolar cells appears to be: 1) mediated through a G-protein, 2) occurs only at L-type channels in the axon terminal and not at T-type channels in the soma, and 3) is limited to classes of "on" and "off" bipolar cells with processes that ramify in a limited region of the inner plexiform layer.

DOPAMINE AFFECTS THE OPEN PROBABILITY OF GAP JUNCTION CHANNELS IN WHITE PERCH HORIZONTAL CELLS. D.G. McMahon, A.G. Knapp, and J.E. Dowling, The Biological Laboratories, Harvard University, Cambridge, MA. 02138.

Dopamine, acting through cAMP-dependent protein phosphorylation, reduces the gap junctional conductance between teleost retinal horizontal cells (Lasater and Dowling, 1985, PNAS, 82). We have examined the transjunctional current noise from pairs of voltage-clamped white perch (Roccus americana) H1-type horizontal cells in order to ascertain how dopamine modifies the characteristics of individual gap junction channels.

Cell dissociation, culture, and recording methods were as previously described. Gap junctional gating events were evident as equal and opposite changes in the holding current of the clamp circuits. When individual gating events could be visualized the smallest were of 40-50pS conductance, but most were in the 90-100 and 120-150pS ranges. Analysis of the holding current mean and variance (Sigworth, 1980, J. Physiol., 307) during application of dopamine suggests that the open probability of the channels is dramatically reduced, from p>0.5 to p<0.2, during uncoupling. These experiments yield unitary conductance estimates of 30-47pS and channel numbers of 467-1459 (N=4). These unitary conductance values, while low compared with those reported for other gap junction channels, are consistent with the reported size of subconductance levels of heart cell gap junctions (Veenstra and DeHaan, 1986, Science, 233).

D_1 AND D_2 DOPAMINE LIGANDS ACT SYNERGISTICALLY TO MODIFY PHOTORECEPTOR TO HORIZONTAL CELL SYNAPTIC TRANSFER IN XENOPUS RETINA. P. Witkovsky and S. Stone. Dept. Ophthalmol., NYU Med. Ctr., NY, NY 10016.

In the mesopic state, rod and cone inputs to the horizontal cell (HC) combine; their relative proportions vary according to the particular stimulus employed. HC responses consist of an early peak (cone and rod input) and a later plateau (rod input). The intensities of red or green flashes were adjusted to give the same HC plateau, the responses were digitized and subtracted to yield the putative cone input. The D_1 agonist, SKF 38393, the D_2 agonist, LY 171555 and the D_2 antagonist, metoclopramide all changed both the amplitude and the kinetics of the cone input to the HC, whereas they altered the amplitude, but not the kinetics of the rod input to the HC. The D_1 agonist induced a larger increase in V_{max} and a faster response time but a smaller HC depolarization than the D_2 agonist. D_1 and D_2 agonist actions were selectively blocked by SCH 23390 and metoclopramide, respectively.

These findings suggest that D_1 and D_2 agonists work through separate but synergistic mechanisms. It appears that the primary action of dopamine ligands is on the cone input, whereas the rod input is scaled by a shunt. A model for a shunt is proposed based on the anatomical finding that axon branchlets enter both rod and cone bases. Using standard values for passive membrane properties and known values for glutamate-sensitive synaptic channels, a resistive network will be described that explains some of the effects observed physiologically. Supported by EY03570 to P.W. and EY06960 to S.S.

ORGANIZATION OF THE INNER PLEXIFORM LAYER IN THE RABBIT RETINA. J.K. Heussy*, R.F. Dacheux* and E. Raviola, Dept. of Anatomy, Harvard Medical School, Boston, MA 02115.

Amacrine cells (ACs) were impregnated with the Golgi technique or injected with horseradish peroxidase and the distribution of their dendrites in the inner plexiform layer (IPL) was investigated. The IPL is unequally subdivided into a cone bipolar (outer 4/5) and a rod bipolar (inner 1/5) lamina. In turn, four sublaminae (S1-S4) are defined within the cone bipolar lamina by the dendritic arborizations of unistratified ACs. The most scleral sublamina, S1, corresponds to one class of wide-field, unistratified ACs; S2 to outer starburst ACs; S3 to the wide-field, unistratified, ON-OFF ACs and to a class of narrow-field, unistratified ACs; S4 to inner starburst ACs and to another class of wide-field, unistratified ACs. The rod bipolar lamina (S5) contains the dendrites of two classes of rod ACs: indoleamine-accumulating ACs and bistratified ACs (AII). The vitreal dendrites of the two types of AII amacrines, narrow- and wide-field, spread tangentially in S5, whereas their lobular appendages occupy S1 and S2. Four classes of bushy, varicose ACs were observed: a narrow- and a wide-field type distributed throughout the IPL (S1 through S5); a second class limited to the cone bipolar lamina (S1 through S4); a third class confined to the outer IPL (S1 and S2) and a fourth to the inner IPL (S4 and S5). There is a precise correlation between layering of AC dendrites and distribution of the axon terminals of bipolar cells. (Grants EY03011 and EY01344).

68.12

CO-RELEASE OF GABA AND ACETYLCHOLINE BY AN AMACRINE CELL. R. H. Masland and D. M. O'Malley. Department of Physiology, Harvard Medical School, Boston, MA 02115.

The cholinergic amacrine cells of the rabbit retina contain GABA as well as acetylcholine (Brecha et al., 1988; Vaney and Young, 1988). We have developed methods by which the release of both compounds may be studied simultaneously. Isolated retinas are incubated in the presence of 3H-choline and 14C-GABA. The retinas, which then contain 3H-acetylcholine and 14C-GABA, are superfused and the compounds released into the medium are analyzed by electrophoresis and differential scintillation counting.

Stimulation of the retina by various flashing or moving lights triggers an increased secretion of 3H-acetylcholine. The simultaneously measured release of 14C-GABA is unaffected by any photic stimulation thus far tested. GABA is readily released by elevated K+, and the release can be shown autoradiographically to occur from the cholinergic cells. Three different blockers of GABA reuptake increased the basal release of GABA but did not unmask a light--induced release. 14C-GABA endogenously synthesized from 14C-glutamate behaved the same way as 14C-GABA accumulated from the medium. Under our conditions a 2-3% change in GABA release would have been detectable.

Flashing light depolarizes the cholinergic cell enough to more than double its rate of release of acetylcholine, and yet that same depolarization does not measurably change the rate of release of GABA by the cell. The two releases appear to be controlled differently.

68.13

NON-VESICULAR STORAGE OF GABA IN THE RETINA. D. M. O'Malley and R. H. Masland, Department of Physiology, Harvard Medical School, Boston, MA 02114.

GABA and acetylcholine, which are co-localized in one type of amacrine cell, are released differently: most of the release of acetylcholine is Ca++-dependent and appears to occur by exocytosis of synaptic vesicles, while GABA release appears in these cells (and some others; Schwartz, 1986) to be carrier-mediated. If so, one would expect their sites of storage to be different.

Isolated rabbit retinas were labeled to contain 14C-GABA and 3H-acetylcholine. Subsequent incubation in the presence of black widow spider venom caused a large increase in the release of 3H-acetylcholine but no increase in the release of 14C-GABA. Disrupting the retina's plasma membranes by freezing and thawing, which in synaptosomes is reported to release cytoplasmic contents but retain vesicles (Israel, 1981), retained 40% of the retina's 3H-acetylcholine but only 6% of its 14C-GABA. Immunobeads labeled with an antibody to synaptic vesicle antigen P38 (synaptophysin) were used to precipitate synaptic vesicles (Buckley and Kelly, 1985) from retinal homogenates. The beads brought down 25% of the total acetylcholine initially present, but essentially no GABA.

These are the results expected if the cell releases acetylcholine by exocytosis of vesicles and GABA by transport from the cytoplasm. Because the mechanisms are distinct, the same amacrine cell is capable of releasing acetylcholine without releasing GABA, and vice versa.

DIFFERENTIATION AND DEVELOPMENT II

69.1

IN VITRO ANALYSIS OF NEUROGENESIS IN A MAMMALIAN NEUROEPITHELIUM. A.L. Calof & D.M. Chikaraishi. Neuroscience Program, Tufts University School of Medicine, Boston, MA 02111.

A primary event in the formation of the vertebrate nervous system is the generation of neurons from the neuroepithelium of the neural tube and neurogenic placodes. Analysis of the molecular events involved in neurogenesis would be greatly facilitated by a system in which this process could be studied *in vitro*. Such an *in vitro* system has been developed using the olfactory epithelium (OE), an ideal tissue in which to study neurogenesis: the OE contains a limited number of cell types, all identifiable; these cells participate in neurogenesis; and neurogenesis is an ongoing process in this tissue throughout life, reducing the temporal constraints associated with studying this process elsewhere in the nervous system.

Olfactory epithelium from mouse or rat embryos is separated from underlying stroma and placed into culture. Within 24 hours, three cell types appear: an epithelial cell, an immature neuron, and a third cell type; ^{3}H-thymidine labeling and immunocytochemical studies indicate that this third cell type, which divides in culture, may be the immediate precursor of the immature neuron. In serum-free, defined culture conditions, Epidermal Growth Factor enhances the growth of the epithelial cells, but not the generation of immature neurons or their subsequent survival. Nerve Growth Factor, Acidic Fibroblast Growth Factor, and Basic Fibroblast Growth Factor also do not appear to enhance neuronal survival in these cultures. Conditions necessary for the long-term survival of the immature neurons, as well as for their continued generation in primary culture, are being investigated. The derivation of cell lines from these cultures by means of retrovirus-mediated oncogene transfer is also being pursued. *Supported by awards from the Alzheimer's Disease and Related Disorders Association and the Muscular Dystrophy Association to A.L.C.*

MITOGENIC EFFECT OF EMBRYONIC GUT AND STRIATED MUSCLE ON THE NEUROEPITHELIUM OF AVIAN EMBRYOS. T. P. Rothman, J. Fontaine-Pérus*, M. D. Gershon and N. M. Le Douarin. Columbia Univ., P & S, NY, NY 10032 and Institut d'Embryologie, 94736 Nogent-sur-Marne, France.

We have previously shown that neuromuscular tissue of quail or murine gut, back-grafted between the neural tube and somites of younger chick embryos, secretes a short-range diffusible factor that induces unilateral enlargement of the spinal cord [Rothman et al., *Dev. Biol.* 124(1987)331-346]. Experiments were done to determine whether the factor affects proliferation, the timing of its action, and what types of muscle produce it. Embryonic quail foregut (E4) or striated muscle (breast or epaxial; E8-9) or murine bowel or skeletal muscle (triceps or epaxial; E14-15) was backtransplanted between the neural tube and somites of avian embryos (E2). Host embryos were incubated with ^{3}H-thymidine (^{3}H-TdR; 10 μCi). Feulgen stained sections, which permitted quail, chick, or murine cells to be distinguished, were then processed for radioautography. All cells of the neuroepithelium (NE) of host embryos exposed for 24 hrs to ^{3}H-TdR were labeled, although the number of proliferating cells on the side adjacent to grafts greatly exceeded the number on the non-operated side (control). In order to determine when the mitogenic effect first became manifest, NE cells in the S phase of the cell cycle were visualized in host embryos incubated for 2 hrs with ^{3}H-TdR, 6-8, 15 or 22-26 hrs after grafting. A significant increase in the number of cells in S on the operated side was apparent by 15-22, but not by 8 hrs following backtransplantation of any of the investigated muscle. These experiments demonstrate that skeletal muscle as well as enteric smooth muscle is capable of enhancing the rate of proliferation of NE cells after they are experimentally placed together. An effect can be detected as early as 15 hrs after grafting. The muscle derived growth-promoting factor, which is not species specific, must still be identified. 69.3

AN AUTORADIOGRAPHIC ANALYSIS OF NEURONAL PROLIFERATION IN JUVENILE *APLYSIA*. P. W. Hickmott* and T. J. Carew (SPON: M. J. Cohen). Dept. of Biology, Yale Univ., New Haven, CT 06520.

During late juvenile development in *Aplysia* there is a dramatic proliferation of neurons throughout the CNS (Cash and Carew, 1987). To investigate the source of these neurons, we used ^{3}H-thymidine labelling in two different juvenile stages: Stage 11 (before proliferation), and Stage 12 (when proliferation occurs). Previous results (McAllister, et. al., 1983; Jacob, 1984), indicated that some neuronal precursor cells in *Aplysia* originate in body wall ectoderm and migrate into their target ganglia.

We focussed our attention on the abdominal ganglion and its adjacent body wall. In Stage 11, there was uniform labelling of a fraction of cells in the body wall. However, in Stage 12, there was a significant increase in labelling in the region of body wall immediately opposite the ganglion (compared to adjacent control regions) (mean increase=44%; p<.001). Thus, at the time of neuronal proliferation, body wall sites immediately opposite the ganglion show a marked increase in cell division.

We next examined the distribution of labelled cells in the abdominal ganglion at survival times of 1 and 7 days after injection to determine whether cell migration occurs in the CNS. In both stages, the fraction of labelled cells on the outside of the ganglion significantly decreased over time, with a corresponding increase on the inside. Both processes were significantly accelerated in Stage 12 [outside decreases: Stage 11 (p<.05), Stage 12 (p<.001); inside increases: Stage 11 (p<.05), Stage 12 (p<.001)].

Our results suggest: 1) proliferative zones in the body wall are significantly up-regulated late in juvenile development to give rise to widespread proliferation; and 2) cells arriving at their target ganglion continue migrating deeper into the ganglion.

69.4

DEVELOPMENTAL EXPRESSION OF FACILITATORY NEUROPEPTIDES IN *APLYSIA*. E.W.Harkins*, B.B.Worrall*, E.A.Marcus, T.G.Nolen[1], and T.J.Carew. Dept. of Biology, Yale Univ., New Haven, CT 06520, and [1]Dept. of Biology, Univ. of Miami, Coral Gables, FL 33124.

Small cardioactive peptide B has been implicated in synaptic facilitation contributing to sensitization in *Aplysia* (Abrams et al, 1984). With an interest in SCP-B's possible role in the development of learning, we tested SCP immunoreactivity (SCP-IR) in two juvenile stages: Stage 11, when sensitization is absent, and Stage12, when sensitizaiton first emerges.

In Stage 12 animals (5-12 mm, n=19), SCP-IR was found in all central ganglia (total cells, $\bar{x}$=46.5); it was greatest in the buccal ganglia, moderate in the cerebral, pedal, and abdominal ganglia, and least in the pleural ganglia. In most ganglia, specific cells were repeatedly stained. These include B1 and/or B2 candidates in the buccals, two small cells in the pleurals, and a large L10 candidate in the left abdominal ganglion. All SCP-IR showed bilateral symmetry except in the abdominal ganglia. In Stage 11 (1-4 mm, n=25), significantly fewer SCP-IR cells were present, compared to Stage 12 ($\bar{x}$=8.8, p<.002), though the overall staining pattern represented a subset of that seen at Stage 12. Interestingly, Stage 12 not only had more SCP-IR cells than Stage 11, it also had SCP-IR cells that are not observed in adults (Lloyd et al, 1988), including specific cells in the abdominal and pleural ganglia, suggesting that some peptidergic expression may be transient during development.

The 5-fold increase in SCP-IR between Stages 11 and 12 coincides with a 6-fold increase in total cell number (Cash & Carew, 1987) as well as the onset of sensitization and its cellular analog (Rankin &Carew, 1988; Nolen & Carew, 1988). It will now be of interest try to relate the expression of peptides in specific cells to the emergence of specific forms of learning.

OVERALL SEGMENTAL PLAN OF THE EMBRYONIC BRAIN OF A SIMPLE VERTEBRATE, THE ZEBRAFISH B.W.Trevarrow Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403; present address Div. of Biol. 216-76, Cal. Inst. of Tech., Pasadena, Ca 91125

Monoclonal antibodies have been used to analyze segmentation of the brain of the embryonic zebrafish. Hindbrain segments are present as a series of neuromeres containing segmentally organized neurons, glial, fiber tracts, and immunoreactive regions of neuropil. Each segment contains two separate regions, termed neuromeric centers and interneuromeric zones, composed of structures binding different specific antibodies. These two regions form an alternating series along the neuraxis.

Labeling with these antibodies reveals a similar alternating pattern more rostrally. The forebrain and midbrain each behave as single segments, albeit longer than those of the hindbrain. The telencephalon and the major part of the mesencephalon correspond to the neuromeric centers of these segments. The diencephalon and a region including the caudal mesencephalon and cerebellum correspond to the interneuromeric zones.

Throughout the brain the first neurons to develop are located in the neuromeric centers and include cells that project longitudinally. Neurons in the interneuromeric zones develop later, form axons that decussate in ventral fiber tracts, and receive special sensory projections. This simple iterated pattern may reflect a highly conserved plan of organization of the chordate brain. **(supported by NIH grants NS17963, HD22486, and 5 T32 GM0 7413 [Genetics Training Grant at the Univ. of Oregon])**

69.6

DEVELOPMENTAL ACQUISITION OF GABA-LIKE IMMUNOREACTIVITY BY AMPHIBIAN SPINAL NEURONS DIFFERENTIATING *IN VITRO*. N.C.Spitzer, Rosario C.de Baca* and Janet Holliday. Dept. of Biology, UCSD.

The development of membrane properties of embryonic *Xenopus* spinal neurons in culture parallels that seen *in vivo*. We have studied the development of cytoplasmic properties such as neurotransmitter phenotype by examining the appearance of GABA-like immunoreactivity (GLIR) *in vitro*. Cells cultured from neural plate stage embryos differentiate into neurons that can be labeled with antiserum raised against GABA conjugated to BSA . Most immunoreactive neurons display reaction product through-out the cell but a few have only heavily labeled processes and growth cones.

Neurons first display detectable GLIR at 10 hrs in culture. The number of labeled cells, as a per cent of morphologically differentiated neurons, increases steadily over time with the greatest increase (19%) occurring between 12 and 16 hrs. The time course of acquisition of GLIR *in vitro* parallels that of neurons developing *in vivo* (Roberts et al.,1987). By one day *in vitro*, 35% of neurons are labeled when grown in culture medium containing calcium (10 mM) . The percent of immunoreactive neurons at this time is similar to that previously shown to acquire a high affinity GABA uptake system (26%, Lamborghini & Iles, 1985) and the time course of acquisition of these two properties is also similar.

Long duration Ca-dependent action potentials are evoked from these neurons and they also exhibit spontaneous elevations of internal Ca at early stages of development (Holliday and Spitzer,1988). Since Ca influx can influence neurotransmitter synthesis (Walicke and Patterson, 1981), cells were allowed to differentiate in a medium in which Ca was replaced with Mg (10 mM) and EGTA. Only 5% of neurons grown under this condition acquire GLIR. This culture condition does not inhibit the development of the uptake system. The roles of synthesis and uptake in the development of GLIR are under investigation.

THE DEVELOPMENT OF CHOLINERGIC NEURONS IN EMBRYONIC RAT SPINAL CORD. P.E.Phelps, R.P.Barber,* L.A.Brennan,* P.M.Salvaterra, and J.E.Vaughn. Div. of Neurosciences, Beckman Res.Inst.of the City of Hope, Duarte, CA 91010.

Using a monoclonal antibody against choline acetyltransferase (ChAT), we have previously defined 4 groups of cholinergic neurons in cervical spinal cord; i.e., motoneurons (MNs), partition cells, and small neurons around the central canal as well as in the dorsal horn. We have also described their times of origin, with MNs being the first born (E11-12). In this study, we have used both immunocytochemical and biochemical methods to study ChAT expression during embryonic development. ChAT was first detected immunocytochemically in MNs on E13, and all 4 types of ChAT+ cells were identifiable by E17. Immature ChAT+ neurons were found on E14-16 adjacent to, and within, the germinal epithelium thereby demonstrating that the cholinergic phenotype is already expressed by cells during their migratory phase of development. Biochemical assays demonstrated the first detectable levels of ChAT activity at E13 and a 9-fold increase in activity by E17. In combination with our previous results, these findings suggest that 1-2 days are necessary after a spinal cholinergic neuron is born before its neurotransmitter phenotype is detectable. Supported by NIH grant NS18858.

69.8

FIBER TYPE DIFFERENTIATION DURING RAT HINDLIMB MYOGENESIS DOES NOT DEPEND UPON INNERVATION. K. Condon, W. J. Thompson, L. Silberstein, & H. M. Blau*. Dept. of Zoology, Univ. of Texas, Austin, TX 78712 and Dept. of Pharmacology, Stanford Univ., Stanford, CA 94305.

Recent work in chick limb myogenesis has demonstrated that muscle fiber types can differentiate in the absence of innervation. To determine if innervation is necessary for mammalian fiber type differentiation, aneural limbs were produced by injection of the neurotoxin β-bungarotoxin (β-BTX) into rat embryos, a technique developed by A. J. Harris. β-BTX was given at or prior to the time of the initial innervation of muscle fibers in the lower hindlimb (embryonic days 14-15). By several criteria such treatment destroyed the innervation of the hindlimb muscles in these embryos: no nerve processes could be detected with silver stains, no nerve terminals were detected using antibody to a synaptic vesicle protein, and few if any motor neurons were found in the lateral motor column of the lumbar spinal cord. Following injection, development was allowed to continue until embryonic day 19 or 20. In control animals and non-injected littermates, a characteristic and complementary distribution of fast and slow class myofibers (as determined by immunohistochemistry with monoclonal antibodies) is present in the tibialis anterior, extensor digitorum longus and soleus muscles by embryonic day 19 (E19). While aneural embryos show a marked reduction in the number of fibers in these muscles, both fast and slow class fibers are present in their characteristic intramuscular positions. Thus, fiber type differentiation in rat myogenesis appears to occur in the absence of innervation, suggesting that nerves do not instruct the initial differentiation of mammalian muscle fiber types.

THE APPEARANCE OF POSTEMBRYONIC NEURONS IN THE LEECH *HIRUDO MEDICINALIS* IS CONTROLLED BY THE INNERVATION OF THE MALE ORGANS. C.A. Baptista* and E.R. Macagno. Dept. of Biological Sciences, Columbia University, New York, NY 10027.

In adult *Hirudo medicinalis*, the segmental ganglia of the fifth and sixth body segments (SG5 and SG6, also known as the sex SG) contain a few hundred more cells than the other segmental ganglia of the body (Macagno, E., *J. Comp. Neurol.*, 190:2301, 1980). Both SG5 and SG6 innervate the male organs, while the female organs are exclusively innervated by SG6. The extra cells appear to be neurons since they can be stained by two neuron-specific antibodies. The extra cells are added exclusively to the sex SG, begining at about the end of embryogenesis, 30 days after egg-laying, and continuing post-embryonically. If the male organs are ablated before 16 days of development, extra cells do not develop in either SG5 or SG6. In addition, preventing the innervation of the male organs by SG6, up to day 16, again results in a SG6 without extra cells. From 16 days onward, the generation of the extra cells is independent of the male organs. No extra cells appear in non-sex SG that innervate male organs transplanted to ectopic locations at 10 days or later. In contrast, control transplants of male organs done at the same ages are still competent to elicit extra cells in either of the sex SG. These data suggest that the extra cells are generated within the sex SG, by a process that is triggered by an interaction with the male organs during a critical period and mediated through the innervation of the organs by these ganglia.

69.10

SYNAPTIC CONNECTIVITY OF IDENTIFIED LEECH NEURONS IS SPECIFIED BY PERIPHERAL TARGETS DURING EMBRYOGENESIS. C. M. Loer and W. B. Kristan, Jr., Dept. of Biology, B-022, UCSD., La Jolla, CA 92093.

A pair of serotonergic Retzius (Rz) cells is found in each segment of the leech nervous system. Whereas most Rz cells innervate the body wall in their own and adjacent segments, Rz cells in segments 5 and 6 [Rz (5,6)] instead innervate the reproductive tissue, which is found only in those segments. Standard Rz cells also have a denser central arbor than do Rz (5,6) and receive a number of excitatory synaptic inputs which are lacking in Rz (5,6). Early in development, however, all Rz cells grow similar central and peripheral projections. Rz (5,6) only become different from their segmental homologs after contact with their unique target, the reproductive tissue. Early ablation of reproductive tissue causes Rz (5,6) to innervate the body wall and elaborate a central arbor like that of standard Rz cells. Here we report that ablation of reproductive tissue also causes Rz (5,6) to acquire synaptic connections that are appropriate for standard Rz cells.

Ablations or sham operations were performed by removing either reproductive primordia or nearby tissue from early 10 day embryos. Responses of Rz cells in ganglia 3 - 9 to sensory stimuli were recorded in juvenile leeches after completion of embryogenesis. In unoperated control juveniles, as in the adult, standard Rz cells were depolarized by a number of stimuli: pinching the tail, swimming of the leech, and stimulation of pressure mechanosensory neurons (P cells). Rz (5,6) were not excited by any of these stimuli. In reproductive tissue-ablated animals, Rz (5,6) frequently received synaptic input appropriate for standard Rz cells: Rz (5,6) were depolarized by pinching the tail (12/17 cells, 8 leeches), during episodes of swimming (5/11 cells, 6 leeches), and by P cell stimulation (11/13 cells, 8 leeches). Rz (5,6) in sham-operated controls were not different from those in unoperated controls: they were never excited by tail pinching (0/10 cells, 4 leeches), during episodes of swimming (0/5 cells, 3 leeches) or by P cell stimulation (0/8 cells, 4 leeches). These results demonstrate that both structure and function of Rz cells is profoundly affected by the target they contact during embryogenesis.

Supported by NIH grants NS20746 (WBK) and GM07313 (CML).

SEGMENT-SPECIFIC DIFFERENCES IN ACh RECEPTORS ON LEECH RETZIUS NEURONS. W.B. Kristan, Jr. & K. A. French, Dept. of Biology, UCSD, La Jolla, CA, 92093.

The pair of Retzius cells in leech segments 5 and 6 [Rz(5,6)] differ physiologically and morphologically from their homologs in the 19 other midbody segments. These differences depend at least in part upon the growth of particular peripheral processes of Rz(5,6) into the region of the primordial reproductive organs. We report here that Rz(5,6) also differ from all the other Rz cells [Rz(X)] in the type of ACh receptors they have on their somata.

Responses of Rz cells were recorded from the somata while solutions of ACh (10^{-6} to 10^{-4} M) were pressure ejected onto the somata perfused by leech saline solution containing 20 mM Mg^{+2} to block chemical synaptic transmission. The ACh depolarized all Rz(X) cells, but produced a mixed depolarization and hyperpolarization of Rz(5,6). The mixed response always occurred in Rz(5); the depolarizing response in Rz(6) could be seen only after the much stronger hyperpolarizing response was blocked. Depolarizing responses were blocked by *d*-tubocurarine (10^{-5} M), and hyperpolarizing responses were blocked by α–bungarotoxin (10^{-7} M). All the responses were accentuated by eserine (10^{-5} M). These results indicate that there are two kinds of ACh receptors on the somata of Rz cells: all Rz cells have a depolarizing, curare-blockable receptor, and Rz(5,6) have in addition a hyperpolarizing, α–bungarotoxin-blockable receptor. We will determine whether these differences in ACh receptors depend upon the presence of reproductive organs during development, as do other properties of Rz(5,6). [This work was supported by research grants from NIH (NS14410) and the March of Dimes.]

69.12

TWO DISTINCT TYPES OF DEVELOPMENTAL INTERACTIONS BETWEEN IDENTIFIED NEURONS AND CELLS IN THE PERIPHERY OF THE LEECH, *Hirudo*. K. A. French, S. M. Furgal*, and W. B. Kristan, Jr., Dept. of Biology, UCSD, La Jolla, CA 92093.

In the ventral nerve cord of the medicinal leech, the paired Retzius (Rz) neurons in each of the two segments containing the reproductive structures (segments 5 and 6) are different from Rz neurons in all other segments. The two types of Rz neurons differ in target choice, peripheral and central morphology, synaptic input, and somatic ACh receptors. Because many of these differences fail to develop when the embryonic reproductive structures are ablated prior to neurite outgrowth, the distinctive phenotype of the reproductive segment Rz neurons [Rz(5,6)] appears to be induced by an interaction between the developing neurons and some structure in the periphery. Growing Rz(5,6) neurites contact two possible sources of the signal: the primordial reproductive ducts (PRD) and a population of distinctive cells (V-cells) that surround the PRD and lie along the pathway followed by developing Rz(5,6) neurites.

Rz(5,6) neurites initially contact V-cells on the 10th day of development, in an apparently transient association that closely resembles pathfinding interactions seen in other species. Only later, on the 12th day of development, do they first contact and begin to arborize and form synaptic varicosities in the PRD, starting near the genital pore. Because the shift in phenotype from that of standard Rz cells to Rz(5,6) begins on the 10th day, contact with the V-cells, rather than the more conventional contact with the PRD, is the most likely source of the inductive signal. [This work was supported by an NIH Research Grant (NS20746) and a March of Dimes Grant to WBK and a University of California, San Diego OGSR grant to KAF.]

70.1

AXONAL GROWTH AND SCHWANN CELL MIGRATION INTO BASAL LAMINA GRAFTS TO THE RAT SCIATIC NERVE. J.W. Fawcett* and R.J. Keynes. Physiological laboratory and Dept. Anatomy, Downing St., Cambridge CB2 3EG, England.

We have previously shown that grafts of striated muscle extra-cellular matrix, made by extruding the myoplasm from lengths of muscle, are extremely effective in repairing cut peripheral nerves, performing as well as nerve autografts in lengths up to 4cm (J. Neurosurg. 65:354-363).

We have studied the early events following the insertion of a graft into rat sciatic nerves, by immunohistochemistry using antibodies to neurofilament and S-100, which stain axons and Schwann cells (SC) respectively, and by electron microscopy.

7 days after insertion of the graft many axons and SC's are seen growing into the graft from the proximal stump, becoming sparser with distance into the graft, the maximum distance of migration being 0.3cm. All axons were associated with SC's, but some SC's were not visibly accompanied by axons; some of these SC's were in advance of the front of regenerating axons. A few SC's migrated from the distal stump into the graft, but very much fewer than from the proximal stump. By 10 days many axons had crossed the 0.5cm grafts, and many more SC's were present. Later time points showed increases in axon number,size and myelination.

We conclude that Schwann cells precede axons into the grafts, and that factors present in the proximal but not the distal stump exert a strong mitogenic effect on Schwann cells.

70.2

SYNTHETIC GUIDANCE CHANNELS RELEASING BASIC FIBROBLAST GROWTH FACTOR ALLOW BRIDGING OF A 15 MM LONG GAP IN THE RAT SCIATIC NERVE MODEL. A.N. Salessiotis *, S.R. Winn *, P. Aebischer * (SPON: J. T. McIllwain). Artificial Organ Laboratory, Brown University, Providence, RI 02912.

The maximum gap that can be bridged by an impermeable synthetic tube in the rat sciatic nerve model is 10 mm. In the present study we investigated the ability of synthetic nerve guidance channels which release controlled amounts of b-FGF to bridge a 15 mm long gap. Eighteen mm long guidance channels were fabricated by dipping a stainless steel mandril in a polymer solution of poly[ethylene-vinyl acetate] (EVA) containing bovine serum albumin (BSA) and b-FGF. In vitro kinetic studies of protein release from these channels showed an initial burst during the first three days followed by linear release for at least two weeks thereafter. Further in vitro studies indicated that the b-FGF released from the polymer was biologically active as assessed by the ability of channels containing b-FGF to induce neurite extension from PC12 cells in culture. For in vivo studies, 8 mm of rat sciatic nerve was resected, and the proximal and distal nerve stumps were secured 15 mm apart within the guidance channels. Cohorts of 6 animals were implanted for 4 weeks with channels made of pure EVA, EVA/BSA, or EVA/BSA/bFGF. Upon retrieval, 4 EVA/BSA/bFGF channels had cables bridging both nerve stumps whereas none of the pure EVA or EVA/BSA bridged the nerve gap. Two of the nerve cables regenerated in b-FGF releasing tubes contained more than a thousand myelinated axons at the channel's midpoint. We conclude that b-FGF enhances peripheral nerve regeneration and that polymeric tubes releasing macromolecules provide a powerful tool for the study of nerve regeneration.

70.3

CONDUCTION PROPERTIES OF PERIPHERAL NERVES REGENERATED BY USE OF COPOLYMER MATRICES WITH DIFFERENT BIODEGRADATION RATES. I.V. Yannas*, A.S. Chang*, C. Krarup*, R. Sethi*, T.V. Norregaard* and N.T. Zervas. Fibers and Polymers Lab., Mass. Inst. of Tech., Cambridge, MA 02139, Division of Neurology, Brigham and Women's Hospital, Boston, MA 02115 and Division of Neurosurgery, Mass. General Hospital, Boston, MA 02115.

Collagen-glycosaminoglycan (CG) matrices ensheathed in silicone tubes were used to bridge 10-mm gaps in transected rat sciatic nerves. Recovery was monitored electrophysiologically by stimulating the nerve at the sciatic notch and, separately, on the tibial branch and recording the evoked CMAP's at the plantar flexor muscles in the foot. We studied the effect of the average molecular weight between crosslinks $\bar{M}_c$, of CG matrices on the degree of physiological recovery. Matrices with $\bar{M}_c$ = 45 kD ± 20% (low crosslink density, rapid degradation rate) and $\bar{M}_c$ = 12 kD ± 20% (high crosslink density, slow degradation rate) were studied. The average pore diameter was 10 ± 5 μm in both groups of matrices. The results obtained 28 weeks past grafting are shown in Table I. The frequency of recovery of physiological function is greatly enhanced when the silicone tube contains either of the two CG matrices rather than saline. These results support our previous histological observations on the same model. The results also show that a lower crosslink density (higher $\bar{M}_c$) leads to superior recovery. We suggest that the diminished recovery which is observed with the highly crosslinked matrices is due to their significantly lower degradation rate in collagenase. This observation underscores the importance of the detailed physicochemical structure of the CG matrix in the mechanism of nerve regeneration.

Table I. ELECTROPHYSIOLOGICAL EVIDENCE OF REGENERATION (28 wks)

Graft Type	Regeneration Rate	Distal Motor Latency (msec) From Tibial Branch	From Sciatic Notch
CG, M_c = 45 kD	(6/6) 100%	1.84 ± 0.20	3.43 ± 0.49
CG, M_c = 12 kD	(8/8) 100%	2.26 ± 0.20	4.38 ± 0.38
Empty Tube	(1/6) 17%	2.36 ± 0.21	4.08 ± 0.40
Saline-filled Tube	(5/15) 33%	2.47 ± 0.57	4.84 ± 0.73
Normal Nerve	———	1.58 ± 0.17	2.47 ± 0.17

70.4

NERVE GROWTH FACTOR ENHANCES AXONAL GROWTH THROUGH SILICONE CHAMBERS IN MATURE RATS. J.Pryor*, T.Alexander* and K.M.Rich. Department of Neurosurgery, Washington University School of Medicine, St. Louis, MO 63110.

The effect of NGF on axonal growth within a chamber was examined in adult Sprague-Davley rats. After sciatic nerve section and surgical implantation of a silicone chamber with a 7 mm. gap between proximal and distal nerve ends, chambers were filled with either a 1mg/ml NGF-saline solution (experimental) or a normal saline solution (control). Four weeks after the surgery semi-thin cross-sections were prepared and stained with toluidine blue. Total myelinated axonal counts were done at both the extreme proximal and distal segments of the regenerated nerve segment within the chamber. Morphometric analysis of the distal myelinated axons was done with a computer-assisted digital analyzer.

NGF significantly increased the number of myelinated axons growing into the distal end of chamber (2126±437 NGF-saline; 1064±268 saline; P<0.05 Student's t-test). Counts of myelinated axons from the extreme proximal portion of the nerve within the chamber showed fewer myelinated axons in the NGF-treated nerves (3326±562 NGF-saline; 5110±661 saline P<0.10). The ratio of total myelinated axonal counts from distal vs. proximal segments from the same nerves showed a significantly higher number in the NGF-treated group (.13 saline; .62 NGF-saline). There was no difference in mean axonal diameters between groups (2.8μ saline; 2.7μ NGF-saline).

70.5

NERVE REGENERATION ACROSS A 16MM GAP IS ENHANCED BY A FROZEN NERVE AND A "SLOT" TUBE GUIDE IN RATS. C.-B. Jeng & L.-L. Jeng*. Dept. Anat. & Neurosci., Univ. Texas Med. Br., Galveston, TX 77550 & Dept. Anat., Chang Gung Med. College, Tao-Yuan, Taiwan, R.O.C.

When nerve stumps are sutured 16mm apart in an empty silicone tube, nerve regeneration fails. However, some regeneration occurs if cells from the connective tissue have access to the tube lumen through holes cut in the tube wall (holey tube). Here, we ask if regeneration is further improved by a greater access of connective tissue or a frozen-thawn nerve placed at the gap. Under deep Nembutal anesthesia, a 16mm gap between rat sciatic nerve stumps was maintained by a tube with a 1mm x 10mm slot at the middle (slot tube). The gap was either left empty or filled with an autologous fresh sciatic nerve segment or a nerve that had been frozen-thawn three times. Six weeks later, regenerated myelinated axons were counted in the distal sciatic nerve stumps. The myelinated axon numbers are 86 ± 123 with holey tube (Brain Res., 408:239, 1987), 2330 ± 1408 with slot tube, 6111 ± 1185 after frozen nerve transplant and 8508 ± 1445 after fresh nerve transplant. Thus, compared to holey tubes, the slot tubes greatly improve nerve regeneration. A frozen nerve which presumably contains no live cells, is able to enhance nerve regeneration but not as effective as a fresh nerve transplant. (Supported by the American Muscular Dystrophy Association and the Chang Gung Medical Research Fund).

70.6

FACIAL NERVE REGENERATION IN THE SILICONE CHAMBER: INFLUENCE OF NERVE GROWTH FACTOR. Y.-S. Chen*, L.T. Wang-Bennett and N.J. Coker*. Dept. of Otorhinolaryngology and Communicative Sciences, Baylor College of Medicine, Houston, Texas 77030.

The role of nerve growth factor (NGF) was examined in the neural repair of adult rabbit facial nerve using an in vivo preparation. A 35 μl nerve growth chamber was created by suturing the proximal and distal ends of a transected facial nerve (buccal branch) into a silicone tube. A gap of 8 mm in the chamber remained after removal of a 5 mm piece of nerve. Animals were operated bilaterally; one side of the chamber was filled with NGF and the contralateral side was filled with Ringer's solution. Regeneration of the nerves was examined 1 wk to 5 wk following the surgery. The caliber of the nerve bundle, the distribution pattern of regenerating axons, axon number per fascicle, size distribution, and the total number of axons were compared to the preoperative morphology pattern found for that animal. Each buccal branch served as its own control.

The NGF-filled chambers demonstrated an overall larger caliber at 5 wk and a higher density distribution of axon growth at 3 wk and 5 wk. In the early regeneration cases (3 wk), the axon growth profile exhibited more fascicles and less axons while in the 5 wk cases, the intrafascicular axon density increased. Axon size at 5 wk was 80% that of preoperative controls. The histogram of the size distribution revealed the same distribution as in the preoperative control section.

70.7

RETROGRADE TRANSPORT OF HORSERADISH PEROXIDASE DURING FACIAL NERVE REGENERATION. L.T. Wang-Bennett, Y.-S. Chen* and N.J. Coker*(SPON: C.D. Fermin). Dept. of Otorhinolaryngology and Communicative Sciences, Baylor College of Medicine, Houston, Texas 77030.

In the companion abstract (Chen, Wang-Bennett and Coker) we reported that adult rabbit facial nerve (buccal branch) regenerated in a silicone chamber sutured to the stumps of the transected nerve. We then quantified the regenerating axons in the silicone chamber for their ability to uptake and exhibit somatopetal transport of horseradish peroxidase (HRP). We also examined if the somatotopic connection was altered by the regeneration process at 3 wk and 5 wk PO.

Upon resection of the distal end of the regenerating nerve, a 30% HRP solution (35 μl) was injected through the tube wall into a second chamber sutured to the distal end of the nerve stump. Using the histochemical method of Mesulam(1978), the number of labelled cell bodies in the facial motor nucleus (FMN) and the distribution in the subnuclei: lateral, intermediate and medial were analyzed.

In normal acute preparations, most of the HRP-labelled soma were localized in intermediate and lateral subnuclei and few in medial subnucleus. This distribution pattern remained in the 3 wk and 5 wk regeneration groups. However, HRP labelled cell bodies that survived the nerve transection surgery reflected only a small percentage of the axons seen in the center cross section of the regeneration chamber and the density of the HRP reaction product was low and indicated few dendritic processes.

70.8

ACETYLCHOLINESTERASE PROVIDED BY MOTOR AXONS INNERVATING MYOFIBER BASAL LAMINA SHEATHS. L. Anglister and B. Haesaert* (SPON: A. Reches). Anatomy Dept., Hebrew Univ. Med. Sch., Jerusalem 91010, Israel.

Acetylcholinesterase (AChE) consists of asymmetric or globular molecular forms that can be distinguished by their sedimentation coefficients. In frog muscle the major asymmetric form is a 17.5S AChE, while most globular forms are 4-6S AChE. Muscle AChE is highly concentrated in the synaptic clefts at neuromuscular junctions (NMJs). We have shown that motor nerve is capable of producing synaptic AChE and some of it becomes adherent to synaptic basal lamina (Anglister, Soc.Neurosci.Abstr.13:1211, 1987). This study was aimed to determine which molecular forms of AChE the nerve may contribute to NMJs.

Experiments were carried out, as before, on operated cutaneus pectoris (CP) muscles of frog, in which myofibers had been removed from their basal lamina sheaths, while leaving behind intact motor axons, nerve terminals and synaptic basal laminae, but irreversibly blocking all original AChE. At 30 days all synaptic sites were occupied by nerve terminals and showed histochemically the presence of AChE, newly formed by nerve. Biochemical analysis revealed that 30-50% of this AChE was a 17.5S species; an equal fraction migrated as 4-6S molecules. In innervated region of intact frog muscle only 15-20% AChE consisted of 17.5S species, while most (60-70%) were 4-6S forms. The high 17.5S content in the innervated CP-sheaths originated from the motor axons: In the nerve bundle to CP most of the enzyme (50-70%) was 17.5S AChE, while 4-6S species were a minor component (10-20%). Similar composition was found in the brachial nerve from which the nerve to CP branched.

The results show that the motor nerve to CP, which produces all forms of AChE, carries high concentrations of 17.5S AChE. This is also reflected in the high content of this form in the innervated basal lamina preparation, in the absence of myofibers. 17.5S AChE may be destined for synaptic localization or for neurotrophic purposes. (Supported by grants from BSF and Israel Acad. Sci. to L.A.).

70.9

FOCAL REINNERVATION OF MOTOR ENDPLATES IS FASTER BUT LESS PRECISE IN OLD THAN IN YOUNG MOUSE MUSCLE. N. Robbins, M. Kuchynski* & A. Grasso*. Div. Neuroscience, Case Western Reserve Sch. Med., Cleveland, OH 44106.

Slower recovery of function after nerve injury in old animals (Drahota & Gutmann, 1961) might be multifactorial. In order to study age effects on latency of recovery and endplate reoccupation, motor nerve terminals (+/- a few preterminal internodes) were focally destroyed by intramuscular injection of black widow spider venom (BWSV) (Duchen et al., 1981). Soleus muscles of CBF1 mice, aged 5-7 mo. (young) or 25-28 mo. (old), were injected with sufficient BWSV to produce loss of transmission and synaptic destruction within 30 mins.

Two days after BWSV, electron micrographs showed post-synaptic folds with virtually no nerve terminals or with terminal debris. At 3 days, the indirect twitch first returned in 8 out of 9 old muscles but in none of 7 young muscles. One day later, both young and old treated muscles responded, and by 5 days, the ratio, indirect/direct twitch, approached control levels. Similarly, the low calcium/normal calcium twitch ratio recovered earlier in old muscles. In ZIO preparations, regenerated terminals were first found at 3 days in old and at 4 days in young muscle. Both ZIO preparations and whole mounts stained with fluorescent tetanus toxin c fragment and alpha-bungarotoxin (Robbins & Polak, 1988) showed considerably more overgrowth of regenerating terminals beyond the borders of the previous endplate (measured by terminal length or by protrusion beyond bungarotoxin sites) in many old junctions. Thus, nerve recovery from injury and endplate reoccupation do not account for slow functional recovery after denervation in old animals. The latency of recovery in old animals may reflect "conditioning" of neurons (McQuarrie, 1984) by pre-existent increased synaptic structural turnover or pre-existing excess of sprouting factors. The reduced recognition of the synaptic matrix may indicate a loss of synaptic adhesivity in aging neuromuscular junctions. (Support, NIH AG00795, AG06641, and M.D.A.)

70.10

PREFERENTIAL MOTOR REINNERVATION:A SEQUENTIAL DOUBLE LABELING STUDY. T.M.Brushart. Depts. of Orthopaedics & Neurology Johns Hopkins Hospital, & The Raymond M.Curtis Hand Center, Baltimore, Md. 21218.

Previous experiments have shown that when regenerating motor axons are given equal access to terminal sensory & motor branches of the rat femoral nerve, they will preferentially reinnervate the motor branch (J.Neurosci.8:1026)

Both femoral nerves of 30 3 wk.old female Sprague Dawley rats were severed proximally, where sensory & motor axons intermingle, and the stumps were separated by ½ mm. within silicone tubing. Regeneration was evaluated at 2 wks,3 wks, & 2 mos. HRP was applied to one terminal branch of each femoral nerve & Fluoro Gold was applied to the other branch. 48 hrs. were allowed for proximal transport of the tracers, after which the animals were sacrificed & the lumbar spinal cords processed for demonstration of HRP & Fluoro Gold.

The mean number of motor neurons projecting axons into motor & sensory branches was not significantly different at 2 wks (motor 117, sensory 110), but was significantly different (P=.001) at 3 wks (motor 206, sensory 101) & at 2 mos. (motor 219, sensory 78). A mean of 82 motor neurons was double labeled at 2 wks., while significantly fewer neurons were double labeled at 3 wks (47) & at 2 mos.(32).

Regenerating motor axons demonstrated no preference for motor or sensory Schwann cell tubes at early time periods. Neurotropic or contact guidance mechanisms could thus not have influenced their behavior. Subsequent generation of specificity could partially reflect pruning of motor axon collaterals in the sensory branch, though other mechanisms must also be responsible.

70.11

Quantitation of Sensibility in Full Thickness Skin Grafts To The Hand Dr. Julia Terzis & Dr. C. Scilley* E.V.M.S., M.R.C., Norfolk, VA. 23507

Full thickness glabrous and hairy skin grafts were exchanged between glabrous and hairy recipient sites in the upper and lower extremities of nine female Papio Anubis baboons. At the appropriate time intervals ranging from five months to one year, a detailed electrophysiological assessment was carried out of the mechanoreceptive fibers reinnervating the grafts. Subsequently full thickness biopsies of the functionally tested skin areas and adjacent normal skin were taken for study. Detailed light microscopic examination was carried out using Masson's trichrome, Munger's silver stain and Bodian silver stain. From the Masson's stained sections the architecture of the dermis and epidermis in grafted and normal tissue was examined, as was the appearance, location and number of Meissner's corpuscles. In the silver stained sections of glabrous tissue the innervation of the grafted and normal tissue was compared by recording the number of Meissner's corpuscles as well as the number of individual nerve fibers present in the papillary dermis per centimeter of specimen. In the hairy skin, the number of hair follicles present in the dermis as well as the number of nerve bundles per centimeter were compared in the grafted and normal tissue. All grafts maintained their basic architecture independent of their recipient site. No Meissner's corpuscles survived any of the tissue transfers. All grafts showed a decrease in the density of innervation. The innervation was best maintained in the transfer of full thickness glabrous skin grafts to the hand. The morphological parameters will be correlated with the electrophysiological data. This study attempts to provide for the first time a rational basis for the type of sensibility we obtain in full thickness skin grafts by considering the quality of reinnervation at the level of individual nerve fibers.

AMINO ACIDS: GABA AND BENZODIAZEPINES I

71.1

REGIONAL DISTRIBUTION OF BENZODIAZEPINE/GABA RECEPTOR mRNA (α SUBUNIT) IN RAT BRAIN. P. Montpied, B.M. Martin, S. Cottingham, B.K. Stubblefield, E.I. Ginns, S.M. Paul SPON: J. Kelsoe. Sections on Molecular Pharmacology and Neurogenetics, NSB, NIMH, Bethesda, MD 20892.

