Preliminary results indicated that cortical cells antidromically activated from LPl responded with a mean latency of 1.6 ms. All cortico-LP units were selective to orientation and were tuned to relatively low spatial frequencies (0.4 c/deg). Most units responded to moving visual noise and had properties similar to the special complex cells described by Palmer and Rosenquist (1974). So far, no cells were antidromically activated from the LPl and the colliculus. These results suggest that complex cells in area 17 projecting to LPl do not project to SC. 550.2

ULTRASTRUCTURAL DEVELOPMENT OF VISUAL CORTICOTECTAL PROJECTIONS IN THE CAT.

L.L. Bruce. Div. Anat., Creighton Univ., Omaha, NE 68134.

The corticotectal projection in adult cats has precise topographic and laminar targets. Yet in neonates the projection extends beyond these targets. To determine how the growing cortical axons interact with neurons in the superior colliculus to acquire their adult specificity, biocytin was injected into the visual cortex in animals aged 0 to 35 days. The superior colliculus was processed for electron microscopy.

Examination of labeled cortical axons in the superior colliculus showed that the axons do not follow dendrites, axons, or glia for any significant distance. Labeled contacts were present even at 1 day of age and increased in frequency over several weeks. At the earliest ages most contact zones contained few synaptic vesicles as the only indication of developing synapses. For several weeks following birth, the number of presynaptic vesicles increased and synaptic clefts and postsynaptic densities became more defined. The labeled axons often contacted profiles that contained vesicles. The number of vesicles in these profiles decreased with age. In adults corticotectal axons are believed to synapse with dendrites and thus the neonatal cortical axons may be contacting developing dendritic profiles.

CORTICOTECTAL PROJECTIONS IN THE CAT. J.K. Harting, B.V. Updyke, and D.P. Van Leishout*. Department of Anatomy, University of Wisconsin-Madison, Madison, WI 53706 and Department of Anatomy, Louisiana State University, New Orleans, LA 70112

The possible significance of the patchy, mosaic-like organization of afferents within the stratum griseum intermediale (SGI) of the cat superior colliculus is slowly emerging. One particularly fruitful approach has involved comparing the spatial relationships of various tectopetal fiber systems to specific transmitter and enzyme markers and, most important, to each other. The general theme of these light microscopic studies has been that functionally related afferents end in patches, lattices or domains, where they are coordinated in order to influence collicular neurons involved in controlling eye and axial body movements.

As a prerequisite for determining specific compartments and their components, we have been studying the laminar, sublaminar and, in many instances, the patchy distribution of twenty-four corticotectal projections. Our findings reveal that fourteen cortical areas project exclusively to the SGI. All of these corticotectal systems innervate limited regions of the SGI, and the great majority end in patches. One particularly interesting finding is that several corticotectal systems target what we have termed the middle tier of the SGI (Harting & Van Leishout, 1991). Such cortical input arise from SIV, SV, lateral frontal eyefields, cingulate cortex, and area 4. We have previously shown that nigral and trigeminal inputs also end in this tier, but in a complementary, nonoverlapping fashion. At this time we are investigating the specific spatial relationships of several of these "middle tier" corticotectal systems to each other, and to various subcortical collicular afferents.

THE MORPHOLOGY AND PROJECTIONS OF CORTICOTECTAL CELLS IN THE OWL'S VISUAL CORTEX. I.C. Gynther and J.D. Pettigrew. Vision, Touch and Hearing Research Centre, The University of Queensland, Qld. 4072, Australia.

In the owl, corticotectal neurons are involved in the control of visually-guided behavior via their influence on the tectum. This, together with the large size, abundance and wide distribution of corticotectals makes them one of the most important classes of output neuron in the owl's visual cortex. In this study, we have combined dye-labelling in the whole brain and in fixed brain slices to determine details of the morphology and projections of corticotectal cells in the visual cortex of tytonid owls. Corticotectal neurons were the largest cell type in cortex and possessed numerous dendritic spines, as is also true in mammalian visual cortex. However, in contrast to mammals, corticotectals in the owl were located above the granular layers and had axons which passed superficially, just below the pia.

An unusual feature of owl corticotectals was that, as a class, they projected bilaterally. This is probably due to the fact that the rostral portion of the tectum deals with the region of binocular overlap and so each tectum would share part of the visual field with each visual cortex. However, although the corticotectal population as a whole projected bilaterally, individual neurons did not, since we rarely found double labelled cells in cortex after placing different retrograde dyes in corresponding regions of each tectum. There was no indication that corticotectal cells were segregated within cortex (e.g. into columns or stripes) based on the laterality of their projections. On the contrary, cells projecting to both tecta were often found side by side. The existence of patches of corticotectal efferent fibres within the tectum (Bagnoli et al., Brain Behav. Evol., 1991, in press) suggests that segregation may occur instead at the output level. Such segregation appears similar in principle to that producing ocular dominance columns although, here, the segregation of efferents in a tectal patch cannot be due to the fibres being derived from a common eye but rather appears to be related to their derivation from the same hemisphere.

CORTICOSTRIATAL AND CORTICOTECTAL PROJECTIONS FROM THE CAT LATERAL SUPRASYLVIAN CORTEX. J.G. McHaffie, B.E. Stein and M. Norita. Department of Physiology, Medical College of Virginia, Richmond, VA, 23298 and Department of Anatomy, Niigata University Sch. of Medicine, Niigata 951, Japan.

The relationships between the visual cortex and the striatum (ST) of the cat is poorly understood. The present experiments were an attempt to determine if regions along the lateral suprasylvian cortex (LS), known to sent projections to the superior colliculus (SC) also project to the ST, and if so, to determine whether corticostriatial and corticotectal axons arise from the same neurons. Injections of the anterograde tracer biocytin into the posterior portion of LS resulted in dense label in both ST and SC. In ST, labeled fibers and terminals were found predominately in the caudal part of the head of the ipsilateral caudate nucleus and the caudal portion of the ipsilateral putamen. These cortical injections also resulted in label in the superficial and deep laminae of the ipsilateral SC. After paired injections of retrogradely transported fluorescent dyes into ST and SC, numerous labeled LS neurons were observed in lamina V and modest numbers in lamina III; however, whereas corticostriatial neurons were found in laminae III and V, corticotectal neurons were seen only in lamina V. Although labeled neurons from each injections were intermingled in lamina V, very few were double-labeled. These data suggest that while ST and SC receive substantial visual inputs from the same cortical area, the nature of that information may be quite different. Supported by NEI grant EY05554.

550.6

POSTNATAL ONTOGENESIS OF CORTICOSTRIATAL AND CORTICOTECTAL PROJECTIONS FROM THE CAT LATERAL SUPRASYLVIAN CORTEX. M. Norita, B.E. Stein and J.G. McHaffie. Dept. of Anatomy, Niigata Univ. Sch. of Med., Asahimachi Niigata 951, Japan and Dept. of Physiology, Medical College of Virginia, Richmond, VA, 23298.

To evaluate the postnatal ontogenesis of corticostriatal and corticotectal projections from the lateral suprasylvian cortex (LS), we injected the anterograde tracer biocytin into LS in neonatal cats aged 1-60 days postnatal (dpn). At the light microscopic level, both corticofugal pathways were already present at birth. Although the terminations of these projections appear to have topographies approximating those of adults, neonatal terminal regions were much more densely labeled. To determine whether these neonatal projections represent actual synaptic endings or merely the presence of labeled fibers, we examined the ontogeny of synapses with the electron microscope. Although labeled axon terminals could be found in both ST and SC at 1 dpn, their number was minimal. During the first postnatal month, the number of labeled synapses gradually increased. We suggest that the protracted synaptic development of these neural pathway underlies the protracted development of visually-guided orientation behavior. Supported by NEI grant EY06562.

550.7

POSTNATAL DEVELOPMENT OF CHAT AND ACHE ACTIVITY IN VISUAL STRUCTURES OF THE CAT. D.D. Dunning[1], J.G. McHaffie[1], B.E. Stein[1] and C.D. Ross[2]. Dept. of Physiol., Med. Coll. of Virginia, Richmond, VA, 23298[1] & Dept. of Otorhinolaryngol., Univ. of Okla., Oklahoma City, OK, 73190[2].

The postnatal maturation of cholinergic enzymatic activity was determined by radiometric assay in select cortical and subcortical visual structures of the developing cat (0-56 days). ChAT activity increased progressively from birth except for a transient decrease about day 28. Adult ChAT activity was similar between the following pairs of structures: superficial superior colliculus (SC) and lateral geniculate (LGN), deep SC and pulvinar (Pul), area 17-18 and lateral suprasylvian cortex (LS). AChE activity increased after birth then decreased gradually to adult levels in all structures except visual cortex, which had a flat profile, and Pul, which had a slightly higher level at birth than adulthood. AChE in LGN and Pul peaked early (day 7) but fell rapidly to adult levels, whereas SC peaked late (day 28), declining gradually to adult levels. The caudal half of SC had higher activities in both superficial and deep layers, beginning at about day 14 for ChAT and day 42 for AChE. Decreasing AChE/ChAT ratios are consistent with a significant non-cholinergic role of AChE in early postnatal life.

550.8

PHYSIOLOGICAL MATURATION OF THE VISUAL TOPOGRAPHY IN THE CAT SUPERIOR COLLICULUS. C.-Q. Kao, J.G. McHaffie, M.A. Meredith and B.E. Stein. Departments of Physiology and Anatomy, Medical College of Virginia, Richmond, VA, 23298.

Anatomical and behavioral studies indicate that central visual fields are likely to develop before peripheral ones. The present experiments were initiated to determine the physiological maturation of the visuotopy in the superior colliculus (SC). Single and multiunit responses were recorded in urethane-anesthetized kittens (7-50 dpn). A systematic exploration of the SC at about the time of eye opening (9 dpn) revealed topographically organized, visually-responsive neurons in superficial layers. Although fewer responsive neurons were found in younger animals, the visuotopy appears to exist prior to eyelid opening. There was no evidence that neurons in a particular region of the SC became responsive before any other; thus neurons with central fields were not active earlier than those with more peripheral fields. The superficial layer topography was evident before most deep layer neurons were responsive to visual stimuli. These data contrast with observations that early visual behaviors depend first on the central retina. Supported by NEI grant EY06562.

CORTICAL CONVERGENCE ON MULTISENSORY OUTPUT NEURONS OF CAT SUPERIOR COLLICULUS. M.T.Wallace, M.A.Meredith and B.E.Stein, Depts. Physiol. and Anat., Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298

In cat superior colliculus (SC), the convergence of inputs from different sensory modalities (Stein and Arigbede, 1972), and the integration of these inputs by single neurons (Meredith and Stein, 1986) has been well established. Multisensory responses in SC neurons are dynamic, and are likely subject to modulation by experience and behavioral state: functions believed to be derived from higher cortical centers. We examined the accessibility of multisensory SC neurons to cortical inputs by means of orthodromic stimulation. Chronically prepared cats had arrays of stimulating electrodes implanted in visual (PLLS, ALLS, AEV), auditory (Field AES) and somatosensory (SIV) cortices. A total of 249 (from a sample of 413) neurons received cortical input from at least one of these areas. Many multisensory cells (112/189) received input from two or more cortical areas. In general, multisensory neurons receiving convergent cortical input demonstrated a strong interactive effect when stimuli from more than one modality were presented. Antidromic stimulation revealed that most (77%) multisensory cells which received convergent cortical input were also efferent neurons that projected into the tectoreticulospinal tract. These results demonstrate that cortex can modulate the integrated multisensory signals which form a major component of the crossed descending output from the SC, through which attentive and orientation behavior can be mediated.

IDENTIFICATION OF CELLS IN THE SUPERIOR COLLICULUS SUBJECT TO WIDESPREAD INHIBITION. R. M. Douglas and K. E. Anderchek,* Depts. of Ophthalmology, Psychology and Physiology, Univ. British Columbia, Vancouver, B.C. V5Z 3N9

A winner-take-all circuit must exist somewhere between the visual and oculomotor systems. We have proposed (Douglas & Vetter, 1986) that an inhibitiory circuit capable of selecting one focus of activity lies in the SC. To identify which cells may be involved, iontophoretic application of glutamate or acetylcholine was used to increase the discharge levels of SC neurons in urethane-anesthestized rats. Only cells lying in the intermediate layers showed strong inhibition to electrical stimulation of the contralateral SC. This inhibition could be blocked by bicuculline. Many of these cells could be activated antidromically from the brainstem. In addition, brainstem stimulation produced inhibition but also revealed that many projection neurons were insensitive to glutamate. The results are consistent with target selection being the last processing step in the SC.

550.11

THE EFFECTS OF SEROTONIN AND ITS ANALOGUES UPON VISUAL NEURONS IN THE HAMSTER'S SUPERIOR COLLICULUS. X. Huang and R. D. Mooney. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699-0008

The superficial layers of the rodent superior colliculus (SC) are innervated by serotoninergic fibers from the nucleus raphe dorsalis and contain multiple serotonin (5HT) receptor subtypes, including $5HT_{1A}$, $5HT_{1B}$, $5HT_{1D}$, and possibly $5HT_2$. This raises the possibility that 5HT may exert differential effects in the SC through interactions with different receptors. We recorded single cells with multibarrelled pipettes and characterized their receptive fields. Using micropressure application, 5HT and/or an analogue was ejected from the pipette as the cell responded to electrical stimulation of the optic chiasm or visual patterns. Visual activity was strongly suppressed by 5HT in 81% (35/43) of the neurons tested; only 5% (2/43) were excited and 14% (6/43) showed no effect. No differential effects on cells with particular receptive field types were noted. Two $5HT_{1A}$ agonists 8-hydroxy-2[di-n-propylamino]tetralin (8-OH-DPAT) and 5-carboxamidotryptamine (5CT) had weaker suppressive effects than 5HT: 8-OH-DPAT suppressed 43% (3/7) of cells tested and 5CT suppressed activity in all 3 cells tested, but was less potent than 5HT. The $5HT_{1B}$ agonist m-trifluoro-methyl-phenyl-piperazine (TFMPP) had no effect on visual activity of 3 cells tested. Antagonists for $5HT_{1\,\&\,2}$ receptors spiperone and mianserin blocked the suppressive effects of 5HT in all cells tested (n=8: 4 each agent); while ketanserin, a $5HT_2$ blocker, was ineffective (n=6) and methiothepin, a $5HT_{1A\,\&\,2}$ antagonist, showed no consistent effect (n=4). We conclude that the effects of 5HT on visual activity in the hamster's SC are primarily mediated through $5HT_{1A}$ receptors and a second, as yet unidentified subtype.

ADENOSINE MODULATES RETINOTECTAL TRANSMISSION IN GOLDFISH. W. M. King and J. T. Schmidt. Dept. of Biol. Sci., SUNY-Albany, Albany NY 12222.

Presynaptic adenosine receptors inhibit the release of many neurotransmitters in brain and decrease quantal content at the neuromuscular junction. Since retinal ganglion cells have high levels of adenosine and adenosine receptors on their terminals, Braas *et al.* (P.N.A.S. 84:3906-3910, 1987) have suggested that endogenous adenosine may serve as a coneurotransmitter in the retinal ganglion cells. We evaluated this possibility by testing the effects of adenosine and adenosine agonists and antagonists on retinotectal transmission in an in vitro preparation of goldfish brain.

Concentrations of 100-300 μM adenosine, comparable to those that reduce quantal content at the neuromuscular junction, and 100 μM 2-chloroadenosine, an agonist minimally transported across cell membranes, reduced retinotectal field potential amplitude by 30-50%. They also increased paired pulse facilitation which suggests a presynaptic site of action. These effects were attenuated by the adenosine antagonists caffeine or IBMX (100-200 μM) by 30-60%. Either caffeine or IBMX alone increased the amplitude of the retinotectal field potential, suggesting that endogenous adenosine may limit transmitter release. Since the cAMP analogues dibutyryl-cAMP and 8-bromo-cAMP (1 mM) had negligible effects, the adenosine effect is not likely to be mediated by cAMP. Since we have previously shown that presynaptic nicotinic receptors enhance retinotectal transmission, the present results suggest that transmitter release at optic nerve terminals may be under dual, bidirectional regulation by two neuromodulators acting at distinct presynaptic receptors. (Supported by NIH grant EY03736)

550.13

VISUAL RESPONSES OF NEURONS IN THE NUCLEUS OF THE BASAL OPTIC ROOT OF THE NORTHERN SAW-WHET OWL. Douglas R. Wylie, Steven W. Shaver and Barrie J. Frost, Department of Psychology, Queen's University, Kingston, Ontario, Canada K7L 3N6.

The nucleus of the basal optic root (nBOR) is a component of the avian Accessory Optic System (AOS) which is involved in the analysis of visual "flowfields" resulting from self-motion. The structure of flowfields is qualitatively different for lateral-eyed and frontal-eyed species, thus one might expect differences in the AOS. The AOS has been investigated in the lateral-eyed pigeon, but frontal-eyed birds have not been studied. Using standard extracellular techniques we recorded from neurons in the nBOR of the northern saw-whet owl (*Aegolius acadicus*). Under ketamine anaesthesia this bird has a binocular field measuring 50 X 75 degrees (horizontal X vertical). Neurons in nBOR responded best to large patterns of random dots moving either upward, downward or nasal to temporal (N-T) in the contralateral visual field. Few units preferred temporal to nasal motion. Up units were found in dorsal region of nBOR whereas down units were found ventral to these. N-T units were found in both the lateral margin, and ventral to the down units in the lateral half of nBOR. About half of the units tested responded to stimulation of the ipsilateral as well as the contralateral eye. For all but one cell, the direction preference of both eyes was the same in visual space. In most cases, binocular stimulation resulted in greater modulation of the cells' firing rates than monocular stimulation. These responses resemble those of pigeon nBOR neurons with respect to direction preference; however, few neurons in the pigeon nBOR are binocular. In mammals, there is a greater incidence of binocular neurons in the AOS of frontal-eyed species, compared to those with laterally placed eyes. Together, these data suggest that the avian and mammalian AOS may have developed in a similar fashion with the occurrence of frontal-eye placement.

MULTISENSORY NEURONS IN THE MIDBRAIN OF THE PIGEON. S.W. Shaver and B.J. Frost. *Department of Psychology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.*

The neural integration of information from different sensory systems is required for a variety of functions, and cells responsive to stimulation of more than one sense (multimodal units) have been identified in several species. Multimodal units were identified using extracellular recordings in the pigeon nucleus mesencephalicus lateralis, pars ventralis (MLv). Most units encountered were multimodal and were either visual-auditory, visual-somatosensory, or visual-auditory-somatosensory. Visually-responsive units preferred small moving stimuli and showed no clear directional specificity. Somatosensory-responsive units were maximally activated by gentle brushing of the feathers and beak. Auditory-responsive units tended to be broadly-tuned, or non-responsive, to tone stimuli, but had low thresholds to noise (20-30 dB SPL). Many units displayed large receptive fields with no clear best area. These units responded to visual stimuli presented in a large area of contralateral visual space (up to 80° X 80°). Similarly, the somatosensory receptive fields often extended over the whole contralateral body surface. The auditory spatial tuning for these units tended to be flat in azimuth and elevation, but for some cells was restricted to the contralateral field. For units with clear best areas, the receptive field maps for each mode of stimulation tended to be in register. For instance, units with visual best areas located 90° lateral to midline tended to have similarly located auditory best areas, and showed peak somatosensory responding to stimulation of the lateral body surface. These multimodal cells in the pigeon MLv appear to be well suited to the mediation of attentional and orientational responses to stimulation.

SOME NEURONS IN THE NUCLEUS ROTUNDUS OF PIGEON COMPUTE TIME TO COLLISION. Y-C. Wang and B.J. Frost. Departments of Physiology and Psychology, Queen's University, Kingston, Ontario K7L 3N6, Canada.

Behavioral studies have shown that the avian tectofugal pathway, which is similar to the mammalian colliculo-pulvinar-MT pathway, is involved in processing several important visual attributes, such as color, intensity, pattern, and motion. Our previous results indicated that cells in anatomical discrete zones within the nucleus rotundus of pigeon exhibited specific visual response characteristics associated with these attributes, and about 17% of cells in the dorsal-posterior subarea of the nucleus strongly responded to a looming stimulus. In this study, standard extracellular responses from dorsal-posterior subarea, EMGs from pectoral muscles, and EKGs were simultaneously recorded from awake birds. We have found that looming sensitive neurons are not only very specific to the 3D direction of motion of a "soccer ball" like stimulus, but give their maximum response at a constant time before "collision", even when the size of the stimulus or its velocity were varied over a large range of values. The EMGs always occurred 100-200 ms after the peak looming cell response, and the heart rate increase followed even later. When the looming stimulus was not on a collision course with the bird, the looming cells' response was dramatically reduced and no EMGs, or increased heart rate occurred. We propose that these looming sensitive neurons signal "time to collision" and provide information necessary for an emergency avoidance response by the bird. Supported by NSERC grant A0353 to BJF.

550.16

THE EFFECT OF POSITIONAL DISPARITY ON MOTION RESPONSES OF NEURONS IN THE ACCESSORY OPTIC SYSTEM OF CAT. K.L. Grasse. Dept. Psychology, York University., North York, Ontario, Canada M3J 1P3.

It is widely accepted that the accessory optic system (AOS) provides visual signals for the control of optokinetic nystagmus (OKN). In frontal-eyed animals, the substantial overlap in the visual fields of each eye and a projection from the visual cortex gives rise to an increased incidence of binocularly responsive neurons in the AOS. Visual cortical input has been shown to mediate ipsilateral eye responses and high speed tuning, and can function independently of the contralateral eye. However, binocular tuning characteristics of AOS cells have not been extensively examined. The present study set out to determine if binocular AOS cells are sensitive to retinal disparity. Single units were recorded from the dorsal terminal nucleus (DTN) of anesthetized, paralysed cats. The positions of areæ centrales were determined by fundus reflection. Convergent and divergent disparities were generated by deviating the visual axis of one eye using wedge prisms ranging from ±1-20 diopters (i.e., base-in or base-out, 1 diopter=0.57 deg). A random-dot pattern composed of multiple gray-levels was moved by computer at a constant velocity in the preferred direction. The responses of DTN units to positional disparity fell into 4 categories: 1) cells with tuning profiles similar to "tuned excitatory" responses consisting of a marked facilitation for a single or a small range of disparities (convergent and divergent); 2) cells relatively insensitive to disparity, showing a relatively flat response profile across the entire range of conditions; 3) cells displaying rather complex tuning profiles which usually contained multiple peaks or troughs at different disparity values; and 4) a small number of cells broadly tuned for inhibition. In summary, this study demonstrates that many AOS cells are sensitive to positional disparity and supports behavioral investigations showing that OKN gain is dramatically affected by changes in depth planes defined by disparity. Supported by a grant from NSERC.

550.17

SENSORY MODALITY SPECIFICITY OF NEURONAL RESPONSES WITHIN THE CAT'S SUPRAGENICULATE NUCLEUS.

G. Benedek*, J. Perényi*, G. Kovács*, Y. Katoh*, B. Csákány*, and M. Norita. Dept. Physiol., Albert Szent-Györgyi Med. Univ., Szeged, Hungary and Dept. Anat. Niigata Univ. Sch. Med., Niigata 951, Japan.

The feline insular cortex contains cells sensitive to visual, auditory and somatosensory stimuli. The suprageniculate nucleus (SGn), receiving the superior collicular afferents, seems to be the main subcortical source of afferents towards the insular cortex. We studied the modality specificity of extracellularly recorded SGn cells in barbiturate anesthetized, immobilized, artificially ventilated cats. Of the 136 cells tested 109 showed unimodal sensory characteristics, 23 was bimodal and only 4 was sensitive to all the three modalities. ***Visual*** sensitivity was found in 100 cells. These showed large uniform receptive fields including the area centralis. No retinotopy could be detected. ***Somatosensory*** sensitivity to tactile stimulation was found in 32 cells, and that to nociceptive stimulation in 5 cells. ***Acoustic*** sensitivity was found in 24 cells. No systematic relationship was found in the anatomical position of cells sensitive to various modalities. Our results show sensory properties in SGn similar to that described in the insular cortex. This is in line with the concept of parallel processing of sensory information along a tecto-thalamo-insular cortex route.

CEREBELLUM II

551.1

DOES THE CEREBELLUM PREFERENTIALLY CONTROL MULTIJOINT MOVEMENTS? H.P. Goodkin and W.T. Thach. Departments of Anatomy & Neurobiology and Neurology & Neurosurgery, Washington University School of Medecine, St. Louis, MO 63110.

Inactivation of the cerebellar dentate nucleus in the monkey impairs reaching and pinching with sparing of trained wrist movements (Kane et. al., 26.6, 1989). This result suggests that dentate control of movement is preferentially concerned with multiple joints rather than single joints. The following study tests this hypothesis.

Two juvenile Rhesus monkeys (*Macaca mulatta*) have been trained to insert their right hand into a "pinch" manipulandum. The apical pads of the thumb and index finger rest on snap-action switches which are closed by flexion (3-5mm) of the distal phalanx of these digits. Digits 3, 4, and 5 are held firmly in place in the manipulandum. Cued by an LED display, the monkey performs 3 tasks: (1) closure of the thumb switch by flexion of the THUMB, (2) closure of the index finger switch by flexion of the INDEX finger, and (3) closure of both switches by the combined simultaneous flexion of the thumb and index finger (PINCH). Force analysis confirms that the THUMB and INDEX tasks are performed, on average, independently. Analysis of EMG (recorded from the shoulder girdle, arm, forearm, and intrinsic hand muscles) shows that the PINCH task is performed using only muscles that are active during the THUMB, INDEX, or both tasks; no muscle is recruited uniquely for PINCH. Thus, the two independent movements are combined into a synergic sum. This combination of two independent movements into a synergic sum is the crucial factor that is missing from previous ablation and single unit recording studies which address the question of whether cerebellar control of coordination is at the single joint or the multijoint level. (NIH grant NS12777)

551.2

INFERIOR OLIVE DISEASE IN MAN IMPAIRS LEARNING NOVEL SYNERGIES W.T.Thach, J.G.Keating, and H.P.Goodkin, Depts of Anatomy & Neurobiology, Neurology and Neurosurgery, and The IWJ Rehab. Institute, Washington University Medical School, St. Louis, Mo. 63110.

In throwing, the eyes (and head) fixate the target, and serve as reference aim for the arm. Coordination between gaze direction and arm throw is a skill: it is developed and maintained by practice. When wedge prism spectacles are placed over the eyes with the base to the right, the optic path is bent to the right, and the eyes (and head) move to the left to fixate the target. The arm, calibrated to the line of sight, throws to the left of the target. With practice, the calibration changes, and the arm throws closer to and finally on-target. Proof that eye (and head) position is the reference aim for the arm throw trajectory occurs when the prisms are removed and the arm throws. The eyes are now on-target, but the eye-head-arm calibration for the previously leftbent gaze persists: the arm throws to the right of target an amount almost equal to the original leftward error. With practice, eye-head position and arm synergy is recalibrated: each throw moves closer to and finally on-target.

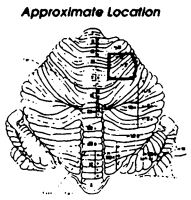
Baizer showed in macaques that the adjustment is abolished by cerebellar lesion (Baizer and Glickstein, 1974). Weiner et al (1983) obtained similar results in patients with cerebellar disease, and showed that adaptation was not impaired in disease of corticospinal or basal ganglia systems. We here confirm these results in patients with pure cerebellar cortical disease (1 infarct, 2 cortical atrophies). We have also studied two patients with MRI-documented inferior olive hypertrophy. Both had palatal myoclonus and progressive ataxia of trunk and gait. Neither showed adaptation on this task, despite near-normal throwing performance (cf also Gauthier et al 1979). Finally, we studied patients with lesions presumed to involve mossy fibers of the middle cerebellar peduncle, who also show impaired adaptation (cases of ataxic hemiparesis, with contralateral lesions of the basis pontis involving leg corticospinal and arm pontocerebellar fibers, according to Fisher, 1978).

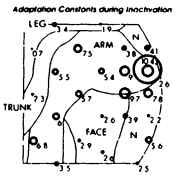
These results indicate that cerebellar cortex, inferior olive, and mossy fibers are all necessary for the adaptation, but they do not distinguish the roles played by each (NIH grant NS12777).

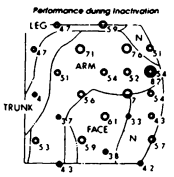
551.3

THE CEREBELLAR CORTICAL AREA REQUIRED FOR ADAPTATION OF MONKEY'S "JUMP" TASK IS LATERAL, LOCALIZED, AND SMALL. J.G. Keating and W.T. Thach. Dept. of Anatomy and Neurobiology, Washington University Sch. Med., St. Louis, MO 63110.

We obtained numerically independent measures of adaptation and performance during adaptation of a wrist ballistic movement to a visual target ("Jump") as described previously (Soc. Neurosci. Abs. 314.15, 1990). An "inactivation map" of cerebellar cortex was made by systematic injection at 24 sites of 2µl of 1µg/µl muscimol and attempting to induce adaptation. Inactivation of a small area (2x2mm) of cortex in the extreme lateral hemisphere resulted in a marked slowing of adaptation (larger circles) with no significant change in performance of the task. Circles are overlaid on a somatosensory receptive field map of units in Purkinje cell layer. (NIH grant NS12777)







551.4

THE KINEMATICS OF THE DECOMPOSITION OF TWO-JOINT ARM MOVEMENT INITIATION IN NORMALS AND PATIENTS WITH CEREBELLAR ATAXIA. S.G. Massaquoi* and M. Hallett. Human Motor Control Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892.

Seven patients with cerebellar degeneration and seven age and sex-matched controls, all right handed, were asked to make 80 (2 blocks of 40 trials) left to right cross-body arm movements in the horizontal plane such that the hand traced a precisely linear path on a datatablet. As the thorax and wrist were immobilized, the linearity of the movements directly reflected the precision of shoulder-elbow coordination. Linearity was assessed quantitatively during the first 150 milliseconds of movement.

At lower peak velocities (<20 inches/second) there was a very gentle curvature, convex relative to the body, in both normals and patients. At higher peak velocities, both patients' and normals' trajectories demonstrated a component of increased convexity. Patterns ranged from sigmoids (first concave then convex) to convex arcs. Normals typically produced mild, more balanced sigmoids while patients produced heavily convex sigmoids or bowing arcs. Generally, for any level of peak velocity (> 20 i/s), the magnitude of nonlinearity was significantly greater in patients than in normals independent of pattern.

We conclude that during the initiation of attempted linear cross-body arm movements, normals and patients produce systematically nonlinear trajectories at increased hand speeds which differ primarily in the magnitudes of their convex components. This implies a general, velocity-related failure of interjoint coordination in human arm movement which is significantly more severe in patients with cerebellar ataxia.

LEARNING OF ARM TRAJECTORY FORMATION IN PATIENTS WITH CEREBELLAR DEFICITS.
H. Topka, S.G. Massaquoi*, T. Zeffiro, and M. Hallett. Human Motor Control Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892

Recent studies suggest that the cerebellum plays a role in adaptation learning of reflexes such as the vestibulo-ocular reflex. To investigate its role in skill learning, we studied 18 patients with cerebellar cortical atrophy and olivo-ponto-cerebellar atrophy and 15 healthy controls.

Subjects were instructed to perform a multi-joint arm movement on a data tablet generating a trajectory connecting 5 viapoints in a given sequence. Movements were to be performed at a constant total movement time and spatial error was determined. After completion of the first 100 trials at a target movement time of 3500 ms, subjects were instructed to continue for another 100 trials at their maximum speed.

At slow speed both patients and controls reduced the error over trials. Rate of improvement was similar. When starting the fast movements, both groups initially showed increased error. Normal subjects then improved rapidly, while patients showed only gradual improvement. When fast movements were requested first, patients improved less rapidly than normals. Errors in patients correlated with mean square jerk of the trajectory.

Patients with cerebellar deficits can exhibit normal rate of skill learning at slow speeds, but are slower than normals for high movement speeds. The problem appears to be a difficulty in improving the details of the execution of their performance.

FORELIMB REACHING IN CATS WITH LESIONS OF THE DEEP CEREBELLAR NUCLEI: ACCURACY AND INTERJOINT COORDINATION S. E. Cooper & C. Ghez Ctr for Neurobiol. & Behav., Columbia Univ. & NYS Psychiatric Inst., New York, NY, 10032.

Gordon Holmes noted that, while cerebellar hemisphere lesions impaired performance of single-joint movements, multi-joint movements were more inaccurate than the sum of single-joint errors would suggest. Recently, some authors have proposed that the lateral/intermediate cerebellum is concerned with multi-joint movements *per se*.

We have studied a multi-joint forelimb reaching movement in cats (modified from Gorska & Sibirska 1980). We find that reaching to targets of different heights is accomplished by scaling of a common elbow flexion trajectory, but that movements at other joints of the limb (eg. wrist & shoulder), closely coordinated with the elbow flexion, are essential for successful task performance. Interruption of the output of lateral and intermediate cerebellum by lesions of the lateral and interpositus nuclei produced severe inaccuracy in reaching, including both increased variability and systematic directional biases. Much of the inaccuracy was due to failure to produce wrist and shoulder movements that were coordinated with the basic elbow flexion.

Normal cats can alter the pattern of coordination of wrist and shoulder with elbow in order to generate a reaching trajectory which avoids an obstacle. Following deep nuclear lesions, cats could not alter the pattern of coordination to avoid an obstacle: on every trial the paw collided with the obstacle, and only then made a corrective response.

These results suggest that the cerebellum contributes to the coordination between movements at different joints which is essential to accurate multi-joint movement. (NS19205 & GM32099)

NETWORK PROPERTIES OF THE OLIVO-CEREBELLAR CIRCUITRY DURING SPONTANEOUS ALTERATIONS IN LIMB COORDINATION. Sheryl S. Smith. Dept. of Anat., Inst. for Neurosci., Hahnemann Univ., Phila., PA

The goal of this study was to examine properties of a well- defined neural network across changes in its functional state, as defined by specified behavioral correlates of network activity. The rubro-olivo-cerebellar circuit at the level of the paravermal cerebellum plays a role in coordination of the distal limbs. The present study was conducted to determine the behavior of individual neurons in the circuit, recorded chronically as ensembles of 10- 20, during tests of limb coordination across spontaneous changes in functional state, here defined as changes in the speed and accuracy of limb trajectory. Hormonal (estrous) fluctuations are associated with marked alterations in limb coordination. Limb response to changes in treadmill speed is most accurate on the night of behavioral estrus following endogenous increases in estradiol and progesterone, relative to diestrus (lower hormone levels). For this study, female rats were chronically implanted with arrays of microwires (50 µ dia, Calif. Finewire) to record from Purkinje (Pnj) cells of the paravermal cerebellum and inferior olivary neurons, simultaneously. Neuronal activity was monitored during treadmill paradigms employing i.) constant speed (4 or 11 cm/s) or ii.) variable acceleration. Typically, Pnj cell discharge is correlated with limb movement, while olivary discharge is correlated with errors in placement or transitions in terrain. Increases (42-74%) in cerebellar discharge and decreases (15-24%) in olivary discharge correlated with treadmill locomotion were observed on estrus relative to values obtained on diestrus during both paradigms. In addition, olivary activity tested on estrus during variable acceleration was three- fold higher than corresponding discharge correlated with constant speed locomotion. Cross-correlation analysis at this time revealed increases in the amplitude of Pnj cell responses to olivary triggers. Sensorimotor gating at the level of the DAO (Gellman et al, 1985) may underlie error signal capabilities of this structure. Increased amplitude (by 50%) of olivary responses to forepaw stimulation during non-movement was observed on estrus . In contrast, estrus was associated with a greater decrease (by 30%) in olivary response during movement relative to diestrus values. These results suggest that alterations in the emergent properties of the olivo- cerebellar circuit accompany changes in its functional state associated with the estrous cycle. *(Supported by NS 25809.)*

COMPLEX SPIKE DISCHARGES IN RELATION TO INITIATION OF VOLUNTARY MOVEMENT IN MONKEY. J.-P. Pellerin, M.-T. Parent* and Y. Lamarre. Centre de Recherche en Sciences Neurologiques, Département de Physiologie, Université de Montréal, Québec, Canada, H3C 3J7.

Climbing fiber responses (CFR) of cerebellar Purkinje cells (Pc) were recorded in the anterior and posterior lobes of the cerebellum in a monkey trained to perform elbow flexion or extension in response to randomly presented visual, auditory and somesthetic cues. In the anterior lobe, Pc showed CFR in relation to the somesthetic cue only. In the lateral part of the posterior lobe, Pc showed CFR only following the visual cue at a latency of 80-200 ms. The probability of firing increased for shorter reaction time (RT) and decreases for longer RT. In the vermal part of the posterior lobe, Pc were activated in three ways: 1) PC showed CFR following the auditory cue at a latency of 50-120 ms. As in the lateral hemisphere, the firing probability is dependent on the RT, 2) some Pc showed CFR 50-120 ms before the onset of the movement in response to visual and auditory cues only, and 3) others were activated in the same way for all three modalities. Moreover, CFR were not associated with oculomotor events, and they were reduced or abolished when the monkey did not respond to the cues or perform a self-paced movement. These results suggest that the olivocerebellar system may be involved in the rapid initiation of movement triggered by an externally presented cue, and this may be accomplished by modulating the Pc responsiveness. CEREBELLAR CONTROL OF PROPRIOCEPTIVE GAIN: A NEW PARADIGM M. Gorassini and A. Prochazka, Division of Neuroscience, Univ. of Alberta, Edmonton, Alberta, T6G 2S2, CANADA.

It is thought that one of the roles of the cerebellum is to control the gain of sensorimotor transmission in extracerebellar reflex pathways, in particular, the proprioceptive system. Sherrington has called the cerebellum the "head ganglion" of the proprioceptive system. We wish to test the hypothesis that the cerebellum controls the stretch sensitivity of muscle spindle receptors by influencing fusimotor output. Perhaps abnormalities in the control of proprioceptive gain contribute to the ataxia and tremor seen in cerebellar disease. To test this, we have developed a preparation that will allow us to record muscle afferent discharge during reversible inactivation of the cerebellar cortex in the freely moving cat. An injection port chronically placed over the paravermal cortex acts as a guide for the injection of 100 µl of 2% lidocaine onto the cortical surface. Recording microelectrodes are inserted into the L7 dorsal root ganglion and single unit activity is transmitted by telemetry. To date, we have implanted two cats and have observed in both, marked ataxia and large postural deficits in limbs ipsilateral to the injection site. These deficits are reversible and temporary, lasting for only 3 to 5 minutes on average. If fusimotor abnormalities contribute to this ataxia, we will be able to monitor this in the afferent recordings. In support of this, we have observed a marked increase in spindle discharge upon injection of lidocaine and cooling of the cerebellar cortex in two acute experiments. (Supported by MRC of CANADA.)

SITES OF MOTOR LEARNING IN THE VESIBULO-OCULAR REFLEX (VOR) PREDICTED BY A DYNAMICAL NETWORK MODEL. T.J. Sejnowski and S.G. Lisberger, The Salk Institute, La Jolla, CA 92037, and Department of Physiology, University of California, San Francisco, 94143.

A dynamical neural network model of the VOR and smooth pursuit eye movements was used to explore possible sites of plasticity of the VOR. The model had processing units that were nonlinear leaky integrators interconnected in a pattern based on the known anatomy of the VOR pathways. There were two vestibulo-motor pathways: a direct one through the brainstem and an indirect one through the cerebellar flocculus. The flocculus also received negative visual feedback related to image velocity and positive feedback related to output eye velocity. We used a gradient descent optimization procedure i) to adjust the parameters of the model so it achieved good tracking during VOR and smooth pursuit trials and ii) to determine how the network would reduce the amplitude of the VOR while maintaining excellent pursuit.

Reductions in the amplitude of the VOR in the model were achieved by decreasing the connection weights in the vestibular input to the brainstem. The connection weights in the vestibular input to the flocculus increased during the early stages of learning, as suggested by M. Ito, but decreased during the later stages, as demonstrated by F. Miles et al. Because gradient descent optimization allowed learning at all sites in the model, we conclude that the pattern of weight changes resulted from other factors, such as the anatomical structure of the network and the requirement for accurate dynamic tracking during visual and vestibular stimulation. Similar factors may determine the sites of local learning mechanisms in the VOR pathways in the brain. (Supported by DARPA through the Office of Naval Research and the Howard Hughes Medical Institute).

552.2

A NETWORK MODEL OF THE CEREBELLUM THAT USES A TRAINED SET OF PATTERN GENERATORS TO CONTROL A SINGLE DEGREE-OF-FREEDOM JOINT. N.E. Berthier, A.G. Barto and J.C. Houk, Dept. of Computer and Information Science, Univ. of Mass., Amherst, MA 01003.

Recently we proposed a model of motor control that considers the cerebellum an array of modules that function as adjustable pattern generators (APGs, Houk et al., *Neural Networks for Control*, Miller, Sutton & Werbos, 1990). The model requires that the correct subset of APGs be used for a given movement. The selection and use of APGs is determined by the postsynaptic effects of proprioceptive and teleceptive parallel fibers that convey information about the internal and external state of the organism. The response of an APG to its inputs is adaptively altered by the action of climbing fibers which are seen as providing private training signals evaluating the APG's contribution to movements.

The current research is an extension of previous work where APGs were trained to control movements of a planer, kinematic arm. In that work a physiologically inspired learning rule was used to adapt parallel fibers conveying target information to a Purkinje cell. Because only one target line was active at a time this was equivalent to adapting a single parallel fiber per trial. In the present experiments, we sought to extend the learning rule to more realistic situations where all the parallel fiber inputs to an APG are adapted and where APGs must act cooperatively to control a single degree-of-freedom joint with nonlinear muscle dynamics. Simulations were performed in which parallel fiber inputs provided redundant, irrelevant, or distracting information. In these simulations, a subset of the APGs could be trained to move the joint to one target, and a different subset trained to move the joint to another target of greater joint angle. COMPUTATIONAL MODELS OF THREE REGIONS OF THE CEREBELLUM. M. Kawato and H. Gomi*. ATR Auditory and Visual Perception Research Laboratories, Sanpeidani, Inuidani, Seika-cho, Soraku-gun, Kyoto 619-02 Japan.

In supervised motor learning, one of the most essential and difficult problems is how to convert the error signal measured in the sensory space (trajectory error in the task-oriented coordinates) into the error signal for the motor command in the coordinates of muscles. We proposed the feedback-error-learning approach where the feedback motor command is used as an error signal to train a neural network which then generates a feedforward motor command.

The cerebellum is divided into three functionally distinct parts: the vestibulocerebellum, the spinocerebellum, and the cerebrocerebellum with distinctive anatomical connections although the cellular organization of the cerebellar cortex is simple, regular and uniform. The feedback-error-learning neural network was originally proposed as a model for the cerebrocerebellum. The spinocerebellum receives sensory information from the periphery. We proposed a closed loop control system based on the feedback-error-learning as a model of the spinocerebellum. Flocculus is known to play an essential role in adaptive modification of the vestibulo-ocular reflex (VOR) and the optokinetic response (OKR). Although the neural circuit itself does not contain any feedback controller, the visual system measures the combined eye and head velocity (retinal slip) and plays a role of differential-type feedback controller converting trajectory error into the motor command error. Our combined model of the flocculus and the ventral part of the flocculus (thought to be a part of the flocculus until recently) explains modification of the VOR, OKR and smooth pursuit. This model resolves the long lasting controversy about adaptive roles of the monkey flocculus in the eye movements. Thus, learning functions of all the three parts of the cerebellum can be coherently understood by the feedback-error-learning scheme.

PRESYNAPTIC CIRCUITRY OF THE DORSAL SPINOCEREBELLAR TRACT IS A PARALLEL DISTRIBUTED NETWORK. C.E.Osborn and R.E.Poppele. Depts of Physiology, Michigan State Univ, East Lansing, MI 48824 and Univ of Minnesota, Minneapolis MN 55455.

We present a new description of the functional organization of the dorsal spinocerebellar tract (DSCT) which accounts for the extensive polysynaptic component of its behavior. A reevaluation of DSCT function was required by several recent findings including: 1) a profound influence of interneurons on DSCT activity evidenced by the polysynaptic activation of 80% - 90% of the DSCT by afferents from a single muscle, and 2) a widespread convergence of affferents from muscle, joint and skin onto interneurons projecting to the DSCT.

We show in a representative population of DSCT neurons in cat that the activity of individual cells is affected by diverse sensory receptors activated by hindlimb movements. Population responses are characterized by a distribution of diverse response types among the units of DSCT. We found no evidence for distinct presynaptic pathways or functional cell types. These data are consistent with a model for the DSCT having a parallel distributed presynaptic circuitry. According to the model, DSCT activity results from a weighted distribution of inputs onto an extensive interneuronal network projecting to DSCT neurons.

A METHOD OF EXTRACELLULAR MICROSTIMULATION WITH COINCIDENT RECORDING. I. D. Hentall. Univ. of Ill. Coll. of Med., Rockford, Illinois, U.S.A. 61107-1897.

To record and stimulate in the extracellular field with one electrolyte-filled micropipette (3M NaCl) requires that sub-millivolt signals be visible <0.5 ms after passing several μA Major problems are capacitative stimulus artifact and transient tip potentials (TTPs). I removed the former by electronic switching between current source and amplifier input, which leaves a tolerable if inconvenient switching artifact. TTPs, which reach 1-20 mV and last >2 ms, were shown to result from depletion of ions entering the microelectrode, and to vary as the square of measured impedance. Pressure ejection of 3M NaCl, and differential recording and stimulation with matched microelectrodes (one in brain, one elsewhere) minimized them. Several discretely recruited spikes were usually detected 0.5 ms after rectangular stimulus pulses (1-3 μA) in the cerebellar cortex of pentobarbital-anesthetized rats. All-or-nothing properties and refractoriness within 2-5ms were evident for the spike of lowest threshold. Longer, complex waveforms were also sometimes found. The technique offers a global search stimulus and improved method of functional brain mapping. (Supported by NINDS grant 26116.)

TEMPORAL RELATIONSHIPS BETWEEN CEREBRAL CORTICAL AND CEREBELLAR RESPONSES TO TACTILE STIMULATION IN THE RAT. J. Morissette, M. Lee, and J.M. Bower. Computation and Neural Systems Program, California Institute of Technology, Pasadena, CA. 91125

Cerebellar granule cell responses to brief (10 msec) tactile stimuli consist of an initial component with a short 8-10 msec latency, and a second component with a more variable and longer 16-32 msec latency. We have recently shown that the longer latency component of this response is much more resilient to neonatal peripheral lesions than is the short latency component (Morissette et al., Soc. Neurosci. Abst. 16,370.1, 1990). Accordingly, we were interested in determining the pathway responsible for this longer latency cerebellar response.

Several different experimental techniques were used to demonstrate that the long latency granule cell layer response component is dependent on a pathway involving the somatosensory (SI) cortex. Lidocaine injections into SI, local SI ablations, and complete midcollicular sections all substantially interfere with the second cerebellar response without having any effect on the short latency response. Further, when tactile evoked responses were simultaneously recorded in both the cerebellar granule cell layer and layer IV of SI cortex, the latencies of both responses were strongly correlated. Intraperitoneal injections of sodium pentobarbital during these recordings produced a highly correlated increase in latency in both the SI and the second component of the cerebellar responses. These results suggest that the topologically organized SI projection to the cerebellum (Bower et al., Brain Behav. Evol. 18,1-18, 1981) influences cerebellar cortex at late and variable latencies. Dual recordings are currently being used to investigate the influence of SI cortex on the late and variable latency cerebellar climbing fiber responses to tactile stimulation.

552.7

TEMPORAL AND SPATIAL ORGANIZATION OF CLIMBING FIBER TACTILE RESPONSES IN RAT CEREBELLAR CORTEX. M. Lee and J. M. Bower, Division of Biology 216-76, Caltech, Pasadena CA 91125.

The climbing fiber (CF) projection to the cerebellum mediates Purkinje cell complex spike responses to tactile stimulation. The temporal and spatial organization of these responses was studied with reference to the well-characterized map of tactile responses in the granule cell (GC) layer of folium crus 2a in rat cerebellar cortex (Bower & Kassel, *J. Comp. Neurol.* 302:768, 1990).

Temporal organization. CF responses to tactile stimulation are sparse, occuring only about 1/5 of the time for regular (1 Hz) punctate stimulation, as seen in dot-raster displays of spike data. This characteristic appears to be related to the 10 Hz periodicity of CF activity (Sasaki *et al., Eur. J. Neurosci.* 1:572, 1989), since stimulation during "off" phases of the excitability cycle have a much lower probability of producing a spike response. CF responses also occur at latencies later than those of GC multiunit responses to the same stimuli, as seen in PST histograms of spike data: CF response latencies are around 50 ms, as compared to 2-5 ms for GC responses. The CF response often involves a rebound spike at 150 ms. These CF response latencies are, however, on the same order as those of GC-mediated increases in Purkinje cell simple spike activity in response to tactile stimulation (Thompson & Bower, this volume).

Spatial organization. CFs with similar tactile receptive fields are arranged in a "patchy mosaic" that is roughly in register with the underlying map of GC receptive fields. Thus CFs with non-contiguous receptive fields can be located close to each other in the cerebellar cortex. However, CF receptive fields are large, typically several times larger than GC receptive fields, and bilateral, even when receptive fields in the underlying GC layer are unilateral. For example, in the center of crus 2a, GCs have receptive fields on the ipsilateral upper lip, but CFs have receptive fields covering both sides of the upper lip.

PROLONGED SIMPLE SPIKE RESPONSES TO ACTIVATION OF THE GRANULE CELL LAYER IN THE RAT CEREBELLUM J.H. Thompson and J.M. Bower. Div. of Biology 216-76, Caltech, Pasadena, CA 91125

For the last several years we have been using our knowledge of the detailed pattern of tactile mossy fiber projections to the granule cell layers of crus IIa to explore the physiological relationships between granule cells and Purkinje cells. Specifically, using *in vivo* extracellular recording techniques, we have monitored Purkinje cell activity in crus IIa of the rat while applying very brief (5 ms) tactile stimuli to perioral regions known to project to underlying or nearby granule cell layer locations. Our results have shown that Purkinje cell responses to these brief peripheral stimuli do consist of a short latency component (5-8 msec) but that there can also be produced a prolonged (100-400 msec) increase in simple spike activity. By discriminating between simple and complex Purkinje cell responses we have been able to show that climbing fibers are also activated by these stimuli at latencies of around 50 msecs (see Lee and Bower, this volume). However, when those trials in which climbing fiber responses do occur (about 1 in 5) are separated from those that have only simple spike responses, the prolonged simple spike response is still present. This result suggests that the mossy fiber / granule cell system is capable of generating prolonged changes in Purkinje cell activity in response to natural tactile stimulation.

We have pursued this result using both *in vitro* intracellular techniques (Jaeger and Bower, this volume) and detailed single Purkinje cell modeling (De Schutter and Bower, this volume).

Supported by NIH grant NS22205.

552.9

A COMPUTER SIMULATION OF PLATEAU POTENTIALS AND SYNAPTIC INTERACTIONS IN PURKINJE CELL SPINY DENDRITES. E. De Schutter and J.M. Bower. Div. of Biology 216-76, Caltech, Pasadena, CA 91125.

EM-reconstruction of granule cell to Purkinje cell synapses has shown a spatial segregation between parallel fiber synapses and synapses from the ascending part of the granule cell axon (G Gundappa-Sulur & JMB, Abstr. Soc. Neurosci. 16: 896, 1990). The position of parallel fiber synapses between the ascending branch synapses and the main Purkinje cell dendrite is compatible with a modulatory role of the parallel fiber segment, with the main excitatory effects coming from ascending fiber inputs from underlying granule cells. Extracellular *in vivo* recordings (J Thompson & JMB., this volume) and intracellular recordings in slices (D Jaeger & JMB., *ibid.*) show that granule cell stimulation generates postsynaptic plateau potentials of 100 to 400 ms in Purkinje cells.

To examine the significance of these plateaus and of the interactions between ascending and parallel fiber synapses we have constructed a detailed compartmental model of a Purkinje cell, based upon anatomical measurements. The model includes sodium, calcium and potassium currents, quisqualate and GABA synaptic conductances and diffusion, buffering and extrusion of calcium. Temporal summation of plateau potentials and the effects of increasing amounts of either random or time-locked parallel fiber and inhibitory stellate cell synaptic activity upon somatic spike firing after an ascending fiber plateau have been examined. The fast increase in internal calcium concentration after application of glutamate on dendrites, and the possible effects of cytoplasmic calcium uptake and release mechanisms have been simulated.

Supported by Fogarty fs F05 TW04368 to EDS and NIH grant NS 22205 to JMB.

552.10

ANALYSIS OF PLATEAU POTENTIALS SEEN IN INTRACELLULAR PURKINJE CELL RECORDINGS WITH SYNAPTIC STIMULATION. D. Jaeger and J. M. Bower. Computation and Neural Systems Program, Caltech, Pasadena, CA 91125

For the last several years we have been exploring the effects of granule cells on Purkinje cells within the rat cerebellar cortex using *in vivo* extracellular recording techniques (J. Thompson and J.M. Bower, this volume). Our data has suggested that purely granule cell input, even in the absence of climbing fiber activation, can generate prolonged (100-400 msec) increases in simple spike firing rates. In the present study we have used *in vitro* intracellular recording procedures to further explore these prolonged effects. Specifically, slices were cut in two orientations; parasaggitally to preserve Purkinje cell inputs from the ascending granule cell axon while significantly reducing input from parallel fibers, and horizontally, to preserve both components of the granule cell input.

Our results reveal that synaptic activation by granule cells produces a prolonged membrane depolarization lasting 100-400 msecs in both the soma and dendrites of Purkinje cells. These depolarizations can generate trains of simple spikes and can sum either temporally or spatially. As in the *in vivo* preparation, prolonged responses occur with or without concomitant climbing fiber activation. A careful examination of the interaction between the climbing fiber response and the prolonged depolarizations has provided critical information for modeling the locations and the properties of the conductances underlying these responses in a realistic Purkinje cell model (E. De Schutter and J. M. Bower, this volume). Supported by NIH grant 22205.

552.11

ANALYSIS OF FACE RECEPTIVE FIELDS IN THE CAT CEREBELLUM A.M. Castelfranco*, G. McCollum, L.T. Robertson R.S. Dow Neurol. Sci. Inst. and Dept. Anat., SD, Oregon Health Sci. Univ., Portland, OR 97201.

The encoding of the location and magnitude of climbing fiber responses to tactile stimulation of the face varied for different regions of the cerebellar cortex. An analysis of the face receptive fields was made of 75 climbing fiber responses encountered in the anterior lobe, of 33 responses from the paramedian lobule (PML), and 52 responses from the crus II of the anesthetized cat. The receptive fields in each region had distinctive configurations and were concentrated on different areas of the face.

The encoding of the skin location depends on the activation of an ensemble of climbing fiber responses in various cortical regions. By overlapping the face receptive fields on a planar diagram, the smallest skin areas (i.e. compartments) that the climbing fiber system could resolve were identified. The receptive fields are unions of compartments, although different combinations of compartments occurred in the three regions. In the anterior lobe, contiguous compartments extended from the ear, along the nose, to the chin; in the PML and the crus II, the contiguous compartments involved the lower jaw and chin; and in the crus II, lines of contiguous compartments included compartments from the ear to the vibrissae, from below the eye to the vibrissae, and from above the eye to the nose tip.

The compartments that were most frequently included in the face receptive fields were the chin, nose tip, and cornea, although there were regional differences (face receptive fields in the anterior lobe mainly included the nose and chin, in the PML, mainly the chin, and in the crus II, mainly the cornea). Thus, the magnitude of the climbing fiber response in to stimulation of the cornea, will be larger in the crus II than in the other regions.

EXPANSION OF TURTLE RUBRAL SOMATOSENSORY RECEPTIVE FIELDS BY LIDOCAINE APPLICATION TO THE CEREBELLAR CORTEX. *R. Sarrafizadeh, J. Keifer, and J. C. Houk.* Department of Physiology, Northwestern University Medical Center, Chicago, IL 60611-3008.

It has recently been appreciated that rubrospinal neurons receive detailed somatosensory information viâ direct and indirect pathways. A recent theory of motor control suggests that cerebellar Purkinje cell inhibition of interpositus neurons sculpts the spatial and temporal features of activity in the cerebellorubral circuits (J. C. Houk *In*: Models of Brain Function, p. 309, 1989). To investigate the role of the cerebellum in the processing of sensory input to the red nucleus we recorded extracellularly from single rubral neurons in the sodium pentobarbitol anesthetized turtle *(Chrysemys picta)*.

The somatosensory receptive fields of single rubral neurons typically covered one or more limbs and parts of the shell, and were composed of excitatory and inhibitory regions. Units were excited by electrical stimulation of the peripheral fields with response latencies that ranged between 20-36 ms. Placement of a small cotton pellet containing 2% lidocaine over the surface of the contralateral cerebellar cortex while recording from a single red nucleus neuron resulted in increased rubral spontaneous activity after several minutes. Both excitatory and inhibitory receptive fields of individual neurons typically expanded in size. Light touch directed to excitatory and inhibitory regions located within the original receptive field resulted in increased responsiveness of each unit's activity. Rubral spontaneous activity and receptive field size and sensitivity returned towards control measurements several hours after lidocaine was washed from the surface of the cerebellar cortex.

The expansion of rubral somatosensory receptive fields may result a.) from inhibition of cerebellar origin that contributes to the shaping of rubral sensory receptive fields, or b.) from hyperexcitability in brainstem circuits released from cerebellar inhibition. These findings are in contrast to previous studies showing a reduction in rubral receptive field size following cerebellectomy perhaps due to reduced excitability resulting from a lesion of the interpositus nucleus.

PURKINJE CELL RESPONSE TO CLIMBING FIBER ACTIVATION AND INACTIVATION IN NORMAL AND GENETICALLY DYSTONIC (*dt*) RATS. M.H. Thorstad, S.E. Stratton and J.F. Lorden. Dept. Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Activation of the inferior olive by harmaline produces a generalized tremor in normal rats. In the *dt* rat, harmaline does not elicit a tremor, but does induce rhythmic activity in olivary neurons. In normal rats, the increased frequency and rhythmicity of olivary activity is conveyed to the cerebellar cortex where high frequency, rhythmic complex spikes and complete suppression of simple spikes are recorded in vermal Purkinje cells. This response is rarely seen in *dt* rats. Recording of vermal Purkinje cells and microstimulation (20-50 µA, 2-8 Hz) of the contralateral caudal medial accessory olive (cMAO) were combined to determine if Purkinje cells in *dt* rats can follow climbing fiber stimulation and if it modulates simple spike activity. In both normal and *dt* rats, complex spikes followed stimulation reliably at all frequencies and significant decreases in simple spike rate were observed. Complete simple spike suppression, typical of the harmaline response, was seen in 17 of 18 cells in normals but only in 4 of 7 cells in *dt* rats. In normal rats, inactivation of the inferior olive produces large increases in simple spike rate. Preliminary results of lidocaine injections (10%, 0.1-0.2 µL) in the cMAO of *dt* rats indicate that although cMAO inactivation silences complex spikes in *dt* rats, the increase in simple spike rate is small in comparison with that seen in controls. These results indicate mechanisms underlying modulation of simple spikes may be abnormal in *dt* rats but that the failure of harmaline to produce sustained increases in complex spike rate cannot be attributed to a failure of Purkinje cells to respond to olivary input. (Supported by a Dystonia Med. Res. Fdn. grant and grant BNS 90-10187 from NSF.)

CONTROL OF POSTURE AND MOVEMENT IV

553.1

RELATIVE PHASE AND THE COUPLING OF THE REACH AND GRASP COMPONENTS IN THE PROSTHETIC HAND. S. A. Wallace, L.E. Carlson* and T. McCullough. Dept. of Kinesiology and Dept. of Mechanical Engineering*, Univ. of Colorado, Boulder, CO 80309.