Oligodeoxynucleotides derived from the reported nucleotide sequence of the bovine brain $GABA_A$ receptor α subunit were used to isolate cDNA clones from a human brain cortex cDNA library constructed in gt11 (Martin et al., in preparation). Using a human 5' cDNA clone (900 bp), whose deduced amino acid sequence is identical to that of the previously reported bovine cDNA (nucleotide sequence is 95% homologous to the 5' bovine cDNA), we have studied the regional distribution of rat brain α subunit $GABA_A$ mRNA's. Total and $polyA^+$ RNA was purified from different brain regions and RNA levels quantitated by Northern analysis using a ^{32}P-labelled cRNA probe. At least 3 species of mRNA (4.8, 4.4, and 3 kb) were observed. The level of $GABA_A$ α subunit mRNA was highest in the cerebellum > thalamus > frontal cortex > hippocampus > parietal cortex > hypothalamus > striatum > medulla/pons. The 3kb mRNA species was present predominantly in the cerebellum and hippocampus and was not detected in several brain regions. In situ hybridization using the same antisense probe revealed a similar regional distribution of mRNA. Studies on the effect(s) of pharmacological agents and environmental stimuli on the level $GABA_A$ receptor mRNA in discrete brain regions are in progress.

71.2

$GABA_A$ RECEPTOR: SITES OF SYNTHESIS MAPPED IN RAT BRAIN BY IN SITU HYBRIDIZATION. H. Mohler, J.M. Séquier, P. Malherbe and J.G. Richards. Research Department, F. Hoffmann-La Roche & Co., Ltd., CH-4002 Basle, Switzerland

Neurons which express the $GABA_A$ receptor are of particular interest as recipient neurons for GABAergic inhibition and as target cells for drugs acting at the benzodiazepine receptor. These neurons have now been mapped by determining the distribution of RNA homologous to cDNA clones encoding the α- and β-subunit of the rat brain $GABA_A$ receptor. The receptor proteins were mapped in adjacent sections autoradiographically and immunohistochemically. Many brain areas containing high densities of $GABA_A$ receptors showed strong hybridization signals with both the α- and β-subunit antisense RNA probes e.g. cerebral cortex. On a cellular level, a dense dendritic localization of $GABA_A$ receptors was correlated with a strong hybridization in the corresponding somata e.g. in mitral cells of the olfactory bulb, pyramidal cells of hippocampus, granule cells of the dentate gyrus as well as Purkinje and granule cells of the cerebellum.

In some brain areas, the intensity of the β-subunit probe was much weaker than that of the α-probe e.g. substantia nigra, while the inverse ratio of hybridization intensity was found e.g. in bed nucleus. This regional heterogeneity in the hybridization pattern may reflect regional differences in RNA stability, transcription rate or subunit composition. The results open the way for studies on the regulation of $GABA_A$ receptor gene expression in normal and pathological brain in situ.

71.3

NEURONAL LOCATION OF ^{3}H-PK11195 AND ^{3}H-RO 5-4864 BINDING SITES LINKED TO $GABA_A$ RECEPTOR.

E. Slobodyansky, C. Ferrarese, A. Guidotti. FGIN, Georgetown Univ., Washington, D.C. 20007.

^{3}H-PK 11195 and ^{3}H-Ro 5-4864 binding was studied in synaptosomes of rat brain and in primary culture of neonatal rat cerebellar neurons and glial cells. In purified synaptosomes, the density of PK-11195 binding sites is 0.1 pmol/mg prot (5 times lower than that found in mitochondria) PK-11195 or Ro 5-4864 binding in synaptosomes is noncompetetively displaced by picrotoxinin, TBPS, bicuculline, but not protoporphyrin. In contrast, in mitochondria, PK-11195 binding is displaced competetively by protoporphyrin, but not by picrotoxinin, TBPS or bicuculline. In neurons, ^{3}H-PK-11195 binds with high affinity to a small number of binding sites (K_d ~ 10 uM, Bmax 300 fmol/mg prot). These binding sites are associated with GABA binding sites in the same subcellular fraction. In glial cells, PK-11195 or Ro 5-4864 binds with high affinity to mitochondria (Bmax 15-20 pmol/mg prot). The binding of ^{3}H-PK-11195 to neurons and glial in primary culture is displaced by DBI (1-86) and one of its natural processing products, TTN (DBI 17-50) with an affinity of 10 µM. TTN also enhances the TBPS-induced inhibition of ^{3}H-flunitrazepam binding in a manner resembling Ro 5-4864.

71.4

3D RECONSTRUCTION OF FLUNITRAZEPAM BINDING ON C6 GLIOMA

K. Ikezaki*, A.W. Toga, K.L. Black*, E.M. Santori, D.P. Becker
Department of Neurology and Division of Neurosurgery, UCLA School of Medicine, Los Angeles, CA 90024

Previous work has shown selective binding of peripheral benzodiazepine receptor ligands to glial tumors. We sought to determine the heterogeneity of binding sites within the tumor and to acquire spatial statistics on their volumes.

Rats were implanted with C6 glioma cells ($5x10^5$) into the parenchyma of the left cerebral hemisphere. [^{3}H] Flunitrazepam (250µCi/rat) was administered i.v. Animals were decapitated 5 min. after radioligand injection, brains were removed and frozen. Twenty micron coronal sections were then processed for autoradiography.

Quantitative autoradiographic and histologic data (100 coronal sections) were digitized and aligned. The geometry was reconstructed by assigning z-values to each coronal section based upon its rostral-caudal position. The cortical surface of the brain was modelled and rendered to provide visual frame of reference. Tumor reconstructions were performed in one of two ways. In the first, outlines were drawn using a digitizing tablet. In the second, the tumor was circumscribed automatically by generating isodensity contours. Statistics were computed for the volume and binding densities. Three dimensional models illustrating the reconstructions of the tumor within the brain were synthesized.

71.5

β-CARBOLINE INTERACTIONS AT THE BZ-GABA RECEPTOR CHLORIDE-IONOPHORE COMPLEX IN THE RAT CEREBRAL CORTEX.

E. Malatynska*[1], R. Knapp[2], M. Ikeda*[2], and H.I. Yamamura[2] (SPON: J. Coffman[1]). [1]Dept. of Psychiatry, Neuroscience Program, Ohio State Univ., Columbus, OH 43210-1228, and [2]Dept. of Pharmacol., Coll. of Med., Univ. of Arizona, Tucson, AZ 85724.

We measured the effects of the benzodiazepine (BZ)-related β-carbolines ZK 93423, ZK 91296, ZK 93426, and DMCM on GABA-stimulated Cl^- conductance into rat cortical vesicles. The addition of 1.0 µM ZK 93423 or ZK 91296 reduced the GABA EC-50 1.8-fold and 1.3-fold, respectively, which is consistent with previous studies (Malatynska et al., Brain Res., 443: 395, 1988) showing that ZK 93423 is a full agonist at the BZ receptor while ZK 91296 is a partial agonist. DMCM inhibits Cl^- conductance in this assay and is thus an inverse-agonist (Malatynska et al., ibid). ZK 93426 (0.01-1.0 µM) antagonizes both ZK 93423 and ZK 91296 in a concentration-dependent manner with full reversal occurring at 1.0 µM for both drugs. However, there is an inhibition of Cl^- conductance at higher ZK 93426 concentrations that is not observed with ZK 93426 in the absence of the agonists. ZK 93426 also antagonizes DMCM but in an incomplete and multiphasic manner. These studies suggest that ZK 93426 may antagonize the effects of the other β-carbolines through a non-competitive mechanism.

71.6

ACUTE BENZODIAZEPINE ADMINISTRATION ALTERS $GABA_A$ RECEPTOR GENE EXPRESSION.

L.G. Miller, W.R. Smith* and W.C. Claycomb*. Depts. of Medicine, Pharmacology, and Biochemistry, LSU Medical Ctr., New Orleans, LA 70112.

The recent cloning and sequencing of the $GABA_A$ receptor has enabled analysis of expression of its gene. Since the "central" benzodiazepine binding site is located on this receptor, we examined expression of alpha-subunit mRNA in cerebral cortex of mice treated with a single dose of lorazepam(10 mg/kg). Total RNA was isolated and transferred to nylon membranes. Hybridization was performed using a radiolabeled synthetic 33-base oligonucleotide complementary to the alpha subunit mRNA. Specific hybridization was observed at 4.3 and 4.8 kb, similar to that reported for alpha subunit mRNA. Autoradiographs were then quantitated by densitometry. In mice treated with vehicle alone, mRNA levels were similar to an untreated control group at 0, 2, 4 and 24 hours after injection(8 AM), but mRNA levels were increased after 8 hours. In lorazepam-treated mice, mRNA levels were similar to controls at 2 and 24 hours, but were increased at 4 and 8 hours. These results suggest that there is a diurnal variation in the expression of alpha subunit mRNA which corresponds to reported diurnal variations in benzodiazepine binding, and that acute lorazepam administration augments mRNA synthesis after 4 hours.

71.7

GABA DOWN-REGULATES GABA/BENZODIAZEPINE RECEPTORS IN CHICK CEREBRAL NEURONS.

M.H. Jalilian Tehrani, J.J. Hablitz and E.M. Barnes, Jr. Depts. of Biochem. and Neurology, Baylor Col. of Med., Houston, TX 77030.

Exposure of cultured cortical neurons (3 h after plating) to 100 µM GABA for 4 days resulted in a 50% reduction in the level of [^{3}H]flunitrazepam binding to intact cells. A 7-day exposure reduced [^{3}H]Flu binding by 70% compared to controls cultured without exogenous GABA. Scatchard analysis indicated that the reduction in [^{3}H]Flu binding was due to a decrease in receptor density rather than affinity. The chronic effect of GABA was dose-dependent with an IC_{50} value of 70 µM. The loss of receptors could be prevented by concomitant exposure of developing neurons to 1 µM R 5135. The association of this labile receptor pool with functional channels was demonstrated by GABA-gated ^{36}Cl flux measurements and patch-clamp recordings. A 7-day exposure to 100 µM GABA reduced the rate of GABA-gated ^{36}Cl uptake by washed cells to 25% of that for untreated controls. Whole-cell recordings of responses to 1-100 µM GABA revealed that currents were reduced by 60-70% in neurons treated for 7 days relative to controls. Prolonged agonist exposure led to a fading of the GABA response, but the rate of this rapid desensitization was not affected by chronic GABA exposure.

CHARACTERIZATION OF SOLUBILIZED MITOCHONDRIAL BENZODIAZEPINE RECOGNITION SITE COMPLEXES.

A.G. Mukhin* and K.E. Krueger (Spon: R. Liu). FIDIA-Georgetown Institute for the Neurosciences, Georgetown University Med. Sch., Washington, D.C. 20007.

A protein of 17 kilodaltons associated with peripheral-type benzodiazepine binding sites has been purified in this laboratory. To investigate the probable association of this protein in a larger macromolecular complex adrenal mitochondrial membranes were photolabeled with [^{3}H]PK 14105, solubilized in 1% digitonin, and fractionated under nondenaturing conditions. Anion-exchange chromatography resolved two components each containing the 17 kilodalton photolabeled protein. Molecular exclusion chromatography of both of these species revealed that they also differed in size, one component being 75-100 kilodaltons and the other about 150-200 kilodaltons in the presence of 0.1% digitonin. Specific binding of [^{3}H]PK 11195 exhibited chromatographic profiles matching those obtained by [^{3}H]PK 14105-photolabeled adducts. These results demonstrate that at least two distinct molecular forms of peripheral-type benzodiazepine binding sites are generated following digitonin solubilization and could be indicative of heterogeneity in these receptor protein complexes. Additional studies are in progress to identify and characterize the proteins comprising these complexes.

IMMUNOAFFINITY PURIFICATION OF BENZODIAZEPINE RECEPTOR. J.-Y. Wu*, C.C. Liao, J.-Y. Liu, M.M. Fieo, and G.H. Yan. Dept. of Physiology, Hershey Medical Center, Penn State University, Hershey, PA 17033

Previously we reported an immunoaffinity procedure for the purification of L-glutamate decarboxylase and choline acetyltransferase [J. Neurochem., 48, S147 (1987)]. Similar approaches were used to purify both the native benzodiazepine receptor (BZR) and its subunits. Briefly, the specificity of monoclonal antibody was first established by ELISA, immunoblotting and immunoprecipitation tests. IgG was then isolated from the ascites and about 5 mg of the well characterized IgG was coupled to Sepharose 4B as immunoaffinity ligand. About 450 mg of Triton solubilized and partially purified native BZR was incubated with the immunoaffinity ligand at 4°C for 4 days. The entire mixture was packed to a column. The column was first washed with 50 mM Tris-citrate buffer, pH 7.2, followed by a specific elution using 0.1 M Na-citrate/citric acid, pH 3. The BZR thus obtained appeared to be homogenous since in SDS-PAGE only two protein bands corresponding to the α and β subunit of BZR were obtained. It is concluded that monoclonal antibody affinity chromatography provides an efficient method for the purification of neuroreceptors such as BZR. (Supported in part by PHS grants NS20978, NS20922 and EY05385.)

[^{3}H]MUSCIMOL AND [^{3}H]FLUNITRAZEPAM PHOTOAFFINITY LABEL THE SAME MOLECULAR WEIGHT BAND IN CODFISH BRAIN GABA/BZ RECEPTOR. L. Deng*, R.W. Olsen, and M. Nielsen† (SPON: J.P. Segundo). Dept. Pharmacology and Brain Research Institute, Univ. California, Los Angeles, CA 90024, and †Psychopharmacology Lab., Sct. Hans Hospital, Roskilde, Denmark.

Codfish brain GABA/benzodiazepine (BZ) receptor was characterized biochemically and pharmacologically by radioactive ligand binding assays, affinity chromatography, sodium dodecylsulfate polyacrylamide gel electrophoresis, and photoaffinity labeling. Scatchard plot analysis of [^{3}H]muscimol binding in extensively washed frozen membrane homogenates indicated one population of binding sites with K_D = 14 nM, Bmax = 2.7 pmol/mg protein. [^{3}H]Flunitrazepam (Flu) binding was exclusively central type (insensitive to Ro 5-4864), showed K_D = 4 nM and Bmax = 1.4 pmol/mg, and was enhanced by GABA (25 % at 1 μM), as in mammalian brain. Codfish brain lipid-enriched fractions significantly increased BZ binding.The receptor was purified 700 fold on a BZ affinity column, giving a single Coomassie blue stained band on SDS gels at 57-58 kD. This single band was specifically photoaffinity labeled by both [^{3}H]muscimol and [^{3}H]Flu, showing that codfish GABA/BZ receptor is a single subunit carrying both GABA and BZ binding sites.

IS THERE AN ADDITIONAL AGONIST SITE WITHIN THE $GABA_A$ RECEPTOR SUPRAMOLECULAR COMPLEX(GRSC): EVIDENCE USING THE NEW ANTIDEPRESSANT FENGABINE. K.G. Lloyd and F. Thuret*.Lab.Etud.Rech.Synthélabo(LERS), Bagneux,F92220.

Fengabine is a novel antidepressant with the pharmacological spectrum of a GABA agonist (Lloyd et al, J.P.E.T., 241:245, 1987). "In vitro" fengabine is inactive at $GABA_A$ receptors or on GABA metabolism; however it stimulates ^{3}H-diazepam binding and "in vivo" decreases cerebellar cGMP levels (Scatton et al, J.P.E.T., 241:251,1987). In order to elucidate its action within the GRSC we studied the effect of fengabine on ^{35}S-TBPS binding to the $GABA_A$ receptor modulated chloride ionophore. With the experimental conditions used (well-washed rat cerebral membranes, NaCl) GABA agonists enhance ^{35}S-TBPS binding. Fengabine and several of its metabolites increased ^{35}S-TBPS binding (Table) with fengabine being the most active. Under these conditions GABA enhanced ^{35}S-TBPS binding with an EC_{50} of 0.5μM and a maximal effect of 29%. Bicuculline (10^{-3}M) completely blocked the enhancement of ^{35}S-TBPS binding by fengabine and its metabolites. Flumazenil (10^{-6}M) did not alter the action of SL79.781, SL81.0013 or SL 81.0048 whereas it moderated the effect of fengabine.

These results demonstrate a $GABA_A$ agonist activity of fengabine and certain of its metabolites. The site of action appears to be close to, but not identical with, the $GABA_A$ recognition site as none of these compounds displace ^{3}H-GABA binding. Thus, it is possible that another site exists within the GRSC which permits a $GABA_A$ agonist effect, but has a different pharmacological profile.

Compound (n=3)	Fengabine	SL79.781	SL81.0013	SL81.0048
EC_{50}(μM)	3.3±0.8	3.5±0.6	1.4±0.2	2.9±0.2
Maximal eff. (%) Increase	47.3±3.8	26.3±3.2	23.7±1.2	39.3±7.5

OPPOSITE MODULATION OF [^{35}S]t-BUTYLBICYCLOPHOSPHOROTHIONATE BINDING BY DELTAMETHRIN AND RO5-4864 IN TROUT BRAIN MEMBRANES. A.J. Eshleman* and T.F. Murray (SPON: R.A. Dodson). Toxicology Program & Coll. of Pharmacy, Oregon State Univ., Corvallis, Or. 97330.

The GABA-gated Cl^- channels are the main inhibitory neurotransmitter-regulated system in the CNS of many vertebrates. [^{35}S]t-Butylbicyclophosphorothionate ([^{35}S]TBPS) is a useful probe to investigate direct and allosteric interactions of compounds with this channel. Rainbow trout (Salmo gairdneri) are exquisitely sensitive to the neurotoxic activity of pyrethroid insecticides, thus this species is a relevant model to explore the interactions of this class of pesticides with these proteins. Ro5-4864 (4'-chlorodiazepam) is a convulsant benzodiazepine that may share with pyrethroids a common site of action in mammalian brain.

Washed P_2 fractions were prepared from rainbow trout brain in a high salt buffer with 5 uM GABA present in the final incubation mixture. Equilibrium saturation assays of [^{35}S]TBPS binding indicated a density of 424±47 fmol/mg protein and a K_d of 115±22 nM. In competition experiments deltamethrin inhibited [^{35}S]TBPS binding by 95% with an IC_{50} of 660±170 nM. The peripheral-type benzodiazepine receptor (PTBR)ligand, Ro5-4864, for which there are no high affinity sites in this species, enhanced [^{35}S]TBPS binding by 80-90%, with an EC_{50} of 1 uM. The maximal enhancement was inversely dependent on [GABA]; with no exogenous GABA it was 130% while with 25 uM GABA it decreased to 37%. Thus both the PTBR ligand and pyrethroid interact with the oligomeric $GABA_A$ receptor, modulating [^{35}S]TBPS binding in opposite directions. A THEORY OF THE HIPPOCAMPUS BASED ON REINFORCED SYNAPTIC MODIFICATION IN CA1. W. B Levy. Dept. Neurosurgery, University of Virginia, Charlottesville, VA 22908.

Moore & Levy (Neurosci. Abstr. '85) show a reinforced version of associative synaptic modification in CA1. There the entorhinal cortex (EC) to CA1 input is shown to act as permissive stimulus for potentiation of an active CA3 to CA1 input. This interaction is unidirectional (CA3 activity is not permissive for modification of EC synapses). The temporal window of associative interaction is as in Levy & Steward (Neurosci. '83), i.e. ordered with the permissive input allowed to follow the other input by 10-20ms. Such observations are consistent with CA3-CA1 synaptic modification in which the strength of a synapse stays proportional to the expected value of its CA3 afferent axon activity given a threshold of EC induced postsynaptic activity is reached in a timely manner in the relevant postsynaptic cell. With a suitable transformation of CA3 activity a CA1 cell could then "compute" the probability of experiencing a threshold EC event in the next 10-20ms. One such transformation is the maximum entropy optimal multiplicative scheme implemented by adding logarithms. Unfortunately such predictions occur only slightly before the predicted EC induced CA1 activity. Zipser suggests a fixed time shifting process, tapped delay lines. Alternately positive feedback loop(s), e.g. CA3-CA3, EC-CA-EC, etc, can act as variable shifting processes. The advantage of feedback over tapped delay lines is that delay lines, while suitable for shifting events into the time window of associative modification, maintain the same delay when generating predictions so that predictions occur just 10-20ms before the predicted event. Feedback, however, can produce earlier predictions by causing successive activity patterns of CA3 to vary only a little from immediately preceding CA3 activity patterns.

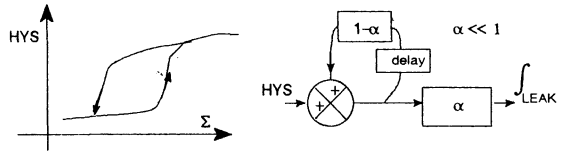
HAUSDORFF NUMBERS CALCULATED FROM POTENTIALS ON THE SURFACE OF THE RABBIT OLFACTORY BULB ARE SPATIALLY UNIFORM AND EVENT-RELATED. Skinner, JE, Martin*, JL, Landisman*, CE, Mommer*, MM, Fulton*, K, Mitra*, M, Mood*, T, Burton*, WD and Saltzberg*, B.(SPON: JE Szilagi). Neurophysiology Section, Neuroscience Program, Baylor College of Medicine, and Neuroscience Signal Analysis Laboratory, University of Texas Medical School, Houston, Texas 77030.

After familiarization with the recording chamber, each of 3 rabbits was presented with a novel odor while recording from an 8 x 8 electrode-array on the surface of the olfactory bulb (bandpass: 20-200 Hz, 3db). The Hausdorff number (HN) is a mathematical descriptor of the number of independent dimensions that appear to generate an observed dynamical process; it can be fractional. Pre-odor epochs (500 msecs each) had HNs that were the SAME, both spatially (mean-HN = 5.04 + 0.02) and temporally (mean HN = 5.04 + 0.02SD). After the odor, the HNs briefly INCREASED ($P<.01$) to new values (6.03 + 0.02), lasting for some seconds, before returning to control. Following only 2 trials of habituation, there was a DECREASE in the odor-evoked HNs. All HNs observed were fractional, with statistical significance. All electrodes showed the same HNs at all times. All HNs had clearly saturated correlation dimensions (15 embedding dimensions); convergence was clear with only 320 digitized data points in the epoch. These results suggest that the electric activities throughout the bulb may be characterized spatially by a single global chaotic attractor, the dimensionality of which is event-related.

72.3

HYSTERESIS, MEMORY & ATTENTION IN ELECTRONIC NEURAL NETWORKS. **J.D. Daniels, Laura Sewall* & C. Brennan***. Div. of Engineering. & Dept. of Psyc., Brown Univ., Prov., RI. 02912.

Connectionist neural network models can be faulted for low memory capacity. Two ways to add biologically plausible memory are with hysteresis non-linearities and with integrators.



In a one-layer neural network, simulated on a computer, we added sigmoid-shaped hysteresis functions connected to leaky integrators at the outputs of the network's Σ amplifiers.

When properly adjusted, the resulting system exhibits some features of attention: An output representing a particular input feature can lock in its response in spite of subtractive and additive noise; and reaction times to cued inputs are faster than un-cued.

If the hysteresis is too wide, modifiable connections (synapses) cannot change enough for the system to learn; if the integration is too slow with respect to input frequency, learning is also impaired.

A NEURAL NETWORK MODEL SHOWING THE ADAPTABILITY OF CONDITIONING. Alex X. D. Yang. (SPON: Charles J. Smith). Department of Physiology, School of Medicine, SUNY, Buffalo, NY 14214.

The adaptability of conditioning was studied with a neural network model. The network consists of neurons interconnected by Hebbian synapses, and works according to complementary principle, a way to store and organize associative memory into a network. Generalization, differentiation and extinction of conditioning were observed, suggesting the complementary principle a possible mechanism by which information is stored in neural tissue.

PRESENCE OF EYEBLINK CONDITIONING IN THE DECEREBRATE DECEREBELLATE RABBIT. T.M. Kelly, J.D. McAlduff* and J.R. Bloedel. Division of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85016.

Lesioning studies have suggested that specific regions of the cerebellar cortex and nuclei are essential for classical conditioning of the nictitating membrane response (NMR) and eyeblink reflex. Although the impairment of the conditioned response (CR) with the ablation of these areas has been widely attributed to the destruction of sites necessary for memory trace formation, data from other experiments imply that the motor aspects of this behavior may be more directly affected. We report here that lesions of the cerebellum including all of the cerebellar nuclei and the overlying cortex do not prevent conditioning of the eyeblink reflex in decerebrate rabbits.

Naive rabbits were decerebrated at a precollicular level, the cerebellar nuclei were aspirated bilaterally, and the remaining cortex ipsilateral to the stimulated eye was removed except for the tip of the hemisphere. A 4 kHz tone was used as the conditioned stimulus (CS) and either electric shock to the periorbital area or corneal air puff was used as the unconditioned stimulus (US). During training, the CS began 350 ms prior to the US and the two were coterminus.

Cerebellar lesions did not prevent conditioning. Rather, CR's were evoked 100-150 ms prior to the US during paired trials and persisted during unpaired trials until extinction was complete. When conditioning was repeated with an interstimulus interval of 500 ms, the same temporal relationship between CR and US was maintained. These results indicate that the cerebellum is not necessary for conditioning of the NMR and eyeblink response in the decerebrate rabbit. Supported by NIH grant# NS21958.

ADAPTIVE GAIN CONTROL OF THE VESTIBULO-OCULAR REFLEX IN GOLDFISH. I. HEMI-CEREBELLECTOMY. R. Baker, M. Weiser*, J.G. McElligott. Dept. Physiol. & Biophys., NYU Med. Ctr., New York, N.Y. 10016 and Dept. Pharmacol., Temple Univ. Sch. of Med., Philadelphia, PA 19140.

Cerebellectomy in either naive goldfish or those with prior VOR training immediately resulted in VOR gains larger than 1.0 (Michnovicz & Bennett, Exp. Brain Res. 66: 287-294, 1987). Those findings were extended by studying adaptive gain control up to several months following various cerebellar lesions. Sinusoidal vestibular and visual stimuli were employed (0.032-2.0 Hz) at 8-40°/sec. Horizontal eye movement gain (eye velocity/head velocity) was tested after training for 4-7 hours. Immediately following hemi-cerebellectomy the adaptive gain modification was partially retained for the eye on the intact side. Combined visual-vestibular interaction produced nearly symmetrical control of velocity in both eyes. One month later adaptive gain training produced nearly normal gain modifications for the eye on the intact side. Gain changes in the contralateral eye occurred to a lesser, more varied extent. In only one case was adaptive gain conjugate. We conclude that normally the cerebellum is a major, if not essential, pathway for adaptive gain control of the velocity of the ipsilateral eye. These data indicate that symmetrical eye velocities are attained through brainstem pathways which, as the next abstract (Weiser et al.) demonstrates, are also modifiable. Supported by EY02007 and NS13742.

72.7

ADAPTIVE GAIN CONTROL OF THE VESTIBULO-OCULAR REFLEX IN GOLDFISH. II. TOTAL CEREBELLECTOMY. M. Weiser*, J.G. McElligott, R. Baker. Dept. Pharmacol., Temple Univ. Sch. of Med., Philadelphia, Pa. 19140 and Dept. Physiol. & Biophys., NYU Med. Ctr., New York, N.Y. 10016

Our accompanying abstract demonstrated retention of adaptive gain control of the VOR following hemi-cerebellectomy. In this study we observed, in 7 of 9 goldfish, the presence of an adaptive gain modification of the VOR in the complete absence of the cerebellum. After acute cerebellectomy that excluded the valvula, VOR gain, typically at lower frequencies, was slightly higher than 1.0. Within the first post-operative month VOR gains stabilized at 1.0 independent of the extent of adaptive gain control that eventually returned. In all experiments, the response to optokinetic and vestibular stimuli alone as well as their interaction remained remarkably unaltered, except for: 1, a significant increase in eye velocity bias; 2, an increasing inability to suppress eye velocity; 3, an asymmetrical adaptive gain control of individual eye velocity and 4, a less robust amplitude of adaptive gain regulation. We conclude that a functional reorganization, unique for each animal, is present in the absence of the cerebellum allowing for continuous VOR recalibration. These observations indicate that neither the cerebellar cortex nor nuclei are necessary for producing the type of adaptive gain control which has been characterized as motor learning. Supported by EY02007 and NS13742.

72.8

CONDITIONING-INDUCED ACTIVATION OF PROTEIN KINASE C IN CEREBELLAR LOBULE HVI. B.Bank*, A.M.Scharenberg*, and D.L.Alkon (SPON: W. Yonekawa). Lab. Mol. Cell. Neurobiol., NIH-NINCDS, Park-5, Rm.435, Bethesda, MD 20892.

Based on previous work in our laboratory we were interested in determining whether PKC redistribution occurs in cerebellar lobule HVI as a result of NMR conditioning. This structure has been shown to be crucial for acquisition and retention of the NMR. PKC was quantified by [^{3}H] phorbol dibutyrate binding to cytosolic and membrane fractions from HVI in a triton X-100/phosphatidylserine mixed micellar assay. The right and left HVI from conditioned, pseudoconditioned (explicitly unpaired CS & US) and naive animals were compared 24h after conditioning. The right eye (and therefore right HVI) was conditioned so that the left HVI could serve as a within animal control. There was a significant redistribution of PKC from cytosol to membrane in HVI of conditioned and pseudoconditioned animals on the right side only. Further comparison of right HVI from conditioned and pseudoconditioned animals revealed a greater decrease in cytosolic PKC and a decrease in total PKC (membrane + cytosol) in the conditioned group. This indicated a greater degree of PKC activation in conditioned HVI resulting in limited proteolysis of PKC, a known consequence of extensive PKC activation. As predicted by the observed PKC redistribution in the right HVI of pseudoconditioned animals, there was a corresponding change in this groups' behavior in the form of increased NMR amplitudes in response to the US over three days of training. These findings suggest that long-term modification of PKC distribution may accompany acquisition and retention of classically conditioned reflexes as well as contribute to pseudoconditioning-induced modification of pre-existing reflexes.

72.9

CONDITIONING-SPECIFIC CHANGES IN HIPPOCAMPAL ^{3}H-PHORBOL-12, 13-DIBUTYRATE AS DEMONSTRATED BY QUANTITATIVE AUTORADIOGRAPHY. J. L. Olds, M. L. Anderson*, L. D. Staten*, D. L. Alkon
Laboratory of Mol. Cell. Neurobiol./NINCDS/NIH Bethesda Md. 20892.

The effect of classical conditioning on the hippocampal distribution of protein kinase C was measured as the changes in specific binding of 3H-PDBU using a modification of the autoradiographic method of Worley et al., (J. Neurosci, 1986). Rabbits were conditioned by paring a 400 msec 1 kHz tone (CS) with a coterminating 150 msec periorbital shock (UCS) for 3 days. Some controls received explicitly unpaired stimuli while others were unmanipulated. Mean bound ^{3}H-PDBU was determined for each animal by computerized averaging of activity along transept lines in autoradiograms of coronal sections of the dorsal hippocampal CA1 region with an MCID Imaging System (Imaging Research inc.). Conditioned animals had significantly higher binding (33 nCi/g±5 vs. 21 nCi/g±3) than pooled pseudoconditioned and naive rabbits (p<.01 Student t-test). These results confirm and extend the earlier findings of Bank et al. (PNAS 1988) and demonstrate that the quantitative autoradiographic method can be used to measure the distribution of learning-dependent changes in protein kinase C within the hippocampus.

72.10

INCREASED CALCIUM-DEPENDENT PHOSPHORYLATION IN RABBIT HIPPOCAMPUS AFTER NM/EYELID CONDITIONING. J.J. Lo Turco, B. Bank*, K.A. Tennes-Rees*, R.J. Delorenzo, and D.L. Alkon. NIH-NINCDS, Park-5, Rm 435, Bethesda, MD 20892. Dept. Neurol., Med. Col. VA, Richmond, VA 23298.

The effect of NM/eyelid conditioning on *in vitro* Ca^{2+}- dependent protein phosphorylation in rabbit hippocampus was studied. 24 h after animals were well trained, hippocampal slices were prepared, and the CA1 and dentate gyrus regions were dissected out. Phosphoproteins were labelled with [γ^{32}P] ATP in the presence of high [Ca^{2+}], and visualized by SDS PAGE. Samples from conditioned, pseudoconditioned and naive rabbits were compared. ^{32}P incorporation was quantified by optical density scanning. There was a 56% increase in the phosporylation of the 50 KD subunit of CaM kinase II (and a corresponsding increase in the 60 KD subunit) relative to pseudoconditioned and naive controls (conditioned: 266.0 ± 12.0, controls: 170.8 ± 11.4, t=5.5, p<.001). There was also a dramatic increase in the phosporylation of a 47 KD phosphoprotein in all conditioned animals. This band was barely detectable in controls. This protein may be F1 (B-50), a substrate for protein kinase C. This is consistent with previous work demonstrating long-term activation of protein kinase C in hippocampal CA1 cells after NM conditioning. Conditioning-specific changes in phosphorylation were not apparent in the dentate gyrus. These results, and those of Bank et al. (1988) indicate that the Ca^{2+}- dependent kinases, CaM kinase II and protein kinase C are persistently activated in rabbit hippocampal CA1 cells by classical conditioning.

72.11

SYNAPTIC PLASTICITY IN THE PARALLEL FIBER-PURKINJE CELL JUNCTION IN ISOLATED TURTLE CEREBELLUM C.Y. Chan, A. Lee* and S.M. Wong* Dept. of Physiology, CUNY Med. School, CCNY, New York, NY 10031.

Synaptic plasticity at the parallel fiber (PF)-Purkinje cell (PC) junction was studied using intracellular recording. PFs were stimulated, without conjoint climbing fiber activation, by identical pairs or trains of current pulses delivered through bipolar electrodes placed on the pial surface. Components were isolated from postsynaptic potentials: Pure EPSPs were selected from on-beam responses. Pure IPSPs were recorded off-beam and their reversal potentials checked. Typically, EPSPs were sensitized by double stimulations. We distinguished 2 types of IPSPs by amplitude and reversal potential. At present, we have tested the type that reversed around 70mV. Double stimulation caused IPSP sensitization that was interval-dependent, peaking around 150 ms; but at longer intervals, IPSP depression occurred, peaking around 300 ms. With a stimulus train, use-dependence was characterized by sensitization of the first few IPSPs and depression of later ones. IPSP depression was reduced by increased stimulus strength. These changes in synaptic potentials were unlikely to result from changes in PF spike amplitude, as our field potential recording showed that the amplitude of PF population spikes did not vary proportionately with postsynpatic potentials. These apparently homosynaptic plastic properties may play a role in nonassociative learning. (Supported by PSC/CUNY 667228 and PHS 2-S07-RR07132).

72.12

ELECTROMYOGRAPHIC RECORD OF EYE WITHDRAWAL CONDITIONING IN THE RESTRAINED OR FREELY MOVING EYE OF THE GREEN CRAB. R. D. Feinman, C. I. Abramson* and R. R. Forman. SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203.

Electromyograms (EMGs) were recorded from the main eye retractor muscle (19a) of the green crab, *Carcinus maenas*, during classical conditioning of eye retraction. In the conditioning procedure, a mild vibration on the carapace, which has no effect on naive animals, was used as a conditioned stimulus (CS). Pairing of the CS with a brief puff of air to the eye as an unconditioned stimulus (US) rapidly led to acquisition of eye retraction during CS presentation. The EMG record was consistent with reports in the literature. Air puff causes retraction of the eye into the carapace and this correlates with a rapid spiking pattern due to the main retractor neuron followed by tonic firing (as long as the eye remains retracted) due to a slow retractor. This reflex is known to be independent of proprioceptive feedback and the EMG pattern in response to air-puff is not changed if the eye is immobilized. We found that the acquired EMG response to the CS was qualitatively the same as the response to the US but was frequently more robust. Using the EMG record as an indicator, the time course of conditioning was found to be similar in restrained eyes and freely moving eyes. Animals that were conditioned with eyes immobilized showed normal patterns of behavior in extinction and re-acquisition when tested after the eyes were freed. The results indicate that the absence of proprioceptive feedback observed in the eye withdrawal reflex of the crab is preserved in classical conditioning. The results suggest that attenuation of the aversive stimulus is not a major factor in acquisition and limit the possible mechanisms of learning that can account for this type of conditioning. (Supported in part by funds from James C. Marlas and the Research Foundation of the State University of New York).

REGIONAL LOCALIZATION OF RECEPTORS AND TRANSMITTERS II

73.1

UNIFORMITY IN THE DISTRIBUTION OF THE MAJOR NEUROTRANSMITTER RECEPTORS TYPIFIES THE PRIMARY MOTOR CORTEX OF ADULT RHESUS MONKEY. M.S. Lidow, P. Rakic, D.W. Gallager, and P.S. Goldman-Rakic. Section of Neuroanatomy, Yale University, School of Medicine, New Haven, CT 06510

Primary motor cortex (Brodmann's area 4) is cytoarchitectonically and functionally different from the rest of the neocortex. 2Here we show that this cortical area is also unusual in the distribution of neurotransmitter receptors. We used the *in vitro* autoradiographic techniques and quantitative densitometry to compare the distribution of norepinephrine: α-1, α-2, β-1 and β-2; acetylcholine: M-1 and M-2; serotonin: S-1 and S-2; dopamine: D-1 and D-2; GABA-A and benzodiazepine receptors in primary motor cortex with the distribution of these receptor subtypes in somato-sensory, prefrontal and occipital cortex of four adult rhesus monkeys. Our results show that in the primary motor cortex all neurotransmitter receptor subtypes have identical laminar distributions with the highest concentrations in layers I and II and the upper strata of layer III. The density of these receptors in the deep strata of layer III and in layers V and VI were significantly lower. The similar distribution of the different neurotransmitter receptors in primary motor cortex stands in contrast to the distribution of neurotransmitter receptors in all other cortical areas examined, where each receptor subtype had an individual and often very distinct pattern of localization. The high concentration of neurotransmitter receptors in the upper strata of primary motor cortex may be associated with the paucity of thalamic input and the virtual absence of granular cells in the middle and deep layers of this cortical area. Supported by U.S. Public Health Service Grants NS22807 and NS07224.

73.2

PHOTOAFFINITY LABELING OF BENZODIAZEPINE RECEPTORS IN SLIDE-MOUNTED SECTIONS AND β-ADRENERGIC RECEPTORS IN INTACT CELLS. *P. Ernsberger, V. Arango, L. Iacovitti, and D.J. Reis* Div. of Neurobiology, Cornell Univ. Med. Coll., New York, NY 10021

Photoaffinity labeling is often used to identify receptors in membrane fractions, but has never been applied to tissue sections or intact cultured cells. We sought to characterize photoaffinity labeling of (a) the GABA-benzodiazepine receptor complex in brain sections and (b) β-adrenergic receptors in cultured glial cells. Slide-mounted brain sections were incubated with 1 nM ^{3}H-flunitrazepam (^{3}H-FLU) in 170 mM Tris-HCl (pH 7.7) containing 10 μM GABA for 40 min at 4°C. Nonspecific binding was defined by 10 μM diazepam. Slides were irradiated with UV for 5 min, then either washed 2 min in buffer to remove nonspecific binding, or stripped of all but covalent binding by a 30 min wash in buffer containing 10 μM diazepam followed by dehydration in alcohol. In rat forebrain, total ^{3}H-FLU binding (2 min wash) was 77 ± 7 dpm/mm^2, of which 37 ± 3 dpm/mm^2 was nonspecific (N = 4 experiments, 6 sections each). Covalent ^{3}H-FLU binding was 31 ± 2 dpm/mm^2, of which 8 ± 1 dpm/mm^2 was nonspecific (N = 9). Sections not irradiated with UV exhibited virtually no covalent labeling (0.3 ± 0.03 dpm/mm^2). Slides were dipped in emulsion, exposed 4 wk, and developed for high-resolution autoradiographic mapping. Neonatal rat glia were cultured on chambered slides and incubated with 0.1 nM ^{125}I-iodocyanopindolol diazirine (^{125}I-ICYPD) in culture medium at 37°C. Nonspecific binding was defined by 10 μM (-)-propranolol. In the dark, binding was rapid ($t_{1/2}$ = 9 min) and reached plateau by 40 min. A 10 min wash at 4°C selectively reduced nonspecific binding. Glia were irradiated with UV for 4 min, fixed in paraformaldehyde, extensively washed, and stained with antibodies to GFAP, a specific glial marker. Covalent ^{125}I-ICYPD binding was 24 ± 2 dpm/mm^2, of which 7 ± 2 dpm/mm^2 represented nonspecific binding to the plastic slide and 7 ± 1 dpm/mm^2 was nonspecifically bound to the cells (N = 3). Autoradiographic grains were selectively localized over positively stained glia relative to adjacent background. We conclude that cellular localization of receptors is made possible by photoaffinity labeling of receptors in tissue sections and in intact cells.

QUANTITATIVE AUTORADIOGRAPHY DEMONSTRATES INCREASED TOTAL AND HIGH-AFFINITY β-ADRENERGIC RECEPTOR BINDING IN CEREBRAL CORTEX OF SUICIDE VICTIMS. *V. Arango, P. Ernsberger, P. Marzuk*, M. Stanley, D.J. Reis and J.J. Mann,* Div. of Neurobiology and Lab. of Psychopharmacology, Cornell Univ. Med. Coll., New York, NY 10021

We have reported an increase in 5-HT_2 receptors in the prefrontal cortex (PFC) of suicide victims by both membrane saturation assays and quantitative receptor autoradiography (Arango et al., *Soc Neurosci Abst* 13:216, '87) and an increase in β-adrenergic receptors in PFC membranes (Mann et al., *Arch Gen Psychiatry* 43:954-9, '86). Using quantitative autoradiography we sought to determine: a) the normal cortical distribution of β-adrenergic receptors; b) whether the increased receptor density observed in brains of suicide victims is localized to a specific cortical layer and region; and c) whether this increase involved high-affinity receptors coupled to adenylate cyclase. Suicide victims and controls were paired for assays by matching for postmortem delay, age and gender (PFC = 8 pairs; temporal cortex (TC) = 9 pairs). Toxicology was negative in all cases for centrally active drugs. Slide-mounted sections (15 μm) were incubated in Tris-sucrose (pH 7.4) containing 2 mM $MgCl_2$ and 60 pM ^{125}I-iodopindolol. Total specific and high-affinity sites were selectively blocked by incubations with 100 μM and 17 nM (-)-isoproterenol (ISO), respectively (Arango et al., *Fed Proc* 46:390, '87). Sections were exposed to Ultrofilm (40-60 h). Digitized images representing non-specific (with 100 μM ISO) or low-affinity plus non-specific binding (with 17 nM ISO) were subtracted from images representing total binding and calibrated against standards. In both groups β-adrenergic receptors were evenly distributed across cortical layers in PFC and TC. Total specific binding was increased 36 ± 6% ($p < 0.001$) in PFC and 16 ± 6% ($p < 0.05$) in TC of suicide victims *vs.* controls. High-affinity sites were increased 56 ± 20% ($p < 0.05$) in TC of suicide victims and 40 ± 24% in PFC ($p > 0.05$). We conclude that: a) β-adrenergic receptors are evenly distributed across cortical layers; b) there are more binding sites in TC than in PFC; c) β-adrenergic receptors are increased in PFC and TC of suicide victims; and d) at least in TC this increase involves functionally coupled sites. (Supported by PHS grant MH40210)

DUAL EFFECTS OF BM-5 IN NEUROPHARMACOLOGICAL INVESTIGATIONS. V.H.Sethy, T.P.Boyle*, J.W.Francis* and R.J.Collins*, CNS Research, The Upjohn Company, Kalamazoo, MI 49001.

The effects of BM-5 vary from tissue to tissue due to differences in muscarinic receptor reserve (Ringdahl et al., JPET 242:464, 1987). We have further investigated BM-5 in neuropharmacological tests, and the results have been compared to those obtained with oxotremorine (OX) and atropine (AT). Both OX and BM-5 produced salivation and lacrimation, whereas only OX elicited tremors (ED50: 0.1 mg/kg) in mice. Atropine blocked muscarinic agonist effects of both OX and BM-5. Furthermore, BM-5 also blocked OX-induced tremors. The ratio of the Ki's of OX, BM-5, and AT in (3H)-QNB and (3H)-OX-M binding was 240, 29, and 0.63, respectively. OX or AT dose-dependently increased or decreased acetylcholine (Ach) concentration in the striatum, hippocampus, and cerebral cortex of rats, respectively. BM-5 significantly ($p<0.01$) reduced striatal Ach content, and this effect was dose-independent. The hippocampal and cortical Ach content was not altered by BM-5. Like OX, BM-5 significantly ($p<0.01$) decreased (3H)-Ach release from hippocampus slices in the presence of HC-3. However, like AT, BM-5 significantly ($p<0.01$) increased release of (3H)-Ach in the presence of eserine. Both AT and BM-5 blocked OX-M-induced phosphoinositide (PI) hydrolysis in the cerebral cortex. However, BM-5, like OX, stimulated PI hydrolysis in the parotid gland. Thus, the in vitro and in vivo studies indicate that BM-5 is a partial agonist of muscarinic receptors and, as a result, has the ability to elicit both agonist and antagonist effects in central and peripheral tissues.

CHARACTERIZATION OF [^{3}H]ALPRAZOLAM BINDING TO CENTRAL BENZODIAZEPINE RECEPTORS IN THE RAT BRAIN. J.P. Yezuita*1, R. T. McCabe[1], D.R. Mahan*2, R.B. Smith*2, and J.K. Wamsley[1]. (SPON: B. Grosser). [1]Dept of Psychiatry, U of UT, Sch of Med, SLC, UT 84132, and [2]Upjohn Co., Kalamazoo, MI 49001.

The triazolobenzodiazepine alprazolam (ALP) is a selective central benzodiazepine (BZ) receptor agonist and used for treatment of panic disorder and anxiety associated with depression. The availability of [^{3}H]ALP has allowed the analysis of binding characteristics to membranes and tissue sections of rat brain. The optimal binding conditions for defining BZ receptors with [^{3}H]ALP were obtained from association, saturation, and displacement studies. Tissues were incubated in 50 mM Tris-HCl (4°C) with [^{3}H]-ALP and equilibrium was reached after 45 min. Saturation analysis of [^{3}H]ALP revealed a K_D of approx. 3 nM. Displacement of [^{3}H]ALP was examined by including related and unrelated ligands. The order of potency for competitive inhibition from BZ sites is triazolam>clonazepam>alprazolam>Ro15 1788>BCCE>quazepam. Both GABA and pentobarbital enhanced [^{3}H]ALP binding. Autoradiographic localization of [^{3}H]ALP binding sites showed a distribution consistent with both BZ receptor subpopulations. These results demonstrate that [^{3}H]ALP binding is saturable, specific, and of high affinity and support previous reports that [^{3}H]ALP has properties related to other central BZ agonists.

73.6

Characterization and Localization of Transferrin Receptors in the Rat Brain. J. Pablo*, S. M. Efange*, D.D. Flynn, W. J. Weiner, and D. C. Mash. Departments of Neurology and Pharmacology, University of Miami School of Medicine, Miami, Fl, 33101.

Transferrin, an iron binding transport protein, and its receptor may regulate the intracellular delivery and subsequent sequestration of iron in the central nervous system. Recent studies have demonstrated that iron uptake by neuron and glial cultures is transferrin-mediated (Swaiman and Machen, Neurochem. Res. 9:1241-1248,1986). Using [^{125}I]-ferrotransferrin, we have characterized the binding site for transferrin on membrane fractions prepared from the rodent forebrain. The distribution of transferrin receptors in the rat brain was investigated by in vitro autoradiography. For binding assays, forebrain samples were homogenized with a Brinkmann Polytron in 10 mM phosphate buffer (pH 7.4) containing 150 mM NaCl. The homogenate was centrifuged at 48,000 g for 10 minutes with an intermediate wash in fresh buffer. Membranes were incubated in phosphate buffer containing bacitracin (80 ug/ml), PMSF (0.5 mM), 0.2% bovine serum albumin and increasing concentrations (0.1 - 50 nM) ^{125}I-labelled and unlabelled transferrin. With 20 - 30 mg of membranes, the amount of specific transferrin binding was 70%. Saturation binding analysis revealed a apparent single class of sites with a dissociation constant of 1.8 nM and a binding site density of 15 pmol/g wet weight original tissue. Estimates of the kinetically determined Kd for forebrain membranes were within the 2 - 5 nM range, in agreement with the equilibrium measurements. Apotransferrin and ferrotransferrin competitively displaced the binding of [^{125}I]-transferrin, while ferritin, cytochrome-C and ceruloplasmin failed to compete for the binding site. Autoradiographic localization studies demonstrate that the distribution of transferrin receptors in the CNS is heterogeneous. The distribution of [^{125}I]-transferrin binding sites is more widespread than the regional content of iron determined with iron histochemistry.

AUTORADIOGRAPHIC VISUALIZATION OF GLUTAMATERGIC NERVE TERMINALS IN RAT BRAIN UTILIZING ATP-DEPENDENT VESICULAR UPTAKE. P. E. Kish* and T. Ueda (SPON: M. Gnegy) Mental Health Research Institute, University of Michigan, Ann Arbor MI 48109.

ATP-dependent glutamate uptake has previously been demonstrated in purified vesicle preparations. Because of the unique properties of the vesicular uptake system, it has been proposed that this plays a crucial role in selecting glutamate for neurotransmission. In this study we have utilized the specificity of of the vesicular uptake system for glutamate to visualize brain areas having glutamatergic presynaptic terminals. Frozen sections of brain were incubated in a mixture containing ATP, ^{3}H-glutamate, the membrane permeabilizing agent digitonin, and high concentrations of aspartate. Aspartate is a competitive inhibitor for glutamate at the high-affinity plasma reuptake system and the postsynaptic receptor, effectively blocking non-vesicular glutamate uptake and binding. Special washing and fixation techniques are required to immobilize the ATP-dependent accumulation of glutamate. We demonstrate that the properties of the glutamate uptake system in frozen sections are highly similar to those observed in the intact synaptic vesicles, namely ATP-dependency, stimulation by chloride, sensitivity to electrochemical proton gradient dissipaters, and specificity for L-glutamate. Extensive areas of the brain are believed to utilize glutamate as a neurotransmitter. Autoradiography of the ATP-dependent glutamate uptake shows regions within the cortex, striatum, thalamus, and layers of the hippocampus and cerebellum with high levels of uptake. This represents the first autoradiographic demonstration of glutamatergic areas in the brain utilizing a purely presynaptic process for detection. (Supported by NSF Grant BNS 8509679.)

FUNCTIONAL ORGANIZATION OF THE UTRICULAR MACULA IN THE CHINCHILLA. J. M. Goldberg, G. Desmadryl*, R. A. Baird and C. Fernández*. Neurobiology Laboratories, University of Chicago, Chicago, IL, USA.

Three kinds of endings are labeled in the utricular macula after extracellular injection of horseradish peroxidase (HRP) into the vestibular nerve. Calyx units supply one or a few type I hair cells in the striola. Bouton units contact several type II receptors in the extrastriola. Dimorphic units supply all parts of the crista and innervate both types of sensory cells. More than 90% of the afferents are dimorphic units, less than 10% are calyx units, and less than 1% are bouton units. Intra-axonal HRP techniques were used to label 52 afferents that had been characterized in terms of their excitatory tilt directions, discharge regularity, and responses to externally applied galvanic currents and to sinusoidal linear head accelerations. The excitatory tilt directions of labeled afferents were consistent with the presumed morphological polarization of the hair cells they innervate. Calyx and striolar dimorphic units are irregularly discharging, phasic afferents. Extrastriolar dimorphic units are regularly discharging and tonic. Galvanic sensitivity (ß) was related to discharge regularity and not to terminal morphology as such. Acceleration gains in irregular units show a 10-20x increase as one proceeds from dc to 2Hz, whereas those of regular units are more nearly constant. Because of these differences in response dynamics, it is best to compare units in terms of their dc gains. Calyx units have dc gains (g_A) that are 3x smaller and galvanic sensitivities (ß) that are 3x larger than the corresponding values for dimorphic units. We can estimate the dc synaptic input (g_S) by the formula, $g_S = g_A/ß$. The values of g_S are 10x lower in calyx, as compared to dimorphic, units. The relatively low g_S of calyx units may reflect the small number of hair cells they contact and the low gain of calyx synapses. The latter may be related to the small number of release sites observed in type I hair cells.

74.2

PHYSIOLOGICAL IDENTIFICATION OF CALYX, DIMORPHIC AND BOUTON AFFERENTS IN THE VESTIBULAR NERVE OF THE SQUIRREL MONKEY. A. Lysakowski, L. B. Minor, C. Fernández* and J.M. Goldberg. Neurobiology Laboratories, The University of Chicago, Chicago, IL, 60637.

Intra-axonal HRP techniques have been used in the chinchilla to relate the peripheral innervation of semicircular-canal afferents with their discharge properties (Soc. Neurosci. Abstr. 12:773). Units can be divided into two classes on the basis of their discharge regularity and rotational gains. The first class, consisting of dimorphic (D) and bouton (B) units, include low-gain, regular and high-gain, irregular units. The second class are calyx (C) units; they are irregular and have low rotational gains. Only a few B fibers were labeled. The present study had two aims: 1) to determine if the same groups exist in the squirrel monkey; 2) to use conduction velocities to identify a group of thin, presumably B fibers. Rather than label axons, we relied on the physiological properties of the afferents. Antidromic conduction velocities were obtained by placing stimulating electrodes in the central part of the vestibular nerve. Discharge regularity was expressed as a normalized coefficient of variation (cv*). Rotational gains and phases (response dynamics) were measured to 2 Hz, sinusoidal head rotations.

In the monkey, as in the chinchilla, there are two groups of afferents. For the first group, there is a positive, nearly linear relation between cv* and rotational gain. The second group consists of irregular units with low rotational gains. Conduction velocities are slightly higher in low-gain (C), than in high-gain (D) irregular units. Presumptive B units were identified by their low conduction velocities; they were regular units whose discharge properties were indistinguishable from those of other regularly discharging, presumably D units. Sensitivity to perilymphatic galvanic currents and rotational response dynamics were related to cv* and not to the afferent type (C, D or B) as such.

(Supported in part by NIH grant NS-01330 and by NASA grant NAG 2-148.)

74.3

THE RELATIONSHIP BETWEEN DISCHARGE REGULARITY AND FREQUENCY OF PRIMARY AFFERENTS OF THE POSTERIOR SEMICIRCULAR CANAL OF THE TOADFISH, OPSANUS TAU. T.Tricas and S.M.Highstein. Depts. of Otolaryngology, Anatomy and Neurobiology, Washington University School of Medicine, St. Louis MO 63110.

Caloric induced modulation of the resting discharge rate of primary afferents of the posterior semicircular canal of the toadfish, Opsanus tau was used to study the relationship of discharge regularity (measured as the coefficient of variation = standard deviation of the interspike interval/mean interval, CV=SD-ISI/mean ISI) to the frequency of discharge. Mean, resting rate for 98 fibers in 6 fish was 36.4 spikes/sec ± 25.2; range = 2 - 98). Caloric stimulation significantly changed the resting discharge rate in 75% of fibers tested; firing rate increased during application of heat and decreased when cooled. Ninety-one % of responsive fibers showed a positive and significant curvilinear relationship between mean ISI and CV. Fibers with high rates of resting discharge tended to have better loglinear changes in CV with firing rate than those with lowers resting rates. Normalization of data should lead to the formulation of a parameter called CV*, unique to each fiber, and independent of resting discharge frequency. We will then investigate the relationship of CV* to the response dynamics of individual primary afferents.

SEMICIRCULAR CANAL AFFERENT RESPONSE DYNAMICS TO ROTATIONAL AND MECHANICAL STIMULATION. J.D. Dickman[1] and M.J. Correia[2]. Depts. of Otolaryngology[12]. and Physiology & Biophysics[2], Univ. of Texas Medical Branch, Galveston, Texas, 77550.

Recently, we developed a method for discrete and reproducible mechanical stimulation of the semicircular canals that allows the animal to remain stationary (Dickman, Reder, & Correia, J. Neuroscience Meth., 1988, in press). The mechanical technique provides a broad frequency range of stimulation and was shown to elicit responses that are directly comparable to those produced by natural rotational stimulation. In the present study, we recorded extracellular single fiber responses from horizontal semicircular canal afferents (HCA) in the pigeon (Columba livia) elicited by both rotational and mechanical stimulation. Sinusoidal frequencies ranged from 0.01 to 15 Hz. Gain and phase values were determined for each response using a fitted sine wave to the binned average of several stimulus cycles. To date, complete protocols have been recorded in 63 HCA units to mechanical stimulation, with complete rotational data also being obtained in 11 of these fibers. For mechanical stimulation, intensity functions of displacement magnitude indicated that for most HCA fibers, a linear range of response occurred between ±0.5 and ±5 μ. Stimulus displacements from ±5.0 to ±10 μ typically elicited responses that showed evidence of rectification and saturation. Bode diagrams of HCA response dynamics indicated that the S-shaped gain and U-shaped phase plots for mechanical and rotational stimulation were analogous when plotted re: mechanical displacement position and re: rotational velocity, respectively. In addition, HCA fiber responses produced by rotational stimulation with a canal fistula introduced (exposed canal duct for concurrent mechanical stimulation) were similar to those reported by Anastasio et al. (J. Neurophys., 1985, 54, 335-347). For example, with the present results, at 0.1 Hz (10 deg/sec max velocity) HCA irregularly firing (CV > 0.2) fibers (N=4) had a mean gain (±SEM) of 1.43 (0.39) $s \cdot s^{-1}/d \cdot s^{-1}$ and a mean phase lead of 31.8 (11.5) degrees. Similarly, at 10 Hz, HCA fibers had a mean gain of 4.17 (0.94) $s \cdot s^{-1}/d \cdot s^{-1}$ and a mean phase lead of 41.6 (7.5) degrees.

Supported in part by NASA grant NAGW-70 and NSF grant BNS 8709303.

74.5

CHANGES IN VISUAL AND VESTIBULAR FUNCTION AFTER CANAL PLUGGING IN THE MONKEY. B.Cohen, D.Helwig,* T.Raphan, J.I.Suzuki,* K.Kaga* and A.Eden. Depts. of Neurology, Physiology, Otolaryngology and Computer Science, Mt. Sinai School of Medicine, New York 10029, Brooklyn College and Teikyo University, Tokyo, Japan.

The semicircular canals were plugged bilaterally in rhesus and cynomolgus monkeys to study effects on OKN, OKAN, the VOR and nystagmus induced by off-vertical axis rotation (OVAR). The lateral canal nerves were also cut bilaterally in several animals. Lesions were verified histologically. The initial jump of horizontal OKN and steady state OKN velocities were enhanced after lateral canal plugging, and the time constant of OKAN became shorter. Thus, direct visual pathways had a higher gain after canal lesions, although velocity storage had habituated. Horizontal but not vertical OKAN was abolished by lateral canal nerve section, but a horizontal component of vestibular nystagmus or OKAN reappeared as animals were tilted upward re the axis of rotation, as previously found by Boehmer and Henn (1985). This demonstrates that the vertical canals can elicit a horizontal component of eye movement and velocity storage, dependent on head position re gravity, even after all input from the lateral canals is lost. Nystagmus was induced by OVAR after all six canals were plugged, as noted by Correia and Money, (1970). The gain decreased by about half, the position dependent velocity modulations increased and the time constant of the velocity storage integrator was shortened. Results were similar after the lateral canals were plugged. There was no effect of anterior and posterior canal plugging on OVAR. This suggests that the lateral canals play the major role in determining the dynamics and steady state properties of the horizontal component of slow phase velocity generated by the velocity integrator. Supported by NS00294, EY04148, EY01867 and a grant from the Young Men's Philanthropic League.

SIGNAL PROCESSING IN THE VESTIBULAR NUCLEI DURING OFF-VERTICAL AXIS ROTATION (OVAR). H. Reisine, T. Raphan, B. Cohen, E. Katz* Depts. of Neurology, Physiology, Mt. Sinai School of Medicine, NY, NY, 10029 and Dept. of CIS, Brooklyn College, Brooklyn, 11210.

Extracellular unit activity was recorded in the vestibular nuclei to determine the role of different classes of units in generating compensatory eye velocity in three dimensions during OVAR. Units related to lateral semicircular canal activation had firing rates proportional to the bias level of the horizontal component of eye velocity during constant rotations (0 to 120 deg/sec) and showed evidence of being related to velocity storage (Raphan et al, 1979). One subclass of these neurons showed little oscillation about the bias level. Another subclass, that paused during saccades, showed a marked oscillation whose phase was time-locked to head position. These neurons were also activated during horizontal OKN and OKAN. Units activated by the vertical semicircular canals also showed evidence of processing a velocity storage component of eye velocity during OVAR. Firing rates were proportional to the bias level of horizontal eye velocity. Although the activity of these neurons was not generally related to static head orientation, it was strongly modulated during OVAR. The amplitude of the modulation increased with head velocity. Otolith related neurons showed no evidence of velocity storage and had activity modulated in accordance with head position during OVAR. Lateral and vertical canal related neurons in the vestibular nuclei appear to encode the structure of velocity storage. The oscillations in the activity of vertical canal related neurons are probably due to oscillations in the three dimensional velocity estimator (Schnabolk & Raphan, 1988) and to cross coupling within the three dimensional velocity storage integrator (Raphan & Cohen, 1988; Sturm & Raphan, 1988). The otolith related neurons probably also contribute to the eye position changes that occur during OVAR. Thus, neuronal classes in the vestibular nuclei contain the requisite signals to generate eye velocity during OVAR. Supported by EY04148, NS00294, EY01867, NAG 2-336.

THE SLOW COMPONENT OF THE VOR (VELOCITY STORAGE) DEPENDS ON COMMISSURAL CONNECTIONS CAUDAL TO THE ABDUCENS NUCLEUS. E.Katz*, J.M.B.V.deJong*, B.Cohen, J.Buettner* (SPON: H. Krieger). Depts. of Neurology & Physiology, Mt. Sinai School of Medicine, City University of New York 10029 & Universities of Amsterdam & Munich

Midline section in the medulla shortens the time constant of the VOR (Blair and Gavin, 1981) and abolishes OKAN (de Jong et al. 1980). In this study we cut commissural connections in the midline of the medulla in cynomolgus monkeys to determine effects on gains of nystagmus induced by rotation of the animal about a vertical axis in darkness, on vertical and horizontal OKN and OKAN, on the nystagmus induced by off-vertical axis rotation (OVAR) and on cross coupling of horizontal to vertical or roll OKAN (Raphan and Cohen, 1987). Lesions extended from 1 to 4 mm below the surface from the posterior border of the abducens nuclei to the obex. After operation quick phases were of normal peak velocity. Although the eyes drifted toward the midposition from lateral positions in darkness, they were held stable in light. The gains of the initial jump in slow phase velocity at the onset of rotation and of OKN were unaffected. However, the time constant of the response to constant velocity rotation fell to approximately 5 sec, the time constant of activity elicited in the semicircular canals, and the slow rise in slow phase velocity during OKN and horizontal and vertical OKAN were abolished. Despite modulations in eye position during OVAR there was no steady state velocity, and cross coupling of OKAN was lost. Each of the lost functions depends on the integrity of the velocity storage mechanism in the vestibular system. The data are compatible with the hypothesis that velocity storage depends on bilateral communication of the vestibular nuclei and/or prepositus complex through the commissural connections caudal to the abducens nuclei. Supported by NS00294 and EY01867.

74.8

MODELLING THREE DIMENSIONAL VELOCITY ESTIMATION DURING OFF-VERTICAL AXIS ROTATION (OVAR). C. Schnabolk and T. Raphan. Dept. of CIS, Brooklyn College, Brooklyn, New York, 11210.

Studies of nystagmus during OVAR suggest that gravity induced moving patterns of otolith activation are responsible for the bias component of slow phase eye velocity (Raphan & Schnabolk, 1988). The purpose of this study was to analyze the characteristics of an extension of the estimator to three dimensions. It was assumed that the estimation of head velocity was done in semicircular canal coordinates. When the head velocity was parallel to a canal axis an accurate estimate of the component of the velocity along the axis was obtained. However, while the other components of head velocity were zero, the estmated values were nonzero. Their instantaneous values oscillated and at times were 60% of the magnitude of the head velocity. Their relatve phase was 90 deg, so that the magnitude of the three-dimensional estimate was approximately constant. Each of these estimates approached zero as the angle between the head velocity and gravity increased toward 90 deg. The improvement was attributed to the standing wave form approached by the associated otolith activation pattern. In other simulations the component of the estimate of head velocity along a canal axis improved as the angle between the head velocity and the axis went to zero. In summary, this study indicates that the three dimensional estimator essentially estimates the component of head velocity perpendicular to gravity. This estimate is then normalized with regard to body orientation. Thus, the internal coordinate basis for normalization is important for determining the planes of optimal head velocity estimation during OVAR. Supported by EY04148, NS00294, EY01867, and PSC-CUNY 668285.

74.9

NEURAL NETWORK MODELLING OF VELOCITY GENERATION DURING OFF-VERTICAL AXIS ROTATION (OVAR). R. Fanelli*[1], C. Schnabolk[2], and T. Raphan[2]. Depts. of Physics [1] and Computer and Information Science[2], Brooklyn College of CUNY, Brooklyn, New York, 11210.

Modelling of slow phase velocity during OVAR has suggested that continuous compensation during OVAR arises from phase detection of otolith activation patterns (Raphan & Schnabolk, 1988). However, it is not clear how these units should be connected to obtain robust estimation over a wide range of tilt angles. The purpose of this study was to construct a neural network model to address this problem and predict the kinds of unit activity that would be necessary to implement such an estimator. A feed-forward network of 25 units trained with back propagation was used. The input units were assumed to be otolith cells with different polarization vectors and cells with delayed versions of the signals (Raphan & Schnabolk, 1988). There were two hidden units associated with each cell and its nearest neighbor. There was also one output cell coding the estimated head velocity. The network was trained with varying velocities and tilt angles over a range of ±50 deg/sec. Within the training range, the neural network model produced velocity estimates that are within 2.8 deg/sec of the input velocity. Outside the training range, velocity estimates declined consistent with the decline in steady state velocity vs. stimulus velocity in monkey (Raphan et al, 1981). Simulation of the activity in the hidden units showed that their nonlinear characteristics were mainly responsible for the robust performance of the network. It suggests that the saturation and cutoff characteristics of neurons in the central nervous system that encode velocity estimation are important for the robust performance of the system. BIOMECHANICS OF THE HEAD-NECK ARTICULATIONS AND HEAD MOVEMENT STRATEGIES IN MONKEY. W. Graf, P.P. Vidal, C. deWaele* and L.C. Evinger. The Rockefeller University, New York, N.Y. 10021, Lab. Physiol. Neurosens. C.N.R.S.,Paris,France, and SUNY, Stony Brook, NY 11794 (Sponsor: E.E. Brink).

We extended our analysis of the head-neck movement system in vertebrates to the monkey by studying the range of motion of the joints of the head-neck ensemble from X-ray photographs of anesthetized animals, and movement strategies from cineradiographic images of unrestrained behaving animals. The range of motion of the head-neck joints in the monkey is restricted in comparison to other vertebrates studied (e.g. of the atlanto-occipital joint to ca. 35 deg versus 90-110 deg in cat and rabbit). X-ray fluoroscopy revealed an extensive utilization of the cervico-thoracic junction for head movement control. In contrast to other vertebrates, e.g. the rabbit, which stabilizes the head largely by engaging the atlanto-occipital articulation, the monkey, when raising or lowering the head, almost exclusively utilizes the cervico-thoracic junction and thus the orientation of the entire cervical vertebral column for head movements. Strategies employed by guinea pigs and cats are in-between these two extremes.

Our collective data establish a relative changing in involvement of major articulations for head movement control comparing rabbit, guinea pig, cat and monkey, indicating increased utilization of the cervico-thoracic junction and a decreasing involvement of the atlanto-occipital articulation. Supported by INSERM and NEI-04613.

DEVELOPMENT OF CERVICO-OCULAR REFLEX IN UNILATERALLY LABYRINTHECTOMIZED SQUIRREL MONKEYS. J. Goldberg and M. Marsh*. Department of Otorhinolaryngology and Communicative Science, Baylor College of Medicine, Houston, TX 77030.

Cervico-ocular reflex (COR) generates eye movements in response to neck rotation. Primates develop a compensatory COR after a total loss of vestibular function. To determine whether such COR also develops as a result of a partial vestibular deficit, COR was measured in squirrel monkeys before and after a unilateral labyrinthectomy.

Eye movements were recorded in 3 dimensions via search coils. The head was fixed in space while the trunk was rotated sinusoidally at 0.01-5.0 Hz, 25° amplitude. This neck rotation did not produce a consistent COR in intact animals. The right labyrinth was destroyed under gas anesthesia. Recording was resumed after the operation and continued for three months.

Alert labyrinthectomized monkeys exhibited nystagmus during neck rotation in the horizontal plane. The horizontal component of the nystagmus was modulated by the rotation. COR *gain*, computed as the amplitude ratio of horizontal slow-phase eye velocity modulation to stimulus velocity, increased with post-operative time. Gain decreased steeply with increasing stimulus frequency, while phase remained near compensatory, except for a small lag at higher frequencies. Thus, at 0.05 Hz, maximum COR gains recorded over the three-month period in three animals ranged from 0.19-0.29, while at 2.5 Hz, the corresponding gains ranged from 0.01-0.04.

These preliminary results indicate that a unilateral loss of vestibular function is sufficient to trigger the development of a compensatory COR.

74.12

EFFECT OF CHANGES IN GRAVITY ON OCULAR COUNTERROLLING IN UPRIGHT AND TILT POSITIONS. S.G. Diamond and C.H. Markham, Dept. Neurology, UCLA Sch. Medicine, Los Angeles, CA 90024.

Parabolic flight on the NASA KC-135 aircraft results in approximately 30s of 0G at the top and 30s of 1.8G at the bottom of each of 40 parabolas typically flown. Four healthy subjects were each tested in 20 parabolas, in the upright and at 30° right ear down (RED) and 30° left ear down (LED) positions, to test the hypothesis that inherent asymmetries of the otolith system, possibly well compensated in the 1G environment on earth, may be unmasked in conditions of hypo and hypergravity.

Three subjects showed no eye torsion while upright, regardless of gravity condition; nor did they have any ocular counterrolling (OCR) while tilted in 0G. In 1.8G at the tilt positions, they had considerably more OCR than at 1G. None of these three subjects became motion sick.

The fourth subject showed eye torsion to the left when at 0G, whether upright or tilted. This leftward bias could also be seen at 1.8G when he was tilted LED, the side that induces rightward OCR. At that position he showed less OCR than he had at 1G. This subject became motion sick.

All subjects had normal OCR in ground-based testing.

These results support the hypothesis that asymmetry of the otolith system may be revealed in unaccustomed gravitational situations, and may suggest that exposure of an asymmetric system to unadapted G conditions could be a factor in the unique motion sickness occurring in space.

ASCENDING PAIN INHIBITION FROM STIMULATION OF THE PERIAQUEDUCTAL GRAY MATTER OF THE RAT. M. M. Morgan, J.-H. Sohn, and J. C. Liebeskind. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563.

Stimulation-produced analgesia (SPA) from the PAG is known to inhibit nociception at the spinal level. Several studies have suggested that pain modulation may also occur via ascending projections from the PAG (Camarata & Yaksh, 1985; Elberdink et al., 1985). The following study was undertaken to determine if ascending projections from the PAG can inhibit nociception. Rats were anesthetized and chronically implanted with a bipolar electrode in the PAG. Immediately prior to electrode implantation, one group of rats had a wire knife lowered 9 mm into the brain just caudal to the PAG in order to disrupt descending output. A control group received no lesion. After one week, both groups were tested on a pain test organized spinally (tail-flick) and one organized supraspinally (hot-plate). Lesioned rats had significantly shorter baseline tail-flick latencies compared to control rats (mean = 3.9 vs 4.3 s), indictating removal of descending inhibition from the PAG. Inhibition of the tail-flick occurred in only 3 of 22 lesioned rats. In contrast, 13 of these 22 rats showed analgesia on the hot-plate test. The threshold for SPA on the hot-plate test was significantly lower than the current producing behavioral effects (e.g. aversive reactions) (mean = 73 and 228 μA, respectively). Non-lesioned rats displayed SPA on both tests at similar currents. These data demonstrate that analgesia can be produced in rats despite a lack of inhibition at the spinal level. Although nociceptive input can be modulated at the spinal level (as demonstrated by inhibition of spinal reflexes), the ability of PAG stimulation to inhibit supraspinally-organized nociceptive responses in the absence of spinal inhibition suggests ascending modulation of nociception. (NIH grant NS07628)

75.2

AXONAL TRAJECTORIES AND TERMINATIONS OF PHYSIOLOGICALLY CHARACTERIZED RAPHE MAGNUS CELLS IN THE CAT. P. Mason and H. L. Fields, Depts of Neurology and Physiology, UCSF, San Francisco, CA 94143.

Physiologically defined populations of pontomedullary raphe magnus (RM) cells have been described that either decrease (off-cells) or increase (on-cells) their discharge rate during the heat evoked rat tail flick reflex. There is evidence that these cells participate in the modulation of both reflexes and secondary sensory cell responses elicited by noxious stimuli.

RM neurons were recorded intracellularly during the paw withdrawal reflex evoked by noxious pinch or heat in the cat. As in the rat, RM cells either increased or decreased their discharge rate during the nociceptive reflex and responded similarly to noxious stimulation applied anywhere on the head or body surface. These cells were termed on- and off-cells respectively. Many of these neurons were also excited by periaqueductal gray stimulation. In order to determine the axonal projections of on- and off-cells, physiologically characterized cells were subsequently injected with horseradish peroxidase (HRP) and the cats were maintained for 24hrs under deep anesthesia. HRP labeled axons had their somata within the RM and sometimes collateralized within the dendritic arbor of the parent cell. Axons typically traveled caudally, although some axons also terminated in brainstem regions rostral to the cell body. The axons of on- and off-cells collateralized extensively throughout the brainstem raphé and medial reticular formation, reaching regions that were both ipsilateral and contralateral to the parent soma. Collaterals were also seen in the lateral pontomedullary reticular formation, the nucleus tractus solitarius and the sensory trigeminal complex. Axonal varicosities and terminal swellings were observed almost exclusively within regions of axonal collateralization. The HRP label in most parent axons diminished 4-6mm from the injection site as the axons traveled caudally over the lateral inferior olive in the caudal medulla.

DOSE-RESPONSE RELATIONSHIP FOR HYPERALGESIA FOLLOWING NALOXONE PRECIPITATED WITHDRAWAL FROM MORPHINE D.H. Kim*, N.M. Barbaro*, and H.L. Fields (SPON: P. Weinstein) Depts of Neurosurgery and Neurology, UCSF, San Francisco, CA 94143.

Hyperalgesia occurs during withdrawal in opiate-dependent animals and humans. Previous work from this laboratory has demonstrated facilitation of spinal nociceptive reflexes in rats given naloxone following an analgesic dose of systemically administered morphine.

In the present study, a dose-response relationship for hyperalgesia was established between intravenously administered morphine and naloxone. Rats were maintained in a lightly anaesthetized state with methohexital, and baseline tail flick latencies (TFL) and paw withdrawal thresholds (PWT) were established. Then the rats were given either saline (control) or morphine (0.5, 1.0, or 2.0 mg/kg), followed by naloxone (0.1, 1.0, or 10.0 mg/kg). There were four rats in each of 12 dosage groups. Saline followed by naloxone, at any dose, produced no change in either TFL of PWT. However, when naloxone administration followed morphine, subsequent TFL and PWT values were significantly ($p<.05$) below baseline levels (hyperalgesia). Increasing doses of morphine (followed by the same dose of naloxone) produced progressively lower TFL and PWT values . In contrast, increasing the dose of naloxone at a given dose of morphine did not increase hyperalgesia.

We conclude that dependence to opiates, as measured by hyperalgesia, develops following a single analgesic dose of morphine. Furthermore, this hyperalgesia is a function of the amount of opiate to which the central nervous system is exposed prior to naloxone precipitated withdrawal.

75.4

ROLE OF NUCLEUS RAPHE MAGNUS (NRM) IN MODULATION OF RENAL AFFERENT INPUT. I.L. Holt*, P.R. Coulombe* and M.M. Knuepfer (SPON: M.A. Walz). Dept. of Pharmacology, St. Louis Univ. School of Medicine, St. Louis, MO 63104.

The supraspinal structures that tonically inhibit somatic and visceral inputs to the spinal cord are, as yet, unclear. NRM stimulation generally enhances this inhibition. We sought to define the extent and source of tonic descending inhibition of renal afferent input in chloralose-anesthetized rats. Activity was recorded in the lower thoracic spinal gray from single neurons responding to renal nerve stimulation (RNS). Neurons inhibited by RNS (8/68) were located deeper than excited neurons and had higher spontaneous discharge rates (SDR). Reversible cold block of the cervical spinal cord (CB) caused an increase in SDR (disinhibition) in 73% of neurons excited by RNS and a decrease (disfacilitation) in 17%. Neurons disinhibited by CB had lower control responses to RNS than disfacilitated neurons. We sought to determine whether the source of tonic descending inhibition arose from the NRM by microinjecting a GABA agonist, muscimol (M), into the NRM (1nmol/1μl over 2 min). In 10/11 neurons, a disinhibition of SDR of similar magnitude was observed both with CB and M (R=0.93). M or CB also caused equivalent changes in RNS-evoked responses. We propose that tonic descending modulation of renal afferent input is widespread and predominantly inhibitory and that the NRM may be the source of the tonic inhibition. ANTINOCICEPTION AND BLOOD PRESSURE CHANGES INDUCED BY ELECTRICAL STIMULATION OF THE DORSOMEDIAL MEDULLA. Sue A. Aicher and A. Randich. Department of Psychology Univ. of Iowa, Iowa City, IA 52242.

This study examined regions of the dorsomedial medulla for stimulation-induced inhibition of the nociceptive tail-flick reflex (TF) in lightly-anesthetized (pentobarbital sodium) rats (n=60). Sixteen tracking sites on the left side of the medulla were examined, extending in 0.5 mm steps from 0.5 mm caudal to 1.0 mm rostral to obex; from midline to 1.5 mm lateral; and from 0.5 mm to 2.5 mm ventral to the dura. At each site the minimum current necessary to inhibit the TF to a 10 sec cut-off was determined (baseline TF 2.5-3.5 sec). If stimulation produced either motor responses or failed to inhibit the TF with less than 200 uA, the trial was terminated. Sites with the lowest current thresholds for TF inhibition were located 1.0 and 1.5 mm lateral to obex, corresponding to placements in the nucleus tractus solitarius (NTS) and the nucleus reticularis ventralis (NRV). Sites in the NRV had lower thresholds to inhibit the TF than sites in NTS. Midline and 0.5 mm lateral sites had higher thresholds and often produced motor responses to stimulation. Threshold current for inhibition of the TF usually produced an increase in mean arterial blood pressure, for sites in either NTS or NRV. These results support the hypothesis that neural substrates involved in cardiovascular regulation interact with antinociceptive systems.

74.6

VAGAL AFFERENT MODULATION OF THE JAW-OPENING REFLEX ELICITED BY PERIPHERAL AND CENTRAL STIMULATION. W. Maixner, E.A. Whitsel*, J. Nestor*, J. Zuniga* and S. Madison*. Dental Research Center, University of North Carolina, Chapel Hill, N.C. 27514.

The outcomes of several studies show that stimulation of cervical vagal afferents (CVA) diminishes putative nociceptive somatomotor reflexes. In the present study we: 1) identified the CVA conditioning parameters that modulate the jaw-opening reflex (JOR) elicited by stimulating oral and perioral test sites (TS's) and 2) examined the ability of CVA conditioning to alter JOR evoked by electrical stimulation of the trigeminal motor nucleus (TMN).

Cats were anesthetized with α-chloralose and TS stimulating electrodes were positioned in the right maxillary canine, gingival tissue, maxillary skin and the TMN. The JOR was recorded from the right digastric muscle in response to TS stimulation at 1.5-2X threshold. Conditioning stimuli (20 msec trains, 333 Hz, 0.1-1.0 msec, 0-10 mamp) were applied to the central end of the right cervical vagus at various conditioning-test intervals (CTI; 0-1000 msec).

For all peripheral TS's, facilitation of the JOR was observed at CTI's less than 20 msec and inhibition of the JOR was observed at longer CTI's (maximum inhibition at CTI = 200 msec). In general, the inhibitory responses were dependent upon conditioning pulse width and intensity. Vagal afferent conditioning failed to alter the JOR evoked by TMN stimulation.

These data support the view that CVA stimulation modulates nociceptive reflexes and that the observed antinociceptive effects do not result from motor inhibition at sites distal to and perhaps including the TMN. Supported by NIDR grant DE0750901.

PROPRIOSPINAL MODULATION OF NOCICEPTIVE RESPONSES OF NEURONS IN THE CAT LUMBAR DORSAL HORN.

J.SANDKÜHLER, Q.G.FU*, E.CARSTENS, B.STELZER*, M. ZIMMERMANN
II.Physiologisches Institut, Universität Heidelberg, West-Germany.

The inhibition of nociceptive spinal dorsal horn neuronal responses by segmental or supraspinal systems has been extensively characterized (see Besson & Chaouch, Physiol. Rev., 67(1987)67-186 for a recent review). Little is known, however, about the impact of ascending or descending spinal interneurons on the transmission of nociceptive information in the spinal cord.

In deeply pentobarbital anesthetized cats extracellular recordings were made from multireceptive spinal dorsal horn neurons at the L_4/L_5 segments. All neurons responded to noxious radiant heating of the glabrous skin on the ipsilateral hindpaw. Focal electrical stimulation (25-100μA, 0.1 ms pulses at 100 Hz) or glutamate microinjections (0.5 M, 30-60 nl) was given at identical sites within the ipsi- or contralateral cord at the T_{11} to L_1 or at sacral segments by means of a multibarrel glass pipette (tip diameter $\leq$ 40μm).

Noxious heat-evoked responses of dorsal horn neurons at the L_4/L_5 segments were reduced by electrical stimulation in the lateral or ventral funiculi, the dorsal columns and the dorsal horn at the T_{11} to L_1 and sacral segments. Only few or no effective sites were found in laminae VI to VIII. Glutamate microinjections, which excite cell bodies only, were effective at sites in the dorsal and ventral horn gray matter at T_{11} to L_1 but not at sacral segments. Inhibitions were produced from sites *ipsi-* or *contra*lateral to the neuron under study with the cord left intact or spinalized at T_8 or T_9 segments, indicating that the activation of supraspinal antinociceptive systems is *not* a necessary component of the inhibition observed.

The present study established that some spinal interneurons arising from the dorsal horn at the thoraco-lumbar junction may modulate the nociceptive responses of dorsal horn cells at the L_4/L_5 segments. SUPPORTED BY THE DEUTSCHE FORSCHUNGSGEMEINSCHAFT, THE DAAD AND FULBRIGHT.

TRANSCRANIAL ELECTROSTIMULATION ENERGY DENSITY DISTRIBUTION IN THE BRAIN AND EFFECTS ON SOMATOSENSORY AND LIMBIC NUCLEI. C.Hymel, P.Jenkins & M.Skolnick* (SPON: R. Marc). Neurophysiology Research Center, University of Texas Health Science Center at Houston, 1343 Moursund, Houston, TX 77030

It has been shown that application of very low amplitude transcranial electrostimulation can elicit profound analgesic effect in rats which is naloxone-reversible. Investigation of the characteristics of the propagation of the stimulation signal through the brain has yielded energy density distribution maps at various points in time during the stimulation pulse. Variations in energy distribution are determined for nuclear regions generally associated with analgesia (i.e. somatosensory and limbic nuclei). These regions are subsequently tested for variations in evoked potentials as a result of electrostimulation alone and in conjunction with the administration of a chemical promotor. The findings include: 1) detection of pulses in the brain from electrostimulation as low as 10 uA, 2) significant attenuation and distortion of the detected waveform as compared to the applied signal and 3) demonstration of asymmetrical in the resultant potential field distribution across the brain.

THE EFFECT OF LOW CURRENT TRANSCRANIAL ELECTROSTIMULATION ON NEUROTRANSMITTER LEVELS IN RAT CSF AND BLOOD PLASMA
O.B.Wilson, R.Warner*, R.Hamilton*, G.Sood*, C.Johnston*, L.Howard*, M.Skolnick UT Hlth.Sci.Ctr., Houston TX 77030

It has previously been reported that low current transcranial electrostimulation (TCES) applied to the apex of the antihelices in the ears of rats induces analgesia, reduces the severity of opiate withdrawal syndrome, and causes changes in the electrophysiological responses of deep brain neurons to noxious tail pinch stimuli. These effects are slow in onset, persist well after stimulation ceases, and are reversed by the opiate antagonist naloxone. Further work also indicates that p-chlorophenylalanine (pCPA), a serotonin formation inhibitor, reduces the analgesic effect of TCES. The implication is that at least one neurotransmitter system is stimulated by TCES.

Using the TCES prescription previously found to have the greatest analgesic effect on rats (charge balanced rectangular waveform with 2msec pulsewidth, 10Hz repetition rate, and 30 minute duration), we have measured the beta-endorphine content of blood plasma and CSF using radio-immuno assays. Blood was obtained by heart puncture of anesthetized animals, whereas CSF was collected by cannulation of the third ventricle and the cisterna magna. Beta-endorphine levels in stimulated and control animals were compared before stimulation and at times 0, 15, 30, 45 and 60 minutes after treatment ended.

In CSF we have investigated the dynamics of dopamine, serotonin and norepinephrine turnover as affected by TCES. The breakdown products dihydroxyphenylacetic acid (DOPAC), hydroxyindoleacetic acid (HIAA) and homovanillic acid (HVA) were assayed using high performance liquid chromatography. CSF samples were obtained at 15 minute intervals before, during, and after TCES from both stimulated and sham-treated control animals.

INTRATHECAL BRADYKININ ACTS ON SPINAL NORADRENERGIC TERMINALS TO PRODUCE ANTINOCICEPTION IN THE RAT. O. Laneuville*, T.A. Reader and R. Couture*. (SPON: A. Ferron). Dept. Physiology, Faculty of Medicine, University of Montréal, Montréal, Qué., Canada.

In the awake restrained rat the intrathecal (i.th.) administration of 8.1 pmol-8.1 nmol of bradykinin (BK) and Lys-BK (KD) enhanced reaction time (RT) to a noxious radiant heat stimulus in a dose-related manner, the fragment BK (1-8) was active only at doses higher than 10 nmol. The increases in RT were greatest at 1 (BK) and 6 (KD) min and RT returned to the basal level within 15 min post-administration. The following order of potency was observed in relation to this response: BK > KD >> BK (1-8). The effect of BK (81 pmol) was unaffected by prior i.th. administration of propranolol (β-adrenoceptor antagonist) and naloxone (opioid antagonist) but was significantly blocked ($P < 0.001$) by idazoxan and yohimbine (α_2-adrenoceptor antagonist) and in rats which received an i.th. dose (20 µg) of 6-hydroxydopamine 1 week earlier. The latter treatment reduced by 60% ($P < 0.001$) the noradrenaline (NA) content in the lumbar spinal cord without affecting the endogenous levels of serotonin, dopamine, adrenaline or their main metabolites. There were no significant change in NA in both the brainstem and heart. In rats pretreated with the neurotoxin or with α_2-adrenoceptor antagonists, the effects of neurokinin B (antinociception) and substance P (hyperalgesia) were preserved. We conclude that BK may inhibit spinal nociceptive sensory transmission and produce analgesia by acting presynaptically on terminals of bulbospinal NA-containing fibers.

DOSE RESPONSE OF INTRATHECAL CLONIDINE IN THE RAT MECHANICAL VISCERAL PAIN MODEL(m-VPM). R.W. Colburn*, D.W. Coombs*, L.L. Rogers*, K.N. Raye*, and M. Addis* (SPON: S.F. Gonsalves) Anesthesia Research Laboratory, Dartmouth Hitchcock Medical Center, Hanover, NH 03756.

Antinociception of the alpha 2- adrenergic agonist Clonidine against an upper abdominal mechanical visceral stimulus has not been tested. We report here the dose response with intrathecal Clonidine in the rat m-VPM. METHODS: 200-250g Sprague-Dawley Rats were implanted (halothane anesthesia) with duodenal VPM balloon catheters(1) and PE-10 suboccipital intrathecal catheters (2). Rats were infused intrathecally with 10ul of 0.1, 1, 10 ug Clonidine HCl or saline followed by a 10 ul saline flush one half hour prior to VPM testing. Testing protocol consisted of 5 balloon pulses(0.5-0.7ml) followed by one minute held inflation. Writhing response was graded on a 0-3 scale(1). RESULTS: Percent control(n=8) writhing responses are shown below.

Dose Clonidine	% Control Response + SE	n
0.1ug	89 + 20	9
1.0	50 + 17	9
10	13 + 8	8

DISCUSSION: Intrathecal Clonidine yields a linear dose response curve over the range of doses tested. M-VPM shows promise as a bioassay for analgesic activity of spinal alpha-adrenergic agonists against visceral pain. 1.Colburn RW, Coombs, DW, Degnan, CC, Rogers LL: Mechanical Visceral Pain Model. A BAG CELL SPECIFIC ANTIGEN COLOCALIZES WITH THE BAG CELL PEPTIDES BUT NOT WITH THE EGG-LAYING HORMONE. W. S. Sossin, T. Kreiner, and R. H. Scheller. Dept. of Biological Sciences, Stanford University, Stanford, CA, 94305

We have recently demonstrated that the amino and carboxy terminal products of the egg-laying hormone (ELH) precursor are packaged into separate dense core vesicles (DCVs) in the bag cells of Aplysia californica (Fisher, J. et al., submitted). The monoclonal antibody (MAb) 4F6 recognizes a bag cell specific protein of 80 kD which is also localized to DCVs. Using double label immunoelectron microscopy, we demonstrate that the antigen recognized by MAb4F6 colocalizes with immunoreactivity to peptides from the amino terminal (e.g bag cell peptides) of the ELH precursor but not with immunoreactivity to the carboxy terminal peptide ELH. Another distinct class of vesicles stains with the MAb 4F6 but not with antibodies directed against peptides from the ELH precursor. The 4F6 specific vesicles are smaller and less dense than the peptide containing vesicles. Thus, at least 5 separate classes of DCVs exist in the bag cells.

76.2

PROGRESSIVE RELEASE OF PEPTIDES FROM BAG CELL NEURONS OF APLYSIA DURING A DISCHARGE. K.J.Loechner, E.Azhderian, R.Dreyer and L.K.Kaczmarek. Dept. of Pharmacology, Yale Univ. Sch. of Med.,New Haven, CT 06510.

Electrical stimulation of bag cell neurons of Aplysia triggers a discharge of action potentials during which several peptides are released. We have examined the time course of release of two of these peptides, α-bag cell peptide (α-BCP) and egg-laying hormone (ELH). Medium (artificial sea water/protease inhibitors) bathing individual abdominal ganglia was exchanged completely at 5 min intervals before, during and after discharges lasting 10-30 min. Peptides in the medium were analyzed by HPLC with post-column derivatization. α-BCP and ELH were identified by retention times, which corresponded to synthetic peptide standards. Pre-discharge samples contained several peaks that did not correspond to known bag cell peptides (n=8). Some of these peaks were diminished during a discharge and recovered after the cells had stopped firing. Samples at times after the onset of a discharge also showed additional peaks, including α-BCP and ELH. A progressive increase in the release of both α-BCP and ELH was seen over the course of the discharge. Once the discharge had stopped, however, the next 5 min sample showed a decrease in both α-BCP and ELH. One hour after a discharge, neither α-BCP nor ELH were detected. Our data show that the release of α-BCP and ELH through the vascularized sheath into the external medium is not tightly coupled to the firing rate of these neurons. The firing rate peaks in the first minute of a discharge and subsequently declines, whereas release increases progressively over the course of a discharge.

76.3

THE NEUROPEPTIDE EGG-LAYING HORMONE OF *APLYSIA* INDUCES PACEMAKER ACTIVITY AND REDUCES ACCOMMODATION OF SPIKING BY MODULATING FOUR IONIC CURRENTS. R.F. Jansen* and E. Mayeri. Department of Physiology, University of California, San Francisco, CA 94143.

Egg-laying hormone (ELH) is a neuropeptide released by the bag cells. It is the hormone that triggers ovulation and it also functions as a neurotransmitter in the abdominal ganglion, where it causes long-lasting excitation of the LB and LC neurons. Using voltage-clamp methods, we previously showed that ELH increases I_R, the inwardly rectifying potassium current and I_X, an inward sodium-sensitive voltage-independent current.

We now report that focal application of ELH (final conc. approx. 10 μ*M*) also suppresses $I_{K(V)}$, a delayed rectifier potassium current and I_A, a transient potassium current, by approx. 20 % each. $I_{K(V)}$ is a slowly activating current that is TEA+-resistant (100 m*M*). It shows slow voltage-dependent inactivation, and reverses close to E_K in a 120 m*M* K^+ medium. I_A is a rapidly activating and inactivating current that can be activated by hyperpolarizing prepulses and is blocked by 5 m*M* 4-AP. ELH modulates all four currents in each LB/LC neuron.

The functional consequences of the actions of ELH are the onset of repetitive spiking and a dramatic reduction in the accommodation of spiking, as measured by a graded series of depolarizing current pulses.

PURIFICATION AND STRUCTURE OF THE DELTA AND EPSILON BAG CELL PEPTIDES OF APLYSIA. G.T. Nagle, M. de Jong-Brink+, S.D. Painter, J.E. Blankenship and A. Kurosky*. Marine Biomedical Institute and *Dept. of Human Biol. Chem. and Genetics, Univ. of Tx. Med. Br., Galveston, TX 77550, and +Dept. of Biology, Free Univ., Amsterdam, The Netherlands.

A factor in the bag cells stimulates calcium uptake into mitochondria of secretory cells in the albumen gland, a female accessory sex gland that deposits a nutritive secretion around oocytes during egg laying. Peptides were extracted from bag cells of 50 animals and fractionated by gel filtration and C18 reversed-phase HPLC. Amino acid sequence analyses demonstrated that the presumed bioactive peptide (delta BCP) was the 39-residue sequence: NH_2-Asp-Gln-Asp-Glu-Gly-Asn-Phe-Arg-Arg-Phe-Pro-Thr-Asn-Ala-Val-Ser-Met-Ser-Ala-Asp-Glu-Asn-Ser-Pro-Phe-Asp-Leu-Ser-Asn-Glu-Asp-Gly-Ala-Val-Tyr-Gln-Arg-Asp-Leu-COOH. This peptide is structurally related to the caudodorsal cell neuropeptide (calfluxin) of Lymnaea, which has equivalent activity in that species. Interestingly, the potential Arg-Arg cleavage site in delta BCP is not utilized in vivo. Amino acid sequence analyses demonstrated that a second, presumably inactive, peptide (epsilon BCP) was: NH_2-Ser-Val-Leu-Thr-Pro-Ser-Leu-Ser-Ser-Leu-Gly-Glu-Ser-Leu-Glu-Ser-Gly-Ile-Ser-COOH. Supported by NSF BNS 17575 and BBS 87 11368, and by NIH NS22079, NS23169 and CA17701.

PURIFICATION AND STRUCTURE OF HISTIDINE-RICH BASIC PEPTIDE AND PEPTIDE I FROM NEURONS R3-R14 OF APLYSIA. S.D. Painter, G.T. Nagle, J.E. Blankenship and A. Kurosky*. Marine Biomed. Inst. and *Dept. Human Biol. Chem. & Gen., Univ. Tx. Med. Br., Galveston, TX 77550.

The R3-R14 neurons contain a myoactive peptide that excites the heart and enhances gut motility in vitro. The gene expressed in these cells encodes three peptides, only one of which (peptide II) has been isolated and sequenced. We report the purification and sequence analysis of the two remaining peptides, the myoactive histidine-rich basic peptide (HRBP) and peptide I. Peptides were extracted and fractionated by gel filtration and C18 reversed-phase HPLC. Amino acid compositional and sequence analyses demonstrated that the structure of the 43-residue HRBP was: <Glu-Val-Ala-Gln-Met-His-Val-Trp-Arg-Ala-Val-Asn-His-Asp-Arg-Asn-His-Gly-Thr-Gly-Ser-Gly-Arg-His-Gly-Arg-Phe-Leu-Ile-Arg-Asn-Arg-Tyr-Arg-Tyr-Gly-Gly-Gly-His-Leu-Ser-Asp-Ala-COOH. Compositional analysis indicated that peptide I was a 26-residue peptide. Sequence analysis of the first 20 residues yielded the following primary structure: NH_2-Glu-Glu-Val-Phe-Asp-Asp-Thr-Asp-Val-Gly-X-Glu-Leu-Thr-Asn-Ala-Leu-Glu-X-Val. The sequences obtained for the two peptides were identical to those predicted from nucleotide sequence analysis of the HRBP gene expressed in neurons R3-R14. Supported by NIH NS 22079, NS 23169, and CA 17701, and by NSF BNS 85 17575 and BBS 87 11368.