Amputees wearing body-powered prostheses have many ways to open and close the prehensor (end effector). Since the cable attached to the prehensor crosses several joints and anchors to the contralateral shoulder, a number of degrees of freedom must be constrained to coordinate the movement of prehensor with the joints responsible for reaching toward an object (for example). In the present case study, we used a relative phase analysis (eg. Kelso, Buchanan & Wallace, in press, Exp. Brain Res.) in an attempt to 'capture' this coordination as the speed of the reach was systemmatically increased. The subject, a below-elbow amputee and an experienced user of a voluntary closing prosthesis, was required to continuously reach forward, momentarily grasp a small cylindric object mounted on a table top and return to the start position. The subject was instructed to synchronize the grasp of the object with a tone produced by a computerized metronome program. Cycling frequency began at .6 Hz and was increased by .06 Hz after every 10 cycles, with five such trials yielding a total of 250 complete reaching cycles. The results indicated that relative phasing of final closing remained consistent at approximately 140 deg across all five transport speeds in spite of clear scaling changes in several kinematic parameters of the reach and grasp. In addition, the standard deviation of the mean relative phase was small (approx. 13 deg) and also consistent, providing evidence for only one stable pattern of coordination. When the subject duplicated these cyclical motions without an object, the relative phase increased nearly 20 deg suggesting a different pattern of grasping later in transport. These results imply that the grasping pattern of coordination in the prosthetic hand is more sensitive to the type of functional goal than on the speed of transport.

SHORT-TERM SYNCHRONIZATION OF MOTOR UNITS IN HUMAN WRIST EXTENSOR MUSCLES : EFFECTS OF SUPERFICIAL CUTANEOUS STIMULATION. A. Schmied*, J.P. Vedel, and S. Pagni*, Lab. Neurosciences Fonctionnelles-CNRS, 13402 Marseille Cédex 9, France.

Pairs of motor units (MU) were recorded in human subjects during isometric voluntary contraction of the Extensor carpi radialis muscles. Relying on audio and visuo-feedback of the action potentials, the subjects kept both MUs discharging steadily within a range of 4 to 12 imp./s. The MUs were characterized by their contraction times and their recruitment thresholds. The temporal relationships between the MUs discharges were analyzed by cross-correlation. Short-term synchronizations likely to involve common inputs were revealed by the presence of narrow central peaks in the cross-correlation histograms.

Among the population of MU pairs (47%) which presented significant short-term synchronization, 70% included two MUs with rather slow contraction times and low recruitment thresholds and 30% included one or two MUs with faster contraction times and higher recruitment thresholds.

The influence of cutaneous inputs on the short-term synchronization of the Extensor carpi radialis MUs was determined by comparing the cross-correlation histograms obtained during voluntary contraction with or without superfical cutaneous stimulation above the recorded muscle.

Reversible significant changes were observed for more than 65% of the tested MU pairs. Reductions of short-term synchronisation were predominant for the pairs with slow contraction times and low recruitment thresholds, while reductions or increases occurred equally for the pairs with fast contraction times and high recruitment thresholds.

No relation was observed between the opposite effects induced by cutaneous stimulations and the frequency of discharge of the MUs.

HANDEDNESS, PRACTICE ORDER, AND ASSIMILATION EFFECTS IN RAPID BIMANUAL MOVEMENT. D.E. Sherwood, Motor Behavior Lab., Department of Kinesiology, University of Colorado, Boulder, CO 80309.

When subjects make rapid bimanual aiming movements over different distances, assimilation effects are typically shown as overshoots in the shorter-distance limb. The effect of practice order and handededness on assimilation effects were assessed by giving 60 right-handed and 32 left-handed male and female subjects practice on 20° (Short) and 60° (Long) reversal movements first separately, then together. Subjects were randomly assigned to a practice order of either Short-long or Long-short and peformed the Short and Long movements in either the left or right hand. For all subjects, overshooting was shown on the dual trials in the shorter-distance limb, showing assimilation effects. Assimilation effects were greatest when the Long movement was practiced just prior to the dual trials, showing practice order effects. Also right-handed subjects showed greater assimilation effects in the non-dominant limb, relative to the left-handed subjects. The findings suggest that assimilations effects can be influenced by practice variables.

COORDINATION OF INDEX FINGER MOVEMENTS. W.G. Darling, G.F. Miller, K.J. Cole. Dept. of Exercise Science, University of Iowa, Iowa City, IA 52242.

The EMG and kinematic patterns of index finger motions involving all 3 joints (metacarpophalangeal - MCP, proximal and distal interphalangeal - PIP, DIP) have received little quantitative study. Previously, kinematics and EMGs (of 4 muscles) of two joint (MCP, PIP) index finger motions were investigated (Darling and Cole 1990 - J Neurophys, 63, 1098-1108). In this report we have studied EMG patterns in all index finger muscles during various motions to examine coordination of index finger motion and posture.

EMGs were recorded using hooked wires inserted into 6 or 7 index finger muscles (extensor indicis EMG was not always recorded). Movements were recorded opto-electronically with infrared emitting diodes placed over the base of the 2nd metacarpal and the centers of the 3 finger joints. Subjects performed 6 types of discrete motions involving: flexion or extension of all joints, flexion or extension at the MCP joint while the interphalangeal IP joints were voluntarily held in flexion, and flexion or extension at the PIP and DIP joints while the MCP joint was voluntary held in flexion. Analysis of velocity profiles showed that there is coupling of PIP and DIP motions during flexion or extension of these joints. The EMG data show: (1) maintenance of flexed MP or interphalangeal joint angles while moving the other joints requires coactivation of several muscles, suggesting that joint stiffness is increased to compensate for dynamic interaction torques and (2) synergist muscle activities are coordinated differently according to the task, and exhibit higher correlations when acting as agonists than as antagonists.

ALTERATIONS IN THE BEHAVIOR OF HIGH-THRESHOLD MOTOR UNITS IN A HUMAN HAND MUSCLE OF OLDER SUBJECTS.
R. M. Enoka, P. M. Barreto* and A. J. Fuglevand. Depts. Exercise & Sport Sciences and Physiology, Univ. Arizona, Tuscon, AZ 85721.

Senescence can be characterized by a decline in the number of motor units in a muscle and, through reinnervation, an increase in the innervation ratio for some motor units. The purpose was to determine if these changes influence the behavior of high-threshold motor units. Seventeen healthy subjects (64-79 years) volunteered for the study. We measure the abduction force exerted by the left index finger. A fine wire bipolar electrode was inserted subcutaneously over the first dorsal interosseous (FDI) muscle and used to measure the potentials of 1-3 motor units. Subjects were instructed to grade the isometic force to various levels (5-100% MVC) and to sustain the force briefly (3-20 s) or to the endurance limit. The presence of action potentials with large amplitude (4 mV) and polyphasic shapes indicated that there had been some motor unit reorganization with age. These changes were accompanied, in some subjects, by altered features of behavior among high-threshold motor units: (1) a reduced ability to smoothly grade force at moderate-to-high force levels; (2) altered recruitment patterns; (3) an increase in the upper limit of recruitment. Despite these changes in high-threshold motor units, neither the MVC (32±8 vs 29±9 N) nor the endurance time of FDI at a sustained target force of 35% MVC (196±86 vs 227±103 s) was statistically different for old (n=17) and young (n=53) subjects, respectively. Although we found age-related changes in the behavior of high-threshold motor units in FDI, the functional significance of these adaptations is unknown.

FIRST REACHES IN HUMAN INFANTS: A KINEMATIC, KINETIC, AND EMG ANALYSIS. E. Thelen, D. Corbetta*, J. Konczak*, K. Kamm*, K. Schneider*, & R.L. Zernicke, Dept. of Psychology, Indiana University, Bloomington, IN 47405.

All normal infants learn to reach, but the processes by which they acquire control over early, undirected arm movements are not known. Here we report on a longitudinal study of 4 normal infants, followed weekly from week 3 as they reached for a toy. We collected 3-D coordinate data from the shoulder, wrist, elbow, and hand of each arm using WATSMART, and used these data to generate kinematic and kinetic descriptions (Schneider, et al 1990). We also collected EMG signals from arm extensors and flexors and two postural muscles.

Infants reached successfully at 12, 15, 22, and 22 weeks. The two earlier reachers produced rapid swipes at the toy embedded in ongoing movements. They damped motion-dependent forces by stiffening through co-contraction. The two later reachers had fewer undirected movements, which generated low motion-dependent torques. They used muscles to counteract gravity.

Reaches were assembled within an ongoing movement context, which differed among the infants. Since all infants were proficient reachers at 6 months, different developmental pathways may lead to similar functional outcomes.

THE RELATIONSHIP BETWEEN SPATIAL PATTERNS OF MUSCLE ACTIVATION AND THE INTRINSIC MECHANICS OF THE ELBOW JOINT.
R.F. Beer, J.P.A. Dewald, T.S. Buchanan and W.Z. Rymer, Depts. of Biomedical Eng. and Physiology, Northwestern University, Chicago, IL 60611.

A functional relationship exists between the intrinsic joint biomechanics provided by passive tissues and the muscle activation patterns dictated by the CNS. This relationship can theoretically be quite simple—the CNS may activate muscles to provide the required torque(s) about the joint axis(es) of rotation while allowing passive tissues to equilibrate torque components in other directions. Alternatively, muscle activation patterns may reflect a strategy designed to reduce passive tissue loading. In this study we have investigated the relationship between activation of the primary elbow musculature and the intrinsic mechanics of the elbow joint.

EMGs were recorded from the muscles of the elbow using surface and intramuscular electrodes while subjects isometrically generated force against a 3-DOF load cell (flexion/extension, varus/valgus, and pronation/supination) located distally on the forearm. In the first set of experiments EMGs were recorded for eight levels of flexion/extension torque ranging from 5-40% of MVC. In a second set of experiments, torque magnitude was maintained constant while the direction of loading was varied over a full range of 360° in the flexion/extension-varus/valgus plane in increments of 15°. Pronation/supination torque was zero in all experiments. The arm was fixed at 90° elbow flexion, neutral forearm position and 90° shoulder abduction.

Although a number of elbow muscles have moment arms about the varus-valgus axis, polar plots of muscle EMG activity as a function of load direction were well predicted using the flexion/extension component of each torque and the torque-EMG relationship established in the first set of experiments. For muscles with linear torque-EMG relationships the polar plots were well fitted by a cosine function with a peak orientation in the flexion-extension direction rather than the muscle's direction of maximum mechanical advantage. These results suggest that for static loads of low to intermediate magnitude the activation of motor nuclei serving the elbow was not modulated to assist the passive tissues in equilibrating varus-valgus torques and argue against significant input to these nuclei from passive tissue (e.g. ligament) based sensory receptors under the stated conditions.

TRUNK MUSCLE ACTIVITY DURING VERTICAL PLANE RAPID ARM MOVEMENTS WHILE SITTING. A. E. Tyler and Z. Hasan. Dept. of Physiology, Univ. of Arizona, Tucson, AZ 85724.

Arm movements are known to be associated with postural adjustments in standing subjects. We have examined in sitting subjects the EMG activity of trunk muscles (paraspinals and abdominals on the right side) to determine the relationship of initial trunk muscle activity to arm movement parameters. Subjects performed a variety of rapid movements of the right arm in a parasagittal plane.

Preliminary data showed distinct and consistent EMG bursts in trunk muscles for all arm movements, with trunk and shoulder muscle onsets approximately synchronous. When the arm was moved downward (from hand above the shoulder to hand in front of the shoulder), the initial trunk muscle activity was consistently abdominal. There was increased paraspinal activity toward the end of the movement to accommodate the forward displacement of the body's center of gravity (CG). For upward arm movements (from hand at side to hand in front of the shoulder), the trunk muscle initially activated depended on whether the target position was within arm's reach or required that the trunk move forward, even though in both cases the CG moved forward. We conclude that the muscle activity pattern chosen by the nervous system to initiate a given arm movement is not determined by the requirements for equilibrium against gravity at the final position.

RAT SKILLED REACHING: MOVEMENT COMPONENTS AND NEOCORTICAL ORGANIZATION Ian Q. Whishaw, Boguslaw P. Gorny* and Sergio M. Pellis, Department of Psychology, University of Lethbridge, Lethbridge, Alberta, Canada, T1K 3M4

Rats are skilled at reaching for and grasping food objects using one limb. The movement can be divided into a subcomponents. Food is localized using olfaction. Using movements of the upper arm, a limb is the lifted and aimed at the food, transported to the food, and the paw is pronated over the food. The digits are opened during the transport phase and are closed after palm contact initiates the retraction phase of the reach. During retraction, the paw is supinated at the wrist in two 90^{o} movements, one occurs during retraction and one after retraction, to present the food to the mouth. Some of these movements can be disrupted by neocortical motor cortex area damage but whole body movements can be used to substitute for the missing reaching movements. On the basis of the behavioral results, cortical anatomy, and cortical electrophysiology, it is suggested that the different components of reaching have partially independent cortical representations. It is also proposed that the similarity of some of the components or rat reaching to human reaching argue for parallel development or homology.

THE EFFECTS OF PREDICTABILITY ON THE INITIATION OF REACHING TO A MOVING TARGET. P. van Donkelaar *, R.S. Gellman, and R.G. Lee. Dept. of Clinical Neurosciences, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Normal human subjects were required to either track a moving target with their extended index finger or reach out and intercept a moving target. In each case, target velocity was either predictable or unpredictable from trial to trial. The position of the index finger was monitored using a WATSMART system. In the tracking task, when target velocity was unpredictable, the movement velocity traces superimposed during the first 50-60 msec. This superimposition was not present when target velocity was predictable. In the interception task, the initial trajectories overlapped for a similar duration when target velocity was unpredictable, but diverged much sooner in the predictable condition.

In both tasks, the initial latency increased as target velocity decreased, suggesting a threshold mechanism for the detection of target motion. Regression analysis (of latency *vs* 1/velocity) revealed that the minimal processing time, as determined by the y-intercept, was greater in the interception task than in the tracking task. Thus, in the interception task planning the appropriate movement took longer than in the tracking task. These results coincide with what has been found for smooth pursuit eye movements, suggesting that the nervous system uses similar strategies to control the initiation of both eye and the limb movements.

MOTOR UNIT ACTIVITY DURING FATIGUING HUMAN ARM MOVEMENTS. S.J. Garland, T. Ohtsuki*, J.D. Cooke. Departments of Physical Therapy and Physiology, University of Western Ontario, London, Canada, N6G 1H1

During sustained, submaximal, isometric contractions, motor units (MUs) in human biceps brachii muscle exhibited a diversity of discharge patterns (Garland et al, 1989). The present experiments were performed to determine if MUs have similar patterns during fatiguing elbow movements.

Subjects performed 100 flexion-extension elbow movements (40°, 0.6 s), utilizing a symmetrical phase-plane tracking paradigm. A constant torque of 2 Nm. opposing extension was applied to the handle moved by the subject. MU activity was recorded from the lateral head of triceps using a branched bipolar fine wire electrode inserted subcutaneously overlying the muscle fascia.

During extension, MUs were phasically active at movement onset and tonically active at the end of the movements. The activity of MUs, which were strongly active in early trials, remained unchanged or decreased with fatigue. Other MUs, which were rarely recruited in early trials, became more active with fatigue. A given MU could be phasically active at movement onset even if its tonic activity was reduced during fatigue. Since the movement performance remained constant despite fatigue, our data suggest that the performance was preserved by the recruitment of additional MUs. These data concur with MU data from fatiguing, sustained, isometric contractions.

DEPENDENCE OF MOTOR UNIT FIRING ON ACCELERATION - DECELERATION CHARACTERISTICS OF HUMAN ARM MOVEMENTS. J.D.Cooke, T.Ohtsuki*, J.Garland. Depts. of Physiology and Physical Therapy, University of Western Ontario, London, Ontario, Canada N6A 5C1

Recent studies have shown that surface electromyographic (EMG) activity is related to the acceleration - deceleration characteristics (ADCs) of the desired movement. We have recorded from single motor units (SMUs) in humans performing movements with specified ADCs.

SMU activity was recorded from the lateral head of the triceps muscle using branched, bipolar fine wire electrodes inserted subcutaneously over the muscle fascia. Utilizing phase plane tracking, subjects made flexion-extension movements about the elbow in which the durations and magnitudes of acceleration and deceleration were varied systematically.

Depending on movement ADCs, a given triceps MU could be phasically active during either or both acceleration and deceleration in extension movements and during deceleration in flexion movements. In extension movements a given MU's activity could be switched from movement initiation to movement termination by altering acceleration and deceleration magnitudes. If, however, the mean acceleration magnitude was constant, any active MU continued to be active for all acceleration durations tested. There was no evidence that changes in the duration of surface EMG bursts were produced by recruitment of new MUs late in the burst period. Rather the duration of MU firing varied with the acceleration and deceleration durations.

A given motor unit can thus be active both when its muscle is acting as an agonist and as an antagonist. When and whether the unit is active depends on the desired acceleration and deceleration characteristics of the movement.

LOSS OF PROPRIOCEPTION PRODUCES DEFICITS IN INTERJOINT COORDINATION. R.L. Sainburg*, H. Poizner, Center for Molecular and Behavioral Neuroscience - Rutgers University, Newark, NJ, 07120. C. Ghez, Center for Neurobiology and Behavior, New York Psychiatric Institute, New York, NY 10032.

Specific large fiber sensory neuropathies (LFSN) produce severe disorders of posture and movement. Recent studies (Neurosci. Abst. 14: 953) have revealed large direction-dependent *spatial errors* in the feedforward control of multijoint movement. Proprioceptive information about the limb was shown to be necessary to compensate for directional variances in inertia that arise because of its multiple degrees of freedom (Neurosci. Abst. 16:1089). In the present study we asked whether proprioceptive input is also necessary for the *temporal coordination* of joint motions since motion at individual limb segments may produce torques at other segments. We studied the trajectories of repetitive "slicing" gestures made by a 43 y/o woman with LFSN and by 9 normal controls. Hand, wrist, elbow and shoulder points were digitized using a WATSMART system. The patient was unable to maintain the normal linearity and planarity of individual or successive movement cycles and the velocities at the different joints were temporally decoupled. A large anomalous velocity disruption at the wrist occurred at the end of shoulder flexion before shoulder extension when the inertial resistance to ongoing motion is maximal. This error resulted from a lack of synchronization of shoulder and elbow joint motions. It reflected an interaction torque at the elbow which was not adequately compensated by active muscle contraction. The anomalous forearm deflection was velocity dependent, increased with added mass and decreased when the subject could visualize her arm during movement. We conclude that in multijoint movements, proprioceptive input is critical to assure the temporal coordination of muscle commands needed to counteract or to efficiently utilize movement-dependent torques.

553.14

ORGANISATION OF CUTANEOUS FACILITATION OF HAND MUSCLE RESPONSES TO TRANSCRANIAL MAGNETIC STIMULATION. P.H. Ellaway, N.J. Davey*, D.W. Maskill*, and P. Romaiguere*. Dept. of Physiology, Charing Cross and Westminster Med. Sch., London W6 8RF, U.K.

Changes in motoneurone excitability and reflex responses to cutaneous stimulation depend critically on the location of skin stimulation. We have examined the effect of cutaneous stimulation on the response of adductor pollicis (AP), first dorsal interosseus (FDI) and abductor digiti minimi (ADM) muscles to transcranial magnetic stimulation (TMS) of the brain. EMG activity was recorded using surface electrodes. The motor cortex was stimulated using a Novametrix Magstim 200 with a 9 cm coil, centred at the vertex, at a strength just suprathreshold for a response in the relaxed muscle, in the absence of cutaneous stimulation. The EMG responses were rectified and the average voltage calculated. Mechanical stimulation of the skin, using a stiff brush, elicited facilitation of TMS responses in 9 of 11 normal subjects (aged 22-64 yrs). Brushing alone elicited no EMG activity. The degree of facilitation was dependent on the site of cutaneous stimulation. Facilitation of muscles was particularly strong (up to 450% in AP) from skin overlying the metacarpo-phalangeal and carpo-metacarpal joints. Brushing the palmar and dorsal surfaces of the little finger strongly facilitated the ADM response to TMS.

Electrical stimulation of digital nerves up to 5 times perceptual threshold, as reported by Day et al., (J. Physiol. 399:68P, 1988), could inhibit responses to TMS. In the same subjects brushing the skin produced facilitation of TMS responses but not inhibition.

We conclude that stimulation of the skin overlying joints associated with the action of a certain muscle is particularly efficacious in facilitating the response of that muscle to TMS.

553.15

CHARACTERISTICS OF HAND PATH CURVATURE FOR PLANAR, MULTIJOINT ARM MOVEMENTS. C.M. Karst, Department of Therapeutic Science, University of Wisconsin-Madison, Madison, WI 53706.

There are conflicting reports in the literature regarding the kinematic characteristics of the hand paths associated with multijoint reaching movements. The aims of this study were to: (1) better characterize the kinematic details of the hand path for a wide variety of planar reaching movements; and (2) attempt to relate those characteristics to the muscle activation patterns responsible for the movements.

Normal, adult subjects performed self-paced reaching movements in 12 different directions and from different initial limb configurations. Kinematic data were obtained using a WATSMART motion analysis system, and EMG activity was recorded from shoulder and elbow muscles involved in the movements. Hand paths were characterized by the direction and extent of the major curvature and by the number and location of inflections. These kinematic characteristics were found to vary in a consistent manner relative to the initial limb configuration and the spatial direction of movement. These direction-dependent variations in hand path characteristics were then studied in relation to initial muscle activation patterns. Changes in the direction of curvature appeared to be associated with qualitative changes in the EMG pattern (e.g. the switch from initial flexor activity to initial extensor activity at one joint), while changes in the extent of curvature and the location of inflection points were associated with variations in the relative timing and magnitude of the initial EMG activity at the shoulder and elbow.

553.16

ARM AND TRUNK SYNERGIES IN POINTING MOVEMENTS IN NORMAL SUBJECTS AND PATIENTS WITH CEREBELLAR DEFICITS. A.M. Iannone, M. Hallett, S. Stanhope* R. Vail*. Human Motor Control Section, NINDS, Bethesda and MCO, Toledo.

The coordination of unconstrained multijoint movement in three dimensional space is a difficult task and one that gives patients with cerebellar deficits particular difficulty. We studied the kinematics of one such movement and compared the performance of patients with that of normals. Subjects sat on a chair and rested their right arms on a table in front of them. Pointing movements were made to targets at shoulder height and distances that were 80%, 100% and 120% of arm length. Movements were made at freely chosen "fast" and "slow" speeds. Anterior-posterior movements of the trunk and angles of the shoulder and elbow were measured using the Vicon System.

The movements of the different body parts was consistent in each individual for each task, but clearly changed with movements of different distance. For example, the trunk movement was backwards for the short distance, minimal for the middle distance and forward for the long distance. Movements of the trunk, shoulder and elbow were simultaneous and were coordinated to produce a nearly linear trajectory of the finger to the target. While the patients usually showed normal simultaneous movements of the different body segments, the coordination was impaired resulting in misdirected, multisegmented trajectories. These trajectories showed variable errors in the ratio of forward and vertical movement needed for a smooth trajectory. In particular the movement of the trunk in the long distance movement was abnormal because it moved twice the distance of normal subjects. The reason for this is not clear.

The coordination of these multijoint movements is characterized by similar time course of the individual components. Patients with cerebellar deficits are abnormal not because of timing errors, but by virtue of inaccurate component movements.

553.17

EFFECTS OF STATIC TORQUE LOAD ON POSTURAL ACTIVITY ASSOCIATED WITH RAPID WRIST MOVEMENT AND ARM HOLDING IN MAN. F. Aoki Department of Rehabilitation Research, Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo 173.

Effects of static torque loading on phasic postural activity associated with rapid wrist movement were examined and compared with effects on tonic postural activity during arm holding. Subjects, holding their arm in a horizontal plane with the forearm supinate, made a rapid wrist flexion in response to a tone signal. Motor tasks were executed in 6 conditions, involving combinations of 3 loads to the wrist (flexor load, extensor load or no load) and two modes of support to the forearm (with or without support). Phasic activities of the forearm and upper arm muscles related to the rapid wrist flexion and tonic activities related to the arm holding were compared with respect to the load and support effects. The tonic activities of both the forearm and upper arm muscles during the arm holding were influenced by the load condition, and activities of the upper arm muscles were affected by the support condition. In contrast to the tonic activities, the phasic activities of the forearm and upper arm muscles related to the rapid wrist flexion were not affected by the load or support condition. These results suggest that tonic postural activities are influenced by static load condition, including the state of support, but phasic postural activities associated with rapid movement are controlled independently of static torque condition.

OPTIMAL ARM MOVEMENTS. M.Dornay, M.Kawato, Y.Uno* and R.Suzuki*. Cognitive Processes Dept. ATR, Kyoto 619-02 Japan and Dept. of Mathematical Engineering, Tokyo University, Tokyo, 113 Japan.

In order to control a voluntary hand movement, the CNS must determine: (**A**) which trajectory (hand path and velocity) should be used while moving the hand. (**B**) What motor commands should the muscles receive to specify each intermediate state of the hand while it is moving. Two main antagonistic approaches have been proposed to explain the control strategies used by the CNS: The *minimum-jerk model (MJM)* proposes a solution only to the trajectory determination problem (problem **A**). An antagonistic approach, the *minimum-torque-change model*, takes into account the structure and dynamics of the arm and predicts simultaneously both the hand trajectory and the joint torques. Both models were criticized for their inability to reproduce some experimental arm movement (Uno et al. 1989; Flash 1990). However, Uno et al. (1989) found that the *minimum-muscle-tension-change model* reproduced human trajectory data quite well based on a simple 2-link 6-muscle model.

The following study is based on our belief that the structure and dynamics of the arm must play a role in the determination of hand trajectory. A detailed dynamic model of the rhesus monkey's arm is used to investigate the possibility that minimizing the rate of change of: A) motor commands to the muscles, B) torque created by each muscle, C) tension created by each muscle, D) potential energy stored by each muscle, during a planar movement in front of the body, can produce by itself realistic trajectories. As a preliminary stage, the *MJM* is utilized for trajectory determinations (problem **A**), and a dynamic local minimization approach is used for motor command determination (problem **B**). Initial trajectories with 100 intermediate cartesian points simulated entirely by the *MJM* are compared to trajectories in which 50 intermediate points are simulated by the *MJM* and 50 intermediate points are predicted by a dynamic optimization approach. Since the *MJM* has good prediction abilities for the tested movements, the results give a hint which of the above dynamic strategies is a good candidate for being utilized by the CNS.

553.19

THE EFFECTS OF TARGET VELOCITY ON HUMAN PREHENSION. H. Carnahan. Dept. of Physical Therapy, Elborn College, University of Western Ontario, London, Ontario, Canada, N6G 1H1.

The purpose of this study was to examine how the kinematic characteristics of the reach and grasp are influenced when individuals reach towards moving targets of various velocities. Subjects were required to reach towards, grasp, and pick up a small object which rolled down a ramp that was aligned directly along the subject's midline. Movements of the wrist, index finger and thumb were monitored with the WATSMART system. Results showed that movement time and time to peak velocity decreased as target velocity increased. As well, peak velocity of the transporting limb increased as target velocity increased, however, at the slowest target speed, peak velocity was actually lower than the peak velocity in the stationary control condition. These results demonstrate that the movement kinematics of the target strongly influence the movement kinematics of the subject's limb. Target movement however, had no influence on the size of peak aperture suggesting that control of aperture may be a "higher order" control variable. (Supported by NSERC).

OVERSHOOT IN THREE-DIMENSIONAL POINTING MOVEMENTS. O. Fookson, M. Berkinblit*, S. Adomovich*, and H. Poizner, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102, Academy of Sciences, Moscow.

Pointing movements were executed by right-handed normal subjects with their eyes closed using their right index finger or a pointer 30 cm in length. Most of the movements were executed from an initial position in which the upper arm was vertical and the elbow strongly flexed, so that the index finger was close to the shoulder joint. A programmable robot arm was used to position 10 targets in 3D space. The movements of the subjects and the robot arm were digitized in 3D with a Watsmart system, and analyzed numerically and graphically. The subject had to begin the movement immediately after closing his eyes and was instructed to touch the target on the tip of the robot's arm during a restricted period of time. Since there was no instruction for the subject to come to the target with a zero velocity, overshooting of targets often occurred. The radial "error" was larger when the distance from the shoulder to the target was longer. However, the distance in 3D space between the target and the final position of the tip of the finger or pointer (3D "error") was found to depend upon the target's location. The 3D "error" could be larger when the target was closer, and shorter when the target was more distant. Finally, for one of the subjects, a 5 sec. delay was introduced between the time the subject closed his eyes and the sound signal to move was given. This delay caused no essential decrease in the movement's efficiency. The possible mechanisms of the observed overshoot in pointing movements will be discused with respect to dynamic regulation of limb posture.

553.21

ARE THERE DIFFERENCES IN POSTURAL SUPPORT STRATEGIES FOR SIMPLE BALANCE TASKS VS TASKS REQUIRING PRECISE HAND STABILIZATION? H. Sveistrup*, J.Massion*, S. Moore, M.H. Hu* and M. Woollacott. University of Oregon, Eugene, OR 97403.

During normal behavior, we are faced with situations in which we must regulate the position of an object in space, eg, when standing and holding a cup of water. When stance disturbances occurs in this situation, the hand position in space is kept within narrow limits to avoid spilling the water. This constraint is required in spite of postural displacements of the body occurring at the same time. Thus a conflicting situation occurs between the two goals of balancing and holding the cup steady. Experiments were designed to determine at what level control strategies change when subjects balance under these conditions. Balance was perturbed by moving the platform on which subjects stood. Instructions were to 1) hold the fingertip steady in space using visual (EOP) or tactile (ECT) cues, 2) hold a cup of water on a tray with no spills (EOTr), or 3) hold the above forearm/arm position but keep the elbow angle stable (EOH, control condition). Both leg, trunk and arm EMG's and body segment positions were recorded. For EOP and ECT conditions, horizontal hand displacement was reduced to 20% of EOH values (4mm vs 20mm), while for EOTr it was reduced less (65% of EOH). However, the movement velocity was slower in EOTr than in EOH conditions. Control of hand position in space was related to a reduced shoulder displacement and to a shortening of the hand-shoulder distance. No clear-cut stiffness change at the ankle joint was noticed prior to disturbance onset but some uncoupling between arm and trunk was suggested by the fact that displacement of hand and elbow markers starts earlier under EOP, ECT and EOTr (see Droulez & Berthoz, 1986). There were no significant changes in the latency or amplitude of EMG responses in leg/trunk muscles across conditions. However minor changes were observed in those of the shoulder and arm.

Results indicate that accurate control of hand position in space during stance disturbance is the result of multilink adjustments involving arm and shoulder which occur without detectable changes in muscle responses of the leg/trunk.

A MODEL OF HUMAN TARGET-DIRECTED HORIZONTAL ARM MOVEMENT J.R. Flanagan, A.G. Feldman and D.J. Ostry. McGill University, Montréal, Canada, Institut de génie biomédical, Université de Montréal, Montréal, Canada.

Last year we presented experimental and simulated trajectories of rapid horizontal arm movements directed towards stationary and displaced visual targets. Simulations were generated with a biomechanical model of two-joint planar arm motion. The model, which is based on the equilibrium point hypothesis, assumes that (a) arm movements are planned in coordinates which specify the equilibrium position (EP) of the endpoint and (b) that the EP of the endpoint shifts at a constant rate towards the presently illuminated target. This year the model, which has been extended to include accurate muscle moment arms, is used to predict both kinematic and electromyographic (EMG) patterns. EMG activity was recorded from biceps, triceps, posterior deltoid, and pectoralis major and arm positions were recorded in 3-D with WATSMART. Movements of varying rate to both single- and double-step visual targets were examined. The results further support the hypothesis that horizontal reaching movements are planned in coordinates of the EP of the endpoint. Moreover, the findings suggest that movements of different speeds are achieved by shifting the EP of the endpoint at different rates. The model is used to examine the interaction between the rate of shift of the EP and the level of co-contraction, both of which are regulated by central commands. The issue of whether kinematic and EMG patterns of double-step movement trials can be predicted by the superposition of patterns of single-step movement trials is investigated.

SYSTEMATIC DIRECTIONAL ERRORS IN PLANAR ARM MOVEMENTS ARE REDUCED BY VISION OF THE ARM. M.F. Ghilardi*, J.Gordon, and C. Ghez. Ctr. for Neurobiol. & Behav., Prog. in Phys. Ther., Columbia Univ. and NYS Psych. Inst., New York, NY 10032.

We have previously shown that in targeted arm movements normal human subjects make systematic direction-dependent extent errors which result from incomplete compensation for variations in the inertial field of the arm. We now report 2 types of systematic errors in movement direction. Subjects moved a cursor from a central starting position to 24 equidistant radial targets on a horizontal digitizing tablet at shoulder level. Target and cursor positions were displayed on a computer screen; the screen cursor was blanked during movement. Starting hand position was varied in different blocks of trials. Vision of the arm was allowed in some blocks and prevented in others. All subjects showed *direction-dependent directional errors* manifest as systematic clockwise (CW)errors in certain directions and counter-clockwise (CCW) errors in others. These resulted in clustering of responses in 4-5 directions, most consistently along the axis of least inertia (orthogonal to the distal segment). These errors were superimposed on *direction-independent directional biases* that varied with the initial hand position. Mean constant errors were CW with initial hand position to the right of the body midline, near zero at the midline, and CCW to the left. These biases were large when subjects could not see their arms but significantly reduced when they viewed their arms during task performance. Direction-dependent errors represent inaccuracies in the specification of movement dynamics, since they vary with limb inertia. Direction-independent errors represent inaccuracies in the specification of joint kinematics as though the nervous system programs joint rotations assuming a midline starting position of the hand and neglecting proprioceptive information about limb orientation. Vision of the arm is needed to bring the intrinsic coordinate system into register with extrinsic coordinates of target location. (NS 22715)

553.24

MUSCLE ACTIVATION WAVEFORMS AND ARM MOVEMENTS IN THREE-DIMENSIONAL SPACE. M. Flanders. Dept. of Physiology, Univ. Minnesota, Minneapolis, MN 55455.

This study related the temporal waveforms of muscle activation to the direction or velocity of the movement of a human arm to targets in three-dimensional space. For the study of direction, targets in different directions were placed in the sagittal plane and the frontal plane, the initial arm position and movement amplitude were constant, and the velocity was moderate (movement time was about 500 ms). For the study of velocity, movement times varied between about 200-1000 ms. Statistical techniques were used to quantify temporal patterns of electromyographic (EMG) activity in 7-9 elbow and/or shoulder muscles. These techniques included a best covariance procedure to calculate temporal delays and a principal component analysis to view the shape of basic EMG waveforms.

The analysis revealed simple neural strategies for generating mechanically complex movements, e.g., basic EMG waveforms are scaled in amplitude and delayed in time to generate movements in different directions.

553.25

A MASS-SPRING MODEL OF TWO-JOINT ARM MOVEMENTS. Nicholas G. Hatsopoulos*, W. H. Warren, Jr.*, and J. A. Anderson. Dept. of Cog. and Ling. Sciences. Brown Univ., Prov. RI 02912.

The mass-spring model (Asatryan & Fel'dman, Biophizika 10) of limb control is extended to two-joint movements and tested against kinematic data from Morasso (Exp. Brain Res. 42). It incorporates a synergy discovered by Mussa Ivaldi (In P. Morasso & V. Tagliasco (Eds.), Hum. Mov. Understand.) which is manifested in a static hand stiffness field that is always oriented toward the shoulder regardless of the position of the hand in the workspace. Two versions of the model are compared. In the first version, the equilibrium position changes abruptly while the torque generated at the joints is gated with a rise-time function. In the second version, the equilibrium position is updated gradually as suggested by various researchers (Bizzi et al., J. Neurosc. 4). The model involves the numerical integration of the equations of motion of a two-joint arm with dissipative "springy" muscles. It is shown that the gradual shift in equilibrium version performs better in matching Morasso's kinematic data. Moreover, the model is able to qualitatively match variable-speed data collected by Atkeson and Hollerbach (J. Neurosc. 5). Finally, two target-switching hypotheses are tested and compared with actual data. The first hypothesis assumes that the first target command is terminated and replaced with the new target command. The second hypothesis states that the first and second target commands are added together vectorally (Flash et al., unpub. man.). The second hypothesis is shown to not only agree with human data as reported by Flash and her colleagues but also to form smoother paths and velocity profiles.

553.26

DISCRETE MOVEMENTS IN RESPONSE TO UNPREDICTABLE CONTINUOUS TARGETS IN HUMAN HAND TRACKING TASKS. F.E. Tendick* and L. Stark. Graduate Group in Bioengineering, University of California, San Francisco and Berkeley campuses, 481 Minor Hall, Berkeley, CA 94720.

Human subjects used a joystick to track an unpredictable two-dimensional target, presented on a CRT display, which had constant speed but varying direction. Subjects responded to the continuous target with brief discrete movements. These movements occurred as rapidly as one per 100 milliseconds, significantly shorter than the response delay. The fast movements consisted of velocity bursts which did not come to rest. These results indicate the possibility of significant parallelism in visual-motor processing. Also, motor programs can be initiated according to a feedforward estimate of position error, without benefit of visual feedback of error. Experiments with brief unpredictable pulse targets support these results.

553.27

COMBINED NEURAL NETWORK AND MATHEMATICAL LARYNGEAL MODEL FOR VOICE PRODUCTION CONTROL. G.R. Farley. Boys Town National Research Hospital, Omaha, NE 68131.

Control of the vocal tract during vocalization involves a complex set of CNS structures. Insight into the function of these structures might be enhanced by the interplay between theoretical models of their function and neural data obtained during vocal behavior. To advance this effort, a two stage model has been developed to control vocal fold tension, a parameter important to fundamental frequency control during vocalization. The first stage of the model is an artificial neural network whose input is the desired vocal fold tension and whose output is analogous to the neural activation of three intrinsic laryngeal muscles: the thyroarytenoid (TA) and the cricothyroid pars oblique (CTo) and rectus (CTr). The second stage of the model calculates from these activation levels the position of the thyroid cartilage relative to the cricoid cartilage, along with accompanying vocal fold tension and length. Network training minimizes the difference between desired and produced vocal fold tension using a genetic training algorithm. When trained, the model can generalize to produce graded vocal fold tensions across the entire available vocal fold tension range. However, different strategies of muscle control can be adopted during training to produce these tensions. Additional constraints now being studied may force the neural network to adopt control strategies limited to those actually used by vocalizing organisms. Nonetheless, the current study demonstrates the feasibility of developing such vocal control models for furthering knowledge of real CNS control systems. [Supported by NIH research grant NS-19624-06.]

INVERTEBRATE MOTOR FUNCTION II

554.1

DUAL INHIBITION OF THE CRAYFISH'S CLOSER MUSCLE BY THE STRETCHER AND COMMON INHIBITORS. T.J. Wiens. Dept. of Zoology, Univ. of Manitoba, Winnipeg, Canada R3T 2N2.

A study of the roles of inhibitory motoneurons in the control of the crayfish claw revealed that the stretcher inhibitor (SI) motoneuron, previously thought to inhibit only the stretcher muscle, also innervates many fibers of the closer muscle strongly and consistently; it does not inhibit any further claw muscles. The same applies to the SI's of the crayfish's walking legs. The claw's common inhibitor (CI) likewise routinely inhibits parts of the closer and stretcher muscles and all other cheliped muscles, with one exception: CI input to the claw's opener muscle could only be demonstrated in some 25% of the claws examined. The CI's of walking legs were confirmed to innervate all muscles including the opener. SI's and CI's unusual distributions may represent adaptations to the closer muscle's size advantage over the opener. The opener inhibitor (OI) was confirmed to innervate only the opener muscle.

SI's and CI's somata were identified intracellularly and stained in claw-ganglion preparations. Both somata lie near the midline, CI's being slightly contralateral and nearer the posterior end of the ganglion. Their form and function suggest homology between the three crayfish limb inhibitors and those of the locust (Watson et al. 1985).

I thank W.J. Heitler, St Andrews, for facilities.

Spiking activity of the common inhibitory motoneurone in crustacean leg. Synaptic connections with excitatory motoneurones and leg sensory afferences.
M. Bévengut* and F. Clarac. Laboratoire de Neurosciences Fonctionnelles, CNRS-LNF2, B.P. 71, 13402 Marseille Cedex 9, France.

The motoneuronal command of the leg muscles in crustacean is composed by excitatory motoneurones specific for each muscle and by a common inhibitory motoneurone (CI) which innervates every leg muscle. During rhythmic locomotory behaviors, such as swimming and walking, excitatory motoneurones display rhythmic bursts of spikes patterned to ensure coordinated muscle contractions while the CI motoneurone fires tonically with an increase of firing frequency at the end of the return stroke. Pre- and post-synaptic inhibition of CI at the neuromuscular junction are performed to suppress contraction of the slow muscle fibers and to speed up relaxation of the fast muscle fibers during leg movements. In isolated nervous preparations, central synaptic relations between excitatory and CI motoneurones are few and correspond to weak excitatory monosynaptic and/or weak inhibitory polysynaptic connections. However leg sense organ afferences have strong mono- and poly-synaptic connections with the CI motoneurone. These results suggest a separate central control of the spiking activity of the excitatory and the CI motoneurones and a specific peripheral control by the sense organs during locomotory behaviors.

554.3

INNERVATION OF THE SWIMMERETS OF CRAYFISH: A PAIR OF MODULAR PATTERN-GENERATING CIRCUITS IN EACH ABDOMINAL GANGLION. B. Mulloney, W.M. Hall*, C. M. Sherff, G. Braun-Weninger* and A. Chrachri*. Zoology and Neurobiology, Univ. California, Davis CA 95616 USA.

Each swimmeret on the abdomen of the crayfish, Pacifastacus leniusculus, is innervated exclusively through one of the paired first segmental nerves, N1, in its segment. Backfills revealed that each N1 contains axons of sixty eight swimmeret motor neurons, two non-spiking stretch receptors and many other sensory afferents. Cell bodies of these motor neurons were located ipsilateral to their axons; none were located in other ganglia. Every motor neuron had dendritic branches in the lateral neuropil. Unilateral nonspiking local interneurons that are components of the swimmeret pattern-generating circuit also have dendritic arbors restricted to the lateral neuropils.

These are anatomical features of a pattern-generating circuit within each half ganglion, a module of the swimmeret system. To test the ability of a module to function independently, we recorded from motor neurons on contralateral sides of one ganglion and activated the swimmeret system by perfusion with proctolin or proctolin plus TTX. With proctolin alone, membrane potentials of contralateral motor neurons oscillated precisely in phase. With proctolin plus TTX, the phases of their oscillations drifted, and bouts of oscillations occurred in one motor neuron when the other's membrane potential was constant. This uncoupling was reversible.

These results would be predicted if each abdominal ganglion contained a pair of modular pattern-generating circuits. Each module consists of all the motor neurons to one limb and all the pattern-generating unilateral local interneurons that synapse with them. A module generates the characteristic alternating bursts of impulses in antagonistic motor neurons. Each is capable of independent operation, but normally is constrained to operate in a coordinated manner.

NEURAL PATHWAYS UNDERLYING BEHAVIORAL PLASTICITY IN RESPONSE TO NERVE CORD TRANSECTION IN THE CRAYFISH. R. Glidden* and M.D. Kirk. Div. Biological Sciences, Univ. Missouri-Columbia, Columbia, MO 65211

Escape swimming in the crayfish consists of alternating extensions and flexions of the abdomen (tail). These movements are driven by nongiant fast extensor and fast flexor motoneurons of the abdomen and require an intact rostral nervous system (as shown by loss of swimming motor output following complete nerve cord transection below the subesophageal ganglion). However, as previously demonstrated (Lee and Wine, 1984), three to four weeks after nerve cord transection between the thorax and abdomen (a T-A cut), the abdominal fast flexor motoneurons and other nongiant motor elements again respond to sensory stimulation in a manner resembling nongiant escape swimming. This behavioral plasticity which is referred to here as hyperreflexia, occurs without regeneration across the transection. We investigated where within the chain of six abdominal ganglia these changes take place. For instance, are there important interganglionic interactions or can a single ganglion express hyperreflexia?

EMG recordings from posterior telson flexor muscles (PTFs) and behavioral observations were made following nerve cord transections at different levels within the abdomen. We found that hyperreflexia occurs in segments posterior to transections between the third and fourth ganglia, as well as between the fifth and sixth ganglia. The latter result indicates that a single abdominal ganglion (i.e., the sixth) is capable of expressing hyperreflexia. However, in T-A cut animals exhibiting hyperreflexia, a second cut between the fifth and sixth ganglia eliminated the response in the PTFs of the tailfan. Thus, intersegmental interactions are important under these conditions. Supported by the HHMI.

MRO POSTURAL REFLEXES IN LOBSTERS DEPEND UPON CENTRAL PROGRAM. S.C. Sukhdeo and C.H. Page. Dept. Biol. Sci. Rutgers Univ., Piscataway, NJ 08855.

Stretch stimulation of the abdominal muscle receptor organ (MRO) of the lobster, *Homarus americanus*, initiated spike discharge of its tonic sensory neuron (SR1). This sensory response evoked a series of reflex responses in the motor efferents of the superficial extensor and flexor muscles of the abdominal postural system. The type of motor response varied according to whether a flexion or extension pattern of spontaneous activity was generated by the postural efferents.

During spontaneous centrally-initiated flexion motor programs, SR1 discharge elicited an assistance response which included excitation of a medium size flexor excitor (f3) and the peripheral extensor inhibitor (e5), and inhibition of at least one extensor excitor. While during spontaneous centrally-initiated extension motor programs, SR1 spiking triggered a resistance response that included excitation of the extensor excitors and the flexor peripheral inhibitor (f5) only, f3 and e5 spontaneous activities were unchanged. Thus reflex reversal occurs between assistance (flexion) and resistance (extension) reflexes.

MORPHOLOGY OF GIANT AXONS AND THEIR TARGET NEURONS IN LOBSTERS. *P.M.Ma, Dept. Neurobiology, Harvard Medical School, Boston, MA 02115.* In lobsters and crayfish, serotonin and octopamine are neurohormones that modulate many behaviors, including escape tail-flips mediated by the medial (MG) and lateral (LG) giant axons in the ventral nerve cord. For example, serotonin decreases the excitability of giant axons by modulating their primary afferent inputs. To explore the possibility that amines also modulate escape behavior on the output side, studies were performed to examine the structure of giant axons and to locate and identify their target neurons. The giant axons of larval and juvenile lobsters were dye-injected and the branching patterns of the axons within each ganglion were analysed. Dye-coupled neurons were tentatively considered to be electrically coupled. MG axons originate in the brain and project, with few branches, to the caudal ganglion. Coupling between the pair of MG axons occurs in both the brain and the caudal ganglion. LG axons are a syncytium with contributions from neurons in each thoracic and abdominal ganglion. These axons extend through the entire nerve cord and are coupled in each thoracic and abdominal ganglion. Stereotyped dendritic processes are seen in each abdominal ganglion; processes are sparse in thoracic ganglia. A few phasic abdominal motoneurons are dye-coupled to the giant axons. The most heavily and consistently coupled neuron appears to be a swimmeret motoneuron since its axon can be traced to the 1st abdominal root. Identification and localization of these neurons should facilitate electrophysiological studies on the modulation of output of giant axons. (Supported by Harvard and NIH)

BIOTIN-STAINING IN THE LOBSTER GIANT-NEURON SYSTEM. *H. Schneider, P.M. Ma & E.A. Kravitz, Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115.*

The lateral (LG) and medial giant (MG) neurons in the lobster nervous system play well known roles in escape behavior. Anatomically, these cells are characterized by large-diameter axons extending through the entire length of the ventral nerve cord. We found that these cells also are characterized by a high endogenous content of the vitamin biotin.

Due to specific and high affinity binding of biotin to avidin, labelled avidin was used to visualize biotin in whole mounts of the lobster nerve cord. With this method a pair of large ventral midline cell bodies in the brain, and pairs of posterior lateral cell bodies were stained in each thoracic and abdominal ganglion. In double-label experiments Lucifer Yellow was injected into LG or MG axons before Texas Red coupled to streptavidin was applied. The results show clearly that the double-labelled cell bodies are those of the MG and LG neurons. Within the giant neurons biotin also was found on filamenteous structures in the LG and punctate structures in the MG axons.

Biotin is known to serve as a cofactor of 4 carboxylases involved with pathways of carbohydrate and fat metabolism. One or more of these enzymes, therefore, seem to be highly concentrated in the giant neurons. This might be important for the function of these highly specialized cells. (Supported by NINDS, Harvard and DFG Schn 368/1-1)

SIMULATION OF THE APLYSIA SIPHON WITHDRAWAL REFLEX CIRCUIT: SLOW COMPONENTS OF INTERNEURONAL SYNAPSES CONTRIBUTE TO THE MEDIATION OF REFLEX DURATION. W.N. Frost, L.G. Wu*, and J. Lieb*. Dept of Neurobiology and Anatomy, Univ of Texas Medical School, Houston, TX 77225.

While traditional electrophysiological approaches can yield detailed circuit diagrams for particular behaviors, it often remains difficult to discern the exact functional roles of the different circuit components. Such insights can, however, be achieved through the use of appropriately realistic circuit simulations. The Aplysia siphon withdrawal reflex has been a useful model system for studies of the cellular mechanisms underlying learning and memory. While circuit modifications related to learning have been identified, interpreting their behavioral significance would be helped by a better understanding of the functional roles of the different circuit components.

We have constructed a simulation of the siphon withdrawal circuit consisting of the LE sensory neurons, the L29, L30 and L34 interneurons, and the LFSa, LFSb, LBS and LDS motor neurons. Each neuron was modeled individually, using an integrate-and-fire scheme, from data collected on its intrinsic electrophysiological properties. Each synapse was modeled from intracellular recordings made of identified synaptic connections.

We are currently using this simulation to evaluate the circuit components responsible for the long lasting firing of the LFS siphon motor neurons which occurs in response to siphon stimulation. Our initial finding is that the slow portion of the two-component fast/slow L29-LFS epsp contributes significantly to LFS firing duration in this circuit. Since the L29 interneurons are strongly excited by siphon stimulation, this connection appears to have an important role in translating short bursts of activity in sensory neurons and the L29 interneurons into a long lasting behavioral response.

MECHANISMS OF BEHAVIORAL CHANGE INDUCED BY BAG CELL NEURONS ON RESPIRATORY MOTOR SYSTEMS IN *APLYSIA*. JLM Morgan, SH Ligman, PH Brownell. Dept of Zoology, Oregon St Univ, Corvallis, OR 97331

Impulse discharge in the bag cell neuroendocrine system of *Aplysia* is known to trigger complex changes in behavior related to onset of egg laying. While much is known about the synthesis, release and neuronal actions of bag cell transmitters, less is known about the behavioral expression of these effects. Several of the ganglion neurons affected by bag cells and their peptide transmitters are motor neurons innervating respiratory organs, the gill and siphon. We have systematically quantified the actions of bag cell activation (BCA) and bag cell peptides infused individually into the ganglionic vasculature. Our results show that BCA and bag cell peptides affected the tonic firing rate of gill and siphon motor neurons, but that no overt changes in tonus of the gill and siphon were associated with the modulated firing frequencies. For example, BCA generally increased the tonic firing rates of gill and siphon motor neurons (LB and LD cells) by 20 to 140 spikes/minute. Similarly, ganglionic infusion of 1-10 μM egg-laying hormone (ELH) tonically excited LD_{G1}, LB_G, and LB_a but did not increase the tonus of the respiratory organs. Likewise, infusion of α-bag cell peptide inhibited all gill and siphon motor neurons at different thresholds, but was not correlated with relaxation of the gill and siphon. However, both bag cell peptides and BCA affected the amplitude and frequency of respiratory pumping, a phasic contraction of the mantle organs mediated by a network of interneurons. These results suggest bag cell peptides act globally to modulate excitability of motor circuits, facilitating their responsiveness to coordinated synaptic inputs without directly influencing behavior of their target organs. (NIH NS18681, OR Heart Assoc. 80-962, Sigma XI).

SEROTONIN - SENSITIVE NEURONS IN THE PEDAL GANGLION OF *Pleurobranchaea californica* ARE SEROTONIN IMMUNOREACTIVE. Lee Sudlow and Rhanor Gillette. Dept. of Physiology and Biophysics, Univ. of Ill, Urbana, Ill. 61801.

Locomotion associated with the appetitive and aversive behaviors of the sea slug, *P. californica*, is governed by the pedal ganglion (PedG). We sought to identify the effector cells of the PedG involved in locomotion. Cobalt backfills of the pedal nerve labelled 11 somata at the medial lobe and numerous others at the anterior pole of the PedG. Many of these neurons are known to have a serotonin-activated cAMP-dependent Na^+ current ($I_{(cAMP\text{-}Na^+)}$; Huang & Gillette, Soc. Neurosci. Abs. 13:459, 1987). Single channel analysis of $I_{(cAMP\text{-}Na^+)}$ yielded an opening time constant of 2.27 ± 0.12 msec with a conductance of 40 pS. It was surprising to find that many of the neurons also exhibited serotonin immunoreactivity. Self-re-excitation of these serotonergic neurons in the PedG may contribute to the prolonged changes in the locomotory activity of the slug.

CHEMOSENSORY RESPONSE TO METAMORPHIC INDUCER ACTIVATES A CENTRAL PATTERN GENERATOR IN A LARVAL MOLLUSC. E.M. Leise and M.G. Hadfield*. Pacific Biomedical Research Center, Kewalo Marine Laboratory, University of Hawaii, Honolulu, HI 96813.

Planktic larvae of the sea slug Phestilla sibogae settle and metamorphose in response to a small (<500 dalton), water-soluble, organic molecule produced by their adult food source, the coral Porites compressa. Sensory receptor neurons in the larval epidermis are probably responsible for recognizing the inducer compound. We hypothesize that excitation of the putative chemoreceptor neurons triggers metamorphosis by activating controlling circuits in the larval CNS. The events of metamorphosis include relatively rapid phenomena, such as loss of the ciliated swimming organ and detachment of the larva from its shell, as well as sequential tissue rearrangements and cell movements. To test our assumptions we are studying the responses of the larval NS to the metamorphic inducer.

Experiments are conducted on 10 day-old metamorphically competent larvae. Extracellular and intracellular recordings are made in vivo from unanesthetized, deshelled and restrained larvae or from isolated larval heads in vitro. The tissue is bathed in filtered seawater (SW), SW containing the inducer compound (I-SW), or SW conditioned by exposure to non-inducing corals. I-SW elicits several alterations in the activity of the CNS and velum, the larval swimming organ. One to 2 mins after addition of I-SW, the frequency and duration of compound spikes indicative of velar ciliary arrests change. Spontaneous bursts of action potentials from smaller units become rhythmic (~0.5 Hz) after the preparation is exposed to the inducer for 1 to 2 hrs. Experiments on larvae with only the visceral hump removed suggest that the rhythmic bursts are associated with the stereotypical posture taken by larvae initiating metamorphosis.

Correlations of specific neural patterns and buccal muscle contractions with dynamic stages of the feeding cycle of Helisoma trivolvis. B.C. Arnett and A.D. Murphy Dept. of Biol. Sci., Univ. of Illinois at Chicago,Chicago, Il. 60680

Rhythmic feeding behavior in Helisoma is characterized by dynamic stages of protraction, retraction, and hyper-retraction of the feeding apparatus. This behavior is generated by a buccal pattern generator composed of three neuronal subunits (S1, S2 and S3). Each subunit is an independent oscillator but can be temporally linked to either one or two of the other subunits to produce a variety of motor patterns. The neuromodulators serotonin, dopamine, and GABA can reliably phase-lock the subunits to evoke particular neural patterns. In order to correlate these resulting neural patterns with consequent behaviors specific for each neuromodulator, I have simultaneously videotaped movements of the buccal mass and recorded intracellularly from identified buccal motoneurons that provide a monitor of the functional state of the pattern generator. The results are consistent with our hypotheses that: S1 activity mediates the protraction of the radula and odontophore cartilage and flattening of the buccal mass; S2 activity mediates retraction of these oral structures; and S3 activity results in the hyper-retraction of these structures. Supported by NIH R01 NS26145.

CHARACTERIZATION OF A FEEDING NEURON CONTAINING THE NEUROPEPTIDE APGWa IN THE POND SNAIL, LYMNAEA STAGNALIS. RP Croll[1], CR McCrohan[2]* and MW Baker[1]. [1]Dept. Physiol. Biophys. Dalhousie Univ.,Halifax, Canada B3H 4H7 and [2]Dept. Physiol.Sci.,Univ. Manchester, Manchester M13 9PT, UK.

The tetrapeptide, APGWa, has been localized in the CNS of several molluscs (Van Minnen et al, this volume). One neuron which exhibits APGWa-like immunoreactivity in Lymnaea is located on the ventral surface of each cerebral ganglion between the bases of the median and superior lip nerves. The cell sends a single axon into the ipsilateral cerebral-buccal connective and from there into the buccal ganglia where it produces numerous immunoreactive varicosities in the neuropile. We have recently identified a cell with similar location and anatomy which receives excitatory synaptic input and is active during the radula protraction phase of the feeding cycle. Sustained depolarization of this cell appears to inhibit feeding related activity in buccal neurons. The observation that APGWa is found primarily in neurons controlling male reproduction in Lymnaea suggests that the cell might help suppress feeding during mating.

SENSORIMOTOR INTEGRATION: MUSCLE II

555.1

INABILITY OF HUMANS TO FULLY ACTIVATE MUSCLE DURING SUSTAINED CONTRACTIONS AT DIFFERENT FORCE LEVELS. A.J. Fuglevand, K.M. Zackowski*, K.A. Huey*, and R.M. Enoka. Depts. Exercise & Sport Sciences and Physiology, Univ. Arizona, Tucson, AZ 85721

During a constant-force submaximal contraction, there is a gradual decline in the force capacity of active motor units. The nervous system, therefore, can increase motor unit recruitment and discharge rate in order to maintain the desired force. The purpose of this study was to examine changes in neural drive to muscle, as reflected in the surface EMG, during sustained contractions. Subjects (n = 32) were instructed to sustain an isometric abduction of the index finger to exhaustion at one of three force levels: 20%, 35%, or 65% of maximum voluntary contraction (MVC) force. Surface EMG and abduction force of first dorsal interosseous were monitored throughout the fatiguing task. Endurance times for the three force levels were significantly different from one another (534±195 s, 246±110 s, and 66±23 s for the 20, 35, and 65% MVC groups). The mean power frequency of EMG declined in parallel for all three groups, reaching a similar value at exhaustion (49.7, 42.6, and 44.7 percent of initial for 20, 35, and 65% groups). EMG amplitudes at exhaustion, expressed as a percent of MVC EMG, were 45.2, 54.4, and 81.0% for the 20, 35, and 65% MVC groups. These results suggest a force-level-dependent inability of the nervous system to fully activate muscle at exhaustion during sustained contractions. This incomplete activation parallels the decline in neuromuscular propagation observed during submaximal contractions (Fuglevand et al., *3rd IBRO World Congr. Abstr.*, in press).

555.2

INFLUENCE OF ELECTROMYOSTIMULATION (EMS) AND EXERCISE HISTORY ON VOLUNTARY FORCE IN MEN.

T. Hortobágyi, N.J. Lambert† and R.G. Israel. *Human Performance Laboratory and †Department of Physical Therapy, East Carolina University, Greenville, NC 27858.*

Prior reports have suggested that maximal voluntary isometric and lengthening forces may be neurally inhibited in sedentary men. We have examined the influence of activation and strength-training history on the force-velocity relationship in 6 strength-trained and 6 sedentary men, hypothesizing that EMS added to voluntary effort would not further enhance voluntary isometric, shortening, or lengthening forces in the trained men. Over four days, maximal isometric (MVC), tetanic, and shortening and lengthening constant angle isokinetic forces at 6 velocities were measured in the arm flexors under voluntary condition and with EMS (2.5 kHz sine wave, 50 burst·s^{-1}, 50% duty cycle) superimposed on the voluntary muscle actions. Trained men were 31% stronger than untrained controls ($P < .05$). Voluntary shortening forces decreased with increasing shortening velocities and were less than MVC in both groups ($P < .05$). EMS + voluntary forces never exceeded voluntary forces. The EMS + voluntary force-velocity curve was similar to the voluntary curve. Lengthening forces, as expected, exceeded MVC only in the trained men ($P < .05$). EMS + lengthening forces were also greater than EMS + MVC in untrained men ($P < .05$). These data suggest that a lack of neural inhibition may allow trained men to volitionally exert lengthening forces to a full capacity. However, it is inconclusive whether inhibition or other factors hamper untrained men to attain lengthening forces greater than MVC.