SEQUENCE OF PEDAL PEPTIDE - A NOVEL NEUROPEPTIDE FROM THE CNS OF APLYSIA. P. E. Lloyd & C. M. Connolly* Dept. of Pharmacol. & Physiol. Sci. & Comm. on Neurobiol., Univ. of Chicago, Chicago IL 60637.

We have identified a novel neuropeptide in Aplysia nervous tissue. The peptide was termed Pedal peptide (Pep) because it was predominantly synthesized in the pedal ganglia. Pep was purified and sequenced from pooled extracts of pedal ganglia and the following sequence proposed:

Pro-Leu-Asp-Ser-Val-Tyr-Gly-Thr-His-Gly-Met-Ser-Gly-Phe-Ala

Enzymatic hydrolysis indicated that Pep had a free carboyxl terminal. A peptide with the proposed sequence was synthesized and compared with the native peptide. Chromatographic properties of the two peptides under 3 different conditions were identical. Native and synthetic Pep produced the same electrophysiological responses in neuron L5 in the abdominal ganglia. The cell body of L5 was covered with a network of Pep-immunoreactive terminals. Both peptides produced net inward currents that were associated with a decrease in membrane conductance. The results from these two procedures confirmed that the proposed Pep sequence was correct. Quantitative measurements of the incorporation of ^{35}S-methionine into Pep suggest that cell bodies which synthesize Pep were present predominantly in the pedal ganglia but should also be found in other central ganglia as well. Pep-like immunoreactive neurons were found predominantly in the pedal ganglia and less frequently in the other ganglia (Pearson & Lloyd, these abstracts). Quantitatively, Pep constitutes one of the predominant peptides in the nervous system of Aplysia. Pep does not appear to be a member of any other previously identified peptide family. Supported by NIH grant 23569 and a Whitehall grant.

76.7

IMMUNOCYTOLOGICAL LOCALIZATION OF PEDAL PEPTIDE IN THE CNS AND PERIPHERY OF APLYSIA. W. L. Pearson* & P. E. Lloyd. (SPON: L. Minor) Comm. on Neurobiol. & Dept. of Pharmacol. & Physiol. Sci., Univ. of Chicago, Chicago, IL 60637.

Immunocytology using antisera raised to conjugated pedal peptide (Pep) was used to localize the peptide in the CNS and periphery of Aplysia. A total of over 200 neurons in the CNS exhibited Pep-like immunoreactivity. As expected from results presented elsewhere (Lloyd & Connolly, these abstracts), immunoreactive neurons were heavily concentrated in the pedal ganglia primarily in a broad ribbon on the dorsal surface of each ganglion. This ribbon was comprised of about 60 large contiguous neurons. Several smaller groups of neurons were also found on the ventral side of each pedal ganglion. Smaller and less numerous immunoreactive neurons were found in the cerebral, buccal, and abdominal ganglia. Pleural ganglia contained only 1 or 2 very small positive neurons. A number of neurons primarily located in the abdominal ganglia had dense networks of immunoreactive varicose fibers surrounding their cell bodies. Many immunoreactive axons were observed in peripheral nerves, particularly those nerves leaving the pedal ganglia. Analyses of sections of body wall indicated that Pep-like immunoreactivity was localized to a series of fibers and large varicosities, many of which appeared to be associated with vascular spaces. A significant proportion of the Pep in the body wall appears to come from neurons in the pedal ganglia. Experiments in which newly synthesized Pep in the pedal ganglia was labelled with ^{35}S-methionine indicate that very large amounts of the labelled peptide were transported by fast axonal transport down peripheral nerves towards and into the body wall. These results suggest that Pep is a transmitter-like neuropeptide which is likely to have a number of important physiological actions in Aplysia. Supported by NIH grant 23569 and a Whitehall grant.

BUCCALIN: DISTRIBUTION OF IMMUNOREACTIVITY IN THE *APLYSIA* NERVOUS SYSTEM AND BIOCHEMICAL LOCALIZATION TO IDENTIFIED MOTOR NEURON B16. I. Kupfermann, E. C. Cropper, M. W. Miller, A. Alevizos, R. Tenenbaum, and K. R. Weiss. Cntr. Neurobiol. & Behav., Coll. Phy. & Surg., Columbia Univ., NYS Psychiatric. Inst., New York, NY 10032.

In order to study modulation of the muscles involved in feeding responses in *Aplysia* we have been investigating peptide cotransmission in the accessory radula closer (ARC) muscle. This muscle, which is involved in the biting response, is innervated by two cholinergic motor neurons B15 and B16. Previous work has indicated that contractions of the ARC can be potentiated by the peptides SCP_A and SCP_B, which are present in neuron B15, and the peptide myomodulin, which is present in neuron B16. It has also been shown that in addition to the SCPs B15 contains a third peptide, buccalin, which decreases rather than increases the size of muscle contractions. Since buccalin appears to act presynaptically, yet modulates muscle contractions produced by stimulation of either B15 or B16 we hypothesized that buccalin was present in B16 as well as B15.

As previously shown for B15, physiologically identified B16 neurons marked with Lucifer Yellow exhibited buccalin-like immunoreactivity in whole mount preparations. Other identifiable cell bodies and richly staining neuropilar regions were present in each of the ganglia. Immunoreactive varicosities, indicative of buccalinergic innervation were present in tissues of the genital system (hermaphroditic ducts, penis retractor muscles) and feeding system (esophagus and ARC muscle). Double-labeling of the ARC muscle revealed two populations of varicosities, one immunoreactive to both $SCP_B$and buccalin (presumably from B15), and a second population exhibiting only buccalin-like immunoreactivity (presumably from B16).

The presence of authentic buccalin in B16 was demonstrated by radiolabeling B16 neurons with ^{35}S methionine and showing coelution of synthetic buccalin and B16 radioactivity through three different sequential RP-HPLC gradients. Furthermore, gas phase sequence analysis of B16 radioactivity yielded counts in cycle two, the only position where methionine is present in buccalin. Therefore, neuron B16 as well as neuron B15 contains buccalin. These data indicate that the two motor neurons for the ARC muscle contain unique as well as overlapping peptides that can provide types of modulation common to both neurons as well as specific to one or the other.

76.9

ACTION AND STRUCTURE OF PARABUCCALIN - A NOVEL NEUROPEPTIDE LOCALIZED TO CHOLINERGIC BUCCAL MOTONEURONS B15 AND B16 OF *APLYSIA*. K.R.Weiss, E.C.Cropper, R.Tenenbaum*, F.S.Vilim and I.Kupfermann. Cntr. Neurobiol. & Behav., Columbia U., and NYS Psychiatr. Inst., N.Y., N.Y. 10032.

Contractions of the ARC muscle are modulated by several peptides that are present in the cholinergic motoneurons B15 and B16. In an attempt to define the full complement of modulatory neuropeptides in the ARC, we fractionated an extract of 1000 muscles using HPLC, and bioassayed the fractions for modulatory actions on ARC contractions elicited by motoneuron stimulation. This uncovered the presence of several substances that were able to either potentiate (SCPa, SCPb and myomodulin) or depress (FMRFa and buccalin) ARC contractions. We have now purified and sequenced another inhibitory peak. A synthetic carboxy-terminally amidated replica of the established sequence had the same retention time and bioactivity as the native peptide. Furthermore, the amidated peptide comigrated through four stages of HPLC with ^{3}H-Leu labeled peptides synthesized by B15 and B16. This confirmed that the structure of the peptide is Gly-Leu-Asp-Arg-Tyr-Gly-Phe-Val-Gly-Gly-Leu-a and localized it to B15 and B16. This peptide, which we have named parabuccalin, shares 7 of 11 residues with buccalin, a peptide we previously characterized. The structural similarity of these two peptides is reflected in the similarity of their actions on the ARC. Both depress motoneuron, but not ACh elicited contractions and depress the EJPs. Thus both peptides appear to exert their action via presynaptic inhibition of ACh release from motoneurons and may function in combination with other peptides to permit selective control of the amplitude and relaxation of muscle contractions. Thus, ARC motoneurons contain different families of structurally related peptides, some of which such as the SCPs potentiate contractions, and others like the buccalins, depress contractions. Possible subtle differences in the actions of these related peptides remain to be explored.

76.10

FUNCTIONAL CHARACTERIZATION OF THE PEPTIDERGIC ARC MOTOR NEURONS B15 AND B16 OF *APLYSIA*: ACTIVITY PATTERNS DURING FEEDING IN FREE MOVING ANIMALS. E. C. Cropper, I. Kupfermann, and K. R. Weiss. Cntr. Neurobiol. & Behav., Columbia Univ. P & S, & NYS Psych. Inst., NY, NY 10032.

The two cholinergic ARC motor neurons B15 and B16 contain multiple bioactive peptides which, when exogenously applied, modulate parameters of muscle contraction. While there is considerable data on the biophysical and biochemical characteristics of these neurons, their role in behavior and the precise function of the peptides they contain is poorly understood. This is, in part, due to the fact that practically nothing is known about their physiological firing patterns. For this reason electrodes were implanted in the ARC muscle and synaptic currents were recorded during the different feeding-related behaviors of *Aplysia*; biting without ingestion of food, biting followed by swallowing, i.e., ingestion of a strip of food, and rejection. Synaptic currents from B15 were distinguished from those of B16 by sacrificing animals and comparing responses evoked by intracellular motor neuron stimulation to those recorded during feeding. Correlations between synaptic events and behavior were made with the aid of video recording and a transducer which recorded tension developed between the radula halves during ingestion of a strip of seaweed.

These experiments demonstrate that B15 and B16 do indeed fire during the consummatory feeding response, during closure of the radula, and that they fire at frequencies which in reduced preparations produce significant muscle contractions. The data also show that one motor neuron is not simply a functional duplicate of the other. While both neurons fire during biting (with or without ingestion of food), during rejection only B16 fires. Furthermore, during biting, the firing patterns of the two neurons are markedly different; B16 always fires alone for about one second and then the two neurons fire together for a period of time that is dependent on whether or not food is ingested. If food is ingested, the motor neurons can fire for as long as 6 seconds, whereas food is not present they typically fire for 3 seconds or less.

In conclusion, we have characterized the physiological patterns of activity of the two ARC motor neurons B15 and B16. These patterns can now be simulated in reduced preparations where it will be possible to test in a behaviorally relevent context hypotheses concerning the role of peptide cotransmission in the ARC neuromuscular system.

76.11

CELLULAR DYNAMICS OF PEPTIDES CONTROLLING EGG-LAYING BEHAVIOR AND GROWTH IN THE SNAIL *LYMNAEA STAGNALIS*. E.W. Roubos*, W.R.A. van Heumen*, E.D. Schmidt* and J. Slootstra* (SPON: ENA). Dept. of Biology, Vrije Universiteit, P.O. Box 7161, 1007 MC Amsterdam, The Netherlands.

The Caudodorsal Cells (CDC) of the snail *Lymnaea stagnalis* control egg-laying behavior by releasing *ca* 11 peptides. Two genes encoding for these peptides have been characterized. Peptide dynamics have been studied with tannic acid and immunoelectron microscopy. The peptides are partly colocalized in secretory granules. Release occurs from neurohaemal terminals into the haemolymph, and from collaterals into the intercellular space of the CNS. Neurohaemal release is calcium-dependent and occurs during a 1 h of electrical activity ("discharge"). Most likely, first the αCDCP-peptide and then other peptides are released. The discharge is initiated by membrane depolarization and is mediated by cAMP. Release from the collaterals occurs at morphologically unspecialized release sites ('nonsynaptic communication'). It is stimulated by depolarization and is calcium-dependent, but unlike neurohaemal release, it is minimal during the discharge. This suggests that neurohaemal and collateral release are controlled independently. Apparently, the CDC control peripheral targets (gonad, accessory sex glands) by neurohaemal secretion, whereas collateral release regulates CNS targets inter- and motoneurons). CNS receptors for one of the CDC-peptides, calfluxin, have been localized.

The Light Green Cells (LGC) stimulate body growth by releasing an (molluscan) insulin-related peptide (MIP) from neurohaemal axon terminals into the haemolymph. The MIP-gene has been characterized. The LGC are under control of two types of dopamine-receptor and an adenylate-cAMP system. MIP seems to belong to a large family of insulin-(related) peptides that control growth throughout the animal kingdom.

It is suggested that complex behavior is controlled in a multipeptidergic way, whereas body growth is controlled in a more simple (conservative?) fashion, by one peptide.

77.1

CUES FOR THE ADJUSTMENT OF SYNAPTIC STRENGTH IN THE CRICKET. A. Chiba* and R.K. Murphey (SPON: M. Hirsch). Department of Biology, SUNY Albany, NY 12222.

Synapses made by cercal sensory receptors change their strengths during postembryonic development (Chiba et al., Science in press 1988). We focused on three identified receptors which had different synaptic strengths in control animals, and examined the role of age and receptor hair size in adjusting synaptic strength. First, we changed the age of the presynaptic structure by cutting the cercal nerve in the 7th or 8th instar, and allowing the sensory axons to regenerate. The strengths of three identified synapses on the medial giant interneuron were the same as in control adults. This result eliminated the age of the presynaptic structure as a cue for adjusting synaptic strength. Next, we changed the age of the entire receptor, including the sensory neuron soma, by amputating the cercus in the 6th or 7th instar, and allowing cercal regeneration to occur. The three receptors of interest could usually be identified on the regenerate cercus. Their synapses had strengths which were better correlated with receptor size than with their absolute age. The result seems to eliminate age of the sensory neuron soma as a controlling variable. We are testing the hypothesis that hair size is coupled to synaptic strength through its effect on sensory neuron activity. Supported by an NSF grant to RKM.

THEME AND VARIATIONS ON NEURONAL EVOLUTION S. R. Shaw, Life Sciences Ctr., Dalhousie Univ., Halifax, NS, Canada.

Evolutionary considerations have found relatively little place in modern neuroscience, to the extent that it is unclear which features of neurones change during evolution. From Golgi/EM neuroanatomy of the insect visual system, I now confirm our earlier inference based on axon counts, that all the cell types present in the lamina neuropil of recent Diptera have recognizable homologs in Stratiomyidae, a family of ancient lineage that probably diverged >200 Myr ago. Additionally, the relative position occupied by each neurone within the lamina cartridge has been identified, and has remained practically invariant.

By contrast, the relative sizes of the neurones and the positions of some monopolar cell bodies vary markedly between the distant families. Of more functional significance, the branching patterns and synaptic terminations of neurones have altered, some radically, some less so, implying that other synaptic connections must have changed beyond the one already documented (Shaw and Meinertzhagen, PNAS 85: 7961, 1986). Some of the implied connectivity changes have been confirmed directly by EM. A picture emerges of extreme developmental constraints on the basic architecture of the cartridge, contrasting with plasticity of the synaptic connections. Of the possibilities that can be detected with neuroanatomical approaches, synaptic promiscuity emerges as the most likely vehicle for evolutionary progression. [Supported by NSERC Canada, A9593]

77.3

MODIFICATION OF TRANSMITTER RECEPTOR PROPERTIES MEDIATED BY CELL CONTACT PRIOR TO SYNAPSE FORMATION. S. Sanchez-Armass* and P. Drapeau, McGill University Centre for Neuroscience, 1650 Cedar Ave., Montreal, Canada H3G 1A4.

Identified leech neurons reform specific synapses in culture. Serotonergic Retzius cells can reinnervate pressure sensitive (P) neurons and activate only one of the two 5-HT receptors in the target P cells: the Cl (gCl_S) but not the monovalent cation receptor channels ($gCation_S$), as observed in vivo. We have examined the mechanism of receptor selection.

$gCation_S$, the non-synaptic response, was reduced 5-fold both in innervated P cells and in P cells contacted but not yet innervated by Retzius cells. Depleting the Retzius cells of 5-HT by incubation in reserpine did not prevent the reduction of $gCation_S$ whereas incubating single P cells with 5-HT did not affect $gCation_S$. Both receptors were observed in the Retzius cell but $gCation_S$ was unaffected by synapse formation. These results suggest that the reduction of $gCation_S$ occurs upon cell contact prior to synapse formation and is specific for the target neuron. The loss of counter-effective postsynaptic receptors appears to be a prelude to synapse formation. We are testing the effects of modifying the Retzius cell surface in order to obtain direct evidence for a contact-mediated selection of receptors. Supported by the MRC of Canada and the FRSQ and FCAR of Quebec.

COMPETITION BETWEEN CONVERGENT SYNAPSES IN DEVELOPMENT: ELECTRICAL ACTIVITY MODULATES EFFICACY AND NUMBER OF INPUTS. R.D. Fields, C. Yu, E.A. Neale, and P.G. Nelson. Lab. of Develop. Neurobiology, NIH, NICHD, Bethesda, MD 20892.

Afferents of (DRG) neurons converging on spinal cord neurons of mice in vitro form more and stronger synapses when exposed to a phasic pattern of electrical stimulation during development. Synaptic efficacy was diminished in competing afferents which were not provided with electrical stimulation, but the number of axonal inputs was not reduced. Dissociated neurons were cultured in a three-compartmental chamber such that axons from DRG neurons in the two side compartments formed synapses on spinal cord neurons in the central compartment. A phasic pattern of electrical stimulation was applied to the DRG axons extending from one of the side compartments, and the amplitude of EPSPs was compared after 3-5 days of stimulation. The median EPSP amplitude increased from 5.5 mv in unstimulated controls to 10.0 mv in stimulated afferents, and decreased to 3.9 mv in non-stimulated convergent inputs ($p < 0.03$). The number of inputs, determined by graded stimulation, increased from a mean of 1/side to 1.6 after stimulation ($p < 0.001$), but non-stimulated afferents also increased to 1.4, because of an increased number of these inputs to proximal neurons. Activity-dependent synaptogenesis and modifications of synaptic boutons may not progress to elimination of weak convergent or proximal afferents.

77.5

DEVELOPMENT OF THE RETINOTECTAL PROJECTION IN ZEBRAFISH EMBRYOS UNDER TTX-INDUCED BLOCKADE OF NEURONAL ACTIVITY

C.A.O. Stuermer Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft 7400 Tuebingen FRG

To determine whether an impairment of neural activity would affect the pathfinding of growing retinal axons and/or the precision of the developing retinotectal map zebrafish embryos of 28-34 h of age were injected with 9-19 nl, 0.12 mmol TTX prior to axonal outgrowth. The embryos were paralyzed for several days. Axons from either dorsal (D) and ventral (V) or nasal (N) and temporal (T) retina were stained with DiI and DiO in embryos at 35, 48 and 56 h of age and viewed at 70 to 86 h.

Similar to axons of normal embryos, the TTX-blocked axons from D and V retina traveled through separate aspects of the optic nerve and tract and terminated at retinotopically correct sites in tectum. T and N axons were segregated in the nerve but mixed in the tract and initially coextensive over the rostral tectal half. Then, N axons progressed into and settled in the caudal tectum whereas T axons ended in rostral tectum as in normal embryos. Individual TTX-blocked axons were of normal morphology. They were either unbranched or carried a few filopodial sprouts. At retinotopic sites, they gave rise to terminal arbors ranging in size between 8 x 14 to 14 x 33 μm at 70-75 h, and between 11 x 18 to 42 x 62 μm at 78-83 h (mean arbor size: 17 x 27 μm). Thus, the arbors in TTX-blocked embryos were no larger than normal arbors. The tectal area covered by the mean of the arbors was 1,3 %.

These findings suggest that TTX-induced impulse blockade does not interfere with the formation of orderly pathways nor with the establishment of a precisely ordered retinotopic map in zebrafish embryos.

77.6

AXON-TARGET INTERACTIONS ARE ARRESTED AND ABNORMAL IN WEAVER CEREBELLUM

C.A. Mason, Dept. of Pathology, College of Physicians and Surgeons of Columbia University, New York, N.Y. 10032.

In the weaver mouse cerebellum, granule neurons fail to migrate along Bergmann glial processes and die in ectopic positions. To understand how afferent axons respond to the loss of one target cell population, we examined axon morphology and cellular relations by labeling axons with HRP in cerebellar slices, or with rhodamine via their brainstem sources in intact animals, and correlative electron microscopy. The majority of afferents in mature weaver cerebellum have large oval en passant terminals that follow the contours of the misoriented dendrites and the soma of Purkinje cells. Rhodamine injections into the inferior olives identify these axons as climbing fibers, and show that exuberant arbors innervate multiple Purkinje cells at the perikaryal level, despite the loss of perisomatic processes. Compared to the wild type, a reduced number of mossy fibers are labeled via their pontine source, and mossy terminals have immature shapes. Terminals of both afferents contact Purkinje cells and the few surviving granule neurons.

This view of afferent morphology in the mutant cerebellum supports previous physiological and ultrastructural data, and shows a wider range of effects from the loss of the granule neuron, implicated as a primary site of action of the weaver gene. The maintenance of multiple innervation and immature terminals suggests an auxilliary model, that molecules mediating interactions among a number of neuron and glial cell populations are defective in weaver, yielding both reduced specificity and arrested development. Supported by NIH grant NS 16951.

77.7

TARGET-DEPENDENCY OF CATECHOLAMINERGIC AFFERENTS IN AN ANIMAL MODEL OF MICROENCEPHALY INDUCED BY PRENATAL METHYLAZOXYMETHANOL ADMINISTRATION. MP Abbracchio*, M Cimino*, M Di Luca*, L Mennuni*, P Zaratin* and F Cattabeni, Inst. Pharmacol. Sci., Via Balzaretti 9, 20133 Milan, Italy.

The administration of the antimitotic agent methylazoxy methanol (MAM) to pregnant rats at day 15 of gestation results in a microencephaly in the offspring characterized by a reduced cortical field. Noradrenergic afferents to the cortex seem to develop normally, leading to a consistent hyperinnervation. We have studied whether this hyperinnervation found in 2-month-old offspring could undergo regressive events, in view of the known target-dependency of synapse survival. Noradrenergic cortical markers were measured in 1, 2 and 4-month-old offspring of pregnant rats treated with graded doses of MAM. A dose-dependent increase of these markers was observed in 1 and 2-month-old animals, whereas at 4 months these markers were significantly lower in treated animals. This pattern was observed also in n. striatum for the dopaminergic afferents. We can therefore conclude that also the catecholaminergic system is target-dependent although regression seem to occur over a much longer period of time when compared to other systems, as recently reported by Ashwell (Dev. Brain Res. 35, 199, 1987) in the same animal model.

77.8

CRITICAL PERIOD FOR ANDROGENIC BLOCK OF NEUROMUSCULAR SYNAPSE ELIMINATION. C.L. Jordan, M.S. Letinsky and A.P. Arnold. Departments of Psychology and Physiology, UCLA, Los Angeles, CA 90024.

In the androgen-sensitive levator ani (LA) muscle of the rat, the normal developmental transition from multiple to single innervation of muscle fibers (mfs) occurs largely between postnatal days (P) 14-28 and androgen treatment during this time blocks this transition. Adult LA muscles retain their neonatal pattern of multiple innervation after juvenile (P7-34) androgen treatment (Jordan, Letinsky and Arnold, Soc. Neurosci. Abstr. 12: 1213). Juvenile androgen treatment also increases the diameter of adult LA mfs. The present experiment was done to determine when in development androgen is most effective in preventing synapse elimination and altering the size of adult mfs.

Male rats were castrated on P7, 21 or 35, then given daily injections of either testosterone propionate (TP) or the oil vehicle during the 2 weeks following castration. All animals were sacrificed at 9 weeks, and their LA muscles removed and stained with tetranitroblue tetrazolium, which stains motor axons and their terminals. TP during the first treatment period (P7-20) increased the percentage of multiply innervated mfs in 9 week LA muscles (54% in TP-treated vs. 12% in oil-treated) without increasing the size of LA mfs (26.8 μm vs. 27.0 μm). TP during the two subsequent periods had little or no effect on the amount of multiple innervation (P20-34: 24% in TP vs. 19% in oil; P35-48: 25% vs. 24%), but did increase mf size (31 μm in TP vs. 25 μm in oil; 36 μm vs. 28 μm). These data suggest that there are different critical periods for androgen effects on synapse elimination and on muscle fiber size, and that androgen can prevent synapse elimination independent of its effect on muscle fiber size. Supported by NIH grants HD15021 and HD7228.

77.9

SELECTIVE ELIMINATION OF CROSS-COMPARTMENTAL INPUTS DURING SYNAPSE ELIMINATION. S.P. Donahue* and A.W. English. Dept. Anatomy. Emory Univ. Atl, GA 30322.

Neuromuscular compartments are the territories of muscle innervated by primary (first order) muscle nerve branches. We used intracellular recording to examine the distribution of nerve terminals from axons coursing in different primary nerve branches to the medial head of the rat lateral gastrocnemius (LGm). We exposed and cut the LGm primary nerve branch, thus denervating all fibers innervated exclusively by axons coursing in the cut branch. During the first postnatal week of life, only about 5% of cells in LGm received innervation from axons which crossed into the LGm head from an adjacent compartment. The synapses responsible for this innervation were less able to evoke muscle cell action potentials. They were also restricted to an area of LGm not having a tendinous boundary to separate LGm from adjacent LG compartments. The loss of these inputs occurred at a rate different than that of compartmental synapse elimination: no cross-compartmental innervation could be detected at a time when 50% of muscle cells remained polyinnervated (P7). Furthermore, tenotomy delayed compartmental synapse elimination but had no effect on the loss of cross-compartmental innervation. We conclude that a very small number of axon branches initially cross compartment boundaries and that these branches are lost selectively during synapse elimination. Supported by USPHS Grant 20545.

77.10

SYNAPSE ELIMINATION IS SLOWED BY PARTIAL POSTSYNAPTIC ACTIVITY BLOCKADE IN THE NEONATAL RABBIT SOLEUS MUSCLE. E. M. Callaway and D. C. Van Essen, Division of Biology, Caltech, Pasadena, CA 91125.

To examine the role of postsynaptic activity in regulating the rate of neuromuscular synapse elimination, we continuously superfused α-bungarotoxin (α-BGT) over the surface of neonatal rabbit soleus muscles. Superfusion was begun at 6 days postnatal and continued for a variable duration (2 to 5 days) before muscles were analyzed. *In vitro* tension measurements indicated that suprathreshold synaptic transmission was blocked in only a small minority of the soleus muscle fibers. The percentage of polyinnervated fibers was assessed both physiologically and anatomically for toxin-treated muscles, contralateral muscles from the same animals, control (saline-superfused) muscles, and normal muscles of the same age.

Within muscles exposed to α-BGT for 5 days, an average of 55% of endplates remained polyinnervated based on either assay. This value was significantly greater than for any of the control groups, in which average polyinnervation ranged from 7% to 18%. Differences between toxin-treated and control groups were smaller at intermediate ages (8-10 days), but were statistically significant after just 2-3 days of the treatment. The anatomical assay further revealed that the retention of polyinnervation in α-BGT treated muscles was most pronounced near the muscle's surface, where the activity blockade was most extensive. However, endplates at the center were also affected, even though the activity blockade appeared to be minimal in this region.

These observations indicate that the rate of synapse elimination depends upon the levels of functional acetylcholine receptors. Since the percentage of endplates at which synapse elimination was delayed was greater than the percentage whose activity was completely blocked, we infer that synapse loss was slowed even in muscle fibers retaining some postsynaptic activity. Hence, the rate of synapse elimination may be regulated independently at individual endplates in response to graded changes in postsynaptic activity.

A COMPUTER MODEL OF NEUROMUSCULAR SYNAPSE ELIMINATION. J. M. Soha, E. M. Callaway, and D. C. Van Essen, Division of Biol., Caltech, Pasadena, CA 91125.

Synapse elimination is a complex process likely to involve a variety of distinct mechanisms and cellular interactions. It is often difficult to predict reliably how a hypothesized component of this process might affect the sequence of developmental events, and thus contribute to experimentally observed outcomes. We have developed a computer model of neuromuscular synapse elimination that provides an objective framework for analysing the roles which certain proposed mechanisms might play during synaptic maturation.

The current version assumes that presynaptic terminals compete for limited available space at each endplate. The model dynamically simulates the growth or retraction of individual terminals at each iteration. Actual size changes at each terminal are determined stochastically, based upon the momentary bias toward growth or retraction. This growth-retraction bias is calculatedly analytically, based upon a set of parameters whose values depend on the mechanism(s) being simulated.

To date, three general mechanisms have been studied: 1) an extracellular synaptic stabilization molecule ("scaffolding"); 2) a muscle-derived trophic factor that is taken up presynaptically and optionally can be transported to the cell body; and 3) intrinsic restrictions on metabolic capacity that reduce the competitive abilities of nerve terminals in proportion to motor unit size. Each hypothetical mechanism was able to simulate most, but not all, of 9 selected experimental observations that are descriptive of both normal and experimentally perturbed development.

The performance of both the scaffolding and trophic factor models is critically dependent on how the size of a presynpatic terminal affects its tendency to grow. Unless larger terminals tend to be at an advantage over smaller ones, synapse elimination proceeds very slowly in these models. We also examined several potential roles for presynaptic and postsynaptic activity. We found that an advantage to less active terminals could simulate development of the orderly relationship between recruitment order and motor unit size known to exist in adult muscles. Supported by NSF grant BNS-8408213.

INTERNEURONS INTERPOSED IN OLIGOSYNAPTIC PATHWAYS BETWEEN THE SUPERFICIAL PERONEAL NERVE AND THE FLEXOR DIGITORUM LONGUS MOTONEURONS IN THE CAT. A. K. Moschovakis, M. Solodkin and R. E. Burke. Lab. of Neural Control, NINCDS, NIH, Bethesda, MD 20892.

Previous work in this laboratory has demonstrated the existence of a disynaptic, low threshold pathway between the superficial peroneal (SP) nerve and the flexor digitorum longus (FDL) motoneurons (Fleshman et al., *Exp. Brain Res.* 54:133, 1984). In an attempt to locate interneurons in this pathway, we employed two approaches: 1) retrograde transynaptic transport of lectin-conjugated horseradish peroxidase (WGA-HRP; see Harrison et al., *Neurosci. Lettr.* 45:15, 1984) to label candidate interneurons; and 2) spike triggered averagIng of ventral root potentials to investigate the location, response properties and synaptic actions of individual segmental interneurons that were activated by low threshold SP afferents. In the anatomical experiments, WGA-HRP was injected bilaterally into the FDL muscle nerves under anesthesia and aseptic conditions. Two days later, the cat was re-anesthetized and maintained under halothane anesthesia for up to 54 hours. The SP of the left leg was continuously stimulated through cuff electrodes with repetitive trains (4 shocks, 200 Hz, 3 trains per sec, 2X threshold) while monitoring the compound action potential through a separate cuff electrode. Transneuronally labelled interneurons were plotted from serial sections after standard tissue fixation and TMB histochemistry. Labeled neurons were scattered bilaterally in laminae V to VII of spinal segments S1 to L4, with greatest concentration in L7 and L6. There were about twice as many labeled neurons on the left (stimulated) side.

Maximum field potentials after stimulation of SP afferents (2xT) were found within a more restricted region in the central and lateral/dorsal horn. This region overlapped the location of some HRP-labeled interneurons. Extra- and intracellularly recorded interneurons (n=26) that responded monosynaptically to SP stimulation (central latency: 0.4-1.2 msec) were found in the same region. Averaged records of ventral root potentials recorded with the sucrose gap technique and triggered from interneuron spikes revealed that some of these cells produce postsynaptic potentials in motoneurons.

78.2

CHEMICAL MODULATION OF MEDULLARY OUTPUT NEURONS WHICH CONTROL EXCITABILITY OF HINDLIMB ALPHA-MOTONEURONS IN CATS. K. Takakusaki*, T. Sakamoto* and S. Mori. Dept. of Physiology, Asahikawa Med. Col., Asahikawa 078 Japan

Pontomedullary reticular formation contributes to the excitability level setting of alpha-motoneurons (MNs). We tried to elucidate pontine contribution to the medullary output neurons in acute, decerebrate cats. A group of reticulospinal cells in the nucleus reticularis gigantocellularis (NRGc) were tonically activated by microinjection of carbachol (100 mM, 0.1-0.25 µl) into the nucleus reticularis pontis oralis (NRPo), while intrapontine injection of noradrenaline (100 mM, 0.1-0.25 µl) resulted in suppression of the NRGc cells. A train pulse microstimulation (20-40 µA, 3 pulses with 1 ms interval) to the NRGc evoked mixed postsynaptic potentials (PSPs) with short (5-20 ms) and long latencies (30-60 ms) in alpha-MNs. With microinjections of carbachol, noradrenaline and atropine sulfate into the NRPo, the stimulus effects of the NRGc upon alpha-MNs changed. With carbachol injection, IPSP components were markedly augmented with suppression of EPSP components, while IPSP components were suppressed with augmentation of EPSP components by noradrenaline and atropine injections. These results indicate that selective activation of acetylcholine and noradrenaline receptive cells in the NRPo modulates the effects of the medullary output neurons upon hindlimb alpha-MNs in a reciprocal manner.

78.3

SYNAPTIC RESPONSES EVOKED BY VENTRAL ROOT STIMULATION IN NEONATAL RAT MOTONEURONS. Z. G. Jiang*, M. Y. Wang* and N. J. Dun. Dept. of Pharmacol., Loyola Univ. Med. Ctr., Maywood, IL 60153

Intracellular recordings were made from antidromically identified motoneurons (MNs) in transverse (500 µm) spinal cord slices removed from neonatal (< 20 days) rats. Ventral root stimulation evoked a hyperpolarizing potential (IPSP) in about 10% of MNs. When recorded at the resting membrane potential between -55 and -75 mV, the mean amplitude and duration of IPSPs was 2.8 mV and 12 ms, respectively. The IPSP was associated with a decrease of input resistance; it was reversed between -70 and -80 mV. Strychnine (0.1-2 µM) as well as d-Tc (10 µM) reversibly blocked the IPSP, indicating that the latter is probably di-synaptic similarly to the Renshaw cell circuitry established for the cat MNs. In addition to the IPSP, ventral root stimulation evoked an excitatory potential (EPSP) in about 30% of MNs. A biphasic response consisting of an IPSP followed by an EPSP was observed in a few MNs. The EPSP exhibited a long latency (1-5 ms); the conduction velocity was estimated to be less than 1 m/s, which is slower than that of the motor axons (8-50 m/s). In the majority of MNs, the EPSP was associated with a decrease of input resistance. As the EPSP was reversibly depressed by low Ca solution and by excitatory amino acid antagonist kynurenic acid (0.2-1 mM), it is probably mediated by an excitatory amino acid. The results suggest that MNs receive excitatory synaptic inputs from fibers coursing in the ventral roots. (Supported by NS24226)

PHARMACOLOGICAL ANALYSIS OF IPSPS GENERATED BY SINGLE INTERNEURONS MEDIATING NON-RECIPROCAL INHIBITION IN THE CAT SPINAL CORD. I. Jiménez*, J. Quevedo*, M. Solodkin* and P. Rudomin. CINVESTAV, México, D.F. 07000

Previous work (J. Neurophysiol. 57: 1288, 1987) has disclosed the existence of several types of intermediate nucleus interneurons with inhibitory synaptic connections on motoneurons. We now investigated the sensitivity to systemic injections of strychnine (STR) and picrotoxin (PTX) of IPSPs elicited by interneurons mediating non-reciprocal postsynaptic inhibition with axon collaterals to the Clarke's column nuclei (CC). In barbiturate anesthetized cats with the dorsal columns sectioned at L1 level, CC stimulation produced monosynaptic IPSPs in the ventral roots (recorded with the sucrose-gap technique) that were abolished by STR (0.1 mg/kg) but not by PTX (1 mg/kg; n=5). STR also abolished the monosynaptic IPSPs elicited by CC stimulation in single spinal motoneurons (n=4). Spike-triggered averaging of root potentials following activity of single interneurons responding to group I and to low-threshold cutaneous inputs that were antidromically activated from the CC, revealed the existence of time-locked population IPSPs in the ventral roots that dissapeared after i.v. STR and were substituted by common excitation potentials (ACEPs; n=5). Computer analysis indicated that after STR no population IPSPs were present in record samples in which ACEPs were smallest. The population IPSPs were not abolished by i.a. PTX that reduced the DRPs produced by stimulation of group I flexor fibers up to 50% of control (n=2). It is concluded that monosynaptic IPSPs generated in motoneurons by interneurons mediating Ib-non reciprocal inhibition are mediated by glycinergic synapses. ELECTROPHYSIOLOGICAL PROPERTIES OF FACIAL MOTONEURONS (FMNs) IN BRAINSTEM SLICES FROM GUINEA PIG. Y. Nishimura*, P.C. Schwindt and W.E. Crill Dept. of Physiology & Biophysics, Univ. of Washington Sch. of Med., Seattle WA 98195.

Electrical properties of guinea pig FMNs were studied in *in vitro* brainstem slices at 30-35°C using constant current injection and voltage clamp. FMNs were identified histologically and by antidromic activation. The response to a subthreshold depolarizing current pulse was larger than to a hyperpolarizing pulse. Subthreshold depolarizing voltage clamp commands from resting potential evoked a persistent, tetrodotoxin (TTX)-sensitive inward current. Injection of suprathreshold depolarizing current pulses evoked repetitive firing characterized by an initial period of rapid adaptation and subsequent maintained firing. The relation between firing rate and current (f-I relation) was bilinear upwards during adaptation, but became shallower and linear during sustained firing. Single evoked action potentials were followed by a fast afterhyperpolarization (fAHP) and a subsequent medium duration AHP (mAHP). Replacement of Ca^{2+} with Co^{2+} abolished the mAHP and corresponding ionic currents, but spike duration was unaffected. The f-I relation became steeper and fast adaptation was reduced. Addition of tetraethylammonium (TEA: 10 mM) abolished the fAHP, prolonged the spike, enhanced the mAHP and reduced firing rate. We conclude that FMNs possess both a fast, TEA-sensitive K^+ conductance involved in spike repolarization and a slower, Ca^{2+}-mediated K^+ conductance that, together with a persistent Na^+ conductance, largely controls the repetitive response. Supported by NIH grants NS16972 and NS22410.

ELECTROPHYSIOLOGICAL PROPERTIES OF ADULT GUINEA PIG HYPOGLOSSAL MOTONEURONS STUDIED IN VITRO. F. Viana and A.J. Berger. Dept. of Physiology & Biophysics, Univ. of Washington School of Medicine, Seattle, WA 98195.

We have recently examined the basic firing behavior of hypoglossal motoneurons recorded intracellularly from transverse brainstem slices of guinea pigs (200-350 g) (Faseb J. 2:A513, 1988). In the present study we used pharmacological agents known to block specific ionic conductances and ionic substitution in the bath solution to characterize the ionic mechanisms underlying motoneuron firing behavior. Action potentials were evoked antidromically or with brief intracellular current pulses. Addition of 10-mM TEA to the perfusate caused a moderate increase in spike duration, suppression of the fast AHP (afterhyperpolarization), and an increase in the medium-duration AHP. Substitution of $Ca2^+$ with $Co2^+$ reduced the medium AHP with no effect on spike repolarization. Under these conditions the steady-state firing frequency was greatly enhanced. Intracellular Cs^+ markedly increased the spike duration, with additional spikes generated on the falling shoulder of the first spike. In the presence of extracellular 10-mM TEA, or in Cs^+-loaded cells after extracellular addition of TTX, a brief intracellular current pulse produced a sustained depolarizing plateau with superimposed spikes. Both the plateau and the spikes were completely eliminated when $Ca2^+$ was substituted with $Co2^+$. We conclude that the firing behavior of hypoglossal motoneurons is complex and is governed by a subtle balance between inward and outward currents. (Supported by NS 14857)

DIRECT EXCITATORY INTERACTIONS BETWEEN RAT PENILE MOTONEURONS. W.F. Collins, III and J.T. Erichsen, Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

In male rats, copulatory behavior is accompanied by rapid penile reflexes involving striated perineal muscles innervated by motoneurons (MNs) in the lumbar spinal cord. Using intracellular recording and staining techniques, we have examined a subset of these MNs (those located in the dorsal medial nucleus (DM or SNB) which innervate the bulbospongiosus (BS) and anal sphincter (AS) muscles) for evidence of electrical coupling. In gonadally intact male rats (Sprague-Dawley; 250-400 g), anesthetized with chloral hydrate or ketamine + xylazine and artificially ventilated, spinal cord segments L_1-S_3 were exposed and all lumbar and sacral dorsal roots cut bilaterally. Intracellular recordings were obtained from antidromically identified DM MNs using KCl (3M) or Lucifer Yellow (LY; 4% in 0.1M LiCl) filled glass micropipettes. Ipsilateral (ipsi) muscle nerves (BS or AS) or the contralateral (contra) PMN were stimulated individually (0.3-0.5 Hz) and the resulting MN response averaged. Short latency (300-700 us; from onset of antidromic field potential), graded EPSPs were observed. Peak amplitudes varied from 30-1200 uV (500-1200 uV, ipsi homonymous nerve stimulation (liminal); 100-400 uV, ipsi heteronymous nerve stimulation; 30-200 uV, contra PMN stimulation). In two experiments (of 8) intracellular LY injection resulted in dye coupling between ipsi DM MNs. These results suggest that rat penile MNs are electrically coupled. COMPUTER MODELING STUDIES OF THE EFFECT OF DENDRITIC LOCATION ON ANALYSIS OF SOMATIC EPSP AMPLITUDE FLUCTUATIONS. M. Solodkin, A.K. Moschovakis, J.D. Clements and R.E. Burke, Lab. of Neural Control, NINCDS and Lab. of Develop. Neurobiol., NICHD. , NIH, BETHEDSA, MD 20892.

A dynamic compartmental model based on the actual morphology of an α-MN was used to evaluate the effect of electrotonic distortion on the amplitude of somatic EPSPs generated by synaptic boutons distributed within a branched dendritic tree to mimic group Ia synapses. We assumed that the probability of activation of each bouton was independent and binomially distributed. Amplitudes of EPSPs resulting from the different combinations of activation probabilities were measured at and around the EPSP peak. Amplitude fluctuation analysis was done under one of two assumptions: 1) all boutons produced identical conductance changes; or 2) all boutons produced identical amplitude EPSPs at the soma (see Jack et al., *J. Physiol.* 321:65, 1981). Using assumption (1), the number of peaks in the EPSP amplitude distribution equals the number of boutons only when all boutons are at the same electrotonic distance from the soma. In addition, because of non-linear interactions between synapses, the increments between peaks are equal only when all these boutons are also located in different dendritic compartments. Under all other conditions, the number of peaks in the noise-free amplitude histograms exceed the number of boutons and are separated by unequal voltage increments. These problems were mitigated only partially when conductances were increased so as to generate EPSPs with equal amplitudes at the soma irrespective of electrotonic distance (assumption 2). The interpretation of quantal EPSP amplitudes educed by deconvolution analysis of synaptic events in the presence of noise is greatly complicated when applied to group Ia EPSPs, which are generated by synaptic boutons that are widely distributed in motoneuron dendrites.

VOLTAGE ATTENTUATION IN CABLE MODELS OF VAGAL MOTONEURONS. R. Nitzan*, Y. Yarom* and I. Segev* (SPON: O. Abramsky). Dept. of Neurobiology, Hebrew University, Jerusalem, Israel.

Cable models of morphologically and physiologically characterized vagal motoneurons from guinea pig brainstem slices were constructed. Four different types of steady-state voltage attenuation factors along the dendritic trees of these models were calculated based on Rall's cable theory: 1) $AF_{T\rightarrow S}$, the attenuation factor calculated iteratively from each dendritic terminal to the soma, averaged; 2) $AF_{S\rightarrow T}$, the attenuation factor from the soma to each of the dendritic terminals, averaged; 3) AF_{av}, or cosh (L_{av}), where L_{av} is the average cable length of the paths from the soma to dendritic terminals; and 4) AF_{peel}, or cosh (L_{peel}), where L_{peel} is the cable length calculated by "peeling" exponentials from voltage transients in the model, produced by a brief current injection to the soma. A new parameter, $\Upsilon = AF_{T\rightarrow S}/AF_{S\rightarrow T}$, is defined to characterize the asymmetry of voltage attenuation in the dendritic tree in the centripetal as compared to the centrifugal direction. In these cells, $AF_{T\rightarrow S} = 7.3$, $AF_{S\rightarrow T} = 1.4$ and $\Upsilon = 5.1$. Comparison between AF_{av} (1.2) and $AF_{S\rightarrow T}$ (1.4) shows that AF_{av} is a good estimate for the average voltage attenuation from the soma to the dendritic terminals. On the other hand, AF_{peel} (1.7) was found to be significantly larger than AF_{av} (1.2). This discrepancy is the result of trees whose dendrites have unequal electrotonic lengths, when the recording site (soma) is not in the midpoint of the cable. In this case, L_{peel} may reflect up to twice the average cable length from the soma to dendritic terminals when the dendritic to soma conductance ratio, ρ, is large and even somewhat more when ρ is small. The latter result indicates that, for a correct estimation of cable length of neurons, both electrophysiological and morphological data are essential.

ENCODING OF INFORMATION BY POPULATIONS OF DSCT NEURONS IN THE CAT. R.E. Poppele, Lab. of Neurophysiol., Univ. of Minnesota, Minneapolis, MN and C.E. Osborn, Kresge Hearing Res. Inst., Ann Arbor, MI.

Neurons of the DSCT respond to various stimuli of the hindlimb with long lasting changes in post-stimulus firing probability. Changes produced by small passive rotations of the foot follow stereotyped patterns of excitation and inhibition. These responses were characterized by principal component analysis of their waveform, and response types grouped by cluster analysis.

We investigated the responses of a randomly selected population of 115 neurons to passive flexion and extension of the foot and found that over 95% responded to this stimulus (7 rotations lasting about 100 ms). About half of the neurons in each response group gave the same response to both ankle flexion and extension. The remaining units in each group responded differently according to movement direction but all the responses within a group were generally changed in the same way. For example, units inhibited by flexion were either inhibited the same way by extension or else excited by extension. There were also different combinations of early (20-30 ms) and late (50 ms) responses. Thus, even though nearly all the cells of the DSCT respond to passive rotations of the foot, only a fraction of them encode the direction of the movement.

INPUT FROM THE SPINAL CORD TO THE VL NUCLEUS OF THE CAT THALAMUS. R. Mackel and T. Noda*. The Rockefeller University, 1230 York Avenue, New York, N.Y. 10021.

Intracellular recording techniques were used to study, in chloralose anesthetized cats, synaptic responses in cerebellocerebral relay neurons to dorsal column (DC) and spinothalamic tract (ST) stimulation. All neurons (n=88) were monosynaptically excited from the contralateral deep cerebellar nuclei and 25/88 were identified as thalamocortical projection neurons by their antidromic activation from the motor cortex. The recording sites in VL were anatomically localized by depositing a dye mark(pontamine sky blue) through the micropipette(filled with K-acetate). 74/88 neurons (84%), including 22/25 projection neurons, responded with short or long latency excitatory or inhibitory postsynaptic potentials to single or double shock stimulation of the spinal cord. Six neurons were tested for spatial facilitatory interactions between the DC and ST pathways. They did not respond to DC or ST stimulation in isolation, but were excited(4/6) or inhibited(2/6) when bothpathways were stimulated together. The spinal input to VL is primarely mediated polysynaptically, probably via brain stem structures. The findings extend recent work (1) and show that VL can no longer be regarded as a simple relay between the cerebellum and the motor cortex. Instead it appears to be a site of considerable sensorimotor integration.

COULD SPINOTHALAMIC TRACT (STT) TRANSMIT MUSCLE AFFERENT INPUT TO PRIMARY MOTOR CORTEX (MI) IN MONKEYS? S.F. Hobbs, D.C. Bolser, M.J. Chandler and R.D. Foreman, Dept. Physiol., Univ. of Okla. HSC, Okla. City, OK 73190.

Group II muscle afferent input from hindlimb excites MI (latency 15 ms). Cells in thalamic nucleus ventroposterolateralis oralis (VPLo) project to MI. Dorsal column nuclei and STT project to VPLo. Dorsal columns provide input to MI areas controlling distal limb muscles. Pathways contributing input to MI areas controlling proximal limb and axial muscles are undefined, but anatomical data suggest that STT may contribute. If this is true, STT cells that project to VPLo should 1) receive input from proximal or axial muscles, 2) conduct afferent input from muscle to thalamus in <15 ms, and 3) receive group II afferent input. STT cells in the L_2 to S_3 spinal segments in 9 anesthetized monkeys (Macaca fascicularis) were identified by antidromic activation from VPLo. Mechanical stimulation of thigh, tail, or abdominal muscles excited 25 (86%) of 29 STT cells. Electrical stimulation of muscle afferents was used to determine latency of muscle afferent input in 7 STT cells. Latencies averaged 6.1 ± 0.5 ms from hamstring or tail muscles to STT cells and 5.9 ± 0.6 ms from thalamus to cell for a total latency for muscle to VPLo via STT of 12.0 ± 0.8 ms. Calculated conduction velocity of muscle afferent input ranged between 34 and 58 m/s (mean 46 ± 3 m/s), for the 7 STT cells. These data support the hypothesis that primary motor cortex controlling proximal and axial muscles receive muscle group II input via STT. (NIH grants HL22732, HL07930, NS08150, and HL07304)

PARTIAL SPIKES ARE GENERATED IN THE DENDRITES OF MOTONEURONS. E. Sernagor*, Y. Yarom* and R. Werman* (SPON: H.Parnas). Dept. of Neurobiology, Hebrew University, Jerusalem, Israel.

We have investigated the sites of generation of partial spikes which develop in axotomized cat L_7 motoneurons. Partial spikes appear together with synaptic potentials, usually close to the maximum voltage of excitatory postsynaptic potentials. Partial spikes of different shapes and amplitudes may appear in the same cell as a result of synaptic stimuli from one or more sources. Rarely, partial spikes may appear during inhibitory postsynaptic potentials. The distribution of partial spike amplitudes appeared to be bimodal-like in 35.3% of the cells and monomodal in the others. Partial spike incidence and amplitude are reduced by hyperpolarization while they are increased by depolarization and may even, rarely, be evoked by somatic depolarization alone. We have recorded spontaneous partial spikes which, when averaged, appeared to be elicited by tiny excitatory postsynaptic potentials which could not be clearly discerned in single traces. Indeed, partial spike incidence and amplitude are increased by extracellular iontophoresis of excitatory amino acids without any significant change in the resting potential recorded in the soma, suggesting either that partial spikes are generated in restricted areas characterized by very low tresholds or that they have a more distal origin. Moreover, these findings also indicate that partial spikes might be generated in the vicinity of more-or-less remote excitatory synapses. Shape indices, however, indicate that almost all partial spikes discerned in somatic recordings are generated in the proximal five compartments of a ten compartment dendritic model of electrotonic length, L=1, as found experimentally.

SPINAL CORD AND BRAINSTEM: MOTOR OUTPUT

79.1

ELECTRICALLY AND CHEMICALLY INDUCED LOCOMOTION FOLLOWING ACTIVATION OF THE MEDIOVENTRAL MEDULLA IN THE RAT. N. Kinjo*, Y. Atsuta*, R.D. Skinner, M. Ort Webber* and E. Garcia-Rill, Dept. of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Previous reports from our labs have described the presence of an area in the cat medioventral medulla (MED) which, 1) can be electrically and chemically activated to induce locomotion, and 2) receives input from the mesencephalic locomotor region (MLR) (Garcia-Rill and Skinner, Brain Res. 411, 1987). The present study employed the precollicular transected adult rat preparation to determine the characteristics of this area in the rodent brain. Electrical stimulation of an area 1mm dorsal to the pyramids, posterior to the trapezoid body and anterior to the inferior olive was found to induce controlled locomotion on a treadmill at low thresholds (20-60 μA, 20-50 Hz pulses of 0.5-1.0 ms duration). Injections (0.5 μl) into the same area of the cholinergic agonist, methacholine (0.5 mM), and the GABAergic antagonist, picrotoxin (2-5 mM), were found to induce short episodes of locomotion. Injections of GABA (0.5-1M) into the MED were found to block MLR-induced locomotion. Combined with previous anatomical results showing projections from the MLR to the MED in the rat (Garcia-Rill *et al*, Brain Res. Bull. 17, 1986), these findings suggest that, in the rat, 1) the MED may provide reticulospinal elements which can control spinal pattern generators, 2) this area is under cholinergic and GABAergic influence, and 3) the main descending output of the MLR may be mediated by the MED in the rodent (as in the feline) brain. Supported by USPHS grants NS 21983 and NS 20246.

ROLE OF THE TELENCEPHALON IN LOCOMOTOR-RESPIRATORY COUPLING DURING WALKING IN GEESE. G.D.Funk, W.K.Milsom & J.D.Steeves. Dept. Zoology, U.B.C., Vancouver, Canada.

The role of the telencephalon in synchronizing locomotor and respiratory rhythms was examined in geese by comparing intact birds (n=4) during treadmill walking (8min) with decerebrate geese (n=9) that were induced to walk (10min) by focal electrical stimulation (25-100uA, 60Hz) of: 1) the nucleus and tract of the Trigeminal nucleus (TTD), and 2) the caudal reticular formation. Oxygen consumption, minute ventilation, tidal volume, breathing frequency (fv) and stride frequency (fs) were monitored throughout each trial. The ratio of fs/fv was calculated over each 10 sec interval and percent entrainment (E) was defined as the portion of time fs/fv occurred as an integer or 1/2 integer value (±0.05). The degree of locomotor-respiratory coupling in the two groups was virtually identical (dec=28.9±3.3%; int=28.3±3.9%) and greater than that predicted by random chance. These data suggest that interactions within the brainstem and/or spinal cord are sufficient for the synchronization of locomotor and respiratory rhythms. (supported by NSERC of Canada)

79.3

'FICTIVE' LOCOMOTION ELICITED BY ELECTRICAL OR CHEMICAL STIMULATION OF THE AVIAN MID- AND HINDBRAIN. G.N. Sholomenko and J.D. Steeves. Dept. of Zoology, U.B.C. Vancouver, Canada, V6T 2A9.

Electrical or neurochemical stimulation of sites in the mid- and hindbrain has been shown to evoke locomotion in the acute decerebrate Canada goose or Pekin duck (Sholomenko and Steeves, SN Abs,1987). Our present studies demonstrate that all modes of locomotion (as monitored from activity in peripheral nerves [ENGs]) present in the unparalyzed animal (eg. walking, running, transition from running to flying and flying alone) can also be produced in the curarized decerebrate preparation. The intensity of electrical current necessary to evoke locomotion was slightly higher in the paralyzed condition. Direct intracerebral infusion (chemical stimulation) of carbachol (1μl/27mM in PBS) or NMDA (0.4μl/30mM in PBS) was equally efficatious in both the unparalyzed and subsequently paralyzed trials. These results demonstrate that phasic afferent input is not essential to the expression of a diverse number of avian locomotor patterns at different levels along the spinal axis. (supported by NSERC of Canada)

INTERNEURONS INVOLVED IN STINGRAY LOCOMOTOR PATHWAYS. N.A. Bernau and R.B. Leonard. Marine Biomed. Inst., Univ. of Tex. Med. Branch Galveston, Tx 77550.

Vertebrate spinal cord neurons are capable of generating motor patterns during locomotion. We are using the Atlantic Stingray, Dasyatis sabina, to study the input to these neurons. Stingrays have a simple limb with pairs of segmentally organized and innervated muscle bundles. Extracellular recordings in paralyzed animals were used to study neurons associated with circuits generating locomotion. Stimulating electrodes were placed in the brain stem to evoke locomotion, which was recorded as alternating activity in nerves innervating one pair of elevator and depressor muscles. We recorded from neurons within the spinal cord whose activity was altered during locomotion. Then we tested to see if they receive input from the brain stem or the sensory nerve. Thirty-nine cells were found whose activity was altered during locomotion; 7 cells were tonically excited, 9 were inhibited, and 21 discharged phasically. One of the tonically excited and 6 of the phasic cells received input from the brain stem. One of the tonically excited and 3 of the phasic cells received sensory input. One of the tonic and 1 of the phasic cells received input from both the sensory nerve and the brain stem. These cells may be involved in integrating descending and sensory inputs with pattern generation. This work is supported by NS 11255 and NS 07185.

79.5

PHRENIC NERVE AND DORSAL RESPIRATORY GROUP NEURON RESPONSES TO NORMOCAPNIC HYPOXIA IN KITTENS. A.L. Sica, M.R Gandhi* and A.M. Steele*. Research Center, Schneider Children's Hosp, SUNY Stony Brook, New Hyde Park, New York 11042.

To obtain information about age-related responses of respiratory neuron discharges during normocapnic hypoxia (10% or 15% O2 in N2), dorsal respiratory group (DRG) neuron activities were recorded extracellularly in 24-120 d kittens. Experiments were carried out in anesthetized, paralyzed, artificially ventilated (100% O2), vagotomized and thoracotomized animals. The discharges of many neurons occurred during central inspiratory (I) phases; some, however, discharged during early expiration (E), i.e., early-E neurons. In animals <30 d, hypoxic stimulation (5-6 min) elicited an initial period (1-2 min) of facilitation of phrenic (PHR) and neuronal discharges, followed by a decrease in discharges toward or below control levels, and the occurrence of apnea, i.e, 'biphasic' response of the neonate. Such changes of discharges were typical of both I and early-E neurons. In animals >30 d, PHR discharges were usually facilitated during hypoxia; however, neuronal responses were quite variable: some were facilitated, whereas others were depressed. This latter result is similar to that reported for adult cats, supporting the concept of an uneven distribution of peripheral chemoreceptor afferents among DRG neurons. On the other hand, the decrease and subsequent absence of neuronal discharges in neonatal kittens suggest that such afferents exert a depressant effect upon DRG neurons.

79.6

MICROINJECTIONS OF EXCITATORY AMINO ACIDS INTO THE REGION OF THE KÖLLIKER-FUSE NUCLEUS ALTER PHRENIC MOTONEURONAL ACTIVITY IN THE RAT. M. Fournier & J.L. Feldman. Systems Neurobiology Lab., Dept. of Kinesiology, UCLA, Los Angeles, CA 90024.

The functional organization of the region of the Kölliker-Fuse nucleus (K-F) involved in respiratory control was studied by injecting picomole quantities of excitatory amino acids into discrete areas. Experiments were performed in anesthetized, spontaneously breathing rats. Phrenic (Phr) motoneuronal activity was monitored by recording diaphragm electromyographic activity. Multibarrel pipettes were used for pressure injection of drugs and iontophoresis of a marker. Barrels contained 10 mM solutions of L-glutamate (L-GLU), DL-homocysteic acid (DLH) and kynurenic acid (KYN) prepared in 165 mM NaCl (pH 7.4). A saline barrel was used for control injection. Volumes ejected were directly measured by monitoring the displacement of the meniscus in a barrel. The pipette was positioned in the K-F region using stereotaxic coordinates and was advanced in 50 µm steps at which small volumes (< 20 nL) of drugs were injected. Responses to injection of L-GLU or DLH were markedly site-specific and repeatable with transient increases or decreases of Phr discharge without arterial pressure change. Most potent effects were obtained with DLH injections; volumes < 1 nL could increase Phr discharges for periods > 10 sec. At some K-F sites DLH injection totally abolished Phr discharge for a few sec. Injection of equivalent volumes of saline produced no change in Phr discharge. These effects were attenuated or blocked by concurrent or prior injection of antagonist KYN. These results indicate the heterogeneous organization of the K-F and that receptors for excitatory amino acids are involved in the modulation or transmission of respiratory-related activity. Supported by NIH Grant HL-37941.

Extracellular Recordings from the Turtle Red Nucleus in an *In Vitro* Brainstem-Cerebellum-Spinal Cord Preparation.
J. Keifer and J.C. Houk. Northwestern University Medical School, Dept. Physiology, Chicago, IL, 60611.

The cerebellorubrospinal circuit has been postulated to function in the generation of motor patterns that may be adaptively tuned. This pathway is comprised of recurrent connections among the red nucleus (RN), the lateral reticular nucleus and the cerebellar nuclei, and is thought to form an excitatory feedback loop. Hence, bursts of activity recorded in the RN may be generated through this recurrent circuit and adaptively modulated by inhibitory inputs from cerebellar Purkinje cells. As an initial stage in examining this circuitry in detail, we report extracellular recordings from the RN in an *in vitro* brainstem-cerebellum-spinal cord preparation from the turtle *(Chrysemys picta)*.

The cerebellorubrospinal circuit was activated by stimulation of the contralateral spinal cord while activity in this circuit was sampled with extracellular recordings from RN neurons (n=73). Single units responded to stimulation with latencies clustering into three groups: antidromic responses (3-4msec), short latency synaptic (5-8msec), and long latency synaptic responses (11-14msec). Antidromic responses are not blocked in low Ca-high Mg bathing solution, while units activated at a latency of 5msec and longer are reversibly blocked. Recordings from single units in the RN of this preparation also reveal bursts of activity to single pulse stimulation of the contralateral spinal cord. Preliminary evidence shows that bursting activity is blocked in low Ca-high Mg, suggesting that it is driven by a synaptic network. Furthermore, removal of Purkinje cell inhibition from the cerebellum by cutting the contralateral cerebellar peduncle greatly enhances bursting discharges and spontaneous activity recorded in the RN.

These results show that the cerebellorubrospinal circuitry can be examined in detail in an *in vitro* preparation from the turtle. Furthermore, this preparation makes feasible the examination of the role of this circuitry in the generation of adjustable motor patterns.

79.8

CONVERGENCE FROM CUTANEOUS AND DEEP INPUTS ONTO THE NEURONS OF THE CAT MAIN CUNEATE NUCLEUS(MCN) PROJECTING TO CEREBELLUM AND TO OLIVE. L.Domich and F.J.Rubia*.Dept.of Physiol. U.of Alicante.Alicante;Dept.of Physiol.U.Complutense.Spain.

Convergence between cutaneous and propioceptive afferents onto the MCN neurons is considered key in the sensory-motor integration and kinesthesis. Nevertheless,the data shows a clear discrepancy.For some authors a meagre convergence(2%) is observed(Golovchinsky,1980;Dykes,1983)in marked contrast with others high proportion(69%)reported(Millar,1979). All data belongs to cuneothalamic neurons,less is known about the convergence onto the other cells in the MCN.In previous results(Domich et al,1987) we have reported specific and complex responses on these cells to parameters of movement.

In anesthetized cats,we have analized the responses evoked by a passive movement at wrist level on the cuneocerebellar and cuneolivar projecting cells,identified antidromically. The responses consist in a phasic,rapidly adapting,component or one tonic,slowly adapting,the mostly were the mixed responses.The partial or complete denervation associated or not to cut off of tendons have allowed us to eliminate almost selectively these components.The phasic responses appears to belong to footpad receptors and the two tonic one correspond to joint or muscles inputs.The mixed responses,phasic-tonic, were striking more frequent on cerebellar cells than the olivary projecting cells in which predominate the phasic responses.These data suggest that the convergence exist on the cuneocerebellar and olivary cells projecting and being crucial in the sensory-motor integration processes.

MEMORY SUBSTRATES IN PRIMATE SPINAL CORD PRODUCED BY OPERANT CONDITIONING OF H-REFLEX ARE STILL APPARENT AFTER TETANIC POTENTIATION. J.G. Calaitges*, J.S. Carp, C.L. Lee, and J.R. Wolpaw (SPON: L.D. Reid). Wadsworth Labs, NYS Dpt Hlth, Albany, NY 12201.

Monkeys can gradually increase or decrease the wholly spinal, largely monosynaptic triceps surae (TS) H-reflex if reward depends on reflex amplitude (J. Neurophysiol. 57:443-458, 1987). Conditioning causes changes in lumbosacral cord that persist after thoracic cord transection (Wolpaw & Lee, this vol). We evaluated the effect of tetanic potentiation on these memory substrates.

In 16 animals (Macaca nemestrina), the TS H-reflex in one leg was increased (8 HR↑ animals) or decreased (8 HR↓ animals) by conditioning. Animals were then deeply anesthetized, and monosynaptic reflexes to L6-S1 dorsal root stimulation were recorded from TS nerve in both legs before and after tetanization for 3 days after thoracic cord transection. Animals remained anesthetized throughout and were sacrificed by overdose.

Reflexes were much larger 20 s after tetanization. Nevertheless, the task-appropriate reflex asymmetries visible in the awake animal and in the unpotentiated reflexes of anesthetized transected animals were still apparent. In HR↑ animals, potentiated reflexes were larger in HR↑ legs than in control legs. In HR↓ animals, potentiated reflexes were smaller in HR↓ legs than in control legs. These asymmetries remained through the 3 days of post-transection study.

A possible source of the persistent conditioned reflex asymmetries is plasticity at the Ia afferent-alpha motoneuron synapse. The finding that tetanic potentiation, which also acts at the Ia synapse, does not eliminate these asymmetries suggests that they may reflect a different and more fundamental synaptic modification. RETICULAR FORMATION DISCHARGES AND BEHAVIORAL CHANGES IN THE RAT. O.J. Andy, D.F. Peeler, and M. Andrews*. Depts. of Neurosurgery and Preventive Medicine, U. of Mississippi Med. Ctr., Jackson, Ms. 39216

Reticular discharge-induced behaviors are usually related to the alerting response. Specific sensory and motor control systems located in the brainstem reticular formation were investigated in the adult rat. Bipolar electrodes were placed in the brainstem reticular formation. Electrical stimulation and recordings were made through sockets attached to an acrylic cap screwed to the skull. After 2-3 days of daily stimulations, EEG discharges and behavioral changes occurred. Discharges consisted of fast and slow frequencies with periodic buildups of high voltages. Behaviors consisted of extension of the neck, lowering the head, grooming the face and the tail, deep sleep, and states of varied excitability. Aggression was reduced. Normal behavior followed 1-3 weeks of stimulation.

RETICULO-RETICULAR AND RETICULO-SPINAL CONNECTIONS AFFECTING EMG ACTIVITY IN RAT BACK MUSCLES. A. Robbins*, S. Schwartz-Giblin and D.W. Pfaff. (SPON: M.S. Herness) Lab. of Neurobiology and Behavior, Rockefeller University, N.Y., N.Y. 10021.

Electrical stimulation in medullary reticular formation (MRF) produces EMG activity in rat back muscles, and effective MRF stimulation sites receive a strong projection from contralateral MRF (MRFc) (Robbins et al., Neurosci. Abs. 13: 21.3,1987). To determine if the MRFc cells also project to the lumbar spinal cord, rhodamine microspheres were injected at the effective MRF site and a fluorogold (FG) pellet was implanted in the lumbar spinal cord. The lack of double labeled cells in MRFc indicated that separate cell populations project to the effective MRF site and to lumbar cord. The typical effective MRF site appeared to be dorsal to retrogradely labeled reticulospinal cells. This relationship was tested more precisely by tracking the threshold for EMG activation in the MRF of 2 rats in which a FG pellet had been implanted in the lumbar cord. Highly effective sites were dorsal to the FG labeled reticulospinal cells, and more caudal MRF effective sites were ventral, among FG labeled cells. Dorsal effective MRF sites that do not project to the lumbar cord may powerfully augment direct reticulospinal outputs by virtue of their commissural connections within the MRF, and thus amplify EMG responses in back muscles.

RESPONSE CODING IN POPULATIONS OF PRIMATE CORTICOMOTONEURONAL AND RUBROMOTONEURONAL CELLS AND FORELIMB MOTOR UNITS. E.E. Fetz[1], P.D. Cheney[2], K. Mewes[3] & S. Palmer[4], Depts. of Physiology, Univ. of Wash.[1,4], Seattle, WA, and Univ. of Kansas[2,3], Kansas City, KS.

The post-spike effects of corticomotoneuronal (CM) and rubromotoneuronal (RM) cells on forelimb muscles (12 total) were documented in behaving monkeys by spike-triggered averages of EMG activity. RM cells facilitated more muscles per cell (mean: 3.0 of 6 synergist muscles) than CM cells (2.4/6). Both groups had "reciprocal" cells which also suppressed antagonists of their facilitated target muscles. Unlike CM cells, some RM cells co-facilitated flexor and extensor muscles (5.8 of 12 muscles).

During performance of a standard ramp-and-hold force tracking task the firing patterns of CM and RM cells, as well as single motor units (MU), fell into distinct response types. To estimate population activities the response histograms of different cells were summed (with force ramps aligned) in proportion to the relative frequency of each cell type. The population response histogram of CM cells was phasic-tonic, consistent with the predominant response type. The population response of RM cells was also phasic-tonic, but had a less prominent tonic component. The population histogram of MUs of a muscle was proportional to the average of rectified multiunit EMG, and typically exhibited decrementing activity during the static hold. The phasic discharge of the supraspinal premotor cells was larger and earlier than their target muscle activity, and their tonic discharge was more sustained. The difference between responses of forelimb MUs and these descending inputs may reflect intrinsic motoneuron properties and/or additional sources of synaptic input.

Unlike MUs, which were recruited over a range of forces, the CM and RM cells were usually active at the lowest force levels. The increase in tonic firing rate per increase in static torque was less for RM cells (mean: 117 Hz/Nm) than for CM cells (379 Hz/Nm) and MUs (340 Hz/Nm). These results allow quantitative estimates of the contribution of CM and RM cells to MU activity.

79.13

A STRUCTURAL COMPUTER SIMULATION OF THE INFERIOR OLIVARY NUCLEUS. M. Lee* and J. M. Bower, Division of Biology 216-76, Caltech, Pasadena CA 91125.

A computer model of the mammalian inferior olivary nucleus (IO), constrained by anatomical and physiological data, is described. Our objective is to explore the possible cellular and network mechanisms underlying the correlated climbing fiber-mediated activity observed by recording complex spikes from multiple Purkinje cells in rat cerebellum (Bower & Llinás, *Soc. Neurosci. Abs.* 9:607, 1983; Nelson *et al., Soc. Neurosci. Abs.*, this volume). We are also interested in studying the means by which the low-frequency oscillatory behavior seen in the IO might be initiated and modulated by afferent input and recurrent collateral and deep cerebellar feedback. As a basis for the network model, we have developed a model IO neuron incorporating membrane properties inferred electrophysiologically (*cf.* Llinás & Yarom, *J. Physiol.* 315: 549-567, 1981). Upon suprathreshold stimulation, an initial Na^+ spike is followed by an afterdepolarizing potential mediated by a high-threshold Ca^{2+} conductance; a subsequent afterhyperpolarizing potential (AHP), of variable duration, mediated by a Ca-dependent K^+ conductance; and a low-threshold rebound Ca^{2+} conductance. The low-threshold Ca^{2+} conductance, which is normally inactivated at resting potential, can be activated by rapid repolarization at the close of the AHP and drive the cell to spike again, thus providing a mechanism for intrinsic oscillation of the neuron. Networks of these model neurons are constructed according to known microanatomical features (*e.g.* synaptic glomeruli, dendritic thickets) and available biophysical data. We are examining the capabilities of these cellular and network properties for generation and modulation of oscillatory and spatially correlated patterns of activity in cerebellar cortex. CONTROL OF AMPLITUDE IN A CUTANEOUS REFLEX SUBSERVING LORDOSIS: A ROLE FOR A PROGESTERONE METABOLITE. Susan Schwartz-Giblin and Donald W. Pfaff. Rockefeller University, New York City, N.Y. 10021.

During manually-elicited lordosis behavior, EMG activation in deep back muscles occurs concomitant with vertebral dorsiflexion (Exp.Neurol.1984). Consequently, in urethane-anesthetized rats, a brief latency EMG response recorded in lateral longissimus following electrical stimulation of either the ipsilateral, contralateral or bilateral nerves to flank skin must reflect activity in neuronal circuitry for the behavior. Conditioned reflex testing with EMG recording reveals prolonged facilitation following the contralateral-evoked response but a period of inhibition following the ipsilateral-evoked response. The inhibition has a time course that parallels Renshaw feedback inhibition. Consistent with recurrent inhibition is its dependence on axial motoneuron discharge; a weak ipsilateral EMG response does not inhibit subsequent reflex activity. The progesterone metabolite, 3 α -OH-5 α -dihydroprogesterone (250 ug i.v.) antagonizes the delayed inhibition resulting from ipsilateral cutaneous nerve stimulation.

Contralateral cutaneous pressure and contralateral cutaneous nerve stimulation are known to inhibit Renshaw cells (Wilson et al., J.Neurophysiol. 1964). Therefore, bilateral flank palpation and progesterone may act to increase axial muscle gain by reducing Renshaw negative feedback during lordosis behavior.

PROJECTIONS OF LARGE MUSCLE AFFERENTS TO THE MOTONEURON POOLS OF THIGH MUSCLES IN MAN. Ahmed Bayoumi* and P. Ashby (SPON: R.D.G. Blair) Playfair Neuroscience Unit, Toronto Western Hospital, Toronto, Ont. M5T 2S8

The projections from group 1 muscle afferents to the motoneuron pools of biceps femoris(BI), semitendinosus/semimembranosus (ST), vastus medialis (VM), and vastus lateralis (VL) were examined in man. Muscle afferents were stimulated by electrical stimulation of muscle nerves and by tendon taps. Changes in the firing probability of single motor units were used to derive the afferent connections to individual motoneurons. All muscles examined showed short latency homonymous facilitation. Heteronymous facilitation was easily demonstrated between the two vasti muscles but not from ST to BI nor (unequivocally) from BI to ST. Reciprocal inhibition of ST and BI from low threshold afferents in the femoral nerve was readily demonstrated but inhibition of the vasti was not demonstrable from BI afferents and rarely from ST afferents. These projections differ from those of cats and baboons likely reflecting the differing functions of these muscle in each species.

TETRAETHYLAMMONIUM ATTENUATES HYPOXIA-INDUCED SPREADING DEPRESSION IN HIPPOCAMPAL SLICES. P.G. Aitken and G.G. Somjen. Dept. of Physiology, Duke Univ. Medical Center, Durham NC 27710.

During ischemia or hypoxia, brain tissue typically undergoes a process that is very similar, if not identical, to spreading depression. This hypoxic SD has been shown to be an important part of the mechanisms by which hypoxia/ischemia causes neuronal damage. In these experiments we asked whether the potassium channel blocker tetraethylammonium (TEA) could attenuate hypoxic SD in the CA1 region of hippocampal tissue slices. Transverse rat hippocampal slices were maintained at 35.5°C in an interface chamber. Each slice was exposed to two brief periods of hypoxia, 35-45 minutes apart, one in control medium and one in 10mM TEA (with the order alternated between experiments). The extracellular potassium concentration ($[K^+]_o$), DC potential, and evoked synaptic responses were monitored in stratum pyramidale of CA1. The average $\Delta[K^+]_o$ response was decreased from 41.3 mM in control medium to 17.5 mM in TEA ($p < 0.01$), and the ΔV response was decreased from 14.4 mV to 9.0 mV ($p < 0.05$). Latency of hypoxic SD was also decreased, although the change was not significant (75.4 vs. 105.2 sec). That only part of the K^+ efflux is blocked by TEA suggests that hypoxia opens K^+ channels that do not open under physiological conditions.

SYNAPTIC PHYSIOLOGY OF HIPPOCAMPAL AREA CA1 AFTER TRANSIENT FOREBRAIN ISCHEMIA IN THE GERBIL. L. Urbán*, K. Neill*, B.J. Crain, J.V. Nadler and G.G. Somjen. Depts. Physiology, Pharmacology, Pathology and Anatomy, Duke Univ. Med. Ctr., Durham, NC 27710.

Transient carotid occlusion in the Mongolian gerbil leads to degeneration of CA1 hippocampal pyramidal cells after a delay of 2-3 d. Several lines of evidence suggest that the critical events responsible for delayed neuronal death take place during the first few hours of reflow. The present study tested the hypothesis that pyramidal cell death is preceded by a period of excessive synaptic excitation.

Transverse hippocampal slices were prepared from unoperated and sham-operated control gerbils and from gerbils that had survived from a few minutes to 10 d after occluding both common carotid arteries for 5 min under 2.5% halothane. Synaptic responses were evoked by stimulating the Schaffer collateral-commissural projection to area CA1 or the perforant path and were recorded extracellularly. Effects of ischemia were deduced from analysis of component input-output curves.

Immediately after the occlusion and for the next 4 h the initial slope of the extracellular EPSP in area CA1 was significantly increased with no enhancement of postsynaptic excitability and no change in the amplitude of the antidromic population spike. In area CA1 of slices prepared 10 h after the occlusion both the extracellular EPSP and orthodromic and antidromic population spikes were severely depressed and they continued to decline over the next 2 d. No recovery was detected. In the same slices, responses evoked in the fascia dentata by perforant path or antidromic stimulation were little affected by ischemia. After completion of the recordings, slices were fixed in paraformaldehyde, cut into sections and stained by silver impregnation. Neuronal degeneration in this material was identical to that previously reported in postischemic hippocampal formation perfused in situ.

We conclude that CA1 pyramidal cells lose electrophysiological function well before definite morphological signs of degeneration become visible. Our observation of enhanced excitatory synaptic transmission during the early reflow period supports the idea that delayed ischemic neuronal death results from excessive excitation. (Supported by NIH grant NS 06233.)

80.3

ABSENCE OF ELECTROGRAPHIC SEIZURES AFTER TRANSIENT FOREBRAIN ISCHEMIA IN THE GERBIL. D.R. Armstrong, K. Neill*, B.J. Crain and J.V. Nadler. Depts. Pharmacology, Pathology and Anatomy, Duke Univ. Med. Ctr., Durham, NC 27710.

Certain neuronal populations in the CNS are selectively vulnerable to a brief period of cerebral ischemia. This pattern of neuronal degeneration can be reproduced in the gerbil by occluding both common carotid arteries for 5-10 min. Because many gerbils are prone to develop seizures, it has been suggested that ischemia in these animals initiates seizures and that these seizures are at least partially responsible for the ischemic damage. The present study used depth electrode recordings to determine whether carotid occlusions sufficient to produce extensive brain lesions also evoke electrographic seizures in the damaged regions.

Bipolar EEG recording electrodes were chronically implanted in hippocampal area CA1 and the dorsolateral striatum. Skull screws were implanted in the frontal bone to record neocortical EEG. After a recovery period of 3-14 d, EEG was continuously recorded from freely-moving subjects for 24 h before and 96 h after occluding both common carotid arteries for 5-10 min (N = 16). Five sham-operated gerbils were also studied. At the end of the recording period, the extent of neuronal cell death was determined by silver impregnation.

During the first few hours after the occlusion, the EEG was dominated by delta waves similar to those recorded from human brain after a damaging episode of cerebral ischemia. This period was followed by behavioral hyperactivity associated with a normal-appearing EEG record. Amplitudes of the hippocampal and striatal EEG declined markedly with time during the recording period, presumably as a result of neuronal degeneration. Ictal activity was never recorded, even from animals that suffered extreme damage to the hippocampal formation and striatum. Therefore ischemic cell death in gerbils does not result from seizure activity. (Supported by NIH grant NS 06233.)

PHARMACOLOGICAL CHARACTERIZATION OF THE PERSISTENT DEPOLARIZATION INDUCED BY EXPERIMENTAL ISCHEMIA. R.K. Rader, G.B. Watson, T.H. Lanthorn. CNS Diseases Research, G.D. Searle, Chesterfield, MO 63198.

We are utilizing a model of experimental ischemia (EI) which involves exposure of in vitro hippocampal slices to both hypoxia and hypoglycemia (2mM D-glucose). Synaptic responses are lost within two minutes from the onset of hypoxia and this is followed by anoxic depolarization(AD). During anoxic depolarization, the membrane potential depolarizes up toward zero. The slice is reoxygenated one minute after AD. During reoxygenation, following AD, synaptic failure persists and the membrane potential remains depolarized.

Intracellular recordings show that competitive (100μM CPP) and non-competitive(10μM MK-801 and 30μM PCP) NMDA antagonists perfused during reoxygenation will allow the membrane potential to repolarize and regain an EPSP with action potential. Cells treated with PCP only partially repolarize. Perfusion of the slice with 0.5mM Ca^{++} and 5.0mM Mg^{++} before, during and after AD also allows for repolarization after EI. These data suggest that a calcium channel plays a major role in whether the cell will recover its membrane potential. Studies looking at variety of calcium channel blockers as well as the timing of the protective effect of low calcium will be shown which may determine which channels are responsible for PSF.

80.5

EFFECT OF GLOBAL ISCHEMIC INSULT ON ELECTROPHYSIOLOGICAL RESPONSES OF RAT HIPPOCAMPAL SLICES. F. El-Sabban*, K. H. Reid, H. L. Edmonds, Jr. and C. B. Shields Laboratory for Cellular Neuroscience, School of Medicine, University of Louisville, Louisville KY 40292.

Male Wistar rats (250-300g) were subjected to an 8 minute total loss of blood pressure (global ischemic insult, Edmonds et al, submitted) and then resuscitated, 2-3 weeks prior to study of electrophysiological responses of hippocampal slices in vitro. Unlike controls, these rats consistently showed sound-induced behavioral seizures post-insult. Population spike responses were recorded from the CA1 region in 3.5 mM K+ artificial CSF, using standard techniques (Reid et al, Brain Res 302:387, 1984). When [K+] was raised to 8.0 mM, spontaneous burst activity developed in both CA3 and CA1. Bursts were classified as "countable" (consistently greater than a preset threshold), "detectable" (visible on the display, but less than threshold amplitude) or "absent" (no detectable spontaneous activity). Rats subjected to global ischemia showed fewer "countable" bursts (in CA1 17/70 vs 65/133 in controls, $p<.001$) and more non-bursting slices (35/70 vs 47/133 in controls, $p<.05$) than controls. Burst frequency in CA3 and CA1 was highly correlated in both ischemic ($r=.95$, df 12) and control ($r=.98$, df 86) groups for all "countable" bursts. The lower ability of hippocampal slices from insulted rats to sustain burst activity is consistent with selective destruction of neurons in this region after ischemic insult (Kirino et al, Prog. Brain Res. 63:39,1985). The site of origin of behavioral seizures in these post-ischemic rats remains undetermined.

80.6

GANGLION CELL VULNERABILITY FOLLOWING AN ACUTE EPISODE OF COMPLETE RETINAL ISCHEMIA IN THE CAT. R. Siliprandi*, R. Canella*, G. Carmignoto* and G. Vantini (SPON: L. Facci). Fidia Research Laboratories, Abano Terme, Italy.

An acute episode of complete retinal ischemia in the cat was produced by increasing for 90 minutes the intraocular pressure above the level of the systolic blood pressure. Retinal functionality during and after the induction of the ischemic insult was assessed by means of electroretinographic recordings (ERG). In particular: the electrical activity of the outer retinal neurons was evaluated by recording the ERG in response to a sinusoidally modulated uniform field (FERG) whereas the electrical activity of the inner retinal neurons (particularly the ganglion cells) was evaluated by recording the ERG in response to a contrast reversing grating (PERG). As soon as the ischemic conditions were established both the FERG and PERG responses were simultaneously abolished. However, the recovery of the two ERG responses was found to be different: the PERG was completely impaired even 30 days after the ischemic insult, whereas the FERG always recovered. Morphological analysis performed on transverse sections and whole-mount preparations 30 days after the ischemic episode revealed a dramatic cell death limited to the ganglion cell layer. These results suggest that only a selected population of retinal neurons (presumably the ganglion cells) is selectively damaged following an acute ischemic insult.

80.7

CALCIUM/CALMODULIN-DEPENDENT *IN VITRO* PROTEIN PHOSPHORYLATION IS REDUCED IN ISCHEMIC TISSUE. A. Kochhar*, T. Saitoh, and J.A. Zivin. Dept. of Neurosciences, School of Medicine, Univ. of California, La Jolla, Ca 92093.

Ischemia initiates a series of biochemical events that can eventually lead to cell death. Energy stores are depleted rapidly and intracellular calcium homeostasis is disrupted. These initial ischemic events could have profound effects on the calcium/calmodulin-dependent protein kinase (PK-B) system. We examined the effects of 1 h of ischemia on PK-B-mediated protein phosphorylation in rabbit spinal cord. This ischemia duration produces irreversible neurological damage. Spinal cords were rapidly excised from control and ischemic animals and frozen. Tissue samples were homogenized and centrifuged. In *in vitro* protein phosphorylation assays, membrane and cytosolic fractions were incubated under phosphorylating conditions, in the absence or presence of PK-B activators, calcium and calmodulin. Proteins were separated by SDS-polyacrylamide gel electrophoresis, stained with Coomassie Blue, and phosphorylated proteins were detected by autoradiography. The PK-B-mediated *in vitro* protein phosphorylation pattern was altered in ischemic tissue. *In vitro* phosphorylation of all substrate proteins, particularly in the membrane fraction, was reduced after 1 h of ischemia. This study shows that the PK-B system is affected by ischemia. Alterations in this critical regulatory system may contribute to irreversible ischemic injury.

80.8

NMDA RECEPTOR BLOCKADE DOES NOT DECREASE 45Ca UPTAKE IN CA1 NEUROPIL DURING "ISCHEMIA". D. Lobner* & P. Lipton. Dept. of Physiol., Univ. of Wisconsin, Madison, WI 53706.

5' exposure to buffer equilibrated with 95%N_2-5%CO_2 and devoid of glucose causes long-term transmission failure (LTF) between the Schaffer collaterals and CA1 pyramidal cells in the rat hippocampal slice. If 1mM Ketamine is included in the ischemic buffer there is no LTF (recovery=101±9%). 100uM PCP partially prevents LTF (recovery=36±19%).

We tested the ability of NMDA antagonists to attenuate the calcium build-up in the neuropil of CA1. Slices were equilibrated with 45Ca for 45' and then exposed to ischemia for 5', still in the presence of 45Ca. 5' ischemia increased neuropil Ca by 25%. The increase in the presence of 1mM Ketamine and 100uM PCP were somewhat larger, 35-40%. Thus, tissue accumulation of calcium during ischemia is not mediated by NMDA receptors. Both Ketamine and PCP reduce 45Ca accumulation in control conditions by about 20%.

The results are consistent with 3 possible mechanisms for NMDA induction of ischemic damage. A) NMDA activation in normoxic conditions produces some Ca entry and so raises resting levels of cytosolic Ca. During ischemia cell Ca levels are thus higher and more damaging. B) NMDA activation elevates ischemic cytosolic Ca by releasing Ca from intracellular stores, perhaps producing a relative decrease in total cell Ca accumulation. C) NMDA activation exacerbates damage in a Ca independent fashion.

80.9

ISCHEMIA-INDUCED INHIBITION OF CAM KINASE II ACTIVITY IN GERBIL BRAIN. K. A. Tennes-Rees,*[1] S. B. Churn,*[1] W. C. Taft,*[1] M. L. Billingsley[2] and R. J. DeLorenzo.[1] [1]Dept. of Neurology, Medical College of Virginia-VCU, Richmond VA 23298, [2]Penn. State Univ., Hershey PA 17033.

The precise molecular mechanisms responsible for ischemia-induced cell death are not known. However, loss of Ca^{2+} homeostasis is one event which has been implicated in the mechanism of ischemic brain damage. CaM Kinase II phosphorylation is involved in mediating some of the effects of Ca^{2+} on neuronal function. To examine the effects of ischemia on CaM Kinase II, this study used the gerbil model of forebrain ischemia, which involves cessation of blood flow to the brain for 5 min by bilateral carotid occlusion (Brain Res.447:159,1988). Ischemia significantly decreased the autophosphorylation of the 50 and 60 kDa subunits of CaM Kinase II and also the phosphorylation of other substrates, including synapsin I. This effect was measured in homogenates of both hippocampus and cortex as early as 10 sec and also at 30 min, 2 hours, 2 days and 7 days post-ischemia. No modification in CaM Kinase II activity occurred in brainstem, which is not ischemic in this model. Autophosphorylation of CaM Kinase II purified from ischemic brain was significantly less than that from control. Protein staining, phosphopeptide maps and biotinylated-calmodulin binding properties of purified ischemic kinase were not significantly different from control. The results indicate that ischemia induces a rapid and long lasting change in CaM Kinase II activity and suggest that modification of this enzyme may be an early event in the development of ischemia-induced cell death.

80.10

CALCIUM ACCUMULATION IN GERBIL THALAMUS FOLLOWING REPEATED ISCHEMIC INSULTS. J. Ikeda*, F. Joo*, J. Lohr*, C.A. Reutzler*, T.S. Nowak, Jr. and I. Klatzo. Lab. of Neuropathol.&Neuroanat. Sci., NINCDS, Bethesda, MD 20892

In a series of experiments we have characterized the effects of repeated ischemic insults on physiological, biochemical and histological parameters in gerbil brain. In this study we examined the consequences of 3 ischemic episodes of 1.5 min duration, repeated at 1 h intervals. Upon recirculation there was a hypoperfusion period similar in magnitude and time course to that observed after single or repeated ischemia of longer duration. There was no significant edema at any recirculation interval, in marked contrast to the severe secondary edema observed after repeated 5 min occlusions, and there was negligible mortality. Histological examination at 7 d revealed frequent loss of hippocampal CA1 neurons, as well as a striking accumulation in thalamus of granules which stained positive for calcium and acid mucopolysaccharides, as well as with periodic acid Schiff reagent. There was no apparent cell loss in thalamus. Autoradiographic studies of Ca-45 uptake revealed selective accumulation of label in thalamus beginning within 24 h recirculation, continuing for at least 3 d. Labeling of CA1 was evident at the longer interval. While thalamic injury has also been noted after single ischemic insults, our results suggest that thalamic involvement is particularly evident after repeated carotid artery occlusions in the gerbil.

VISUALIZATION OF HYPOXIA-INDUCED CYTOSOLIC CALCIUM ELEVATION IN HIPPOCAMPAL NEURONS. [1]Y. Kudo*, [1]A. Ogura*, [2]S. Sugita* and [2]H. Higashi* (Spon: T. Amano) [1]Dept. Neurosci., Mitsubishi Kasei Inst. Life Sci., Machida, Tokyo 194 and [2]Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, Japan.

Hippocampal CA1 neurons are vulnerable to hypoxic invasion. In order to analyze the cellular basis of the vulnerability, we exposed the CA1 neurons to a medium deprived of oxygen and monitored cytosolic calcium ion concentration ([Ca]i) by fluoromicroscopic image analysis. When a guinea-pig hippocampal slice loaded with fura-2 was superfused for 10 min with a glucose-free hypoxic medium (gassed with 95% N_2/5% CO_2), a significant elevation in [Ca]i was recognized in a layer of CA1 stratum radiatum. Elevations in [Ca]i in layers of strata pyramidale and oriens were less prominent. A monotonous depolarization of membrane potential indicated an irreversible cell damage. Exposure of a slice to a high K (75 mM)-containing medium for 5 min caused a marked and practically irreversible increase in [Ca]i in s. radiatum. Increases in [Ca]i in s. pyramidale and s. oriens were reversible. A similar tendency was recognized in a dissociated cell culture of rat hippocampal CA1 neurons. When the cultured neuron was exposed to a deoxygenated medium, the rise in [Ca]i was greater in magnitude and longer in duration in cell processes than in cell soma. These results suggest a topographical difference in Ca-mobilizing and Ca-extruding capabilities within single CA1 neurons and a preferential damage of the cell's dendritic region to hypoxic invasion.

80.12

Protein synthesis and ATP in different cell populations of the rat hippocampal slice following 5' ischemia: role of calcium and NMDA receptor activation. K.M. Raley and P. Lipton. Univ. Wisconsin-Madison, Madison, WI 53706.

We previously demonstrated that 5' ischemia (N_2-CO_2-equilibrated buffer lacking glucose) causes a profound and prolonged inhibition of protein synthesis in CA1 pyramidal cells of the rat hippocampal slice. This inhibition is prevented if the ischemic buffer lacks calcium and contains 1 mM ketamine, suggesting that both extracellular calcium and NMDA receptor activation are involved in this effect. The present study documents two additional aspects of the effects of ischemia on protein synthesis in this preparation.

A. Changes in ATP associated with protein synthesis inhibition: effects of NMDA receptor blockade.

ATP levels decrease to <10% of control levels immediately after 5' ischemia in the CA1 stratum pyramidale. 3 hr postischemia, a time when protein synthesis rates are 30% of control rates, ATP levels have recovered to 70% of control levels. 0 Ca^{2+}-1mM ketamine buffer, which completely prevents the protein synthesis inhibition in this cell type, does not attenuate the immediate fall in ATP levels, but does allow a better recovery of ATP levels, to 83% of control levels.

B. Effects of ischemia on protein synthesis in glia and capillary endothelial cells: involvement of calcium and NMDA receptor activation.

In marked contrast to the protein synthesis inhibition in CA1 pyramidal neurons, 5' ischemia produces a dramatic increase in synthesis in glia and capillary endothelial cells (3- and 2-fold, respectively). The stimulation of protein synthesis is not attenuated by exposure to 0 Ca^{2+}-1mM ketamine buffer during the ischemia.

81.1

DEVELOPMENT OF A SUB-SET OF SOMATOSTATIN NEURONS IN RAT VISUAL CORTEX. S.C. Feldman. Dept. of Anatomy, UMDNJ-New Jersey Medical School, Newark, N.J. 07103.

We have previously reported that perinatal visual cortex (VC) contains a population of cells adjacent to the white matter some of which are immunoreactive for somatostatin (SRIF). These cells, which are small and round, may be precursors of SRIF neurons in the adult. Alternatively, they could be glia. To resolve this issue two studies were performed. In the first, birthdates of neurons in VC were determined using ^{3}H-thymidine incorporation into DNA. Autoradiographic analysis demonstrated that the cells in this zone are 'born' between E 15.5-17.5. Autoradiography combined with immunocytochemistry showed that all SRIF containing cells are born by E 17.5. In the second study the identity of the cells in this zone was confirmed by the demonstration that they are immunoreactive for neuron-specific enolase but not for the glial antigens GFAP or S100. Our results suggest that there are two populations of SRIF neurons in VC, an early population born before E15 whose cells reach the surface of the cortical plate before birth and a later set, born after E 15, which synthesize SRIF while in their immature form and before migration is complete. The presence of these cells would also account for the dense plexuses of SRIF-containing fibers in VC during the time of cell migration.

81.2

DISTRIBUTION OF GABA-LIKE IMMUNOREACTIVITY IN PIGEON VISUAL AREAS: POST-HATCHING MODIFICATIONS AND EFFECTS OF UNILATERAL RETINAL ABLATION. G.Fontanesi*, L.Domenici*, P.Bagnoli and P.Streit. Dept.of Physiol.Biochem. Univ., Inst.of Neurophysiol.C.N.R.,Pisa,I-56100 and Brain Res.Inst., Zurich,CH-8029.

The pigeon brain was recently shown to contain numerous GABA-ergic systems which have been identified by means a monoclonal antibody obtained following immunization with GABA-BSA (mAb 3A12; Matute,C. and Streit,P., Histochem.,86:147,1986; Domenici et al.,J.Neurosci.,in press). In the present work we employed mAb 3A12 to investigate: i) the distribution of GABA-like immunoreactivity (GABA-LI) in the pigeon primary visual areas during the first ten days after hatching and, ii) possible changes of GABA-LI distribution in the same areas of adult pigeons which had early unilateral retinal removal. Perfused brains were conventionally cut and processed for immunohistochemistry using the PAP method. GABA-LI distribution in the visual areas changed during the first period after hatching and the adult pattern was reached around the 9th day. From hatching to 9 days, the most primary visual areas showed a progressive decrease in the relative density of labeled cells and an increase of GABA-ir terminal like elements. Adult pigeons with early retinal removal showed an incomplete development of GABA-ergic systems and the GABA-LI distribution was similar to that found at the early posthatching stages. In conclusion, GABA-ergic systems in the pigeon visual areas are incompletely developed at hatching and their maturation seems to depend upon the arrival of retinofugal axons.

CHARACTERISTICS OF CAT GAP: A GAP43-LIKE PROTEIN IN VISUAL CORTEX. H. McIntosh, D. Parkinson, M.B. Willard, and N.W. Daw, Wash. Univ. Med. School, St. Louis, MO 63110.