555.3

EFFECTS OF AGING ON THE ESTIMATED NUMBER OF FUNCTIONING HUMAN MOTOR UNITS. T.J. Doherty*, A.A. Vandervoort*, A.W. Taylor* and W.F. Brown. Faculty of Kinesiology and Dept of Clinical Neurological Sciences, University of Western Ontario, London, Ontario, Canada, N6A 3K7.

This study investigated the age associated loss of motor units in the biceps brachii-brachialis muscles and the resultant effect on force production.

The number of functioning motor units was estimated with the spike-triggered averaging technique (Brown et al, Muscle & Nerve, 11, 423-432, 1989) in 18 active older adults (age 68 +/- 5 yrs) and 15 active younger controls (29 +/- 5 yrs). The peak to peak amplitude of the compound muscle action potential (M-wave)was significantly lower in older subjects as compared to controls ($p < .001$) and the surface recorded single motor unit potential was significantly greater ($p < .05$). Therefore, as expected, older subjects had significantly fewer motor units (195 +/- 85) than controls (352 +/- 81) ($p < .001$) The electrically evoked isometric twitch contraction did not differ significantly between old and young subjects whereas the maximal voluntary contraction was significantly lower in the older subjects.

SYNAPTIC MECHANISMS UNDERLYING SHORT-TERM SYNCHRONIZATION IN HUMAN MOTONEURONS. K.S. Türker, T.S. Miles and M.A. Nordstrom, Department of Physiology, University of Adelaide, SA 5000, Australia.

During a steady, voluntary contraction, there is a small but significant tendency for active motor units to discharge synchronously, rather than completely randomly with respect to one another's activity. These synchronous occurrences are manifest as a central peak in the cross-correlation histogram of the spike trains of most pairs of active units. It has been suggested that this "short-term synchronization" is the result of common post-synaptic potentials from stem neurons that branch to innervate many motoneurons. We have used a new approach to investigate the synaptic events that are responsible for this synchronization. The spike trains of two concurrently-active motoneurons were recorded in human masseter or tibialis during a steady voluntary contraction. Synchronous occurrences of spikes were identified, and the durations of the interspike interval (ISI) preceding the synchronous spikes in both units were compared with random interspike intervals from the same spike train. In some units, the pre-synchronous ISIs were significantly shorter than randomly-selected ISIs from the same spike train. This strongly suggests that the nett synaptic effect which synchronized both units was excitatory. We conclude that the short-term synchronization manifest as a peak in the cross-correlogram is due to common, excitatory synaptic potentials whose amplitudes are significantly greater than those of the normal synaptic potentials that are driving the cell during tonic excitation.

ELECTROMYOGRAPHIC (EMG) AND RANGE OF MOTION (ROM) COMPARISONS BETWEEN STATIC STRETCHING AND PROPRIOCEPTIVE NEUROMUSCULAR FACILITATION (PNF) STRETCHING METHODS IN HUMANS. B.R. Etnyre and S. Overholt*. Human Performance Laboratory, Rice University, Houston, TX 77251

Static stretching and two common PNF techniques were compared for hip flexion ROM and the phasic and quantitative muscle activity of stretched femoral muscles. The stretching techniques for each of 15 subjects were: static stretch (SS), contract-relax (CR), and contract-relax-reversal (CRR). Hip flexion ROM was measured before and after stretching. EMG was recorded from the subject's rectus femoris and biceps femoris muscles. Unlike most previous studies, we precluded electrode "cross-talk" between antagonist muscles by establishing independence of activity of each muscle before testing. The EMG signals were integrated (IEMG) and peak spectral density was determined from fast Fourier transform (FFT) of each trial. All three stretching techniques yielded significant gain in hip flexion ROM compared with the initial condition, $F(3,27) = 9.05$, $p < .001$, (initial = 75°, SS = 82°, CR = 85°, CRR = 85°), with no significant differences was between stretching techniques. Over all stretching conditions only one subject demonstrated biceps femoris activity during stretching (CRR condition: IEMG = 90.6% of control, peak FFT = 67 Hz). Rectus femoris activity during the reversal stretching resulted in average IEMG over subjects of 25.8% and FFT = 50.4 Hz. Although the PNF methods resulted in the greatest gain in ROM they were not significantly different from the SS method. While controlling for cross-talk between electrodes of antagonist muscles, co-contraction between antagonist muscles during the reversal method was observed, but it was uncommon, contrary to results of previous studies.

EVIDENCE FOR FAILURE OF NEUROMUSCULAR TRANSMISSION IN THE NEWBORN DIAPHRAGM. A. R. Bazzy-Asaad, D. F. Donnelly, and G. G. Haddad, Dept. of Pediatrics, Section of Respiratory Medicine, Yale Univ. Sch. of Med., New Haven, CT 06510.

Although neuromuscular transmission (NMT) failure can contribute to diaphragmatic fatigue, it is not clear what its relative contribution is in the newborn as compared to the adult. To examine this question we studied NMT in-vitro in the rat phrenic nerve-hemidiaphragm preparation from animals ages 4-7d (n = 17) and adults (n = 10). Force was generated by the muscle by either stimulating it directly or indirectly via the phrenic nerve at frequencies ranging from 10-100 Hz for a brief period of 1 second. We found that, at a given frequency, the adult muscle generated the same level of force via either route of stimulation. In contrast, muscles from newborn rats generated less force when stimulated via the phrenic nerve than when stimulated directly at all frequencies used. In addition, at frequencies ≥ 40 Hz force generated indirectly could not be maintained during the one second stimulus and fell to about 50% of the peak value at a given frequency. To determine whether this loss of force was due to failure of some muscle fibers to respond to nerve stimulation, we recorded action potentials (AP) intracellularly from single muscle fibers in both age groups using flexible microelectrodes of resistance of 80-100MΩ filled with 3M KCl. We found that in 30% of the newborn fibers (n = 6), in response to a given stimulation frequency, fewer than the expected number of action potentials was recorded. In other cases (even within the same train), end-plate potentials or no change in membrane potential was found. In adult muscles, (n = 4) the expected number of APs was always found. We conclude that in the newborn diaphragm 1) NMT failure occurs in response to brief periods of stimulation over a wide range of frequencies and 2) this failure may be secondary to a decrease in release of neurotransmitter from the nerve terminals.

THE LENGTH-TENSION RELATIONS OF NINE DIFFERENT SKELETAL MUSCLES. M. Solomonow, R. Baratta, H. Gareis, R. Best, & R. D'Ambrosia. Bioengineering Laboratory, LSU Medical Center, New Orleans, LA 70112.

The length-tension relations of nine different muscles in the hind limb of the cat was determined with special emphasis on possible differences that may be function and architecture related. Electrical stimulation at tetanic rates was applied to the sciatic nerve while monitoring isometric force with an FT-10 transducer mounted on a crank operated platform.

Crank operation allowed the measurements of isometric forces from the muscle when completely collapsed (zero force) and up to maximal length when it ruptured. Data from each muscle was normalized with respect to its maximal active force and the length at which it occurred (optimal length). Data from all preparations of the same muscle were pooled and smoothed with a five point moving average.

The results show that the length-tension curves varied widely among the muscles. The FDL, MG, LG, and TP had a symmetric active force, whereas, the Soleus, EDL, PL, and PB had asymmetric active force. The TA had double peaked active force. The passive force started always just before the optimal length except for the Soleus, EDL, and LG in which there was passive force over the full length. The elongation range varied from ±15% to ±30% Lo in most muscle while the TA, PB, and PL had asymmetric range. It is concluded that different muscles have different length-tension relations reflecting their function and structure.

IN-SERIES COUPLING OF SPINDLE RECEPTORS. R. Delgado-Lezama*, E. J. Muñoz-Martínez, J. G. Raya*, R. Cueva-Rolón* and J. Aguilar-Linares*. Dept. Physiol., Biophys. & Neurosci. CINVESTAV-IPN. Apdo. Postal 14-740. 07000-México,D.F. MEXICO

Spindle discharges during muscle contraction (loading response; LR) and/or relaxation were investigated in the soleus of anaesthetized cats. Single Ia spikes were recorded in dorsal roots (L7-S1) filaments. Spindles location was found by pressing the muscle with von Frey hairs (12.5 mg). Perpendicular muscle vibration (250 Hz, variable intensity) was applied to spots 1 mm apart. Maximal sensitivity was restricted to a single spot. Ia fibers showing LR to nerve stimulation were located near either tendon but those showing typical unloading responses (UR) were located at the medial third of the muscle. Contraction of discrete muscle bands were produced by direct stimulation. UR and relaxation firing (RF) were found stimulating on the receptor but stimulating 2-4 cm away in the longitudinal direction, LR appeared and RF decreased or disappeared. Lateral stimulation only gave UR. Thus, spindles are coupled both in-series and in-parallel with extrafusal fibers.

BIOMECHANICAL ACTIONS OF MULTI-ARTICULAR MUSCLES IN THE CAT NECK. W.S. Selbie*, D.B. Thomson, and F.J.R. Richmond. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ont. K7L 3N6 CANADA.

Our goal is to describe biomechanical features of head movement in the cat. In an earlier study we determined that the centres of rotation in the sagittal plane were stationary for all cervical joints; thus, we can consider the cat neck to be a set of rigid segments linked by pin joints. In the present study we have added seven major neck extensors and flexors to our model and we have examined the effect of different postures on those muscle paths. The sites of attachments of these muscles were estimated by dissecting feline cadavers. Many muscles had broad origins that spanned several vertebrae and thus required several independent representations. Muscle paths were computed initially as a straight line from origin to insertion as suggested by the literature. The resultant muscle paths for some long muscles actually passed through the cervical column in some postures and thus required the addition of path constraints such as tethers and pulleys. Even a simple, short extensor such as rectus capitis posterior had a moment arm (at skull-C1) whose magnitude changed by more than a factor of three throughout the physiological range of motion. We are now attempting to determine the minimal path complexity necessary for adequate representation of sagittal plane motion so that eventual extension to three dimensions will be tractable.

FORCE-LENGTH RELATIONSHIP OF FELINE ANTERIOR SARTORIUS RESULTS FROM A COMPLEX INTERACTION OF PASSIVE AND ACTIVE CONTRACTILE ELEMENTS. S.H. Scott, D.B. Thomson, F.J.R. Richmond and G.E. Loeb. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ont. K7L 3N6 CANADA

In glycogen-depletion experiments we have shown that the proximally- and distally-directed nerve branches entering anterior sartorius supply asymmetrically distributed motor-unit territories. These territories are organized partly in parallel, partly in series. Force-length relations of anterior sartorius have now been examined by stimulating either the parent nerve bundle or the individual nerve branches supplying the muscle while the whole muscle was clamped at different lengths. When the proximally- or distally-directed nerve branch was stimulated, the end of the muscle closest to that branch actively shortened while the opposite end lengthened. The resulting force-length curves were not simply a scaled-down version of the force-length curve produced by stimulating the parent nerve bundle; at long whole-muscle lengths, force of the partially activated muscle was enhanced whereas at short whole-muscle lengths, it was diminished. The force-length relations suggested that a complex interaction of both passive and active elements contributed to total force. It remains to be confirmed whether selective recruitment occurs amongst the different subpopulations of motor units, as suggested by reflex studies of Sherrington (1910). The complex mechanics arising from recruitment of asymmetrically distributed motor units raises interesting problems for the neural control of this and possibly other long muscles.

MOTOR-UNIT DISTRIBUTION IN FELINE ANTERIOR SARTORIUS MUSCLE. E. Smits, M.J. Heron*, P.K. Rose, T.T. Gordon and F.J.R. Richmond. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ont. K7L 3N6 and Dept. of Pharmacology, University of Alberta, Edmonton, Alt. T6G 2E1 CANADA.

The success of functional electrical stimulation to reanimate paralyzed muscles will depend on the ability to position stimulating electrodes appropriately within target muscles. Long muscles such as gracilis and sartorius pose a particular challenge because of their complex architecture. Forces produced by their short, tapering, in-series fibers are exerted not onto tendon, but onto other fibers that may or may not be concurrently active. If individual muscle units are not distributed evenly along the length of the muscle, mechanical instabilities may arise. In this study, single motor-units were glycogen-depleted by stimulus trains delivered either intracellularly to motoneurons or extracellularly to single ventral-root axons. In all motor units studied so far (n=8), fibers were distributed asymmetrically, with a relatively high density at one end or in the middle of the muscle, decreasing or disappearing over the remaining length of the muscle. The muscle-unit territories were also confined laterally within long, relatively narrow strips comprising only a fraction of the muscle width. The implication from these studies is that multiple sites of stimulation may be required to ensure a synchronous and mechanically stable distribution of contractile forces in long muscles.

MECHANICAL CHARACTERISTICS OF THE FELINE ANKLE MUSCULATURE. R.P. Young, S.H. Scott and G.E. Loeb. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ont. K7L 3N6 CANADA.

The potential contribution of each muscle to the production of a given movement depends on the instantaneous magnitude and direction of its moment arm and the distribution of motion between its muscle fibers and series-elastic connective tissues. As is typical of many joints, the ankle has multiple muscles acting upon multiple degrees of freedom. Many of the ankle muscles have very short moment arms combined with highly pinnate architectures, which makes direct measurement of these critical parameters difficult and unreliable. We have employed sonomicrometry to measure small increments of motion between bone, tendon and muscle fascicles when the ankle is clamped in various positions of extension/flexion and inversion/eversion during both passive and active conditions of the various muscles. Independent estimates of moment arms were obtained from this relative motion and from the ratio of muscle tension to plantar force produced at the foot clamp. For example, peroneus brevis was found to have a small but constant moment arm contributing to eversion and extension over most of the normal range of motion (as a result of a pulley around the lateral maleolus) whereas the peroneus longus had a larger but changing moment arm contributing to eversion and dorsiflexion (as a result of its tethered tendon path). These morphometric and biomechanical data can now be combined with the available EMG data to assess the relative sensory and motor contributions of these muscles to natural behaviors.

A COMPUTER-MODELING ENVIRONMENT FOR THE ANALYSIS OF KINESIOLOGY, BIOMECHANICS AND SENSORIMOTOR CONTROL IN MULTIARTICULATED LIMBS. G.E. Loeb, Z. Hu*, P. Chiang* and W.S. Levine*. Bio-Medical Engineering Unit, Queen's University, Kingston, Ont. K7L 3N6 CANADA and Dept. of Electrical Engineering, University of Maryland, College Park, MD 20734 USA.

Body movements are the result of a complex interplay between the intrinsic mechanical properties of musculoskeletal systems and their dynamic modulation by the nervous system. For all but the simplest and most constrained systems, an appreciation of these relationships requires quantitative integration and presentation of large amounts of diverse data regarding morphometry, kinematics and dynamics. We have developed a user-interactive environment on the Macintosh II personal workstation that supports the following functions:

Morphometric spreadsheet - generalized system for describing and dimensionless scaling of 3D musculoskeletal architecture;
Analog and video data acquisition - timecode-synchronized spreadsheet files of EMG, transducer and joint position data;
Kinesiological data analysis - editing, temporal normalization and averaging of cyclical data;
Relational database - user-specified data transformations, e.g. estimation of muscle torque from morphometry, EMG, and force-length, force-velocity and active state dynamics;
Iconographic stick-figure display - includes muscle- and joint-specific items selected by the user from the database;
Special functions interface - couples to external code, e.g. equations-of-motion solvers and regulator designers.

THE INFLUENCE OF MUSCLE LENGTH ON MUSCLE FIBRE CONDUCTION VELOCITY (MFCV) AND MUSCLE FATIGUE. L Arendt-Nielsen[1], T Sinkjær[1] and N Gantchev[2]*, [1]Department of Medical Informatics, Aalborg University, Denmark, [2]Bulgarian Academy of Sciences, Sofia, Bulgaria.

Introduction. Theoretically, it has been found that the muscle fibre conduction velocity increase when the diameter increase. During dynamic muscle load the muscle length change continuously, but the importance of length changes for the development of fatigue is not known. The electromyogram (EMG) can be used to clarify some of these aspects. The present study investigated the influence of muscle (vastus lateralis) length on MFCV and on muscle fatigue.

Methods. The EMG responses were evoked by electrical stimulation of the motor point and recorded by a tripolar surface electrode array aligned along the muscle fibre direction. The MFCV (determined by cross-correlation) was measured for 5, 45, 90 and 120 degrees knee flexion at three different background extension torques (0, 25, 50% maximum voluntary contraction). In the second experiment the EMG activity to a static fatiguing contraction (80% MVC) was measured at 45 and 90 degrees knee flexion and the MFCV calculated.

Results. The MFCV declined for increasing muscle length, and increased for increasing background torque from 0 to 90 degrees knee flexion. The MFCV can change approximately 2 m/s dependent on the background force and muscle length. During fatigue the MFCV decline rate (0.047 m/s/s) was significantly higher for the 90 degrees knee angle compared to 45 degrees (0.024 m/s/s).

Conclusion: The muscle length is an important parameter for the propagation velocity of action potentials and for the development of static muscle fatigue.

LEFT-RIGHT COMPARISON OF HOMOLOGOUS MUSCLES WITH REGARDS TO TIME AND FREQUENCY ANALYSIS OF EMG SIGNALS. M. Bilodeau, A.B. Arsenault, D. Gravel, D. Bourbonnais, F. Kemp*. Research Centre, Montreal Rehabilitation Institute and School of Rehabilitation, Faculty of Medicine, University of Montreal, Montreal, Quebec, Canada, H3C 3J7.

The aim of this study was to contrast EMG characteristics of homologous muscles of the right and left sides of normals. Surface EMG signals (16-800 Hz) of anconeus, brachioradialis, triceps and biceps brachii (16 subjects) were recorded during 5-s ramp elbow flexions and extensions. The median and mean power frequency of the power spectrum and the root mean square values of the raw EMG computed at different force levels (10, 20, 40, 60 and 80% MAX) were analysed using two-way ANOVAs for repeated measures. Slopes of the EMG/moment relationships were also computed bilaterally and contrasted using paired t-tests. No significant differences were found ($p>0.05$) in any parameters between right and left homologous muscles. It thus appears that these parameters taken from surface EMG signals can be considered potentially useful measures when comparing the unaffected to the affected side of populations such as hemiplegics.

M. Bilodeau is funded by a MRC studentship.

EFFECTS OF DORSAL NEOCORTICAL STIMULATION ON PERFORANT PATH EVOKED FIELD POTENTIALS IN THE DENTATE GYRUS OF THE RAT. D.L. Korol, B.W. Leonard, B.L. McNaughton, and C.A. Barnes. Department of Psychology and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Modulation of neural excitability in the hippocampus results from activation of various subcortical inputs. Prestimulation of the medial septal and supramammillary nuclei facilitates the population spike (PS) of dentate granule cell field potentials evoked by perforant path (PP) stimulation, probably by suppressing inhibitory interneurons (Mizumori et al., 1989). To address the question of how cortical afferents other than the primary input from entorhinal cortex affect hippocampal dynamics, we examined the effects of prestimulation (at 25 msec) of various neocortical areas on PP-evoked field EPSPs and population spikes in anesthetized rats. Substantial facilitation of the population spike, with little or no change in the field EPSP, can be evoked by prestimulation of some cortical sites, whereas inhibitory effects are observed at other sites. Preliminary mapping studies suggest a clustering of excitatory fields in frontal (motor) fields and inhibitory sites in the parietal visual (OC2m) and somatosensory (HL) areas; however, the effects are clearly at least disynaptic, and state-dependent. More data will be required to determine whether this clustering is consistent. Cortical activation alone often elicited field potentials with latencies varying from 3-16 msec that were correlated with the incidence of facilitation; however, the cortical potential failed to exhibit polarity reversal in the molecular layer, whereas the simultaneously evoked PP potential did reverse polarity. This suggests that the cortically evoked potential is not generated in dentate gyrus.

REDUCED HIPPOCAMPAL LTE IN AGED RATS FOLLOWING CHRONIC ADMINISTRATION OF ACETYL-L-CARNITINE S. Davis, A. L. Markowska[1], C. A. Barnes, B. L. McNaughton, and D. S. Olton[1]. Department of Psychology and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724; Department of Psychology, Johns Hopkins University[1], Baltimore, MD 21218.

Acetyl-l-carnitine (AC), an ester of the endogenous compound carnitine appears to improve, for example, the morphological changes that normally occur in the hippocampus of aged rats (Ramacci et al, Drugs Exptl. Clin. Res., XIV(9), 593-601, 1988), behaviour on the Barnes circular platform and long-term memory performance in the split-stem T-maze (Barnes et al., Neurobiol. Aging, 11, 499-506, 1990), and is under clinical evaluation for treatment of cognitive and neural dysfunctions in aged humans. We have investigated the effects of chronic administration of AC in aged rats on their performance in a spatial version of the Morris water task and on long-term synaptic enhancement (LTE) in the dentate gyrus, using high-frequency electrical stimulation of the perforant path afferents. Three groups of Fischer 344 rats were tested: young (N=5) and aged (N=7) controls and an aged group (N=5) administered AC (75mg/kg/day) for at least 8 months. The data from the behavioural tests suggest that AC-treated rats show small improvements in spatial learning. In these same animals, however, the magnitude of LTE was greatly reduced in the AC-treated rats compared with old and young control animals, although its decay rate appeared to be the same as controls. These unexpected results suggest that AC may interfere with certain mechanisms of synaptic plasticity; however this will need to be verified in a replicate study (presently underway).

AN AGE COMPARISON OF SHORT-TERM EXPLORATORY MODULATION OF RAT PERFORANT PATH SYNAPTIC EFFICACY. C.A.Erickson, C.A.Barnes, B.L.McNaughton, D.F.Gibbons*. Dept. Psychol. & ARL Div. of Neural Systems, Memory and Aging, Univ. Arizona, Tucson, AZ 85724.

Old rats show accelerated forgetting of spatial information. This is correlated with faster decay of electrically induced synaptic enhancement (LTE/LTP) in fascia dentata (Barnes, 1979). Recently, naturally-occuring synaptic changes, termed "short-term exploratory modulation" (STEM), have been identified in rat hippocampus during bouts of exploration (Sharp et al., 1989; Green et al., 1990). Exploration results in an increase in the EPSP component of perforant-path evoked responses and a reduction in the population spike. STEM is cumulative, outlasts the behaviors which produce it, and is blocked by MK-801 (Croll et al., 1990; Erickson et al., 1990). We compared STEM induction in 24 mo and 9 mo old rats chronically prepared for recording perforant path evoked potentials. The rats were plugged into the recording equipment 2 hours prior to the recording session. Perforant path stimuli were delivered every 5 sec to alternate hemispheres and behaviors were scored as either exploratory or non-exploratory. After 1 hr of baseline recording in the home cage, in which the rats typically rested quietly, they were placed for 30 min on platforms containing junk objects. Rats were reinforced for exploration with chocolate milk. Following the exploration phase, the rats were returned to their home cages for the remainder of the 3 hr session. The old rats exhibited significantly less STEM than the young rats; however, the old rats also explored significantly less. Because of the strong dependency of STEM on the cumulative recent history of exploration, we tentatively conclude that the expression of STEM is not substantially affected by the aging process.

RAPID INDUCTION OF *ZIF* 268 mRNA IS PRESERVED IN HIPPOCAMPUS OF OLD F-344 RATS FOLLOWING LTE-INDUCING STIMULATION. C. A. Barnes, C. A. Erickson, B. L. McNaughton, R. Bhat, J. M. Baraban, and P. F. Worley. Dept. of Psych. and ARL Div. Neural Systems, Memory and Aging , Univ. Arizona, Tucson, AZ 85724 and Depts. Neurosci., Neurology and Psychiatry, Johns Hopkins Univ., Baltimore, MD 21205.

The transcription factor *zif* 268 can be rapidly activated in granule cells in the hippocampus by patterned electrical stimuli that induce LTE in both anesthetized and chronically-prepared young rats. Like LTE, *zif* 268 induction is dependent on NMDA receptor activation. In old rats, mechanisms of LTE induction appear to be normal, but the maintenance of LTE is deficient. Accordingly, it was of interest to determine whether mechanisms of *zif* 268 activation are defective in old rats. As a first step we examined 4 young (10 mo) and 4 old (26 mo) rats 2 weeks following bilateral implantation of electrodes into the fascia dentata and perforant pathway. A total of 100 stimulus pulses were given to each hemisphere of each rat: one hemisphere received low frequency (LF) stimulation at 0.1 Hz; the other high frequency (HF) at 400 Hz. *Zif* 268, *c-fos*, *jun* B, and *c-jun* mRNA levels were assessed by *in situ* hybridization, and related to the level of LTE 30 minutes following the HF stimulation. As previously reported, there was no difference between age groups in LTE induction (EPSP change: old = 0.41; yg = 0.44), and no change from baseline in the LF stimulation hemisphere (old = 0.08; yg = 0.07). The new finding here is that transcription factor (TF) responses are similar in the LTE hemispheres of both young and old rats. These data suggest that signal transduction leading from NMDA receptor activation in the dendrite to somatic mRNA responses are intact in old rats, and that factors downstream from TF activation may be disrupted.

AGE-RELATED DECREASE IN CA1 EPSP TO FIBER POTENTIAL RATIO. G. Rao, C. A. Barnes, T. C. Foster and B. L. McNaughton. Department of Psychology and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

We previously reported an age-related decrease in sensitivity to exogenously-applied AMPA in hippocampal subfield CA1, based both on the ability of this glutamate synaptic receptor agonist to attenuate *in vitro* evoked field EPSPs, as well as on a reduction of extracellular field potentials induced by focal application of AMPA in stratum radiatum (Soc. Neurosci. Abs., 16, 776, 1990). If a decrease in post-synaptic sensitivity underlies this observation, it should also be manifested in a decrease in the amplitude ratios of the CA1 EPSP and fiber potential components.

Hippocampal slices were prepared from F-344 male rats at ages 6 and 27 mos (n = 7 rats per group). A recording pipette and a stimulating electrode were positioned in CA1 stratum radiatum and five extracellular evoked potential responses were collected at four intensities (50, 100, 200 and 400 μA). The amplitude of the initial phase of the EPSP and the area of the fiber potential were subsequently analyzed. At all four intensities, the EPSP to fiber potential amplitude ratios were smaller in the old animals. The decline was significant ($p<.005$) at the 100 and 200 μA intensities. This result is consistent with the AMPA results described above.

Experiments employing minimal stimulation to activate single afferent fibers and quantal analysis to estimate mean quantal parameters are in progress to determine whether the reduced AMPA responses and EPSP to fiber potential ratios are accompanied by a reduced apparent quantal size. Supported by AG03376.

QUANTAL ANALYSIS OF LTE: FACTORS WHICH MODIFY EXPRESSION. T.C. Foster, B.L. McNaughton. Dept. Psych. and ARL Div. Neural Systems, Memory and Aging, Univ. Arizona, Tucson, AZ 85724.

We reported that a 30% increase in mean EPSP amplitude during long-term synaptic enhancement (LTE) is due to an increase in quantal size (q) in the absence of changes in transmitter release (m) (Foster & McNaughton, *Hippocampus*, 1991). Malinow and Tsien (*Nature*, 1990) reported a substantial EPSP increase (200%) due to a large increase in m and a small increase in q. We have attempted to determine the factors responsible for the disparate results, including: 1) immature (3-5 wk) rats, 2) reduced temperature (22°C), 3) elevated Ca^{++}, 4) method for LTE induction (pairing 40 pulses, 2 Hz, with postsynaptic depolarization), and 5) low stimulation rates. No single factor accounts for the differences in the magnitude or quantal parameters of LTE observed between the two studies. Significant effects of age and temperature were observed on baseline m. Young rats showed low m values and m was larger at 22°C. The larger m at 22°C could be reduced by using a lower stimulation rate. Whereas, in our studies, there was no average change in m, the magnitude and direction of changes in m following LTE stimulation were negatively correlated with baseline m. Changes in m were mainly due to changes in p. Since p cannot be negative, a floor effect may result from initially low values. The initial value of m, calculated from the mean number of transmission failures for 5 cells reported by Malinow and Tsien, was substantially lower than in most other studies of these synapses. Thus the discrepancy between the two studies may be related to differences in the initial resting p; however, we have no explanation for why Malinow & Tsien did not observe increased m after stimulation in the absence of depolarization. Supported by NS08585 to TCF and NS20331 to BLM.

ADDITIVE RELATIONSHIP BETWEEN PERFORANT PATH LTE/LTP AND STEM SUGGESTS INVOLVEMENT OF DIFFERENT SYNAPTIC POPULATIONS. B.L. McNaughton, C.A. Erickson, C.A. Barnes, G.D. Stevenson*. Department of Psychology and ARL Div. of Neural Systems, Memory and Aging, University of Arizona, Tucson AZ, 85724.

Exploratory behavior leads to a short-term (15-30 min) elevation of synaptic responses evoked in the fascia dentata by electrical stimulation of the perforant path (Sharp et al., Psychobiol., 17:257-269,1989; Green et al., J. Neurosci., 10:1455-1471,1990). Although not permanent, this short-term exploratory modulation (STEM) long outlasts the behaviors that induce it, and has been dissociated from the locomotor component of exploration using a motorized treadmill. Unlike stimulus induced long-term enhancement (LTE), STEM is not due to electrical stimulation *per se*, although both phenomena can be blocked or attenuated by systemic MK801 (Croll et al., Soc. Neurosci. Abst., 16:263, 1990; Erickson et al., Soc. Neurosci. Abst., 16: 442, 1990). To address the question of whether STEM and LTE share a common mechanism of expression we studied the manner in which the two phenomena interact. Possible interactions are occlusion, suggesting a common mechanism, a multiplicative relationship, possibly due to one pre and one postsynaptic effect, and an additive relationship, suggesting independent sites of expression. The absolute, STEM-related EPSP growth (mean 43%) was virtually identical (slope = 1.03) before and after LTE induction (mean 42%), indicating a purely additive relationship. Moreover, whereas LTE was characterized by an increase in EPSP slope, STEM involved an apparent reduction in EPSP onset latency. These data suggest that STEM and LTE may occur at different synapses, and, as suggested by Green et al. 1990 on other grounds, that STEM could represent a rather large growth at a small proportion of synapses. 40-HZ "FLUTTERING" OSCILLATIONS IN THE RAT HIPPOCAMPUS. W. E. Skaggs, B. L. McNaughton and C. A. Barnes. Depts. Neurosci. and Psych. and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724. Email: bill@nsma.Arizona.edu

The hippocampus, because of its large number of cells and laminar architecture, is capable of generating strong extracellular electric fields. In addition to the well studied 6-8 Hz "theta" rhythm, we find that it also gives rise to higher frequency oscillations. These can be heard on an audio monitor as a distinctive "fluttering" sound when a recording electrode passes through the molecular layer and approaches or enters the granule cell layer (the audible component is transient, and appears to be generated by local neuronal injury discharge, which occurs in phase with the underlying EEG oscillation). A series of studies were conducted to characterize these higher frequency EEG oscillations. They are highest in amplitude (about 0.2 mV) in the upper molecular layer of the fascia dentata, but can be detected over a wide region, including the cortex above CA1, and are highly correlated even between the two hemispheres. They appear in anesthetized as well as waking animals, but in waking animals they fluctuate in frequency from 40 to 70 Hz, while under Nembutal anesthesia they are slower (35-45 Hz) and more regular. They increase in amplitude when an animal is actively exploring its environment. These oscillations appear to be generated both in CA1 and in the fascia dentata. It is hypothesized that the oscillations are caused by "ringing" of a feedforward excitation -- feedback inhibition network of glutamatergic granule cells or pyramidal cells and GABAergic basket cells, and that the timing of the oscillation is set by the decay time constant of GABA-a receptor channels. Supported by NIMH grant MH46823.

A HIGH-DENSITY MINIATURE MICRODRIVE ARRAY FOR CHRONIC STIMULATION AND RECORDING OF PATTERNED MULTIPLE SINGLE-UNIT ACTIVITY IN THE RAT HIPPOCAMPUS. M.A.Wilson, B.L. McNaughton, K. Stengel*. Department of Psychology and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Understanding spatial and temporal structure of ensemble activity in the brain has long been a primary objective of neurophysiological research. To record ensemble activity of single units, we have developed an electrode array consisting of 16 independently adjustable microdrives. Each drive houses a recording or stimulation electrode, which can be positioned at any one of 60 penetration sites with 250 μm separation over a 3 mm diameter region. The microdrive array is lightweight and compact enough for use on rats. Independent z adjustment allows optimal placement of individual electrodes for recording single units at various depth-distributed sites in the brain. The use of multi-wire stereotrode or tetrode technology, coupled with multi-dimensional cluster analysis, allows isolation of 3 or more cells at each electrode site. Therefore, this approach provides the means to record simultaneously from 50 or more individual units at sites distributed across the hippocampus. The array has been successfully tested in both acute and chronic preparations in the rat. The development of the microdrive array is being coordinated with the concurrent development of a large-scale multi-channel amplifier/digital signal processing system for waveform acquisition and analysis. The successful application of this system should provide insights into ensemble activity in the hippocampus of the behaving rat and enable the evaluation of systems level hypotheses concerning network coding and function. Supported by NIMH, NSF and the McDonnell-Pew Foundation.

PROGRESSIVE DECREASE OF BEHAVIORAL MODULATION OF HEAD-DIRECTION CELLS IN THE PATHWAY FROM MEDIAL PRESTRIATE TO RETROSPLENIAL CORTEX. L. L. Chen,[1] L.-H. Lin,[1] B. L. McNaughton,[2] C. A. Barnes,[2] and D. F. Gibbons*[2]. Univ. Colorado, Boulder, CO, 80309[1] and ARL Div. of Neural Systems, Memory and Aging, Univ. Arizona, Tucson, AZ, 85724[2].

Cells tuned to allocentric head-direction (HD) are found in both neocortex (posterior parietal cortex; Chen et al.,1988) and periallocortex (post-subiculum; Taube et al., 1990), suggesting a role of these areas in spatial cognition. Of 662 single units from medial prestriate cortex (Oc2M) and retrosplenial cortex (RSA and RSG) in freely-moving rats, 41 HD cells were identified by the criterion of maintained directional bias in the absence of cues or in the dark (RSG-8.5%; RSA-8.4%; Oc2M-2.7%). In some HD cells, directional tuning was modulated by head angular velocity or linear running velocity; there was a progressive decrease of such modulation from neocortex to periallocortex (Oc2M-57%; RSA-15%; RSG-0%), suggesting that neocortical egocentric movement information may be transformed into an allocentric directional representation in the periallocortex. This supports the hypothesis proposed by McNaughton, Chen, & Markus (1991) that an allocentric direction sense might be associatively maintained by combining angular velocity and orientation signals. Also, the preferred direction of most (78%) HD cells persisted in a spatial working memory-radial maze task, irrespective of the presence of salient visual cues or cue rotations; however, during passive rotations, the directional bias of most HD cells was often unrelated to that in the working memory task, and the tuning of many cells rotated when the salient cues were rotated. Thus, task variables such as stimulus significance, motor efference copy, or attention, are also important determinants of HD cell firing. Supported by NS20331.

SPATIALLY SELECTIVE FIRING IN HIPPOCAMPAL PYRAMIDAL CELLS IS AFFECTED BY THE MAGNITUDE OF THE VISUALLY ACCESSIBLE ENVIRONMENT. B. Gaese, M. Jung, B.L. McNaughton, C.A. Barnes. Dept. Psychology & Div. Neural Systems, Memory and Aging, Univ. Arizona, Tucson AZ, 85724.

Leonard (Ph.D Thesis, 1990) noted that, in experiments in which animals had extensive experience with the environment beyond the test apparatus, substantially fewer hippocampal pyramidal cells had discernable "place fields" on the apparatus. Leonard also noted that cells of animals with extramaze experience sometimes had apparent place fields as the animal was carried passively through the environment. These observations, however, were subject to a number of possible alternative explanations, due to confounding variables such as task demands and behavior. In this experiment, we inquired whether size of the visually accessible space would affect the distribution of place specific firing within a small circular apparatus. Two identical 76 cm diameter platforms were used, one with a high cylindrical wall that restricted the animal's access to distal visual stimuli. The other cylinder was transparent. The opaque wall was covered with complex patterns. In the transparent condition, similar patterns were mounted on the room walls. The same cells were tested in both conditions. Behavior (random search for food pellets) was the same in both conditions. Mean firing rates in both conditions were highly correlated (.98) and not different; however, the presence of clear place fields differed substantially. In the distal cue condition, 4/49 cells had high spatial selectivity. In the proximal-only case, 15/49 cells were highly selective. A paired t-test on the spatial selectivity scores was significant ($p < .0007$). We hypothesize that, even without direct physical experience, place fields spread out to occupy the known space. Supported by NS20331

AUDITORY AND HIPPOCAMPAL NEURONAL ACTIVITIES DURING PERFORMANCE OF AUDITORY WORKING AND REFERENCE MEMORY TASKS IN THE RAT. Y. Sakurai. Dept. Psychology, Toyama Med. & Pharm. Univ., Sugitani, Toyama 930-01, Japan.

The auditory cortex (AC) and medial geniculate body (MGB) are related to retention processes and the hippocampal CA1 and CA3 are related to a comparison process in an auditory working memory task (Sakurai, Behav. Neurosci., 104:253, 104:856, 1990). The present study examined more precisely the roles of the auditory and hippocampal regions by recording from single units in them while the rats performed both auditory working and reference memory tasks in a single situation. The working memory task was continuous nonmatching-to-sample with two, high and low tones. The rat pressed a panel (Go) if the tone for the current trial was different than the tone for the preceding trial. The reference memory task was continuous discrimination. The rat made a Go response if the tone for the current trial was high. The apparatus, tone stimuli and the sequence for continuous presentation of the tones were identical between the working and reference memory tasks. Some of the units had mnemonic correlates during tone presentations or delay periods in one of the tasks. These and other behavioral correlates of the units provide more information about how the cortical and limbic regions processes memory. EFFECTS OF THE NMDA ANTAGONIST, MK-801, ON SHIFTS IN THE EPSP TO SPIKE RELATIONSHIP FOLLOWING LONG-TERM POTENTIATION OR SHORT-TERM EXPLORATORY MODULATION OF DENTATE GYRUS EVOKED POTENTIALS. S.D. Croll and E. Bostock. Dept. of Psychology, Queens College-CUNY, Flushing, NY 11367.

We examined whether shifts in the EPSP to spike (E-S) relationship occur following induction of long-term potentiation (LTP) or short-term exploratory modulation (STEM) of dentate gyrus evoked potentials, and whether MK-801 had any effects on the observed shifts. Rats were chronically implanted with stimulating electrodes in the perforant path and recording electrodes in the dentate hilus. Stimulus intensity series were used to assess changes that occurred in the E-S relationship following induction of LTP or STEM. In addition, the effects of .10 mg/kg sc MK-801 (injected 30 min prior) on these effects were examined. Following LTP induction, a significant leftward shift in the E-S relationship was observed. This shift was blocked and reversed to a rightward shift following MK-801 administration. Animals receiving no LTP following vehicle or MK-801 administration showed no shift in the E-S relationship. During STEM, a significant rightward shift of the E-S relationship was observed. This effect persisted for at least 20 min. This rightward shift was significantly reduced by MK-801 administration. These findings suggest a role of the NMDA receptor in the E-S relationship shifts observed following induction of either LTP or STEM.

INDUCTION OF HIPPOCAMPAL PKC EXPRESSION BY SPATIAL DISCRIMINATION LEARNING IS ABOLISHED BY AMYGDALOID KINDLING. H.J.A. Beldhuis,* H. Everts,* E.A. van der Zee* B. Bohus and P.G.M. Luiten, Dept. of Animal Physiology, University of Groningen, P.O. Box 14, 9750 AA HAREN, The Netherlands. (SPON:European Brain and Behaviour Society)

Recent evidence suggests the involvement of protein kinase C (PKC) in the molecular mechanisms by which the hippocampus exerts its influence on information processing. Normal functioning of the hippocampus is of importance for these processes. In the following experiment we investigated the contribution of PKC to spatial discrimination performance. We were interested whether abnormal functional activity indeed impairs spatial learning and the correlated changes appearing in the neural substrate. Adult male Tryon Maze Dull S3 rats (n=16; 300 gr) implanted with bipolar electrodes in the medial amygdala were used 1 week following surgery. They were subjected to a spatial discrimination task (SDT) in a hole board every other day. Daily tetanizations up to 30 days were applied to one group of rats (n=8) at least 2 hours after performing SDT. After completion of the SDT brain sections of 20 μm were processed for immunocytochemistry (ICC) with a monoclonal antibody raised against PKC gamma isozyme. Naive rats were used as controls in the ICC procedure. Learning curves for reference memory (RM) were identical for control and tetanized rats until motor seizure stage 3 had appeared in the tetanized rats. RM of the tetanized rats failed to improve further. PKC expression was increased in the non-tetanized control rats which learned the task, and was mainly located in the granular cell layer. In the tetanized rats PKC expression resembled the pattern as found in the naive controls. The present study shows a correlation between performance in a SDT and PKC expression in the granular cells. These alterations probably reflect molecular processes that provide optimal basis for learning and memory. Disturbance of hippocampal functioning induced by propagated amygdaloid tetanizations prevents these alterations in the neural substrate, and impairs spatial learning. These investigations were supported by the TNO Research Committee on Epilepsy (CLEO A65;HJAB) and Troponwerke (Bayer;EAvdZ).

DIFFERENTIAL CHANGES IN PROTEIN KINASE C EXPRESSION IN RAT CORTEX, HIPPOCAMPUS AND AMYGDALA DETERMINED BY TYPE OF LEARNING TASK. *P.G.M. Luiten, E.A. van der Zee*, H.J.A.Beldhuis*, B. Roozendaal* and S. Cazaubon**. Dept. of Animal Physiology, University of Groningen, The Netherlands.

Protein kinase C (PKC) is a key enzyme for signal transduction and various neuronal plasticity mechanisms. Changes in hippocampal PKC content have been reported after non-invasive conditioning tests. Here, we examined the expression of PKC in rats after different types of learning tasks: Spatial Orientation (SO), Active (AA) and Passive Avoidance(PA). PKC expression was displayed by immunoreactivity (IR) to a monoclonal antibody against the gamma-isoform. Animals were sacrificed 24h after the last performance. PKC was analyzed in neocortex, hippocampal dentate gyrus (DG) and cornu ammonis (CA), and central (Ce) and cortico-medial (CoMe) amygdala of naive (n=20) and learned rats (SO n=20; AA n=20; PA n=10). Region-specific changes of task-induced PKC expression were consistently observed according to the following semi-quant. pattern:

Structure	SO	PA	AA
Neocortex	++	+++	+
Hipp DG	+	o	o
CA	+++	o	+
Amyg Ce	o	o	--
CoMe	o	o	++

In the neocortex increased PKC appeared in a columnar pattern. The hippocampus revealed high PKC levels in clusters of principal cells in DG and CA, while PKC in the central amygdala was strongly decreased after active avoidance learning. The differential changes in PKC expression indicate region and task specificity of PKC.

HIPPOCAMPAL RESPONSES DURING JAW MOVEMENT CONDITIONING FOLLOWING PREEXPOSURE TO UNPAIRED STIMULI. R.L. Borgnis*, L.J. Dreshfield, M. Cahall*, & S.D. Berry. Dept. of Psychology, Miami Univ., Oxford, OH 45056.

It has been documented that preexposure to conditioning stimuli delays the acquisition of classically conditioned responses (Lubow, 1989; Solomon & Moore, 1975). Since hippocampal neural activity precedes and models the behavioral conditioned response, we hypothesized that preexposure to both CS and UCS would delay the acquisition of behavioral and hippocampal conditioned responses. Bilateral recordings were made during jaw movement two-tone discrimination training (TTD). Group TTD animals received 8 days of TTD training while Group UNP animals received 5 days of unpaired presentations of the same stimuli and then 8 days of TTD training. In the TTD task, one tone (CS+ 8KHz) signalled a saccharin solution; another tone (CS- 1KHz) signalled no saccharin. The UNP group was presented a quasi-random sequence of two tones and saccharin and therefore received 240 preexposures of each stimulus before TTD training started. While we did not find a significant difference in behavioral acquisition rates during TTD training, our preliminary neural results for the UNP group indicate an inhibition of firing just after tone onset in early trials that disappears by the end of the first day of conditioning.

OPTICAL MEASUREMENT OF NEURONAL ACTIVITIES OF HIPPOCAMPUS *IN VIVO*. T. IIJIMA and G. MATSUMOTO. Electrotechnical Lab., Tsukuba, Ibaraki 305, Japan.

It has been believed that the hippocampus is composed of multiple "lamella units", each of which includes basically similar excitatory pathway. However, we found the heterogeneity of neuro-circuit in each "lamella unit" through *in vitro* experiments using hippocampal slice preparations.

To reveal the real information processing in hippocampus, it is necessary to obtain the neuronal activities from the multisites of an intact hippocampus. For the purpose we tried the optical recording of neuronal activities from the surface of guinea pig hippocampus *in vivo*. The hippocampal surface was exposed by removing a part of cortex. The neuronal activities were recorded from the alvear surface of the hippocampus stained with a voltage-sensitive dye RH 795. When a stimulus was applied to ipsilateral hippocampus, neuronal activities were obtained from a part of hippocampus as the fluorescence change of about 0.3%.

8-OH-DPAT IMPAIRS RATS' PERFORMANCE IN PASSIVE AVOIDANCE AND WATER MAZE TASKS: ROLE OF POST-SYNAPTIC 5-HT_{1A} RECEPTORS. M.Carli*, L. Cervo*, E.Tatarczynska*, M.T. Tacconi, R. Samanin*. Istituto "Mario Negri", Milan, Italy.

Administered subcutaneously 5 min after the training trial, 100 and 300 µg/kg 8-OH-DPAT significantly increased the retention latencies 24 h later in a one-trial passive avoidance task. A similar effect was found by administering 8-OH-DPAT only before the training trial or before the retention test, but anxiolytic effects or changes in motor activity could be involved in these conditions. At 100 and 300 µg/kg, 8-OH-DPAT significantly impaired choice accuracy in a two-platform spatial discrimination task in the water maze. The effects were potentiated in animals injected intracerebroventricularly with 5,7-dihydroxy-tryptamine (150 µg/20 µl) to destroy serotonin-containing neurons. Administration of 8-OH-DPAT (5 µg/1 µl) in the CA1 region of the dorsal hippocampus, 10 min before the training trial in a passive avoidance task, significantly decreased retention latencies 24 h later. No antidepressant- or anxiolytic-like effects were found with intrahippocampal 8-OH-DPAT. The results suggest that activation of 5-HT_{1A} receptors in the hippocampus interferes with mechanisms involved in learning and memory.

557.2

THE EFFECTS OF 8-HYDROXY-2-(DI-N-PROPYLAMINO)-TETRALIN (8-OH-DPAT) ON DELAYED MATCHING-TO-SAMPLE PERFORMANCE IN RATS.
D. Shurtleff and S.T. Ahlers. Naval Medical Research Institute, Bethesda, MD 20889.

The hippocampus, an area important in working memory, contains a high density of serotonin 5-HT_{1A} receptor subtypes. In the present study the effects of the 5-HT_{1A} agonist 8-OH-DPAT on working memory were evaluated using a delayed matching-to-sample (DMTS) task. Rats (n=4) were required to press one of two front wall levers (right or left) cued by an illuminated light. By pressing the correct lever, they extinguished the light and initiated a delay interval. Following a randomly selected delay of 1, 3, 5, 10, or 15 secs, lights above both levers were illuminated, and the rat was required to choose the previously cued lever. During the delay rats were required to respond on the back wall lever to prevent the use of simple mediating behaviors, such as standing in front of the previously cued lever during the delay. Following saline administration, matching accuracy decreased as a function of delay and ranged from an average of 93% correct at the 1 sec delay to 65% correct at the 15 sec delay. All doses of 8-OH-DPAT reduced matching accuracy relative to saline. The dose of 0.03 mg/kg 8-OH-DPAT (ip) decreased accuracy at the 5, 10 and 15 sec delays, while the 0.1 mg/kg dose decreased accuracy at all delays greater than 1 sec, and the 0.25 mg/kg dose decreased accuracy at all delays. These data indicate that the 5-HT_{1A} agonist 8-OH-DPAT impairs DMTS performance, suggesting the involvement of this receptor subtype in working memory.

557.3

THE SEROTONIN 5HT_{1B} AGONIST TRIFLUOROMETHYLPHENYLPIPERAZINE (TFMPP) IMPAIRS PERFORMANCE ON A DELAYED MATCHING-TO-SAMPLE TASK IN RATS.
S.T. Ahlers[1], J.R. Thomas[1], and J.L. Davis[2]. [1]Naval Medical Research Institute, Bethesda, MD 20889 and [2]Office of Naval Research, Arlington, VA 22217.

Recent research has drawn attention to the interaction of 5-hydroxytryptamine (5HT) and acetylcholine (ACh) in the modulation of memory. Of particular interest are studies demonstrating that specific agonists to the 5HT_{1B} receptor inhibit the release of ACh in the hippocampus. The present study examined whether the 5HT_{1B} agonist TFMPP would impair performance on a delayed matching-to-sample (DMTS) task in rats. Five adult rats were trained on a DMTS task in which they were required to respond on one of two levers (sample stimulus) cued by an illuminated light above the lever on the front wall of a standard operant chamber. Following a random delay of 1, 3, 5, 10 or 15 seconds, both lights were illuminated and rats were required to correctly respond on the lever previously cued. During the delay interval rats responded on a fixed-interval schedule on the back wall lever to prevent position bias or the adoption of simple mediating response patterns. When rats were given saline injections, accuracy decreased from 93% at the 1 sec delay to 71% at the 15 sec delay. Administration of 0.1 mg/kg TFMPP (ip) decreased accuracy at the 3, 10, and 15 sec delays while doses of 0.25 mg/kg and 0.5 mg/kg shifted the delay gradient downward across all of the delays (88% at 1 sec to 55% at 15 sec). These results indicate that short-term or working memory is impaired by the low dose of the 5HT_{1B} agonist. Because higher doses of TFMPP lowered accuracy at the short delays, TFMPP may have impaired acquisition as well.

557.4

5-HT DEPLETION DOES NOT AFFECT SPATIAL MEMORY.
H.P.Davis, C.Hendrix*, D.H.Park, A.C.Towle, & B.T.Volpe. Dept. Psychol. Univ. Colorado, Colorado Springs, CO 80907 and Dept. Neurol. & Neurosci., Cornell Univ. Med. Ctr. @ Burke Inst. Med. Res.

The neurotransmitter serotonin (5-hydroxytryptamine, 5-HT) may play an important role in learning and memory. It has also been suggested that 5-HT abnormalities may mediate some aspects of the cognitive disorders associated with Korsakoff syndrome and Alzheimer's Disease. We evaluated the effect of intracisternally applied serotonergic neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT) on learning and memory in rodents. Three day old rats were treated with pargyline (40 mg/kg, ip) followed by 5,7-DHT (50 ug/pup) and returned to the dam for a month. At 53 days of age the tryptophan hydroxylase (TPH) activity was assayed radioenzymatically with ^{14}C-tryptophan in the dorsal raphe nuclei, caudal brainstem and hypothalamus in some animals. 5,7-DHT treated animals demonstrated marked reduction (90%) in TPH activity compared to matched controls. At 75 days of age, rats were tested on a learning set problem in the Morris water maze for 5-days followed by 30 days of testing in a 12-arm radial maze with 8 of the 12 arms baited. In the Morris water maze, the latency to locate the hidden platform and the swim path length did not significantly differ for 5,7-DHT treated and control rats ($F < 1.0$). Similarly, 5,7-DHT treated rats did not re-enter arms more frequently than control rats (working errors), or enter unbaited arms more frequently (reference errors) ($F < 1.0$). These results suggest that 5-HT does not play a critical role in processing of spatial information.

METHYLENEDIOXYAMPHETAMINE: EFFECTS ON BEHAVIOR AND SEROTONIN. A.G. Romano, J.A. Harvey, S.E. McMaster* and V.J. Aloyo. Dept. Pharmacol. Med. College of Pennsylvania, Philadelphia, PA 19129.

Previous studies have demonstrated that the hallucinogen methylenedioxyamphetamine (MDA) enhances the acquisition of conditioned responses (CRs) during Pavlovian conditioning of the rabbit's nictitating membrane response. This study examined whether the enhanced acquisition of CRs produced by MDA was related to its known neurotoxic actions on serotonergic neurons or to its ability to produce a presynaptic inhibition of 5-HT neurons. A dose of MDA (10 μmol/kg) that enhanced CR acquisition during a one hour acquisition session also produced an increase in frontal cortex content of 5-HT and a decrease in 5-HIAA that persisted for the first two hours after injection. The turnover of 5-HT as indexed by the 5-HIAA/5-HT ratio was also significantly decreased. These effects were not seen in hippocampus. Immunocytochemical methods failed to reveal any evidence of a neurotoxic action of MDA at doses of 10 or 20 μmol/kg. We suggest that the enhanced acquisition produced by MDA may be due to an inhibition of 5-HT neurons resulting from the presynaptic release of 5-HT. (Supported by NIDA grant DA04944-04).

SCH 23390 ATTENUATES AMPHETAMINE-PRODUCED ENHANCEMENT OF RESPONDING FOR CONDITIONED REWARD IN RATS. R. Ranaldi* and R.J. Beninger. Dept Psych, Queen's Univ, Kingston, Canada, K7L 3N6.

Dopamine (DA) D1 receptors may play a role in reward. The present study evaluated the effects of a D1 antagonist on amphetamine (AMPH)-produced enhancement of responding for conditioned reward (CR). Rats were exposed to two levers, one producing a 3-s lights-off (LO) stimulus and the other a tone (T), for 5 40-min sessions (S). The levers were removed and during 4 Ss rats were exposed to 80 presentations of LO (on a random time 45-sec schedule) paired with food. Testing consisted of two Ss with the levers again present. Results showed that the saline group increased responding for LO more than for T from pre- to post-pairing, confirming that LO became a CR. AMPH (0.1 to 5.0 mg/kg, ip, 5 min before test Ss) produced a dose-dependent enhancement of responding specifically for the CR. SCH 23390, a D1 antagonist (5.0 ug/kg, sc, 2 h before test Ss), shifted the locus of rise in the AMPH dose-response function toward higher AMPH doses. These results implicate the D1 receptor in reward. (Funded by N.S.E.R.C.).

DELAYED-NON-MATCH-TO-SAMPLE PERFORMANCE IN THE RADIAL ARM MAZE: EFFECTS OF DOPAMINERGIC AND GABAERGIC AGENTS. T.C. Napier and J.J. Chrobak. Department of Pharmacology, Loyola University Chicago, Maywood, IL 60153

Central dopaminergic transmission has been implicated in memory processes. The delayed-non-match-to-sample radial arm maze (DNMTS-RAM) is a useful tool for studying memory in the rat, allowing for an examination of neurobiological treatments on time-dependent memory processes using within-subject designs. The present experiments examined the effects of several direct acting dopaminergic agents on performance of this task. Pretesting administration of the dopamine agonists, apomorphine (D1-D2; 0.25, 0.5 and 1.0mg/kg), quinpirole (D2; 0.1mg/kg), or SKF38393 (D1;3mg/kg) decreased the rate of responding (seconds/choice), but did not affect any indice of accuracy at a 1hr retention interval. Similarly, posttraining administration of quinpirole (0.1, 0.2, 1.0 and 2.0mg/kg), SKF38393 (0.3, 3.0 and 6.0mg/kg), sulpiride (D2 antagonist; 3, 10 and 30mg/kg) or SCH23390 (D1 antagonist; 0.01, 0.1 and 1.0mg/kg) did not affect accuracy, although quinpirole produced a dose-dependent decrease in response rate, assessed 10 hrs post-treatment. For comparison, pre- and post-training administration of the benzodiazepine chlordiazepoxide (CDP) was also tested and produced dose-dependent (1-5mg/kg) impairments in accuracy at both a 1 and 4 hr retention interval. The effects of CDP are consistent with evidence indicating that GABAergic agents can influence memory processes. In contrast, the present findings indicate that alterations of dopaminergic neurotransmission are not sufficient to alter the memory processes required for accurate performance of this DNMTS-RAM protocol. (Supported by DA05255 to TCN and an Ill. Dept. Public Health grant to JJC).

ALTERED SOCIAL ODOR PRODUCTION AND OLFACTORY ADAPTATION IN DSP-4-TREATED RATS. C. Cornwell-Jones, J. Green*, D. Krasenbaum*, T. Palfai* and E. Byer*. Behavioral Neuroscience Lab., Syracuse Univ., Syracuse, NY 13244.

Two experiments examined possible reasons for impaired adaptation to new home-cage odors previously observed in DSP4-treated rats. In the first experiment, male rats were injected s.c. with either water or the NE neurotoxin DSP-4 on the day of birth and at the time of weaning were placed in a new bedding type in either small or large cages. Olfactory preferences were measured 10 days later. DSP-4-treated rats housed in small cages preferred the old bedding odor to the new one, and therefore failed to adapt. All other groups showed no preference. In a second experiment, normal infant and juvenile rats preferred soiled nest shavings from control rats, to shavings which had housed DSP-4-treated animals. The results suggest that DSP-4-treated rats produce abnormal odors which, when concentrated in a small area, may interfere with olfactory learning. Supported by NSF grant #DIR-8900931 to CC-J.

SYSTEMATIC ELIMINATION OF DISCRIMINATION CUES MAY PROVIDE A MODEL OF DEPRESSION. A. L. Beggs, S. Barbay*, and S. Hotard*. Department of Psychology, University of Southwestern Louisiana, Lafayette, LA 70504

A test apparatus designed after that of Harlow was used to present discrimination trials to rhesus monkeys. Two stimulus objects covered food wells that were randomly baited, keeping stimulus object and reinforcement congruent. Initially, the stimulus objects differred in color, size, and form. On subsequent days, stimulus objects were changed so as to eliminate all discrimination cues. On the final day of experimentation animals were injected with imipramine or saline and tested with all discrimination cues available. Although no significant difference was found between groups on test performance, linear trend analysis revealed that fewer correct responses were made as discrimination cues were removed. Also, as discrimination cues were removed, responses to the same side of the tray tended to increase. In a second experiment with the same 12 subjects, with treatment conditions reversed, a new set of stimulus objects was employed but color, size, and form relationships were maintained. L-tyrosine given to subjects orally increased the number of correct responses over control subjects. Again, correct responses decreased as discrimination cues were eliminated and responses to the same side of the tray increased.

557.10

EFFECTS OF D-AMPHETAMINE ON EXTRACELLULAR NOREPINEPHRINE LEVELS IN THE AMYGDALA OF FREELY MOVING RATS AS MEASURED BY *IN VIVO* MICRODIALYSIS. **M.H. Meseches and J.L. McGaugh. Center for the Neurobiology of Learning and Memory and Department of Psychobiology, University of California, Irvine, CA 92717.**

It is well established that retention is influenced by posttraining administration of drugs, such as amphetamine, which affect catecholaminergic systems. Extensive pharmacological evidence suggests that such memory-modulating influences may be mediated, in part, by the release of norepinephrine (NE) within the amygdala. To examine this implication the present experiment examined the effects of peripherally administered amphetamine on release of amygdala NE.

One week prior to the experiment, guide cannulae were unilaterally implanted dorsal to the central nucleus of the amygdala in male Sprague-Dawley rats. The microdialysis probe was inserted 1 mm past the tip of the guide cannula and artificial cerebrospinal fluid (CSF) was perfused (0.5 μl/min) through the probe overnight. Thirty minutes prior to the collection of the first sample, the CSF flow rate was adjusted to 2.0 μl/min, and samples were collected every 15 minutes. After establishing a stable baseline, d-amphetamine (0.2 or 2.0 mg/kg; s.c.) was administered. Samples continued to be collected until NE levels returned to baseline. NE was quantified with HPLC-EC. NE levels increased after systemic administration of d-amphetamine. Previous findings demonstrate that peripheral, but not central, administration of amphetamine facilitates retention of an inhibitory avoidance task. Taken together with our previous findings, these results suggest that the effect of amphetamine on learning and memory may be due to increased noradrenergic activity in the amygdala.

ADRENERGIC SYSTEMS AND DNA SYNTHESIS IN THE RAT BRAIN. C.Lamberti-D'Mello[2]*, A.G.Sadile[2], A.Cerbone[2], T.Menna*, C.Buono*, F.Rafti*, S.Amoroso[*4], L.Annunziato[4] and A.Giuditta[3]* (SPON: European Brain and Behaviour Society). IIGB, CNR, Naples; [3]Dip. Fisiologia Generale ed Ambientale; [2]Dip. Fisiol. Umana "F.Bottazzi"; [4]Dip.Farmacol., II Fac. Medic. & Chir., Univ. Naples "Federico II", Naples, I.