We are studying biochemical changes during the critical period of cat visual cortex. Our studies have concentrated on GAP43/F1/B50 because of its association with axonal growth, axonal regeneration and synaptic plasticity.

We have purified a GAP43-like protein (cat GAP) from cat forebrain and identified it in the cat visual cortex. Its isoelectric point is about 4.7 and its apparent molecular weight in SDS gels varies inversely with the acrylamide concentration. The mobility of purified cat GAP in SDS gels is slightly less than that of GAP43. Similarly, the GAP43-like protein in membranes from cat visual cortex, which is recognized on immunoblots, has a lower mobility than GAP43. Cat GAP chromatographs with an apparent MW weight greater than 100 kD on gel filtration. Following cleavage of a blocked N-terminus, an amino acid sequence was obtained (-RRTKQVEKND-) which is identical to amino acids 6-15 of rat GAP43 (Karns et al, Science 236:597-600, 1987). As in visual cortex, the forebrain concentration of cat GAP is decreased after the peak of the critical period.

In summary, we have isolated a GAP43-like protein and demonstrated its presence in cat visual cortex. We have shown that it has the expected properties. Amino acid sequencing data is also consistent with its identity as a GAP43-like protein. In addition, we have shown, both chromatographically and immunologically, that its concentration declines after the peak of the critical period.

POSTNATAL CHANGES IN GENE EXPRESSION IN KITTEN VISUAL CORTEX AND THE EFFECTS OF DARK-REARING. R.L. Neve and M.F. Bear. The Children's Hospital, Boston, MA 02115, Brown University, Providence, RI 02912.

The kitten striate cortex displays considerable synaptic plasticity during a critical period of postnatal development. We are exploring the possibility that specific patterns of gene expression bestow the cortex with this remarkable capacity to change.

RNA isolated from the visual cortex of kittens at various postnatal ages was examined with Northern blots and quantitative dot blots to determine the developmental course of expression of several genes. Expression of the growth associated protein GAP-43 was 6.6x the adult level at postnatal day 10 (P10, the youngest age examined). GAP-43 RNA dropped steeply to 170% of adult by P36, and decreased gradually thereafter. In contrast, the expression of the α subunit of calcium/calmodulin dependent kinase II (CaM kinase II) was only 14% of adult level at P10 and rose to adult level by P53. Glutamic acid decarboxylase (GAD) RNA levels were somewhat variable and did not show a clear developmental trend.

Visual experience given to kittens that have been reared in complete darkness from birth leads to extremely rapid changes in cortical organization, even after the classically defined critical period. When GAP-43 gene expression was analyzed in P31-43 striate cortex from dark-reared kittens, levels of its RNA were found to be ~150% of those in control kittens of the same age, and was comparable to the increase in GAD expression. CaM kinase II gene expression showed the most striking change: its RNA was increased 2-fold in dark-reared kittens compared to normal. (Supported by NIH grant NS06929)

POSTNATAL CHANGES IN GLUTAMATE-STIMULATED PHOSPHATIDYL INOSITOL TURNOVER IN NEOCORTICAL SYNAPTONEUROSOMES. S.M. Dudek, W.D. Bowen, and M.F. Bear, Center for Neural Science and Division of Biology and Medicine, Brown University, Providence, RI 02912.

NMDA receptors have recently received a great deal of attention for their role in activity dependent synapse modification at several locations, including the developing visual cortex. A current working hypothesis is that the NMDA-dependent calcium flux acts as an intracellular second messenger specifically to increase synaptic gain. Recent work in other laboratories has suggested that excitatory amino acid (EAA) receptors may also be linked to the metabolism of inositol phospholipids (PI), particularly during early postnatal development. As a first step toward exploring the possible role of this second messenger system in activity-dependent synapse modifications in the neocortex, we have studied the development of glutamate (GLU) stimulated PI turnover in unfiltered rat cortical synaptoneurosomes.

Using the method of Gusovsky and Daly (*Neuropharm.* 27(1) 95-105,1988), GLU-stimulated accumulation of ^{3}H- inositol phosphate was measured in Li-pretreated synaptoneurosomes prepared from rat neocortex at different ages. Maximum stimulation was observed at [GLU] $\geq$ 300 μM, and in adults was ~30% above basal levels. In striking contrast, the maximum stimulation in 1 week rats was 135%, 4.5 times the adult level. At 3 weeks, the maximum stimulation was still 2.7 times adult. However, by 5 weeks of age, the GLU-stimulated PI turnover was reduced to the adult level. To assess the subtype of EAA receptor involved in the stimulation of PI turnover by GLU, synaptoneurosomes from 3 weeks rats were stimulated with either ibotenate (IBO), kainate (KA), or NMDA. IBO concentrations as low as 10 μM produced stimulation of ~45% above basal; the other agonists had negligible effects even at mM concentrations.

These data suggest that a specific subclass of EAA receptor, linked to PI metabolism, is transiently expressed in the neocortex during early postnatal development. Preliminary experiments in kittens indicate that significant GLU-stimulated PI turnover occurs in the striate cortex as late as 50 days of age, suggesting a possible link with the critical period for experience-dependent synapse modification. 81.6

AUTORADIOGRAPHIC LOCALIZATION AND ONTOGENESIS OF BINDING SITES FOR THE VESICULAR ACETYLCHOLINE TRANSPORT BLOCKER AH5183 (VESAMICOL) IN THE CAT VISUAL CORTEX. G. Prusky and M. Cynader, Department of Ophthalmology, The University of British Columbia, Vancouver, BC, Canada V5Z 3N9.

Vesamicol, a noncompetative inhibitor of high-affinity acetylcholine transport into cholinergic vesicles, was used as a selective marker of cholinergic nerve terminals in the developing cat visual cortex. [^{3}H]Vesamicol binds specifically, saturably and with a heterogeneous distribution to slide-mounted sections of adult cat visual cortex. During the first week of postnatal life, specific [^{3}H]Vesamicol binding sites are homogeneously distributed across all visual cortical layers. The second and third weeks of postnatal life are characterized by the development of a pattern with dense binding localized in the superficial (layers I-III) and deep (layers V-VI) cortical layers with the highest concentration in the superficial layers. The basic laminar distribution remains similar during the next several weeks, but the density of binding sites in the deep layers increases and becomes most prominent. By 10 weeks of age the adult pattern of binding is achieved with the most concentrated labelling in the superficial cortical layers with less pronounced binding the the deep layers. The developmental profile of [^{3}H]Vesamicol binding sites do not closely follow the idiosyncratic M_1 and M_2 muscarinic (Prusky et al, 1987) or nicotinic (Prusky et al, 1988) receptor profiles. It may, however, reflect their combination.

INSITU HYBRIDIZATION AND IMMUNOCYTOCHEMICAL LABELING OF GABA NEURONS DURING DEVELOPMENT OF MONKEY VISUAL CORTEX. AE Hendrickson, RD Mehra*, BioStructure & Ophth., U. Wash., Seattle 98195 and A Tobin, Biology, UCLA, Los Angeles 90024

We have examined the developmental sequence for the inhibitory neurotransmitter GABA in Macaca visual cortex. Immunocytochemical (imcyt) staining was done on frozen sections of aldehyde-fixed brain using antisera to GABA and to its synthetic enzyme glutamic acid decarboxylase (GAD). Insitu hybridization was done on the same tissue using a S35-labeled riboprobe generated from a cDNA clone for human GAD. Both labels were done at F75, 125, 162 and postnatal 1d, 3d, 9wk, 20wk, and 5+ yrs.

Imcyt labeling for GABA at F75 showed multipolar cells in subplate, marginal zone (MZ) and deep cortical plate (CP), and vertically-oriented cells resembling migrating neurons in upper CP. By F125 GABA+ neurons filled whole of cortex and adjacent white matter, with little change thereafter. GAD labeling in somata was seen first in deep cortex and layer 1 at F90-125 and later in upper layers. GAD label in neuropile was faint until near birth, rapidly increased to more than adult level by P6-9wk, and then decreased to adult levels. Insitu labeling for GAD at F75 showed a few heavily-labeled cells under and in lower CP and many in MZ; lighter labeling occurred in upper CP. By F162 all cortical layers contain many labeled cells with 50% more grains than in adult cortex. These findings indicate that GAD message increase occurs simultaneously or slightly earlier than imcyt-detectable product. (NIH EY01208, EY04536, EY01730)

ALTERATIONS IN THE $GABA_A$ RECEPTOR COMPLEX IN CAT VISUAL CORTEX FOLLOW EARLY VISUAL DEPRIVATION. C. Shaw* and M. Cynader (SPON: D.E. Mitchell), Dept. of Ophthalmology, University of British Columbia, Vancouver, Canada V5Z 3N9

We have shown that the number of $GABA_A$ receptors in cat visual cortex increases dramatically following early monocular eyelid suture (Shaw and Cynader 1987, 1988). We have now examined another aspect of the $GABA_A$ receptor complex, i.e., the benzodiazepine receptor, and those GABA receptors not associated with this complex ($GABA_B$). Cats of the following groups were studied: normally reared; early monocular eyelid suture (MD); early split chiasm - MD(XCMD); adult MD; adult monocular enucleation (ME); early strabismus; dark reared (DR). Receptors were labelled as follows: $GABA_A$ - [^{3}H]muscimol; benzodiazepine (BZ) - [^{3}H]flunitrazepam; $GABA_B$ - [^{3}H]baclofen. Slide-mounted sections from various animals were incubated appropriately, and apposed to Ultrofilm. Later, the sections were scraped from the slides and the bound radioactivity measured. For $GABA_A$ receptors significant increases in number were obtained following early MD (+93%) and XCMD (+80%) ($P<0.001$). Smaller increases followed adult MD (+40%), adult ME (+31%), or DR (+59%) ($P<0.04$). For BZ receptors, only early MD increased BZ receptor number (+64%). For $GABA_B$ a decrease (-37%) in the cortex contralateral to the open eye was found after early MD. Thus, major changes in the $GABA_A$ receptor complex follow various forms of visual deprivation with greater effects on $GABA_A$ than BZ receptors and opposite smaller effects on $GABA_B$ receptors. These changes argue for an overall alteration in the "chemical circuitry" of the cat visual cortex following abnormal visual experience.

81.9

ORGANIZATION AND PLASTICITY OF GABA NEURONAL SUBPOPULATIONS IN MONKEY AREA 17, IDENTIFIED BY COEXISTENCE OF CALCIUM BINDING PROTEINS K. Omidi*, S.H.C. Hendry, E.G. Jones, and P.C. Emson. (SPON: C.N. Honda) Dept. of Anatomy & Neurobiology, University of California, Irvine, Irvine, CA 92717 and Institute of Animal Physiology, Cambridge, UK.

GABA neurons immunoreactive for either parvalbumin or 28 kD vitamin D-dependent calcium binding protein (calbindin) were examined in area 17 of normal and monocularly deprived Old World monkeys (M. fascicularis). Calbindin immunoreactive neurons make up a large proportion of the GABA cells in layers II & III and as described previously for New World monkeys (Celio et al., 1986; Nature 323:715-717) they surround the patches of cytochrome oxidase (CO) staining. However, in monkeys injected monocularly with tetrodotoxin, the immunostaining around deprived patches is greatly reduced while the staining around the non-deprived patches appears to increase and invade the patches.

Parvalbumin immunostained somata and processes are present in all layers but are densest in layers IVA and IVC. In addition, immunostained processes in layers II & III form patches that coincide with the CO patches. Most of the parvalbumin processes in layers II & III and in layers IVA & IVC do not display GABA immunoreactivity, but arise from large axons that invade the cortex from the underlying white matter. The immunostaining of parvalbumin somata and processes is greatly reduced within layers IVA, IVC and the layer II-III patches of columns dominated by a TTX-injected eye. These findings indicate that calbindin and parvalbumin immunostaining in separate populations of area 17 GABA neurons and in afferent axons, possibly originating in the LGN, varies with synaptic activity. Supported by NEI Grants EY 06432 & EY 07193.

LONG-TERM SYNAPTIC POTENTIATION AND NMDA RECEPTORS IN THE RAT PUP VISUAL CORTEX F.Kimura* T.Tsumoto, A.Nishigori* T.Shirokawa, Dept. of Neurophysiol., Biomed. Res. Center, Osaka University Medical School, Kitaku, Osaka, 530 Japan

Among the three types of excitatory amino acid receptors, N-methyl-D-aspartate (NMDA)-preferring receptors are suggested to be involved in synaptic plasticity in the developing visual cortex (Tsumoto et al., Nature, 327, 513, 1987). Long-term potentiation (LTP) of synaptic efficacy is a form of synaptic plasticity seen in the hippocampus. In this study, we tested whether LTP could be induced in the visual cortex and if so, whether the induction of LTP could be blocked by a selective NMDA receptor antagonist, 2-amino-5-phosphonovalerate (APV). Visual cortical slices were prepared from rat pups aged between 21 and 40 days. Activities of neurons in layers II/III of the cortex were recorded extracellularly as field potentials or intracellularly as synaptic potentials evoked by electrical stimulation of the underlying white matter. In 17 of the 33 slices tested, LTPs of the field responses were induced by tetanic stimulation (5 Hz for 60 sec) of the white matter. LTPs of excitatory post-synaptic potentials (EPSPs) were also observed in 6 of the 11 cells tested. An application of APV with 25-50 μM prevented the induction of LTP in 11 of the 12 slices in which field responses were measured and in 9 of the 10 cells in which EPSPs were observed. These results suggest that NMDA receptors may play a role in inducing LTPs in the rat pup visual cortex.

81.11

EFFECT OF CORTISOL ON PLASTICITY IN THE CAT VISUAL CORTEX N.W. Daw, H. Sato and K. Fox, Dept. of Cell Biol., Washington Univ. Med. Sch., St. Louis, MO 63110.

Glucocorticoids are known to be low in young rats, and to be inhibitory to the development of their nervous system (Sapolsky & Meaney, Brain Res. Rev. 11,65-76, 1986). We tested whether glucocorticoids affect plasticity in the cat visual cortex, and whether their rise correlates with the decline of the critical period. Kittens were injected with glucocorticoid, starting around 35 days of age, with one eye closed around 45 days and recordings made into the cortex contralateral to the closed eye around 55 days under halothane anesthesia. Three untreated binocular animals were normal controls. Three animals with eyelid suture but no glucocorticoid treatment were monocularly deprived controls. Treated animals were given daily doses of cortisol in sesame oil, two each at 1, 10 and 20 mg/kg/day.

Three numbers were calculated from the ocular dominance histograms: weighted shift, weighted binocularity and percentage of cells in group 7. All three showed dose-dependant changes with cortisol treatment such that 10 mg/kg/day reduced plasticity by about half and 20 mg/kg/day almost eliminated it. Glucocorticoid treatment therefore resulted in a reduction of the ocular dominance shift. Measurement of cortisol levels in normal kittens show that levels are low a few days after birth and rise to adult levels after three months of age. Cortisol levels therefore affect plasticity, and rise along with the decline of the critical period, but are not correlated with the start of the critical period at 2-3 weeks of age.

81.12

COMPARISON OF THE VISUAL CORTICAL SEROTONIN SYSTEM IN NORMAL AND DARK REARED CATS. G.D. Mower and R. Rustad*. Dept. of Neuroscience, The Children's Hospital, Boston, MA 02115.

Serotonergic innervation and receptors in visual cortex (VC) develop during the early postnatal period. The present study asked whether normal development of the serotonin (5-HT) system requires visual experience by comparing normal and dark reared (DR) cats.

In-vitro receptor binding techniques, using (^{3}H) 5-HT as the ligand, were used to compare VC of normal and DR cats. Saturation kinetics and pharmacological specificity indicated that the binding was to a single high affinity (2nM) site with the characteristics of the 5-HT_1 receptor. A consistent increase (20%) in specific binding was found in DR cats in each of 4 matched comparisons. This difference reflected an increase in Bmax and no change in Kd. Autoradiography indicated that 5-HT_1 receptors are distributed rather uniformly across all VC layers and there was no marked difference between normal and DR cats. Analysis of 5-HT_2 receptors is in progress.

Immunohistochemistry (anti-5-HT) showed that 5-HT fibers are densest in superficial layers (I-III), least dense in layer IV, and intermediate in deep layers (V,VI). This distribution was similar in normal and DR cats.

These results indicate that the VC 5-HT system matures to a large extent independently of visual experience. The increase in receptor number due to dark rearing could be related to the elevated VC plasticity of DR cats.

81.13

EXPERIENCE-DEPENDENT SYNAPTIC MODIFICATIONS IN THE VISUAL CORTEX STUDIED USING A NEURAL NETWORK MODEL. Eugene Clothiaux*, Mark F. Bear and Leon N Cooper (SPON: D. Berson). Center for Neural Science and Department of Physics, Brown University, Providence, RI 02912.

Neurons in the mature visual cortex of normal cats are tuned for the orientation of a bar of light and most respond to stimulation of either eye. Both of these properties depend on the visual environment experienced during a critical period of postnatal development. For example, prolonged binocular deprivation eliminates orientation selectivity, and binocular connections are modified after brief periods of monocular deprivation, strabismus, and reverse suture. The question we have asked is whether a single mechanism can account for these varied experience-dependent synaptic modifications.

We have found that a mean field neural network architecture (Cooper and Scofield, *PNAS* 85: 1973, 1988), with some LGN-cortical synaptic modification according to the learning rule devised by Bienenstock, Cooper and Munro (BCM, *J. Neurosci.* 2: 32, 1982), successfully accounts for the experimentally observed results in all cases. A critical feature of the BCM learning rule is a "modification threshold": a critical level of postsynaptic activity at which the sign of the modification changes from negative to positive. Further, the value of the modification threshold is itself a function of the average postsynaptic response. The results of more recent pharmacological experiments in which cortical activity was manipulated by the chronic administration of muscimol (Reiter and Stryker, *Soc. Neurosci. Abs.* 13: 344.2, 1987) and APV (Kleinschmidt et al., *Science* 238: 355, 1987) may be readily understood in terms of changing the relationship of the postsynaptic response to the modification threshold. We have begun exploring the hypothesis that the physiological basis of the modification threshold is a critical level of NMDA receptor-dependent calcium flux. A molecular model based on this assumption is currently under development. Preliminary analysis indicates that the model captures the essential features of the BCM theory and hence is able to account for the various experience-dependent modifications that have been observed in visual cortex. (Supported by ONR contract N000-14-86-K-0041)

LITHIUM REDUCES EFFECTS OF MONOCULAR DEPRIVATION. T. Ohashi*, K. Imamura and T. Kasamatsu. Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115.

Lithium salts have been effectively used to treat manic-depressive disorders. Lithium at low concentrations decreases release of catecholamines (but not serotonin) from nerve endings in the brain. Lithium at therapeutic concentrations also blocks adrenergic and cholinergic agonist-induced increase in GTP binding in rat neocortex, suggesting that G proteins are the molecular site of lithium's action (Avissar et al., 1988). Recently, contributions of both adrenergic and cholinergic afferents to the regulation of ocular dominance plasticity has been implied in kitten visual cortex (Bear and Singer, 1986). In the present study, we wanted to test directly the involvement of lithium-mediated mechanisms in this matter.

Several-week-old kittens were i.p. injected with 25 mg/kg Li_2CO_3 2-3 times daily for 10 days, preceding monocular lid suture which lasted for a week. The lithium injections were repeated throughout the week of monocular deprivation. Ocular dominance distribution was assessed following Hubel and Wiesel's criteria (1962). In visual cortex of lithium-injected kittens, we found that 1) a shift in ocular dominance to the nondeprived eye was less than usually expected following brief monocular deprivation, and 2) the proportion of binocular cells was higher than that in control. We conclude that ocular dominance plasticity may be in part regulated by lithium-mediated mechanisms. [NIH Publications #85-23, Rev. 1985]

81.15

EXTRAOCULAR PROPRIOCEPTIVE INPUTS TO VISUAL CORTEX : AN ELECTROPHYSIOLOGICAL STUDY DURING DEVELOPMENT IN THE CAT. C. Milleret *, E. Gary-Bobo * and P. Buisseret * (SPON : European Brain and Behavior Society). Lab. de Neurophysiologie, Collège de France, 75231 Paris, FRANCE, Cedex 05.

We have previously shown that unit activity in Area 18 can be modulated by stimulation of the proprioceptors of the extraocular muscles in normal cats (Milleret et al., 1987). In the present study, we examined the development of these projections between 3 weeks of age and adulthood.

Responses of cortical single units to intraorbital stimulation of the afferents from either the Inferior obliquus (electrical stimulation of its branch of the IIIrd nerve, S1) or of the Rectus lateralis (stretch, S2) were recorded in anaesthetized and paralyzed cats and processed as PSTH. Efficiency of the stimuli was monitored by recording field potentials from the superior colliculus where proprioceptive inputs from extraocular muscles have already been described (Donaldson and Long, 1980). Proprioceptive origin of the responses was ascertained by their reversible disappearance after local application of xylocaine onto the stimulated nerve or into the streched muscle.

Our results show that : (1) the percentage of cells activated either by S1 or S2 decreased with age (S1, 85 to 65% ; S2, 65 to 45%) ; (2) the majority of these responsive cells displayed a selectivity for an orientation of the visual stimulus close to the orthogonal of the action plane of the muscle from which they receive proprioceptive inputs ; (3) this relation sharpened during development.

Thus, a specific organization seems to develop in normal rearing conditions between a given extraocular muscle and some visual cortical cells.

81.16

POSTCRITICAL-PERIOD PLASTICITY IN VISUAL CORTEX CELLS OF EARLY MONOCULARLY DEPRIVED AND LATE SPLIT CHIASM CATS. U. Yinon and A. Hammer*. Physiol. Lab., Goldschleger Eye Res. Inst., Tel-Aviv Univ. Faculty of Medicine, Sheba Med. Center, Tel-Hashomer, 52621, Israel.

Whether neuronal plasticity exists after the critical period for monocular deprivation effects, was studied in early monocularly deprived cats following cancellation of the direct geniculocortical contralateral pathways during maturation. 12 cats were monocularly deprived (MD) from birth; in 8 of them the decussating optic nerve fibers were transected in the chiasm during adulthood (OCMD). Unit recording was extracellularly made in visual cortex areas 17 and 18. In the MD cats 86.5% of the cells reacted to the nondeprived eye, 3.2% to the deprived eye and the rest of them binocularly. In the OCMD cats 78.9% of the cells responded to the nondeprived eye, 12.7% to the deprived eye and the rest of them binocularly. In the hemisphere ipsilaterally to the deprived eye of the MD cats 83.2% of the cells were driven by the nondeprived and 4.2% by the deprived eye while in the OCMD cats 32.8% of the cells in this hemisphere had reacted to the nondeprived eye and 40.5% to the deprived eye. Thus, the postnatal occupation of cortical cells by the experienced eye is not final and can be remarkably reduced even after the termination of the plasticity period.

81.17

POSTNATAL DEVELOPMENT OF GABA-ERGIC INHIBITION IN RAT NEOCORTEX. H.J. Luhmann* and D.A. Prince. Stanford University Medical Center, Dept. of Neurology, Stanford, CA 94305.

Maturation of the GABAergic system was studied in layers II/III of rat neocortical slices between P4 and P35. Evoked IPSPs could be first demonstrated at P13 and often consisted only of the bicuculline (BMI)-insensitive, long-latency component. By about P16, nearly all cells also showed a fast IPSP, which could be blocked by BMI. Spontaneous, BMI-sensitive IPSPs were recorded with 2 M KNO_3 electrodes from adult animals and before the maturation of evoked IPSPs in P9-P10 cells. Both $GABA_A$-and $GABA_B$-responses were elicited by extracellular pressure ejection of GABA and baclofen respectively in the first postnatal week. In neurons younger than P10, GABA application at the soma and apical dendrite most often produced a pure depolarizing ($GABA_A$-2) response, but occasionally biphasic hyper- and depolarizing responses were present (see also Mueller, A.L. et al., J. Neurosci., 4: 860, 1984). At this age, somatic $GABA_B$-responses were relatively weak and fragile and could be evoked in only about 40% of the cells. By about P25, the GABAergic system was mature and characterized by multiphasic $GABA_A$- and clear somatic $GABA_B$-responses.

The presence of GABA-receptors before the formation of inhibitory synaptic circuits in immature rat cortex, suggests that GABA might have a non-neurotransmitter function in early postnatal development.

81.18

CHARACTERIZATION AND ONTOGENESIS OF AN ATROPINE-SENSITIVE EFFECT OF CARBACHOL ON THE *IN-VITRO* VISUAL CORTEX. G. Vaknin AND T.J. Teyler. NE Ohio Univ. College of Medicine, Rootstown, OH 44272.

The basal forebrain is the source of major excitatory acetylcholine (ACh) afferents to the cortex. The action of ACh on the synaptic response of the hippocampus and olfactory cortex *in-vitro* was found to be suppressive and atropine-sensitive. The levels of muscarinic receptors in the cortex of developing rat are reported to peak in adults with a small decline in aged rats. The present study is focused on the characterization and ontogenesis of an atropine-sensitive effect of carbachol (CCH) on the superficial layers (100-250um below the pial surface) of the *in-vitro* rat visual cortex. Stimulation was delivered in the same cortical layer, 300-400um lateral to the recording site using a microbipolar electrode. The Current Source Density analysis revealed sinks in layers II/III with corresponding sources below in layer IV. After establishing a stable baseline, 100uM CCH was added to the perfusate for two min, follwed by a recovery period of 20-30 min, after which 10uM atropine was added and perfused with the CCH for two min. CCH suppressed the synaptic response; atropine eliminated the CCH effect. The ontogenesis of the muscarinic depression was studied in four age groups: 9-10d, 15d, 30-40d and 20 months. The results indicate a significant difference between the infants (10-15% suppression) and the adults (30-40% suppression). The recovery time after CCH administration was shorter in infants (10 min) compared to adults (20-30min). Supported by ONR & EPA.

82.1

CARDIAC SYMPATHOEXCITATORY RESPONSES TO L-GLUTAMATE MICROINJECTIONS INTO THE INTERMEDIOLATERAL COLUMN (IML) OF THE SPINAL CORD OF THE RAT. K. Sundaram*, J. Murugaian* and H.N. Sapru, Section of Neurosurgery, UMDNJ - New Jersey Medical School, Newark, NJ 07103.

Mean arterial pressure (MAP), heart rate (HR), the rate of increase in the left ventricular pressure (dp/dt) and contractility index were monitored in pentobarbital anesthetized, immobilized and artificially ventilated male Wistar rats. On the right side, microinjections (10-20 nl) of L-glutamate (0.9-1.77 nmol in 0.9% saline, pH 7.4) into the IML at T2 level produced marked tachycardic responses with small changes in contractility and no changes in MAP. On the left side, microinjections of glutamate into the IML produced marked increase in dp/dt and contractility index with small increase in HR and no change in MAP. These responses were smaller at T1 and T3 level and absent at C8 and T4 level. N-methyl-D-aspartic acid (NMDA), 1-100 pmol, induced similar responses. The effects of glutamate and NMDA were blocked by microinjections of GDEE and D-AP7, respectively. This model may prove to be useful in studies involving interactions between brain stem cardiovascular areas and the IML.

Support: NIH (HL 24347) and AHA (NJ).

82.2

EFFECT OF SPINAL GAMMA AMINOBUTYRIC ACID RECEPTOR BLOCKADE ON TONIC AUTONOMIC INPUT TO CARDIOVASCULAR EFFECTORS. W. Laskey* (SPON. G. Melvill Jones) Dept. Physiology McGill University, Montreal, P.Q. H3G 1Y6.

Blockade of spinal gamma aminobutyric acid (GABA) receptors increases arterial pressure (AP) and heart rate (HR) of rats (Gordon, F.J. Brain Res. 328:165, 1985). To determine if GABA mediated inhibition has a supraspinal source, effect of spinal GABA receptor blockade was compared in CNS-intact and spinal rats. Male S-D rats were anesthetized, paralyzed and artificially ventilated. Bicuculline methyl iodide (BMI) was administered intrathecally at the caudal edge of the thoracic cord. AP and HR were monitored via a carotid artery. In CNS-intact rats, 5-10 µg BMI increased AP and HR, but 2.5 µg BMI lowered AP by 43.2 ± 2.2 mmHg (n=6, P 0.01) without changing HR. The depressor, but not the pressor response to BMI was abolished by spinalization. Both responses were abolished by ganglionic blockade (20 mg/kg hexamethonium i.v.). The depressor response was abolished by adrenalectomy. These data suggest that GABA mediated tonic inhibition of sympathetic preganglionic neurons (SPN) controlling the heart and the blood vessels has a major propriospinal component, while that exerted on SPN innervating the adrenal gland is dependent on a supraspinal input to these neurons.

82.3

SEROTONIN REGULATION OF SYMPATHETIC OUTPUT AT THE SPINAL LEVEL: INTRATHECAL STUDIES. V.V. Romita,* and J.L. Henry (SPON: S. Lal) Depts. Physiol & Psychiat., McGill Univ., Montreal, H3G 1Y6

Serotonin was administered intrathecally at the T9 or T2 spinal level in male Sprague Dawley rats (300-350 g) anaesthetized with urethane (2.5 g/Kg). Effects on heart rate and arterial pressure were studied. Administration of 100 nmoles at the T9 spinal level had no effect on heart rate or arterial pressure (n=3); 200 nmoles caused an increase in heart rate to a maximum of 22 ± 6.7 bpm at 2 min after administration (n=13). Arterial pressure was unaffected. At the T2 level 200 nmoles of serotonin increased heart rate by a maximum of 45 ± 8.4 bpm at 2 min (n=14). Again arterial pressure was unaffected. Vehicle failed to change heart rate or arterial pressure at either spinal level (n=31). Prior intrathecal administration of 200 nmoles of methysergide, a serotonin antagonist, partially blocked the effects on heart rate elicited by administration of 200 nmoles of serotonin at the T2 spinal level (n=8). Hexamethonium (10 mg/kg i.v.), a blocker of nicotinic transmission in autonomic ganglia, did not block the effects of serotonin on heart rate (n=4). After intrathecal administration of 15 µL of lidocaine, serotonin was without effect on heart rate or arterial pressure (n=10). These results suggest that serotonin regulates sympathetic output by an action at the spinal level, possibly with a non-nicotinic relay in the sympathetic ganglia. (Supported by a grant from the Quebec Heart Foundation to JLH)

82.4

RELEASE OF TONIC INHIBITION OF SYMPATHETIC OUTPUT BY INTRATHECAL ADMINISTRATION OF BICUCULLINE AND STRYCNINE TO THE T2 SPINAL SEGMENT IN THE RAT Hong, Y.,* K. Yashpal* and J.L. Henry (Spon: S.N. Young), Depts. Physiol. & Pschiatry, McGill Univ., Montreal, H3G 1Y6

Sympathetic preganglionic neurones in the intermediolateral nucleus of the spinal cord are depressed by GABA and by glycine when applied directly by iontophoresis (Brain Res. 277:365, 1983). To determine whether GABA and glycine are involved in tonic inhibition of these neurones the respective antagonists were given intrathecally to male Sprague Dawley rats (approx 350g) anaesthetized with urethane (2.5g/kg i.p.) and implanted acutely with a PE-10 intrathecal catheter passed via the atlanto-occipital junction to the T2 level. A PE-60 catheter in the carotid artery was used to measure arterial pressure and heart rate. After 30 min for stabilization, baseline readings were taken over 5 min and bicuculline methiodide (1 µg; n=6) or strychnine SO4 (25 or 100 µg; n=12) were given (in 10 µL of artificial CSF). Bicuculline increased arterial pressure (2-15 min; peak 10 min) with little or no effect on heart rate. Strychnine increased heart rate (2-11 min; peak 4 min) without an effect on arterial pressure. CSF alone had no effect on either parameter (n=8). These results suggest that GABA and glycine express tonic depression of sympathetic output, specifically regulating arterial pressure and heart rate, respectively.

(Supported by a Quebec Heart Foundation grant to JLH; KY is a Fellow of the Canadian Heart Foundation)

SUBSTANCE P AND TRH: EFFECTS ON ADRENAL AND NON-ADRENAL SYMPATHETIC PREGANGLIONIC NEURONES IN CAT THORACIC INTERMEDIOLATERAL NUCLEUS. S.B. Backman, H. Sequeira-Martinho* & J.L. Henry. Depts. of Physiol.& Psychiat., McGill Univ., Montreal, Quebec H3G 1Y6.

As substance P (SP) and thyrotropin-releasing hormone (TRH) coexist in nerve terminals apposed to adrenal and non-adrenal sympathetic preganglionic neurones (SPNs) (Brain Res.415:137,1987), in the present study the two types of SPN were compared for their responses to SP and to TRH. Cats were anaesthetized (chloralose), paralyzed (pancuronium bromide) and ventilated artificially. Multibarrelled micropipettes were used to record single unit extracellular spikes in the intermediolateral nucleus of spinal segments T8-T10. Barrels for iontophoresis contained SP (1mM in 0.16M NaCl, pH 5.5), TRH (5mM in 0.16M NaCl, pH 5.5) and control solution (0.16M NaCl, pH 5.5). A unit was classified as SPN if it responded antidromically to electrical stimulation of the greater splanchnic nerve or adrenal medulla, with non-adrenal SPNs responding only to stimulation of the nerve. SP and TRH (30-100 nA) increased the firing rate of 4/7 adrenal, 13/24 non-adrenal SPNs, and of 3/12 adrenal, 10/29 non-adrenal SPNs, respectively. Depression was not observed. Excitation was always typically slow in onset (0.5-1 min) and prolonged in after-discharge (0.5-2.5 min). These data suggest that adrenal and non-adrenal SPNs are excited by SP and TRH. (Support: Quebec Heart Fndn. grant to JLH; Can. Heart Fndn. award to SBB & NATO award to HS-M.)

STIMULATION OF SUPRASPINAL ALHPA$_2$-RECEPTORS BY CLONIDINE INHIBITS THE PRESSOR RESPONSE TO INTRATHECAL INJECTION OF NEOSTIGMINE IN CONSCIOUS RATS. V. Magri and J.J. Buccafusco. Dept. Pharmacology and Toxicology, Med. Col. Ga. and Vet Admin. Med. Ctr., Augusta, Georgia 30912.

Intrathecal (i.t.) injection of neostigmine (NEO) produces a marked increase in blood pressure in freely-moving rats. The pressor response is mediated through local inhibition of cholinesterase and through the release of spinal acetylcholine (Soc. Neurosci. Abs. 13:745). Our earlier studies have also demonstrated that stimulation of central alpha$_2$-receptors with clonidine inhibits the release of acetylcholine. The purpose of this study was to determine whether i.t. injection of (1-10µg) clonidine could block the pressor response to i.t. injection of NEO. 5µg NEO produced a pressor response (41mmHg) which became maximal by 10-15 min and remained elevated for at least 90 min. Pretreatment with i.t. clonidine did not significantly reduce the pressor response to NEO but delayed its onset. In contrast, 100µg s.c. or 10µg injected into the cisterna magna each significantly reduced the pressor response to i.t. NEO. Supraspinal administration of clonidine also inhibited the behavioral changes to i.t. NEO. These results are consistent with the presence of an ascending spinal cholinergic system sensitive to clonidine inhibition which mediates a hypertensive response following i.t. injection of cholinergic agonists. Supported by HL30046 and the Vet. Admin.

82.7

THE PRESSOR RESPONSE TO SPINAL CHOLINERGIC STIMULATION IN SPONTANEOUSLY HYPERTENSIVE (SHR) AND NORMOTENSIVE (NT) RATS. N.F. Makari, V. Magri and J.J. Buccafusco. Dept. Pharmacology and Toxicology, Med. Col. Ga. and Vet Admin. Med. Ctr., Augusta, GA 30912.

Several laboratories have demonstrated that central cholinergic stimulation in SHR results in an exaggerated pressor response as compared to NT controls. Recent studies in this laboratory have demonstrated a spinal cholinergic pressor system in the NT rat. The purpose of this study was to determine whether the pressor response to spinal cholinergic stimulation is enhanced in SHR. In freely-moving rats previously implanted with intrathecal (i.t.) and intraarterial catheters, i.t. injection of neostigmine or carbachol (1-5µg) produced a dose-related hypertensive response in both strains of rats. While both agonists produced similar maximal increases in blood pressure in NT rats, the pressor responses to both agonists were significantly greater in SHR, although neostigmine was more effective in this regard. These differences were more apparent at the lower doses where the response to 1µg of drug in the SHR was increased by 77% and 109% of the response in NT rats for carbachol and neostigmine, respectively. The facts that both direct and indirect acting agonists produced greater responses in SHR and that spinal depletion of acetylcholine did not reduce blood pressure in SHR suggest that the spinal cholinergic pathways involved ascend to higher centers. NEUROPEPTIDE Y-, SUBSTANCE P-, AND 5-HT-IMMUNOREACTIVE SYNAPSES IN THE INTERMEDIOLATERAL CELL COLUMN OF RABBIT UPPER THORACIC SPINAL CORD. I.J. Llewellyn-Smith*, D.A. Morilak and J.P. Chalmers* (SPON: M. West). Department of Medicine, Flinders University, Bedford Park,South Australia 5042 Australia.

Two groups of neurons in the rostral ventrolateral medulla oblongata (RVLM), which have spinal projections and may have vasopressor functions, are adrenaline/neuropeptide Y (NPY) neurons and substance P (SP)/5-HT neurons.We sought to establish in rabbit upper thoracic spinal cord whether nerve fibers containing NPY, SP or 5-HT formed synapses in the intermediolateral cell column (IML), where vasomotor sympathetic preganglionic neurons are located. Rabbits were perfused with phosphate-buffered 4% formaldehyde, 0.5% glutaraldehyde with or without 0.2% picric acid, and rapidly post-fixed with microwaves. Vibratome sections (80um) of T4-T6 were washed in 50% ethanol, stained to reveal NPY-, SP- and 5-HT-immunoreactive nerve fibers using an avidin-biotin-horseradish peroxidase detection system, and processed for electron microscopy. At the light microscope level, the IML in T4-T6 contained dense plexuses of varicose NPY-, SP- and 5-HT-immunoreactive nerve fibers. At the electron microscope level, all three types of fibers made synapses with clustering of vesicles and membrane densities.

These observations are consistent with a direct synaptic connection between RVLM neurons containing NPY, SP, or 5-HT and sympathetic preganglionic neurons, which could mediate the pressor responses seen upon stimulation of the RVLM.

82.9

ULTRASTRUCTURAL EVIDENCE OF PEPTIDERGIC AND MONOAMINERGIC INPUTS TO SYMPATHETIC PREGANGLIONIC NEURONS (SPNs) IN THE INTERMEDIOLATERAL CELL COLUMN (IML) OF THE RAT AND RABBIT. P.L.Vera,K.E.Miller & V.R.Holets, University of Miami, Dept. of Neurological Surgery, Miami, Fl. 33136.

Peptidergic and monoaminergic processes have been located within IML, closely apposed to retrogradely labeled SPNs (Holets & Elde,1982,Neurosci.,7:1155;Vera et al.;Soc.Neurosci.Abs.,1987,13:734). However, anatomical evidence for actual synaptic contacts between descending transmitters and SPNs can only be obtained at the ultrastructural level. The object of this study was to examine the relationship between different peptidergic and monoaminergic transmitters and SPNs located within IML of the rat and rabbit, in an attempt to identify direct synaptic contacts between the two systems.

In order to identify SPNs in the rat (n=4), the cervical sympathetic trunk was exposed to HRP. In the rabbit (n=4), IML can be clearly identified within the lateral horn at upper thoracic segments, where it is partially separated from the intermediate grey matter by the intermediolateral fasciculus. Animals were perfused with 4% paraformaldehyde and vibratome sections (40-50 um) of segments T2-T4 were taken. In the rat, tissue was processed for HRP histochemistry. Subsequently, Substance P-, enkephalin-, and serotonin-like immunoreactivity was visualized using an immunoperoxidase reaction. The sections were then osmicated and embedded for electron microscopy.

In the rat, labeled terminals for each transmitter were observed in contact with retrogradely labeled processes. In the rabbit, labeled terminals were found on presumptive SPNs within IML forming both somatic and dendritic terminals.

COEXISTENCE OF NEUROCHEMICALS IN VENTRAL MEDULLARY CELLS THAT PROJECT TO THE INTERMEDIOLATERAL CELL COLUMN (IML) OF THE RAT. C.A. Sasek, M. Galeazza#, M. Wessendorf and C.J. Helke. Uniformed Services Univ. of the Health Sci., Bethesda, MD 20814.

Substance P (SP), serotonin (5HT), thyrotropin releasing hormone (TRH) & enkephalin (ENK) are contained in neurons of the ventral medulla, an area involved in cardiovascular regulation. SP, 5HT & TRH neurons project to the IML. ENK containing neurons also project to the spinal cord but their exact site of termination is unknown. Each of these neurochemicals has been localized in fibers in the IML. It is not known if SP & TRH; TRH, SP & 5HT; or ENK & TRH, SP or 5HT coexist in ventral medullary IML projecting cells. Consequently, we examined the extent of coexistence of SP, 5HT, TRH and ENK in ventral medullary cells that project to the IML.

Rats received 40nl injections of rhodamine labeled microspheres into the T3 IML. Colchicine was given ICV 4d later, and 24 h later animals were perfusion fixed. Tissue was sectioned at 4um. Using dual color immunofluorescence, adjacent sections were immunostained with a combination of a monoclonal rat SP antibody and a rabbit antiserum to either 5HT, sequence 160-169 of pre-pro-TRH or ENK.

ENK, 5HT, SP and TRH were each localized to IML projecting cells in ventral medullary nuclei, including N. reticularis magnocellularis pars alpha, N. reticularis paragigantocellularis lateralis and paraolivary N. Some cells in these nuclei that colocalized SP & 5HT; SP & TRH; or SP, TRH & 5HT also projected to the IML. Coexistence of ENK with the other neurochemicals in IML projecting cells occurred only rarely. These results indicate that ventral medullary sites important in cardiovascular regulation contain neurons that project to the IML and that can be subdivided based on their neurochemical content.

LOCALIZATION OF TYROSINE HYDROXYLASE (TH) AND PHENYLETHANOLAMINE N-METHYLTRANSFERASE (PNMT) CONTAINING CELLS IN THE MEDULLA OF THE DOG. G.A. Iwamoto, J.H. Mitchell*, M. Sadeq* and G.P. Kozlowski, Dept. of Veterinary Biosciences, Univ. Illinois, Urbana, IL. 61801 and Dept. of Physiology, U.T. Southwestern, Dallas, TX. 75235.

TH and PNMT containing cells of ventrolateral medulla are associated with cardiovascular control in many species. The TH cells are identified with the A1 area and associated with depressor responses while the PNMT cells (C1 area) are associated with pressor responses. Although it is often the species of choice for cardiovascular studies, no one had attempted to localize these areas in the dog. Using immunocytochemical methods, we found that the TH containing cells of the dog were localized much as they are in both cat and rat with two major concentrations of cells, one located in the ventrolateral and the other in the dorsomedial medulla. The ventrolateral group (A1) were located within 1.5-2mm of the ventrolateral surface and extended from the pontomedullary border to a few mm caudal to the obex. The dorsomedial group (A2) was concentrated in the region just medial to the solitary tract at levels ranging from the obex to the rostral pole of the inferior olive. The PNMT containing cells groups were different in the dog compared with the cat and rat. The ventrolateral cells (C1), as in the rat, but not the cat,were found in a column-like group which ranged from the level of the obex to the pontomedullary border. The dorsomedial group (C2) was far less extensive than either cat or rat, consisting of only a few cells in the area occupied by the A2 group. (Supported by HL 06296 and HL 37400)

82.12

FUNCTIONAL MAPPING OF THE CANINE ROSTRAL VENTROLATERAL MEDULLA (RVL) WITH L-GLUTAMATE AND PHENYLETHANOLAMINE N-METHYLTRANSFERASE (PNMT) IMMUNOHISTOCHEMISTRY. **KJ Dormer, DA Ruggiero, M Anwar* and SR Ashlock*. Physiol. & Biophy., Univ. Okla. HSC, Okla. City 73190 and Lab. Neurobiol., Cornell Univ. N.Y., N.Y. 10021.**

Coincident with kainic acid RVL lesions and their performance sequelea in the conscious dog it was necessary to match function with the analagous C-1 cell group. To demonstrate cardiorespiratory function we injected 100 mM L-glutamate into areas that electrically increased arterial pressue (AP) and respiration. Mongrel dogs (13-18 kg) were anesthesized with alpha-chloralose and instrumented to record AP, heart rate (HR) and respiration. Inductive plethysmography (Respitrace) monitored spontaneous chest and abdomenal excursions. Stereotactic injections of L-glu increased AP 12-35 mmHg and decreased HR 15-25 bpm. Respiratory rate and depth were increased 10-20% above resting control. Responses were limited to a region extending 2 mm rostral-caudal just ventral to the n. retrofacialis. Immunohistochemical staining of RVL for PNMT in other dogs revealed a diffuse population of cells extending in a 4+ mm horizontal column, 4 mm lateral to obex, including the retrofacial zone that elicited excitatory cardiorespiratory responses. Summary: only a limited portion of the diffuse PNMT-containing cells in the dog RVL has vasomotor function and these cells are intermingled with cells exhibiting respiratory control.

82.13

A NEW SYMPATHOINHIBITORY AREA IN CAT MEDULLA: EFFECTS ON CARDIOVASCULAR TONE AND BAROREFLEX. C.W. Dempesy and D.E. Richardson. Lab. of Neurosurgery, Tulane Univ. Sch. of Med., New Orleans, LA 70112

We report a new vasodepressor area (VDA) located superior to the rostral ventrolateral medullary area (RVL) that maintains vasomotor tone. Specifically, the VDA occurs at the level of the caudal pole of the nucleus paragigantocellularis lateralis, dorsal to the retrofacial nucleus, and medial to the infratrigeminal nucleus. Microinjections of glutamic acid (Glu, 5 nmol) into the VDA induce striking hypotension and bradycardia, and indicate that the cell group involved is narrowly confined. The Glu responses are unaffected by either atropine (Atr, 1.2mg i.v.) or bilateral vagotomy, but are blocked (90%) by combined propranolol & regitine treatment (1mg & 3mg respectively/kg) or cervical cord transection. Bilateral microinjections of either muscimol (100 pmol) or kainic acid at toxic dose (KA, 200 pmol) into the VDA induce long-term elevation of blood pressure tone. Baroreflex (BR) chemically induced with phenylephrine (30 ug, i.v.) was shown with Atr (i.v.) to be 80% (± 10%) sympathetically mediated. This part of the BR could be eliminated by bilateral microinjections of KA (toxic dose) into the VDA. These data suggest that the VDA provides inhibitory regulation of the RVL and functions as part of the baroreceptor reflex arc. The relationship between the VDA and sites reported to possess similar properties in the caudal ventrolateral medulla has yet to be determined.

82.14

BLOOD PRESSURE MEDIATED CHANGES IN EPINEPHRINE, NOREPINEPHRINE, ASCORBATE AND URATE RELEASE FROM ROSTRAL VENTROLATERAL MEDULLA OF RAT MEASURED BY IN VIVO DIALYSIS. D. Bhaskaran, P.A. Mason and C.R. Freed. Depts. of Med. and Pharm., Univ. of Colo. Health Sci. Ctr., Denver, CO 80262.

We have previously used in vivo electrochemistry (EC) to study blood pressure induced changes in neurochemical release from rostral ventrolateral medulla (C1 area) (Neurosci abst. 227.12, 1987). Phenylephrine (PHEN)-induced hypertension led to a fall in the catechol peak and an increase in the hydroxyindole peak while nitroprusside (NITRO)-induced hypotension was associated with an increase in the catechol peak and a reduction in the indole. Because of ambiguity in the signal measured by EC, we have repeated these experiments using in vivo dialysis to recover neurochemicals for assay by HPLC. Male Sprague-Dawley rats, 300-350 g, anesthetized with urethane had femoral artery and vein catheterized. An in vivo dialysis probe 300 μ diameter with tip length 500 μ was implanted in the C1 area and perfused with Ringer's at a rate of 1.5 μl/min. Blood pressure was changed with infusion of PHEN or NITRO for one hour. The dialysate was analyzed for epinephrine, norepinephrine, ascorbate and urate. Preliminary results showed that PHEN reduced norepinephrine and epinephrine release while NITRO increased the concentration of both catechols. Uric acid and ascorbic acid concentrations were unchanged by either treatment.

82.15

Pressor Systems Involved in the Maintenance of Arterial Pressure After Lesion of the Rostral Ventrolateral Medulla (RVLM). K.L. Cochrane* and M.A. Nathan. University of Texas Health Science Center, San Antonio, TX 78284-7764.

In an earlier study (Cochrane et al., 1988), we found that hypotension after electrolytic lesion of the RVLM is anesthetic-dependent. The current study was designed to examine the pressor systems which may support mean arterial pressure (MAP) after RVLM lesion in pentobarbital (50 mg/kg iv) anesthetized rats. In protocol 1, sequential administration of captopril (5 mg/kg, iv) reduced MAP from 103±5 mmHg to 87±5 mmHg and a vasopressin antagonist (AVPX, 30 ug/kg, iv) reduced MAP to 62±5 mmHg. Spinal transection (ST) further decreased MAP (39±2 mmHg). In protocol 2, sequential administration of AVPX lowered MAP from 117±5 mmHg to 102±7 mmHg and captopril further reduced MAP to 55±5 mm Hg. The MAP was subsequently reduced after ST (33±1 mmHg). In protocol 3, the kidneys were bilaterally denervated prior to RVLM lesion. Renal denervation decreased MAP from 112±5 mmHg to 89±3 mmHg. RVLM lesion subsequently decreased MAP to 64±5 mmHg. AVPX (51± mmHg), captopril (35±4 mmHg) and ST (26±3 mmHg) did not significantly decrease MAP. The results show that after RVLM lesion, normotension is maintained by the neural release of renin and the subsequent synthesis of angiotensin II. Supraspinal sympathetic activity is abolished after RVLM lesion and renal denervation. Therefore, an area lying outside of the RVLM maintains MAP via the neuroendocrine vasoconstrictor effects of the renin-angiotensin system (Supported by HL33635).

82.16

CAROTID ARTERIAL RESISTANCE REDUCED BY STIMULATION OF AN AREA DORSAL TO THE FACIAL NUCLEUS OF CATS. J. S. Kuo*, M. R. Wang* and C. Y. Chai* (SPON: M. J. Wayner). Dept. of Med. Res., Veterans Gen. Hosp., Dept. of Physiol. and Biophysics, Natl. Def. Med. Ctr. and Inst. of Biomed. Sci., Academia Sinica, Taiwan, Republic of China.

Electrical stimulation of or glutamate injection into a small area just dorsal to the facial nucleus (DFA) elicited an ipsilateral reduction in common carotid resistance (CCR-reduction) with no or minimal change in other cardiovascular parameters in chloralose-urethane-anesthetized and pancuronium-paralyzed cats. The maximal reduction was elicited by electrical stimulation at 20-80 Hz and 0.2-0.8 ms or by glutamate injection at dose of 50-10 nmol. The CCR-reduction was completely abolished by hexamethonium (5 mg/kg, i.v.). It was potentiated dose-relatedly by physostigmine (0.03-0.06 mg/kg, i.v.), but partially attenuated by atropine at a dose as high as 2 mg/kg, i.v.. It was largely reduced by ipsilateral section of the facial nerve root and completely abolished by additional interruption of the glossopharyngeal nerve root. However, CCR-reduction was not abolished by ipsilateral cervical sympathectomy. These findings suggest that DFA-induced CCR-reduction is mediated via facial and glossopharyngeal nerves, involving partially muscarinic and partially non-muscarinic mechanisms. CCR-reduction may not result from inhibition of sympathetic system.

82.17

THE EFFECT OF STIMULATION OF THE PERIAQUEDUCTAL GRAY ON CARDIOVASCULAR RESPONSES IN THE RABBIT. A. Wilson* and B.S. Kapp, Dept. of Psychology, University of Vermont, Burlington, VT 05405.

The midbrain periaqueductal gray (PAG) has been implicated in cardioregulation in the rabbit (Tan and Dampney, 1983), a finding consistent with the demonstration of a projection originating primarily from the posterior ventral PAG to the solitary complex in this species (Wilson and Kapp, 1987). This experiment was designed to determine the effects of electrical and chemical stimulation of the ventral posterior PAG on heart rate and blood pressure in the anesthetized rabbit.

Chloralose-anesthetized, paralyzed New Zealand rabbits were prepared with triple-barrel micropipettes through which electrical stimulation (75-150uA, 100 Hz, 1.0 sec), glutamate (1.0M; 100-200nl) or saline could be administered. Electrical stimulation of the posterior, ventral PAG invariably elicited bradycardia (40-60BPM, latency ≅ 1.0 sec) immediately preceding and accompanied by pressor responses (10mm Hg). Glutamate injected at the same sites elicited bradycardia (25-60 BPM, latency 7-12 sec) and typically depressor responses (15-30mm Hg). These results indicate that activation of ventral PAG cell bodies elicits bradycardia and that the differing blood pressure responses may reflect, in part, fiber activation by electrical stimulation. Supported by AHA grant 861277.

82.18

LESIONS OF THE PARABRACHIAL NUCLEI DEPRESS RECOVERY OF ARTERIAL PRESSURE FOLLOWING HEMORRHAGE. D.G. Ward and J.H. Ward*. H. M. Ward Memorial Lab., Valley Home, CA 95384.

The role of the parabrachial complex (PBN) in control of arterial pressure was examined in 53 conscious freely-behaving male rats. On Day-0, under ketamine anesthesia (150 mg/kg), a femoral arterial catheter was exteriorized to a spring tether attached between the scapulae. Bilateral lesions were directed toward either the lateral PBN or the medial PBN. One group of animals served as a control. Mean arterial presure (MAP), basal water intake and urine volume were measured daily for five days. On Day-2 mean arterial pressure (MAP) was measured for 20 min following a 15 ml/kg·3 min hemorrhage (HEM). The shed blood was reinfused and HEM was repeated on Day-5. MAP was significantly higher in lateral PBN animals than in medial PBN animals on Day-5 and Day-2. However, there were no significant differences within groups between Day-5 and Day-2 in recovery of MAP following HEM. Lateral PBN animals were associated with greater decreases in MAP following HEM than either medial PBN animals or controls.

	Day-5 PreHEM	Day-2 PreHEM	0 m post	20 m post
Control	110 ±9	115 ± 6	-49 ±15	-11 ± 8
Medial	102 ±9	107 ±11	-47 ±21	-14 ±10
Lateral	130 ±9	118 ±11	-62 ±15	-28 ±11

Water intake and urine volume were not significantly different among the three groups throughout the five days of measurement. Thus, in the freely-behaving rat neural elements in the lateral PBN play a demonstrable role in control of arterial pressure. (supported by USPHS HL36034)

Pressor Responses from the Parabrachial Complex: Lack of Correspondence Between Electrical and Glutamate Stimulation. F.J. Gordon, Dept.of Pharmacology, Emory Univ. School of Medicine, Atlanta, GA 30322.

The purpose of these studies was to determine if activation of neurons in the parabrachial complex (PBC) with L-glutamate would elicit cardiovascular responses similar to those obtained using electrical stimulation. Rats were anesthetized with urethane, paralyzed and respirated. In 11 rats, 30 sites in the PBC were tested using multibarrel glass pipettes containing a carbon fiber for electrical stimulation (20 sec trains, 100 uA, 0.5 msec). Microinjections (50 nl) of L-glutamate (20 and/or 200 mM) or artificial cerebrospinal fluid (ACSF) were then delivered from adjacent pipette barrels. Electrical stimulation (10-80 Hz) yielded frequency-dependent increases in mean arterial pressure (MAP) ranging from 7 ±2 to 54 ±3 mmHg. Microinjections of 20 and 200 mM L-glutamate increased MAP by only 4 ±1 mmHg (n = 25) and 5 ±1 mmHg (n = 14) respectively. These changes in MAP, although small, were significantly different ($p < .01$) from those produced by ACSF (1 ±1 mmHg; n = 10). Virtually identical results were obtained from a subset of sites in the Kolliker-Fuse nucleus (n=7). These results suggest that pressor responses evoked by electrical stimulation of the PBC are mediated predominantly by activation of fibers of passage because presumed activation of cell soma by L-glutamate produced only minimal changes in arterial pressure.

82.20

LOCUS COERULEUS NEURONS ARE ACTIVATED BY RIGHT ATRIAL STRETCH RECEPTORS. J.H. Jhamandas, S. Kaufman* and R.J. Reiffenstein. Depts. of Medicine and Pharmacology, University of Alberta, Edmonton, AB, Canada, T6G 2B7.

Previous studies have indicated that rat locus coeruleus (LC) neurons respond by reciprocal alterations in firing rate to changes in blood pressure. We have assessed the influence of activating cardiac atrial receptors on the excitability of LC neurons.

Extracellular recordings were obtained from identified LC neurons in urethane anaesthetized Long-Evans rats. These animals had been previously implanted with inflatable, indwelling balloon catheters with the tip located at the superior vena caval (SVC)/right atrial (RA) junction. Activation of right atrial receptors, consequent to inflation of the balloons with 0.05 ml of physiological saline, evoked a prompt but unsustained increase in the firing rate of 13 out of 17 LC cells without a significant change in mean arterial blood pressure. Histological verification of LC recording sites and the position of balloon catheters within the SVC/RA junction was performed in each animal.

Central projections of cardiac receptors beyond the level of the medulla need further study; the present results indicate that the LC may be an important site for transfer of cardiovascular-related information from right atrial baroreceptors throughout the CNS.

EFFECTS OF ACUTE AND CHRONIC ETHANOL EXPOSURE ON CRAYFISH BEHAVIOR AND SYNAPTIC TRANSMISSION. J. A. Blundon and G. D. Bittner. Dept. Zoology and Inst. for Neurol. Sci., Univ. TX, Austin, TX 78712.

The effects of ethanol (EtOH) exposure on behavior and synaptic transmission were examined in crayfish (*Procambarus clarkii* and *P. similans*). Hemolymph (blood) concentrations of EtOH of 50 - 100 mM produced behavioral signs of intoxication in crayfish (i.e. significant increases in righting reflex times and significant decreases in tail-flip escape responses) within 6 hours. Crayfish showed signs of tolerance to 50 mM EtOH after 2 weeks as determined by a return to control behaviors. Crayfish exhibited withdrawal symptoms of hyperactivity following removal of EtOH from aquarium water after 4 weeks of exposure. Data previously collected in our laboratory (Friedman *et al.*, 1988) suggests that EtOH has a concentration dependent biphasic effect on synaptic transmission in the opener excitor neuromuscular junction of the crayfish walking leg. Acute applications of 10 - 100 mM to the opener neuromuscular junction produced an increase in the probability of neurotransmitter release as measured by an increased frequency of spontaneously released neurotransmitter quanta. EtOH concentrations of 300 - 600 mM resulted in a decrease in excitatory junction potentials due to decreased postsynaptic membrane resistance. We are currently comparing effects of acute EtOH application on synaptic transmission in crayfish showing signs of intoxication, tolerance and withdrawal. Supported by NIAAA grant #AA07746.

INCREMENT OF CORTICAL BRAIN MICROVASCULARISATION FOLLOWING AGING, CORTICAL INSULT AND CHRONIC ALCOHOLISATION. M. Gewiss*, Ch. Heidbreder* and Ph. De Witte (SPON :European Brain and Behavior Society). Lab. Psychobiology,Univ. Louvain, B-1348 Louvain-la-Neuve.

Among the experimental models used to maintain high blood ethanol levels in animals chronically, the inhalation procedure seems to be one of the most appropriate to obtain constant high blood ethanol level. After sejourning 2 to 4 weeks into the alcoholised chamber rats were then perfused with a nuclear emulsion allowing to reveal the brain vascularisation. All the vessels, including terminal and lateral branches were measured and the lengths were summed up (in squares of .000625 mm² of the cerebral cortex). These measurements were also performed on brain adult animals after lesioned by aspiration and on rat brain aged of 2 years old. Our results show that cortical microvascularisation network increases after 2 weeks staying into the alcoholized chamber to remain at the same hypervascularization level after 4 weeks alcoholization. It has to be noticed that animals present this cortical hypervascularization before preferring the alcoholized bottle in a free test (water vs. alcohol 10% v/v). A similar enhancement of the microvascularization network was observed on aged brain animals and at day 6 after a cortical insult. These results thus tend to show that alcoholised adult animals present the same vascular evolution when compared to chronological aged animals and to animals which were brain insulted.

REGIONAL BRAIN METABOLISM DURING ALCOHOL INTOXICATION IN HUMAN SUBJECTS MEASURED WITH PET. N.D. Volkow, A.P. Wolf*, R.H. Hitzemann, S. Dewey, J. Logan, B. Bendriem*, and S. Vitkin*. Brookhaven National Laboratory, Upton, NY 11973.

We investigated the effects of acute alcohol administration on regional brain glucose metabolism in healthy volunteers (n = 6). Measurements of regional brain metabolism were done using 5-6 mCi of ^{18}F-deoxyglucose (FDG) on the PET VI. Subjects were scanned twice on consecutive days. The first scan was done under baseline conditions (eyes open, ears unplugged). For the second scan, subjects were given 1 g/kg 98% ethanol p.o. FDG was administered 30 min later. Global glucose metabolism in the brain decreased an average of 10% following alcohol ingestion. Regional changes in brain metabolism showed that the decrease occurred in cortical areas and in the cerebellum. Relative changes in glucose metabolism were quantified by dividing the metabolic activity in the region by the metabolic activity in the central slices. The basal ganglia showed a relative increase in metabolism. The average relative values for left and right basal ganglia during baseline were 1.28 and 1.23 and, during intoxication, 1.45 and 1.40, respectively. The changes in metabolism after alcohol intoxication were different from the changes reported in cerebral blood flow (CBF), suggesting regional uncoupling of CBF and glucose metabolism by alcohol. ETHANOL SUPPRESSES ACTIVITY OF RHYTHMICALLY BURSTING NEURONS OF THE MEDIAL SEPTAL AREA IN FREELY MOVING RATS. B.S. Givens and G.R. Breese. Univ. North Carolina Chapel Hill, NC 27514.

The medial septal area (MSA) is thought to play a role in the sedative effects of ethanol. In urethanized rats, ethanol suppresses firing in MSA cells and disrupts the rhythmically bursting pattern of activity. We report here the effects of ethanol on MSA neurons in freely moving rats.

Rats are fitted with head-mounted microdrives then placed on a rotorod apparatus and attached to standard recording equipment. After isolation of a single MSA cell, rats are injected with ethanol (0.75, 1.5, or 3.0 g/kg i.p.). There is a dose-dependent decrease in firing to ethanol in most neurons. The decrease is dose-related and lasts 30-120 minutes. The bursting pattern of activity is maintained in most cells at the 0.75 and 1.5 g/kg dose, but the burst frequency decreases from 6.2 to 5.0-5.7 bursts/second. At 3.0 g/kg, ethanol severely disrupts neural activity which then returns simultaneously with behavioral recovery.

Acute administraion of ethanol in freely moving rats results in similar changes in MSA neuronal activity as observed in the urethanized rat. Supported by NCARA fellowship #8611.

PROTEIN KINASE C AND ETHANOL-INDUCED UP-REGULATION OF CALCIUM CHANNELS IN PC12 CELLS.
R.O.Messing, A.B. Sneade*. Department of Neurology and Gallo Research Center, Univ. of California, San Francisco, CA 94110.

Long-term exposure to ethanol increases voltage-dependent Ca uptake and the number of binding sites for Ca channel antagonists in PC12 cells. Since activation of protein kinase C (PKC) modulates Ca currents in several tissues, we investigated whether PKC is involved in ethanol-induced Ca channel up-regulation in PC12. PC12 cells grown in 200 mM ethanol for six days showed an increase in ^{45}Ca uptake of 82 ± 5% over untreated control cells, whereas cells grown in ethanol plus the PKC inhibitor sphingosine (1 μM) showed an increase of only 40 ± 2% ($p < 0.002$ compared to ethanol-treated cells). N-Acetylsphingosine (1 μM), a sphingosine derivative that does not inhibit PKC did not significantly reduce the response to ethanol. Sphingosine alone did not alter ^{45}Ca uptake in cells cultured without ethanol. Exposure to 200 mM ethanol for 6 days increased the V_{max} for PKC in detergent-solubilized cell extracts by 66 % (148 ± 6 in control vs. 245 ± 9 pmol/min/mg of homogenate in ethanol-treated cells; $p < 0.02$). These findings suggest that Ca channel up-regulation during chronic ethanol exposure is mediated by PKC. Increased PKC-dependent phosphorylation could possibly result from an increase in the amount of PKC present in ethanol-treated cells.

CHRONIC ETHANOL INTOXICATION EFFECTS ON LIMBIC ELECTROPHYSIOLOGIC ACTIVITY.
R.K.Harper*, R.M.Harper and H.L. Lesse (SPON: S. Eiduson). Depts of Psychiatry and Anatomy, UCLA, Los Angeles, CA 90024.

We assessed the effects of acute and chronic ethanol administration on excitability of limbic structures by measuring the threshold and duration of electrically induced afterdischarges (AD) in kindled cats. Electrodes were placed in amygdala and hippocampus; jugular vein was cannulated. AD thresholds and durations were determined following acute injections of 1.6 g/kg 15% ethanol and during 10 day chronic ethanol periods (determinations at 1 and 24 h). Marked elevations in AD threshold and reductions in both AD duration and propagation occurred at 1 h only. Control condition tonic-clonic convulsions were replaced by minimal mouth movements and transient arrest reactions, demonstrating protective action against limbic seizures. On 4th, 6th, 8th and 10th day after onset of chronic ethanol, 1 h thresholds decreased and durations increased relative to saline and ethanol baseline tests; behavioral response was limited to brief automatisms. No 24 h effect. Following alcohol abstinence, anti-convulsant effects of ethanol recovered to 1 h baseline; 24 h tests showed no change. Behavioral signs of intoxication diminished in degree over chronic ethanol days and remained reduced throughout post-chronic challenges. Thus, ethanol exerts a short-term effect on limbic excitability; tolerance and sensitization attenuate ethanol's initial depressant actions.

EFFECT OF ALCOHOL AND NICOTINE ON CYTOTOXIC RESPONSE OF HUMAN LYMPHOCYTES.
M.P.N. Nair*, Z.A. Kronfol and S.A. Schwartz*. The University of Michigan, Ann Arbor, MI 48109.

The in vitro effect of ethanol (EtOH) and nicotine on natural killer (NK), antibody dependent cellular cytotoxic (ADCC), and lympokine activated killer (LAK) cell activities and immunoglobulin synthesis by normal lymphocytes was investigated. Lymphocytes precultured with EtOH at concentrations of 0.4 and 0.6% (V/V) produced significant suppression of NK (K562, U937 and HSB targets) and ADCC (SB target) activities. In target binding assays, EtOH decreased the target binding capacity of effector cells. The generation and lytic capacity of LAK cells were also significantly affected by EtOH when added at the initiation of culture. Nicotine at concentrations of 5 and 10 ug/ml, produced significant inhibition of NK activity. Nicotine (2 ug/ml) and EtOH (0.01, 0.1 and 0.2%) at noninhibitory concentrations when added separately, showed significant suppression of NK activity when used in combination. Addition of nicotine to a pokeweed mitogen induced B cell activation system resulted in suppression of Ig synthesis by normal lymphocytes. These studies suggest that EtOH and nicotine may have significant immunomodulatory effect on human lymphocytes that may be of clinical relevance.

GABA-MEDIATED INHIBITION OF CA1 POPULATION SPIKES IN HIPPOCAMPAL SLICES OF CHRONIC ETHANOL-TREATED RATS.
R. A. Palovcik, B. E. Hunter and D. W. Walker, Department of Neuroscience, University of Florida and V. A. Medical Center, Gainesville, FL 32610.

Hippocampal slices from chronic ethanol-treated (CET) and sucrose-fed control (SUC) rats, cut 400 microns thick from septal and temporal hippocampal poles, were maintained in a Haer slice chamber. CET rats were fed a nutritionally complete diet containing ethanol for 20 weeks followed by an eight week withdrawal period. SUC control rats were pair fed the same diet but with sucrose isocalorically substituted for ethanol. Stimulation of stratum radiatum (SR) with a bipolar electrode produced an evoked population spike, recorded extracellularly in stratum pyramidale (SP). The same recording, iontophoretic, and stimulating electrodes were used on slices from CET-SUC pairs to directly compare measured electrophysiological parameters.

Population spike responses in temporal pole slices of SUC rats were of lower amplitude than those in septal pole slices of SUC rats whereas CET rats had comparable amplitudes of evoked action potentials in both septal and temporal poles. Iontophoretic ejection of GABA into SP was more effective at blocking SR-evoked action potentials than ejection into SR or stratum oriens (SO) in both CET and SUC rats. There were no significant differences in the effect of GABA iontophoresis between CET and SUC rats in septal vs temporal hippocampal poles. Ejection of bicuculline enhanced total population spike amplitude more when applied to SP than SO or SR. Duration of bicuculline enhancement of population spikes was longest for temporal pole slices from SUC rats, whereas CET rats showed equivalent effects of bicuculline on septal and temporal poles. The overall effects of bicuculline on amplitude of population spikes were greater for CET than for SUC rats in both septal and temporal poles.

Alterations in responsiveness of ventral hippocampal slices between CET and SUC rats revealed by bicuculline reflect changes in GABA circuitry of the hippocampus that do not alter postsynaptic responsiveness of CA1 pyramidal neurons to GABA.

EFFECTS OF ETHANOL ON PURKINJE NEURONS IN RAT CEREBELLAR BRAIN SLICES.
William R. Proctor and Thomas V. Dunwiddie. Dept. of Pharmacology, Univ. of Colo. Hlth. Sci. Ctr. and Veterans Administration Med. Ctr., Denver, CO.

The acute effects of superfusion with ethanol were characterized on cerebellar Purkinje neurons recorded intracellularly in rat cerebellar slices (350 μm, sagittal sections from the vermis). Perfusion with 100 mM ethanol had minimal effects on the resting membrane potential (0.4 ± 0.2 mV hyperpolarization), and on the membrane input impedance (2.0 ± 2.7% reduction). Complete current/voltage curves for 2 cells examined before, during and after washout of ethanol were essentially identical. In addition, synaptic responses elicited by stimulation of the climbing fibers, showed only a small reduction in the epsp amplitude (10 ± 8.1%). A number of the neurons showed a characteristic pattern of firing consisting of periods of highly regular 30-60 Hz firing, which gradually became more irregular, and was then followed by a rapid hyperpolarization (6-10 mV). This was followed by a relatively long (5-10 sec) period of electrical silence during which the membrane gradually depolarized back to baseline, which was followed by a return to repetitive firing (see Llinas and Sugimori, J. Physiol. 305:171, 1980 fig. 11). Ethanol consistently modified this pattern by shortening the period of repetitive spiking. Passing a constant current through the intracellular recording electrode under control conditions to depolarize or hyperpolarize the cell did not reproduce the firing pattern produced by ethanol. The pattern of firing during the active periods, and the shape of the action potential showed no significant effect of ethanol treatment. These results suggest that ethanol treatment (100 mM) has little direct effect on the membrane potential or input impedance of Purkinje neurons, but might modify either the calcium or potassium conductances that underlie the periods of repetitive firing and the subsequent inhibition respectively.

CONTENTS OF SEROTONIN, DOPAMINE AND THEIR METABOLITES IN THE CNS OF HIGH- AND LOW-ALCOHOL-DRINKING LINES OF RATS.
J.M. Murphy, M.A. Gongwer*, W.J. McBride, L. Lumeng* and T.-K. Li* Inst. Psych. Res. & Regenstrief Inst., Indiana Univ. Sch. Med. & VA Med. Ctr., Indianapolis, IN, 46223.

This study was designed to test the hypothesis that voluntary, high alcohol intake is associated with an imbalance of serotonin (5HT) and dopamine (DA) systems in certain CNS regions. Levels of 5HT, DA and their metabolites (5HIAA, DOPAC and HVA) were assayed in CNS regions of two rat lines selectively bred from the N/Nih heterogeneous stock for high- or low-alcohol-drinking (HAD or LAD) behavior. Contents of 5HT and/or 5HIAA were lower ($p<0.05$) for the HAD compared with the LAD line (N=11-12/line) in 3 regions studied thus far: nucleus accumbens (ACC; 3.1±0.1 vs 3.6±0.1 nmol/g for 5HIAA); frontal cortex (7.3±0.1 vs 8.0±0.2 nmol/g for 5HT) and posterior striatum (4.6±0.2 vs 5.6±0.3 nmol/g for 5HT and 3.3±0.1 vs 4.1±0.2 nmol/g for 5HIAA). Only the ACC yielded a difference ($p<0.05$) between the two lines in the contents of DA (46.4±0.2 for HAD vs 51.1±0.8 nmol/g for LAD), DOPAC (5.1±0.2 for HAD vs 6.0±0.1 nmol/g for LAD), and HVA (2.4±0.1 for HAD vs 3.0±0.1 nmol/g for LAD). The data are consistent with the hypothesis that abnormal functioning of certain 5HT and DA systems are associated with high alcohol drinking behavior. (Supported by AA-03243 and AA-07462.)

ETHANOL, BRAIN DOPAMINE CONDENSATION PRODUCTS, AND DOPA IN THE DIET. M.A. Collins, N. S. Ung-Chhun*, D. Pronger* and B. Cheng*. Biochem., Loyola Med. Sch., Maywood IL 60153.

We suggest that diet may be responsible in part for reported increases in rat brain levels of salsolinol (SAL), a condensation product of dopamine (DA) and acetaldehyde (AcH), following chronic ethanol (EtOH). With capillary GC/MS and deuterated standards, we assayed SAL and related condensation products, as well as DA and DOPAC, in brain areas of rats ingesting EtOH (6 mo; 10-14 g/kg/d)--but in a nutritionally complete liquid diet rather than in water with rat chow, as per previous researchers. In contrast, EtOH resulted in either no changes or moderate decreases in regional levels of SAL and other condensation products, while striatal DA and DOPAC were reduced 1/3. Concerned that the diets with EtOH may be a reason for the discrepancy over SAL, we analyzed chow and liquid diet for DOPA, SAL and related amines. Quantities of DOPA and SAL were found in chow, but not in liquid diet. In the EtOH/chow studies, we suspect that sustained intake of rat chow DOPA provided, upon decarboxylation, a unique pool of DA which reacted in the EtOH-ingesting rat with circulating AcH. Of significance is that this may have occurred at the brain capillary endothelial barrier rather than within neurons, and EtOH might even form AcH at this site also. Rat chow SAL could further contribute, but dietary DOPA was probably the key factor. Supported by NIAAA.

83.12

THE SELECTIVITY AND SENSITIVITY OF DIMYRISTOYL-PHOSPHATIDYLCHOLINE LIPOSOMES TO PERTURBATION BY N-ALCOHOLS. R. Hitzemann and K. Dains*. Psychiatry Service-VAMC, Northport, NY 11768.

The partition coefficients "K" of a non-electrolyte "i" into two membranes "x" and "y" are related by, $\log K_{i,y} = \log K_{i,x} * S_{x,y} + R_{x,y}$ where S is the selectivity constant(see Diamond and Katz, J.Mol. Biol.17:121, 1974). When $S_{x,y}$ is < 1, membrane "x" is more hydrophobic(from a partitioning perspective) than membrane "y". We propose that since the perturbation of membrane structure induced by non-electrolytes is highly correlated to K, the above equation could be re-written, substituting P for K, where P is a measure of membrane perturbation. From this perspective, $R_{x,y}$ is a measure of the difference in membrane sensitivity, independent of the partitioning electrolyte. We have utilized this selectivity/sensitivity concept to analyze the perturbation of DMPC membrane order induced by C1 to C8 n-alcohols; order was monitored by fluorescence polarization with either DPH or TMA-DPH as the membrane probes. Comparing the domains monitored by DPH and TMA-DPH at 30 C, the DPH domain is nearly 10 times more sensitive to perturbation by the n-alcohols than the TMA-DPH domain; as expected the DPH domain is significantly more hydrophobic($S_{x,y}$=0.65+0.08).

83.13

EFFECT OF ETHANOL ON THE NEUROSTEROIDS CONCENTRATIONS IN THE RAT BRAIN. O.C.Vatier*, F.E.Bloom, Preclin.Neurosci. & Endocrin., Scripps Clinic & Research Foundation, La Jolla, CA 92037.

3ß-hydroxy-Δ5 steroids such as pregnenolone (P), dehydroepiandrosterone (D), and their sulfate esters (PS and DS) exist in rat brain at higher concentration than in blood, and persist after removal of gonads and adrenal glands. Although the role of these steroids in brain function is still unknown, previous studies have showed that the levels may be functionally regulated. This study sought to establish the relationship between blood alcohol levels (BAL) and the concentration of P,PS,D and DS in different structures of the rat brain. Sprague Dawley male rats (175g) were given ethanol (16%in saline,IP) to obtain BALs of 150mg%. Control were given a equal volume of saline. Animals were sacrified two hours later and the brain quickly dissected for steroids assays. The results (N=24-36) shows a averaged 75 % decrease of D+DS in the olfactory bulbs (OT), olfactory tubercules (OT), amygdalas (A), hypothalamus (H). The mean concentration of D+DS in these combined regions is: 0.78+0.24ng per wet weight in ethanol-injected rats and 3.24+0.44ng per wet weight in controls. There is approximately the same depletion in each regions studied (OB=average loss=75%; OT=80%; A=75%; H=60%). There were no significant changes observed in the concentrations of P and PS. In conclusion, the dehydroepiandrosterone (D) seems to be a reliable marker of the alcohol intoxication in the rat brain the possible differential effects of ethanol exposure on D versus DS are still under investigation as is the time courses of the recovery from intoxication. Additionals datas will be required to determine the metabolic implications of this decrease, and its possible physiological significance. (NIAAA Grant #06420).

83.14

ANESTHESIA-DEPENDENT EFFECTS OF ACUTE ETHANOL IN HIPPOCAMPAL CA3 FIELD ELECTRICAL ACTIVITY. J.R. Criado and L.P. Gonzalez. Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190-3000.

Studies have shown that ethanol and general anesthetics can alter membrane ionic conductance and therefore the electrical properties of neurons. To study the acute effects of ethanol and its possible interactions with general anesthetics, a field potential laminar analysis of the hippocampal CA3 field was performed under two different anesthetics: halothane (1%) and urethane (1.2 g/kg). Male Sprague-Dawley rats were surgically prepared and bipolar stimulating electrodes were positioned in the ventral hippocampal commissure contralateral to the hippocampal CA3 recording site. Glass micropipettes filled with 2% Pontamine Sky Blue in 0.5M sodium acetate were used for extracellular field potential recordings. Evoked field potentials were recorded at 100u intervals throughout the CA3 field. After baseline data were collected, a moderate dose of ethanol (1.5 g/kg) was injected. In general, ethanol produced a decrease in the amplitude of positive field potentials and an increase in negative field potentials in rats under halothane anesthesia. However, acute ethanol in the urethane preparation resulted in an increase in both the negative and positive field potentials.

Supported in part by NIAAA grant AA07254 and a Presbyterian Health Foundation Grant.

ARYLSULFATASE A ELECTROPHORETIC VARIANTS IN ALCOHOLIC PATIENTS. P. Manowitz*, R. Bradley*, R. Nora*, and S. Chokroverty* (SPON: J. Ravens). UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, and Veterans Administration Medical Center, Lyons, NJ.

The purpose of this study was to determine if electrophoretic variants of arylsulfatase A (ASA) occurred more frequently in alcoholic patients than controls. ASA catalyzes the degradation of sulfatides, which are part of the opiate receptor, the GABA receptor, and the Na^+-K^+ ATPase.

Twelve percent (17/143) of alcoholic patients have variant ASA's of the III_A, III_B, and IV_B pattern as determined by electrophoretic analysis of blood samples. While none (0/208) of the psychiatric patients without alcoholism have the III_A or III_B variants, two percent (5/208) of these patients have the IV_B variant. Only 0.6 percent (1/159) of the healthy control subjects have a variant of ASA, in this case a III_A variant.

These data support the hypothesis that the III_A, III_B, and IV_B variants of ASA are associated with alcoholism and may be predisposing factors for this disease.

As part of this study of ASA, a more sensitive enzyme assay using high performance liquid chromatography with an electrochemical detector has been developed with detection of p-nitrocatechol, the artificial enzymatic products, at a level of 0.3 picomole. (Supported by a grant from the UNICO Foundation.)

EFFECTS OF ETHANOL ON THE INHIBITORY GTP-BINDING PROTEIN-MEDIATED ADENYLATE CYCLASE INHIBITION IN RAT CEREBRAL CORTEX. S. Hatta*, T. Saito, F. Tsuchiya*, H. Ohshika* and N. Takahata*. Departments of Pharmacology and Neuropsychiatry, Sapporo Medical College, Sapporo 060, Japan.

Ethanol (EtOH) has been suggested to stimulate adenylate cyclase (AC) in vitro through an increased function of the stimulatory GTP-binding protein (Gs). However, effects of EtOH on the inhibitory GTP-binding protein (Gi)-mediated inhibitory pathway of AC still remain unclear. The present study was conducted to examine EtOH effects, in vitro, on the Gi-mediated AC inhibition caused by GppNHp in the presence of forskolin (100 μM) in rat brain cortical membranes (CM).

CM were prepared from male Wistar and Fischer 344 rats. The forskolin-activated AC was inhibited about 30% with GppNHp (0.01 - 0.3 μM) in CM from Wistar rats. The concentration of GppNHp required for half-maximal inhibition of AC ("$GppNHp_{50}$") was 84.8 nM and 34.9 nM in control and EtOH (500 mM)-treated CM, respectively. In CM from Fischer 344 rats, GppNHp-induced inhibition of the forskolin-activated AC was about 20%. The "$GppNHp_{50}$" value in control was 63.8 nM, and EtOH did not alter the "$GppNHp_{50}$" value.

These results suggest that EtOH in vitro may alter the Gi function in Wistar rat CM, besides its effects on the Gs function, and EtOH effects on the Gi function in CM are different between in Wistar and Fischer 344 rat CM.

83.17

EFFECT OF INTOXICATING DOSES OF ETHANOL ON HIPPOCAMPAL INHIBITORY PROCESSES ASSESSED IN THE RAT DENTATE GYRUS. Steven J. Henriksen, Yung Kim, and James Wiesner. Research Institute of Scripps Clinic, 10666 N. Torrey Pines Road, La Jolla, CA. 92037.

Low doses of ethanol affect cognitive processes thought to employ, in part, hippocampal circuitry. In an attempt to investigate the neurochemical substrates for the action of ethanol in this structure, we have studied the action of systemically, locally, and intraventricularly administered ethanol on a variety of electrophysiological measures of granule cell excitability in halothane anesthetized, and unanesthetized, rats. All routes of ethanol administration produce dose-dependent reversible decreases in the spontaneous discharge of randomly encountered single granule cells. Stimulation of the perforant path afferents to the dentate gyrus also elicits dose-dependent ethanol responses. Low doses of ethanol (0.5-1.5 gm/kg i.p.) produce no effect on "field-evoked" EPSPs recorded from the dendritic zone of termination. In addition, singly-evoked population spikes (PS) (quantified by input-output analysis), or conditioning PS (evoked in paired-pulse [PP] paradigms) were also unaffected by these ethanol doses. However, recurrent inhibition assessed by PP analysis demonstrated a significant increase following low doses of ethanol. This enhancement of PP inhibition by ethanol, but not after saline, was partially reversed by systemic administration of atropine. Therefore, cholinergic processes may play a role in the action of ethanol on recurrent excitation/inhibition observed in the dentate gyrus.

83.18

THE EFFECTS OF ETHANOL ON SYNAPTIC TRANSMISSION IN THE ABDOMINAL GANGLION OF APLYSIA CALIFORNICA. Alan J. Grant* and Steven N. Treistman. The Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Earlier work from this laboratory has indicated that calcium currents within identified Aplysia neurons are reduced by clinically relevant concentrations of ethanol. Since calcium currents are known to play an important role in release at synaptic terminals, we might expect that low concentrations of ethanol will affect synaptic transmission. To test this, we examined the effects of ethanol on synaptic function in the Aplysia abdominal ganglion. Acetylcholine, serotonin, gamma-aminobutyric acid, and dopamine are known to be acting at the synapses which we studied, and some of the synaptic linkages examined were cyclic nucleotide-mediated. In most synapses, concentrations of ethanol lower than 100 mM had minimal effects on transmission. By simultaneously voltage-clamping cell L10 and recording postsynaptic potentials in follower cells during ethanol exposure, we were able to compare the changes in calcium current with changes occurring in cholinergic transmission, and these results will be discussed.

These studies were supported by a grant from the Public Health Service.

SPECIFIC BINDING OF [^{3}H]INOSITOL - 1, 4, 5 - TRISPHOSPHATE TO CEREBRAL CORTICAL AND CEREBELLAR MEMBRANE FRAGMENTS FROM ETHANOL SENSITIVITY (LS) AND RESISTANT (SS) MICE. T.L. Smith and E.C. Turbak. Veterans Administration Medical Center, Tucson, AZ 85723 and Department of Pharmacology, University of Arizona, Tucson, AZ 85724.

In a variety of tissues nanamolar concentrations of IP_3 stimulate the release of Ca^{+2} sequestered within the endoplasmic reticulum. Since ethanol affects CNS Ca^{+2} disposition, it was of interest to characterize [^{3}H]IP_3 specific binding in two different brain regions from mice specially bred for differential sensitivity to the hypnotic effects of ethanol. Membrane fragments from cerebral cortex or cerebellum of LS and SS mice were suspended in 50 mM Tris buffer (pH 8.3) containing NaCl, 20 mM KCl, 100 mM; EDTA, 1 mM. Tissue samples (350 - 500 µg protein) were incubated for 10 mins at 4° in the presence of 10 to 160 nM [^{3}H]IP_3 (20 Ci/mmol) in a final volume of 0.5 ml and the reactions stopped by rapid vacuum filtration. Scatchard analysis of the binding data from cerebral cortex of LS and SS mice yielded: (LS) Bmax, 256 +13 fmoles/mg protein; K_D, 18 ± 2 nM. (SS) Bmax, 229 + 30 fmoles/mg protein; K_D, 26 + 7 nM. Similar analyses of cerebellar membrane fragments from these mouse lines yielded: (LS) Bmax, 1142 + 250 fmoles/mg protein; K_D, 33 + 7 nM. (SS) Bmax, 1243 ± 260 fmoles/mg protein; K_D, 8 + 1 nM. Ethanol added in vitro up to 500 mM had no significant effect on [^{3}H]IP_3 specific binding to cerebellar tissues from either LS or SS mice. It is concluded that only differences in [^{3}H]IP_3 dissociation constants are observed in cerebellar tissues from LS and SS mice which may not generalize to other brain areas. (Supported by a Vet. Admin. Medical Research Grant).

ALCOHOL ADMINISTRATION REDUCES THE NUMBER OF IMMUNOREACTIVE VASOPRESSIN PERIKARYA. G.P. Kozlowski, J.H. de Schweinitz* and M. Sadeq*. Dept. of Physiology, Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235.

Vasopressin (VP) has been shown to enhance learning and memory which is negatively affected in alcoholics. We sought to determine the effects of 5% ethanol (ETOH) administration on VP-containing neurons using a simultaneous pair-feeding system of Israel et al. Twenty-five male Long-Evans rats were used. Two experimental groups (n=5/gp) received a Bio-Serv liquid diet containing ETOH for 5 or 15 days. Three groups of control animals were administered: (1) solid diet (Lab Chow) pellets and water ad libitum, (2) control liquid diet (isocaloric to the ETOH group) for either 5 or, (3) 15 days. The animals were perfuse-fixed and their brains processed for immunocytochemistry using rabbit anti-VP 710 and the ABC kit from Vector Laboratories. All of the VP-immunopositive perikarya having a nucleus were classified into 6 nuclear areas and manually counted. All three groups of control animals had significantly more VP-containing perikarya than the 15 ($p<0.01$) day ETOH group. The 6 nuclear areas studied were: anterior commissural (ACN), supraoptic (SON), suprachiasmatic, paraventricular, retrochiasmatic of the SON and anterior hypothalamic. Significant ($p<0.05$) decreases in numbers of VP-containing neurons (e.g. mean of 2339 for 15 da ctrl vs. 1647 for 15 da ETOH) occurred in all areas except for the ACN in 15 days ETOH group. Supported by AA-06014.

ANGIOTENSIN II MEDIATES DRINKING ELICITED BY HISTAMINE IN RATS. **F. S. Kraly and R. Corneilson*. Dept. of Psychology, Colgate Univ., Hamilton, NY 13346.**

Drinking elicited by s.c. histamine (H) was preceded by 10 min by s.c. captopril (CA; 100 mg/kg), to prevent the synthesis of angiotensin II (AII) in circulation and in brain, or 0.9% NaCl in Sprague-Dawley male rats in 1-hr tests for drinking. CA attenuated (72% inhibition) but did not abolish drinking elicited by the ED_{100} dose (20 mg/kg) for H. This inhibition was reversed by s.c. AII (0.12 mg/kg). Selective gastric vagotomy attenuated drinking elicited by H or by 1 mg/kg AII, and when combined with CA, vagotomy abolished drinking elicited by the ED_{100} for H. The ED_{100} for H and 0.12 mg/kg AII were additive in their effects on water intake. CA abolished drinking elicited by the ED_{50} (2.5 mg/kg) for H. This blockade was surmounted by s.c. AII. The ED_{50} for H and 0.5 mg/kg AII were additive in their effects on water intake. Inhibition of drinking by CA was not nonspecific; e.g., CA failed to inhibit drinking elicited by 0.5 mg/kg AII. Antagonism of H_1 and H_2 receptors (1 mg/kg dexbrompheniramine and 16 mg/kg cimetidine i.p.) for H abolished drinking elicited by H without inhibiting drinking elicited by 0.12 mg/kg AII. These findings are consistent with the hypothesis that the renal renin-angiotensin system through AII mediates histamine's dipsogenic effect in rats.

GABA DISRUPTION OF INTRACEREBROVENTRICULAR INFUSED ANGIOTENSIN II IN RATS. K.A. Roberts, J.W. Harding and J.W. Wright. Dept. of Psychology and VCAPP, Washington State University, Pullman, WA 99164

An initial experiment established a dose-response relationship between the intracerebroventricular (icv) infusion of angiotensin II (AII: 0, 0.1, 1, 10 and 100 pmol/2 ul aCSF/min) for 5 min and resulting water consumption in Spontaneously Hypertensive Rats (SHR), Wistar-Kyoto (WKY) and Sprague-Dawley (SD) normotensive controls during the 30 min measurement period. The results indicated an exaggerated intake by the SHR at the two highest doses in agreement with a previous report that utilized icv bolus injections of AII (Wright et al., 1987). From these data the 100 pmol dose of AII was selected for further study because it most reliably displayed this strain difference in consumption. A second experiment utilized icv pretreatment infusion of GABA (0, 10, 100 and 1000 nmol/2 ul aCSF/ min) for 5 min followed by the icv injection of AII(100 pmol in 2 ul aCSF) in SD rats. The results indicated progressive reductions in AII-induced water consumption with increasing dose of GABA, and confirm earlier reports of an interaction between central gabanergic and angiotensinergic systems (Unger 1983).

	n	Mean Water Intake (ml/30 min)		n	Mean Water Intake (ml/30 min)
aCSF	5	10	100 nmol	13	6
10 nmol	8	8	1000 nmol	11	2.2

HYDROMINERAL HOMEOSTASIS IN FISCHER 344 RATS: ROLE OF HYPOTENSION IN ANGIOTENSIN-RELATED WATER AND NACL INTAKE. F.A. Caputo*, N.E. Rowland and M.J. Fregly* (SPON: V.C. Pellis). Depts Psychol & Physiol, Univ of Florida, Gainesville, FL 32611.

Fischer 344 (F344) rats differ from many other strains by their absence of spontaneous preference for NaCl solutions. We have also found that they drink less in response to acute treatment with either the B-adrenergic agonist, isoproterenol (ISOP) or extracellular dehydration with polyethylene glycol. We now report that ISOP produces comparable elevations in plasma renin activity and heart rate in F344 and Sprague-Dawley (SD) rats. In contrast, ISOP produces less hypotension in F344 than SD, and the higher water intake in SD may thus relate to their lower blood pressure for a given plasma concentration of angiotensin (ANG) II. We are presently examining whether the reduced NaCl preference and appetite in F344 may be related to these cardiovascular differences. Acute administration of ANG II (200 ug/kg SC) induced intake of both water and 0.15M NaCl in F344 and SD rats, with no apparent strain difference. In contrast, ANG I (133 ug/kg, SC) produced water, but no 0.15M NaCl intake in F344 rats; SD rats drank both water and NaCl after ANG I. The ANGI-induced intakes of water and NaCl were not significantly altered in either strain by pretreatment with the ANG converting enzyme inhibitor, captopril (3 mg/kg).

84.4

CENTRAL NOREPINEPHRINE INFUSIONS RESTORE DRINKING TO ANGIOTENSIN II IN RATS WITH CATECHOLAMINE DEPLETIONS OF THE MEDIAN PREOPTIC NUCLEUS (MNPO) AND THE ORGANUM VASCULOSUM OF THE LAMINA TERMINALIS (OVLT). J.T. Cunningham & A.K. Johnson. Depts. of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa.

Our laboratory previously has shown that 6-hydroxydopamine (6-OHDA) injections into the MnPO and OVLT produce specific drinking deficits to angiotensin (ANG). This deficit can be reversed by tranplanting norepinephrine containing tissue into the injection sites. In the present study, we attempted to reverse the 6-OHDA-induced defict to ANG with central infusions of norepinephrine (NE). Male rats were injected with 6-OHDA (N = 8) or vehicle (VEH, N = 7) into the MnPO and the OVLT and guide cannulae were placed into each lateral ventricle. Drinking tests were conducted with carbachol (50 ng/2 ul) to ensure the patency of each cannula. The 6-OHDA group drank significantly less to saline infusions and bolus injection of ANG (S + ANG 50ng/2ul) than did the VEH group. Central icv infusions of NE (100 nmole/15 ul 0.5 ul/min) with saline bolus injection (NE + S) did not induce drinking in either the 6-OHDA or VEH groups. When ANG was injected during NE infusion (NE + ANG), the 6-OHDA group drank significantly more than the previous S + ANG and the NE + S treatments. NE replacement restores drinking to ANG in rats with catecholamine depletion of the MnPO and the OVLT.

ATRIAL NATRIURETIC PEPTIDE INJECTIONS INTO THE SUBFORNICAL ORGAN REDUCE DRINKING TO ANGIOTENSIN II. K.J. Ehrlich*, J.B. Simpson and D.A. Fitts. Dept. of Psychology, Univ. of Washington, Seattle, WA 98195.

Intracerebroventricular application of atrial natriuretic peptide (ANP) attenuates the water intake generated by central angiotensin II (ANG). One possible site for this antagonism might be the subfornical organ (SFO), a circumventricular organ that has high concentrations of receptors for both ANG and ANP. The SFO is a primary site for the dipsogenic action of circulating ANG, and thus is a logical site for antagonism of ANG-induced drinking by ANP. This study examined the effect of a pretreatment of ANP on ANG-induced water drinking at the SFO. Long-Evans rats were fitted with cannulas in the SFO under equithesin anesthesia. On each of three test days, the rats received two 0.5-μl injections into the SFO including a pretreatment followed 5 min later by 10 pmol ANG. On days 1 and 3 the pretreatment was a saline vehicle; on day 2 the pretreatment was vehicle (n=7), 100 pmol (n=6), or 230 pmol α-human ANP (n=7). Water intakes (ml/30 min ± s.e.m.) are shown below. ANP significantly reduced water intake generated by ANG at the SFO at both doses ($p<.05$). Thus, the SFO may be a site for the antagonism of drinking to ANG by ANP.