To study the role of brain adrenergic systems in brain DNA synthesis (BDS), adult male Sprague-Dawley rats were randomly assigned to one of six groups. The control rats received the radioactive precursor only or the drug's vehicle two hours before the precursor. The experimental rats received at time 0 the α-adrenergic antagonist phentolamine (5 μg), the β-antagonist propranolol (10 μg), the α-agonist phenylephrine (1 μg) or the β-agonist isoproterenol (12.5 μg). All rats were given 2 h later 50μCi ^{3}H-thymidine intraventricularly and sacrificed 0.5h later. BDS was measured in several brain regions by the incorporation of ^{3}H-thymidine into DNA. The vehicle decreased BDS in neocortex, and increased it in the septum, neostriatum, hypothalamus, cerebellum and rest of the brain. It had no effect in the hippocampus and midbrain. In comparison with the group receiving the drug vehicle, α- and β-agonists and antagonists induced several significant effects, depending on the brain region. The results suggest a modulatory role of central adrenergic systems in brain DNA synthesis. **(Supported by CNR and MURST 40% grants).**

557.12

ROLE OF THE DORSAL NORADRENERGIC BUNDLE IN BRAIN DNA SYNTHESIS IN RATS. A.Cerbone[3], A.G.Sadile[3], C.Lamberti-D'Mello[3]*, T.Menna*, C.Buono*, F.Rafti*, S.Amoroso[*4], L.Annunziato[4] and A.Giuditta[2]*, IIGB, CNR, Naples; [2]Dip. Fisiol.Gen. & Amb.; [3]Dip. Fisiol. Umana "F. Bottazzi"; [4]Dip. Farmacol., II Fac. Medic. & Chir., Univ. Naples "Federico II", Naples, I.

To study the role of brain adrenergic systems in brain DNA synthesis (BDS), adult male Sprague-Dawley rats bilaterally lesioned in the dorsal noradrenergic bundle (DNB) by injection of 6-OH-dopamine or were sham-lesioned. One week later they were given at time 0 the α-agonist phenylephrine (1 μg), the β-agonist isoproterenol (12.5 μg), or the drug's vehicle. Two hours later all rats received an intraventricular injection of 50μCi ^{3}H-thymidine, and were sacrificed 0.5h later. BDS was measured in several brain regions by the incorporation of ^{3}H-thymidine into DNA. DNB-lesioned rats showed a higher BDS in the hippocampus, neocortex and hypothalamus which was reversed by the α- or β-agonist. No effect occurred in the septum, neostriatum, cerebellum and remaining brain. The results suggest (i) a tonic inhibitory effect of DNB on BDS in the hippocampus and, indirecttly, in the hypothalamus mediated by α- and β-adrenergic systems; and, (ii) a phasic inhibitory effect mediated by both α- and β-systems in the neocortex, and by the β-system in the cerebellum. Thus, a modulatory role of adrenergic systems on brain DNA synthesis is inferred. **(Supported by CNR and MURST 40% grants).**

SPATIAL ASSOCIATION OF VASOPRESSIN AND β ADRENERGIC RECEPTORS IN THE LIMBIC SYSTEM OF THE RAT BRAIN.

R.E. Brinton●, R.H. Thompson* and C.W. Ho*✻. ● Depart of Molecular Pharmacology and Toxicology, and ✻ USC STAR Program, School of Pharmacy, University of Southern California, Los Angeles, CA 90033

Associative learning and memory have been shown to be dependent upon spatial and temporal contiguity of paired stimuli (Pavlov, 1927). This work explores whether principles of associative learning observed at the behavioral level of analysis, such as the requirement of spatial and temporal contiguity of paired stimuli, also occur at the molecular level. To investigate this question we have used the association between the neurotransmitters, norepinephrine (NE) and vasopressin (AVP). Together, these neurotransmitters have been found to influence memory of an associative task (Kovacs et al., 1979). Moreover, vasopressin has been found to potentiate noradrenergic-induced accumulation of cAMP in hippocampal slices (Brinton and McEwen, 1989).

Autoradiographic mapping of the distribution of β [1] NE and V[1] AVP receptors was conducted in the rat brain limbic system. Analysis of these receptor maps was undertaken to determine the spatial association between these two receptor systems. Results of these studies showed a dramatic rostral-caudal gradient for V[1]AVP receptors, with the density of V[1] AVP receptors lowest in the rostral portions of the hippocampus and amygdala and greatest in the rostral-caudal transition regions of the hippocampus and amygdala. β [1] NE receptors showed a rostral caudal gradient distinct from that for AVP receptors. The area showing the greatest degree of spatial association between the two receptor systems occurred in the rostral-caudal transition region of the hippocampus particularly in theposterior rostral portions of the dorsal CA subfields and dentate gyrus and in the ventral CA[1] region and in the amygdalo-hippocampal zone. Supported by NIH grant MH46036 to R.E.B.

NEURAL PLASTICITY IV

558.1

A BRIEF BURST OF ACTION POTENTIALS CAUSES A LONG-LASTING TRANSITION FROM QUIESCENCE TO EITHER PACEMAKER OR OSCILLATORY ACTIVITY IN A SPECIFIC *HELISOMA* NEURON. F.H.Bahls and P.G. Haydon. Dept. of Zoology and Genetics, Iowa State University, Ames, IA 50011.

Brief periods of intense synaptic activity can lead to long-term modifications in the strength of synaptic connectivity, a process thought to underlie learning and memory. We have asked whether brief periods of electrical activity also lead to long-term modifications in neuronal membrane properties which affect the integrative nature of a neuron.

To address this question, single identified neurons B19 of the pond snail *Helisoma* were plated in primary cell culture. After 3-7 days in culture, intracellular recordings revealed that these cells were either electrically silent or exhibited low frequency pacemaker activity. Quiescent cells were depolarized for 1-5s to evoke a brief burst of action potentials. After termination of the depolarizing current pulse, the electrical state of neurons changed from quiescence before the burst to pacemaker activity which could last for greater than 30 minutes.

When depolarizing stimuli were provided for shorter durations which did not induce the long-lasting pacemaker activity, a characteristic decaying afterdepolarization was revealed which we suggest underlies the electrical state change.

Networks of electrically coupled neurons B19 were also investigated. A burst of action potentials evoked a change from quiescence to oscillatory bursts of action potentials throughout the network. These observations indicate that brief periods of electrical activity can cause long-lasting changes in the intrinsic membrane properties which regulate action potential firing patterns and are capable of triggering oscillatory activity in neural networks.

558.2

SHORT AND LONG TERM CHANGES IN SYNAPTIC PHYSIOLOGY IN THE DENTATE GYRUS DURING ASSOCIATIVE LEARNING IN THE RAT. S. Laroche, V. Doyère* and C. Rédini Del Negro*. Dépt de Psychophysiologie, PN2, CNRS, 91198 Gif-sur-Yvette, France.

Synaptic transmission, paired-pulse inhibition and facilitation, and the ability of perforant path-to-dentate granule cell synapses to sustain long-term potentiation (LTP), were examined during classical conditioning. Fifteen rats were chronically implanted with a recording electrode in the dentate gyrus and a stimulating electrode in the ipsilateral perforant path. Animals were submitted to 4 sessions of 8 paired or unpaired tone-footshock presentations. Associative learning was measured by conditioned suppression of lever-pressing for food. Potentials evoked in the dentate gyrus were monitored during and for 1 hr after each conditioning session. Associative learning was accompanied by an increase in the slope of the field EPSP which persisted for more than 20 min after conditioning trials. Only a slight increase in EPSP slope was observed at early stages of pseudoconditioning. This increase however never outlasted trial presentation and was followed by a persistent depression of synaptic transmission. A lasting reduction in spike amplitude was observed in both groups although the effect was more pronounced in pseudoconditioned rats. A paired-pulse paradigm with varying delays and pulse intensities was used to examine alterations in facilitation, early and late inhibition. LTP induced 5 days after learning (6x400Hz-20ms trains) was significantly increased in conditioned relative to pseudoconditioned rats. The main results show that associative learning is accompanied by an increase in synaptic efficacy in the dentate gyrus that outlasts the training episode and a prolonged increase in the capacity of the synapses to support LTP. The differential between synaptic potentiation in conditioning and synaptic depression in pseudoconditioning provides evidence that synaptic strengthening or weakening can be determined by contingencies between environmental events.

558.3

VARIANCE OF PERFORANT-PATH/DENTATE-GYRUS (PP/DG) EVOKED POTENTIAL (EP) MEASURES ACROSS THE I/O CURVE DURING BEHAVIORAL IMMOBILITY AND MOVEMENT IN RATS. E.L. Hargreaves and D.P. Cain. Dept. Psychology, Univ. of Western Ontario, London, Ont., CANADA, N6A 5C2.

Nine EP measures were evaluated across the I/O curve during immobility and wheel walking/running. Measures were 1) EPSP slope: a) average b) maximum c) prior to pop-spike roll-off; 2) pop-spike: d) onset-to-peak amplitude e) peak-to-tangent amplitude f) area; 3) onset/timing: g) latency of pop-spike onset h) duration of pop-spike i) ratio of onset-to-peak pop-spike duration / peak-to-offset pop-spike duration. Adult male rats were implanted with stimulating and recording electrodes in the PP/DG system. After recovery full I/O curves were recorded (10 intensities; 50-1000 Uamps; 10 sweeps/intensity/behavior). Individual sweeps were analysed and the measures averaged and plotted for each animal. Results indicate that the variability of the EP measures was reduced at the higher intensities, except for 1), which showed the opposite trend. Most measures revealed differences between recording during behavioral immobility versus movement, with immobility typically having a steeper slope, higher amplitude, or more synchrony. A reversal of this pattern was seen in g, where EPs recorded during movement had a shorter onset. This difference was also more pronounced in measures 1), than in the other measures, with b showing largest difference. Additionally, this difference was more reliable at the higher intensities, and in 1) was also greater at these intensities. Finally, EP measures displayed more variability during immobility than during movement. Other measures are now being examined. Supported by a grant from NSERC to D.P.C.

ACTIVITY-DEPENDENT EFFECTS ON INTERNEURON EXCITABILITY REGULATE DENTATE GRANULE CELL RESPONSES TO AFFERENT STIMULATION Steffensen, S.C.*, Moneta, M.E.* and Henriksen, S.J., Research Institute of Scripps Clinic, La Jolla, CA 92037

To further our understanding of dentate inhibitory circuitry we have studied the effects of intra-, inter- and extra-hippocampal stimulation on extracellularly recorded field potentials and single-unit activity in the anesthetized rat. Interneuron cell types were differentiated from dentate granule cells (DGCs) and hilar "mossy cells" by the following criteria: 1) location and morphology (biocytin labeling), 2) driven response and 3) spontaneous activity. DGCs were found approximately 50-75 µm below reversal of the population EPSP (pEPSP), had a perforant path evoked threshold spike latency of 3.5 ms ± 0.2 S.E.M., followed high frequency mossy fiber stimulation (5 pulses, 2.5 ms intervals) and exhibited little bursting activity. Hilar "mossy cells" were encountered approximately 200-400 µm below reversal of the pEPSP, were not driven by perforant path stimulation and fired in bursts with spike amplitude and interval decrement. Interneurons were found appoximately 75-150 µm below reversal of the pEPSP, had a perforant path evoked threshold spike latency of 8.8 ms ± 0.5 S.E.M., did not follow high frequency mossy fiber stimulation, discharged multiply outside the envelope of the evoked field potential and exhibited little bursting activity. The number of interneuron discharges was dependent on PS amplitude and PP interval. Single stimulation of either the ipsilateral hilus, contralateral hilus or the medial septum elicited a single interneuron spike in the dentate, markedly increased perforant path evoked PS amplitudes (210% of control at 80ms conditioning interval) and decreased perforant path PP inhibition. Brief high frequency stimulation of these inputs (3 pulses, 2.5 ms intervals) markedly decreased perforant path PS amplitudes (10% of control) and PP inhibition. The number of perforant path evoked interneuron discharges was unaffected by stimulation of these afferents. The ability of these inputs to increase perforant path evoked PSs and decrease PP inhibition may be explained by their activity-dependent differential effects on interneuron somata and terminals. KINDLING-INDUCED HYPER-RESPONSIVENESS OF NEURONS *IN VIVO*. G.C. Teskey, and R.J. Racine. Department of Psychology, McMaster University, Hamilton, Ontario, Canada L8S 4K1.

The alterations in brain function that accompany kindling may in part be based on an increase in the bursting properties of neurons. Previous reports addressing this possibility have utilized intracellular recordings from either a hippocampal or amygdala-piriform coronal slice preparations. The present study examined the effects of kindling on neuronal response patterns *in vivo*. We also investigated changes in baseline, and spontaneous firing patterns as opposed to discrete evoked or spontaneous burst responses. Male hooded rats were implanted with a stimulating electrode in the amygdala and extracellular recording stereotrodes in the perirhinal and piriform areas. After recovery from surgery, EEG and unit activity was recorded using the Discovery software (Brainwave, CO) which allows the discrimination of single unit responses from a multiunit record. Rats were then kindled to a stage five seizure with either a massed kindling procedure which consisted of several daily 60 Hz, 1 sec, 400 µA stimulations or a rapid kindling procedure which consisted of one 3 Hz, 1000 µA stimulation approximately 60 sec in duration. One, three and seven days following kindling, unit activity was reassessed. Our preliminary observations indicate that kindling caused an increase in the baseline firing rate of units as well as the shorter mean latency inter-spike intervals which reflect the increase bursting response. KINDLING INDUCES LONG - LASTING ALTERATIONS IN RAT NEOCORTICAL EVOKED POTENTIALS. C.A. Chapman, G.C. Teskey, and R.J. Racine. Department of Psychology, McMaster University, Hamilton, Ontario, Canada L8S 4K1.

Prior attempts to induce a long-lasting potentiation of evoked responses in the rat neocortex with high frequency stimulation have met with limited success. Here we report that kindling reliably induces a long-lasting alteration of the callosal-neocortical evoked response in the rat. Male hooded rats were chronically implanted with a bipolar stimulating electrode in the corpus callosum and a bipolar recording electrode in the ipsilateral neocortical sensorimotor area. Two weeks later, a series of four baseline input/output (I/O) response curves were recorded over an eight day period. Rectangular 100 µsec biphasic pulses were applied at 12 different intensities to the callosum. The potentials evoked in the neocortex were analyzed for onset latency, onset slope, maximum peak amplitude, and latency of maximum peak. Four groups of animals were tested, one group did not receive kindling stimulation while animals in the other three groups received either one, seven, or twenty-five daily stimulations (600 µA, 60 Hz, 1 sec train duration). Post-manipulation I/O's were recorded for up to two months. Our results indicate that 7 AD's induce an increase in the amplitude of the early component and the appearance of a late component, while 25 AD's induce an apparent depression in the amplitude of the early component and a further enhancement of the late component. Thus, kindling, but not high frequency stimulation, can readily induce a long-term alteration in the evoked callosal-neocortical response. (Supported by NSERC)

LONG LASTING EFFECTS OF MPOA KINDLING INDUCTION OF SEXUAL BEHAVIOR IN NON-COPULATING MALE RATS. R. Paredes, E. Basañez*, A. Abraham* and V. Romero*. Escuela de Psicología, Universidad Anáhuac. México. D.F.

It has been shown that sexually inactive male rats display sexual behavior when electrical kindling is established in tha medial preoptic area (MPOA). This induction of sexual behavior is not observed when inactive male rats are kindled in the amygdala (AMG). The purpose of the present experiment was to evaluate if the induction of sexual behavior produced by MPOA kindling, has long lasting effects.

Male wistar rats were tested 3 times with receptive females. The animals that did not show any sexual behavior were implanted in the right MPOA. One week after, the animals were retested 3 times with receptive females to assure that they were non-copulators. They received 2 standard kindling stimulus daily and sexual behavior was registered twice a week. Once kindling was fully established, no more stimulus were delivered to the animals and sexual behavior was monitored for 10 months. A non-copulating sham kindling group was observed for the same time. MPOA kindling induced sexual behavior. The rats consistently displayed the bahavior through the 10 month period. Some of the sham kindling group rats occasionally displayed sexual behavior. These results suggest that the neuronal changes produced by kindling induce a permanent change in sexual behavior.

558.8

PATHWAY SPECIFICITY OF ISOPROTERENOL-INDUCED PLASTICITY IN THE DENTATE GYRUS: REPLICATION AND EXTENSION. M. R. Pelletier, R. D. Kirkby and M. E. Corcoran. Dept. of Psychology, U. of Victoria, Victoria, BC, V8W 3P5, Canada.

Previous research has demonstrated that application of β-noradrenergic agonists in vitro can produce long-lasting potentiation (LLP) of field responses evoked in the dentate gyrus (DG) by single-pulse stimulation of the medial perforant path (MPP) and long-lasting depression (LLD) of responses evoked by stimulation of the lateral perforant path (LPP) [Dahl & Sarvey, PNAS, 1989]. We attempted to replicate and extend these important observations.

Transverse hippocampal slices from male hooded rats were placed in an interface chamber. After stable baselines of responses evoked in the molecular layer of DG by stimulation of MPP or LPP were obtained, (-) isoproterenol (ISO) at 1 µM was bath-applied for 30 min, followed by a 30-min wash. High-frequency stimulation (HFS) was then applied to the afferent path. Other slices were subjected to a counterbalance condition, in which HFS was followed by bath-application of ISO.

ISO produced LLP of the MPP-evoked response and LLD of the LPP-evoked response. Subsequent HFS produced a further increase of the MPP-evoked response and recovery to baseline of the LPP-evoked response. In the counterbalance condition, HFS produced LLP of both MPP and LPP-evoked responses. Subsequent application of ISO further potentiated the MPP-evoked response but had minimal effects on the LPP-evoked response.

These results confirm the pathway specificity of the effects of ISO on responses evoked in the DG. They also suggest that the effects of ISO and HFS on responses evoked by MPP stimulation are additive.

558.9

ALTERING THE IMPACT OF EARLY REARING ON THE RAT'S SPATIAL MEMORY WITH PRE- AND POSTNATAL CHOLINE SUPPLEMENTATION. R.C. Tees, E. Mohammadi* and T.J. Adam*. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C. V6T 1Z4, Canada

Recent work suggests that pre- and postnatal choline chloride dietary supplementation during development results in long-term facilitation of working and reference memory in rats (Meck et al., 1989). Stimulation history has also been reported to have long-term effects on spatial competences in adult animals.

The purpose of the present experiment is to examine the effects of pre- and postnatal supplemental choline on the impact of early rearing regimes including dark rearing (DR), and complex rearing (CR). Acquisition and retention of spatial and nonspatial water-based discriminations in CR and DR rats were examined. Subsequently, these rats were given atropine sulfate and re-evaluated.

Results indicate that both pre- and postnatal choline supplementation enhanced performance on working memory in the spatially oriented task, for rats reared in any environment evaluated. A main effect of enrichment was also obtained. Further, atropine administration was demonstrated to impede the efficacy of working memory in all groups tested. These results suggest that neonatal choline supplementation enhances working memory performance in the adult rat.

558.10

REPEATED INJECTIONS OF SCOPOLAMINE HYDROBROMIDE AMELIORATE THE BEHAVIORAL EFFECTS OF SUBSEQUENT SEPTAL LESIONS. A.M. Schneider*, E. Thomas, W. Martin*, M.G. Folwell*, A. Payne*. Depts. of Psychology, Swarthmore College Swarthmore, PA 19081 and Bryn Mawr College, Bryn Mawr, PA 19010.

The relation between drug tolerance and recovery of function following brain damage was examined. Rats were tested in a standard passive-avoidance two-compartment box. Ordinarily rats will step from a small lighted compartment to a large dark compartment with short latencies. Step-through latencies are increased by either a single injection of scopolamine hydrobromide or bilateral lesions in the septal area. The increased latencies seem to be the result of increased fear of the new compartment and, therefore, appear to be a form of neophobia.

Rats given repeated injections of scopolamine hydrobromide (2 mg/kg), 2 injections per day for 3 days, show tolerance to the neophobia produced by the drug and if the injections are given prior to surgery, show tolerance to the neophobia produced by the lesions. The data are taken as evidence that tolerance to scopolamine and recovery from septal lesions are mediated by the same mechanism, and if that mechanism is in place before the brain is lesioned, the deleterious effects that ordinarily result from the lesion are ameliorated.

558.11

BEHAVIORAL TOLERANCE (BT) TO MORPHINE IN SPINAL RATS. C. Advokat and C. McInnis*. Psychol. Dept., LSU, Baton Rouge, LA. 70803

Behavioral tolerance refers to the fact that many behavioral drug effects are significantly reduced if animals have practiced the response before they receive the drug. We have studied the neural basis of BT by using the spinal, nociceptive tailflick (TF) reflex. TF pretreatment reduced the analgesic effect of morphine and this decrease was retained for at least 1 day after spinalization. To clarify the stimulus-response conditions required for BT, separate groups of intact rats were preexposed to either thermal TF, mechanical tail pinch (TP), or thermal hot plate (HP) nociceptive stimulation, pseudo TF trials or habituation to the experimental context. All rats were spinalized 24 h later and tested with the TF the next day, at 30, 60, 120 and 180 min after 3.0 mg/kg, sc morphine. There was an overall decrease in the antinociceptive effect of morphine in the experimental groups relative to nonpretreated spinal rats, but this was only significant for the TF, TP and HP conditions. The data suggest that BT to morphine, assessed with the TF, in acute spinal rats, requires preexposure to a nociceptive stimulus but not specific pretreatment with the thermal TF test.

EFFECT OF ENRICHED ENVIRONMENT AND MORRIS WATER MAZE TRAINING ON BRAIN CHOLINE ACETYLTRANSFERASE ACTIVITY. G.A. Park, B.A. Pappas, S. Murtha and A. Ally*. Dept. of Psychology, Carleton University, Ottawa, Canada, K1S 5B6.

Weanling Long-Evans rats were raised in an enriched (ENR) or impoverished (IMP, standard caging, two rats per cage) environments for 50 days. Subsequently, half of the rats underwent testing in the Morris Water Maze to assess spatial learning. The maze-trained and the untrained rats were then assayed for choline acetyltransferase (ChAT) activity in frontal and remaining cortex, hippocampus and caudate as determined by *de novo* acetylcholine (Ach) synthesis using tritiated acetyl-coenzyme A as a precursor.

The ENR-reared rats learned the platform location in the maze significantly faster than did the IMP-reared rats. The ENR-reared rats showed significantly elevated ChAT activity in the caudate and this was not further affected by maze training. Maze training did increase ChAT activity in the caudate of IMP-reared rats, however. Maze-training also increased ChAT activity in the frontal cortex and hippocampus, but only for ENR-reared rats. Thus ENR rearing significantly and enduringly augmented Ach synthesis in the caudate. Maze training caused a lesser increase in Ach synthesis in IMP-reared rats. ENR rearing also seemed to prime the hippocampus and frontal cortex such that these areas show increased Ach synthesis after maze experience. Brain Ach synthesis is affected by environmental complexity.

ABSENCE OF BEHAVIORAL LONG TERM POTENTIATION IN RATS LEARNING A WATER MAZE TASK. **D.P. Cain, E.L. Hargreaves, Z. Dennison, and F. Boon. Dept. Psychology, Univ. of Western Ontario, London, Ont., CANADA, N6A 5C2.**

In an effort to evaluate the occurrence of behavioral LTP we studied the electrophysiological properties of the perforant path-to-dentate gyrus (PP/DG) pathway in rats before and after they learned a water maze task that is known to be disrupted by lesions of this circuit. After implantation of a stimulating electrode into the PP and a recording electrode into the hilus of the DG averaged responses to single pulses applied to the PP yielded baseline input/output (I/O) curves. All stimulation was delivered while the rats were immobile. The rats then learned to escape onto a hidden platform in a Morris water maze. Four blocks of 4 trials were administered over a period of 6 hr. All rats mastered the task as assessed by learning curves and probe trials. Post training I/O curves were identical to baseline I/O curves as assessed through EPSP maximum slope and population-spike peak to tangent amplitude. Trains of high-frequency pulses were applied subsequently through the PP electrode and these induced significant and enduring electrophysiological LTP, indicating that the stimulation/recording arrangements were capable of detecting plasticity in this circuit. We conclude that under the conditions of this study normal spatial learning occurred in the absence of behavioral LTP in the PP/DG circuit. Supported by a grant from NSERC to D.P.C.

IDENTIFICATION OF THE PATTERN OF PENIS INNERVATION IN THE POND SNAIL *LYMNAEA STAGNALIS*. A.ter Maat, A.W.Pieneman*, Y.A. van Duivenboden* and R.F. Jansen. Vrije Universiteit, De Boelelaan 1087, 1081 HV Amsterdam.

Copulation behavior in the hermaphrodite pond snail *Lymnaea stagnalis* is a 2-4 hr sequence of behavioral acts of variable durations that leads to intromission of the penis and subsequent transfer of semen. The latter behavior has a fixed duration of 36 ± 4 min at 20° C. Male copulation behavior can be induced by isolation of the animals for over two days, in which case copulation is reciprocal, i.e. the animals alternate between male and female roles. The neurons that project in the penis nerve have been identified using cobalt and nickel-lysine backfills. Neurons in three major clusters were stained. Combined intracellular and extracellular recordings confirmed this finding. The clusters are located as follows: 1. the I cluster of the right pedal ganglion; 2. the anterior lobe of the right cerebral ganglion; 3. the ventral lobe of the right cerebral ganglion The neurotransmitter content of these clusters is at least partially known: they contain serotonin, and the peptides APGWamide and FMRFamide, respectively. We are currently investigating the roles of these neurons in penis eversion and retraction.

A pair of interneurons located in the pedal ganglia has been identified. This pair modulates the electrical activity in two of the aforementioned clusters (ventral lobe and I cluster). In addition, they cause strong excitation of the metacerebral giant cells involved in feeding and weak excitation of the caudodorsal cells, a command system for egg laying. Based on these effects, they were termed small wide acting pedal neurons (SWAP neurons).

In order to analyze the functioning of the network outlined above we have started to record from its constituents in the freely behaving animal.

559.2

IN VIVO REGISTRATION OF SPIKING IN THE METACEREBRAL GIANT NEURONS DURING EGG LAYING RELATED BUCCAL RASPING IN THE POND SNAIL, *LYMNAEA STAGNALIS*. R.F.Jansen, A.W.Pieneman* and A. ter Maat. Faculty of Biology, Vrije Universiteit, Amsterdam, The Netherlands.

The egg laying behavior of the pond snail is composed of three phases: Resting, Turning and Oviposition. One of the characteristics of egg laying behavior is the almost total absence of buccal rasping in the 1st, Resting phase (< 50 rasps/10 min.), immediately followed by vigorous rasping (150/10 min.) in the 2nd and 3rd, Turning and Oviposition phases. As shown earlier, this rasping is caused by the coordinated action of feedback from the ovotestis and neuropeptides released from the caudodorsal cells prior to egg laying, and apparently serves to clean the substrate. We therefore investigated the electrical activity of the metacerebral giant cell (MCG), an interneuron that modulates the feeding apparatus, in relation to egg laying. Animals were equipped with fine wire electrodes on one or both the MCG's, and both behavior and electrical activity were recorded. After the experiment, the recorded spiking activity was identified as coming from the MCG by recording synchronous spiking in the contralateral MCG. The dramatic change in the rate of buccal rasping during the transition from Resting to Turning phase behavior seen in normal animals was, surprisingly, not reflected in the rate of spiking of the MCG. After oviposition had ended, however, a significant drop in MCG spiking occurred. This low level of spiking was then maintained for many hours. Since these experiments were done in the absence of food stimuli, we became interested in the interaction between food stimuli and egg laying. In the presence of a chemical stimulus (sucrose, 3.4 gr/l) control animals rasp at high rates (125/10 min) that are maintained for many hours. In egg laying animals, however, the buccal rasping drops to approx. 40/10 min immediately after the projected start of the first, Resting phase of egg laying. It appears that buccal rasping during egg laying is first suppressed, and then increased in the 2nd and 3rd phases. We are currently investigating the role of the MCG in this suppression of rasping in the presence of food stimuli.

559.3

FLUORESCENT DYE LABELING OF STATOLITH AND STATOCONIA IN Aplysia californica. H.A. Pedrozo*, and M.L. Wiederhold. Dept. of Otolaryngology, The University of Texas Health Science Center at San Antonio, TX. 78284-7777.

The gravity receptor organs in Aplysia californica are bilateral paired statocysts. These contain dense statoconia within a fluid filled cyst. The gravitational pull on these calcium rich statoconia causes their interaction with the mechanosensory cells forming the wall of the statocyst. The use of calcium binding fluorescent dyes enables us to more easily determine structural differences between the single statolith with an amorphous interior, present in larval Aplysia and the multiple statoconia with lamellar calcification seen in the post-metamorphic Aplysia 2.0 mm in length or larger. It also allows us to determine the rates of calcium deposition and stone formation. Two fluorescent dyes are employed, tetracycline hydrochloride and xylenol orange. Pluricolor fluorescent labeling is achieved by alternating 24 hr pulsing periods with tetracycline and xylenol orange,with 24 hrs between pulses. The optimum pulsing concentration for tetracycline hydrochloride is 300 mg per liter of sea water for larval Aplysia and 100 mg per liter of sea water for newly metamorphosed Aplysia. For xylenol orange, the optimum concentrationis 20 mg per liter of sea water for both larval and newly metamorphosed Aplysia. Despite structural differences between statolith and statoconia, both can be labeled with the same calcium binding dyes. Supported by NASA Space Biology Program.

EARTH-STRENGTH MAGNETIC FIELD STIMULI THAT ELICIT SPIKING IN AN IDENTIFIABLE MOLLUSKAN NEURON. Kenneth J. Lohmann and A. O. Dennis Willows. Dept. of Biology, University of North Carolina, Chapel Hill, N.C.; Dept. of Zoology, University of Washington, Seattle, WA 98250.

The marine mollusk *Tritonia diomedea* can orient to the magnetic field of the earth (Lohmann and Willows, *Science*, 235: 331-334 (1987)). Two large, identifiable neurons (L Pe 5 and R Pe 5) in the brain of *Tritonia* respond with enhanced electrical activity to changes in earth-strength magnetic fields (Lohmann et al., in press, *J. Exp. Biol.*). These cells may be components of a neural circuit underlying detection of the geomagnetic field or orientation to it. To study the magnetic field parameters that best elicit responses from L Pe 5 and R Pe 5, we have constructed a computer-controlled coil system consisting of three Rubens cube coils arranged orthogonally; two coil systems control the horizontal component of the magnetic field while a third controls the vertical component. An earth-strength field can therefore be generated in any direction or rotated to a new position at variable rates during experiments. Responses of L Pe 5 to changes in horizontal fields, vertical fields, field intensity, and inclination angle are compared.

ORIENTATION TO WATER-FLOW IN *TRITONIA*: BRAIN STRUCTURES ASSOCIATED WITH RHEOTAXIS. J.A. Murray, G. Brown, and A.O.D. Willows. Friday Harbor Laboratories, Friday Harbor, WA 98250.

The nudibranch gastropod *Tritonia diomedea* orients to and moves into water-flow (rheotaxis). Field observations indicate that the slugs orient to tidal flow (R=.41, p<.001; n=80). Additionally, flow-tank experiments show that orientation to current reduces hydrodynamic drag. We examined the neural basis of this rheotaxis behavior by recording intracellularly from the brain, in a semi-intact animal preparation. Neurons of the pedal and cerebral ganglia responded to water-flow directed to the oral veil and rhinophore sheaths with bursts of EPSPs and action-potentials (Murray & Willows 1990, SNS Abstracts, 313.3). The activity of the functional motoneuron Pd3 ipsilateral to the flow stimulus was greater than that of its contralateral homologue.

Intact slugs oriented in a sea-water flume with flow rates only 1 cm/s (Rayleigh, p<.001). When Left Cerebral Nerve#1 is cut, the slug continued to orient, and it oriented significantly when all the left cerebral nerves (1-4) were cut. Cutting LPdN3 reduced turning to the left but orientation remained strong. Initial experiments indicated that when all 8 brain nerves (L&RCeN1-4) innervating the head were cut, the slugs' ability to orient to flow was diminished (Rayleigh, .10>p>.05; n=6). Future experiments will determine the respective contributions of each of these cerebral nerves.

We successfully filled the somata of neurons with neurites in each of the brain's nerves using a nickel filling and rubeanic acid developing process which is simpler than cobalt fills with silver intensification. The nerve fills may help us to identify neurons involved in rheotaxis, if we find that certain nerves are more important than others in their contribution to this behavior.

PROTEIN SYNTHESIS BY INDIVIDUAL, PUTATIVELY HOMOLOGOUS NEURONS IN DIFFERENT SPECIES OF NUDIBRANCH MOLLUSCS. C.M.F. Lohmann* and A.O.D. Willows. Friday Harbor Laboratories, 620 University Road, Friday Harbor, WA 98250.

Morphological and behavioral considerations suggest that specific neurons in different species of sea slugs may be evolutionarily homologous. We have further investigated this possible homology by using gel electrophoresis to study protein synthetic patterns of several identifiable neurons from four nudibranch species. For example, all nudibranchs that we have examined possess a large, white (under epi-illumination) neuron in the pedal ganglion similar to Pedal 5 of *Tritonia diomedea*. Analysis of Pedal Neuron 5 and its putative homologs shows that all produce one major and several minor bands near 45-55 kD. The results thus indicate that neurons of similar morphology have similar protein banding patterns and support the hypothesis of evolutionary homology. These findings, coupled with existing behavioral and neurophysiological data, imply that 1) similar behavior in different species may be mediated by homologous neurons and 2) differences in behavior may involve different uses of the same neurons.

A NEW SENSE ORGAN IN CEPHALOPODS: SENSORY HAIR CELLS ON THE NECK OF THE SQUID *LOLLIGUNCULA BREVIS*. T. Preuss* and B.U. Budelmann. Marine Biomed. Inst., Univ. Texas Med. Branch, Galveston, TX 77550.

Decapod cephalopods, such as cuttlefish and squids, are able to move (pitch, roll and yaw) their head relative to the body. However, no data yet exist on possible receptors that detect such movements. Using morphological techniques (LM, TEM, SEM, and cobalt tracing), we describe, for the first time, a receptor organ that possibly serves as a neck proprioceptor organ.

In the squid *Lolliguncula brevis*, epidermal hair cells exist on the dorsal side of the neck underneath the nuchal cartilage, close to the animal's midline on either side (left and right) of the nuchal crest. The cells can be divided into 4 groups, each with 20-30 presumably primary sensory cells. Each cell carries between 30 and 300 kinocilia, arranged in an elongated ciliary group, with a morphological polarization parallel to either the longitudinal or the transverse axis of the animal. The hair cells are innervated by a branch of the postorbital nerve. Cobalt tracing shows that all hair cells project ipsilaterally (and perhaps contralaterally) to one brain area only, the ventral part of the ventral magnocellular lobe. This area receives afferents from the equilibrium receptor systems as well.

In summary, the data indicate that the epidermal neck hair cells are sensory in nature and presumably serve to monitor the position of the head relative to the body.

TEMPORAL SELECTIVITY AND RESOLUTION IN THE AUDITORY SYSTEM OF THE GREEN TREEFROG (*HYLA CINEREA*). S.E. Allan* and A.M. Simmons. Psychology Department, Brown University, Providence, RI 02912

Differences in rate of amplitude modulation (AM) carry biologically-relevant information for many species of frogs, and these may be reflected in the temporal resolving power of their central auditory system. Multi- and single-unit activity were recorded in the torus semicircularis (TS) of the green treefrog in response to AM noise stimuli varying in rate and depth of modulation. Selectivity to AM rates and the ability to resolve depth of AM were examined by changes in overall firing rate and synchronization to the modulation frequency. Different types of filter functions for AM were found. These include temporally-tuned units with best AM rates of 50 Hz and 300 Hz, which correspond to the natural AM rates of the species' vocalizations. A characteristic dip in sensitivity at 100 Hz, the AM rate of a sympatric species' call, was also apparent. Comparable threshold functions were found using a psychophysical technique. Temporal modulation transfer functions were low-pass in shape, with thresholds reaching 100% depth at AM rates above 100 Hz. The minimum integration time calculated from these functions ranged from 1.0 - 2.5 ms and the difference limens for detectable amplitude changes at the best AM rates varied between .136 dB - 1.09 dB.

AMPLITUDE MODULATION IS AN ATTRACTIVE FEATURE OF *X. LAEVIS* SONG. M.L.Tobias, R.E.Bivins*, S.Nowicki†, D.B.Kelley. Dept. Biol. Sci., Columbia Univ., N.Y., N.Y. 10027, †Dept. Zool., Duke Univ., Durham, N.C. 27706

Male *Xenopus laevis* frogs attract females with rapidly alternating fast and slow trills known as mate calls. The clicks that make up the fast trill portion become progressively louder whereas the clicks of female-typical release calls - ticking - are not amplitude modulated. Sex differences in synaptic efficacy at the laryngeal neuromuscular junction contribute to amplitude modulation by regulating the number of contracting muscle fibers. We thus wished to determine whether amplitude modulation is critical to the attractiveness of male song. An artificial mate call in which the fast trill portion was of uniform amplitude equal to the loudest click was constructed. This modified call was presented to hormone-primed, sexually receptive females in alternation with an unmodified mate call and white noise. The initial angle of turn - towards or away from the speaker- was used to measure the female's phonotaxic response. Receptive females turn towards normal mate calls (positive phonotaxis) and away from white noise (negative phonotaxis). Females are ambivalent to amplitude modified calls; turning towards or away from the call at equal frequencies. The data suggest that amplitude modulation of mate calls - particularly the soft onset of the fast trill - is an important attractive feature for the female. Because amplitude modulation reflects the weak synapses at male neuromuscular junctions, females appear capable of responding appropriately to a sexually dimorphic synaptic property.

ACOUSTIC NICHE PARTITIONING BY THREE SPECIES OF NEOTROPICAL FROGS. B.E. McClelland, W. Wilczynski, J.M. Wicks, and A.S. Rand. Dept. of Psychol., Univ. of Texas, Austin, TX, 78712, and Smithsonian Tropical Res. Inst., Balboa, Panama

Three closely related frog species, Hyla ebracatta, H. phlebotes, and H. microcephala, breed sympatrically and can be found in mixed choruses. We investigated acoustic communication in these species in a mixed chorus in Gamboa, Panama. All have high frequency, broad-band advertisement calls, but mean dominant frequency differs among the species: H.e.: 3.2 kHz; H.p.: 3.8 kHz; H.m.: 6.1 kHz. H.e. and H.p. calls also differ in temporal structure; H.p. and H.m. calls are similar in this respect. Mean basilar papilla tuning (determined by midbrain recordings) also differs among the species: H.e.: 2.6 kHz; H.p.: 2.8 kHz; H.m.: 5.3 kHz. Thus these species partition the acoustic channel used for communication in the frequency domain and, in the two species (H.e. and H.p.) where BP tuning predicts reception of both calls, in the temporal domain as well. Morphometric studies indicate volumetric changes in the middle and inner ear cavities coincide with tuning differences. Both are largest in H.e., intermediate in H.p., and smallest in H.m., as would be expected if these features contribute to the resonance of the ear. Additional studies are underway to determine if call differences are reflected in species differences in laryngeal structure. Supported by the Smithsonian Institution and NIMH R01 MH 45350. We thank D.L. Greene for assistance.

ACOUSTIC MODULATION OF HYPOTHALAMIC FUNCTION IN HYLA CINEREA. J. D. Allison. Dept. of Psychology, Univ. of Texas, Austin, TX, 78712.

Previous studies reveal that the preoptic area (POA) and ventral hypothalamus (VH) of anurans receive input from thalamic and midbrain auditory nuclei. We examined the responses of POA and VH units to acoustic stimuli using standard electrophysiological techniques. Spontaneously active units were isolated and then stimulated for 2.5 min. with eigher conspecific mating calls (MC) or white noise (WN) pulses followed by a 2.5 min. "No stimulus" period. The protocol was repeated. Some cells were presented with both stimulus protocols. PST histograms were generated to examine spike rates and patterns. Differences in spike rates between stimulus conditions were then assessed using the Tukey HSD *a posteriori* test of significance. Thirty-eight POA units were examined, 10 (26.3%) of which increased their firing rate in response to the MC stimulus. Nine (39.1%) of 23 VH units examined increased their firing rate in response to the MC stimulus. Only 1.3% (2/15) of the POA units and 1.1% (1/9) of the VH units responded to the WN stimulus. Thus ε biologically important social cue (the mating call) modulates the activity of some POA and VH neurons. This work was supported by NIMH grant R01 MH45350 to Walter Wilczynski.

MORPHOLOGICAL CORRELATES OF AUDITORY SENSITIVITY IN ANURAN AMPHIBIANS. **J. H. Fox. Department of Psychology, University of Texas, Austin, TX 78712.**

Comparative studies involving anuran audition are often limited by the paucity of threshold data that have been reported. Certain well documented morphological characteristics may correlate with auditory sensitivity and may therefore be useful as sensitivity indices, enabling comparative work with more diverse taxa. In this study, a database was compiled, and the relationships were examined between snout-vent length (SVL), tympanum area (TA), amphibian and basilar papilla hair cell populations (HCAP and HCBP), and auditory sensitivity measures derived from "cochlear" potential (CP), eighth nerve (8N), and torus semicircularis (TS) audiograms. Sensitivity to white noise was estimated on the basis of reported audiograms and was subdivided into amphibian papilla (AP) and basilar papilla (BP) frequency range components. SVL, TA, and HCAP correlate positively with all sensitivity measures in the AP range. In the BP range, both SVL and TA correlate positively with 8N and TS sensitivity but not with CP sensitivity, and HCBP correlates with no sensitivity measure. Partial correlational analysis indicates that only TA significantly predicts auditory sensitivity, relating more strongly to BP than to AP sensitivity. This relationship probably derives from the direct proportionality between TA and collected acoustic force, also characteristic of other tympanic devices such as microphones. The differential relationship of TA with AP and BP measures is consistent with the differential reliance of these organs on tympanic sound conduction. The correlations involving HCAP, HCBP, and SVL probably derive secondarily from complex interactions with TA.

SPECTRAL AND TEMPORAL CUES PRODUCED BY THE EXTERNAL EAR OF THE BIG BROWN BAT, Eptesicus fuscus AND THEIR RELEVANCE TO SOUND LOCALIZATION. J.M. Wotton*, T. Haresign and J.A. Simmons. Department of Psychology and Section of Neurobiology Brown University, Providence, RI 02912.

Sound pressure level recordings were made from isolated ears of Eptesicus fuscus to determine the binaural and monaural acoustic cues used in localization. The transfer functions and impulse responses of the external ears were calculated for sound sources located at many different azimuths and elevations. Temporal and spectral cues changed systematically with the position of the sound source. Measurements made after the removal of the tragus show that monaural cues for elevation appear to be produced by pinna-tragus reverberations. The information available to the bat and represented in the transfer functions and impulse responses has been shown to have behavioral relevance for the bat in sound localization experiments.

RESPONSE PROPERTIES OF NEURONS IN THE BIG BROWN BAT, Eptesicus fuscus, TO CLOSED FIELD DICHOTIC STIMULATION. T. Haresign, M. Ferragamo*, and J. Simmons. Hunter Laboratory, Brown University, Providence, R.I. 02912

Extracellular recordings were made from the inferior colliculus (IC) and auditory cortex of Eptesicus fuscus. Using a closed field dichotic stimulation system, units were tested to determine their best frequency (BF), latency, interaural intensity difference (IID) tuning, and interaural time difference (ITD) tuning. Units were functionally classified according to their binaural response properties. The most common type of IID tuning among the units tested is EI tuning (contralateral ear excitatory, ipsilateral ear inhibitory). In the IC there is a wide distribution of BF's and latencies, suggesting that one of the functions of the IC may be to act as a latency disperser. Many of the EI units are sharply tuned for frequency and show a sharp boundary between excitation and inhibition in their IID tuning curves. These units should be very sensitive to spectral differences between the ears.

A COMPUTER SIMULATION OF THE UNIFIED PERCEPTION OF TIME AND FREQUENCY BY THE BIG BROWN BAT. P.A Saillant*, J.A. Simmons and S.P. Dear. Dept. of Psychology and Section of Neurobiology, Brown University, Providence, RI 02912

A newly developed Spectral Correlation And Transformation algorithm (SCAT) has demonstrated the ability to reproduce the performance of the big brown bat, *Eptesicus fuscus*, in behavioral experiments designed to measure glint resolution, phase sensitivity and amplitude latency tradeoff. The SCAT algorithm is constructed around known physiological properties of inner hair cells, delay-tuned neurons and other components of the bat auditory system, and in addition, incorporates novel, physiologically motivated, processing elements. Like *Eptesicus*, the SCAT algorithm can detect the separation between each pair of glints in targets separated by as little as 4 μs. Jitter experiments in which the phase of the returning echo is inverted by 180^0 show that bats perceive the inverted crosscorrelation function of the emission and echo. This effect is reproduced by SCAT as a result of the temporal properties of delay-tuned FM neurons responding to dominate peaks of the group delays in each filter bank. Amplitude-latency trading experiments, in which the temporal and spectral contributions to complex image formation can be dissociated, have also been replicated by SCAT showing that the novel transforms it employs can help facilitate our understanding of auditory perception in bats. HUNTING AND ECHOLOCATION BEHAVIOR IN THE FISHERMEN BAT NOCTILIO LEPORINUS IN THE FIELD. H.-U.Schnitzler, E. Kalko*, I. Kaipf* and A. Grinnell. Dept. Animal Physiology, Univ. of Tübingen, D-7400 Tübingen, Fed. Rep. Germany.

We photographed foraging *Noctilio leporinus* in Costa Rica and recorded their echolocation signals simultaneously. In the flapping search flight, the bats fly about 50 cm over water emitting groups of 2-3 CF and CF-FM pulses of up to 14 ms long. In the extended leg search flight, the bats fly only a few cm over water with their legs straight back. Eventually, they lower their feet to dip into or to rake through the water emitting groups of short CF-FM signals interspersed with 1-3 longer CF and/or CF-FM signals. The bats use three hunting strategies. The pointed dip is directed to a single target to scoop it out of the water. At pointed dips out of the extended leg search flight, the bats do not react to the target in their echolocation behavior. However, at pointed dips out of the flapping search flight, which we evoked with a water jet simulating a jumping fish, the bats reacted with a reduction in pulse duration and interval, finally producing short FM signals. At the directed rake, the bats rake through patches of many jumping fish with no reaction in their echolocation behavior. Therefore we think that they do not localize a single fish, but get enough information to direct their flight to the area with high jumping activity. The random rake strategy is used if there are no jumping fish around. The bats make very long rakes in areas which previously had many jumping fish. As the bats have no way of knowing if fish are still there, we think that they catch fish only by chance. The bats need 50-200 dips or rakes to catch a fish.

LEARNED RELEVANCE OF SPECIES-SPECIFIC VOCALIZATIONS AND THEIR ^{14}C-2-DG PATTERNS IN AUDITORY CORTEX IN THE DEGU (OCTODON DEGUS)

S. Braun*, D. Bonke[1], and H. Scheich. Institute of Zoology, TU-Darmstadt and CE Merck[1], D-6100 Darmstadt, Germany

In a Chilenian rodent, the degu, early learning of species-specific vocalizations between mother and offspring was investigated. Degus are highly social and live in large family structured colonies. Degu mothers vocalize while nursing their pups, which are precocial at birth. Behavioral studies of degu pups using a discrimination task revealed an approach to mother calls while pups raised by muted mothers failed to react. This leads to the assumption that the behavioral significance of the calls is learned early during nursing sessions. 2-DG experiments in pups using mother calls and pure tones as stimuli revealed dorso-ventrally oriented bands of high glucose uptake in several areas of auditory cortex. Bands appeared to be wider and more complex in animals stimulated with mother calls or elements of them compared to the same number of bands obtained with pure tones. As the calls showed a complex spectral and temporal pattern results are compatible with a distributed representation of them in tonotopic maps.

SELECTIVE RESPONSES OF MACAQUE TEMPORAL NEURONS TO COMPLEX SOCIAL STIMULI. L.A. Brothers & B.D. Ring. UCLA-Sepulveda VA Medical Center & UCLA Brain Research Institute, Sepulveda CA 91343.

The present study extends previous observations in medial amygdala and adjacent cortex of neurons selective for social features. Moving visual and/or auditory stimuli lasting 2s were presented to an alert subject while recording in the region of the right amygdala. Stimuli were drawn from an extensive library of macaque behavior stored on laser disk. Neuronal responses were compared to responses elicited by relevant control stimuli differing from target stimuli along one or more dimensions. Of 533 cells analyzed, 14 showed selective responses to features of presented stimuli, for example, agonistic content. The response of one cell to segments depicting a retreating animal was significantly enhanced by concomitant presentation of the animal's vocalizations. Such neurons may participate in integrations necessary for forming high-level social representations.

BEHAVIOR PATTERN ORGANIZATION IN 6 MAMMALIAN SPECIES. G.E. Gerstner, L.J. Goldberg. Section of Oral Biol., Sch. of Dent., Brain Res. Instit., Sch. of Med., UCLA, Los Angeles, CA 90024).

Ethology and behavior ecology studies are often interested in behavioral adaptations; however, they often model behavior as being ideally or optimally adapted. In other words, they rarely consider the existence of neuromuscular physiological components that restrict the evolutionary potential of behaviors. We believe that behaviors are suboptimally adapted as a result of various physiological constraints. The current study was undertaken to provide insight in this regard.

Six giraffes, 4 okapis, 4 roe deer, 6 kangaroos, 4 red pandas, and 3 raccoons) were videotaped for 10 hr periods on 4 separate occasions over a 1.5 yr period. Every behavior pattern occurring during each 10 hr videotaping session was classified in such a way that cross-species comparisons could be made. Behavior pattern durations and occurrences throughout the 10 hr periods were then analyzed to determine what features were similar among all 6 species.

The results indicate that: 1) over 80% of the behavior patterns were similar in all 6 species, 2) of these patterns, their relative frequency of occurrence was similar in all 6 species, 3) a temporal hierarchy of behavior patterns was similar in all 6 species, with spectral peaks occurring near 0.5 s, 3-6 s, 1-2 min, 10-20 min, 1-1.5 hr. The results of this study support the hypothesis that many aspects of behavior organization are conserved in the mammalian lineage, indicating potential physiological restrictions on the evolutionary potential of behavior. We acknowledge the assistance of the San Diego Zoo and Wild Animal Park, Los Angeles Zoo, and Phoenix Zoo staffs. This study was supported by PHS Grant DE00205.

A MODEL OF NERVOUS SYSTEM FUNCTION DURING CLASSICAL AND INSTRUMENTAL CONDITIONING. A.H. Klopf, J.S. Morgan* and S.E. Weaver*. Wright Laboratory, Wright-Patterson Air Force Base, Ohio 45433-6543.

A computational model of nervous system function during classical and instrumental conditioning is proposed. The model assumes the form of a network of control systems. Each control system is capable of learning and is referred to as an associative control process (ACP). Learning systems consisting of ACP networks, employing the drive-reinforcement learning mechanism (Klopf, 1988) and interacting in a real-time, closed-loop fashion with environments, are capable of being instrumentally conditioned, as demonstrated by means of computer simulations. The simulated systems learn, in multiple-T mazes, to chain responses that eventually lead to primary positive reinforcement. The systems also learn to avoid primary negative reinforcement. The temporal order in which the responses are learned is consistent with that observed in animal learning. Also, consistent with animal learning experimental evidence, the ACP network model accounts for a wide range of classical conditioning phenomena. The ACP network is intended as a model of limbic system, hypothalamic, and sensory-motor function, suggesting a relationship between classical and instrumental conditioning that is consistent with Mowrer's (1960) two-factor theory of learning.

Proprioceptive cues necessary for deciphering the mormyrid fish electrosensory world. J.Serrier*, A.Kleiser* and K.Grant. Dept. of Neurophysiol. Sensor., Lab. of Physiol. Nerveuse CNRS F-91198 Gif-sur-Yvette

In mormyrid fish, the electric organ discharge (EOD) is the energy source for the electrosensory system involved in active electrolocation. Current flow through cutaneous electroreceptors will depend on the relative position of the electric organ in the tail and the rest of the body and integration of proprioceptive information is therefore necessary to the electrosensory processing network to compute an accurate central image of the environment. Static body position-related activity has been recorded previously in the *eminentia granularis posterior (EGp)* of the cerebellar caudal lobe (Bell et al., in preparation) and it is probable that integration occurs in this structure which projects via granule cells to the underlying electrosensory lobe.

Recording was carried out in the caudal lobe under metomidate anesthesia which renders the fish insensitive to painful stimuli without supressing the EOD, spinally commanded motor activity (reflex swimming) or electrosensory primary afferent activity. During spontaneous swimming movements it was shown that tonic firing frequency of many *EGp* units is tuned to tail curvature; intracellular biocytin labelling identified these units as fibers which run throughout the *EGp* and which probably originate from the spino-cerebellar tract. In these fibers there seemed to be no relation between the recorded proprioceptive activity and the EOD command. A second class of unit was found close to the border of *EGp,* in the molecular region of the posterior caudal lobe. These were direction sensitive to movement and gave a precise dynamic coding of tail position. Similar units from the opposite side of the brain showed a reciprocal firing pattern. Again there was no relation to the EOD command. However, clear EOD-related activity can be recorded in other neuronal elements in the caudal lobe and it is likely that both types of motor-related information will reach the electrosensory lobe via this relay.

560.2

THE POLARITY PREFERENCE OF TUBEROUS ELECTRORECEPTORS IS AFFECTED BY FREQUENCY TUNING J. R. McKibben and C.D. Hopkins Section of Neurobiology and Beharvior, Cornell University, Ithaca, NY 14853.

Weakly electric fish localize and approach electric organ discharges (EODs) from conspecifics and artificial electrical dipoles by aligning their body axis parallel to the local electric field vector while swimming along curved current lines to reach the source. We are interested in the sensory mechanism behind the **polarity** preference for approaching the "head" electrode of a dipole. Yager and Hopkins (S.N. Abstract 548.2, 1990) already demonstrated that sensory cues about the axis of an electric field are provided by individual electroreceptors positioned over the body surface.

We recorded from burst duraction coders in silenced *Hypopomus sp.* while presenting homogeneous fields from single period sine waves (1 kHz carrier) at 15° intervals around a circle. We determined the number of spikes per stimulus for various amplitudes and directions, and measured polarity sensitivity along the best axis while varying the stimulus carrier frequency from 100 to 6000 Hz. We also measured frequency-tuning curves for these receptors.

With a 1 kHz stimulus, most receptors had asymmetric polar sensitivity plots, nearly all with the strongest response oriented inward, perpendicular to the skin. Fewer units had symmetrical sensitivity plots. When the stimulus frequency was varied, we found two types of units differing in their polarity preference responses. **Type I** units gave strongly asymmetrical responses to carrier sine waves near the best frequency (BF) of the receptor, but more symmetrical responses when stimulated at frequencies above or below the BF. **Type II** units gave symmetrical responses to stimuli near the BF but became weakly asymmetrical at frequencies below the BF. Receptors of both types may reverse asymmetry. The two response types had, respectively, narrow-band and low-pass tuning curves. We simulated these frequency-dependent changes in polarity preference electronically using either a low-pass or a band-pass filter followed by a rectifier. Our data establishes that information is available to the CNS that would permit polarity discrimination.

Conditional Oscillatory Discharge in Topographic Maps of the Electrosensory Lateral Line Lobe (ELL). R.W. Turner, J.R. Plant and L. Maler, Dept Anat, Univ Ottawa, Canada K1H 8M5

The weakly electric fish *Apteronotus leptorynchus* generates an electric organ discharge (EOD) to electrolocate objects in their enviroment. The frequency of EOD amplitude modulations (AM) are processed in 3 independent topographic maps (segments) in the ELL. Each segment contains a primary circuit of pyramidal (PC) and granule (GC) cells arranged in a laminar fashion, and 5 GABAergic inhibitory cell types. PCs in each segment respond *in vivo* to a restricted range of AM frequencies (Shumway 1989), increasing from Centromedial segment (CMS,1-8 Hz) to Lateral segment (LS,40-120 Hz). Maler (1988) thus suggested that the ELL acts as an array of temporal filters. In *in vitro* ELL slices, focal ejections of bicuculline (BIC; 50 μM) in only the CMS GC layer evoked oscillations of PC and GC field potentials (10-40 min) restricted to CMS, corresponding to an intracellular 10-20 mV PC membrane oscillation and rhythmic spike discharge (5-6 sec period). Hyperpolarization blocked PC spike discharge and reduced oscillation amplitude without affecting period. Focal ejections of TTX in the GC layer blocked oscillations. Unit recordings reveal that spike frequency and burst duration differs across ELL segments (CMSf = 12 ± 3, *Dur* =1.4 ± .4 s; LSf = 66 ± 29, *Dur* =.61 ± .04 s; n=13). These data suggest that intrinsic segmental mechanisms may contribute to the tuning of PC discharge to AM modulations *in vivo*.

560.4

DEVELOPMENT OF THE MULTIPLE MAPS OF THE ELECTROSENSORY LATERAL LINE LOBE (ELL) IN EIGENMANNIA. S. Viete. SIO, UCSD A-002, La Jolla, CA 92093.

The electrosensory lateral line lobe (ELL) of the weakly electric fish Eigenmannia contains 3 somatotopic maps of tuberous electrosensory input. The multiple maps receive identical primary afferent information as each afferent sends collaterals to all 3 maps, the central medial (CM), the central lateral (CL) and the lateral map (L).

In order to determine when and how the tuberous 3 maps develop, we applied HRP either to the supraorbital ramus (SO-AVN) or the preopercular-mandibular ramus (PM-AVN) of the anterior lateral line nerve (AVN) or the anterior lateral line nerve ganglion itself.

The study revealed that all three maps emerge prior to the onset of the jamming avoidance response (JAR) in juvenile Eigenmannia. The three maps develop successively, from medial to lateral. The primary afferents seem to make contact in one target area, before collaterals branch off to innervate the second and third target area. The central lateral map is the first and only one until the fish has reached a body length of 9 mm. After further growth (9.5 -11.5 mm) the central lateral map develops, and finally the third map is formed at a body length of 12 mm. This developmental succession appears to reflect the evolutionary history of these maps.

DESCENDING SENSORY INFORMATION PROJECTS HOMOTOPICALLY TO THE ELECTRORECEPTIVE DORSAL OCTAVOLATERALIS NUCLEUS IN SKATES

R. A. Conley and D. Bodznick
Wesleyan University Biology Dept., Middletown, CT 06457

The dorsal granular ridge (DGR) in elasmobranchs is a part of the vestibulolateral cerebellum which projects via parallel fibers to the dorsal octavolateralis nucleus (DON), the primary electrosensory nucleus. Somatotopic representations of electrosensory and propriosensory information in DGR and the topography of the DGR to DON projection suggest that the projection is homotopic. A homotopy has now been demonstrated by activating the parallel fibers with a stimulating electrode placed in DGR. Evoked potential and unit responses were recorded electrophysiologically in DON.

The evoked potential is characterized by a positivity at 4 ms latency followed by a negativity. The positivities are believed to be synaptically induced depolarizations on the dendrites of the DON ascending efferent neurons. Upon parallel fiber activation, typically one or two spikes followed by a long-lasting suppression are elicited in the ascending efferent neurons. Responses to electric fields are reduced in magnitude when presented during this suppression period.

Peak evoked potential amplitudes and unit responses to parallel fiber activation occur only in areas of the DON containing units whose receptive fields correspond with the composite receptive field recorded at the stimulation site in DGR. The data show a homotopic projection of information from DGR onto DON.

LAMINAR SEGREGATION OF FUNCTION IN THE TORUS SEMICIRULARIS OF WEAKLY ELECTRIC FISH. S.J. Call and G.J. Rose. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112.

The processing of sensory information in laminated structures is a common feature of vertebrate central nervous systems. To understand the functional significance of laminar organization, we studied the processing of electrosensory information in the dorsal torus semicircularis of Eigenmannia. This region of the midbrain consists of 12 laminae and approximately 55 neuron types.

We investigated structure-function relations in the torus by labeling physiologically characterized neurons with Lucifer Yellow. Ampullary and tuberous information is processed differentially within the laminae of the torus: neurons of lamina 3 and lamina 5 are predominantly ampullary and tuberous in function, respectively.

Tuberous units respond well to "beats.," i.e., modulations of signal amplitude and phase, that result from the interaction of foreign signals with the fish's own quasi-sinusoidal electric organ discharge. The "beat rate" is proportional to the magnitude of the frequency difference between these two signals. Some units respond well to low beat rates but poorly to high rates (i.e., "low-pass" temporal filtering).

We observed subthreshold fluctuations in the membrane potentials of toral neurons that reflect the patterns of modulations of signal amplitude and phase. Changes in the structure of these psps that accompany changes in the beat rate have provided insight into the mechanism of temporal filtering. Models of these mechanisms will be presented. Supported by grants from NSF and Sloan Foundation.

LONGITUDINAL TRACKING RESPONSES OF GYMNOTIFORM FISH. G.J. Rose and J.C. Canfield. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112.

A variety of behaviors serve to stabilize sensory images on receptor arrays. In one class of these behaviors, global movements of the "surround" elicit compensatory movements of the receptive surface. Previous studies have shown that weakly electric fish are able to track aggregate lateral movements of surrounding objects using exclusively the electric sense.

We now report measurements of longitudinal tracking responses of Eigenmannia and Sternopygus. These movements were elicited by moving a "shuttle" in which the fish was situated. Fish were able to track longitudinal motion of the shuttle using visual or electrosensory cues.

The gain and phase of tracking responses were studied as a function of the magnitude and frequency of shuttle motion. Fish were able to track velocities of shuttle motion of at least 4 cm/s with little decrement in gain.

We delivered signals that excited ampullary receptors, tuberous receptors, or both during longitudinal tracking of various velocities of shuttle motion. The jamming effects of these stimuli will be presented. Supported by grants from NSF and Sloan Foundation.

A SUBLEMNISCAL PREPACEMAKER NUCLEUS IN GYMNOTIFORM ELECTRIC FISH DEPOLARIZES RELAY CELLS OF THE PACEMAKER NUCLEUS VIA NMDA-TYPE RECEPTORS. C.H.Keller[1], M.Kawasaki[2], W.Heiligenberg, G.Kennedy, W.Metzner. Neurobiol. Unit, Scripps Inst. Oceanog., UCSD, La Jolla, CA 92093; and [1]Inst. of Neurosci., U. of Oregon, Eugene, OR; [2]Dept. Biology, U. of Virginia, Charlottesville, VA.

The medullary pacemaker nucleus of gymnotiform fish is an endogenous oscillator which triggers each electric organ discharge (EOD) by a single command pulse. The pacemaker nucleus consists of electrotonically coupled 'pacemaker' cells, which generate the rhythm, and 'relay' cells, which follow the pacemaker cells and excite the spinal motor neurons of the electric organ. By injecting choleratoxin into the pacemaker nucleus, we have retrogradely labelled a hitherto unknown sublemniscal nucleus which, in addition to the classical diencephalic prepacemaker nucleus, provides input to the pacemaker nucleus.

Stimulation of the sublemniscal nucleus in the genera Sternopygus and Hypopomus causes a sustained depolarization of the relay cells that shuts down the regular electric organ discharges over a period of several seconds. Pressure injection of the NMDA receptor blocker, APV, to the pacemaker nucleus reversibly prevents this response while not affecting other forms of modulations of the pacemaker that are not mediated by NMDA. The same sublemniscal nucleus was also labelled in the genera Eigenmannia and Parapteronotus, but its functional significance has yet to be determined.

560.9

ULTRASTRUCTURAL EVIDENCE OF GABA-ERGIC INHIBITION AND GLUTAMINE-ERGIC EXCITATION IN THE PACEMAKER NUCLEUS OF THE GYMNOTIFORM ELECTRIC FISH, **HYPOPOMUS**. G.Kennedy* and W.Heiligenberg. Neurobiology Unit, Scripps Institution of Oceanography, UCSD, La Jolla, CA 92093

The medullary pacemaker nucleus of Hypopomus is an endogenous oscillator which triggers each electric organ discharge (EOD) by a single command pulse. The pacemaker nucleus consists of electrotonically coupled 'pacemaker' cells, which generate the rhythm, and 'relay' cells, which follow the pacemaker cells and excite the spinal motor neurons of the electric organ. The pacemaker cells receive two separate and independent inputs from the complex of the diencephalic prepacemaker nucleus, a GABA-ergic inhibition and a glutamine-ergic excitation. Whereas the inhibition slows down and, eventually, arrests the pacemaker cycle, the excitation accelerates the pacemaker cycle in a smooth and gradual manner.

We have labelled the two inputs to the pacemaker nucleus anterogradely by injecting HRP to the respective sites of the prepacemaker complex. By using respective immunogold-labelled antibodies and en-grid staining techniques, we then demonstrated GABA and glutamate in labelled synaptic profiles of ultra-thin sections of the pacemaker nucleus. The two types of synapses were interspersed on the surfaces of somata and dendrites of pacemaker cells.

MIDBRAIN AND DIENCEPHALIC LINKS WITHIN THE NEURONAL NETWORK UNDERLYING THE JAMMING AVOIDANCE RESPONSE IN EIGENMANNIA.

Walter Metzner and Walter Heiligenberg. UCSD A-002, SIO, La Jolla, CA 92093.

Weakly electric fish of the genus Eigenmannia avoid jamming electrosensory stimuli from neighbouring fish by either increasing or decreasing the frequency of their own electric organ discharge (EOD), depending on the sign of the difference to the neighbour's EOD frequency (jamming avoidance response, JAR). The sign of the frequency difference is evaluated by neurons within the deeper laminae of the torus semicircularis dorsalis (Tsd) of the midbrain. Intracellular recording and labelling of neurons of the Tsd show that these sign selective neurons project to those parts of the nucleus electrosensorius complex (nE) that control either the rise (nE↑) or the decrease of the EOD frequency (nE↓). Extracellular injections of cholera toxin into the nE↑ and nE↓, respectively, reveal that these areas project to the anterior thalamus (ATh). It is the ATh, where stimulation with L-glutamic acid causes the most prominent smooth rise in the EOD frequency. Intracellular labelling of neurons of the medial part of the diencephalic prepacemaker nucleus (PPn-G) shows that their dendrites reach into the ATh. The same neurons modulate the frequency of the medullary pacemaker nucleus.

AFRICAN ELECTRIC FISH, *GYMNARCHUS*, USE THE IDENTICAL COMPUTATIONAL ALGORITHM AS SOUTH AMERICAN ELECTRIC FISH FOR THEIR JAMMING AVOIDANCE RESPONSES. Masashi Kawasaki. Department of Biology, University of Virginia, Charlottesville, VA 22901.

Both African wave-type electric fish, *Gymnarchus*, and South American wave-type electric fish, *Eigenmannia*, gradually shift the frequency of electric organ discharges (EODs) away when they encounter a neighbor of similar discharge frequency. *Gymnarchus* and *Eigenmannia* are quite unrelated belonging to different superorders of fishes and believed to share no common electroreceptive ancestor. The occurrence of this jamming avoidance response (JAR) both in such unrelated phyletic groups invites behavioral and physiological comparison (Bullock et al., 1975). In this study, behavioral tests were performed in curarized *Gymnarchus* to identify basic computational algorithms involved in their JAR.

Fish's own EOD was silenced by curare and a replacement signal, S_1, was offered through a pair of electrodes located in the mouth and at the tail. A signal mimicking neighbor's EOD, S_2, was delivered through the other pair of electrodes straddling the fish. The JAR occurred depending solely upon the frequency differences between S_2 and S_1, and S_1 did not require to be phase-locked to the pacemaker activities which were monitored by a suction electrode attached to the tail, suggesting that the sensory mechanisms for the JAR do not involve the internal reference to the pacemaker activities. When S_1 and S_2 were electronically added and offered through the same pair of electrode, no jamming avoidance response occurred, suggesting that the differential phase comparison is involved. These two computational features for the JAR are identical as those used in *Eigenmannia*.

SEXUALLY DIMORPHIC DISTRIBUTION OF SUBSTANCE P AND ITS ROLE IN THE REGULATION OF COMMUNICATION IN AN ELECTRIC FISH. M.M. Weld[1], L. Maler[1], R. Quirion[2] and S. Kar[2]. [1]Dept.of Anatomy, University of Ottawa, Ottawa, Ontario, Canada K1H 8M5, and [2]Douglas Hospital Research Centre, Verdun, Quebec, Canada H4H 1R3.

Apteronotus leptorhynchus emits a continuous electric organ discharge (EOD) of constant frequency which is used in electrolocation. The EOD is controlled by the medullary pacemaker nucleus (PM) whose only known input is from the diencephalic prepacemaker nucleus (PPn). The PPn thus controls transient changes in the frequency of the EOD, called "chirps", which are used in communication.

Immunohistochemical studies revealed a major system of substance P-like immunoreactivity (SPli) which originated in the hypothalamus and, in males only, innervated many areas of the diencephalon, including the PPn, its ventral territory (VT, an area containing dendrites of PPn cell bodies), and 2 hypophysiotrophic nuclei. Hypothalamic SPli innervation of the diencephalon was absent in females. Our results suggest that a SP system of hypothalamic origin is involved in regulating both endocrine events and sexual/territorial-related behavior in males. No sexual dimorphism of SPli was found in the telencephalon, mesencephalon or rhombencephalon. Neurokinin 1 and 3 (NK_1 and NK_3) receptors were found in the brain by autoradiography; their distribution showed a very close correlation with that of SPli, in particular the NK_1 receptor, which preferentially binds SP, was found in the VT.

Neuroactive substances were injected into the PPn of curarized, respirated fish to evoke chirps. Glutamate evoked short chirps (8 msec) similar to spontaneous chirps. Substance P-evoked chirps were longer (25 msec) and had a more complex waveform. Glutamate was most effective in the PPn proper. In contrast, SP was most effective in the VT of the PPn, an area with abundant dendrites from PPn cell bodies, dense SPli and NK_1 receptors.

RETROGRADE TRACING AND IMMUNOHISTO-CHEMISTRY OF ELECTRIC LATERAL LINE LOBE (ELL) NEURONS OF THE TELEOST *GNATHONEMUS PETERSII*, MORMYRIDAE. T. Szabo, J.-P.Denizot*,M. Ravaille-Véron*,C.C. Bell, U. Bonn*. Dept. Neurophysiol. Sens., Lab. Physiol. Nerveuse, C.N.R.S., F-91198 Gif/Yvette Cedex.

Retrograde labeling following mesencephalic injections of HRP showed that only a limited number of ELL neurons are efferent. These are distributed between ganglion and deep fiber layers. Ganglion cells have basal dendrites extending into the granular layer where lateral line nerve afferents terminate, suggesting disynaptic connections between primary afferents and the mesencephalon. Small intralobar injections of HRP demonstrated projections from small cells of the intermediate layer to the molecular layer.

Immunohistochemistry revealed that a large number of ganglion and beard cells are glutamatergic. The somata of ganglion and beard cells were surrounded by GAD-IR terminals and GAD-IR boutons were also distributed along dendritic trees in the molecular layer. Identified efferent cell bodies also bore GAD-IR endings. Small cells in the molecular layer and commissural axons with cells of origin in the deep fiber layer were GABA-IR. GAD-IR terminals were also observed surrounding cell bodies of the ELL nucleus. Granule cells in the ELL dorsal (DLZ) and medial (MZ)zones, but not in the ventrolateral zone (VLZ), and terminals at the ventral border of the molecular layer were labeled with anti-calbindin antibodies. Serotoninergic fibers have also observed previously in all ELL layers.

560.14

EVIDENCE FOR DISTINCT BUT OVERLAPPING POPULATIONS OF COMMISSURAL AND GABA-IMMUNOREACTIVE NEURONS IN THE MEDULLARY ELECTROSENSORY NUCLEUS OF THE LITTLE SKATE, *RAJA ERINACEA*. C.H. Duman and D. Bodznick. Dept. of Biology, Wesleyan University, Middletown, CT 06459.

Activity of neurons of the dorsal octavo-lateralis nucleus (DON), the primary electrosensory nucleus in elasmobranchs, is modulated by electrical interference from the animals own ventilation, but to a much lesser degree than that of the primary afferent fibers. There is physiological evidence that inhibitory commissural connections between the bilateral dorsal nucleii are part of a mechanism for rejecting common-mode noise signals such as ventilatory interference (New and Bodznick, 1990). We have begun anatomical characterization of the commissural pathway. Retrograde transport of horseradish peroxidase or fluorogold injected into the DON resulted in labelling of commissural cells in both central and peripheral zones of the contralateral DON. Double-labelling studies indicate that a population of commissural cells in the central zone labelled by retrograde transport of fluorogold, also show GABA-immunoreactivity. GABA-immunoreactivity was also displayed in non-commissural central zone cells and in stellate cells of the molecular layer of the DON. The doubly labelled cells are likely candidates for mediators of a common-mode noise rejection mechanism in the DON.

NEUROETHOLOGY AND VISION IN THE BIOLUMINESCENT FISH, PORICHTHYS NOTATUS. A. F. Mensinger and J. F. Case*. Vanderbilt Univ., Nashville TN 37240 and Univ. of California, Santa Barbara, CA 93106.

The midshipman fish, Porichthys notatus, is a nocturnal predator that feeds on luminescent organisms. Fish were presented with photic stimuli characteristic of luminescent prey. Flash intensity, wavelength, duration, pulse frequency and source diameter were regulated.

Fish were attracted to flashes of specific wavelength (470-530 nm), pulse frequency (0.03-0.07 Hz) and duration (250-750 ms). Higher pulse rates (>0.20 Hz) and longer flashes (>2500 ms) evoked negative responses while intermediate values yielded graded reactions. Increasing source diameter while maintaining equal intensity, reduced number of positive responses. Negative stimuli elicited faster responses.

Juvenile P. notatus must acquire exogenous sources of luciferin to remain luminescent. Fish are attracted to photic signals characteristic of these sources and avoid light that may expose themselves to predation.

CENTRAL NEURAL SUBSTRATES FOR THE CONTROL OF SMOLT TRANSFORMATION IN SALMON (*SALMO SALAR* L.) **P. Ekstrom, T. Ostholm, B. Holmqvist, B. Moverus, L. Ebbesson, and S. Ebbesson***
Dept. of Zoology, Univ. of Lund, Lund, Sweden and Inst. of Marine Science, Univ. of Alaska, Fairbanks, Alaska 99775

Smolt transformation (ST) involves major changes in the physiology and behavior of salmon. During ST the fish change from territorial to schooling behavior, start seaward migration, and form an olfactory memory (imprinting) of their native stream. It is not known how ST is regulated. However, there is evidence that changes in photoperiod are important external cues. To identify the central control systems that may regulate ST, we have traced the neuronal connections of the retina, the optic tectum, the photosensory pineal organ, the olfactory projections and the hypophysiotrophic centers by means of DiI tracing. The results were then correlated with immunocytochemically defined monoaminergic and peptidergic neuronal systems.

The most striking results were (1) the extensive retinohypothalamic projection, (2) the absence of a cyto- or chemoarchitectonically circumscribed nucleus comparable with the suprachiasmatic nucleus in mammals, (3) the extensive pineal projections to the dorsal thalamus and periventricular pretectum, (4) the close association of putatively dopaminergic (DA) neurons with afferent axons from both the retina and pineal organ, (5) DA neurons in the hypothalamic and dorsomedial optic nuclei that project to the optic tectum, (6) a close association of DA neurons in the telencephalon with the olfactory projections. In all, our results indicate a central role for dopamine in the central processing of sensory information known to be essential for several aspects of smolt transformation in salmon.

TASTE MEDIATES INNATE FEEDING BEHAVIOR WHILE OLFACTION FACILITATES CONDITIONED DISCRIMINATION OF AMINO ACIDS BY CATFISH. T. Valentincic (University of Ljubljana, Yugoslavia), S. Wegert and J. Caprio (Louisiana State University)

The inhibition of feeding in channel catfish Ictalurus punctatus by "the longterm central escape state" was reduced by maintaining animals individually in aquaria with black gravel, by regular feeding and by the longterm avoiding of visual stimuli which release escape behavior. Naive channel catfish responded to L-alanine and L-arginine (>1μM) and L-proline (>1mM) with the following patterns of feeding behavior: maxillary and mandibular barbel movements, orienting posture, search swimming, bottom and wall searching, turning and snapping. Catfish were subsequently conditioned during 40 trials to swim 90 seconds for a food reward following an application of the amino acid stimulus. The conditioned "search swim" consisted of 40-90 turns greater than 90° compared to 0-40 turns in response to non-conditioned amino acids. Conditioned channel catfish discriminated L-alanine, L-arginine and L-proline from each other and from all non-conditioned amino acids. Following surgical removal of the olfactory organs, animals previously conditioned to 10^{-5}M L-proline did not respond behaviorally to L-proline at concentrations $<10^{-4}$M, whereas strong snapping behavior was triggered by 10^{-3}M L-proline. L-arginine and L-alanine at 10^{-5}M released short-lasting feeding responses in the anosmic catfish; however, even after 45 - 150 re-conditioning trials the anosmic catfish did not show discrimination between the tested amino acids. These results suggest that: a) the conditioning was a result of olfactory input, b) the increased food search in catfish cannot be conditioned by taste alone, and c) the taste mediated responses to amino acids including snapping are most probably innate. Supported by NSF BNS-8819772 and ONR 00014-90-J-1583.

HORMONAL CONTROL OF BEHAVIOR III

DOCA PRETREATMENT ENHANCES NEURONAL ACTIVITY AND SENSITIVITY TO ANGIOTENSIN II IN THE FOREBRAIN OF RATS. S.N. Thornton and S. Nicolaïdis*. Neurobiologie des Régulations, Collège de France, 11 place Marcelin Berthelot, 75231 Paris CEDEX 05, France.

A rapid and substantive sodium appetite can be initiated in rats that have been pretreated with a low dose of deoxycorticosterone acetate (DOCA) for 3 days, that in itself does not initiate the appetite, and then given an intracerebroventicular injection of a below threshold dose of angiotensin (AII). We have investigated electrophysiologically the effects of these treatments on neurons of the septum and anterior hypothalamus.

Male wistar rats, controls (non treated) or experimentals (pretreated, DOCA 0.5 mg/kg s.c.), were anaesthetised with urethane and the femoral artery catheterised. A 7 barrelled microiontophoretic electrode attached to an extracellular recording electrode was then advanced through the cortex into the anterior ventral hypothalamus where unit activity was recorded.

In the medial septal area, but not in other areas, a greater number of active neurons were recorded in rats pretreated with DOCA than found in the controls (10.2 + 1.1 / electrode decent, n = 19, vs 6.3 + 0.6 / decent, n = 25, P<0.01). In the treated animals Io AII produced a marked enhancement of neuronal activity, something never seen in the controls. Io of aldosterone increased neuronal acitivity of both control and experimental rats but subsequent Io of AII produced marked excitation only in DOCA treated animals. Similar results were obtained in rats treated with DOCA up to 10 days before the electrophysiological recordings.

This long term and persistent DOCA induced enhancement of neuronal activity and excitability to AII could be the mechanism whereby a sodium appetite, induced by the synergistic action of these two hormones, is stimulated. (Supported by MH 43787)

MEMBRANE-BOUND CORTICOSTEROID RECEPTOR IS COUPLED TO A G-PROTEIN. M. Orchinik, T. F. Murray, and F.L. Moore. Dept. Zoology, Oregon State University, Corvallis, OR 97331-2914.

Steroids hormones alter neuronal activity through intracellular receptor-mediated changes in protein synthesis and through poorly understood interactions with receptors on neuronal membranes. Recently we characterized a high-affinity corticosteroid receptor in synaptic membranes from an amphibian brain, *Taricha granulosa* (Orchinik et al., in press, *Science*). The receptors were localized autoradiographically in the neuropil in discrete brain regions and they appear to mediate rapid behavioral responses to corticosterone (CORT). Since the binding site is not linked to the $GABA_A$/benzodiazepine receptor, we performed radioligand binding studies to determine if the receptor is coupled to guanine nucleotide binding proteins. The specific binding of [^{3}H]CORT in a neuronal membrane preparation was inhibited in a concentration-dependent manner by guanine nucleotides. The rank order potency to inhibit [^{3}H]CORT binding was GTP-gammaS > Gpp(NH)p > GTP > GDP = GMP. Although addition of Mg^{2+} to EDTA-treated membranes did not significantly enhance [^{3}H]CORT binding, Mg^{2+} enhanced the potency of guanine nucleotides to inhibit [^{3}H]CORT binding. These data provide the first evidence for the coupling of steroid receptors to G-proteins; they suggest a transduction mechanism that could account for rapid neuronal responses to corticosteroids.

THE EFFECTS OF GLUCOCORTICOIDS ON HIPPOCAMPAL PLASTICITY
C. Pavlides, Y. Watanabe & B.S. McEwen. The Rockefeller University, New York.

High glucocorticoids levels are detrimental to hippocampal (HPC) anatomy, physiology and behaviors closely associated with this structure. We investigated the effects of chronic and acute corticosterone (CS) administration on HPC long-term potentiation (LTP). Male rats were injected with CS (40 mg/kg/day, s.c., in sesame oil) or the vehicle for 21 days. Forty eight hours following the last injection the animals were tested for LTP by applying a high frequency stimulus (HFS) to the perforant path (PP) and recording extracellular field potentials in the dentate gyrus granule cell layer. In a second group of animals LTP was tested 1-2 hours following a single injection of CS or the vehicle.

The mean plasma levels of CS were determined to be high 1 hour (68.63 ± 8.24 μg/100ml) following CS injections but returned to normal 48 hours (9.17 ± 2.31 μg/100ml) later, at time of testing. The CS plasma levels of the control animals was determined to be at a low level 1 hour (17.16 ± 6.97 μg/100 ml) and 24 hours (15.18 ± 3.52 μg/100ml, time of testing) after the last vehicle injection.

In vehicle injected controls, HFS of the PP produced a substantial degree of potentiation, as measured by both the slope of the EPSP (18.76 ± 2.04%) and the population spike (100.96 ± 35.16%), in comparison to baseline. In contrast, LTP induction in chronic CS injected animals was significantly ($P < 0.05$) lower than in controls for both the slope (12.78 ± 1.50%) and the population spike (30.10 ± 10.01%) . Similar reductions in LTP induction were seen for the acute CS animals (slope, 4.83 ± 4.92%; spike, 34.93 ± 11.03%, from baseline).

The results indicate that CS may induce both acute and chronic effects on HPC plasticity and that these effects are probably due to different mechanisms.

GLUCOSE REVERSES THE BEHAVIORAL EFFECT OF FOOD DEPRIVATION AND ADRENALECTOMY IN THE PORSOLT SWIMMING TEST. D. Jefferys and J.W. Funder. Baker Medical Research Institute, Prahran, Victoria 3181, Australia.

In the Porsolt swimming test rats become progressively immobile over a 15 min test period, and on retest 24 h later are immobile for ~70% of a 5 min retest. Adrenalectomized (ADX) rats acquire the response normally but on retest remain immobile ~35% of the time, an effect reversed by glucocorticoids and kappa–selective opioids. Hypothyroid rats neither acquire nor retain the response, an effect reversed by T_4 or T_3. Rats food deprived for 24 h, like ADX rats, acquire the response but do not retain it on retest. We here present dose response studies on the effect of glucose administration on the behavioral response to food deprivation, ADX and hypothyroidism, and the effect of dexamethasone, ketocyclazocine and T_4 on the response to 24 h food deprivation. Glucose (≥100 mg/kg) reversed the effect of food deprivation, but at 1–1000 mg/kg was without effect in the hypothyroid rat; in contrast, at 1000 mg/kg glucose reversed the effect of ADX up to 1–2 h after initial exposure, but not 1 h prior to retest. Dexamethasone (6 μg/rat), ketocyclazocine (25 μg/rat) or T_4 (15 μg/rat) reversed the effect of food deprivation. The results from the present studies provide further evidence for a critical role of metabolic factors in modulating the acquisition and retention of behavioral responses. The specific site and mode of action of glucose in these circumstances awaits investigation.

THE RELATIONSHIP BETWEEN HIPPOCAMPAL LESIONS AND GLUCOCORTICOID LEVELS IN AN ANIMAL MODEL OF WANDERING IN ALZHEIMER'S DISEASE. R. Donahue, J.P. Ryan, and R.L. Heintz*. Department of Psychology, State University of New York at Plattsburgh, Plattsburgh, New York 12901.

The focus of the study is to better understand the elevated glucocorticoid levels in Alzheimer's disease. An animal model was used to determine the effect of dorsal hippocampal lesions on neurohormonal and behavioral functions. Thirty-three Long-Evans rats were divided into three groups of twelve: an experimental lesioned group, a control sham-lesioned group and a control non-lesioned group. Experimental lesions were produced by injecting 15 ug/ul of colchicine bilaterally into the dorsal dentate gyrus. Colchicine has been found to mimic some of the neuropathological and neurobehavioral aspects of Alzheimer's disease. The control sham-lesioned group received bilateral injections of saline in the same areas of the brain. The control non-lesioned group received no surgery but underwent anesthetic procedures. Animals were then subjected to behavioral testing using the Morris water maze. Behavioral testing resulted in a significant impairment in spatial memory in the colchicine group in comparison to the control group. Blood samples were taken from all animals before surgery and twice after behavioral testing. All blood samples were taken between 0800 and 1200 hours to avoid changes in circadian glucocorticoid levels and measures were also taken to avoid stress induced glucorticoids. Blood samples were assayed using the HPLC and alterations in glucocorticoid levels were observed. The study suggests a role for the hippocampal modulation of glucocorticoids in Alzheimer's Disease.

561.6

STRESS INDUCED CORTISOL SECRETION INFLUENCES INFORMATION PROCESSING IN MAN. G. Fehm-Wolfsdorf, D. Nagel* and H.L. Fehm*. Depts of Medical Psychology and Internal Medicine, University of Ulm, D 7900 Ulm, Germany.

Glucocorticoids are assumed to exert differential effects on central nervous functions via different receptor types described in rat brain (de Kloet & Reul, 1987). In man we previously studied the influences of hydrocortisone, which increases cortisol levels, as opposed to dexamethasone, which suppresses endogenous cortisol secretion, on sensory functions. In auditory tasks opposite effects of these steroids were most prominent on stapedial reflex: with higher cortisol levels reflex needed more dB to be elicited. In the present experiment we studied this effect during stress induction. In 24 subjects repeated measurements of stapedial reflex and salivary cortisol levels were carried out timed in parallel. Unexpectedly ss were asked to deliver a videotaped speech in bright light which led to a sharp rise of cortisol levels in most of the ss. A second control session followed the identical time course without speech. Significantly more dB were needed to elicit stapedial reflex at the time of cortisol maximum as compared to the minimum after recovery from stress 100 minutes later or to control session. Our results suggest that high glucocorticoid secretion attenuates perceptual abilities.

561.7

AROMATASE ACTIVITY IN PREOPTIC AREA, HYPOTHALAMUS, AND AMYGDALA OF INTACT AND CASTRATE C57BL/6J, DBA/2J, AND B6D2F1 MALE HOUSE MICE. Sinchak, K.[1], C.E. Roselli[2] and L.G. Clemens[1]. [1]Dept. Zoology and Neuroscience Program, Michigan State University, E. Lansing, MI 48824. [2]Dept. of Physiology, Oregon Health Sciences University, Portland, OR 97201.

Most male B6D2F1 hybrid house mice continue to copulate after castration while males of the parental inbred strains (C57BL/6J and DBA/2J) do not. Retention of copulatory behavior after castration in the B6D2F1 male is estrogen dependent, and inhibited by treatment with an aromatase inhibitor (ATD). However we could not distinguish between castrated males that continued to copulate and those that did not based on levels of serum androgens and 17β-estradiol as well as aromatase activity (AA) and estrogen receptor levels in the preoptic area (POA), hypothalamus (HYP), and amygdala (AM) (Soc. Neu. Abst. #308.12, 1990). Because castration abolishes copulatory behavior in the C57BL/6J and DBA/2J strains of mice, but not B6D2F1 males unless treated with ATD, we wished to determine if there are strain differences in AA in the POA, HYP, and AM of intact and castrated C57BL/6J, DBA/2J, and B6D2F1 mice. Adult males were either castrated or sham castrated 18 weeks prior to removal and dissection of the brain for AA assay. Levels of AA in the POA and HYP were greater in intact DBA/2J males than C57BL/6J and B6D2F1 males ($p < 0.05$), but no strain differences were seen in the AM. Compared to intacts, castration reduced AA in each brain region of all three strains of mice ($p < 0.05$). However there were no strain differences in AA in any brain region after castration. In conclusion neural AA differs between strains of intact mice, however, based on this measure we cannot distinguish between strains of mice that differ in the display of copulatory behavior after castration.

IN VITRO DEVELOPMENTAL CHANGES IN BRAIN AROMATASE OF THE DOVE AND GERBIL. J. B. Hutchison, A. Wozniak, S. D. Holman and R.E.Hutchison. MRC Neuroendocrine Development & Behaviour Group, IAPGR, Babraham, Cambridge, CB2 4AT, UK.

Aromatization of testosterone to estradiol is required for differentiation of brain structure and behavior. In the dove and gerbil aromatase forms estrogen in preoptic cells associated with male sexual behavior. We compared the *in vitro* kinetic properties of the aromatase in the two species. 3H-testosterone and -androstenedione were used as substrates. Adult dove aromatase is > 3 times as active as in the developing (days 1-3 posthatching) POA, and has a Km 10 times lower than the developing enzyme (4 and 40 nM, respectively). Thus, there seem to be two isoenzymes of dove aromatase with different Km values, the more active adult form being only expressed in later life. The kinetics of aromatase activity in the gerbil show a different developmental pattern to the dove, with neonatal preoptic aromatase twice as active as the adult. Km (30 nM) does not change during development , and neonatal preoptic aromatase activity does not show any sex dimorphism. Significant aromatase activity is also present in the neonatal cortex, but is absent from the adult. Preoptic aromatase activity in both developing and adult gerbil is much lower than in the dove. Using 3H-androstenedione as substrate similar Km values were obtained for the aromatase within each species. We conclude that (a) there are species differences in the preoptic aromatase; (b) the substrate affinity of the avian enzyme and possibly its form changes during development. This change is not evident in the mammalian (gerbil) brain.

ARE BRAIN MECHANISMS OF SEXUAL BEHAVIOR IRREVERSIBLY LATERALIZED BY NEONATAL ANDROGENS IN GERBILS? S. D. Holman and J. B. Hutchison. MRC Neuroendocrine Development & Behaviour Group, IAPGR, Babraham, Cambridge, CB2 4AT, UK.

Androgens are linked to asymmetric brain development in the gerbil. The volume of the left, but not the right, sexually dimorphic area, pars compacta (SDApc) is related to the rate of the male-type upsweep ultrasounds (Holman and Hutchison, Dev. Brain Res., 1991). We compared the effects of neonatal castration (NC, n=8), laryngeal motor nerve denervation (LD, n=25) and sham control (SD, n=18) in adult males on SDApc volume and vocalizations. Left and right SDApc volumes were measured 96 h after surgery. Upsweep vocalization rates (per min) were significantly reduced in the LD group (pretransect.= 44.7±7.2: post-transect.=0.4±0.03), remained constant in the SD group, but were partially demasculinized in NC males (22.5± 6.0). Other sexual behaviors were not changed in LD and SD groups. After transection or sham-treatment the correlation between left SDApc volume and pretransection emission rate was highly significant in both groups (LD, rho=0.64, $p<0.002$: SD, rho=0.68: $p<0.01$), but the right SDApc volume and pretransection emission rates in the LD group also reached significance (rho=0.46, $p<0.05$. SD, rho=0.34, $p>0.1$). A symmetrical relationship was also found in NC males (left, rho=0.68, right, rho=0.71, $p<0.05$). We conclude that (a) the asymmetric relationship between vocalizations and SDApc is eliminated by neonatal castration suggesting a role for gonadal hormones in lateralization during development and (b) brain asymmetry in sexually active males can be modified by de-efferentation showing that brain plasticity is not irreversibly affected by neonatal hormones.

561.10

AGING AND PREOPTIC AREA AROMATASE IMMUNOREACTIVITY IN MALE JAPANESE QUAIL. M.A. Ottinger, N. Thompson, T. Dellovade[+], N. Harada*[|], and E.F. Rissman[+]. Univ. of Maryland, College Park, MD 20742, [+]Univ. of Virginia Charlottesville, VA 22903, and [|]Fujita Health Univ. Toyoake, Japan.

An age-related decline in reproductive, endocrine, and behavioral responses occurs in male Japanese quail. Decreased behavioral activity precedes measurable changes plasma testosterone and estradiol. Changes in hypothalamic catecholamines and reductase activity have been found during aging. This experiment investigates the immunoreactivity (IR) of aromatase enzyme (AR) in the preoptic area of young and aged male quail. Five young (6 months) sexually active and five old (3 yrs) behaviorally inactive males were compared using a polyclonal antibody raised in rabbit against human aromatase enzyme. Colocalization of AR-IR and estrogen receptor IR was examined using a monoclonal antibody (H222 provided by Abbot Labs) raised against purified estrogen receptors (ER) in rat. Results show a correlation in aging males of declining testes size, plasma testosterone, sexual behavior and both quantity of AR positive stained cells and the density of stain within these cells. In addition, in aged animals a larger proportion of AR-IR cells colocalized with ER in aged males compared with young males. Supported by NSF grant BNS 9021226 (EFR) and USDA 88-37242 (MAO).

561.11

RAPID VISUALIZATION OF OCCUPIED ESTROGEN RECEPTORS IN THE RAT BRAIN BY IN VITRO AUTORADIOGRAPHY. M. J. Walters, T. J. Brown, R. Hochberg* and N. J. MacLusky. Dept. Obst. and Gyn., Univ. Toronto, Toronto, ON M5G 1L7 and Yale Univ. Sch. Med., New Haven, CT 06510.

Quantitative receptor autoradiography is a powerful tool for studying steroid hormone binding in the brain, as it permits a precise quantification of radiolabeled hormone uptake combined with a high degree of anatomical resolution. Until now, autoradiographic characterization of estrogen binding in the brain could only be achieved through *in vivo* administration of radiolabeled estrogen prior to removal of the tissue samples for processing. We now report the development of an autoradiographic procedure which utilizes exchange labeling of occupied neural estrogen receptors by ^{125}I-estrogen *in vitro*. Intact adult female rats were injected with a saturating dose of unlabeled estradiol (36 µg/kg) 60 min prior to sacrifice. Thin frozen sections (16-20 µm) were cut through the hypothalamus and preoptic area, thaw-mounted onto microscope slides, and rapidly re-frozen. The sections were then incubated with 2 nM ^{125}I-labeled 11β-methoxy-16α-iodo-estradiol, a synthetic estrogen, for 1-8 hr at 37°C. The sections were washed, dried, and exposed to a sheet of high-resolution Hyperfilm for 24 hr. High levels of binding were evident in the medial and periventricluar preoptic areas, bed nucleus of the stria terminalis, ventromedial nucleus of the hypothalamus, the arcuate-median eminance region, and in the amygdala. Maximal binding was obtained at 2 hr and remained stable for up to 8 hr. Background labeling was low and compared favourably with that obtained with *in vivo* labeling methods. No specific labeling was evident in sections incubated with a 100-fold molar excess of unlabeled estradiol, in sections obtained from ovariectomized females, or in sections incubated at 4 or 25°C. This technique circumvents many of the problems inherent in *in vivo* labeling procedures and permits, for the first time, the selective autoradiographic analysis of occupied estrogen receptors in the brain.

IN SITU HYBRIDIZATION FOR ESTROGEN RECEPTOR mRNA IN THE MALE RAT BRAIN FOLLOWING LONG TERM TESTOSTERONE DEPRIVATION AND REPLACEMENT. C.A. Lisciotto and J.I. Morrell. Institute of Animal Behavior, Rutgers Univ., Newark, NJ 07102.

Following long term testosterone (T) deprivation, several days of T exposure is required to restore T-dependent behaviors, including male reproductive behavior. In situ hybridization was used to determine the location and relative amount of estrogen receptor (ER) mRNA in the male rat brain following T deprivation and replacement. Adult male rats were gonadectomized, and 6 weeks later received T or cholesterol via silastic implant, sc. After 3, 10, or 21 days of T exposure, the rats were tested for male reproductive behavior and were sacrificed. ER mRNA was detected by hybridization to an 850 base ^{35}S-labeled cRNA probe (ER cDNA - M. Muramatsu). Hybridization (1 X 10^6 cpm/slide) took place at 60°C for 20 hrs; autoradiographic exposure: 2-6 wks. Robustly labeled ER mRNA containing cells were abundant in the medial preoptic area, bed nucleus of the stria terminalis, arcuate and ventromedial nuclei of the hypothalamus. T exposure altered the relative amounts of ER mRNA. T exposure for 10-21 days was necessary to fully restore male reproductive behavior. We are currently comparing the time course of T-induced alteration in ER mRNA and T-mediated restoration of male reproductive behavior.

CASTRATION ALTERS TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE MEDIAL AMYGDALOID NUCLEUS OF MALE HAMSTERS. S.E. Asmus and S.W. Newman, Department of Anatomy and Cell Biology, University of Michigan, Ann Arbor, MI 48109-0616.

The medial amygdaloid nucleus (Me) processes chemosensory and hormonal information essential for mating behavior in the male Syrian hamster (*Mesocricetus auratus*). With colchicine pretreatment, the hamster Me contains a large population of tyrosine hydroxylase-immunoreactive (TH-IR) neurons, distributed preferentially in the midrostral and caudal regions of this nucleus. To determine whether TH production in these cells is influenced by gonadal steroids, the number of TH-IR neurons was compared in Me of castrated and intact hamsters. At 2, 4, 6 and 12 weeks after castration, age-matched intact and castrated males were injected intraventricularly with colchicine and perfused 48 hrs later with 4% paraformaldehyde. Coronal brain sections (40 um) were incubated with a monoclonal TH antibody (1:10,000; Incstar) which was visualized using the immunoperoxidase technique. The number of TH-IR neurons in midrostral Me declined to 48% of control values 4 weeks after castration. This number returned to control values 12 weeks after castration. The number of TH-IR neurons in caudal Me was similar in castrated and intact animals at all postcastration intervals. These results suggest that circulating testosterone maintains the levels of TH in midrostral Me, a region where lesions eliminate mating behavior. (Supported by NIH, NS 20629 to SWN).

THE IMPORTANCE OF BRAIN AROMATIZATION FOR SEXUAL DIFFERENTIATION OF ZEBRA FINCH BRAIN. A.P. Arnold & B.A. Schlinger. Department of Psychology and Laboratory of Neuroendocrinology of the Brain Research Institute, UCLA, Los Angeles CA 90024-1563.

The development of extreme sexual dimorphism in brain regions controlling song in zebra finches is thought to be controlled by estrogen secreted by the young male. The evidence favoring this hypothesis is that development of the song system is strongly masculinized by estradiol (E_2) treatment of young females. However, questions persist about the role of estrogen in neural development because E_2 can also have demasculinizing effects in young females, and it is not clear that there are sex differences in plasma levels of estrogen during development. We have re-measured plasma levels of sex steroids during the first 13 days after hatching, and can detect no sex differences in levels of E_2, estrone (E_1), testosterone, androstenedione (A), or dihydrotestosterone.

We also measured aromatase activity (^{3}H-A conversion to ^{3}H-E_1 and ^{3}H-E_2) in various tissues of hatchlings. Aromatase was abundant in ovary but was not detected in testes, adrenals, or other peripheral tissues of males. Aromatase was also found in di- and telencephalon, but there was no sex difference in homogenates of whole brain or in cellular subfractions of telencephalon. The distribution of aromatase suggests that if estrogen is the primary masculinizing agent during development of the vocal control system of males, it is synthesized locally in brain at sites appropriate for action on that neural circuit. In contrast, because the developmental pattern of gonadal aromatase (high in ovary, low in testis) is similar to non-songbirds, demasculinization of copulatory behavior in zebra finches may rely on ovarian estrogen as is assumed to occur in other avian species. Preliminary studies indicate the possible importance of sex differences in estrogen catabolism in the process of sexual differentiation. Supported by NIH grants NS08649, DC00217, and NSF grant BNS9020953.

561.15

THE BRAIN AS A SOURCE OF CIRCULATING ESTROGEN. B.A. Schlinger & A.P. Arnold. Department of Psychology and Brain Research Institute, UCLA, Los Angeles CA 90024-1563.

Local conversion of androgen to estrogen (aromatization) often precedes androgen action in the male brain. While the enzyme aromatase is ordinarily restricted to limbic structures in brain of higher vertebrates, it is also found throughout the telencephalon of zebra finches. Estrogen (E) also circulates at high levels in males of this species. However, when we measured aromatase activity in testes, adrenals, brain and other tissues of adult male zebra finches, activity was found only in brain. Because of the abundance of aromatase in telencephalic microsomes, we have postulated that circulating E in males of this species is derived from brain.

To test this hypothesis, we measured E synthesis *in vivo* by quantifying ^{3}H-E (estrone and estradiol) in the circulation of males and females after injection of ^{3}H-androstenedione (^{3}H-A). Authentic ^{3}H-E was present in jugular vein plasma 5 min after as little as 185 pg ^{3}H-A (1 µl propylene glycol) was injected into the aromatase-rich dorsal telencephalon. Despite the recovery of similar amounts of ^{3}H-A in blood, ^{3}H-E was undetected in jugular plasma after identical ^{3}H-A injections into the cerebellum. ^{3}H-E was also present in plasma collected from the carotid artery 5 min after injection of 1 to 6 ng ^{3}H-A into the ovary but not after injection into the left testis. Finally, 5 min after 50 µl saline containing 6 ng ^{3}H-A was injected into the jugular (near the thorax) of males, ^{3}H-E was present in jugular plasma (collected near the skull) but not in carotid plasma. These results show that plasma androgen can be converted to E by brain and released back into blood. Moreover, the absence of E in male plasma after androgen is injected outside of aromatase-rich brain regions suggests that relatively little E synthesis occurs outside of brain. This control of plasma E by brain synthesis represents a novel neuroendocrine mechanism for regulating body levels of a sex steroid hormone. Support: NSF BNS-9020953 and NIH DC00217.

NEURAL DISTRIBUTION OF ESTROGEN RECEPTOR AND LHRH IMMUNOREACTIVITY ASSOCIATED WITH PUBERTY IN THE FEMALE MUSK SHREW. T.L.Dellovade and E.F.Rissman NSF Center for Biological Timing, Univ. of Virginia, Charlottesville, VA 22901

Female musk shrews are sexually receptive shortly after weaning (21 days of age) and are fertile by 23-25 days of age. Also, females have adult steroid hormone concentrations in plasma and have completed their reproductive tract development by weaning. To describe the neural mechanisms associated with the onset of puberty in this species we used estrogen receptor (ER) and LHRH immunocytochemistry on brains from 10,20,25 and 40 day old females. We used a rat monoclonal antibody raised to human estrogen receptor, H222 (Abbott Labs) and a rabbit polyclonal antibody to LHRH, LR1 (provided by Dr. Benoit) as primary antibodies. The neural distribution of ER immunoreactivity (IR) in the 25 day old females did not differ from that found at 40 days of age. In addition, there is a similar density of positively stained cells in the preoptic area (POA) and hypothalamic nuclei at all ages. In contrast, the limbic regions, including the lateral septum,bed nucleus of the stria terminalis,and several nuclei of the amygdala,have fewer positively stained cells at 10 and 20 days of age. LHRH-containing cells and fibers extend from the accessory olfactory bulb to the median emminence along the basal regions of the brain at all ages. The medial POA has many LHRH positive fibers at 10 and 20 days of age, but very few positive cell bodies. In contrast,this same area contains many LHRH-IR cells and a less dense fiber network at 25 and 40 days of age. These results indicate that by 25 days of age the distribution of both ER-IR and LHRH-IR is similar to that seen in 40 day old animals. These neuroanatomical findings are consistent with our behavioral and hormonal data. Supported by NSF grant BNS 9021226.

DISSOCIATION KINETICS OF NEURAL ESTROGEN RECEPTORS. X. Chen* and N. G. Simon. Center for Molecular Bioscience and Biotechnology, Lehigh University, Bethlehem, PA 18015

The biological potency of a steroid-receptor complex may be linked to its dissociation rate (k_{-1}) after transformation to a form capable of binding to DNA. Understanding this process may help elucidate a mechanism contributing to neural target tissue sensitivity or insensitivity to a particular steroid, but to our knowledge such studies have been conducted only with receptor complexes from peripheral tissues. Preliminary experiments showed that factors limiting this work were the relatively low concentration of neural receptors and their instability during warming in vitro. By binding estrogen-estrogen receptor (ER) complexes to hydroxylapatite (HAP) prior to activation, sufficient material was available to quantitate in vitro dissociation kinetics. CF-1 female mice were maintained in accordance with Federal guidelines for animal care. Hypothalamic ER were incubated with 15 nM $[^3H]E_2$ for 6 - 8 hrs at 0°, bound to HAP and activated by warming at 29° for 15 min. The dissociation reaction showed both fast and slow components consistent with peripheral ER studied in a free receptor assay. The k_{-1} for the two components were $5.1 \pm 2.3 \times 10^{-1}$ min^{-1} and $8.6 \pm 1.8 \times 10^{-3}$ min^{-1}. Salt concentration (0.04M or 0.4M KCl) did not significantly affect the dissociation rate of either the fast or slow component, although the 0.4M KCl condition slightly increased the proportion of activated ER.

ANDROGEN AND ESTROGEN CONCENTRATING NEURONS IN THE MEDIAL PREOPTIC AREA AND MEDIAL AMYGDALOID NUCLEUS OF THE MALE SYRIAN HAMSTER. S.W. Newman, R.I. Wood, J. M. Swann, and R.K. Brabec*. Department of Anatomy and Cell Biology, University of Michigan, Ann Arbor, MI 48109-0616.

The medial preoptic area (MPOA) and medial amygdaloid nucleus (Me) are essential for male sexual behavior in the Syrian hamster. These nuclei integrate chemosensory stimuli and gonadal steroid signals, both of which are required for mating behavior. The objective of this study was to compare the distribution of androgen and estrogen-concentrating neurons in MPOA and Me in the male hamster using steroid autoradiography for estradiol (E2), testosterone (T) and dihydrotestosterone (DHT). Adult males (n=4 per group) received two ip injections of tritiated steroid 6-7 days after castration. The brains were removed and frozen 2h after the first injection, and 6 um frozen sections were mounted onto NTB-2 emulsion-coated slides. The slides were developed with D-19 after exposure for 11-16 months. In both MPOA and Me, neurons were more abundant and more heavily-labeled with E2 treatment than with either T or DHT. Estradiol and DHT-labeled cells were scattered throughout Me, with a high concentration in posterodorsal Me. T-labeled cells were confined to posterodorsal Me. In MPOA, the majority of E2 and DHT-labeled neurons were in the medial preoptic nucleus (MPN) and the preoptic regions of the medial bed nucleus of the stria terminalis. T-labeled cells in MPOA were most prevalent in the MPN. Throughout Me and MPOA, the distribution of E2-labeled cells is more widespread than that of T or DHT. These results provide a detailed comparison of E2, T, and DHT-concentrating neurons in nuclei important to the control of mating behavior. (Supported by NIH-NS-20629)

561.19

LOCALIZATION OF THE CANARY ANDROGEN RECEPTOR mRNA. K.L. Nastiuk and D.F. Clayton. Lab. of Animal Behavior, Rockefeller Univ., New York, NY 10021.

In order to investigate the mechanisms by which gonadal steroids regulate plasticity in the avian song control circuit, we cloned the canary androgen receptor (cAR) and have begun experiments to examine its localization. By in situ hybridization using single-stranded 35S-labelled RNA probes, the receptor message can be detected in the brain but is of very low abundance. The cAR mRNA appears to be relatively enriched in several of the functionally defined song nuclei of the canary brain, including HVc, RA and MAN, which concentrate labeled testosterone (Arnold, JCN 189:421, 1980). We are now using the cAR probe to ask: what cell types in the song circuit express the gene? is there a relationship between cAR gene expression and phases of song development and plasticity? is the cAR gene itself under gonadal steroid regulation (for example, by estrogens which are sufficient to induce "masculinization" of the song circuit in young female zebra finches)?

561.20

ESTROGEN-RECEPTOR IMMUNOREACTIVE NEURONS IN THE FOREBRAIN OF ADULT MALE AND FEMALE FERRETS. S.A. Tobet, M. Basham*, T.O. Fox, & M.J. Baum. Dept. of Biochem., EK Shriver Ctr., Waltham, MA 02254 & Prog. Neurosci., Harvard Medical School, Boston, MA 02115, & Dept. of Biology, Boston University, Boston, MA 02215.

We have previously described estrogen binding neurons in and around the preoptic/anterior hypothalamic area (POA/AH) of male and female adult ferrets using autoradiographic methods (Tobet & Baum, 1991; Dev Brain Res, in press). The present study confirms and extends our observations to estrogen receptor immunoreactive neurons throughout the basal forebrain in the context of regional selectivity and sex differences. Estrogen receptors were visualized using the H222 estrogen receptor antibody (Abbott Laboratories) and Nickel/DAB reaction product (H222ir). One of the most striking features of H222ir cells was the presence of H222ir in neuronal processes. All cells with H222ir in processes also contained H222ir in nuclei, although the converse was not true. In females, increased estradiol levels were associated with decreased immunoreactivity in processes. Cells in the bed nucleus of the stria terminalis and ventrolateral septum were notable for the absence of H222ir in processes. The lateral hypothalamus was rich in H222ir processes in both sexes. More H222ir was noted in the processes of female cells in the dorsal lateral septum and medial POA/AH and at the level of the descending fornix and caudal anterior commissure. The H222ir in neuronal processes in the region comparable to the MN-POA/AH in females presented the appearance of nuclear grouping even though no nucleus is apparent by Nissl stains. The differential dendritic organization of estrogen-binding in multiple brain regions might provide another level of regulation for sex-selective estrogen-dependent functions.

ARGININE^8-VASOPRESSIN (AVP) POTENTIATES ACUTE ETHANOL-INDUCED MOTOR IMPAIRMENT IN THE RAT. P.H. Wu*, J.F. Liu*, S.J. Mihic*, Y. Israel and H. Kalant*. Department of Pharmacology, Univ. of Toronto, and Addiction Res. Foundation of Ontario, Toronto, Canada M5S 1A8.

Earlier studies have shown clearly that AVP maintains ethanol (EtOH) tolerance after cessation of chronic EtOH treatment. However, the acute interaction of AVP and EtOH has not been well characterized. For that purpose, male Sprague Dawley rats (200 g) were trained on the moving belt test, to a criterion of less than 1.2 sec off belt in a 2 min trial. They were then tested under EtOH (1.5 g/kg IP), and assigned to groups (6 animals/group) matched with respect to their EtOH impairment scores. The EtOH dose-response relationship (range 1.0 - 2.0 g/kg) on the moving belt test was then determined in the same rats, after pretreatment with saline, AVP (10 µg SC or 10 ng ICV), the AVP-V_1 receptor antagonist [Des-Gly^9,d(CH$_2$)$_5$^{1},O-Et-Tyr^2,Val^4,Arg^8]-vasopressin(10 ng ICV), and the V_1 antagonist in combination with AVP (both given ICV, the antagonist 30 min before the AVP). AVP produced a 16% decrease of ED50 for EtOH when given either SC [$F(1)=11.49$, $p<0.002$] or ICV [$F(1)=10.78$, $p<0.002$], without altering blood alcohol levels. Neither AVP nor the V_1 antagonist alone caused any motor impairment. AVP potentiation of EtOH effect was abolished by co-administration of the V_1 antagonist, but the antagonist alone did not attenuate the EtOH effect. Other rats were made EtOH-tolerant by 5 daily injections of either EtOH alone (1.8 g/kg IP) or EtOH (1.5 g/kg IP) + AVP (10 µg SC), each followed by a practice session on the moving belt. In both sets of tolerant animals, AVP potentiation of acute EtOH effects was still seen on day 6 [$F(1)=57.29$, $p=0.000$]. The mechanism of this AVP potentiation of EtOH is unknown, but the failure of the V_1 antagonist alone to alter the effect of EtOH suggests that endogenous AVP is not involved directly in modulating EtOH intoxication. Supported by NIAAA grant #1 R01-AA08212-02.

CIRCADIAN ACTIVITY AND STARTLE AMPLITUDE IN RATS EXPOSED TO CONSTANT LIGHT: EFFECTS OF OVARIECTOMY AND E2 REPLACEMENT. J. Kaster*, I. R. Cohen and J. Buelke-Sam. Toxicol. Res. Labs, Lilly Res. Laboratories, Eli Lilly & Co., Greenfield, IN 46140.

Estradiol (E2) treatment fails to elicit an LH surge in ovariectomized (OVX) rats following short-term exposure to constant light (LL) (Neurosci. Abst., 16: 1200, 1990). In this study, 55 Fischer 344 rats housed in a 12 hr light: 12 hr dark condition (LD) were assigned to 1 of 3 treatment groups: intact; OVX on Day 0; or OVX on Day 0 and E2 Silastic implant on Day 7. Half of each treatment group was placed into LL on Day 0. Activity under LL or LD was measured on Days 7-9 for 23 hrs/day in SDI figure-8 monitors. Acoustic and tactile startle amplitudes were measured in automated SDI chambers on the morning of Day 10. There were no significant effects of treatment during the first hour or on the pattern of activity over days within either lighting condition. However, LD rats from all groups showed greater habituation across test days during the first hours of testing, as well as greater total activity during the D phase. LL rats showed activity bursts distributed throughout the 23-hr sessions. Startle amplitude of the OVX and OVX+E2 groups was decreased significantly only in the LD rats. Tactile startle was significantly greater than acoustic startle for LL and LD rats from the intact and OVX groups, but not for OVX+E2 rats. Together, these results suggest that OVX, with or without E2 replacement, interacts with lighting condition to alter startle, but does not affect the LD circadian pattern of activity or the disrupted pattern produced by LL.

562.2

N-METHYL ASPARTIC ACID INJECTIONS INTO THE MEDIAL AMYGDALA FACILITATE MATERNAL BEHAVIOR IN RATS. M. Numan, M.J. Numan* and J.B. English*. Dept. of Psychology, Boston College, Chestnut Hill, MA 02167.

The inhibitory role of the medial amygdala (MA) in maternal behavior control was explored. Injections of neurotoxic doses of N-methyl aspartic acid (NMA: 8 ug/ .4 uL) into MA facilitated maternal behavior in nulliparous female rats when pups were presented to them 12 days following the injections. This effect was specific to MA in that NMA injections into the basolateral amygdala were ineffective. Also, the facilitatory effect of NMA injections into the MA was eliminated when ovariectomies were performed at the time of brain surgery. In a subsequent experiment, vaginal smear data indicated that NMA-MA injections induced a pseudopregnant state that lasted about 13 days in females that retained their ovaries. That this pseudopregnant state contributed to the facilitation of maternal behavior was supported by the finding that bromocriptine (a drug that blocks prolactin release) administration suppressed both pseudopregnancy and the facilitation of maternal behavior induced by NMA-MA injections. A final experiment is testing this view further by presenting test pups to females 24 days, rather than 12 days, after NMA-MA injections. It appears that a neuroendocrine mechanism underlies the observed facilitation of maternal behavior.

Supported by a Whitehall Foundation grant.

DO SEXUALLY MONOMORPHIC PATTERNS OF PLASMA E_2 AND ANDROGENS DURING NESTLING DEVELOPMENT ACCOUNT FOR THE LACK OF A SEX DIFFERENCE IN ADULT SINGING BEHAVIOR IN THE EUROPEAN ROBIN? E.S. Hiatt and H. Schwabl*. *Max-Planck-Institut für Verhaltensphysiologie, Andechs, D-8138, W. Germany; Dept. of Biology, Northeastern Univ., Boston, MA 02130 and Rockefeller Univ. Field Research Center, Millbrook, NY 12545.*

Circulating levels of estradiol-17β (E_2), aromatizable testosterone (T) and non-aromatizable 5-dihydrotestosterone (DHT) were measured in male and female European robin chicks from day 3 to day 19 after hatching. E_2 concentrations were not different between the sexes, but varied significantly with age in males. Levels in males were higher during days 13 and 17 than days 11 and 19, when they were close to basal (50 pg/ml in our RIA system). Levels of T were low though not basal during the first days after hatching in both sexes. They were high at the time of fledging (day 13-15) and decreased by day 19 to basal (50-100 pg/ml). No sexual dimorphism in T levels was apparent. Levels of 5-DHT were very high in both sexes during the early nestling phase and then steadily decreased to basal levels by day 19 in both sexes. These results are consistent with the hypothesis that in species of songbirds in which both sexes sing as adults, as in the robin, levels of sex steroid hormones are elevated and sexually monomorphic during early development, when the neural song control system is organized.

INFUSIONS OF RAT PROLACTIN AND HUMAN PLACENTAL LACTOGEN INTO THE MEDIAL PREOPTIC AREA STIMULATE MATERNAL BEHAVIOR IN OVARIECTOMIZED, NULLIPAROUS RATS. R.S. Bridges and M. Freemark[1]*. Dept. Comparative Medicine, Tufts University School of Veterinary Medicine, North Grafton, MA 01536 and [1]Dept. Pediatrics, Duke University Medical Center, Durham, NC 27710.

The onset of maternal behavior at parturition is induced in part by the changes in hormone secretion during gestation. In rats, infusions of ovine (o) prolactin (PRL) into either the lateral ventricles or the medial preoptic area (MPOA) of steroid-primed, bromocriptine-treated, nulliparous females stimulates maternal behavior (Proc. Natl. Acad. Sci. USA 87, 8003, 1990). The present study examined the effectiveness of the endogenous lactogen, rat (r) PRL, and a heterologous lactogen, human placental lactogen (hPL), in the neural-hormonal stimulation of maternal care. Adult nulliparous rats were ovariectomized and fitted with bilateral cannulas directed at the MPOA. One week later each rat was implanted s.c. with progesterone- (treatment days 1-11) followed by estradiol-filled (days 11-17) Silastic capsules. Endogenous PRL was suppressed by twice daily injections of bromocriptine (days 11-17). From days 11-13 animals received 5 bilateral infusions of rPRL (40 ng/side), hPL (40 ng/side) or vehicle (0.4 µl). Testing for maternal behavior with foster young was conducted daily from day 12 to 17. Both lactogens stimulated a rapid onset of maternal behavior. Latencies to pup retrieval and full maternal behavior were significantly shorter in the rPRL and hPL groups (0.5-1.5 days) than in vehicle controls (4.0 days). These results demonstrate that rPRL and a heterologous placental lactogen, hPL, stimulate maternal care when infused into the MPOA, and suggest that the behavioral effects of PRL may be shared by other endogenous lactogenic molecules, i.e. placental lactogens. EFFECTS OF ENERGY INTAKE, DEMAND, AND PARTITIONING ON NESTBUILDING IN SYRIAN HAMSTERS. A. J. Bhatia, J. E. Schneider*, and G. N. Wade. Neurosci. and Behav. Prog., Depart. of Psychology, Univ. of Mass., Amherst, MA 01003.

Female mammals use a variety of strategies to insure a constant supply of energy for the cellular processes necessary for survival and optimal reproduction. For example, increased nestbuilding in response to cold exposure decreases the energy demands for thermoregulation. We have been studying the effects of food intake and cold ambient temperatures on nestbuilding in Syrian hamsters.

In experiment 1, there was a trend toward lower nestbuilding scores in females fed diets associated with the highest food intake and body weight gain at ambient temperature 22°C. However, when females were housed at 5°C, the differences in nestbuilding among the diet groups were exaggerated and were statistically significant ($p < 0.05$).

In many species, energy partitioning varies with reproductive state. Syrian hamsters lose body fat content without changing food intake during pregnancy. In experiment 2, hamsters showed significant increases in nestbuilding in response to both pregnancy and low ambient temperature (22 vs. 5°C) ($p < 0.05$). In the third experiment, nestbuilding was measured in ovariectomized hamsters implanted with either estradiol (E), progesterone (P), E+P, or empty Silastic capsules. There was a trend toward larger nests with significantly lower body fat contents in hamsters treated with E or with E+P. Taken together, the above results suggest that nestbuilding is increased in Syrian hamsters under environmental and reproductive conditions in which energy demand is high and energy availability low. COCAINE DISRUPTS MATERNAL BEHAVIOR IN LACTATING RATS. C.H. Kinsley, A. Bauer*, M. Beverly*, D. Turco* & J. Wellman*. Department of Psychology, University of Richmond, VA 23173.