	Days		
Pretreatment	1	2	3
Vehicle	3.24±1.01	4.26±0.64	4.79±0.90
100 ANP	5.31±1.24	2.87±0.91	2.88±1.45

SUBFORNICAL ORGAN: SITE OF DIPSOGENIC ACTION OF ANGIOTENSIN II. S. Cohen, M. Kadekaro, M.L. Terrell, H. Lekan, H. Gary, Jr. and H.M. Eisenberg. Div. of Neurosurg., Univ. of Tex. Med. Branch, Galveston, TX 77550

The subfornical organ (SFO) and the anterior ventral portion of the third ventricle (AV3V area) contain angiotensin II (AII) receptors and are putative sites of dipsogenic action of peripheral AII. The objective of this study was to identify the primary site of action of AII, employing the deoxyglucose (DG) technique. Male adult Sprague-Dawley rats (n=41) were used. Under Equithesin anesthesia the ventral stalk of the SFO was stereotaxically disconnected from the AV3V area using a knife with a retractable blade. For the sham operation, the knife was lowered into the brain but the blade was not extruded. The DG experiments were performed three days after the surgery. Rats in each surgical group were infused with either saline or AII (2.5 μg/min) for 45 min starting 10 min before the injection of DG. Lesioned animals (n=7) drank less than sham-operated rats (n=14), in response to AII [0.9 ml (SD 0.9) vs. 2.9 ml (SD 1.8)]. Glucose utilization in the SFO, however, increased in lesioned rats to the same extent as in the sham-operated animals in response to AII. In the AV3V area and in the hypothalamo-neurohypophysial system the responses to AII were also similar in both groups of animals. From these results, we conclude that the SFO is the main site of dipsogenic action of AII but that the activation of the hypothalamo-neurohypophysial system by the AII does not depend on inputs from the SFO.

84.7

INTRACEREBROVENTRICULAR AMASTATIN POTENTIATES DRINKING TO ANGIOTENSIN AND HYPERTONIC SALINE. **M. J. Sullivan, T. G. Beltz and A. K. Johnson. Departments of Psychology, Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242.**

The aminopeptidase A and leucine aminopeptidase inhibitor, amastatin, has been demonstrated to increase the half-life of iodinated angiotensins (ANG) in the ventricles of the rat. In this study, the effects of amastatin delivered into the lateral ventricle on central ANG-induced or carbachol-induced drinking and peripheral ANG-induced and hypertonic saline-induced drinking were evaluated. Rats were prepared with a cannula into the lateral cerebral ventricle. Central effects were examined by administering 100 nmoles amastatin alone, 100 pmoles ANG alone or both 100 nmoles amastatin and 100 pmoles ANG. Central effects of amastatin on drinking to carbachol (CARB) were testeded by administering 100 pmol amastatin alone, 50 ng CARB alone or both 100 nmoles amastatin and 50 ng CARB. Effects of central amastatin on drinking to peripheral ANG or hypertonic saline (HTS) challenges were assessed by delivering either artificial cerebrospinal fluid or amastatin (100 nmoles) into the ventricle and ANG (1.5 mg/kg) or hypertonic saline (1 ml 3% NaCl/100 gm) subcutaneously.

Amastatin potentiated the dipsogenic effects of centrally administered ANG, in all likelihood as a result of inhibition of degradation of the exogenously applied peptide. Amastatin had no effect on CARB-induced drinking. The dipsogenic actions of peripherally injected ANG and HTS were also significantly enhanced by the inhibitor. These data suggest the involvement of central peptidergic synapses in drinking to osmotic and hypovolemic stimuli.

84.8

EFFECTS OF IV AND/OR ICV CAPTOPRIL INFUSIONS ON THE DRINKING AND PRESSOR RESPONSES TO IV ANG I IN THE RAT. M. M. Robinson, G. P. McLennan* and A. K. Johnson. Dept. of Physiol., The Univ. of Western Ontario, London, Canada, N6A 5C1 and Dept. of Psychol. and Pharmacol. and The Cardiovascular Center, Univ. of Iowa, Iowa City, 52242.

We investigated the effects of IV and/or ICV infusions of Captopril (Capt.; 1 ug/min), on the drinking and pressor responses to IV Ang I (100 ng/min). IV Capt. (begun 30 min before IV Ang I) had no effect on the drinking response (6.5 ± 1.4 vs 5.3 ± 1.2 ml/90 min), whereas, ICV Capt. abolished drinking (1.0 ± 0.5 not significantly different from saline treated controls; 0.8 ± 0.3 ml/90 min). Both IV and ICV Capt., given separately, reduced the pressor response (Controls = 39.5 ± 2.1 mmHg vs ICV Capt. = 23.6 ± 2.7 mmHg or IV Capt. = 21.9 ± 7.3 mmHg; Mean change in MAP 90 min after start of IV Ang I). IV and ICV Capt., given together, further reduced the pressor response to 12 ± 1.1 mmHg. The effects of ICV Capt. were not due to leakage into the general circulation since a double dose of Capt. (2 ug/min), given IV, did not reduce the pressor response any more than a single dose (20.6 ± 3.1 mmHg). Neither IV nor ICV Capt. had any effect on the drinking or pressor responses to IV Ang II (100 ng/min). These results suggest that conversion of blood borne Ang I to Ang II, destined to act at brain sites to stimulate drinking or a neural pressor response, occurs in the brain rather than in the lung. (NIH Grant HL 14388)

84.9

SHAM DRINKING IN DEHYDRATED RATS: PHARMACOLOGICAL INHIBITION AND THE COMBINATION OF EXTRACELLULAR AND INTRACELLULAR STIMULI. N.E.Rowland, J.J.Salisbury* and M.J.Fregly*. Depts Psychol & Physiol, Univ of Florida, Gainesville, FL 32611.

Natural dehydration by fluid deprivation for 24hr is followed by a copious amount of drinking in rats with open gastric fistulas (sham drinking). In a 1hr test, about 80 ml is ingested, at an almost steady rate. In a first study we found that pretreatment with either the dopaminergic antagonist, spiroperidol (30 ug/kg), or the noradrenergic alpha 2 agonist, clonidine (12 ug/kg), reduced the sham drink by about 50%. The inhibition was comparable in each of the 15min segments of the 1hr test, and was at least as great as the inhibition of real drinking (closed fistula) at these doses. This suggests that the antidipsogenic action of these agents is not through modulation of post-ingestional signals, and also that a 'fatigue' or motor hypothesis is inadequate. Instead, it appears that these agents act directly on aspects of the neural circuitry involved in the quantitative expression of behavior.

In a second study, we examined whether the copious sham drinking after dehydration (a mixture of intracellular IC and extracellular EC depletions) could be mimicked by the combination of IC (NaCl) and EC (polyethylene glycol PEG) challenges. Surprisingly, neither stimulus alone nor the combination produced a robust sham drinking response: open and closed fistula rats drank comparable amounts.

84.10

SEXUAL DIMORPHISM OF NEED-FREE SALT INTAKE IN THE RAT R.R. Sakai*, J.A. Witcher*, N.T. Adler, and A.N. Epstein. (Spon: S. Frankman) Departments of Biology and Psychology, Univ. Pennsylvania, Philadelphia, PA 19147.

Need-free salt intake in rats is sexually dimorphic. Females, from a pre-pubertal age, ingest more salt than age-matched males. To determine whether salt intake is influenced by neonatal androgen, day-one male rats were orchidectomized and day-one females were androgenized (1 mg testosterone propionate-TP). Day-one orchidectomized males displayed exaggerated female-like salt intakes throughout life. Day one androgenized females displayed male-like salt intakes through 70 days, at which time their intakes rose to that of normal females.

To determine whether TP exposure during adulthood alters need-free salt intake gonadectomized (GNX) adult males and females were implanted with silastic tubing containing TP or cholesterol (CHOL). TP suppressed salt intake in both sexes. Repeated sodium depletions produced incremental increases in need-free salt intake for both CHOL males and females. TP suppressed these increases in both sexes. However, after removal of TP all animals displayed the elevated salt intakes that result from histories of sodium depletions.

A developmental role of androgen for salt intake is indicated since heterotypical salt intake is produced in genetic males throughout life by day one orchidectomy and in genetic females (through pubertal age) by day one androgenization. An activational role for androgen is indicated with the observed suppression in TP treated GNX adults. Androgen's suppressive effects on need-free salt intake following repeated sodium depletions are expressed only as long as androgen is present.(NSF NS03469 to ANE and NIH HD04522 to NTA)

84.11

THE EFFECTS OF VENTROMEDIAL HYPOTHALAMIC LESIONS ON DIURNAL DRINKING BEHAVIOR AND LIPID PEROXIDATION IN THE RAT. J. H. Peck and R. R. Jenkins. Depts. of Psychology and Biology, Ithaca College, Ithaca, NY 14850.

Ventromedial hypothalamic (VMH) lesions produce a variety of behavioral and physiological changes, the most notable of which is overeating which leads to obesity. It has been demonstrated that the obesity effects of the VMH lesion are a result of damage to the ventral noradrenergic bundle and not to the VMH itself.

Oxygen centered radicals are constantly formed during metabolism. Biological systems are normally protected against radical damage by a wide array of defenses. Under certain conditions the defense is overwhelmed and the resultant lipid peroxidation alters membrane functions and integrity.

Rats were either lesioned or sham operated and allowed to recover from surgery for 1 week. The rats were then placed in drinkometer cages where their daily drinking behavior could be monitored. After 8 weeks, the rats were sacrificed and heart, liver, kidney and skeletal muscle tissue was taken for the assay of catalase, superoxide dismutase, lipid peroxidation and percent fat. Results showed the expected weight gains and a disruption of the daily drinking rhythm. There was an apparent enzyme induction in lesioned animals. The catalase and superoxide dismutase enzymes were correlated with percent fat in the tissues studied. The mechanism is yet to be determined.

84.12

THE EFFECT OF DORSOMEDIAL HYPOTHALAMIC NUCLEI (DMN) KNIFE CUTS ON FOOD (FI) AND WATER (WI) INTAKE, BODY WEIGHT (BW) AND FEEDING RESPONSES TO 2DG, CCK AND NALOXONE. L.L. Bellinger. Dept Physiol, Baylor Coll Dent, Dallas TX 75246.

Rats with DMN lesions (Bellinger, Am J Physiol 252:R938, 1987), have reduced FI,WI,BW (but normal body composition) and altered ingestive responses to 2-deoxyglucose (2DG), cholecytokinin (CCK) or naloxone (NOX). In the present study, 150g male rats fed chow were given knife cuts either posterior (PC), lateral (LC), dorsal (DC), ventral (VC) or anterior (AC) to the DMN or sham (S) operations. Histology confirmed correct cut positioning in all groups (grps) (n=7-13) except AC. Rats with PC or VC were hypophagic and had reduced BW ($P<0.01$) compared to S. Plasma Na^+, K^+ and osmolality were similar in all grps. WI effects were variable with PC and LC being slightly attenuated. After receiving 2DG (300mg/kg, i.p.) all grps, except LC, increased ($P<0.05$) their FI at 1,2, and 3 h. Following i.p. CCK injections (3.0ug/kg) all grps, except PC, showed attenuation ($P<0.05$) of FI at 30 min, with the VC and LC grps having a greater ($P<0.05$) suppression than S. When tested with NOX (1ug/kg) the VC and S grps had reduced FI ($P<0.05$) at 1,2 and 3 h. Rats with PC showed no reduction of FI, while the DC and LC grps had attenuated FI ($P<0.05$) only at 2 h. The data show that loss of 2DG feeding and NOX suppression of FI can be disassociated from changes in daily FI or BW and that the reduced FI and BW of DMN lesioned rats involves tracts to/from the L and P DMN

Supported in part by BCD research funds.

CATCH-UP GROWTH IN RATS THAT WERE FOOD-RESTRICTED PRIOR TO LESIONS IN THE DORSOMEDIAL HYPOTHALAMIC NUCLEI (DMNL): THE FIRST 48 HOURS AFTER OPERATION AND REALIMENTATION. Lee Bernardis, Larry Bellinger, Marge Kodis* and Mary Jane Feldman*. VAMC Buffalo & SUNY/Buffalo, Buffalo, NY 14215

Forty-five day(d)-old male Sprague-Dawley rats were maintained ad libitum (AL) for 11 d. During the subsequent 21 d, some of the rats were continued AL whereas others were fed half of the amount eaten (RR) by the AL rats. At this point some of the RR and some AL rats received DMNL, whereas other RR and AL rats were sham-operated (CON). Following surgery, all rats were refed AL and killed 2 d later. Rats that were RR-DMNL had the same body weights as RR-CON. Whereas AL-DMNL rats showed the characteristic hypophagia, RR-DMNL rats ate as much as RR-CON, ate more than AL-DMNL and utilized food energy as competently as RR-CON. Testes growth/metabolic size (KU) was greater in RR than in AL rats, irrespective of brain manipulation. On the other hand, liver growth/KU was greater in RR rats only in the case of the DMNL rats. Plasma glucose was similar in all groups, whereas plasma insulin was higher in both RR groups vs. the two AL groups. Plasma growth hormone, glucose-U-C14 incorporation and body composition data will be presented at the meeting. The data are taken to mean that the processes underlying catch-up growth supervene in DMNL rats at the same time and to the same degree as in CON. With other data, this supports our contention of an "organismic" set point in DMNL rats. Supported by VA and Baylor funds.

84.14

NORMAL ULTRADIAN GROWTH HORMONE (GH) RHYTHM IN GROWTH RETARDED RATS WITH DORSOMEDIAL HYPOTHALAMIC LESIONS (DMNL). S.L.Byrd*and L.L.Bellinger (SPON: B. Hutchins). Dept. of Physiol., Baylor Coll. Dent., Dallas, TX 75246.

Rats with DMNL are hypophagic and have reduced linear growth and body weight (BW), but normal body composition (Bernardis and Bellinger, Brain Res Rev 12:321,1987). Growth related hormones are normal in DMNL rats when measured several wks after L. In the present study, male Sprague Dawley rats (180g BW) received jugular cannulas and on return to pre-cannulation BW 4.2±0.5 d they received bilateral electrolytic (1.0 ma, 5 s) DMNL or sham (S) operations. The rats were then bled ($\bar{x}$=6.9 d after L) every 15 min between 0600-1215 h; L:D 12:12, lights out 1430 h. Plasma was saved for assay, whereas the rat's RBC's were suspended in a 10% BSA solution and returned to the animal. GH was assayed using materials (rGH-I-5, S-5, RP-2) supplied by NIDDK and NHPP. DMNL (n=8) rats were hypophagic (6d $\bar{x}$ = 13.4±1.0 vs 16.8±0.9g, $P<0.05$) and weighed less (185.4±4.9 vs 201.4±4.8g, $P<0.05$) than S (n=9) at sampling. Total GH secretion as computed from the area under each rat's ultradian pattern was similar in both groups (DMNL vs S, 3986.4±481 vs 4363.2±556, ns) as was mean 6 h GH secretion (DMNL vs S, 22.0±2.6 vs 24.4±3.2 ng/ml, ns). Peak secretion intervals were similar in both groups (DMNL vs S, 3.7±0.2 vs 3.3±0.2 h) and DMNL rats had more peaks over 100ng/ml than S. The data suggest that the reduced growth of DMNL rats cannot be readily explained by a deficiency in GH secretion. Supported by BCD research funds.

84.15

CHOLECYSTOKININ-INDUCED CONDITIONED ODOR-PREFERENCE IS BLOCKED BY THE SELECTIVE ANTAGONIST L-364,718. A. Weller* and E.M. Blass. (SPON: E.C. Lotter). Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD 21218

Cholecystokinin (CCK) octapeptide reliably produces single-trial conditioned odor-preference in neonatal rat pups. This was achieved by pairing exposure to a novel orange odor with saline (i.p.) or CCK (2 ug/kg in 5-day-old and 0.25 or 0.5 ug/kg in 11-day-old rats). After twenty-four hours, subjects that had previously received CCK remained significantly longer than controls on the side of a choice arena that contained an orange scent. This also holds for weaning age rats. In contrast, adult rats failed to show conditioned odor-preference.

This conditioned response to CCK can be blocked by a CCK antagonist. Pups received the selective antagonist of peripheral CCK receptors L-364,718 (1.4 or 14 ug/kg) or vehicle (DMSO), 45 minutes before they were exposed to orange odor paired with either CCK (0.06 ug/kg) or saline. Forty-eight hours later, the CCK group stayed significantly longer than saline controls over the orange side of the choice arena ($t(25)=2.229$; $p<0.035$). This was totally blocked by L-364,718 at both doses ($p>0.8$). On a molar basis, the lower dose's antagonism is at a 64:1 ratio (antagonist: ligand). This is within the range in which binding studies have shown blockade by L-364,718 of peripheral-type but not of CNS-type CCK receptors (Chang and Lotti, PNAS 83:4923, 1986). Therefore, our results suggest a peripheral site for CCK's initial action in causing conditioned odor preference in 11-day-old rats.

84.16

CHRONIC ALTERATIONS IN SEROTONIN METABOLISM DIFFERENTIALLY AFFECT FOOD INTAKE AND MEAL PATTERNS IN OBESE AND LEAN ZUCKER RATS. T.J. Kalogeris*, T.W. Castonguay, N.E. Rowland and J.S. Stern*. Food Intake Laboratory, Dept. of Nutrition, University of California, Davis, CA 95616.

In order to characterize the possible role of serotonin in the hyperphagia of the obese rat, the effects of chronic administration of d-fenfluramine, a 5-HT releaser, on meal patterns were compared in lean and obese Zucker rats. Six week old female Zucker rats (12 lean, 12 obese) were adapted for 3 wks to ad libitum access to semipurified diet (modified AIN 76) and water, and their meal patterns were monitored. They were then implanted subcutaneously with osmotic minipumps which delivered d-fenfluramine at 3 or 6 mg/kg/day. Food intake and meal patterns (meal size, MS; meal frequency, MF) were monitored for another 5 d. Rats were decapitated and their brains analyzed for 5-HT. The low dose of d-fenfluramine had no effect on meal patterns of either phenotype. At the high dose, lean rats depressed their intake by 38% the first 2 days after implantation. During this period, there was no clear change in MS, while MF was depressed. Average daily intake and MF returned to baseline by day 4. Obese rats showed a 32% depression in intake the first 2 days after implantation which returned toward, but never recovered to more than 85% of baseline intake. Obese meal patterns over the five day post-implantation period were characterized by a persistent depression in MS and no clear effect on MF.

84.17

CHANGES IN BRAINSTEM METABOLIC ACTIVITY ASSOCIATED WITH GASTRIC DISTENSION IN 6-DAY-OLD RAT PUPS: AN ANALYSIS OF AVERAGED 2-DEOXYGLUCOSE AUTORADIOGRAPHS. C.B. Phifer and W.G. Hall. Dept. of Psychol., Duke Univ., Durham, NC 27706.

In very young rat pups, gastric distension is the single gastrointestinal control mechanism for intake termination. Thus its neural substrate should be relatively easy to isolate and also of prime interest. Six-day-old rats with closed pyloric nooses and chronic gastric cannulas either rested without stimulation or received gastric infusions of isotonic saline during 1 hr of [14-C] 2-DG incorporation (30 uCi/100g,sc). Autoradiographic images corresponding to several levels in the brainstem were averaged for pups in each condition. Differences in activity between groups were revealed by subtracting one average image from another.

Difference images revealed that brains of pups with distended stomachs had increased metabolic activity in the nucleus tractus solitarius, particularly at the level of area postrema and in the medial portion of the nucleus. Increased activity was also apparent in the dorsal motor nucleus of the vagus. Relative to pups without gastric distension, pups with distension had less activity in several reticular areas, including medullary, caudal pontine and caudoventrolateral. These results reinforce earlier findings on gastric projections via the vagus and also suggest that gastric distension may cause depression in reticular areas with projections to ingestion-related motor nuclei. (Supported by NICHD Grant HD-17457).

84.18

SUCKLING-INDUCED CHANGES IN BRAINSTEM METABOLIC ACTIVITY: 2-DEOXYGLUCOSE AUTORADIOGRAPHIC DIFFERENCE MAPS. L.M. Terry and W.G. Hall. Department of Psychology, Duke University, Durham, NC 27706.

The topography of neural metabolic activity was compared in 6-day-old rat pups that were 1) resting quietly; 2) searching for a nipple on the ventrum of a dam; or 3) attached and suckling a nipple during a 1 hr [14-C] 2-deoxyglucose (2-DG) incorporation period (30μCi/100g BW, sc). Autoradiographic images corresponding to sections of the neural axis at several levels of the brainstem were selected for each experimental group and analyzed. Difference images were then generated by subtracting average images from one another.

Relative to pups at rest, pups searching for a nipple showed increased metabolic activity in spinal trigeminal nuclei (ventral portions of the interpolar and oral subnuclei) and in distinct reticular regions. Searching pups had decreased activity in the facial nucleus. In contrast, pups that had attached to a nipple and were suckling showed marked activity, relative to resting pups, in the spinal trigeminal nucleus (medial interpolar subnucleus), nucleus ambiguous and in distinct reticular nuclear regions associated with attachment. Suckling pups had decresed activity in the solitary tract nucleus. Together, these results reveal that two primary components of mammalian suckling behavior, searching and attachment, have different neural substrates.(NICHD Grant HD-17457).

ORAL INFUSION OF FAT OR SUCROSE PRODUCES OPIOID-MEDIATED SINGLE-TRIAL ODOR PREFERENCES IN NEONATAL RATS. D.J. SHIDE* & E.M.BLASS Dept of Psychology, Johns Hopkins University, Baltimore MD 21218.

Central and peripheral administration of morphine, paired with a novel odor in Day 5 rats, results in a preference for that odor when testing occurs on Day 10. Intraoral infusion of a sucrose, polycose, or corn oil solution in the Day 10 rats elevates pain threshold and reduces isolation-induced vocalizations; these effects are reversed through naltrexone pretreatment. The following experiments tested the hypothesis that oral infusions of substances implicated in opioid-mediated ingestive behavior could influence associations made with a novel odor in Day 6 rats. In Exp. 1, Day 6 pups were exposed to a novel orange odor for 30 min while either corn oil, 7.5% sucrose, 32% polycose, distilled water, 0.1% quinine, mineral oil, or nothing was infused through jaw cannulae into their mouths. When tested 2 days later, Day 8 pups that had received infusions of corn oil or 7.5% sucrose significantly increased time spent over orange-scented bedding versus plain bedding when compared to control pups. Exp. 2 investigated potential contributions of the endogenous opioid system to this conditioned preference. Prior to conditioning, Day 6 pups received either an IP injection of naltrexone (0.5 mg/kg) or isotonic saline. Pups were then exposed to orange-scented bedding while either corn oil, 7.5% sucrose, or nothing was intraorally infused. Day 8 pups that had received saline injections paired with infusions of corn oil or 7.5% sucrose showed a preference for orange bedding when compared to no infusion controls. Pre-treatment with naltrexone before conditioning abolished this effect. These findings suggest that intraoral infusions of corn oil or 7.5% sucrose are reinforcing when associated with a novel environmental stimulus, and this effect appears to be mediated through the endogenous opioid system.

DETERMINING THE BASIS OF ORIENTATION SELECTIVITY THROUGH COMPUTATIONAL MODELS OF CORTICAL CIRCUITRY.

M.A.V. Gremillion* and Bryan Travis* (SPON:D.Sinex). Center for Nonlinear Studies, Los Alamos National Lab, Los Alamos, NM 87545.

Orientation selectivity is a key feature of the physiological response patterns of visual cortex neurons. In order to understand the circuital computations that underlie functional behaviors in V1, we have simulated the circuitry of macaque primary visual cortex and its connections from the LGN. In this model a 3-D cortical module has layers 1-4B, 4C-alpha and 4C-beta, 5 and 6; cell types distributed among the layers include spiny stellates, pyramidal cells and five kinds of local inhibitory neurons. Ratios, distributions, connections and geometry of cell types were derived primarily from the work of Jennifer Lund and colleagues. Neuronal activity is determined through a modified membrane potential algorithm. The model allows us observe single neuron, planar, and columnar patterns of activity over time; theories of orientation selectivity can thus be tested.

Preliminary findings using this model suggest a new understanding of orientation selection. Our results indicate that *planes* of neurons may be the relevant computational unit for these properties. The density of cells per type as well as the ratio between types results in a functional geometry which contributes to the ability of cells to be orientation selective. In addition, while it is well-established that LGN parvocellular neurons project to layer 4C-beta, it is not known whether X-on and X-off cells project to the same or different populations of cells in that layer. We predict that X-on and -off cells project to the same inhibitory neurons but to two different sets of spiny stellate cells. Distributions of 'on' and 'off' spiny stellates would then form two interleaved mosaics that are out of phase with respect to each other. This difference in phase insures that on and off pathways remain separate but interact via common connections to inhibitory neurons, sharpening the edge between light and dark regions. Those patterns of activity are read by neurons in other layers, which then respond with "simple" or "complex" behavior depending on the degree of input from layer 4C.

SIMULATION OF EARLY PROCESSING OF VISUAL CONTOURS.

S. Hochstein, A. Kalay and L. Rudolph. Inst. of Life Sciences and Dept. of Computer Sciences, Hebrew University, Givat Ram, Jerusalem 91904, Israel.

The complex patterns of neural activity at primary cortical levels are studied via computer simulation based on a mathematical model of the first stages of visual information processing. Cortical cells were modelled as receiving information from a few X-LGN cell afferents whose receptive field sensitivity functions were characterized by Difference-of-Gaussians. We simulated four cortical cell types: Simple cells summed two inputs linearly and complex cells summed them non-linearly, while adding cells summed two ON-center X-cell inputs and differencing cells summed one ON-center and one OFF-center cell input. We found that different stimulus dimensions may be detected by different cortical cell types. The most efficient orientation detectors may be the adding cells, whereas the differencing cells may be the best edge and shape detectors.

85.3

TRANSMISSION EVENTS IN MAMMALIAN VISUAL CORTEX THAT INVOLVE NMDA AND NON-NMDA GLUTAMATE RECEPTORS.

R. B. Langdon, M. Esguerra and M. Sur, Dept. of Brain and Cognitive Science, E25-618, Mass. Inst. of Tech., Cambridge, MA 02139 USA.

The participation of NMDA and of non-NMDA glutamate receptors in the ascending and tangential transmission of excitation in adult rat visual cortex was assessed by recording field potentials in slices taken from area 17. When stimuli were applied to infragranular layers or the white matter, pre- and postsynaptic (Ca++ dependent) population spikes and slower, radially oriented dipoles were observed both radial to the stimulus and tangentially displaced by up to 1.5 mm. The following pharmacological data were obtained while recording in the supragranular layers: All postsynaptic responses were profoundly antagonized by 0.5 or 1.0 mM kynurenic acid. In normal medium (1.2 mM Mg++), late potentials (later than 10 msec) were smaller and decayed faster when 2-amino-5-phosphonovaleric acid (APV, 20 to 50 uM) was applied, whereas closely paired stimuli and low Mg++ medium enhanced late responses. Low Mg++ also produced new response inflections suggestive of disinhibited postsynaptic activity. Both of these effects of low Mg++ were reversed by APV.

These data are indicative of distinct roles played by NMDA and non-NMDA glutamate receptors in visual cortex. They imply that NMDA receptor-mediated currents can substantially enhance the intracortical spread of excitation when the block present in physiological [Mg++] is lifted.

85.4

DIRECTIONAL SELECTIVITY OF CELLS IN THE VISUAL CORTEX IS INDEPENDENT OF OTHER REPONSE PROPERTIES.

J.P. Nordmann*, C. Casanova and R.D. Freeman. Neurobiology group. Minor Hall. University of California. Berkeley CA 94720.

For most neurons in the visual cortex, the strength of response varies according to the direction of stimulus motion. Cells in the cat's striate cortex are also characterized by other properties like orientation, spatial and temporal frequency selectivities. We have asked if direction selective cells in striate cortex constitute a homogeneous group with overall properties which can be clearly distinguished from those of cells that are not selective for direction.

Drifting sinusoidal gratings were used to characterize receptive field properties. A total of 102 simple cells and 90 complex cells were studied. A direction index (DI) defined as: DI= 1- response in the non-preferred direction/ response in the preferred direction was used. We find that 33% of simple cells and 37% of complex cells respond equally to both directions (DI<0.5). For all these cells, the two optimal directions were always 180 degrees apart, and the orientation bandwidth was identical in each direction (r=.99, p<0.001). Small proportions of simple (17%) and complex (12%) cells, having a DI between 0.5 and 0.7, were considered to be direction biased. We find similar proportions of simple and complex cells that are directionally selective (50% and 51%, respectively; DI>0.7). In addition, a substantial number of complex cells show a suppression of discharge below the spontaneous levels in the non-preferred direction (DI>1). Preliminary results indicate that this supression is maintained when the size of the grating is reduced to fill only the receptive field area.

We do not observe major differences between the properties of cells according to direction selectivity. In the group of simple cells, there is a small tendency for directionally selective cells to be more narrowly tuned for orientation (r=0.4, p<0.02). In the complex cell group, directional cells tend to exhibit lower degrees of modulation than non-directional neurons. These results indicate that direction selectivity is independent of other response characteristics of cortical neurons. 85.5

EFFECT OF ELECTRICAL STIMULATION OF LOCUS COERULEUS ON THE ACTIVITY OF NEURONS IN THE CAT VISUAL CORTEX.

H. Sato, K. Fox and N. W. Daw, Dept. Cell Biology, Washington Univ. Sch. Med., St. Louis, MO 63110.

To understand the functional role of the projection from locus coeruleus (LC) to visual cortex and the noradrenaline receptor types involved, we studied the effect of electrical stimulation of LC on the activity of area 17 neurons in conjunction with iontophoresis of α- and β-antagonists in the anesthetized and paralyzed cat. Bipolar stimulating electrodes were implanted in both LC stereotaxically.

Fiftynine cells were recorded in area 17. 66% (23/35) of the cells recorded in layers II,III and IV and 47% (7/15) of the cells in layer VI were suppressed. 67% (6/9) of the cells recorded in layer V and 53% (8/15) of the cells in layer VI were excited by stimulation of LC. The suppressive effect was antagonized by β-adrenergic antagonists and the facilitatory effect was antagonized by α-adrenergic receptor antagonists. α-antagonists suppressed the activity of cells. β-antagonists were predominantly facilitatory but in one third of cells they were suppressive. α- and β-receptor antagonists affected most neurons in all layers of area 17 which suggests that both α- and β-receptors affect the activity of most individual cells. Activation of LC did not improve the signal to noise ratio of the activity of neurons.

In summary, noradrenergic effects in area 17 are primarily facilitatory in layers that project to subcortical areas and primarily suppressive in layers that project to other cortical areas.

85.6

ORGANIZATION AND PROPERTIES OF RECEPTIVE FIELDS OF CORTICAL NEURONS (AREAS 17, 18, 19 AND PMLS) ARE TIME-VARIANT.

H.R.O. Dinse, K. Krüger, J. Best, HA. Maillot, W. von Seelen (Spons. EBBS) Dept. of Zoology III, Biophys. Sect., University of Mainz, West Germany

From single cell responses to stationary small-field stimuli applied at different locations within a grid of subfields in random order we compiled temporal sequences of response planes (TSRP) and from the responses to stimulation of the rf-centre with bars of light of varying lenghts and orientations we compiled temporal seqences of tuning curves (TSTC) for bar lenght and bar orientation in steps of 20 msec.

The TSRP showed that each location within the rf exhibited its own temporal characteristic. This is a clear index that the spatial and temporal behaviour is not separable in cortical cells. Non-separability has some remarkable implications for rf properties. Time-variance has been observed for the rf dimensions and for orientation selectivity and hypercomplexity in the case of stationary stimulation. We found selectivity after an initial phase of non-selective excitation (24 %) and a change of selectivity over time (34 %). In the case of moving stimuli one has to expect strong influences of speed and direction of motion as well as of orientation and lenght of the stimuli (i.e. form) on the total response characteristics, which could be experimentally verified suggesting that rf properties are *time-* and *stimulus variant*.

The following aspects are closely connected to non-separabilty of space and time: 1. Non-separability can lead to the phenomenon of *nonlinear spatial summation* because of the complex temporal behaviour even if the cell is *linear* in the true sense of system theory. 2. Non-separable spatio-temporal filters might be optimal adapted for the analysis of moving stimuli. 3. In more than 50 % of the cells specificity is no longer correlated with spikerate. This is taken as strong evidence for the biological significance of a *time code*, in which a temporal modulation over a range of up to 500 msec carries stimulus information.

The experimental data and their interpretation are in close agreement with the outcome of a computer network model, based on a mean, lamina specific neuroanatomy (Krone et al 1986, *Proc Roy Soc* 226:421), which revealed high structured temporal response patterns due to intracortical positive feedback.

RETINOTOPIC REPRESENTATION OF MOVING STIMULI IN CAT VISUAL CORTEX. - SIMULTANEOUS RECORDINGS WITH AN ARRAY OF EIGHT MICROELECTRODES. H. Koch* & HRO. Dinse Dept. of Zoology III Biophys. Sect., University of Mainz, D-6500 Mainz, West Germany

We recorded single neurons with an array of 8 independent microelectrodes in the cat visual cortex simultaneously. The distance between each recording site varied between 1 and 2 mm. The recordings were performed in area 17/18 along the border at the vertical meridian. The overall visual field representations of the recording sites extended up to 30 degrees visual angle. After plotting the rf of each neuron, bars of light and background of visual noise were swept at various speeds along trajectories adjusted to stimulate each rf. On the basis of PSTHs, the resulting trajectories and the so-called *apparent velocity* for the spread of activity across the cortex were calculated off-line and compared with the actual trajectories of the stimulus.

When the *apparent velocity* was determined for pairs of neurons that were stimulated one after the other, there was no smooth motion of activity across the cortex, but motion typically either preceded or lagged behind the stimulus. In most cases, the observed *mean apparent velocity* was not identical with the speed of the stimulus. The absolute difference between *mean apparent velocity* and actual stimulus speed could amount up to 100 %. The responses to the forward and backward motion differed in that the trajectories of cortical activity were always shifted towards the direction of the stimulus, which resulted in an *offset* for the two directions in the range of 1 to 5 degrees visual angle.

While the retinotopic map was roughly preserved in a trajectory of activity across the cortex, there were a number of deviations on a finer scale (width of rf), that have to be discussed in relation to motion processing and the meaning of retinotopic and non-topographic mapping.

CLASSIFICATION OF NEURAL ACTIVITY IN V_1 OF THE AWAKE MACAQUE AS PRODUCED BY GANZFELD ILLUMINATION. T.M. Wengenack* C.M. Checkosky* and S.J. Bolanowski Jr. (SPON: S. Demeter). Dept. of Physiol., U.R. Med. Sch., Rochester, NY 14642.

Unlike the binocular case, continuously presented, monocular Ganzfelder fail to produce 2-C^{14}-deoxyglucose uptake in the cytochrome oxidase (CO) patches of layers II-III of macaque striate cortex (Bolanowski et al., SN Abstr. 10: 730, 1982). Thus, although neurons in these patches respond to diffuse illumination, they must also be involved in binocular vision. For the purposes of classification and to relate neural responses to the CO patches, we have measured single unit activity (n=163) in striate cortex of the awake macaque to achromatic monocular and binocular Ganzfelder. Several classes of responses have been identified: transient, 14%; slowly adapting, 10%; luxotonic, 36%; mixed, 10%; and not driven, 30%, with 47% being only monocularly activated. Of the units binocularly activated (23%, n=38), 29% show binocular summation of the monocular responses, 24% show averaging, 13% show inhibition, and 8% show suppression. The remaining 26% have mixed properties. Most (92%) of the units having binocular interactions were luxotonic. We note that some of these binocular response types correlate with psychophysical phenomena found under Ganzfeld conditions. For example, binocular brightness summation occurs in the Ganzfeld and the "blankout" effect produced with monocular but not binocular Ganzfelder may be controlled by the inhibitory and/or suppressive mechanisms.

85.9

EFFECTS OF A REMOTE STIMULUS ON CORTICAL CELL RESPONSES Molotchnikoff S. and C. Morin* and F. Leporé, département des Sciences biologiques, Université de Montréal. Montréal Québec, Canada. H3C 3J7.

It is well established that the introduction of a remote stimulus (RS) outside the boundaries of the classical receptive field (RF) influences the light responses of a unit which is stimulated by a circumscribed target positioned in its RF. This phenomenon has been demonstrated in cats and rabbits at the geniculate and collicular levels. Since both of these structures provide inputs (directly or indirectly) to the cortex, it is expected that responses of cortical cells will be influenced by the addition of a remote stimulus. The proposed experiments are designed to test this hypothesis, in anesthetized (Ketamine, N_2O/O_2 70/30%) and paralyzed rabbits. Animals are prepared for single cell recordings from area 17 (V1). The test stimulus is a slit sweeping across the RF, while the RS is a LED. Although the experiments are in an early stage it appears that 50% of cells (N = 18) had their responses modified by the RS if the receptive field is close to the optic axis, conversely only 30% (N = 10) of cells with an eccentric RF had their discharges altered by the RS. In addition, responses to horizontal movements are more affected than responses to vertical displacement. Thus, it appears that cortical cell responses differ if more than one stimulus is present in the visual field.

INFLUENCE OF AFFERENTS ON SPATIAL- AND TEMPORAL-FREQUENCY PROCESSING BY NEURONS IN THE CAT'S POSTEROMEDIAL LATERAL SUPRASYLVIAN (PMLS) VISUAL CORTEX. L. Tong, W. Guido and P.D. Spear. Dept. of Psychology and Neurosciences Training Program, Univ. of Wisconsin, Madison, WI 53706.

The PMLS cortex receives converging visual afferents from thalamus and cortex. We investigated the extent to which spatial- and temporal-frequency processing by PMLS neurons depends on afferents from cortical areas 17 and 18.

Recordings were made from PMLS neurons in normal adult cats and in adult cats that had ipsilateral areas 17 and 18 removed 24 hr earlier. The cells were presented with drifting sine-wave gratings and responses were assessed with Fourier analysis. In normal cats, most cells had spatial resolutions from 0.1 to 1.6 c/deg and optimal spatial frequencies from 0.05 to 0.2 c/deg. Removing inputs from areas 17 and 18 had no significant effect on these properties or on contrast sensitivity. When tested at the optimal spatial frequency, most normal PMLS cells showed band-pass temporal-frequency tuning with 3-10 Hz optimal temporal frequency and 14-22 Hz temporal-frequency cutoff. Removing areas 17 and 18 had no significant effect on temporal-frequency cutoff but may have altered some of the tuning characteristics.

Previous studies have shown that PMLS neurons depend on inputs from ipsilateral areas 17 and 18 for elaboration of direction selectivity. The present results suggest that spatial- and temporal-frequency selectivity of PMLS neurons are generated largely on the basis of thalamic inputs.

85.11

ANATOMICAL AND ELECTROPHYSIOLOGICAL INVESTIGATION OF THE INSULAR VISUAL AREA IN THE CAT. M.Norita, T.P.Hicks, G. Benedek* and Y.Katoh*. Fujita-Gakuen Health Univ. School of Med., Toyoake 470-11, Japan.

Electrophysiological recordings of extracellular unit responses were performed using carbon fiber-containing glass micropipettes in cats anesthetized with barbiturate and immobilized with gallamine triethiodide. After identifying a point in the insular visual area physiologically, WGA-HRP was injected at that site. The anatomical results indicated that retrogradely labeled cells were found not only in a variety of cortical regions but also in some subcortical structures. Cortically, densest labeling was found in AEV and LS (mainly in ALLS, PLLS and DSL). Moderate labeling was observed in the cingulate and parasplenial gyri and in areas 8, 20, 35 and 36. Weaker labeling was seen in agranular insular cortex. Subcortically, a number of labeled cells were observed in the LM-Sg complex, some in the VM complex and the intralaminar nuclei of the thalamus and in the lateral amygdaloid nucleus, and a few in the claustrum and basal nucleus. The insular visual area has been shown to receive afferents from structures belonging to the extrageniculate visual system (e.g. AEV, LS, LM-Sg complex) as well as to those belonging to the limbic system (e.g. cingulate gyrus, amygdala), suggesting that this insular area may be involved in higher levels of cerebral functioning.

85.12

VISUAL, AUDITORY AND OCULOMOTOR PROPERTIES OF SINGLE NEURONS IN THE POSTERIOR ECTOSYLVIAN GYRUS OF THE ALERT CAT. E.M. Bowman, W.A. Thomas* and C.R. Olson. Psych. Dept., Princeton Univ., NJ, 08544.

The cortex of the cat's posterior ectosylvian gyrus (p.e.g.) contains two districts dominated respectively by auditory and visual afferents (Bowman & Olson, J. Comp. Neurol., in press). These districts are probable homologues of areas occupying the superior temporal gyrus and sulcus of primates. In order to examine sensory and oculomotor activity in the p.e.g., we have recorded from single neurons in cats trained to make eye movements to visual and auditory targets.

Sixty-four neurons were studied during performance of this task. Of these, 19 responded only to visual stimuli, 19 responded only to auditory stimuli and 4 were bimodal. Nine of the visual neurons exhibited enhanced responses to a saccade target when it was accompanied by an isoazimuthal tone burst. In 6 of 10 auditory neurons, the response to a noise burst was attenuated when it was presented during fixation of a visual target.

The angle of the eye in the orbit influenced the activity of 21 of the neurons examined in the saccade task. Dependence of this effect on orbital position was confirmed in 4 neurons by repeating the task under reduced ambient illumination or with the head rotated relative to the stimulus. The activity of 17 neurons was altered during saccades, but, in all cases, this activity could be explained by visual reafferent stimulation.

We conclude that neurons of the posterior ectosylvian gyrus: (1) exhibit bimodal responses; (2) modulate their activity according to gaze angle; and (3) do not participate phasically in the generation of saccades.

85.13

SENSORY AND OCULOMOTOR PROPERTIES OF SINGLE NEURONS IN THE POSTERIOR CINGULATE CORTEX OF THE ALERT CAT. S.Y. Musil, M.J. Consuelos* and C.R. Olson. Psychology Department, Princeton University, NJ 08544.

Recent studies from our laboratory have demonstrated that the posterior cingulate cortex (CGp) of the cat is linked by strong, reciprocal and topographic pathways to cortical areas with sensory and oculomotor functions. These include area 7p (Olson and Lawler, J. Comp. Neurol. 259:13-30, 1987) and the medial frontal eye field (Olson and Jeffers, J. Comp. Neurol. 266:73-94, 1987). The visual and oculomotor connections of CGp far outweigh the limbic connections stressed in traditional accounts.

To test the hypothesis that CGp is directly involved in sensory and oculomotor processes, we have recorded from single neurons in cats implanted with scleral search coils and trained to make saccadic eye movements to visual-auditory targets. All phases of the experiment were under computer control.

Out of 98 neurons studied to date, 68 underwent a consistent change of activity in connection with the task. Firing was modulated according to the position of the eye in the orbit (43 neurons), during the perisaccadic period (44 neurons) or throughout the task (17 neurons). Only 6 of 98 neurons were activated by onset of the fixation or saccade target. With stimuli other than those employed in the task, however, 26 of 67 neurons tested exhibited somatosensory responses and 11 of 52 neurons tested exhibited auditory responses.

These results support the view that CGp is involved in sensory and oculomotor processes.

85.14

SENSORY AND OCULOMOTOR PROPERTIES OF SINGLE NEURONS IN AREA 7 OF THE ALERT CAT. C.R. Olson. Psychology Department, Princeton University, Princeton, NJ 08544.

In cat, as in monkey, visual information is relayed over transcortical pathways to a large set of interconnected oculomotor and association areas including area 7 (Olson and Lawler, J. Comp. Neurol. 259:13-30, 1987). To clarify the functions of this widespread cortical network, we have begun to carry out single-neuron recording experiments in alert cats trained to make saccadic eye movements to visual and auditory targets. We describe here results obtained from area 7 and compare them to results obtained in parallel studies of posterior cingulate cortex and the posterior ectosylvian visual belt (see accompanying abstracts).

Out of 40 area 7 neurons studied to date, all were activated during some phase of the saccade task. Ninety percent fired bursts in conjunction with saccades; firing commonly began before the saccade and persisted in the dark. Fifty percent underwent prolonged increases or decreases of activation during the entire task or certain phases of it; the determinants of the tonic firing were complex and never reduced simply to the angle of gaze. Thirty percent fired phasically in response to onset of a foveal or peripheral target. When tested outside task context, more than half of the neurons exhibited visual, somesthetic or auditory responsiveness, often with convergence. Suppression of auditory responses during fixation of a visual target was observed in 2 of 3 cells tested.

Area 7 differs markedly from posterior cingulate cortex in that many more neurons fire phasically to visual target onset; moreover, firing before and during saccades is more robust and more sharply time-locked to eye movements. Area 7 differs from the visual belt in containing neurons that carry saccade-related motor signals.

85.15

VENTRAL V3 IN THE CEBUS MONKEY: VISUAL TOPOGRAPHY AND PROJECTIONS TO V1 **R.Gattass, A.P.B.Sousa*, M.G.P.Rosa* and M.C.Piñon*. Instituto de Biofísica Carlos Chagas Filho, Rio de Janeiro 21941 Brazil.**

The visual topography of ventral extrastriate cortex was studied in four anesthetized and paralized Cebus apella, by means of multi-unit recordings. Ventral V3 (V3v) is a strip of cortex, anterior to V2, which contains a topographically organized representation of the upper visual quadrant up to 60 degrees eccentricity. In V3v, the representation of the horizontal meridian is located posteriorly and is congruent with that of V2, while that of the upper vertical meridian is located anteriorly. The foveal representation is located laterally, in the inferior occipital sulcus, while the periphery is represented medially and anteriorly, in the tentorial surface. The cortical magnification factor (CMF) decreases with increasing eccentricity and is highly anisotropic. For a given eccentricity, CMF along isopolar dimension is about 3 times greater than that along the isoeccentric one. After injections of fluorescent tracers in V1, labelled cells are found, mostly in the infragranular layers, within visuotopically corresponding portions of V3v. Projections to V1, similar to those from V3v, are also observed from a dorsal area, anterior to V2 in the lunate sulcus. This area contains, at least, a partial representation of the lower visual quadrant, and may correspond to the dorsal extension of V3v.

85.16

VISUAL TOPOGRAPHY OF AREA TEO IN MACAQUES. D. Boussaoud*, L.G. Ungerleider, and R. Desimone. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

Previous studies have shown that the inferior and ventral occipitotemporal cortex contains the upper visual field representations of areas V2, V3, and V4. To delineate any additional visual areas in this region, we mapped it with multiunit recordings in three anesthetized, paralyzed rhesus monkeys over repeated recording sessions. Anatomical tracers were injected at the end of the recordings. Anterior to the V4 border, which corresponds roughly to the representation of the horizontal meridian, we found a crude representation of the central 40-45° of the upper quadrant of the contralateral visual field. We tentatively term this area TEO, following Bonin and Bailey. Like V4, TEO appears to form an elongated dorsal-to-ventral band, and the representation of visual eccentricities seems to parallel that of V4. The representations of the foveal and parafoveal visual fields are located on the inferior convexity of the hemisphere, adjacent to area TE, and the representation of the upper periphery lies on the ventral surface of the hemisphere, adjacent to visually unresponsive cortex. The location of label following injections in TEO suggests that it receives inputs from area V4 and projects in turn to area TE.

Analysis of object motion in the ventral part of the macaque MST area. K. Tanaka, M. Fukumoto*# and H. Saito. NHK Sci. & Tech. Res. Labs. and #Univ. of Tokyo, Tokyo, Japan.

To infer the functional subdivision within MST, we studied response properties of cells in the ventral part of MST in paralyzed monkeys (M. fuscata) anesthetized with N_2O. Only directional cells which responded to a straight equidistant movement clustered there. The size of the excitatory receptive field ranged wide, whereas a movement within a small field (5-20 degs in diameter) generally evoked larger responses than that over a wide field. Such preference to a small-field movement is also shown by a half of cells in MT, the area which projects to MST. What is new in the ventral MST is that some cells behaved as if they responded to a relative movement of an object and its background. They did not respond to a movement of a wide textured field, but they started to respond to it if a small stationary mask was placed anywhere within the receptive field. The direction in which they responded was opposite to the preferred direction for a small-field movement. This reversal of effective direction can not be explained by a directionally antagonistic center-surround organization, since the response to the annular stimulus disappeared when the fringe of the mask was made blurred by remoting the mask from the screen. The vanishment and emergence of texture components at the fringe may be crucial for the response. With our previous results for the dorsal MST, we propose that information of object motion and that of field motion are processed separately in the ventral and dorsal MST, respectively.

85.18

BINOCULAR DISPARITY SENSITIVITY OF CELLS IN AREA MST OF THE MONKEY. H. Komatsu, J. P. Roy, and R. H. Wurtz Laboratory of Sensorimotor Research, National Eye Institute, N.I.H., Bethesda, MD 20892.