Though much attention has been devoted to the behavioral and physiological consequences of cocaine (COC) abuse, little is known regarding the effects on maternal behavior (MB). We examined whether COC affects the initiation (late pregnancy) and/or maintenance (postpartum [PP]) phases of MB. In Exp. 1 COC (5 or 10 mg/kg) or saline was administered on PP day 5 or 6 and MB scored. 5 mg/kg was marginally effective ($p < .1$), whereas 10 mg/kg significantly disrupted full MB. Exp. 2 (with 10 mg/kg) examined specific elements of the disruption and found increases in the latencies to contact, retrieve, lick, group and crouch over pups. In Exp. 3 osmotic mini-pumps containing 20 mg COC/kg/day or saline were implanted sc in day 14 pregnant rats. MB testing was performed on days 1-2 PP together with a T-maze pup-retrieval test on PP days 3-5. COC disrupted MB and performance in the T-maze tests, in general, rendering the females less attentive to young. COC -- perhaps owing to its purported dopamine system activity -- may be affecting prolactin, a hormone which stimulates MB. (Supported by U. Richmond FRC).

RECOVERY FROM HABENULA LESION-INDUCED DEFICITS IN MATERNAL BEHAVIOR. K.P. Corodimas, J.S. Rosenblatt,* A.D. Mayer* and J.I. Morrell. Inst. Animal Behavior, Rutgers Univ, Newark, NJ 07102.

Previously we demonstrated that bilateral lesions of the habenular complex (Hbc) made on day 12 of pregnancy severely disrupt the hormonal onset of maternal behavior (MB) (retrieving, nursing and nestbuilding) in the rat for 7d. However, by day 8 of testing (13 days after the lesion) the majority of animals in the Hbc lesion group displayed complete MB compared with unoperated controls. These results suggested two hypotheses: either there was a recovery of function during the 13d following the lesion, or pup exposure for 8d stimulated MB despite the lesion. We tested these hypotheses. Bilateral Hbc lesions were made 4 days earlier on day 8 of pregnancy to determine if the passage of time (13d) following the lesion was sufficient for behavioral recovery. All animals were hysterectomized, ovariectomized, and given 20ug/kg estradiol benzoate on day 16 of pregnancy, then tested 48h later with pups for MB. The majority of Hbc-lesioned animals show complete MB by day 3 of testing. Thus, Hbc lesions made earlier in pregnancy result in an earlier recovery in MB. These data suggest that a neural recovery process requiring approximately 13 days may account for the behavioral recovery seen after Hbc lesions. (HD22983 to J.I.M.)

HORMONAL AND ENVIRONMENTAL INFLUENCES ON MALE INCUBATION IN SEX-ROLE REVERSED SHOREBIRDS. A.J. FIVIZZANI, L.W. ORING* AND M.E. EL HALAWANI* Biology Dept., Univ. of North Dakota, Grand Forks, ND 58202 and Animal Sci. Dept., Univ. of Minnesota, St. Paul, MN 55108.

In a few avian species such as the spotted sandpiper and Wilson's phalarope, males provide all or most of the incubation and brooding of young. Plasma levels of prolactin, the hormone most associated with parental care in birds, is sex-reversed being greater in incubating males than in females. Plasma testosterone declines rapidly at incubation and experimentally maintained high levels interfere with normal incubation behavior. Administration of the androgen blocking agent flutamide, facilitates the onset of incubation. Experimentally switching eggs of know incubation duration to produce longer or shorter than normal incubation periods for particular males indicates that the presence of eggs maintains prolactin beyond the normal time of hatch and the presence of chicks or absence of eggs results in a decline in prolactin before the normal time of hatch. Male incubation appears to be correlated with elevated prolactin, low testosterone and the continued stimulus of eggs in the nest.

SILASTIC MELATONIN IMPLANTS INDUCE OUT-OF-SEASON SEXUAL BEHAVIOR IN MALE RHESUS MONKEYS. J. G. Herndon, T.H. Robertson*, J.J. Turner* and D.C. Collins*. Yerkes Reg. Primate Res. Ctr. and V.A. Med. Ctr. Emory Univ., Atlanta, Georgia 30322

Seasonally breeding adult male rhesus monkeys (n=8) were moved from outdoor breeding groups to a light-controlled (16L:8D) indoor environment on June 21 (mid non-mating season), and remained on this lighting schedule for 18 months. At the onset of the following mating season, males were randomly divided into two groups and underwent 4 phases of 17 weeks of Melatonin (s.c. Silastic capsule producing 70-80pg/ml serum melatonin) or Control (empty capsule) treatment. For group A, the sequence of control (C) and melatonin (M) treatments in the 4 phases of the study was CMCM; for group B, the sequence was CCMC. The reproductive status of untreated outdoor-housed rhesus monkeys during the four 17-week phases was: (1) early mating season, (2) late mating season - early non-mating season, (3) mid non-mating season, and (4) early mating season. In both groups, phases 1,2, and 4 were characterized respectively by increasing, decreasing and increasing mounting frequency, testosterone level and testis volume. This is similar to the seasonal pattern shown by outdoor-housed animals, and likely represents persistence of an endogenous reproductive rhythm. During phase 3 (when outdoor-housed animals showed no sexual behavior), the group receiving melatonin (group B: CCMC) displayed significant increases in frequencies of mounting. Males not receiving melatonin during phase 3 (group A: CMCM) mounted at a significantly lower rate. Testosterone levels and testis size in the two groups changed with season, but the two groups never differed from each other. The effects of melatonin on sexual behavior thus are independent of changes in testicular function. (NIH grant RR-00165 and Department of Veterans Affairs).

DIFFERENTIATION OF PERIMENSTRUAL SYMPTOM CATEGORIES AND ENDOCRINE CORRELATES. C.A.Cahill. University of Kansas Medical Center, School of Nursing and School of Medicine Kansas City, KA 66103.

The etiology of dysphoria associated with the last week of the menstrual cycle has puzzled many. Attempts to associate changes in gonadal hormones with symptom severity and type have not demonstrated clear cut associations. Several hypotheses have been offered to explain this apparent contradiction. One possibility is that several different mechanisms are associated with Perimenstrual Symptoms (PS) which may be reflected in different types of symptoms, symptom severity and symptom patterns. In this study, 40 women were selected for study based on symptom type and severity. Twenty women with minimal symptoms and twenty with moderate to severe depression-like symptoms were studied over three consecutive menstrual cycles. Plasma samples were collected twice per week and analyzed for beta-endorphin-like immunoreactivity, cortisol, prolactin and progesterone. During data analysis, six unique patterns of PS were noted. This poster will report attempts to associate hormone levels and patterns with the more rigorous symptom pattern categories.

562.11

BIRTH ORDER AND LEFT-HANDEDNESS: INTERACTION OF PARITY AND SEX ON DIRECTION OF ASYMMETRY IN MICE Robert L. Collins. The Jackson Laboratory, Bar Harbor, ME 04609.

During selective breeding for degree of lateralization for handedness in mice, an interaction of parity and sex emerged for the direction of asymmetry. This interaction affected quantitative and qualitative measures of laterality in males of both HI and LO selected lines. During generations G_8, G_9, and G_{10}, first-litter males were more often left-handed (RPE $\leq$ 25), and second-litter males were more often right-handed (RPE $\geq$ 25): $Pr(RH|L_1) = 0.434$; $Pr(RH|L_2) = 0.557$ ($N_1 = 451$; $N_2 = 210$; $\chi^2 = 8.79$; $p = 0.003$). This interaction was confirmed 5 years later when selection was reimpressed during G_{28}, G_{29}, and G_{30}: $Pr(RH|L_1) = 0.399$; $Pr(RH|L_2) = 0.601$; ($N_1 = 367$; $N_2 = 143$; $\chi^2 = 17.0$; $p = 0.00004$). No changes in frequencies of dextrality were observed for female mice: $Pr(RH|L_1) = 0.480$ and 0.503; $Pr(RH|L_2) = 0.406$ and 0.490, respectively; N's = 585 and 665.

The parity by sex interaction increased as a function of generation number in each selected line. This could be due to cumulative influences of unavoidable inbreeding in finite populations, or to a correlated response to selection for handedness itself—both HI and LO lines necessarily were selected for success in the food reaching task (Collins, In S. D. Glick, *Cerebral Lateralization in Nonhuman Species*, Academic Press, 41–70, 1985).

The male parity effect observed in the selected mouse lines is consistent in type and direction with that suggested by Bakan (*Nature* 229:195, 1971) who reported increased left-handedness in human males of high-risk birth orders (1 and 4+). This finding, however, has proved difficult to replicate (Searleman *et al, Psychol. Bull.* 105:397–405, 1991). Laterality patterns in male offspring of differing birth order may be mediated by hormonal or immunological differences between primiparous and multiparous dams or by differential maternal care. The parity effect also may explain the sporadic and sometimes conflicting reports of nonequiprobably distributed asymmetries in male laboratory animals.

562.12

SEX AND AGE DIFFERENCES IN THE SPONTANEOUS LOCOMOTOR ACTIVITY OF THE MONGOLIAN GERBIL (MERIONES UNGUICULATUS): MULTIVARIATE AND TEMPORAL PATTERNS. **L.A. Mead, E.L. Hargreaves, K.-P. Ossenkopp, and M. Kavaliers. Dept. Psychology and Div. Oral Biology, Univ. Western Ontario, London, Ont., CANADA N6A 5C2.**

A multivariate assessment of the spontaneous locomotor activity of the laboratory bred Mongolian gerbil (Meriones unguiculatus) was obtained using a Digiscan animal activity monitoring system. Motor activity data were collected for 12 consecutive 5 min. samples from each of 42 gerbils obtained from 6 separate litters (aged 24, 39, 62, 116, 150, or 197 days). Variables examined included: total distance travelled (TD), average distance (AD), average speed (AS), number of horizontal movements (NM), time in horizontal movement (MT), time per horizontal movement (TMT), number of vertical movements (NV), time in vertical movement (VT), and time per vertical movement (VMT). Results indicated that across the 12 samples, all activity measures (except AS and TMT) declined for both males and females. Overall differences in locomotor activity between males and females were found over the one hour period on the measures AD and AS. Females exhibited higher levels of activity. Initial sex differences on the measures TD, NV, and VT were strongly reduced after approximately 30 minutes. Age also had an effect on spontaneous activity. All measures of activity increased at the early ages (i.e. for the litters aged 24, 39, and 62 days), and remained relatively constant thereafter (i.e. for the litters aged 116, 150, and 197 days). The activity levels over the one hour period declined more rapidly for the younger litters on the measures of TD, AD, NM, and MT. These results extend previous work examining sex differences in laboratory rats and meadow voles using the Digiscan System.

ICV PROLACTIN DECREASES INFUNDIBULAR VIP - LIKE IMMUNOREACTIVITY IN INCUBATING DOVES.

C. J. Saldanha and R. Silver. Barnard College of Columbia University, New York, NY. 10027.

Several lines of evidence suggest that vasoactive intestinal polypeptide (VIP) is a prolactin (PRL) releasing factor in birds. Systemic VIP increases, while antibodies to VIP decrease plasma PRL. Additionally, VIP releases PRL from dispersed pituitary cells *in vitro*. Although VIP-like immunoreactive cells are widely distributed in the avian hypothalamus, one group in the infundibulum (INF) increase in diameter during incubation.

To assess whether PRL influences hypothalamic VIP, the effect of icv ovine PRL (o-PRL) was investigated. Breeding doves were given 6 daily injections of o-PRL beginning on incubation day 8 (I 8), while controls received vehicle. Body weight and incubation behavior was monitored during incubation. Following perfusion on I 14, crop weights and gonadal states were measured. The brains were removed, sectioned, and alternate sections were stained for VIP and gonadotropin releasing hormone (GnRH).

O-PRL decreased detectable VIP-like immunoreactive cell number in the INF, but did not change lateral septal VIP or medial preoptic (MPOA) GnRH cell number. O-PRL treated subjects had lower crop weights on I 14, but did not differ from controls in incubation behavior or gonadal state. The results suggest that during incubation, central PRL regulates its own secretion by acting on INF VIP cells. Moreover, the site of feedback is limited to the population of VIP cells that increase in diameter during incubation. Supported by NIMH grant 29380-15.

EFFECTS OF ESTRADIOL ON EXTINCTION OF CONDITIONED TASTE AVERSIONS: TIME OF ACTION. D.L. Yuan and K.C. Chambers. Department of Psychology, USC, Los Angeles, CA 90089.

Testosterone (T) prolongs extinction of conditioned taste aversions (CTAs) by acting on processes associated with extinction not acquisition. Estradiol (E) increases extinction rate and prevents T from prolonging extinction. The following studies were designed to determine whether E acts during acquisition or extinction. In both studies, a CTA was induced with 0.15M LiCl (10 ml/kg) after access to a 10% sucrose solution and daily extinction trials were initiated 10 or 23 days later. In study 1, the extinction rates of gonadectomized (GX) females given E before and during acquisition and extinction (E/E) were significantly faster than those of GX females given no hormone before and during acquisition and extinction (0/0). The extinction rates of the E/E females and GX females given E before and during acquisition but not extinction (E/0) did not differ and those of the 0/0 females and GX females given E before and during extinction but not acquisition (0/E) did not differ. In study 2, the extinction rates of 0/0 and 0/E GX females were not different. The rates of both of these groups were significantly faster than those of GX females given E during but not before extinction. Thus, E accelerates extinction when present before and during acquisition but prolongs extinction when present during extinction. These results can be accounted for by E toxicity. ONR N00014-89-J-1296

EFFECTIVENESS OF TESTOSTERONE IN PROLONGING EXTINCTION OF CONDITIONED TASTE AVERSIONS IN FLUID DEPRIVED MALE RATS IS DEPENDENT ON LICL DOSE. E.A. Brownson, C.B. Sengstake,* K.C. Chambers. Neurobiology and Psychology, USC, Los Angeles, CA 90089 and Psychology, PSU, Portland, OR 97207.

Extinction of a conditioned taste aversion (CTA) is modulated by both testosterone (T) and fluid deprivation (FD). Males with normal physiological levels of T exhibit slow extinction rates and gonadectomized males show fast extinction rates. Fluid deprived intact males also exhibit fast extinction rates. The following two studies were designed to determine the relationship between T and FD in Fischer 344 males. In both studies, a CTA was induced in males under a 23 hr FD schedule or under nondeprivation (ND) conditions. The FD and ND males were injected with either a high dose of LiCl (0.30 M, 20 ml/kg) or a low dose (0.15 M, 10 ml/kg). Daily extinction trials began 2 days later. In the first study, blood was drawn from the males prior to the first extinction trial. For both doses of LiCL, the serum T levels in FD and ND males were not different but extinction rates were faster in FD males than ND males. In the second study, FD males were implanted with blank or T-filled capsules. Rates of extinction were faster in blank-treated FD males than ND males. T restored extinction rates to the level found in ND males when the FD males were injected with the high dose of LiCl but not the low dose. These results suggest that FD does not act on a T mechanism to increase extinction rate. ONR N00014-J-1296

562.16

EFFECTS OF GONADECTOMY ON EXTINCTION OF CONDITIONED TASTE AVERSIONS IN FISCHER 344 MALE RATS. K.C. Chambers, E.A. Brownson and D.L. Yuan. Departments of Psychology and Neurobiology, USC, Los Angeles, CA 90089

Extinction of a conditioned taste aversion (CTA) is slower in male rats than females. The extinction rates of Sprague-Dawley (SD) gonadectomized (GX) males are not different than those of females but the rates of Fischer 344 (F344) GX males are slower than those of females. The following experiments were designed to determine whether testosterone (T) plays a role in extinction of CTAs in F344 males. In experiments 1 and 2, a CTA was induced with LiCl (0.15 M, 10 ml/kg) after presentation of a novel 10% sucrose solution and daily extinction trials were initiated 2 days later. In experiment 1, the extinction rates of intact males and GX males were not significantly different. In experiment 2, the extinction rates of untreated GX males were significantly faster than those of GX males implanted with T-filled capsules that produced high physiological levels of T. In experiment 3, the serum T levels of intact F344 and SD males were not significantly different. These results indicate that T prolongs extinction in both F344 amd SD males. However, F344 males appear to be less sensitive to T than SD males. Since GX F344 males but not GX SD males have slower extinction rates than females, perinatal hormones may play a more important role in F344 rats than SD rats. ONR N00014-J-1296

562.17

HORMONAL MODULATION OF THE CUTANEOUS CONTROL OF LORDOSIS IN INFANT AND ADULT RATS.

G.S. Benedict and C.L. Williams. Depts. of Psychology, Columbia University and Barnard College, New York, NY 10027.

Previous work from our laboratory has shown that when 6-day-old rats are stroked on the sides, flanks, and rump they display a lordosis-like response that is facilitated by priming with estradiol benzoate (EB) and progesterone (P). In adult female rats, it is believed that cutaneous input from the anterior curve of the hip is the critical sensory input for the facilitation of lordosis (Kow & Pfaff, 1976). The purpose of this study is to determine the cutaneous control of lordosis in 4- to 6-day-old and adult rats and to determine whether hormone priming influences the specificity of this control. Subjects were denervated on the waist (W), a region containing the anterior curve of the hip, or on the sides (S), a region from axilla to tailbase, or sham denervated. In neonates, denervation of the W and S significantly decreased lordosis of both hormone primed (100 μg EB and 0.5 mg P, administered 40 and 4 hrs prior to testing) and unprimed rats. In contrast, in adult females primed with 100 μg EB and 0.5 mg P, denervation of the W and S had no effect on manually stimulated lordosis. When priming doses of EB were lowered to 5 μg EB and 0.5 mg P, the S-denervated group showed significantly less lordosis than W- or sham-denervated females, which did not differ. When EB priming was given without added P, denervati ons of the W and S were equally effective in reducing lordosis frequency. Results suggest that the waist region is the critical cutaneous input for the facilitation of lordosis in infants and adults. However, the specificity of this input is not under hormonal control in 6-day-old rats and is modulated by EB and P in adult females.

PROGESTERONE WITHDRAWAL INCREASES ANXIETY IN A RAT MODEL. M.A. Gallo,* J.E. Fletcher and S.S. Smith, Dept. of Anatomy, Inst. for Neurosci., Hahnemann Univ., Philadelphia, PA 19102.

Physiological levels of systemically injected progesterone (P) have been shown to amplify GABA responses of neurons within a model CNS circuit (Smith et al, 1987a,b,c;1989) in a manner similar to the benzodiazepines (BDZ), an effect due to 3αOH-DHP (Harrison et al, 1987), a metabolite formed locally from P. In addition, anxiolytic properties of P have also been demonstrated (Rodriguez-Sierra et al, 1984). The goal of the present study was to test the hypothesis that withdrawal from chronic P treatment could increase anxiety in a rat model using the conditioned defensive burying paradigm. For this paradigm, rats were first habituated to the plexiglass test chamber prior to exposure to an electrified probe (0.05-1 mA from a 350 V source). Once shocked, rats were monitored during subsequent burial of the probe with cage sawdust. Parameters assessed included latency, duration, frequency and pile height of probe burial. Decreases in the latency and increases in the duration of probe burial, compared with control values, are specific as measures of anxiety in that these changes are produced by anxiogenic β-carboline treatment (Tsuda et al, 1989) and reversed by administration of BDZ but not morphine, at analgesic doses (Treit et al, 1981). For the present study, female rats were exposed to 4-day P treatment (500 μgs daily, i.p., in sesame oil) concurrent with 17β-estradiol priming (2 μgs, daily, i.p. in sesame oil) for the first 2 days of the injection schedule. On day 5, withdrawal from chronic P treatment produced increases in anxiety as determined by significant decreases (33%, $P < 0.01$) in latency and increases in duration (55%) of probe burial compared with vehicle-injected controls ($n = 6$, both groups). This anxiogenic effect produced by withdrawal from the steroid could be reversed with subsequent administration of P (500 μgs, i.p.) on day 6 to an estradiol-primed animal. These results suggest that under physiological conditions, "withdrawal" from P during the hormone cycle may increase anxiety. In contrast, combined replacement therapy with estradiol and P is anxiolytic in these animals. The present findings may have relevance for the etiology and treatment of PMS-related anxiety in humans. *(Supp. by NS 25809 to SSS.)*

563.1

EFFECTS OF NEONATAL ADMINISTRATION OF VASOPRESSIN ON CARDIAC AND BEHAVIORAL RESPONSES TO EMOTIONAL STRESS IN ADULT RATS. B.Buwalda*, C.Nyakas*, J.M.Koolhaas* and B.Bohus. (SPON: European Brain and Behaviour Society) Department of Animal Physiology, Centre for Behavioural, Cognitive and Neuro-sciences, University of Groningen, P.O.Box 14, Haren, The Netherlands.

The basis for an adequate neuronal circuit, needed for succesful coping with environmental challenges, is established in the development of inter-neuronal communication. The present study will show the effects of early exposure to the neurohypophyseal peptide arginine-8-vasopressin (AVP) on adult autonomic and behavioral responses to emotional stress. Attention has been also paid to the effect of neonatal exposure to AVP on the modulating properties of vasopressin on the bradycardiac stress response in adulthood. AVP was administered subcutaneously on postnatal days 3-7 in a high (10 μg/100gr bodyweight) and a low dose (1 μg/100gr b.w.) to male Wistar rats. Control animals were untreated or saline injected. Behavioral observations in a novel environment of a complex maze indicated that neonatal administration of AVP increases exploratory behavior in a dose-dependent way. Cardiac monitoring during the conditioned emotional stress of fear of inescapable electric footshock showed that neonatal administration AVP has little effect on bradycardiac stress response. The analysis of cardiac responses also suggested an adult hyposensitivity to AVP in rats treated neonatally with AVP. Furthermore, low doses of AVP were very effective in impairing avoidance behavior in this test situation.

The data indicate that neonatal administration of AVP exerts long-lasting effects upon memory processes related to emotional stress and on the behavioral adaptation to novelty. Neonatal administration of AVP is less effective in changing autonomic stress responses, suggesting a differentiation in time of the critical period of central vasopressinergic systems involved in the regulation of behavior and autonomic functioning.

NEONATAL STRESS ALTERS DEVELOPMENT OF BRAIN OXYTOCIN RECEPTORS. L.R. Noonan, J.D. Caldwell, L. Li, C.H. Walker, C.A. Pedersen and G.A. Mason. Brain and Development Research Center and Dept. of Psychiatry, School of Medicine, University of North Carolina, Chapel Hill, NC 27599.

A standard neonatal stress procedure consisting of separation and return of rat pups to the mother for brief, daily periods has been shown to permanently diminish endocrine and behavioral stress responses, an effect that may be partially explained by increases in brain glucocorticoid and GABA receptors. We hypothesized that oxytocin (OXT) receptors would be also affected by infant stress because OXT has been reported to modulate stress responses during infancy and adulthood. We separated or did not separate (control condition) Sprague Dawley rat pups for 20 minutes per day, beginning at postnatal day 2 and ending at the time of sacrifice on day 4, 8, 14, or 22. Oxytocin receptor binding was performed using the specific antagonist ^{125}I-OTA. Scatchard analysis indicated that neonatal stress caused a decrease in OXT receptor number (B_{max}), but no changes in affinity (K_D), in hippocampus, cortex and remaining forebrain. There was a 40-60% decrease in OXT receptors in the stress condition at day 4 compared with day 4 controls. The magnitude of this difference decreased across age, although small differences were still evident at day 22 in cortex and remaining forebrain, but not in hippocampus. A developmental decrease in brain OXT receptors produced by infant stress may provide a mechanism by which permanent decreases in stress responsiveness occur.

TESTOSTERONE-DEPENDENT VASOPRESSIN IN RELATION TO AGGRESSIVE BEHAVIOUR. J.C. Compaan[1], J.M. Koolhaas[1], R.M. Buijs[2], C.W. Pool[2], A.J.H. de Ruiter[1], G.A. van Oortmerssen[1]. (SPON: European Brain and Behaviour Society) [1]Univ. of Groningen, Dept. of Anim. Physiol., P.O.Box 14, 9750 AA Haren, [2]Netherlands Instit. for Brain Res., Meibergdreef 33, 1105 AZ Amsterdam, the Netherlands.

In this study we used mice, genetically selected for aggression. At adult age aggressive males, with a Short Attack Latency (SAL), possess a higher plasma testosterone (T) level compared to males with a Long Attack Latency (LAL). In contrast, at neonatal age, in LAL males a higher T production occurs. In the adult brain, the vasopressinergic (AVP) innervation of the lateral septum (LS) is less abundant in these SAL males. Probably, the neonatal difference in plasma-T level is involved in a differential development of the AVP system in these two selection lines of mice. So far, it is unknown to what extent this system is involved in the differentiation in aggressive behaviour. Therefore adult SAL and LAL males were castrated, and aggression and AVP content were measured 15 weeks later. We found an almost complete reduction in LS innervation of AVP in both selection lines. No difference was found in the nucleus of the solitary tract, a T non-dependent AVP containing nucleus. Surprisingly, only the LAL males show a reduction in aggression. Thus, although AVP in LS is T dependent in both selection lines, only the LAL males are affected in aggression after castration. This suggests a differential involvement of T dependent AVP systems in the organization of aggressive behaviour in the two selection lines of mice.

The investigations were supported by the Foundation for Biological Research (BION-426.061), which is subsidized by the Netherlands Organization for Scientific Research.

SEXUAL DIMORPHISM IN THE VASOTOCIN SYSTEM OF THE BULLFROG. S.K. Boyd, C.J. Tyler and G.J. DeVries. Department of Biological Sciences, University of Notre Dame, Notre Dame, IN 46556; Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Since vasotocin levels in amphibian brains are influenced by gonadal steroids and differ by sex, we used immunocytochemistry to identify which AVT pathways show sex differences in the bullfrog (Rana catesbeiana). AVT-immunoreactive cells were observed in the septal nucleus, amygdala pars lateralis, magnocellular preoptic area, suprachiasmatic nucleus, hypothalamus, and pretrigeminal nucleus. Immunoreactive fibers were broadly distributed in hypothalamic and extra-hypothalamic areas. The most obvious sex differences were found in the amygdala pars lateralis, which showed significantly more immunoreactive cells and fibers in male than in female bullfrogs. In the suprachiasmatic nucleus, AVT immunoreactive cells were larger in females than in males but did not differ in number. Since the areas that showed sex differences in vasotocin distribution have also been implicated in reproductive behaviors, they may form the neural substrates for the effects of vasotocin on sexually dimorphic behaviors in amphibians.

SITE-SPECIFIC INJECTIONS OF A SELECTIVE OXYTOCIN RECEPTOR ANTAGONIST AFFECTS FEMALE SEXUAL BEHAVIOR D.M. Witt & T. R. Insel, NIMH, LCS, Section on Comparative Studies of Brain and Behavior, Poolesville, MD 20837.

Previous studies indicate that oxytocin (OT) facilitates female sex behavior and the selective OT antagonist (called OTA) blocks these behavioral responses (Witt & Insel, Endocrinology, June 1991). Although OT receptors have been extensively mapped in the CNS, the specific regions that mediate OT's effect on sexual behavior remain unknown. Brain regions regulating OT-mediated behaviors were determined by site-specific injections of OTA (10 - 100 ng). Injections were administered via bilateral cannulae guides positioned over the medial preoptic area (MPOA) or the ventromedial nucleus (VMN) of the hypothalamus, regions known to mediate sexual behavior. Ovariectomized female rats, primed with estradiol benzoate (sc, 1 μg, for 2 days) and progesterone (sc, 250 μg, for 1 day), received bilateral injections of OTA (5, 25, or 50 ng / side) or artificial CSF (0.5 μl / side). Injections of OTA into the VMN significantly reduced lordosis quotients (LQs), proceptive hopping/ darting and increased rejection behaviors. These behavioral responses occurred at doses considerably lower than those required with icv administration. In contrast, our preliminary studies indicate that OTA injections in the MPOA did not affect LQs, but decreased proceptive behaviors such as physical contact. Results from these site-specific experiments, along with the icv studies, are consistent with the hypothesis that OT plays a physiological role in the expression of female sexual behavior.

ACTIVATION OF C-*FOS*-LIKE PROTEIN IN PVN OXYTOCIN CELLS DURING MALE SEXUAL BEHAVIOR. T. R. Insel and D.M. Witt, Lab. Clin. Sci., NIMH, Poolesville, MD 20837

The protein product of the c-*fos* oncogene has been previously used to map neuronal activity at the cellular level following seizures, dehydration, stress, and a variety of drug treatments. In the current study, induction of a c-*fos*-like protein was detected immunocytochemically following male sexual behavior to determine neuronal sites of activation associated with mounting and ejaculation. Sexually experienced male Sprague-Dawley rats were studied after (a) ejaculation, (b) intromission and mounting without ejaculation, or (c) exposure to a testing arena vacated by an estrous female. Induction of c-*fos*-like protein was not evident in the medial preoptic area (MPOA) following any of the treatments, although this area has been previously implicated in the mediation of male sex behavior. Treatment effects were noted in the paraventricular nucleus of the hypothalamus (PVN) with increases of 300-500% in the number of parvocellular neurons expressing c-*fos* following either mounting or ejaculation. Significant but less striking increases (60-100%) in c-*fos* expression were noted in magnocellular divisions of the PVN. Double-labelling experiments indicated that approximately 25% of these *fos* - positive cells also expressed oxytocin, but few expressed vasopressin. Ongoing experiments are investigating other neuropeptide phenotypes. These results are generally consistent with other techniques implicating extra-hypothalamic oxytocin projections in the mediation of male sex behavior. The absence of c-*fos* induction in the MPOA does not rule out the possibility that some other transcription factor may be associated with cellular activation in this region.

TRANSIENT INCREASE IN CENTRAL OXYTOCIN BINDING ASSOCIATED WITH PARTURITION. C.A. Pedersen, C.H. Walker, J.D. Caldwell, G.A. Mason, Dept. of Psychiatry, BDRC and the Neurobiology Curriculum, School of Medicine, The University of North Carolina, Chapel Hill, NC 27599-7250.

Soloff et al, (1979) demonstrated that oxytocin (OT) binding in the uterus increases dramatically a few hrs prior to parturition and then subsides as quickly postpartum. Mayer and Rosenblatt (1984) observed that maternal response to neonates emerges rather abruptly a few hrs before parturition. These observations have led to us hypothesize that a transient rise in central OT binding may also occur at parturition and may be related to the activation of maternal behavior. To test our hypothesis, we employed a radioligand assay to measure OT binding in dissected brain sites in 6 SD rats on days 16-17 of pregnancy, 6 rats in midparturition or less than 2 hrs after delivery of the last pup, and 6 lactating rats 5-7 days postpartum. In the amygdala and the MPOA we measured a significant 20-25% increase in OT binding at midparturition. By 5-7 days postpartum OT binding in these sites returned to the lower levels occurring in late pregnancy. In the VTA, OT binding rose fourfold at parturition compared to late pregnancy. OT binding in the VTA declined almost 50% by 5-7 days postpartum but remained significantly elevated over late pregnancy levels. The MPOA, amygdala and the VTA have all been implicated in the activation of maternal behavior. A transient rise in OT binding in these brain sites at parturition may trigger the onset of maternal behavior even as the transient rise in binding in the uterus facilitates the onset of labor.

PROGESTERONE - OXYTOCIN INTERACTIONS: EFFECTS ON SEXUAL RECEPTIVITY. J. D. Caldwell, C.H. Walker*, G.A. Mason*, and C.A. Pedersen; BDRC & Dept. of Psychiatry, School of Medicine, Univ. of North Carolina, Chapel Hill, NC 27599-7250

Both the peptide oxytocin (OXT) and the steroid progesterone (P) enhance female sexual receptivity. Here we present evidence that they interact at several levels to achieve this behavioral effect. P treatment changes the pattern of OXT recovery by microdialysis from the medial preoptic area (MPOA) and ventromedial hypothalamus. Estradiol benzoate (EB) treatment increased OXT recovery and resulted in surges of OXT which were lower in P treated animals until four hours after injection when OXT recovery increased dramatically. In OVXed rats given 0.5 μg EB for three days a 500 μg P injection significantly increased the density of OXT receptors in membrane fractions from the MPOA of animals mounted twenty times by males. In OVXed rats given 0.25 μg EB for three days the infusion of 1 μg/side of the OXT antagonist [Pen^1, pMePhe^2, Thr^4, Orn^8]OXT into the MPOA before injection of 250 μg P significantly ($p<.001$) reduced lordosis quotients 4 hours ($t_{25}=3.82$) and 6 hours later ($t_{25}=2.64$; $p<.02$). In adrenalectomized (ADXed)-OVXed rats, given 25% corticosterone implants, infusions of OXT significantly ($p<.01$) increased sexual receptivity ($t_{18}=3.54$). OXT significantly ($p<.05$) facilitated receptivity in sham-ADXed animals ($t_{21}=2.27$) but not in ADXed-OVXed animals receiving cholesterol implants. OXT and P interact to the extent that P affects OXT release patterns and OXT receptor density. Both OXT and P may need to be present for the other to enhance sexual receptivity.

HOMOZYGOUS BRATTLEBORO RATS DISPLAY ATTENUATED CONDITIONED FREEZING RESPONSES. James D. Stoehr*, Savio Cheng*, Frances McCann and William G. North, Dept. of Physiology, Dartmouth Medical School, Hanover, NH., 03756.

Rats homozygous for hereditary hypothalamic diabetes insipidus (Brattleboro rats) lack measurable levels of AVP in the CNS and peripheral circulation, while rats heterozygous for this condition have a reduced capacity to synthesize AVP that results in levels that are less than half of those found in normal Long-Evans (LE) rats. In the present study we examined the influence of AVP on conditioned freezing behavior to aversive shock treatment by comparing the responses of Brattleboro homozygous (DI) rats, Brattleboro heterozygous (HZ) rats, and LE rats. Animals were placed in a sound-attenuated shock chamber on the training day and given a series of 3 footshocks (1 mA, 0.75 sec, 20 sec inter-shock interval). On the following four days the rats were placed in the chambers where they had received their shock and levels of spontaneous freezing evaluated.

For each of the four days, DI rats displayed significantly less freezing behavior when compared with LE rats and HZ rats. HZ rats displayed trends towards attenuated freezing responses when compared with LE rats. The data then imply that, in rats, a correlation exists between the capacity to produce AVP, and the amount of freezing displayed. These preliminary results suggest that vasopressin may play a significant role in the appropriate autonomic and emotional responses to fearful stimuli.

563.10

OXYTOCIN-INDUCED FACILITATION OF LORDOSIS IS MEDIATED BY THE PELVIC NERVE, K.M.Moody, J.L.Steinman, B.R.Komisaruk and N.T.Adler, Inst. of Neuroscience, Univ. of Penn., Phila.Pa, and Inst. of Animal Behavior, Rutgers Univ. Newark, NJ. Peripheral oxytocin administration increases receptivity in ovariectomized rats. When the uterus is removed, these effects are lost, suggesting that increased uterine contractility is mediating this effect. To determine a mechanism by which oxytocin-induced uterine contractions facilitate lordosis, pelvic, hypogastric and combined neurectomies were performed. Ovariectomized rats received .25ug EB for three days and 500ug P, four hours prior to behavioral testing. Ten minutes before testing, females received either .1cc saline or 2.1ug oxytocin. They were then placed into an arena with a sexually experienced male. Males were allowed to deliver 10 mounts or intromissions and the LQ for each female was determined. One week later, the test was repeated and the drug treatments were reversed. Animals then received either bilateral pelvic, hypogastric or combined neurectomy. After recovery, animals were tested as described. The results indicate that pelvic and combined neurectomies have a significantly greater effect on reducing oxytocin-induced facilitation of behavior than hypoastric neurectomy. This suggests that the pelvic nerve is more important than the hypogastric nerve in mediating the stimulatory effects of oxytocin on receptivity.

563.11

VASOPRESSIN $V1_A$-RECEPTOR BINDING IN RAT AND HAMSTER BRAIN: EFFECT OF GONADAL STEROIDS. A.E.Johnson, S. Audigier*, C.Barberis*, S.Jard*, H.E.Albers, Karolinska Institute, Clin. Res. Ctr., Huddinge Hosp., Huddinge, Sweden; Centre CNRS-INSERM de Pharmacologie-Endocrinologie, Montpellier, France; Depart. of Biology and Psychology, Lab. of Neuroendocrinology and Behavior, Georgia State University, Atlanta, GA.

In rats and hamsters, central vasopressin (VP) transmission is involved in the regulation of a variety of social behaviors that are dependent on circulating gonadal hormones. In rats, testicular steroids modulate VP transmission by altering the synthesis of VP in certain brain regions but does not appear to regulate central VP receptor binding. In hamsters gonadal steroids do not affect VP peptide levels, however their affect on central VP receptors are unknown. To further investigate the role of VP transmission in the regulation of steroid-dependent behavior, the distribution and regulation of central VP-receptors by testicular steroids was studied in rats and hamsters using the highly selective $V1_A$-receptor ligand, ^{125}I-labelled Phaa-D-Tyr(Me)-Phe-Gln-Asn-Arg-Pro-Arg-Tyr-NH_2 (^{125}I-OK). Slide mounted tissue sections were preincubated in 50mM Tris buffer (pH7.4, 15min, 20°C) followed by a 1 hr incubation (20°C) in buffer containing 50pM ^{125}I-OK ± 1μM unlabelled arginine-VP, 5mM $MgCl_2$, 0.1mM bacitracin and 0.1% BSA. The incubation was terminated by washing the sections in ice-cold buffer containing $MgCl_2$. Labelled sections and standards were apposed to film for four days and autoradiograms were analyzed with a computer-assisted densitometer. The results of initial studies revealed binding sites in the expected locations such as the lateral septum, hippocampus, superior colliculus and NTS in rats and hamsters. Additional binding sites were found in the lateral hypothalamus, dorsal raphe, and pineal. The role of testicular hormones in the regulation of ^{125}I-OK binding is currently under investigation.

563.12

ESTROGEN REGULATION OF OXYTOCINERGIC INNERVATION OF THE VENTROMEDIAL NUCLEUS OF THE HYPOTHALAMUS (VMN). L.M. Flanagan, M. Frankfurt and B.S. McEwen, Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

Recent evidence suggests that the pituitary hormone oxytocin (OT) acts as a neurotransmitter in the brain to modulate female sexual behavior. Earlier reports from this laboratory demonstrated that OT receptor binding in the VMN is induced by estrogen treatment, and that progesterone causes this binding to spread laterally. In the present series of experiments the OT innervation of the VMN was examined. Using immunocytochemical techniques, oxytocin fibers in the VMN were compared in ovariectomized rats treated with oil or estradiol (10 μg in 100 μl, for 2 days, sc). The number of OT fibers in the VMN was small, whereas the number of fibers passing laterally to the VMN, en route to the pituitary, was relatively large. No differences were observed in the OT fibers within the VMN in the oil-treated versus the estradiol-treated group (n=9 per group). In a second experiment, the retrograde tracer Fluorogold (FG) was injected into the VMN of female rats. Seven days later the rats were perfused, and OT neurons were stained with the immunofluorescent marker Texas Red. Colabelling of OT with FG occurred only occasionally when FG injections were confined to the VMN (n=4) . Taken together, these results suggest that OT fibers do not innervate the VMN itself but rather VMN dendrites that extend laterally towards the OT fiber tract. Thus, the progesterone-induced movement of OT receptors may be the key factor that allows the facilitative effect of OT on sexual behavior. We currently are performing radioimmunoassays of micropunches of the VMN and the area lateral to the VMN to measure OT levels in ovariectomized rats treated with oil or estradiol. AVP-IMMUNOREACTIVE PROJECTIONS TO THE MEDIAL PREOPTIC-ANTERIOR HYPOTHALAMIC CONTINUUM (MPOA-AH) IN SYRIAN HAMSTERS. **A. C. Hennessey, D. C. Whitman & H. E. Albers.** Depts. of Biol. & Psych., Georgia State Univ., Atlanta, GA 30303.

Vasopressin, within the MPOA-AH, is critically involved in the neural control of flank marking. Using a retrograde tracing method combined with ICC for AVP, the present study identified afferents of the MPOA-AH that were immunoreactive for AVP. Hamsters (n=6), previously implanted with guide cannula aimed at the MPOA-AH, received a 100 nl injection of a cocktail of fluorescent microspheres and AVP (9 uM). Hamsters flank marked immediately after MPOA-AH microinjection (mean= 83 ± 20.4). Areas found to project to the MPOA-AH include: the median preoptic nucleus, septohypothalamic nuclei, bed nucleus stria terminalis (BNST), paraventricular nucleus (PVN), amygdala, ventromedial hypothalamus, arcuate nucleus, raphe nuclei and periaqueductal gray. Afferents which were also immunoreactive for AVP include: the median preoptic nucleus, BNST, and the PVN. (Supported by NSF BNS-8910863)

SEPTO-HYPOTHALAMIC ORGANIZATION IN THE CONTROL OF FLANK MARKING BEHAVIOR IN GOLDEN HAMSTERS: EVIDENCE FOR BILATERAL RECRUITMENT OF THE ANTERIOR HYPOTHALAMUS. C.F. Ferris, Y. Delville, M. Potegal, and G.J. DeVries. Dept. of Physiology, Univ. of Mass. Med. Ctr., 55 Lake Avenue N, Worcester, MA 01655, USA.

Microinjection of arginine vasopressin (AVP) into the lateral septum (LS) or anterior hypothalamus (AH) stimulates flank marking , a stereotypic motor behavior in hamsters. The present studies were undertaken to determine which of these two sites is more critical in the organization and expression of AVP-dependent flank marking. Since the LS and the AH have unilateral and reciprocal connections, AVP was injected into the LS in animals with neurotoxic lesions in the ipsilateral AH, or AVP was injected into the AH in animals with ipsilateral lesions in the LS. Lesions in the AH block AVP-stimulated flank marking triggered from the LS but not vice versa. The efficacy of the neurotoxic lesions was assessed by the loss of AVP receptor binding following *in vitro* autoradiography. Furthermore, unilateral lesions of the AH also blocked flank marking stimulated by AVP injections in the contralateral LS, suggesting that flank marking requires the recruitment of neurons from both sides of the AH. The following data support this notion. First, unilateral lesions of the AH block flank marking induced by AVP injection in the contralateral AH. Second, unilateral injection of AVP into the AH stimulates comparable c-*fos* immunolabelling within both sides of the AH. However, anterograde track tracing with Phaseolus vulgaris leukoagglutinin showed very little cross over between both sides of the AH, suggesting the existence of an unknown site providing bilateral recruitment of the AH for the expression of flank marking.

563.15

SEXUALLY DIMORPHIC AND TESTOSTERONE-DEPENDENT VASOPRESSIN BINDING IN THE AREA OF THE VENTROMEDIAL NUCLEUS OF THE HYPOTHALAMUS IN HAMSTERS. Y. Delville and C.F. Ferris. Dept. of Physiology, Univ. of Mass. Med. Ctr., 55 Lake Avenue N, Worcester, MA 01655, USA.

[^{125}I]-[d(CH_2)$_5$, 7-sarcosine, 8-arginine]vasopressin was used to study the neural distribution of vasopressin binding in hamsters. Interestingly, vasopressin binding was observed in the area of the ventromedial nucleus of the hypothalamus (VMHA) and the ventral premammillary nucleus (PMV), apparently overlaying previously described distributions of estrogen receptors in rodents. This binding appears to be specific for V_1 vasopressin receptors. Vasopressin binding was inhibited by incubation with nanomolar concentrations of either vasopressin or a selective V_1 antagonist. In comparison, micromolar concentrations of either a selective V_2 antagonist or oxytocin were necessary to inhibit vasopressin binding in the hypothalamus. However, this distribution of vasopressin binding sites was only observed in males. Females did not have any vasopressin binding within the rostral portion of the VMHA. At more caudal levels, including the PMV, vasopressin binding was present in females, but ostensibly smaller in area. Furthermore, in adult male hamsters, these vasopressin binding sites appear to be testosterone-dependent. Binding in both the VMNA and the PMV disappears within one month after castration, while being maintained in testosterone-treated animals.

The existence of sexually dimorphic and testosterone-dependent vasopressin binding has never been reported in the brain, neither has the existence of binding in the VMHA/PMV. Experiments are currently in progress to test the behavioral significance of these binding sites.

563.16

CRF ENHANCES FEAR AND DEPRESSES BEHAVIORAL ACTIVITY FOLLOWING INFUSION INTO THE PARABRACHIAL NUCLEUS. M.F. Aaron*, C.M. Lorenz*, C.B. Nemeroff, and J.M. Weiss. School of Medicine and Department of Psychiatry, Duke University Medical Center, Durham, NC 27710.

In the experiments reported here, we found that corticotropin-releasing factor (CRF) infused into the parabrachial nucleus (PBN) depressed behavioral activity in a swim test and increased anxiety in a modified Britton open field test where water-deprived animals are tested for their reluctance to drink. Male Sprague-Dawley rats were surgically implanted with guide cannulae 3-4 mm dorsal to the PBN bilaterally (P: -9.3 mm (from bregma), L: -2.3 mm (from midline)). Following 1-2 days post-operative recovery, rats were made water-deprived by limiting access to water (1 hr daily for 3 d) and were then tested in a 36 cm X 36 cm Plexiglas enclosure with a water spout suspended 2 cm above the center of the floor. Following an initial baseline session (10 min) in the enclosure, animals were given a fear conditioning session of grid shock for 30 min (0.8 mA for 2 sec every 2 min). The following morning, rats were injected with CRF (5ng to 500 ng) or vehicle (artificial CSF) in the PBN via 31 gauge needle extending to -7.2 mm (from top of skull) and reexposed to the shock chamber (30 min; 3 shocks given) to increase fear. Animals were then tested again in the enclosure followed by activity testing in a swim tank.

In comparison to CSF treated controls, CRF infused into the PBN significantly decreased the time spent drinking and increased inactivity ("freezing") in the modified open field ($p < 0.05$). In the swim tank, CRF infusion decreased struggling and increased floating. These results suggest that CRF acting in the PBN is anxiogenic and depresses active behavior. (Supported by NIMH MH-42088 and MH-42637).

BEHAVIORAL AND ENDOCRINE RESPONSES TO SOCIAL CONFLICT STRESS IN RATS: EFFECTS OF A CRF ANTAGONIST, α-HELICAL CRF$_{9-41}$ K.T. Britton[3],E. Merlo Pich[4] ,S.C. Heinrichs[4],K.A. Miczek[1], C. Rivier[2] and G.F. Koob[4]. [1]Tufts University, Dept. of Psychology, [2]Salk Institute, Peptide Biology Laboratory, [3]VA Medical Center,La Jolla and [4]Dept. of Neuropharmacology, Scripps Clinic and Research Foundation, 10666 N. Torrey Pines, La Jolla, CA 92037.

A model of social interaction stress involves the placement of naive intruder rats in the home cage territory of a resident counterpart. The resulting intraspecific aggression produces characteristic defensive behaviors and a reliable increase in plasma ACTH and corticosterone levels in intruder rats during the encounter. In order to characterize the stress-like effect of this resident/intruder interaction, the post-encounter increase in emotionality of intruder rats was studied in the Elevated Plus-Maze, a sensitive measure of the behavioral reactivity to novelty and stress. Social conflict produced a hyperemotional response in intruders by reducing the time spent on exposed relative to enclosed arms of the maze.

Since central nervous system CRF-containing neurons may mediate the stress response induced by social conflict, in the present study we examined the ability of a CRF antagonist, α-helical CRF (9-41), to affect the post-encounter increase in emotionality demonstrated on the Plus-Maze. Following a twenty minute exposure to resident animals, intruder rats received infusions of α-helical CRF(9-41) [5 and 25 μg ICV]. Administration of 25 μg reversed the stress-induced hyperemotionality relative to non-stressed controls. Bilateral, intra-amygdala microinjection of 250 ng, but not 500 ng, was equally effective in blocking the conflict-induced suppression of open arm exploration. These data point to the possible involvement of CRF-containing terminals within the amygdala in mediating the behavioral effects of social interaction stress in the rat.

INTERACTION BETWEEN BRAIN CORTICOTROPIN RELEASING HORMONE (CRH) AND BENZODIAZEPINE (BZ) SYSTEMS ON PUNISHED BEHAVIOR. S.F. de Boer, J.L. Katz and R.J. Valentino. Dept. of Mental Health Sciences, Hahnemann Univ., Philadelphia, PA 19102 and NIDA ARC, Baltimore, MD 21224.

Clinical and preclinical findings implicate a link between brain CRH and BZ/GABA-ergic systems in stress and anxiety. This potential interaction was further investigated by comparing CRH, a BZ inverse-agonist (DMCM), and electric-shock as punishers in a modified Geller/Seifter paradigm. Rats were trained on a multiple fixed ratio (FR20) schedule for food reinforcement. Responses in the first component of the schedule were not punished. In the second component, the first response of the FR produced subthreshold shock (0.22 mA) that decreased responding by 10-15%. The components (3 min) alternated 5 times in a session. CRH (0.1-5.6 μg, i.c.v.), DMCM (3-100 μg, i.c.v.) and shock (Δ=0.1-0.7 mA) decreased rates of punished responding at lower doses/intensities than those that decreased rates of nonpunished responding, giving rise to dose/intensity related decrements in suppression ratios (indicating selective proconflict effects). The BZ agonist, chlordiazepoxide (CDP, 10 μg, i.c.v.) had no effect on responding when subthreshold shock was presented. However, CDP antagonized the suppressant effects of equieffective doses/intensities of CRH (1 μg), DMCM (56 μg) and shock (0.75 mA). Pretreatment with the CRH antagonist, α helical CRH$_{9-41}$ (50 μg, i.c.v.) blocked and attenuated, respectively, the suppressant effects of CRH and high intensity shock, but had no effect on the suppression by DMCM. The present results indicate that: 1) CRH, DMCM and shock all serve as punishers; and 2) The BZ agonist, CDP antagonizes all 3 punishers while α helical CRH$_{9-41}$ antagonizes only CRH and shock. Thus, the anxiogenic effects of CRH and shock may share similar mechanisms, while those of DMCM may be different.

CRF ALTERS MONOAMINE AND MONOAMINE METABOLITE LEVELS IN DISCRETE MOTOR AREAS IN AMPHIBIAN BRAIN. C.A. Lowry, K.J. Renner, L.M. Laughlin*, and F.L. Moore. Dept. of Zoology, Oregon State University, Corvallis, OR 97331-2914.

Studies using mammals and the amphibian *Taricha granulosa* indicate that CRF may elicit neuroendocrine, autonomic, and behavioral events following exposure to stressful stimuli. Included among the behavioral responses to CRF is an increase in locomotor activity. Evidence suggests that in rodents CRF-induced locomotor activity may be mediated by monoamine systems. The present study investigated in *T. granulosa* the effects of intracerebroventricular injections of CRF on monoamine and monoamine metabolite levels in discrete brain areas.

We characterized the distribution of epinephrine, norepinephrine, dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC), 5-hydroxytryptamine (5-HT), and 5-hydroxyindoleacetic acid (5-HIAA) using brain microdissection and HPLC with electrochemical detection. The mean DOPAC/DA ratio was 0.460 $\pm$ 0.050 and the mean 5-HIAA/5-HT ratio was 0.164 $\pm$ 0.017, values considerably lower than those typically observed in mammals. In separate studies we injected control solutions or CRF (25-50 ng), measured locomotor activity 35 min after treatment, then measured monoamine and monoamine metabolite levels in specific brain areas. Compared to control animals, CRF-injected animals displayed increased locomotor activity in an open field and had altered levels of monoamines or monoamine metabolites in two brain areas, the ventral striatum and the periventricular organ (hypothalamic circumventricular organ). In CRF-treated animals the ventral striatum had lower 5-HIAA/5-HT ratios, suggesting that 5-HT utilization was decreased, while the periventricular organ accumulated DA and 5-HT without altering metabolite levels. These data indicate that CRF-induced locomotor activity is associated with changes in the 5-HIAA/5-HT ratio in the ventral striatum and with DA and 5-HT levels in the periventricular organ. Supported by NSF BNS-8909173.

DRUGS OF ABUSE—ETHANOL

564.1

EFFECT OF (+)MK-801 AND KETAMINE ON RAPID TOLERANCE, CROSS-TOLERANCE AND CHRONIC TOLERANCE. J.M. Khanna, J. Weiner*, P.H. Wu* and H. Kalant*. University of Toronto, Toronto, Canada M5S 1A8 and Addiction Research Foundation, Toronto, Canada M5S 2S1

Hypothermia and motor-impairment (tilt-plane test) were used to assess whether N-methyl-D-aspartate (NMDA) receptors play a role in the development of rapid tolerance to ethanol, i.e., tolerance to a second dose of ethanol given 24 hrs after the first dose. Results showed that (+)MK-801 and ketamine blocked the development of rapid tolerance to ethanol on both tests. Similarly, both NMDA antagonists blocked cross-tolerance from ethanol to chlordiazepoxide as well as from chlordiazepoxide to ethanol on both tests. These data suggest that the role of NMDA receptors in ethanol tolerance may be similar to their role in memory and learning, involving a facilitation of transmission in certain synapses. In contrast, both NMDA antagonists failed to block chronic tolerance to ethanol in either test. They did not modify blood alcohol levels in any of the groups, so that the blockade of rapid tolerance cannot be attributed to changes in pharmacokinetics of ethanol. It is possible that NMDA antagonists lose their effectiveness with chronic administration or that the phenomena of rapid tolerance and chronic tolerance have basic differences not previously reported. Supported in part by NIAAA grant No. 1 Rol AA08212-02.

CHRONIC ETHANOL TREATMENT ALTERS SENSITIVITY TO ACETYLCHOLINE IN RAT HIPPOCAMPUS. B.S. Rothberg and B.E. Hunter, Department of Neuroscience, University of Florida, Gainesville, FL 32610.

Sensitivity of hippocampal field potentials to local (iontophoretic) application of acetylcholine (ACh) was investigated in chronic ethanol treated (CET) and sucrose-fed (control) rats. CET and control rats were fed a liquid diet containing either ethanol or sucrose for 28 weeks. Five to six months after ethanol or sucrose was withdrawn, hippocampal slices were taken and ACh was applied in stratum pyramidale or stratum radiatum of CA1 to observe population spike facilitation or field EPSP inhibition, respectively. An antidromic-orthodromic paired pulse paradigm (PPP) was also used to assess interactions with recurrent inhibition.

Population spikes were facilitated to a considerably lesser extent in CET slices relative to controls, while no treatment differences were observed for dendritic EPSP inhibition. Although preliminary, PPP data suggested that ACh interactions with inhibitory circuitry were also affected. These results suggest a heterogenous effect within CA1 to the chronic actions of ethanol. Since these cholinergic responses have been linked to differing muscarinic receptors, our results may reflect a distinct susceptibility of muscarinic receptor subtypes to the neurotoxic effects of ethanol.

564.3

EFFECTS OF CHRONIC ADMINISTRATION AND ABRUPT WITHDRAWAL OF ETHANOL ON CORTICOTROPIN-RELEASING FACTOR (CRF) CONCENTRATIONS IN DISCRETE RAT BRAIN REGIONS. M.A. Vargas , M.J. Owens, C.L. Ehlers and C.B. Nemeroff. Depts Psychiat. & Pharmacol., Duke Univ. Med. Ctr., Durham. NC 27710 and Dept. Neuropharmacol., Res. Inst. Scripps Clin., La Jolla, CA 92037.

Corticotropin-releasing factor (CRF), acting as a neurotransmitter in both hypothalamic and extrahypothalamic areas, is involved in mediating the endocrine, autonomic and behavioral responses to stress. Short- and long-term exposure to alcohol has been demonstrated to activate the hypothalamo-pituitary-adrenal (HPA) axis in both humans and laboratory animals. Because many of the signs and symptoms observed in animals and humans following ethanol withdrawal resemble those of stress, we investigated the effect of chronic ethanol administration (28 days) followed by abrupt ethanol withdrawal on hypothalamic and extrahypothalamic CRF concentrations, and CRF receptor number and affinity. CRF concentrations were not altered by chronic ethanol administration or withdrawal in any of the thirteen brain regions studied. CRF receptor density was significantly increased in the prefrontal cortex, piriform cortex and cerebellum following chronic ethanol administration. CRF receptor number was decreased in the anterior pituitary following ethanol chronic treatment and abrupt withdrawal, indicative of down-regulation of CRF receptors due to increased CRF release into the hypophyseal portal vessels. The present results indicate that ethanol exerts effects on extrahypothalamic CRF neurons. Supported by NIMH MH - 42088.

CHRONIC ALCOHOL EXPOSURE AFFECTS GABAERGIC INNERVATION IN THE DENTATE MOLECULAR LAYER. E. Fifkova, H. Eason*, and P. Schaner*. Dept. of Psych., Univ. of Colorado, Boulder, CO 80309.

The effect of chronic alcohol exposure and withdrawal from this exposure has been studied in the alcohol-sensitive LS_{IBG} line and alcohol-insensitive SS_{IBG} line (30 mice total). The mice were fed for 4 months either with a control isocaloric liquid diet or with an isocaloric liquid diet containing ethanol (23.5% ethanol derived calories). Some of the ethanol treated mice were withdrawn from the diet for 1 month. Subsequently the mice were prepared for electron microscopy and the GABA terminals were labeled with antiGABA antibodies using a gold probe in a postembedding protocol. GABA terminals make symmetric contacts either on dendrites or dendritic spines of the dentate granule cells. The number of axodendritic and axospinous synapses were counted separately for the proximal third and distal two-thirds of the dentate molecular layer. A gradual loss of axodendritic synapses was seen in the LS mice. A 14.5% loss (statistically nonsignificant) of axodendritic synapses occurred after 4 months of ethanol exposure. This loss continued during the withdrawal period resulting in 38% fewer axodendritic synapses ($p = 0.005$). No changes were observed in the number of axospinous synapses. No loss in either type of contacts was seen in the SS line following ethanol exposure and withdrawal. However, when LS and SS controls were compared, significantly fewer axodendritic synapses (by 29%, $p = 0.033$) were observed in the SS line.

These observations are in line with our previous findings showing a loss of GABAergic basket cells in LS mice following chronic alcohol exposure. This observation could be interpreted as an adaptation of the nervous system to the depressing effect of ethanol. Interestingly, the change starts during ethanol exposure and gets more severe during ethanol withdrawal.

ACTIVATION OF BRAIN STRUCTURES DURING ETHANOL WITHDRAWAL: EVIDENCE FOR A ROLE OF ENDOGENOUS GLUTAMATE

P. F. Morgan, K. Wozniak, N. S. Nadi, J. W. Karanian* and M. Linnoila
LCS, NIAAA & Lab of Neurophysiol., NINDS, Bethesda, MD 20892

Northern hybridization studies using a ^{32}P-c-*fos* murine DNA probe revealed that peak activation of rat brain cells leading to expression of c-*fos* mRNA occurs at 6-8 hr after the initiation of withdrawal from a 7 day continuous exposure to ethanol vapor. This expression was stereospecifically blocked by a 4 hr pretreatment with the NMDA receptor-associated ion channel blocker, MK-801 (10 mg/kg, *i.p.*). During this period of withdrawal, the concentration of glutamate in the dialysate from a 2 mm microdialysis probe implanted into rat striatum under chloral hydrate anesthesia was estimated by HPLC to be 120 pmol/30 ul vol/20 min. This was a significant ($p<0.01$) 3-fold increase over the control value of 30 pmol/30 ul vol/20 min. No difference was seen in the levels of GABA, glycine, taurine or other detected amino acids. The data suggest a role for glutamate and NMDA receptors during ethanol withdrawal.

564.6

CHRONIC INTERMITTENT ETHANOL IN RATS ALTERS [^{3}H]RO15-4513 BINDING TO DIAZEPAM-INSENSITIVE GABA-RECEPTORS.

D.W. Sapp, N. Kokka* and R.W. Olsen. Dept. Pharmacology, Brain Research Institute, University of California, Los Angeles, CA 90024.

Chronic intermittent ethanol (CIE) administered to rats produces a 'kindling-like' phenomenon in which the PTZ-induced seizure threshold is decreased. A change in PTZ-induced seizure sensitivity suggests that the $GABA_A$ receptor complex is involved in the differences observed between control and CIE animals. $GABA_A$ receptor binding was compared between the two groups of animals using the partial inverse-agonist [^{3}H]Ro15-4513. This ligand was used because of its reported 'alcohol antagonist' activity and its unique binding to both diazepam-sensitive (DZ-S) and diazepam-insensitive (DZ-IS) sites. Crude membrane homogenates were prepared from both the cortex and cerebellum. Several differences in binding were observed between the two groups of animals. In the cerebellum of CIE animals, the binding of Ro15-4513 to DZ-S sites is increased while the binding to DZ-IS sites is decreased, i.e., the ratio of DZ-IS is decreased. Scatchard analysis indicates that the affinity of Ro15-4513 for the DZ-IS sites is decreased two-fold. The ability of diazepam to displace Ro15-4513 binding is also increased in CIE animals. Chronic ethanol thus produces a change in the properties or amount of DZ-IS binding sites for Ro15-4513, possibly mediated by a switch in subunit gene expression.

ALTERATIONS IN TASTE REACTIVITY TO ALCOHOL IN RATS GIVEN CONTINUOUS ALCOHOL ACCESS FOLLOWED BY ABSTINENCE.

P.J. Bice and S.W. Kiefer, Dept. of Psychology, Kansas State University, Manhattan, KS 66506-5302.

Taste reactivity tests were used to examine the oro-facial responses of rats (n=16) to the taste of alcohol during four tests: the first test was before alcohol experience; the second test was done after four weeks of continuous access to 10% alcohol (and water); the third test occurred after two more weeks of 10% alcohol access; the fourth test was then done four weeks later, during which time the rats received water only. For each reactivity test, rats were preented with 10%, 20%, 30%, and 40% alcohol and their orofacial reactivity videotaped and then scored for ingestive and aversive responding. Results showed that there was an increase in the number of ingestive responses from test one to test three. The number of ingestive responses recorded during test four, after the alcohol had been removed for four weeks, was almost identical to that of the first exposure. Aversive responses tended to decrease from test one to test three but then increased slightly during test four. It was concluded that the palatability of alcohol increases with continued consumption and then returns to pre-experience levels if rats are without alcohol for a period of time.

HEIGHTENED EMOTIONALITY INDUCED BY ETHANOL WITHDRAWAL IS BLOCKED BY INTRA-AMYGDALA INFUSION OF α-HELICAL CRF$_{9-41}$

S.C. Heinrichs, S. Rassnick, K.T. Britton[1], and G.F. Koob. Dept. of Neuropharmacology, Scripps Clinic and Research Foundation, 10666 N. Torrey Pines Rd. and [1]Dept. of Psychiatry, VA Medical Center, La Jolla, CA 92037.

A previous study in our laboratory demonstrated that the Elevated Plus-Maze is a sensitive measure of increased reactivity associated with ethanol withdrawal. Withdrawal of ethanol from chronically intoxicated rats reduced exploration of exposed, lighted walkways in favor of enclosed, darkened arms of the maze. This reduction in time spent on the exposed arms reflects a heightened emotionality produced by ethanol withdrawal and was blocked by low doses of a corticotropin-releasing factor antagonist, α-helical CRF(9-41), administered centrally [Baldwin et al, *Psychopharmacology* 103:227-232, 1991]. The specific neuronal substrate for this effect is unknown, however, the amygdala contains a high density of CRF neurons and is integral to emotional reactivity in numerous tasks.

The present study examines the effect of α-helical CRF(9-41) administered into the central nucleus of the amygdala on the ethanol withdrawal-induced increase in emotionality. Following a 17 day period of consumption of ethanol-containing liquid diet (8.5% v/v), bilateral infusion of a-helical CRF(9-41)[250 and 500 ng IC] reversed the hyperemotionality on the Plus-Maze at eight hours post-ethanol exposure. The most effective intra-amygdala dose (250 ng IC) did not affect the behavior of ethanol withdrawn rats when administered intracerebroventricularly (250 ng ICV). Similarly, 250 and 500 ng intra-amygdala doses of CRF antagonist did not affect the Plus-Maze performance of non-dependent rats. These results suggest that a specific, CRF-containing limbic system nucleus may participate in the maladaptive state of behavioral hyperreactivity present during ethanol withdrawal in humans.

ONDANSETRON-INDUCED REVERSAL OF ANXIOGENIC BEHAVIORS UPON WITHDRAWAL FROM ETHANOL: ASSESSMENT BY BEHAVIORAL ALTERATIONS IN THE ELEVATED PLUS-MAZE.

P.L. Prather, S.M. Rezazadeh and H. Lal, Department of Pharmacology, Texas College of Osteopathic Medicine, Ft. Worth, TX 76107.

Buspirone, which reduces serotonin (5HT) neurotransmission through $5HT_{1A}$ autoreceptor stimulation, attenuated the anxiogenic behaviors related to ethanol withdrawal as observed by behavioral changes in the elevated plus maze (EPM) (Alcohol, In press). The current study determined whether ondansetron, which decreases 5HT function through antagonism of $5HT_3$ receptors, would also attenuate anxiogenic behaviors observed during withdrawal. Long-Evans hooded rats were fed a nutritionally complete diet that provided adequate ethanol (4.5% w/v) to produce dependence but without any loss in body weight or nutritional deficiency. To cause withdrawal symptoms, the ethanol diet was discontinued after four days. Twelve hours after the last dose of ethanol, separate groups of rats were injected IP with either the vehicle (1 ml/kg) or ondansetron (0.0025, 0.01, 0.04 or 0.16 mg/kg) and placed on the elevated plus-maze 60 min later for a 5 min observation period. Animals experiencing withdrawal and injected only with vehicle, displayed behavior similar to that produced by injection of anxiogenic drugs. There was a marked reduction in % of both the entries onto and the time spent on the open-arms of the EPM. In contrast, ondansetron pretreatment resulted in reversal of the anxiogenic behavior as demonstrated by a dose-dependent increase in open-arm activity back to control values. These data suggest that ondansetron may be efficacious in alleviating an important symptom of ethanol withdrawal. (Supported by Glaxo Group Research).

564.10

EVALUATION OF ANXIOGENIC BEHAVIORS DURING ETHANOL WITHDRAWAL IN THREE STRAINS OF RATS UTILIZING THE ELEVATED PLUS-MAZE.

S.M. Rezazadeh, P.L. Prather, A.H. Rezvani and H. Lal, Dept. Pharmacology, Texas Coll. of Osteopathic Med., Ft. Worth ,TX, 76107 and Skipper Bowles Center for Alcohol Studies, Univ. of North Carolina School of Med., Chapel Hill, NC, 27599.

Fawn hooded (FH) rats are deficient in brain serotonin function and consume more ethanol (ETOH) than Wistar (W) rats from which they were derived. However, the consequences of these differences on ETOH pharmacology and/or ETOH dependence are not known. Long-Evans (LE) rats show anxiogenic behaviors during ETOH withdrawal (*JPET* 247:508, 1988). This study compared ETOH pharmacology and ETOH withdrawal in FH, W and LE rats. Male rats were fed a nutritionally balanced diet containing 4.5% ETOH (12 g/kg/day) for 2 bouts of 4 d each. They were tested in the elevated plus-maze (EPM) 14 h after the last ETOH dose, following each bout. During ETOH administration, daily consumption of ETOH diet in FH rats was 34% and 23% higher than that consumed by W and LE rats, respectively. FH rats exhibited 83% and 93% lower intoxication scores than W and LE rats, respectively. Upon withdrawal from the first ETOH bout, the % time spent on and entries made onto the open-arms of the EPM were reduced in FH and LE rats but not in W rats as compared to their respective controls. However, after withdrawal from the second bout of ETOH, only LE rats showed reduction in open-arm exploration. In conclusion, FH rats consumed the most ETOH and exhibited the least intoxication. LE rats showed anxiogenic behaviors during withdrawal from either bout of ETOH administration, while W rats did not show any reduction in open-arm activity during withdrawal. In contrast, FH rats showed anxiogenic behaviors only following the first bout. Thus, FH rats displayed greater preference for ETOH while exhibiting reduced sensitivity to ethanol's pharmacological effects. (Supported by grants NIAAA #AA06890-03 & NC-ARA9103.)

Increased natural killer cell activity and concanavalin A induced lymphocyte proliferation following Chronic alcohol consumption. S. Razani-Boroujerdi, S. M. Smith* and S. Tokuda* Dept. Micro. & Path., Sch. Med., Univ. New Mexico, Albuquerque, NM 87131.

Although alcohol is presumed to be immunosuppresive, there is no agreement regarding its effects on immune responses. The present study examined the effect of chronic alcohol consumption on natural killer cell (NK) activity measured by ^{51}Cr labeled Yac−1 cell lysis and on concanavalin A (Con A) induced lymphocyte proliferation. Male Wistar rats were implanted with gastrostomy catheters which permitted continuous intragastric infusion of liquid diet and ethanol for six weeks. The dose of ethanol was 30% of caloric intake which progressively increased to 40% and resulted in mean blood alcohol levels of 240 mg/100 ml. Control rats received isocaloric dextrose instead of ethanol. Our result showed that: 1) NK activity was 50 to 60 percent increased and, 2) proliferative response with Con A was two to three fold increased in alcoholic rats. Both alterations were statistically significant at $p < 0.05$. The increase in Con A response may suggest an increase in IL−2 production following chronic alcohol consumption and may be a contributing factor in the elevation of NK cytotoxicity. (Support provided by NIH Grant NS 24008).

TRANSCRANIAL ELECTROSTIMULATION (TES) OF BRAIN OPIOID STRUCTURES (BOS): EXPERIMENTAL TREATMENT OF ALCOHOL WITHDRAWAL SYNDROME (AWS) AND CLINICAL APPLICATION. E.M. Krupitsky*, Ya.S. Katznelson*, V.P. Lebedev, N.V. Flood*, M.A. Patterson*, J.M. Lipton and G.P. Kozlowski. Pavlov Inst. of Physiol., Leningrad, 199034; Neuro Systems Inc., Dallas, TX. 75238 and Dept. Physiol., UT. Southwestern Med. Ctr., Dallas, TX. 75235

Numerous investigations on AWS have demonstrated a functional insufficiency in endogenous opioid systems. Since TES is a regime which selectively activates the BOS, our aim was to investigate the efficacy of non-invasive TES on ameliorating AWS. The method of Erickson et al. (Pharm. Bio. Behav., 13:781, 1980) was used to induce AWS and score withdrawal signs. TES induced an increase in the β-endorphin (BE) level in rat cerebrospinal fluid from 15.93±2.17, to 53.25±6.1 pmol/$_L$ ($p<0.01$) and met-enkephalin from 3.61±1.39 to 7.86±0.94 pmol/ml. Marked therapeutic effect of TES was also demonstrated in this animal model. Clinical double-blind placebo-controlled studies showed that TES of BOS was an effective method in the treatment of AWS in patients. After the TES treatment in AWS patients, the BE concentration in plasma rose from 5.86±0.72 to 10.66±0.65 pmol/L, $p<0.01$. There was a three-fold increase of BE concentration just after one TES session. Small changes in the stimulating parameters results in reduction of both BOS activation and clinical efficacy.

564.13

NORADRENERGIC FUNCTION AND ETHANOL INTOXICATION. C.J. McDougle, J.H. Krystal, L.H. Price, G.R. Heninger, D.S. Charney. Yale Univ. Dept. of Psychiatry, New Haven, CT 06519.

Preclinical and clinical studies have demonstrated that ethanol (ETOH) increases norepinephrine (NE) turnover in the brain. The purpose of this investigation was to assess the effects of the alpha-2 adrenergic receptor antagonist, yohimbine (YOH), on the behavioral manifestations of ETOH intoxication in healthy human subjects. METHODS: 12 subjects participated in 4 double-blind test conditions: placebo ETOH (2.8 mL of 95% ETOH floated on an appropriate mixer p.o.)/placebo YOH (0.45% saline I.V.), ETOH (1.1 mL/kg of 95% ethanol p.o.)/placebo YOH, placebo ETOH/YOH (0.4 mg/kg YOH I.V.), and ETOH/YOH. Fifty minutes after subjects consumed the active or placebo ETOH, they received a 10-minute I.V. infusion of active or placebo YOH. Ratings of intoxication (Sensation Scale (SS)), symptoms of anxiety (Panic Attack Symptom Scale (PASS)), and a subjective feeling of euphoria-high were obtained at baseline and throughout the study. RESULTS: The global Analysis of Variance (ANOVA) of the 4 test conditions revealed significant ETOH X YOH X time interactions for total SS score ($p<0.0001$), total PASS score ($p<0.0001$), and for self-ratings of high ($p<0.0001$). The ANOVA of the ETOH/YOH condition vs the ETOH/placebo YOH condition revealed significant YOH X time interactions for total SS score ($p<0.005$), self-rating of high ($p<0.001$), and a trend for total PASS score ($p<0.17$), with the ETOH/YOH condition being highest on all three variables. CONCLUSIONS: The combination of YOH-induced increases in NE and ETOH produces a significantly greater degree of intoxication and high than ETOH alone. This suggests that central noradrenergic function may contribute significantly to the intoxicating and euphorogenic effects of ETOH in man. Neurochemical data will also be presented.

GENDER DIFFERENCES IN BLOOD-ETHANOL AND RECALL OF PROSE AFTER ACUTE INTOXICATION. R. M. SHARP*, B. E. Beckwith, and T. V. Petros. Psychol. Dept., Univ. of North Dakota, Box 7187, Grand Forks, ND 58202.

Although many studies have documented the detrimental effect of pre-trial treatment with ethanol on memory in males, few studies have explored the effects of pre-trial treatment on memory in women. Those that have demonstrated greater impairment in memory for women at the same ml/kg dose of ethanol given to males. Male and female subjects who reported being in good health and reported being moderate users of ethanol were given either 1.0 ml/kg of absolute ethanol or the masking solution in a double-blind design. After about 55 mins. they read several expository prose passages and were asked to recall each passage immediately after hearing it. Ethanol significantly impaired recall of the prose passages in males and females. However, the deficit was greater in women than in men. Furthermore, although there was no significant gender difference in peak blood ethanol, women showed a steeper increase in concentration of blood ethanol than men. Recall scores were negatively correlated with concentration of blood ethanol in women but not in men.

564.15

ETHANOL (ETOH) AND REGIONAL BRAIN MONOAMINES IN MICE. M. G. Hadfield and C. Milio*. Medical College of Virginia, VCU, Richmond, VA 23298

We studied acute effects of ETOH (3.5 g/kg p.i. 60 min. post injection) on regional brain monoamine levels in mice and in the respective metabolite/neurotransmitter ratios by HPLC. For the norepinephrine (NE) system, 3-methoxy-4-hydroxyphenylglycol (MHPG) was decreased in the amygdala (AMY) and was increased in the hypothalamus (HT) while the MHPG/NE ratio was increased in the prefrontal cortex (PC) and the HT. For the dopamine (DA) system, DA was decreased in the olfactory tubercle (OT), 3,4-dihydroxyphenylacetic acid (DOPAC) was increased in the PC and septum (SP) and DOPAC/DA was increased in the PC, SP, striatum (ST) and HT. Homovanillic acid (HVA) was increased in the PC and ST while HVA/DA was increased in the same regions plus the olfactory bulbs (OB). 3-methoxytyramine (3MT) was decreased in the OT and ST. The serotonergic system was not altered. The results demonstrate that ETOH produces selective regional changes in catecholamines in mouse brain with a predominant influence on DA systems, and to a lesser extent, on NE activity. The predominant brain structures affected belong to the limbic system. This may help explain why ETOH exerts such a strong influence on emotional behavior and mood.

564.16

BIOPTERIN (BH_4) METABOLISM AND CNS ETHANOL SENSITIVITY IN LONG-SLEEP (LS) AND SHORT-SLEEP (SS) MICE. T. A. French*, J. M. Masserano, M. A. Hossain and N. Weiner. Dept. of Pharmacology, Univ. of Colo. Health Sciences Center, Denver, Colo. 80262.

Catecholamine neuronal systems are involved in mediating differences in CNS ethanol (ETOH) sensitivity between LS (more sensitive) and SS (less sensitive) mice. ETOH (4.2 g/kg at 30-240 min) decreases in vivo tyrosine hydroxylase (TH) activity to a much greater extent in specific brain regions of LS mice than in SS mice. The present study examines the possibility that ETOH-induced (E-I) alterations in the metabolism of the TH cofactor, BH_4, may influence these differences in TH activity and thus relate to ETOH sensitivity. ETOH (4.2 g/kg at 60-120 min) does not result in any changes in BH_4 levels in the cerebellum, hypothalamus or brain stem of either LS or SS mice. However, treatment with BH_4 (10-30 mcg, i.c.v) or synthetic cofactor 6-MPH_4 (100 mg/kg, i.p.) alone will increase TH activity in these areas by up to 50% and, given prior to ETOH, will reduce E-I sleep times in LS mice by 30-40%. This BH_4 or 6-MPH_4 pretreatment is associated with a marked attenuation of the E-I decrease in TH activity in the cerebellum, hypothalamus and brain stem of LS mice. Thus, BH_4 or 6-MPH_4 treatment apparently results in reduced ETOH sensitivity in LS mice by nonspecifically enhancing TH activity rather than by countering any specific ETOH actions to alter brain BH_4 levels. (Supported by NIAAA grant #03527.)

564.17

OPIATE-INDUCED CONDITIONED TASTE AVERSION IN MICE SELECTED FOR DIFFERENTIAL SENSITIVITY TO ETHANOL.
F. O. Risinger, S. I. Lawley, and C. L. Cunningham.
Oregon Health Sciences University, Portland, OR 97201-3098.

Mice selectively bred for sensitivity (COLD line) or insensitivity (HOT line) to ethanol-induced hypothermia also display similar sensitivities to opiate-induced hypothermia. In the present experiment, genetic differences in the hedonic (aversive) effects of levorphanol were characterized using taste conditioning. Fluid deprived COLD and HOT mice were given six taste conditioning trials at 48-h intervals. On each trial, access to a saccharin solution was followed by injection of levorphanol (3 mg/kg on trials 1-4, 6 mg/kg on trials 5-6). Saccharin-levorphanol pairing produced aversion that was greater in HOT mice. Rectal temperatures determined before injection and 60 m after injection revealed greater levorphanol-induced hypothermia in COLD mice. These data support previous findings suggesting that genetic selection for sensitivity/insensitivity to ethanol has resulted in alterations in response to opiates. Also, this outcome is consistent with the notion that drug-induced hypothermia is related to drug's hedonic effects.

GENETIC SIMILARITIES BETWEEN ETHANOL- AND NICOTINE-INDUCED CONDITIONED TASTE AVERSION.
N.E. Colley[1], T.K. Landon[2*] and A.C. Collins[1,2].
[1]Psychology Department and [2]Institute for Behavioral Genetics, University of Colorado, Boulder, CO 80309.

Recently, we presented data which demonstrated that genetic differences exist in the acquisition and extinction of nicotine induced conditioned taste aversion. In attempt to ascertain if these differences exist for another drug of abuse, male mice from 3 inbred strains (DBA/2J/lbg, C3H/2lbg and C57BL/6J/lbg) were tested for differences in ethanol-induced conditioned taste aversion. Mice were injected with varying doses of ethanol (between 0 and 3.5 g/kg) after ingestion of a novel saccharin solution. Two bottle choice preference between saccharin and water was then measured over a 14 day time period. Evidence was obtained which suggests that there are genetic differences in the acquisition and extinction of ethanol induced conditioned taste aversion and that these differences are dose dependent. Futhermore, similarities exist among the inbred strains for conditioned taste aversion whether nicotine or ethanol is the unconditional stimulus. This finding may indicate that common genes control the aversive properties of these two agents.

ALTERATION OF ETHANOL-STIMULATED ACTIVITY BY DOPAMINERGIC COMPOUNDS.
E.H. Shen*, M.R. Jefferson*, J.C. Crabbe, and T.J. Phillips. V.A. Med. Ctr., and Dept. of Med. Psych., OR Hlth. Sci. Univ., Portland, OR 97201.

Selectively bred FAST mice are highly stimulated by ethanol (EtOH), whereas the oppositely selected SLOW mice are much less sensitive to this locomotor stimulating effect. The possibility that dopamine (DA) systems mediate EtOH-induced locomotor stimulation was investigated using DA-ergic compounds. Alpha-methyl-p-tyrosine (AMPT) significantly depleted norepinephrine (NE) and DA levels in both lines; but did not alter locomotor responses to EtOH. Sulpiride, a D_2-specific antagonist, did not alter baseline activity or the activity of animals given EtOH. However, haloperidol, a less specific D_2-antagonist, partially blocked the stimulant response of FAST mice to EtOH. SKF-38393, a D_1-receptor agonist, slightly increased activity in both saline-treated and EtOH-treated FAST mice. The activity of saline-treated SLOW mice was not altered by SKF-38393; but the depressant effect of EtOH seen in the SLOW line was reversed by coadministration of the agonist. The fact that EtOH-stimulated activity was antagonized by haloperidol but not sulpiride suggests that both D_1 and D_2 receptors are involved in this response. Alternatively, it may be that neurotransmitter systems other than DA and NE are involved. Studies to identify the neurochemical substrates responsible for the differential ethanol sensitivity of FAST and SLOW mice are continuing.

EVIDENCE THAT G-PROTEINS MODULATE BEHAVIORAL AND PHYSIOLOGICAL ACTIONS OF ETHANOL.
M.J. Durcan, R.G. Lister, P.F. Morgan and M. Linnoila. Laboratory of Clinical Studies, NIAAA, DICBR, Bldg. 10 Rm. 3C102, 9000 Rockville Pike, Bethesda, MD 20892, USA.

A number of neurotransmitter receptors (for example, α_2 adrenoceptors, adenosine A_1 and $GABA_B$ receptors) linked to their effector mechanisms by pertussis toxin sensitive guanine-nucleotide binding proteins (G-proteins) have been postulated to modulate of the actions of ethanol. In this study, male NIH Swiss mice were pretreated with pertussis toxin (0.5 and 1.0 µg/animal, i.c.v., 7 days prior to testing). These pretreatments reduced the ataxia induced by a 2.4 g/kg dose of ethanol. Pertussis toxin treated animals also exhibited a diminished hypothermic response to ethanol (2 g/kg), although the toxin treated animals had lower body temperatures prior to ethanol administration compared to sham treated animals. The binding oligomer of pertussis toxin, which lacks the enzymatically active protomer subunit, was inactive. These results suggest that pertussis toxin sensitive G-proteins may modulate some the behavioral and physiological effects of ethanol.

EFFECT OF ETHANOL AND ATROPINE ON REACTION TIME IN RATS.
Z.M. Post , P.K. Randall and C.K. Erickson . Div. of Pharmacol., Coll. of Pharm., Univ. of TX, Austin, TX 78712.

The purpose of this study was to determine whether striatal cholinergic function is involved in the mechanism by which ethanol (EtOH) slows reaction time (RT) in rats. Male Sprague-Dawley rats were intrastriatally and bilaterally implanted with guide cannulae. Two weeks after surgery, the rats were trained in a RT task to release a bar, as fast as possible, in response to a light and buzzer in order to avoid a mild footshock. In a 6x6 completely balanced Latin Square design, rats received intragastric EtOH (20% w/v in water, 0 or 2.0 g/kg) and intrastriatal atropine (ATR, 0, 0.8, or 8 ug in 1 ul 0.9% saline). RT was recorded in msec every 15 min. for 2 hrs. Placement of cannulae was verified with histology.

EtOH significantly slowed RT ($p < 0.01$). However, the degree to which EtOH slowed RT tended to depend on the dose of ATR given, i.e., EtOH plus 0.8 ug ATR was more effective in slowing RT than EtOH plus saline, and EtOH plus 8 ug ATR slowed RT even more. This dose-response effect was marginally significant as represented by the EtOH by ATR interaction term in the analysis of variance ($p = 0.09$). The effect was further supported in a less conventional followup analysis, in which cumulative frequency distributions formed for each treatment group were compared using nonlinear curve fitting techniques.

The dose of EtOH used in this study was high enough to interfere slightly, but significantly, with the rats' speed of reaction. Treatment with EtOH plus ATR enhanced this interference. It appears that the RT response is mediated in part by the cholinergic function of the striatum, and that EtOH and ATR, alone and in combination, alter cholinergic function, and thus, RT. (Research funds from Univ. of TX, Austin.)

565.1

ALCOHOL PALATABILITY IN RATS AS MEASURED BY TASTE REACTIVITY, LICK RATE, AND CONSUMPTION. N.B. Elder, P.J. Bice and S.W. Kiefer. Department of Psychology, Kansas State University, Manhattan, KS 66506-5302.

The palatability of alcohol for rats was tested using three dependent measures under conditions of mild fluid deprivation: taste reactivity, lick rate, and consumption. Eleven rats received 0.5%, 3%, 6%, 9%, 12%, and 15% (v/v) alcohol in separate tests. Each measure was examined separately and correlations between the measures were calculated to determine their interrelationships. Results showed that ingestive responding was consistent and high for all concentrations; aversive reactivity was consistently low except at the 15% concentration. Lick rates for .5%, 3%, and 6% were essentially identical to water. Rates were lower for the 9% and 12% solution while the 15% solution produced the lowest lick rates. Consumption of the low concentrations was equal to that of water baseline and dropped significantly at the 9% concentration and above. The only consistent correlations found between the separate measures were for lick rate and consumption. Taste reactivity was not significantly correlated with either lick rate or consumption, suggesting that reactivity to alcohol solutions may be reflective of processes different from those that regulate licking behavior or actual consumption.

565.2

BUPRENORPHINE PRODUCES DOSE- AND TIME-DEPENDENT EFFECTS ON ETHANOL SELF-ADMINISTRATION. K.R. Domanque, H.L. June, T.D. Smith, J.T. Dixon, A. Norona[1], M.J. Lewis. Neurobehavioral Laboratory, Howard University, Washington, DC 20059 and OSA, NIAAA, Rockville, MD 20857[1].

Buprenorphine (B), a mixed opioid agonist-antagonist used clinically, has been shown to reduce opioid and cocaine self-administration (SA). Given these effects on such different drugs of abuse, we examined its effects on ethanol (E) SA in freely feeding and drinking animals. Rats learned to consume increasing concentrations of E using a two bottle-limited access paradigm. All animals showed a preference for 11% E(v/v) over water after several weeks of training. Intraperitoneal injections of B (0.03-3.00 mg/kg) given at 1.5 hr prior to E access suppressed drinking greatly. Administration of B 4 hr before E access, however, suppressed drinking only at higher doses (0.30 - 3.00 mg/kg). Low doses (0.03 - 0.15 mg/kg) of B at 4 or 5 hr before E access increased drinking. These data show that B has complex effects on E SA involving several possible neurochemical mechanisms.

EFFECTS OF NUCLEUS ACCUMBENS MICROINJECTIONS OF RACLOPRIDE ON ETHANOL SELF-ADMINISTRATION IN THE RAT. H.H. Samson, G.A. Tolliver and M. Haraguchi Alcohol and Drug Abuse Institute, University of Washington, Seattle, WA 98195

Adult, male Long-Evans rats were initiated to lever press with 10% ethanol (v/v) reinforcement using the sucrose-fading technique. Following initiation, bilateral cannula guides directed at the n. accumbens were surgically implanted. Following recovery, the animals received a single bilateral injection once weekly, 10 min prior to the daily 30 min operant session. Doses of 0.1, 0.5 and 1.0ug/brain of the D2 antagonist, raclopride were tested. No animal received more than a total of 5 microinjections.

At the 0.5 and 1.0 doses, raclopride was found to significantly decrease total session responding. No systematic effects were observed at the 0.1 dose. This decrease was the result of termination of the normal pattern of responding sooner in the session, with no marked effect upon momentary response rates. This is similar to the effects observed with systemic administration of haloperidol under the same reinforcement conditions. The decrease in ethanol self-administration resulting from raclopride is clearly different in both pattern and nature when compared to the effects of DA agonists microinjected into the n. accumbens.

565.4

ETHANOL SELF-ADMINISTRATION IN RATS IS MEDIATED BY GABA AND GLUTAMATE MECHANISMS WITHIN THE BASOLATERAL NUCLEUS OF THE AMYGDALA.. S. Rassnick and G. F. Koob. Department of Neuropharmacology, The Res. Instit. of Scripps Clinic, La Jolla, CA 92037.

GABA and glutamate neuronal systems may mediate the reinforcing properties of ethanol (E) since acute E has been shown to facilitate the activity of the GABA/benzodiazepine receptor ionophore complex and to inhibit the activity of the NMDA/glutamate ion channel complex. The basolateral nucleus of the amygdala is part of the limbic system, involved with processing sensory information into emotional behaviors and contains GABA and glutamate. The purpose of this study was to test the effects of GABA and glutamate receptor antagonists into the basolateral nucleus of the amygdala of Wistar rats trained to orally self-administer E. A two-lever free choice task was used: responses at one lever delivered E (10 % w/v) and responses at the other delivered the same quantity of water (30 min daily sessions). Bicuculline methiodide, a competitive GABA antagonist, selectively reduced E reinforced responding, (2.5, 5, 10, & 20 ng; 5 ng as the most effective dose), without altering water responses. A NMDA-selective glutamate antagonist, 2-amino-5-phosphonovaleric acid (APV) also suppressed E responding (1.5, 3, & 6 µg; 1.5 µg as the most effective dose). Doses of 3 and 6 µg produced a trend toward suppressing responding for both E and water. These results contribute further support for GABA and glutamate as neurochemical mediators of the acute reinforcing effects of E and suggests that the underlying neural circuitry includes the amygdala as an anatomical substrate (Supported in part by AA05297, AA06420, and The Alcoholic Beverage Medical Res. Foundation).

REINFORCING PROPERTY OF ETHANOL: RELATIONSHIP BETWEEN NEUROCHEMICAL RESPONSE AND SELF-ADMINISTRATION. B.A. Blanchard*, C.L. Merski* & S.D. Glick. Department of Pharmacology and Toxicology, Albany Medical College, Albany, NY, 12208.

It has been suggested that the reinforcing properties of ethanol, like other drugs of abuse, are related to dopamine (DA) release in the nucleus accumbens (e.g., DiChiara & Imperato, 1988). Using brain microdialysis, we examined the effect of 0.5 g/kg ethanol (i.p.) on extracellular concentrations of DA, DOPAC and HVA in nucleus accumbens and striatum in adult male and female Long-Evans rats. Among males, ethanol produced an increase in DA release in striatum (approximately 160% of basal release) that persisted for 1 hour, but had no effect in nucleus accumbens. In contrast, females showed increased DA levels in both nucleus accumbens (peaking at 190% of baseline) and in striatum (200% of baseline), with a more prolonged elevation in striatum (1.5 hours). No consistent changes were observed in DOPAC or HVA concentrations in either sex. To examine the relationship between neurochemical response to ethanol and its reinforcing properties, we are currently training these same rats to bar press for oral ethanol reinforcement. To date, it appears that females consume greater amounts of ethanol than males. Since females but not males showed increased DA release in nucleus accumbens following ethanol administration, this suggests that DA release in the nucleus accumbens may indeed be important in mediating the reinforcing properties of ethanol. However, since males do consume ethanol, a role for striatal DA release can not be ruled out.

ADRENERGIC DRUGS AND RATS' INTAKE OF ALCOHOLIC BEVERAGE. C.L. HUBBELL, J.D. DELCONTE*, C.A. AMENDOLA*, M.L. NICHOLS* and L.D. Reid. Rensselaer Polytechnic Institute, Troy, NY 12180.

Rats were deprived of fluids daily for 22-h and then given 2-h to take water and a sweetened alcoholic beverage. When intakes of ethanol were stable, dose-response assessments of a number of adrenergic drugs were performed. Following a day when all rats received placebos, there was a day when various groups received one of a number of doses of a drug. Methoxyidazoxan, a specific alpha-2 adrenergic antagonist, and yohimbine, another alpha-2 antagonist, each decreased intakes of ethanol in a dose-related manner without reducing intakes of water. Methoxyidazoxan, in a dose of 3.0 mg/kg, administered interperitoneally, 15 min before the session, produced a marked reduction in intake of alcohol. Clonidine, an alpha-2 agonist, produced a slight increase in intake of ethanol at one dose, but that dose also increased intake of water. Desipramine and nomifensine, which both have adrenergic effects, decreased intake of ethanol at a dose that had minor effects on intake of water. These data, with the exception of that of clonidine, support the idea that adrenergic mechanisms play a role in ethanol's self-administration.

565.7

EFFECTS OF COCAETHYLENE ON ETOH SELF-ADMINISTRATION. R.W. Hughes, H.L. June, H.L. Spurlock, J.T. Dixon, L.H. Hicks, M.J. Lewis. Neurobeh.Lab., Howard Univ.,Washington,DC.

The concurrent abuse of ethanol (E) and cocaine has recently been more frequently reported clinically. This combination has been shown to produce cocaethylene(CE), the ethyl ester of benzoylecgonine. This compound has been found to be self-administered (SA) by primates and to also block reuptake and increase the release of dopamine in rats. The present study examined CE's effects on E SA in freely feeding and drinking rats. Animals learned to consume increasing concentration of E over several weeks using a limited access procedure. All rats showed a preference for 11% E over water. CE (1.0 mg/kg, ip) injection increased E and water consumption. A higher dose (2.5mg/kg, ip) of CE decreased E consumption while not affecting water intake. The effects of CE on E SA appear similar to those of psychomotor stimulants.

565.8

EFFECTS OF ORAL ETHANOL SELF-ADMINISTRATION AND RO15-4513 ON WHEEL-RUNNING BEHAVIOR. M.A. Bixler, H.L. June, M.J. Lewis. Neurobehavioral Lab., Howard University, Washington, DC 20059.

We have found that ethanol (E) produced dose-related reductions of wheel-running (WR) performance. RO, an inverse BDZ agonist, has been found to antagonize the E-induced suppression of several behaviors. Recently, we have found that RO (.063-3.00 mg/kg, ip) failed to antagonize the depressant actions of experimenter-administered (EA) E (0.75 g/kg, ip) on WR.

The present study examined the actions of orally self-administered E on WR and of RO (2.5 & 5.0 mg/kg) effects on these behavioral responses. Rats who had acquired a preference for E were given 10 min tests of WR following intake of E (11% v/v) during a two-bottle choice of E and water. Unlike with EA injection, oral intake of up to 1.6 g/kg of E did not suppress WR. RO alone and in combination with oral E did substantially reduced WR similar to EA E. These data suggest that route of administration plays an important role in the effects of E on WR. Moreover, RO suppresses WR behavior alone and in combination with E independent of route of administration.

565.9

EFFECT OF SEROTONIN ANTAGONISTS ON THE DEXFENFLURAMINE (D)-INDUCED ATTENUATION OF ETHANOL INTAKE IN WISTAR RATS. D.M. Tomkins*, E.M. Sellers and G.A. Higgins. Depts. of Pharmacology & Medicine, University of Toronto and Clinical Research & Treatment Institute, Addiction Research Foundation, Toronto, Ontario, Canada M5S 2S1.

Using a computerized drinkometer system, we recently demonstrated that D, a 5-HT releaser and uptake inhibitor, reduces ethanol intake in a dose-related manner in rats allowed continual access to water and 5% ethanol (Higgins et al, JPET, submitted). The aim of the present study was to assess which 5-HT receptor subtypes may be involved in the mediation of this effect. Ethanol-preferring rats receiving saline injections consumed between 2.4-3.3 g/kg ethanol during the 12 h dark phase. D (1 mg/kg s.c.) 1 h prior to lights out produced a marked attenuation in ethanol (-28%, $p < 0.01$) in relation to food (-4%, $p < 0.01$) intake. The reduction in ethanol intake was due to an increase in the latency ($p < 0.01$) and a reduction in the number of drinks ($p < 0.01$); drink size was unaffected. The reduced ethanol intake could be reversed by pre-treatment with either metergoline (1 and 5 mg/kg i.p., $p < 0.01$) or ritanserin (1 and 3 mg/kg, $p < 0.01$) which when given alone had no significant effect on ethanol intake. Ondansetron (0.01, 0.1 and 1 mg/kg) and xylamidine (3 mg/kg) had no significant effect on D-induced reduction in ethanol intake. However, 0.1 mg/kg ondansetron alone significantly reduced ethanol intake by 17% ($p < 0.05$). The reversal of the D-induced reduction of ethanol intake by the non-selective 5-HT antagonist metergoline and the 5-$HT_{1C/2}$ antagonist ritanserin, but not by either ondansetron (5-HT_3 antagonist) or xylamidine (peripheral 5-HT_2 antagonist) suggest a role for central 5-$HT_{1C/2}$ receptors in the mediation of this effect.

565.10

EFFECTS OF ADRENALECTOMY AND SUBSEQUENT CORTICOSTERONE TREATMENT ON ETHANOL CONSUMPTION IN MALE WISTAR RATS. C. Fahlke, J. A. Engel,* C. J. P. Eriksson, E. Hård and B. Söderpalm.Depts. of Psychology, Pharmacology, Psychiatry and Neurochemistry, Univ. of Göteborg, Sweden and Research Lab., ALKO, Helsingfors, Finland.

Stress is accompanied by a rise in the secretion of adrenocortical hormones and it may be considered whether or not these hormones, and especially corticosterone, exert an influence on ethanol consumption. In the present investigation this issue was addressed by studying the effect of adrenalectomy (ADX) and subsequent corticosterone treatment on ethanol intake. During a three week period before ADX the intake of water and 6% (w/v) ethanol was recorded for 60 male rats. Based on their individual preferences for ethanol the rats were partitioned into one ADX group and one sham-operated group. ADX rats received a 0.9% saline solution instead of water and 6% ethanol solution based upon a 0.9% saline solution. Fluid intake was recorded for 8 days after ADX and sham-operation. The ADX and control groups were each divided in two subgroups. One subgroup from ADX rats and one from the sham-operated rats received corticosterone in their fluid bottles (25 mg/1000 ml fluid) according to a method developed by Akana, S. F. et al (Am. J. Physiol. 1985, 249: R527-R532). The remaining two subgroups served as controls for the corticosterone treatment. Fluid intake was recorded for another period of 8 days. The results showed that ADX rats significantly decreased their ethanol intake and preference compared to the sham-operated controls. There was no difference between groups in total fluid intake. Treatment of ADX rats with corticosterone caused a significant increase of ethanol intake and preference compared to the ADX controls. Corticosterone restored the intake of ethanol to a normal level. This suggest that corticosterone is involved in the regulation of ethanol consumption.

565.11

ANGIOTENSIN II AND CAPTOPRIL ENHANCE ETHANOL INTAKE IN RATS. D.A. Fitts. Dept. of Psychology, Univ. of Washington, Seattle, WA 98195.

Chronic infusions of angiotensin II into the lateral ventricles for 7 days increased water intake at 5 and 20 pmol/hr and increased intake of 6% (v/v) ethanol at 20 pmol/hr relative to baseline values and to vehicle-infused controls. Captopril placed into the drinking fluids at 0.1 mg/ml for 4 days significantly increased intake of 4 to 8% ethanol in three of four experiments and never significantly reduced ethanol intake. Functionally identified lesions of the subfornical organ (SFO) totally abolished captopril-enhanced water intake but did not appear to affect the increased intake of 6% ethanol during captopril treatment. The data appear to reflect a general increase in fluid intake rather than a specific appetite for alcohol, such as would be expected with NaCl solutions, but this increase with captopril appears to be independent of the SFO. Our results with angiotensin and captopril were opposite to previously published reports by others, and the data question whether it is appropriate to use converting enzyme inhibitors to treat problem drinking in humans (e.g., Spinosa, G., et al., Alc. Clin. Exp. Res., 12, 65-70, 1988). Supported by NS-22274.

CCK-8 INHIBITS ETHANOL AND FOOD INTAKE IN RATS SELECTIVELY BRED FOR ETHANOL SENSITIVITY. S.L. Sandoval*, Y.J. Clayborne* and P.J. Kulkosky. Dept. of Psychology, Univ. of Southern Colorado, Pueblo, CO 81001.

Cholecystokinin octapeptide (CCK-8) is a brain-gut neuropeptide shown to inhibit intake of food and alcohol in a variety of species. Recently, Draski and colleagues developed strains of Norway rats differing in sleep time after acute injection of ethanol. We measured the intake of 5% alcohol, food and water in water-deprived rats with high, low, and control alcohol sensitivity (HAS, LAS, and CAS), after ip injection of CCK-8 (0-8 μg/kg). LAS rats consumed significantly more ethanol than HAS or CAS rats, which did not differ reliably. Injection of CCK-8 significantly and equivalently inhibited alcohol and food intake in each group of rats. Water intake following alcohol was unaffected by prior CCK-8 injection. Differences in alcohol sensitivity in these rats cannot be attributed to differential sensitivities to CCK-8. However, differences in alcohol consumption are inversely related to sensitivity to alcohol's anesthetic effect. (Supported by NIH Grant No. RR-08197).

EFFECTS OF SEROTONERGIC AGENTS ON ETHANOL DRINKING IN THE P LINE OF ALCOHOL-PREFERRING RATS. J.M. Murphy, R.B. Stewart L. Lumeng*, T.-K. Li* and W.J. McBride. Dept. Psychology, Purdue Sch. Sci., IUPUI, Indiana Univ. Sch. Med., Regenstrief Inst. & VAMC, Indianapolis, IN 46202.

Several drugs known to act on CNS serotonin (5HT) systems have been observed to alter alcohol consumption. Compared with rats of the alcohol-nonpreferring NP line, P rats have been shown to have lower levels of 5HT in most forebrain regions and an upregulation of some 5HT receptor subtypes. The present study tested the effects on alcohol consumption of subcutaneous injections of buspirone, a $5HT_{1A}$ agonist (1.0-9.0 mg/kg), and two $5HT_3$ antagonists, MDL72222 and ICS205930 (0.01-3.0 mg/kg). Adult female P rats (n=8 or 9/group) were given ad lib access to food and water, but access to a 10% (v/v) ethanol solution was restricted to 4 h/day. Rats were first habituated to saline injections. Each drug dose was given before alcohol access on 4 consecutive days. Rats were given saline injections and returned to baseline intakes on days between drug doses. Buspirone caused a dose-dependent decrease in alcohol intake, mostly during the first hour of ethanol access ($p<0.001$ compared with saline). MDL72222 and ICS205930 did not significantly alter ethanol intake. The findings indicate a role for $5HT_{1A}$ receptors in alcohol drinking of P rats, but no evidence for the involvement of $5HT_3$ receptors was obtained. (Supported by AA07611 and AA08553)

565.14

REGIONAL DIFFERENCES IN BRAIN CONTENT OF TRH BEFORE AND AFTER HIGH DOSE ETHANOL IN ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) RATS. S. Morzorati, S. Keim*, S. Katner*, M.J. Kubek. Depts. Psych., Med. & Anat. & Regenstrief Inst., Indiana Univ. Sch. Med., Indianapolis, IN 46202.

This study was designed to evaluate the endogenous levels of TRH in the brains of P and NP rats at baseline (Exp 1) and after high dose Et (Exp 2). For Exp 1, alcohol-naive rats were sacrificed. For Exp 2, rats lost their righting reflex after a sedating dose of Et (3g/kg). Rats were sacrificed at either a fixed time while still sedated, or when they righted themselves. TRH content was measured in 17 brain regions.

Baseline septal TRH was lower (40%, $P<.05$) in P compared to NP rats. After high dose Et, P rats righted themselves sooner ($P<.0005$) and at higher Blood ACs ($P<.0005$) than NP rats, and TRH content in the medial septum of both lines was higher (50%, $P<.05$) compared to baseline. At the fixed time point, TRH content did not differ from baseline levels. These data support the notion that the medial septum is involved in the analeptic action of TRH. We hypothesize that high Brain AC suppresses central TRH systems. As Brain AC falls, TRH activates septohippocampal neurons to produce arousal. P rats righted themselves sooner because their septal TRH receptors may be more sensitive than those of NP rats. (Supported by AA07611 & NS25661).

565.15

ELECTROPHYSIOLOGICAL MEASURES OF SENSITIVITY TO ETHANOL, MK-801 AND DIAZEPAM IN ALCOHOL -PREFERRING AND NON-PREFERRING RATS. C.L. Ehlers, R. I. Chaplin*, W. Kaneko*, S.L. Lopez*, L. Lumeng and T.K. Li. Dept. Med., Indiana Univ. Sch. Med., and VAMC Indianapolis, IN 46223 and Dept. Neuropharm., Res. Inst. Scripps Clinic, La Jolla, CA 92037

Studies in men at genetically increased risk for the development of alcoholism have demonstrated that they may have a qualitatively different response to acute doses of ethanol. Differential sensitivity to the acute effects of ethanol has also been found in alcohol-preferring (P) and non-preferring (NP) rats. In the present study, the acute response to ethanol, as well as diazepam and the noncompetitive NMDA receptor antagonist MK-801, was assessed in P and NP rats using EEG and auditory event related potentials (ERPs). Nine P and 9 NP rats were implanted with electrodes in cortex (CTX), dorsal hippocampus (DHPC), thalamus (THAL), and amygdala (AMYG). Rats were administered vehicle, ethanol (0.75 mg/kg), diazepam (1.5 mg/kg) and MK-801 (0.1 mg/kg) 20 minutes prior to EEG and ERP recordings. P and NP rats were found to differ on EEG and ERP measures following vehicle administration, in that P rats had more power in the low (1-2 Hz) and high (32-64 Hz) frequency ranges, reduced theta frequency (6-8 Hz) in the EEG, and reduced N1 component amplitudes in CTX and DHPC. In response to ethanol, P rats differed from NPs in that they displayed less EEG slowing and less reduction or increases in ERP component amplitudes. No EEG or ERP differences were found in response to diazepam in P and NP rats. In response to MK-801, P rats did demonstrate less slow waves and less reductions or increases in ERP amplitudes. These studies indicate that in addition to differences in baseline, P rats have reduced electrophysiological effects of both ethanol and MK-801, suggesting that differential response of brain glutaminergic systems may underlie differences in acute sensitivity between P and NP rats. (supported by AA00098, 06059, 07611)

EEG EFFECTS OF ORAL ETHANOL SELF-ADMINISTRATION IN ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) RATS. P. Robledo, L. Lumeng, T-K. Li, and C. L. Ehlers. Dept. of Med. Indiana Univ. Sch. of Med., Indianapolis, IN, and Department of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla CA 92037.

Electrophysiological measures have been shown to differ in human subjects at genetically increased risk for alcoholism both prior to and after challenge doses of ethanol. In the present study EEG was recorded from indwelling electrodes in rats which were selectively bred for alcohol-preferring (P) and non preferring (NP) behaviors during an ethanol self-administration paradigm. Initially, 0.2% saccharin solution was available on a FR1. Ethanol was then added to the saccharin solution in increasing concentrations while saccharin was faded progressively. EEG recordings were obtained in three conditions: 1) 0.2% saccharin 2) 5% ethanol and 3) 10% ethanol. Differences in mean power and peak frequency were statistically compared. P rats were found to have overall increases in EEG spectral power in the theta frequency ranges in all experimental conditions (4-6 Hz, $p<0.006$; 6-8 Hz, $p<0.07$). Ethanol self administration, as compared to saccharin, was found to produce an increase in mean EEG power in both P and NP rats in all frequency bands (4-6 Hz, $p<0.06$; 6-8 Hz, $p<0.002$; 8-16 Hz, $p<0.01$; 16-32 Hz, $p<0.001$), and a decrease in peak frequency in 3 of the bands (4-6 HZ, $p<0.006$, 6-8 Hz, $p<0.002$, 8-16 Hz, $p<0.04$). The pattern of EEG changes observed following ethanol consumption however differed in the P vs. NP rats, and paralleled their consumption patterns. In NP rats, EEG changes were more prominent in the 5% condition, and decreased in the 10% condition where they pressed little for alcohol. In contrast, P rats demonstrated the largest EEG effects in the 10% condition concomitant with increases in their consumption rates. These studies suggest that P rats may need to drink more alcohol to experience the same EEG effects as NP rats. This finding may represent part of the substrate for the difference in alcohol preference between the two rat lines. (supported by AA06059)

565.17

EFFECTS OF AMPHETAMINE AND SCOPOLAMINE ON MOTOR ACTIVITY IN ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) RATS. R.B. Stewart, R.N. Russell*, F. Franada* and J.M. Murphy. Dept. Psychology, Purdue Sch. Sci., IUPUI, Indiana Univ. Sch. Med. & Regenstrief Inst., Indianapolis, IN 46202.

Motor activity is increased following low to moderate doses of ethanol in P but not in NP rats. The present study tested P and NP rats for differential sensitivities to pharmacological agents that increase motor activity. Using a counterbalanced within-subject design, P and NP rats (n=16/line) received intraperitoneal injections of saline or amphetamine (0.25-2.0 mg/kg). Two other groups (n=16/line) were injected with saline or scopolamine (0.25-2.0 mg/kg). Rats were tested for one hour after injections in a photocell activity field. Compared with P rats, amphetamine caused a more potent dose-dependent increase in activity for rats of the NP line, with the greatest difference at 1.0 mg/kg ($p<0.001$). In contrast, scopolamine increased activity more in the P rats, with the greatest difference at 0.5 mg/kg ($p<0.005$). Since amphetamine and scopolamine are known to act primarily on CNS dopamine and cholinergic systems, respectively, the differential behavioral excitatory effects of these drugs in the P and NP lines of rats could indicate that selective breeding for alcohol preference and nonpreference may be associated with a functional divergence in brain dopaminergic and cholinergic systems. (Supported by AA07611 and AA08553)

565.18

DENSITIES OF $5\text{-}HT_3$ RECEPTORS IN THE CNS OF ALCOHOL-PREFERRING (P) AND ALCOHOL-NONPREFERRING (NP) LINES OF RATS. W.J. McBride, E. Chernet*, D.T. Wong, D.W. Robertson, L. Lumeng* and T.-K. Li*. Indiana Univ. Sch. of Med., VA Med. Ctr., and Lilly Research Labs., Indianapolis, IN

The densities of $5\text{-}HT_3$ recognition sites labelled with [^{3}H] LY 278584 were determined in the CNS of alcohol-naive, adult male rats (N=4 each) from the alcohol-preferring (P) and non-preferring (NP) lines by quantitative autoradiography. Coronal sections (20 um), prepared from frozen brains, were incubated for 1 hour at room temperature in a Tris-HCl buffer containing 2.0 nM [^{3}H] LY 278584. Among the cortical areas, the highest densities (16-37 fmol/mg prot) were observed in (a) layers 1 and 2 of the medial prefrontal and cingulate, (b) piriform and (c) entorhinal regions. High (18-31 fmol/mg prot) densities were also observed in the amygdala and ventral hippocampus. Low binding (4-9 fmol/mg prot) was observed in the nucleus accumbens. In general, there were no differences in the densities of $5\text{-}HT_3$ sites between P and NP rats. The results do not indicate any abnormality in CNS $5\text{-}HT_3$ receptors which could be associated with high alcohol drinking behavior. (AA08553, AA07462, AA07611)

RO15-4513 EFFECTS ON ETHANOL-INDUCED LOCOMOTOR ACTIVITY IN ALCOHOL-PREFERRRING AND NON-PREFERRING RATS. H.L.June, and M.J. Lewis, Neurobehav. Lab., Howard Univ., Washington, DC 20059.

Ro15-4513(RO), an inverse BDZ agonist, has been shown to block ethanol self-administration in selectively bred ethanol (E) preferring P and non-preferring NP rats. This compound has also been found to antagonize E-induced locomotor effects in unselected rats. The present study investigated the effects of RO on locomotor activity of P and NP rats.

P rats initially showed higher levels of activity than NP rats during baseline measurement of activity. Injections (ip) of RO (2.5 and 5.0 mg/kg) and E (0.75 g/kg) each were given alone and in combination with each other prior to testing. E alone reduced activity in both P and NP rats, although P rats showed less reduction. RO alone and in combination with E produced greater suppression of locomotor activity in both rats than E alone. These data shows that RO does not antagonize E-induced locomotor depression in P and NP rats. Moreover, they demonstrate the intrinsic depressant effects of the RO and the lack of generality of its effects in blocking E's action.

BRAIN AND PITUITARY β-ENDORPHIN SYSTEM OF THE AA AND ANA RATS. J.P. De Waele, K.Kiianmaa* and C. Gianoulakis. Douglas Hospital Research Centre, McGill University, Verdun, Québec; *Research Laboratories, Alko ltd. Helsinki, Finland

Genetically determined differences in the activity of specific components of the endogenous opioid system may be partially responsible for the preference or aversion to ethanol exhibited by selectively bred strains of animals. In the present studies the content of POMC mRNA in the pituitary and hypothalamus as well as of immunoreactive β-endorphin (irβ-EP) in distinct regions of the brain and the pituitary gland of the alcohol-preferring AA and alcohol avoiding ANA rats were measured under basal conditions. The content of irβ-EP was significantly higher in the septum and significantly lower in the amygdala and periaqueductal grey matter of the AA rats, while there was no significant difference among AA and ANA rats in the arcuate nucleus, nucleus accumbens, caudate, hippocampus and cortex. The content of POMC mRNA but not of irβ-EP was significantly higher in the hypothalamus and neuro-intermediate lobe of the AA rats, while in the anterior pituitary the content of both ir-βEP and POMC mRNA were significantly higher in the AA than ANA rats. Thus there are specific differences in the brain and pituitary β-endorphin systems among the AA and ANA rats. The importance of these differences on controlling the voluntary ethanol consumption is under investigation.

EFFECTS OF TEMPERATURE AND ETHANOL ON GABA-STIMULATED CHLORIDE UPTAKE IN LS AND C57 MICE. D.A. Finn, K.W. Gee, P.J. Syapin, M. Bejanian and R.L. Alkana. Dept. Molec. Pharmacol. Toxicol., Univ. So. Calif., LA, CA 90033.

Offsetting ethanol hypothermia influences behavioral sensitivity to ethanol. The direction of the response depends upon genotype, with ethanol sensitivity increasing in C57 and decreasing in LS mice. Genetic differences also exist in the effects of ethanol on GABA-gated chloride (Cl) channel activity. These differences are consistent with selectively bred differences in behavioral sensitivity to ethanol. Therefore, we hypothesized that changes in behavioral sensitivity to ethanol induced by offsetting hypothermia might be due to an interaction of temperature and ethanol at the GABA$_A$/benzodiazepine receptor complex (GBRC). We found that increasing in vitro temperature from 30 to 38°C eliminated the significant effect of ethanol (25-100 mM) on GABA-stimulated Cl uptake in LS mice, which was present at 30°C. In contrast, there was no significant effect of ethanol (50-200 mM) or temperature (30 & 38°C) on GABA-stimulated Cl uptake in C57 mice. These results suggest that an interaction between temperature and ethanol at the GBRC might explain the negative relationship between temperature and ethanol sensitivity found in LS mice, but it cannot explain the positive relationship between temperature and ethanol sensitivity found in C57 mice. PHARMACOLOGICAL AND NEUROCHEMICAL STUDIES IN HOT AND COLD MICE. J.F. Stuart*, J. Dorow*, J.C. Crabbe and D.J. Feller, VA Medical Center and Oregon Health Sciences University, Portland, OR 97201.

Mouse lines are being selected which are sensitive (COLD1,2) and resistant (HOT1,2) to ethanol induced hypothermia. HOT/COLD mice (both replicates) were tested for hypothermic sensitivity to drugs acting through receptor or ion channel specific mechanisms: dexmedotomidine, α2-adrenergic agonist; adenosine agonist; caffeine, adenosine antagonist and phosphodiesterase inhibitor; and diltiazem, calcium channel blocker. COLD mice (both replicate lines) were significantly more sensitive than HOT mice to diltiazem, but not dexmedotomidine. C2 mice were more sensitive to adenosine drugs.than H2 mice, while H1/C1 mice were equally sensitive.The diltiazem data suggests that calcium channel function may be involved in ethanol's effect on body temperature. We previously showed that opiate agonists are more potent in COLD compared to HOT mice. Receptor binding with [3H]DAMGO, a μ-opiate agonist, and morphine inhibition of forskolin stimulated adenylate cyclase were studied in frontal cortex, remainder of cortex, hypothalamus and brain stem from HOT/COLD mice. DAMGO binding was less only in the frontal cortex of COLD compared to HOT mice. However, morphine inhibition of adenylate cyclase was similar in both mouse lines for the frontal cortex and other brain areas. These data suggest that differences between HOT/COLD mice in sensitivity to opiate drugs is not mediated through changes in μ-opiate receptor function.

These studies were supported by Grants AA05828, NIDA Contract 271-87-8120, AA06548 and AA08621.

DRUGS OF ABUSE—COCAINE: PHARMACOLOGY

566.1

MODULATION OF THE DISCRIMINATIVE-STIMULUS EFFECTS OF COCAINE BY MU AND KAPPA OPIOIDS. R.D. Spealman and J. Bergman. Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772.

The discriminative-stimulus (DS) effects of cocaine alone and after pretreatment with selected opioids were determined in squirrel monkeys using a two-lever choice procedure. When tested alone, cocaine engendered dose-related increases in cocaine-appropriate responding, reaching a maximum of 97-100% at doses of 0.3 mg/kg or greater. Pretreatment with the mu agonists morphine, levorphanol, and methadone and the partial agonist buprenorphine potentiated the DS effects of cocaine such that the cocaine dose-effect curve was shifted to the left by as much as 30-fold. In contrast, pretreatment with the kappa agonists U50,488 and CI 977 attenuated the DS effects of cocaine, shifting the cocaine dose-effect curve to the right by up to 3-fold. None of the opioids engendered cocaine-appropriate responding in the absence of cocaine. Pretreatment with the opioid antagonists naltrexone and MR2266 did not alter the DS effects of cocaine. Naltrexone did, however, antagonize the cocaine-potentiating effects of both morphine and buprenorphine. The results show that activation of mu and kappa receptors can modulate the DS effects of cocaine in different ways, which may reflect their opposing influences on dopamine release. 566.2

DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE: LACK OF ANTAGONISM BY BUPRENORPHINE, MORPHINE OR NALTREXONE. P. Doty, A.B. Johnson*, M.J. Picker* and L.A. Dykstra. Dept. of Psychology, Univ. of North Carolina, Chapel Hill, NC 27599.

Recent reports indicate that buprenorphine, an opioid agonist/antagonist, suppresses cocaine self-administration in rhesus monkeys and enhances cocaine's reinforcing effects in a place preference procedure in rats. Given these findings, the present study was conducted to evaluate the effects of buprenorphine on another component of cocaine's action, namely its discriminative stimulus effects. Using a two-lever drug discrimination procedure, rats were trained to discriminate a dose of 10.0 mg/kg cocaine from saline. During substitution tests, both cocaine (1.0-10.0 mg/kg) and d-amphetamine (0.1-3.0 mg/kg) substituted for the cocaine stimulus in a dose-dependent manner. In contrast, buprenorphine (0.03-0.56 mg/kg), morphine (0.3-10.0 mg/kg) and naltrexone (1.0-10.0 mg/kg) failed to substitute for the cocaine stimulus, up to doses that substantially decreased rate of responding. Across the dose range examined, buprenorphine (0.03-0.56 mg/kg) failed to alter the stimulus effects produced by cocaine or d-amphetamine. Morphine (0.3-10.0 mg/kg) and naltrexone (1.0-10.0 mg/kg) also failed to alter cocaine's stimulus effects. Thus, although buprenorphine may alter the reinforcing effects of cocaine, the present study demonstrates that buprenorphine does not alter the stimulus properties of cocaine in rats. (Supported by PHS grants DA 07244 and DA 02749).

566.3

ANXIOGENIC EFFECTS OF COCAINE.

A. Laurel Gorman*, X-M. Yang, Adrian J. Dunn and Nick E. Goeders. Dept. of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130-3932.

Cocaine use in humans is sometimes accompanied by feelings of anxiety and panic. Previously, we reported that chronic administration of cocaine (20 mg/kg i.p.) induced anxiety-like behaviors in rats tested in defensive withdrawal. We now report similar effects on defensive withdrawal after the same dose of cocaine given acutely. Acute or chronic cocaine administration both significantly increased plasma concentrations of corticosterone, and decreased catabolite-amine ratios for dopamine and serotonin in brain regions collected immediately after testing for defensive withdrawal. A central mechanism was suggested for the effect of cocaine because i.c.v administration of cocaine (50-200 ng) produced dose-dependent increases in defensive withdrawal behavior.

An anxiogenic explanation is supported by the observation that chlordiazepoxide (5.0 mg/kg, i.p.) pretreatment prevented the acute cocaine-induced increases in defensive withdrawal. Also, acute cocaine (20 mg/kg, i.p.) elicited anxiety-like responses in mice tested in the elevated plus-maze. Drug-induced decreases in the number of entries and the total time spent in the open arms were attenuated by i.p. L-propranolol (2.5 mg/kg) and ketanserin (5.0 mg/kg). These results indicate that cocaine acts by a central mechanism to induce anxiety-like behaviors in rats and mice.

566.4

EFFECTS OF ALPRAZOLAM ON INTRAVENOUS COCAINE SELF-ADMINISTRATION IN RATS. N.E. Goeders, M.A. McNulty* and G.F. Guerin. Dept. of Pharmacology & Therapeutics, LSU Medical Center, Shreveport, LA 71130.

The following experiments were designed to investigate the effectiveness and specificity of alprazolam on intravenous cocaine self-administration. Alprazolam was investigated since this drug has been proven to be clinically effective in the treatment of anxiety and panic attacks and has been proposed to be useful in the treatment of some types of depression. Cocaine use and withdrawal have also been associated with anxiety, depression and even panic attacks in some cases. Alprazolam was tested under a multiple schedule of intravenous cocaine presentation and food reinforcement. Cocaine (0.5 mg/kg, ip) was available during the first hour of the session under a fixed-ratio 4 schedule of reinforcement. During the second hour, food presentation (45 mg pellets) was available under a discrete-trial fixed-ratio 10 schedule of reinforcement. The animals were pretreated with alprazolam (0, 0.5, 1.0, 2.0 and 4.0 mg/kg, ip) thirty minutes prior to the start of the behavioral session. Initial exposure to alprazolam resulted in non-specific decreases in both cocaine- and food-maintained responding. However, although the animals quickly became tolerant to the effects of the drug on food reinforced responding upon subsequent testing with alprazolam, dose-related decreases in cocaine self-administration were maintained. These data suggest that pharmacological properties inherent to alprazolam (i.e., anxiolytic) specifically altered cocaine reinforcement without affecting responding maintained by food. Experiments are currently in progress to determine the nature of these effects by completing dose-response curves with cocaine and by determining whether the benzodiazepine receptor antagonist, flumazenil (Ro 15-1788), will reverse or attenuate the effects of alprazolam on cocaine self-administration. Supported in part by USPHS Grant DA06013.

566.5

DISCRIMINATIVE STIMULUS EFFECTS OF LOCAL ANESTHETICS IN RATS TRAINED TO DISCRIMINATE BETWEEN COCAINE AND PROCAINE. J.H. Graham*, S.E. Robinson, R.L. Balster, Dept. of Pharmacology and Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298-0613.

In previous studies, several local anesthetics were shown to have cocaine-like discriminative stimulus effects. For the present study a two-lever drug discrimination procedure was used to train rats (N=6) to discriminate between 10 mg/kg cocaine (associated with one lever)and either 55 mg/kg procaine or saline (associated with the other lever) in order to separate the local anesthetic effects of cocaine from its central stimulatory effects. After the subjects were trained, substitution tests were conducted with cocaine (1.0-30 mg/kg), procaine (6.3-110 mg/kg), dimethocaine (1.0-30 mg/kg), lidocaine (3.7-59 mg/kg) and amphetamine (0.1-3.0 mg/kg). Cocaine, dimethocaine, and amphetamine generalized completely from the training dose of cocaine in a dose-dependent manner. Procaine showed no generalization from cocaine, and lidocaine showed little cocaine-lever responding, even at doses that disrupted behavior. These results provide further evidence that cocaine discrimination is not based on its local anesthetic effects and that dimethocaine, which has high affinity for the cocaine recognition site on the dopamine transporter, has effects more similar to cocaine than procaine. (Supported by NIDA grants DA-00490 and DA-07027 and the Commonwealth of Virginia Center for Drug Abuse Research)

566.6

EVALUATION OF THE EFFECTS OF BUPRENORPHINE IN BOTH A COCAINE SELF-ADMINISTRATION AND A DRUG-DISCRIMINATION PARADIGM. H.O. Pettit, S. Smith*, A.J. Eckstrom*, and G.T. Pryor*, Neuroscience Department., SRI International, Menlo Park, California 94025.

The mixed opioid agonist-antagonist buprenorphine (BUP) can reduce cocaine self-administration in monkeys. Studies were done to help clarify the manner in which buprenorphine can reduce cocaine self-administration behavior. Studies in progress are investigating the ability of BUP to attenuate intravenous cocaine self-administration in rats. Results indicate that a dose of 100 μg/kg (administered i.p. 30 min before testing) significantly attenuates cocaine self-administration. The effects of lower doses are under study. Additional experiments have assessed the effects of BUP on both cocaine and morphine drug-discrimination in rats trained to discriminate drug from saline. BUP (0, 1, 10 and 100 μg/kg, i.p.) substituted for morphine (in morphine trained rats, N=8) but not for cocaine (in cocaine trained rats, N=9). The percentage of animals selecting the drug lever for each dose of BUP was 0, 0, 37 and 87% in morphine rats, and 22, 0, 0, and 11% in cocaine rats. No significant decrease in lever press rates were observed for any dose of BUP. When BUP was combined with the ED_{50} for cocaine or morphine discrimination, a significant increase in the percentage of rats selecting the drug lever was observed in morphine- (N=10), but not cocaine-trained rats (N=13). The percentage of subjects selecting the drug lever for each dose of BUP was 40, 80, 70 and 90% in morphine rats, and 54, 46, 38, and 31% in cocaine rats.The percentage of cocaine trained animals that selected the drug lever did not significantly decrease or increase after BUP administration. When BUP (0.0, 100 and 200 μg/kg) was combined with the training dose of cocaine (5 mg/kg; at which dose approximately 100% responding occurs) no significant decrease in the percentage of rats selecting the drug lever was observed. For each dose of BUP, the percentage of animals selecting the drug lever was 90, 82 and 82%. These results indicate that BUP (1) can attenuate cocaine self-administration in rats; (2) can produce morphine-, but not cocaine-like discrimination effects; and (3) can not attenuate or enhance the discriminative stimulus properties of cocaine.

566.7

CLOZAPINE PRETREATMENT INCREASES BREAKING POINTS ON A PROGRESSIVE RATIO SCHEDULE REINFORCED BY INTRAVENOUS COCAINE IN THE RAT E.A. Loh, T. Fitch*, G. Vickers* & D.C.S. Roberts, Dept. of Psychology Carleton University, Ottawa, Canada, K1S 5B6.

There is substantial evidence to support the hypothesis that dopamine receptor stimulation is essential for psychomotor stimulant reinforcement. Since the atypical neuroleptic, clozapine, is a dopamine antagonist, one would predict it should attenuate the reinforcing effects of cocaine. This was tested by evaluating the effect of clozapine (5-20 mg/kg) on Wistar rats trained to self-administer cocaine (0.6 mg/inj) on a Progressive Ratio schedule of reinforcement.

Paradoxically, clozapine was found to substantially increase breaking points indicating that it in fact potentiated cocaine's reinforcing effects.

Clozapine has actions on other transmitter systems (ie. serotonin) which are likely responsible for this atypical response.

Clearly, all neuroleptics do not block psychomotor stimulant reward.

CHRONIC COCAINE ALTERS THE EFFECTS OF STRESS ON LOCOMOTOR ACTIVITY IN MICE. D.J. Mokler and T.K. Sklutas*, Dept. Pharmacol., Univ. of New England, Biddeford, ME.

Interactions have been reported between cocaine and stress. Specifically, stress has been shown to sensitize animals to the motor activating effects of cocaine. Cocaine and stress are proposed to interact with monoaminergic systems. If the behavioral sensitization of cocaine by stress is due to similar mechanisms then cocaine may alter potentiate the behavioral effects of stress. The goal of the present experiment was to determine the effects of chronic cocaine administration on the behavioral effects of chronic stress. Male C57Bl/6J mice were placed on activity moniters for 1 hour a day for 14 days. One-half of the animals were stressed using an acoustic stress consisting of 1 sec of a 105 db, 8 khz tone presented on a variable time 90 sec schedule (0-360 sec range). Three hours following the session half of the animals were injected with 25 mg/kg cocaine HCl or saline. Thus there were four treatment groups: CON - no stress, vehicle; COC - no stress, cocaine; STRESS - stress, vehicle; STRESS-COC - stress, cocaine. CON animals showed a similar level of activity throughout the 14 days of study. STRESSed animals showed an enhanced locomotor activity which varied between 125% (Day 10) and 230% (Day 13) of control. COC animals (cocaine administered 3 hrs after the session) showed an initial increase in activity on days 2-4 which returned to control levels from days 5 through 14. STRESS-COC animals also showed an initial increase in activity on days 1-4 which also returned to control levels for days 5-14. These data do not support a sensitization of the behavioral effects of stress by chronic exposure to cocaine. The early increase in activity in animals exposed to chronic cocaine suggests that cocaine administered 21 hours before the session may have some continued stimulant effects which tolerates by Day 5. Chronic cocaine reverses the behavioral activation of stress. This may relate to the chronic abuse of stimulant drugs to relieve stress.

DEMONSTRATION OF TOLERANCE TO THE REINFORCING EFFECTS OF COCAINE. M. W. Emmett-Oglesby and J. D. Lane, Department of Pharmacology, TCOM, Fort Worth, TX 76107-2690

Rats were trained to lever-press under a fixed-ratio two schedule of reinforcement, where i.v. cocaine, 0.25 mg/inj, served as the reinforcer. To minimize tolerance during acquisition of responding, total reinforcers were limited to 15 per day (total dose of 15 mg/kg/day). After responding was stable, dose-effect data were obtained, which showed dose-related decreases in the rate of reinforcer intake. Subsequently, rats were treated non-contingently with either saline or cocaine for one week. For this portion of the experiment, subjects were withheld from training, and at 8-hr intervals either saline or cocaine (20 infusions of 1.0 mg/kg) was given. Over the next four days subjects were tested with four doses of cocaine (0.125, 0.25, 0.5 and 1.0 mg/inj). Subjects were then restabilized on the baseline 0.25 mg/inj schedule, and subsequently they were taken through the chronic injection and testing procedure for the other condition (i.e., if treated with saline initially, they now were treated with cocaine). Chronic treatment with cocaine resulted in a roughly two-fold faster intake of cocaine at all doses when compared to the dose-effect curve following chronic treatment with saline. In addition, the lowest dose of cocaine that would maintain self-administration was shifted roughly two-fold to the right. We have previously reported that approximately two-fold tolerance develops to the effects of cocaine used as a discriminative stimulus (e.g., *JPET* **237**:120-125, 1986) when subjects are treated with 20 mg/kg of cocaine every 8-hr for one week. The present data thus expand the overlap of information obtained between the drug-discrimination and drug self-administration paradigms to include tolerance to the reinforcing effects of cocaine. Supported by grants DA RO1-4137 and Texas Advance Technology Research #3711.

566.10

THE PROGRESSIVE RATIO PARADIGM AS A MEASUREMENT OF THE REINFORCEMENT STRENGTH OF COCAINE: AN ANALYSIS OF LONG TERM STABILITY OF BREAKPOINTS AND DOSE/RESPONSE RELATIONS. S. Schenk and R. Peltier, Texas A&M Univ., Dept. Psych., College Station, TX, 77843.

The progressive ratio (PR) paradigm has been applied to the study of the reinforcing effects of intravenously self-administered drugs. Within a test session, the procedure produces an increasing ratio requirement to obtain drug infusions and a "breakpoint", which is the last ratio that is com pleted by the animal. If the assumptions of the paradigm are correct and if long-term stability of breakpoints can be achieved, the procedure offers several advantages in the interpretation of the effects of manipulations on the reinforcement impact of drugs of abuse. We examined the stability of breakpoints for cocaine self-administration over an extended period of several weeks. We also examined dose/response relationships for breakpoints at various cocaine doses in the self-administration procedure (0.25, 0.5 and 1.0 mg/kg/infusion). The results of 70-80 days of testing revealed that breakpoints failed to reach an acceptable level of stability in that they were inconsistent from day to day. In addition, we failed to observe dose dependency either in terms of breakpoints or in terms of number of reinforcements earned. In contrast, when an FR1 schedule of reinforcement was introduced, responding was dose/dependent and reliable. The data argue that the PR procedure, as used under the present circumstances, lacks the internal validity to qualify as an effective measure of the reinforcing impact of cocaine in an intravenous self-administration paradigm.

566.11

EFFECTS OF MAGNESIUM ON RESPONDING MAINTAINED BY COCAINE AND OTHER RESPONSE MAINTAINING STIMULI : SPECIFICITY AND SELECTIVITY OF CHANGES. K.M.Kantak and T.O'Connor*. Lab. of Behav. Neuroscience, Dept. Psychol., Boston University, Boston, MA 02215

In a variety of behavioral experiments, magnesium has been shown to interact with cocaine and other stimulants. Of particular relevance to the present experiments is the recent finding that magnesium maintains responding in cocaine-trained rats. It would be expected, therefore, that injections of magnesium would have rate-altering effects on self-administered cocaine. Five experiments examined the specificity and selectivity of this relationship. Acute and cumulative injections of magnesium (0 - 250 mg/kg s.c.) produced dose-dependent reductions in responding maintained by cocaine (0.1 - 2 mg/kg/infusion). A magnesium-deficient diet produced a dose-dependent increase in cocaine-maintained responding. The acute effects of magnesium injections were specific because food-maintained responding was not affected, however, these effects were not selective because glucose + saccharin-maintained responding was affected in a manner similar to cocaine-maintained responding as was responding maintained by extinction from cocaine. These data indicate that magnesium may be either decreasing responding by increasing the reinforcing properties of cocaine and other highly rewarding substances or suppressing responding by serving as a punishing, aversive or negative stimulus.

EFFECTS OF REPEATED EXPOSURE TO TRIADIMEFON ON SCHEDULE-CONTROLLED BEHAVIOR IN RATS. A.R. Allen and R.C. MacPhail*, Neurotoxicology Div., US EPA, RTP, NC 27711 and Dept. of Psych., UNC-CH, Chapel Hill, NC 27514.

Triadimefon (TDF), a triazole fungicide, has been found to produce acute stimulant-like effects on schedule-controlled behavior and motor activity. Tolerance to stimulant effects on schedule-controlled behavior frequently develops upon repeated exposures, especially when the initial effect is to decrease reinforcement density. The present study was conducted to determine whether behavioral tolerance would develop when TDF was given repeatedly. Effects of TDF on performance maintained by a multiple fixed-ratio 10 fixed-interval 3-minute (mult FR 10 FI 3-min) schedule were determined in twelve male Long-Evans rats. Rats were then divided into two groups. Eight rats received 30 mg/kg TDF daily for 15 days and then 56 mg/kg TDF daily for the following 15 days. The remaining four rats received vehicle (VEH) daily for 30 days. Effects of 56 mg/kg TDF on response rates, reinforcement rates, and FI index-of-curvature (IOC) values were compared before and after daily TDF or VEH administration. Acute administration of 56 mg/kg TDF produced decreases in FR response and reinforcement rates. Effects of this dosage on FI response rates were variable across rats, although reinforcement rates and IOC were decreased. Daily administration of 56 mg/kg TDF attenuated the decreases in FR rates produced by acute administration of that dosage. Daily administration of 56 mg/kg TDF also attenuated the decrease in FI reinforcement rates and in IOC. In contrast, TDF effects after daily VEH administration differed considerably between rats. These results indicate that tolerance can develop to some of the behavioral effects of TDF.

566.13

DISCRIMINATIVE STIMULUS EFFECTS OF COCAINE IN RATS AND MONKEYS. P. Terry, J.M. Witkin and J.L. Katz. Psychobiology Laboratory, NIDA Addiction Research Center, Box 5180, Baltimore MD 21224.

Drug substitution tests in rats trained to discriminate cocaine (10 mg/kg IP) from saline usually reveal dose-related substitution (often partial) by D1 and D2 dopamine agonists. In monkeys, however, neither subtype agonist has clearly engendered cocaine-appropriate responding. We trained independent groups of rats to discriminate 10 or 3 mg/kg cocaine from saline. At the former dose, structurally diverse D1 and D2 agonists produced 40-80% cocaine-lever responding. D2 agonists were less efficacious at the lower than higher training dose, but D1 agonists were equally or more efficacious. Unlike cocaine, cocaethylene and WIN 35,428, which fully substituted, were equipotent across training doses. In squirrel monkeys trained to discriminate cocaine (0.3 mg/kg, IV) from saline, D2 agonists engendered up to 60% cocaine responding, but D1 agonists to date have shown no substitution at all. These results support a potential species difference in the stimulus effects of cocaine, and demonstrate the importance of training dose to the outcome of substitution tests.

566.14

CAGE CLIMBING IN MICE: STUDIES WITH COCAINE. N. L. Katz, H. Ouranos*, L. R. Moser*, D. J. McGinness Grimes* and R. F. Schlemmer, Jr., Dept. of Pharmacodynamics, University of Illinois at Chicago, Chicago, IL 60612.

When Swiss albino mice are placed in a cylinder surmounted by wire mesh, they will climb the mesh briefly and subsequently descend to the cage floor. Then they will spend the majority of time on the floor, climbing intermittently. This activity constitutes normal exploratory behavior. Administration of the drug apomorphine to mice induces compulsive climbing activity. They climb to the top of the mesh and remain in a vertical position for extended periods. Occasionally, they fall, only to quickly arise and resume climbing. As apomorphine is known to stimulate dopamine receptors, climbing behavior is thought to reflect activation of cerebral dopamine receptors. Previous studies suggested that potent agonist activity at central dopamine receptors was required to elicit cage climbing. In the present study, several manipulations were attempted to determine whether or not cocaine can induce cage climbing in mice. To our knowledge, the effect of cocaine on climbing behavior has not been reported. Single doses of cocaine ranging from 1-60 mg/kg injected subcutaneously failed to induce climbing. However, as little as 3 mg/kg acted as a psychomotor stimulant as revealed by locomotor activity measurements. Various doses of cocaine did not alter climbing elicited by simultaneous administration of threshold doses of apomorphine. Climbing failed to occur when cocaine was given with L-DOPA and the monoamine oxidase inhibitor pargyline. A daily injection of cocaine for 3 consecutive days failed to sensitize mice to climbing when they were challenged with cocaine 1 day later. Apomorphine climbing was not influenced when it was given 3 hr after cocaine, i. e., during cocaine withdrawal. These various manipulations could not achieve the degree of stimulation of dopamine receptors required to induce climbing. Other sensitization schedules may reveal cocaine climbing in mice.

566.15

COCAINE-INDUCED CONDITIONED LOCOMOTION: LACK OF *IN VIVO* EVIDENCE FOR ASSOCIATED CONDITIONED NEUROCHEMICAL EVENTS. E.E. BROWN AND H.C. FIBIGER. Division of Neurological Sciences, Dept. of Psychiatry, University of British Columbia, 2255 Wesbrook Mall, Vancouver, B.C. Canada V6T 1Z3

The potent reinforcing effects of cocaine can readily become associated with salient environmental stimuli, which then acquire secondary reinforcing properties. It has been proposed that the reinforcing properties of these conditional stimuli (CSs) are due to the ability of the CSs to elicit similar neural events as the drug itself. Given the large body of evidence that implicates the mesolimbic dopaminergic pathway in the rewarding properites of cocaine, the present study was designed to determine whether stimuli paired with cocaine elicit similar neurochemical changes as cocaine, as assessed by *in vivo* brain microdialysis.

The administration of cocaine (10 mg/kg for 7 days) in association with a specific environment (CS^+) produced significant conditioned locomotion in that environment. Rats that received cocaine in their home cage (CS^-) did not exhibit increased locomotion on the test day, as compared to subjects that received saline in both settings.

When administered acutely, cocaine (10 mg/kg) produced a potent unconditioned effect on interstitial dopamine (300% of basal values) in the nucleus accumbens. In contrast to the ability of repeated pairing of cocaine with a specific environment to produce conditioned locomotion, there was a lack of evidence for concommitant conditional neurochemical events. Specifically, the modest increase in dopamine (10% above basal values) observed after exposure to the conditional environmental stimuli was equal in the CS^+ and CS^- groups. These data do not support the hypothesis that stimuli paired with cocaine produce their behavioural effects by eliciting similar neurochemical effects as cocaine.

566.16

THE RELATIVE CONTRIBUTION OF PERIPHERAL AND CENTRAL COMPONENTS IN COCAINE-INDUCED PLACE CONDITIONING. S.E. Hemby, G.H. Jones, D.B. Neill, & J.B. Justice, Jr. Departments of Psychology and Chemistry, Emory University, Atlanta, GA 30322.

Place conditioning (PC) induced by intraperitoneal (IP) cocaine is considered to be mediated by a local anesthetic and central dopaminergic component (Spyraki et al. 1982). In the present study, cocaine-methiodide, a quaternary salt of cocaine which shares certain pharmacological properties with cocaine but does not permeate the blood-brain barrier, was compared to cocaine for its ability to induce place conditioning when administered either IP or intracerebroventricularly (ICV). Using a completely balanced PC design, rats treated with IP cocaine (15 mg/kg) exhibited a significant preference for the drug-paired compartment on the test day ($P<0.01$). In contrast, rats receiving either cocaine-methiodide (5, 10, or 20 mg/kg) or procaine (25 or 50 mg/kg) did not exhibit a preference. ICV infusions of cocaine (50 μg/2 μl) or cocaine-methiodide (5 or 10 μg/2 μl) produced significant place conditioning for the drug-paired compartment ($P<0.05$). In a separate experiment, IP injections of cocaine (15 mg/kg) increased extracellular dopamine in the NACC, as measured by microdialysis, in addition to increasing locomotor activity while cocaine-methiodide failed to increase either dopamine or locomotor activity. These results suggest that PC induced by IP cocaine is mediated primarily by a central component. Furthermore, the local anesthetic effects produced by cocaine-methiodide and procaine are not sufficient to induce PC with a balanced design.

566.17

PRAZOSIN AND ONDANSETRON ANTAGONISE COCAINE'S EFFECTS ON FIXED-INTERVAL AND FIXED-RATIO BEHAVIOR. F. van Haaren Dept. of Psychology, University of Florida, Gainesville, FL 32611

Three White Carneaux pigeons pecked a key on a multiple fixed-interval (FI) 2 min, fixed ratio (FR) 30 schedule of reinforcement. Cocaine administration 5 min prior to the start of a session (0.3, 1.0, 1.7, 3.0, 5.6 and 10.0 mg/kg) systematically decreased and eliminated FR rates and FI rates in two of the three subjects. FR rates were more affected by lower doses. Response rates of the third subject were not consistently affected by cocaine. Prazosin (alpha$_1$ antagonist) and, later, ondansetron (GR38032F, 5-HT$_3$ antagonist) were co-administered with doses of cocaine which previously decreased response rates. Both prazosin (1.0 mg/kg) and ondansetron (0.10 and 0.50 mg/kg) antagonized cocaine's rate decreasing effects on the FR and FI schedules and reinstated responding where it had previously been totally suppressed. Prazosin and ondansetron in combination with cocaine decreased FR and FI response rates in the subject whose behavior had not been affected by cocaine alone.

566.18

EFFECTS OF REPEATED COCAINE TREATMENT: BEHAVIORAL REORGANIZATION VS. BEHAVIORAL SENSITIZATION. Ernest N. Damianopoulos and Robert J. Carey VA Medical Center, Syracuse, NY 13210

Rats were given 7 daily cocaine injections (50 mg/kg ip) using a Pavlovian conditioning paradigm. Locomotion behavior in terms of meters traversed and rotation patterns grouped into 4 categories of diameter size were measured during daily 20 min tests. Initially, the paired and unpaired groups did not differ on either behavioral measure. By Day 7, however, the paired group exhibited higher levels of locomotion relative to the unpaired group but this effect only reflected the progressive decline in locomotion (habituation) of the unpaired group. Locomotor rotation pattern analysis showed that both the paired and unpaired treatment groups had a similar distribution of rotation frequency across all four categories of diameter size on Day 1 but by Day 7 this rotation pattern changed over into a highly skewed distribution weighted towards the largest diameter size in the paired animals only. Furthermore, the new pattern was retained after a 7-day drug withdrawal period but was exhibited only under drug test conditions. Altogether, the results suggest a context-specific behavioral reorganization rather than a behavioral sensitization.

EFFECTS OF CHRONIC COCAINE ON FOOD COMPETITION IN RAT TRIADS. E. EL-AWADY* AND M.C. WILSON. Dept. of Pharmacol., Sch. of Pharm., Univ. of Mississippi, University, MS 38677.

The purpose of the study was to investigate the effects of cocaine(C) on the competitive behavior of fixed triads of male Wistar rats. Within these triads, rats were ranked during the 4th week of housing according to average competition scores for sucrose pellets. Middle ranking rats were treated daily for 2 wk with C (5.0 mg/kg, IP, b.i.d.). Competition was scored 3-5 hr or 5-7 hr after drug administration. C increased competition scores mainly in the early testing period resulting in some rats achieving the dominant status in the triad.

After treatment, 4 days were designated as a withdrawal period, and 3 additional days as a washout period. The middle ranking rats, based on average scores during the washout period, were treated with C (20 mg/kg, IP, b.i.d for 2 wk). This dose failed to affect the competition; however, competition scores of treated animals increased in all triads during the withdrawal period. This increase declined during washout. Therefore, chronic C affected food competition in time- and dose-dependent manners. (Supported by Res. Inst. of Pharm. Sci.)

CONTINUOUS COCAINE INDUCES PERSISTING BEHAVIORAL AND BIOCHEMICAL CHANGES INVOLVING MUSCARINIC AND BENZODIAZEPINE BINDING SITES. J.W. Lipton[1], M.Waterman[1*], R.W. Olsen[2] and G.D. Ellison[1]. Departments of [1]Psychology & [2]Pharmacology Univ. Calif. Los Angeles, CA 90024.

In attempting to confirm our findings of decreased muscarinic and increased benzodiazepine binding in rat caudate nuclei thirty days after a five day exposure to continuous cocaine, behavioral challenges as well as additional biochemical tests were conducted. Rats were administered continuous cocaine, daily cocaine injections, continuous amphetamine or no drug for 5 days. Forty days after drug exposure, all groups were tested for their responsivity, as measured by automated activity cages, to a low dose of the cholinergic agonist scopolamine. The continuous cocaine group showed a decreased sensitivity to scopolamine as compared to other groups. When tested with a low dose of diazepam, the continuous cocaine group showed the greatest response. However, when observed following an injection of cocaine HCl, the intermittent cocaine group showed the greatest behavioral response. These findings support those of previous studies that indicate the mode of initial cocaine administration is a key factor in the production of persisting changes in behavior. A separate experiment examined the effects of differing exposure lengths of continuous cocaine administration on muscarinic and benzodiazepine binding in the caudate nucleus and hippocampus. Animals were implanted with subcutaneous cocaine pellets for 1, 3 or 5 days, and were sacrificed 12hr, 2 days or 21 days later. Homogenate receptor binding assays were conducted to determine the progressive changes induced by the varying lengths of exposure. Preliminary findings suggest continuous cocaine administration increases benzodiazepine receptor density while decreasing receptor affinity in caudate.

EFFECTS OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA) AND FENFLURAMINE (FFA) ON MOTOR ACTIVITY, BODY TEMPERATURE AND WEIGHT - CHARACTERISTICS OF ACUTE AND REPEATED DOSING. D.B. Miller, K.F. Jensen and J. P. O'Callaghan, U.S. EPA, Res. Tri. Pk., NC 27711.

Research regarding the possible neurotoxicity of MDMA has caused renewed interest in the properties of another amphetamine derivative, fenfluramine (FFA), an anti-obesity drug. MDMA and FFA affect central and peripheral systems dependent on serotonin (5-HT). Both can reduce brain 5-HT levels for many months. MDMA or FFA (0, 5, 10, or 20mg/kg, s.c.) were used to compare 5-HT related endpoints, locomotor activity, body temperature and weight. LE male rats were dosed at 7 AM and 7 PM for 7 consecutive days. Body weights were obtained daily. At 0.5 hr following the 7 AM dose rectal temperatures were obtained and rats were placed in figure-8 mazes for measurement of locomotor activity. MDMA caused hyperactivity at dosages of 10 and 20 mg/kg. Conversely, FFA only produced dose-related decreases in locomotion. Tolerance to the effects of either MDMA or FFA on activity did not occur with repeated administration. MDMA caused hyperthermia with incomplete tolerance to repeated dosing; temperature was still significantly elevated on the final day of dosing. FFA hypothermia was evident at the end of daily maze testing; partial tolerance occurred to this effect. MDMA and FFA reduced body weight as well as food and water consumption during the period of dosing. Both food and water intake returned to control levels within 24 hrs of the last dose. These data suggest MDMA and FFA have different behavioral profiles. SUPPORTED BY NIDA IAG ND-89-4.

CHARACTERIZATION OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA) NEUROTOXICITY USING ASSAYS OF SEROTONIN AND GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP): CHANGES IN SPECIFIC NEOCORTICAL REGIONS IMPLICATE SEROTONERGIC AND NON-SEROTONERGIC TARGETS. J.P. O'Callaghan, K. F. Jensen and D.B. Miller. U.S. EPA, Res. Tri. Pk., NC 27711

Enhanced expression of the astrocyte protein, GFAP, reveals sites of chemical-induced injury to the CNS. By assaying the content of GFAP in specific brain regions we found that the neocortex was a major target for MDMA-induced neurotoxicity. Here we compared the effects of MDMA on GFAP and serotonin (5-HT) in five regions of neocortex to further localize sites of damage. (±) MDMA (25-150 mg/kg, s.c.) was administered to rats twice daily for two days. One group of rats received the 5-HT uptake inhibitor, fluoxetine (10 mg/kg), prior to each dose of MDMA. Rats were killed 2 days post dosing. MDMA depleted 5-HT in a fluoxetine-reversible fashion in all cortical regions. Decrements in 5-HT were as great as 70% but the dose-response relationship was U-shaped; in some regions 5-HT was not depleted at the 150 mg/kg dosage. MDMA increased GFAP by as much as 2-fold in specific regions of frontal and posterior cortex; the effect was graded with dose, detectable at 25 mg/kg, and did not require 5-HT depletion. Fluoxetine antagonized the GFAP increase in frontal but not posterior cortex. These data indicate that MDMA damages serotonergic and non-serotonergic targets in rat neocortex.

CHARACTERIZATION OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA) NEUROTOXICITY USING THE DE OLMOS CUPRIC SILVER STAIN AND GFAP IMMUNOHISTOCHEMISTRY: CHANGES IN SPECIFIC NEOCORTICAL REGIONS IMPLICATE SEROTONERGIC AND NON-SEROTONERGIC TARGETS. K. F. Jensen, D.B. Miller, J.K. Olin*, N. Haykal-Coates and J.P. O'Callaghan. U.S. EPA and *ManTech Environmental. Technology Inc., Res. Tri. Pk., NC 27711.

MDMA (0,25,50,75,100,150 mg/kg) was administered to rats twice a day for 2 days and the animals were sacrificed by transcardial perfusion with fixative under pentobarbital anesthesia 48 hrs postdosing. Additional rats receiving 100 mg/kg were sacrificed at various times after the second and fourth dosages. Frozen sections of the brain were stained with a recent modification of the de Olmos cupric silver stain for neuronal degeneration, GFAP immunoreactivity or cresyl violet. As previously reported, these stains revealed evidence of terminal, axonal and perikaryal degeneration in the neocortex. Such degeneration was dose-dependent and detectable after 25 mg/kg. Degeneration was evident as early as 18 hrs after the second dose of 100 mg/kg and persisted for up to 14 days after the fourth dose. The regional pattern of degeneration did not coincide with known patterns of serotonergic innervation and was only partially blocked by fluoxetine implicating serotonergic as well as non-serotonergic targets.

THE ACUTE AND CHRONIC EFFECTS OF DL-AMPHETAMINE ADMINISTRATION ON BRAIN DNA AND PROTEINS. M. A. Blackshear and B. Quarles*. Dept. of Biological Sciences, Tennessee State University, Nashville, TN. 37209-1561.

The behavioral effects of amphetamine on locomotor activity in crowded and isolated mice have been well documented. This study investigates the effects of amphetamine on brain DNA and proteins after acute and chronic administration. Swiss male mice (26-30g) were used as experimental animals. In the acute studies, the mice received a single injection of 10 mg/kg of dl-amphetamine and were crowded for 30 minutes. In the chronic studies, singly housed mice received daily injections of 10 mg/kg of dl-amphetamine for 14 days. Control animals treated in a similar manner to the drug treated mice received injections of 0.01 ml/gm of physiological saline. DNA was analyzed by phenol-chloroform extraction and the proteins were analyzed by polyacrylamide gel electrophoresis. The administration of a single dose of amphetamine to crowded mice did not appreciably alter whole brain DNA or regional brain proteins. In contrast, chronic amphetamine administration produced differential effects on DNA and proteins. DNA levels were increased in the cortex, but were decreased in the striatum and the midbrain. Brain proteins were unaltered in these regions, except in the midbrain. Repeated amphetamine treatment resulted in a loss of some proteins and an increase in others. The findings suggest that the effects of amphetamine on DNA and proteins may be region specific. Further, these results suggest that the effects of amphetamine are related to exposure time.

WITHDRAWAL-DEPENDENT EFFECTS OF REPEATED AMPHETAMINE ON CALMODULIN CONTENT AND LOCALIZATION IN RAT BRAIN. M.E. Gnegy, G.H. Keikilani Hewlett* and S.L. YEE.* Department of Pharmacology, University of Michigan Medical School. Ann Arbor, MI 48109-0626.

Repeated amphetamine (AMPH) treatment leads to a behavioral sensitization in rats characterized by increases in stereotyped and rotational behaviors. We have found that repeated AMPH increases the Ca^{2+}-binding protein, calmodulin (CaM) in striatum (Roberts-Lewis et al., Brain Res., 384:383, 1986). To determine whether the AMPH-induced increase in CaM shares known characteristics of AMPH-induced sensitization, CaM was measured by RIA in cytosol and 100,000 x g membrane fractions in rat brain areas at 30 min (30m), 2 days (2d) and 30 days (30d) after cessation from an escalating dose regimen of AMPH (from 1 to 8 mg/kg over 4 weeks) or saline. In the 30m group, there was no significant change in CaM in striatum or limbic forebrain but there was a significant decrease in cytosol fractions of frontal cortex and hippocampus. Measurement of CaM 30 min after acute AMPH (8 mg/kg) showed no change in striatal CaM. By 2d, however, CaM was significantly increased in striatal cytosol (60%) and limbic forebrain (40%) membranes over controls. The increased CaM in these fractions was still present 30d after withdrawal. In the 30d group, however, there was no change in CaM in frontal cortex, hippocampus or cerebellum as compared to controls. In the 30d group, challenge with 1 mg/kg AMPH 30 min before sacrifice, elicited a translocation of CaM from membranes to cytosol in the striatum and limbic forebrain of repeated AMPH-treated but not saline-treated rats. Thus the change in CaM occurs in striatum and limbic forebrain, requires time after treatment to develop and exhibits persistence after withdrawal. These are known characteristics of behavioral sensitization to AMPH suggesting that CaM could play a role in the neurochemical changes underlying behavioral sensitization. METHAMPHETAMINE NEUROTOXICITY AND STRIATAL GLUTAMATE RELEASE. B.K. Yamamoto and J.F. Nash. Dept. of Psychiatry, Case Western Reserve Univ., Clev., Ohio 44106

Methamphetamine (MA) neurotoxicity is blocked by the excitatory amino acid antagonist MK801 (Sonsalla et al., 1988). The present study examined in vivo the effects of repeated injections of MA or the MA analog, 3,4 methylenedioxymethamphetamine (MDMA) on extracellular levels of glutamate (GLU) and dopamine (DA) in the rat striatum. Male rats were implanted with microdialysis probes into the anteromedial caudate-putamen. Dialysate samples were collected every 30 min. Following a 1.5 hr stable baseline, vehicle or equimole doses of MA (7.5 mg/kg) or MDMA (9.2 mg/kg) were injected i.p. 3 times every 2 hrs into awake rats. Dialysates were analyzed for amino acids and biogenic amines by HPLC/EC. One week later, rats were sacrificed and the caudate dissected and assayed for DA, 5HT and metabolites. MA produced a cumulative elevation in extracellular GLU resulting in a 9-fold increase 2 hrs after the third injection. In contrast, MDMA produced a non-significant 1.8-fold increase. Each injection of MA or MDMA also produced an immediate and reproducible increase and subsequent decrease towards baseline in extracellular DA levels. DA and HVA tissue content were significantly depleted by 32% and 37% respectively, in MA but not MDMA-treated rats. No changes were detected in 5HT or 5HIAA content. These results provide support for a GLU-mediated mechanism of MA neurotoxicity. These data also suggest that, in contrast to MA, MDMA toxicity may be mediated by a mechanism other than through an elevation in extracellular GLU.

CHRONIC CORTICOSTERONE ADMINISTRATION BLOCKS BEHAVIORAL SENSITIZATION TO AMPHETAMINE. J.R. Pauly, S.R. Robinson and A.C. Collins. Institute for Behavioral Genetics and Dept. of Psychology, U. of Colorado, Boulder, CO 80309.

The biochemical mechanisms that regulate sensitization to amphetamine (AMPH) are not clearly defined although several studies have implicated corticotrophin releasing hormone (CRH) as a possible component of the system. In the present study, female DBA mice were adrenalectomized (ADX) or sham-operated and implanted with 80 mg hormone pellets containing 100% cholesterol, 100% progesterone or a 60% corticosterone/40% cholesterol mixture (CCS60). Following a 3 day recovery period, locomotor activity (number of photocell interrupts in 5 min.) was measured in a circular open field arena, 15 min. following a saline injection. Treatment groups did not differ in activity following the saline challenge. On the 4 subsequent testing days, saline administration was continued for some animals while others received AMPH (5.0 mg/kg). CCS60 animals (SHAM and ADX) were initially more sensitive to AMPH than other treatment groups but did not develop behavioral sensitization. ADX animals were initially insensitive to AMPH but developed sensitization, although the magnitude was not the same as in sham-operated animals. Animals with progesterone implants had patterns of sensitization that were identical to control animals. CRH levels in the CCS60 animals are probably negligible due to enhanced negative feedback by high plasma CCS levels that persist throughout the duration of testing. These data support the hypothesis that drug-induced changes in the hippocampal-pituitary-adrenal-axis may underscore the development of behavioral sensitization to AMPH. THE NMDA RECEPTOR ANTAGONIST MK-801 BLOCKS THE DEVELOPMENT OF SENSITIZATION TO THE LOCOMOTOR ACTIVATING EFFECTS OF AMPHETAMINE IN THE RAT.
P. Vezina and B. Zurakowski*. Neurosciences, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario K1Y 4E9 Canada.

The NMDA receptor has been shown to be involved in long-term potentiation and kindling as well as in some types of learning and memory. In the present study, the possibility that this receptor might also play a role in the development of sensitization to the locomotor activating effects of amphetamine was examined. The ability of the NMDA receptor antagonist MK-801 to block its development was assessed. Different groups of rats were injected with either saline or MK-801 (0.3 mg/kg, i.p.) prior to each of five injections of amphetamine (1.0 mg/kg, i.p.) or saline given every third day. On a subsequent test for sensitization, all animals received saline followed by amphetamine (0.5 mg/kg, i.p.). Animals' locomotor activity was monitored following all injections. MK-801 by itself produced dramatic increases in locomotion but, unlike those produced by amphetamine, these did not increase with repeated injections nor did they produce enhanced responding to amphetamine on the test for sensitization. More importantly, animals receiving MK-801 prior to each amphetamine injection showed no evidence of sensitized locomotion on the subsequent test. These results are consistent with those of earlier reports (Karler et al., Life Sci., 45: 599, 1989) and suggest that NMDA receptors play an important role in the development of sensitization to the locomotor effects of amphetamine. They also demonstrate that the repeated elicitation of increased locomotion by itself is not sufficient to produce sensitized locomotor responding.

567.9

ATTENUATION OF THE LOCOMOTOR ACTIVITY AND THE STRIATAL AND NUCLEUS ACCUMBENS DOPAMINERGIC RESPONSES TO AMPHETAMINE BY NALOXONE . M.S. Hooks, D.N.C. Jones, J.B. Justice, Jr., and S.G. Holtzman, Deptartments of Chemistry and Pharmacology, Emory University School of Medicine, Atlanta GA, 30322

Naloxone (NX), an opioid antagonist, has been shown previously to reduce behavioral effects of amphetamine (AMPH) in rats. The neurochemical basis of this interaction is unknown, but could be due to the ability of NX to attenuate the dopaminergic response to AMPH. The present study tested this possibility by determining the effects of NX on 1) stimulation of locomotor activity by AMPH, and 2) AMPH induced release of dopamine (DA) in the striatum (STR) and the nucleus accumbens (NACC) using in vivo microdialysis.

In the first experiment, rats were initially treated with either NX (5 mg/kg) or saline and 30 min later received increasing cumulative doses of AMPH (0.0, 0.1, 0.4, 1.6, and 6.4 mg/kg) at 30 min intervals. Gross locomotor counts following AMPH administration were significantly lower for rats pretreated with NX than for rats pretreated with saline ($p<0.005$). In the second experiment the same drug treatments were given in addition to microdialysis in either the STR or NACC. There was an overall decrease ($p<0.05$) in STR DA concentration between rats treated with NX and those treated with saline. This difference occurred only after AMPH injection and was dose-dependent, ($p<0.0001$). No overall differences were observed in dopaminergic response in the NACC between the two groups, although a Treatment x Time interaction was observed, ($p<0.001$) due to differences between the groups during the later portion of response to 6.4 mg/kg AMPH. There was also a difference in locomotor activity following AMPH treatment between NX and saline treated subjects which were dialyzed, ($p<0.0005$). The STR rats treated with saline showed a larger % increase in DA levels, ($p<0.001$) following AMPH treatment than the NACC rats treated with saline. No differences between STR and NACC dopaminergic responses were observed in NX pre-treated rats.These findings suggest that a decrease in the dopaminergic response to AMPH is the mechanism by which NX attenuates behavioral stimulant effects of AMPH. (Supported in part by grants DA00541 and RSA DA00008).

567.10

REPEATED ADMINISTRATION OF MK-801 PRODUCES SENSITIZATION TO ITS OWN LOCOMOTOR STIMULANT EFFECTS BUT BLOCKS SENSITIZATION TO AMPHETAMINE
M.E. Wolf and M.R. Khansa. Department of Psychiatry, Cellular and Clinical Neurobiology Program, Wayne State Univ. Sch. of Med., Detroit, MI, 48207.

Repeated administration of amphetamine (AMPH) results in an augmentation of the locomotor stimulant effects elicited by subsequent AMPH challenge. The present study examined the possibility that this behavioral sensitization may require stimulation of N-methyl-D-aspartate (NMDA) receptors. Rats received injections of saline, AMPH (1 mg/kg), the NMDA antagonist MK-801 (0.25 mg/kg), or AMPH + MK-801 on days 1-3 and 6-10. Rats were tested for horizontal locomotor activity on several treatment days to verify that a progressive augmentation of responsiveness to AMPH was occurring. On day 14, all rats were challenged with 0.5 mg/kg AMPH and tested for locomotor activity. Sensitization was observed only in the repeated AMPH group, indicating that coadministration of MK-801 blocked the development of sensitization. On day 17, all rats were challenged with 0.25 mg/kg MK-801. The MK-801 and AMPH + MK-801 groups showed robust sensitization, indicating that repeated MK-801 produced sensitization to its own locomotor stimulant effects and that this was not blocked by AMPH coadministration. On day 13, all rats were challenge with saline. The AMPH group showed greater activity than the saline group, suggesting the development of conditioned locomotion. However, conditioned locomotion was blocked by coadministration of MK-801. These results suggest that behavioral sensitization may resemble long-term potentiation, a more thoroughly characterized form of synaptic plasticity, in that both require NMDA receptor stimulation for their induction. *In vivo* microdialysis studies are underway to examine dopamine-glutamate interactions which may account for these findings. Supported by NARSAD and the PMA Foundation.

567.11

INJECTION OF 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA) INTO THE NUCLEUS ACCUMBENS SEPTI (NAS) PRODUCES BEHAVIORAL ACTIVATION IN RATS. C.W. Callaway, M.A. Geyer. Department of Psychiatry, UCSD School of Medicine, La Jolla, CA 92093-0804.

MDMA is a derivative of amphetamine that potently increases release of both serotonin (5-HT) and dopamine (DA). Systemic administration of MDMA to rats produces locomotor hyperactivity that is dependent upon 5-HT release (JPET 254: 454-464). This study examined the contribution of different sites to the behavioral effects of MDMA. Male sprague-dawley rats were surgically fitted with guide tubes for intracranial microinjections. Behavioral testing began at least one week post surgery and employed a behavioral pattern monitor (BPM) in which infrared photobeams tracked the position of the rat inside a 30.5 x 61 cm Plexiglas box. Injection of MDMA (10 or 30 ug in 1 ul) into the NAS produced locomotor hyperactivity lasting 30-40 min. Injections of MDMA (10 ug) into the dorsolateral caudate were ineffective. Although the locomotor activating effects of systemically administered MDMA are antagonized by pretreatment with 5-HT uptake inhibitors, fluoxetine pretreatment (10 mg/kg) did not alter the response to intraaccumbens MDMA. Furthermore, a congener of MDMA that more selectively releases 5-HT, MBDB (3, 10 or 30 ug), did not produce hyperactivity when administered into the NAS. Previous studies found that MBDB and MDMA have similar behavioral effects after systemic administration. These studies thus suggest that MDMA administered into the NAS produces behavioral activation by virtue of the DA releasing properties that MDMA shares with amphetamine and not via the 5-HT releasing properties that MDMA shares with MBDB.

567.12

THE NON-COMPETITIVE NMDA ANTAGONIST, MK801, BLOCKS THE DEVELOPMENT OF CONDITIONED ACTIVITY TO AMPHETAMINE (AMPH). J. Stewart and J.P. Druhan. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montréal, Québec, Canada, H3G1M8.

It has been reported (Karler et al,1989) that preinjections of MK801 block the development of behavioral sensitization to repeated intermittent injections of AMPH, suggesting that NMDA receptor activation is directly involved in the neural changes underlying sensitization. It is known, however, that when preexposure to AMPH is explicitly paired with the testing environment, the expression of sensitization is environment-specific and animals tested under saline show conditioned behavioral activation in that environment. We compared the development of conditioned activity to 1.5 mg/kg AMPH in animals pretreated with either 0.25 mg/kg MK801 or saline prior to activity box injections, using a conditioning procedure in which groups of animals received AMPH in the activity boxes and saline in the home-cage, saline in the activity boxes and AMPH in the home-cage, or saline in both environments. On a test for conditioning, when all animals received only saline in the activity boxes, no evidence for conditioned activity was found in animals previously given AMPH there in the presence of MK801, suggesting either that MK801 blocks the development of conditioned control of sensitization to AMPH and not the development of sensitization, per se, or that MK801 interferes with the unconditioned action of AMPH preventing the development of both conditioning and sensitization.

567.13

AMPA/KAINATE GLUTAMATE RECEPTOR ANTAGONISTS IN THE NUCLEUS ACCUMBENS SELECTIVELY DECREASE THE HYPERMOTILITY RESPONSE TO AMPHETAMINE. D.L. Willins*, L. J. Wallace, M.C. Gerald, and N.J. Uretsky. College of Pharmacy, The Ohio State University, Columbus, OH 43210.

Previous studies show that activation of AMPA and/or kainate (A/K) receptors in the nucleus accumbens (NA) stimulates locomotor activity (LMA). In the present study experiments were conducted in order to determine whether A/K receptors in the NA play a role in the hypermotility response to the psychostimulant drugs, amphetamine, caffeine, and scopolamine. Both DNQX (1 µg/0.5 µl) and GAMS (5 µg/0.5 µl), which are A/K receptor antagonists, injected bilaterally into the NA inhibited the hypermotility responses to D-amphetamine (0.5 mg/kg, s.c.) but not to caffeine (20 mg/kg, s.c.) or scopolamine (0.5 mg/kg, s.c.). In contrast, AFQX, a chemical analog of DNQX which has very low potency in competing for AMPA binding sites, did not inhibit LMA elicited by amphetamine. Neither A/K antagonist significantly affected LMA in control animals. These findings suggest that activation of A/K receptors in the NA is important in amphetamine-stimulated locomotion. Since the response to amphetamine, but not caffeine or scopolamine, is mediated by endogenous dopamine in the NA, the results suggest an association between glutamatergic and dopaminergic transmission at this site.

567.14

EFFECTS OF INTRA-ACCUMBENS INJECTION OF THE GLUTAMATE ANTAGONIST DNQX ON PLACE PREFERENCE AND LOCOMOTOR ACTIVITY INDUCED BY AMPHETAMINE. R.T. Layer, N.J. Uretsky, and L.J. Wallace. College of Pharmacy, Ohio State University, Columbus, OH 43210.

Dopaminergic terminals within the nucleus accumbens (NA) mediate locomotor activity (LMA) and positive reinforcement elicited by amphetamine. Glutamatergic afferents to the NA from limbic structures may also participate in these effects. The purpose of this study was to determine whether an AMPA/kainate receptor antagonist within the NA could inhibit amphetamine-induced LMA or reinforcement as measured by conditioned place preference (CPP). Rats were trained for 8 days, with 4 amphetamine pairings (1 mg/kg, sc) to one compartment and 4 saline pairings to the other. One group of rats received DNQX (1 µg/0.5 µl) in the NA via implanted cannulae at the time of amphetamine injections. Rats were tested for CPP on the 9th day. LMA was monitored on all training and test days. Consistent with data from open field tests, DNQX inhibited amphetamine-induced LMA by 60% during the first training session. However, DNQX reduced LMA by only 20% on the 2nd amphetamine training day and not at all in the final two training sessions. Thus, the interaction between dopaminergic and glutamatergic neurons in the NA may change with exposure to amphetamine. This confounding variable makes interpretation of CPP data difficult, although preliminary data suggest that DNQX treatment inhibits amphetamine-induced CPP.

567.15

MK-801 PARTIALLY ANTAGONIZES THE LOCOMOTOR AND STEREOTYPIC EFFECTS OF METHAMPHETAMINE. G.M. Farfel, N.E. Ferguson and L.S. Seiden. Department of Pharmacological & Physiological Sciences, The University of Chicago, Chicago, IL 60637.

MK-801, a non-competitive NMDA receptor antagonist, has been shown to attenuate both behavioral sensitization (Karler, et al., Life Sci., 45:599-606) and dopaminergic neurotoxicity (Sonsalla, et al., Science, 243:398-400) produced by repeated administration of psychomotor stimulants. To determine whether MK-801 (MK) antagonizes behaviors elicited by a neurotoxic regimen of methamphetamine (MA), rats (n=16/group) were administered 4 injections of either MA (10 mg/kg) or saline (S; 1 ml/kg) i.p., spaced 1 h apart. In addition, half of the rats in each group received MK (2.5 mg/kg) and half received S (1 ml/kg) i.p., 15 min before and 3 h after the first MA or S injection. Two observers scored the animals' behavior 1 h after the first MA or S injection, and 1, 4, 12, 24 and 48 h after the last injections. Differences in behaviors between treatment groups were assessed using Kullback's information statistic. One hour after the first injection, locomotor activity (LMA) was higher in the MK/MA and MK/S animals than in the S/MA and S/S groups, while the S/MA group scored higher in sniffing than the others. Piloerection (PILO) was higher in the S/MA and MK/MA groups than in MK/S and S/S. One hour after the last injection, the S/MA group scored higher in LMA than the others, while the MK/MA group scored highest in splayed body and the MK/S group exhibited significant swaying. PILO was not different in any group at this time point, but the S/MA group exhibited exopthalmia which was significantly different than either S/S or MK/MA. By 4 h, MK/MA animals scored higher than the others in LMA, rearing or falling (from a rearing position), while S/S and S/MA were not moving. At 12, 24 and 48 h, behaviors did not differ between groups. The results indicate that MK-801 attenuates the stereotypic and locomotor behaviors engendered by a neurotoxic regimen of MA. MK-801 also attenuates MA-induced exopthalmia but not piloerection. (Supported by DA-00085.)

RESPONSE SPECIFICITY IN THE INFLUENCE OF A SHOCK-POSTPONEMENT SCHEDULE ON THE EFFECTS OF *d*-AMPHETAMINE AND COCAINE ON PUNISHED RESPONDING IN SQUIRREL MONKEYS. T. Tatham* and J.E. Barrett. Behavioral Pharmacol. Lab., Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Squirrel monkeys' low-rate punished lever pressing (food-reinforced fixed-interval schedule with superimposed fixed-ratio shock) is reliably unaffected or decreased by *d*-amphetamine (AMP). However, concurrent or prior exposure to a shock-postponement (avoidance) schedule causes AMP to dramatically increase punished responding, thereby reversing the typical effects of AMP. The present research examined whether exposure to avoidance, per se, reverses AMP's effects or whether the reversal of effects occurs only when both avoidance and punishment are within the same response system (lever-pressing). The present research arranged the contingencies on distinctive manipulanda -- punishment on a lever and avoidance on a pull-chain; the effects of AMP and cocaine were determined before and after exposure to chain-pull avoidance. In contrast to the effects of arranging both contingencies on the same manipulandum, the present procedure produced no appreciable differences in the effects of either drug on punished responding, suggesting that the reversal of cocaine and AMPs' effects is restricted to the response modality in which avoidance is presented. This research was supported by DA 06828.

A DRUG DISCRIMINATION ANALYSIS OF *l*-DEPRENYL. S. Yasar, C.W. Schindler, C. Cohen*, E.B. Thorndike*, S.R. Goldberg* and I. Szelenyi*#. NIDA Addiction Research Center, Baltimore, MD 21224 and #ASTA Pharma AG, Frankfurt, FRG.

The potential antiparkinsonian agent *l*-deprenyl is a selective inhibitor of B-type monoamine oxidase (MAO). However, *l*-deprenyl is an amphetamine derivative which is metabolized *in vivo* to *l*-amphetamine. As the clinical use of amphetamine-like psychostimulants is limited by development of tolerance and dependence, we tested *l*-deprenyl for amphetamine-like and for cocaine-like discriminative stimulus effects. The discrimininative stimulus properties of *l*-deprenyl were studied in *d*-amphetamine-trained and in cocaine-trained animals using a drug discrimination paradigm (shock discrimination test). We also examined *d*-deprenyl for *d*-amphetamine-like discriminative stimulus effects to determine the stereospecificity of the isomers of deprenyl.

Male Fisher rats were trained under a fixed-ratio 5 (FR 5) schedule of stimulus shock termination to respond on one lever after an i.p. injection of either 1.0 mg/kg *d*-amphetamine or 10.0 mg/kg cocaine and on the other lever after no-drug treatment. *l*-Deprenyl (2.0-17.0 mg/kg) generalized to neither *d*-amphetamine nor to cocaine. In contrast to *l*-deprenyl, *d*-deprenyl, which would be metabolized to *d*-amphetamine, generalized to the *d*-amphetamine stimulus dose-dependently (2.0-10.0 mg/kg). These results suggest that, contrary to a previous report (Psychopharmacology **101**, S40), *l*-deprenyl does not consistently generalize to *d*-amphetamine. Furthermore, in additional experiments, *l*-deprenyl (2.0 mg/kg) given 1 hour before the *d*-amphetamine injection, did not shift the dose-response curve of *d*-amphetamine, further indicating a lack of interaction of these compounds as discriminative stimuli. These data confirm clinical findings, that *l*-deprenyl is free of abuse potential.

NEURONAL SUBSTRATES OF THE DISCRIMINATIVE STIMULUS EFFECTS OF D-AMPHETAMINE. B. J. Van Groll and J. B. Appel. *Behavioral Pharmacology Laboratory, Department of Psychology, University of South Carolina, Columbia, SC 29208.*

In two experiments, 36 rats were trained to discriminate 1 mg/kg of *d*-amphetamine from saline; they were then given compounds that purportedly act selectively at different NE, DA or 5-HT_3 receptor subtypes, either alone or in combination with the training drug. Adrenergic agonists (clonidine, salbutamol, nisoxetine) did not mimic and NE antagonists (yohimbine, propranolol) did not block the d-amphetamine cue. While several compounds that stimulate postsynaptic DA receptors (metoclopramide, SKF 23390 and quinpirole) did not have amphetamine-like properties, sufficiently high doses of the DA uptake inhibitor GBR 12909 mimicked, and at least one dose of Sch 23390 (0.75 mg/kg) blocked the training stimulus. Two 5-HT_3 antagonists (MDL-72222 and ICS 105-290) did not substitute for, but did potentiate the effects of low doses (0.25-0.4 mg/kg) of *d*-amphetamine; this potentiation was blocked by prazocin. It was concluded that both inhibition of DA uptake and 5-HT_3 receptor mechanisms might be involved in the discriminative stimulus effects of *d*-amphetamine.

CARDIOVASCULAR EFFECTS OF METHAMPHETAMINE IN SQUIRREL MONKEYS. C.W. Schindler, J.-W. Zheng*, S. R. Tella* and S.R. Goldberg*. NIDA Addiction Research Center, Baltimore, MD 21224 and Georgetown University School of Medicine, Washington, DC 20007.

The recent discovery of the abuse of methamphetamine (METH) in a smokable form known as "ice", suggests that abuse of this drug may be increasing. As such, it is important to investigate the potential toxic consequences of its abuse. We studied the effects of METH on cardiovascular function in squirrel monkeys, a model we have used extensively to study the cardiovascular effects of cocaine. Squirrel monkeys were implanted with chronic arterial and venous catheters and the effects of METH were studied while the animals were conscious and seated in a standard squirrel monkey restraining chair. METH (0.1-3.0 mg/kg, i.v.) produced a dose-dependent increase in blood pressure. Its effects on heart rate were more complex, with lower doses (0.1-0.3 mg/kg) producing increases in heart rate and higher doses (1.0-3.0 mg/kg) producing decreases. To determine the pharmacological mechanisms involved in METH's effects, we tested a number of drugs as pretreatments to an injection of 0.2 mg/kg METH. This dose produced a maximal heart rate increase. The alpha-1 antagonist prazocin (0.1 mg/kg, i.v.) completely antagonized the effects of METH on blood pressure, while the beta antagonist propranolol (3.0 mg/kg, i.v.) completely antagonized the tachycardiac effect of METH. Propranolol also appeared to potentiate the effects of METH on blood pressure by prolonging its effect. These effects are similar to those observed previously with prazocin and propranolol when tested against cocaine (FASEB J. 5, A1587). Unlike its effects against cocaine (Life Sci. 48, 1547), however, the dopaminergic antagonist haloperidol (0.03 mg/kg, i.m.) antagonized both the pressor and tachycardiac effects of METH. Thus, while METH and cocaine produce similar effects on cardiovascular function, they may be mediated through different mechanisms, with dopaminergic mechanisms being more important for METH than for cocaine.

ETHANOL REGULATES TYROSINE HYDROXYLASE GENE EXPRESSION IN N1E-115 NEUROBLASTOMA CELLS. Greg G. Gayer*†, Adrienne Gordon†¶ and Michael F. Miles¶ Ernest Gallo Research Center and, Departments of †Pharmacology and ¶Neurology, Univ. of Calif., San Francisco, CA 94143. Previous studies show that changes in catecholoamines contribute to neurophysiologic effects of ethanol. We have therefore studied ethanol-induced changes in tyrosine hydroxylase (TH), the rate-limiting enzyme for catecholamine biosynthesis, in N1E-115 neuroblastoma cells. Northern and Western blot analyses showed that a 3 day treatment with 25-200 mM ethanol caused a dose-dependent increase in TH-mRNA and protein levels in N1E-115 cells. Subclones of N1E-115 stably transfected with a plasmid containing the TH promoter fused to a chloramphenicol acetyltransferase (CAT) reporter gene showed ethanol-induced increases in CAT activity. These data suggests that ethanol modulates TH gene transcription. Simultaneous treatment of transfected cells with 100 mM ethanol and either 1 mM prostaglandin E_1, 10 mM (-)-N^6-(R-phenylisopropyl)-adenosine, or 0.5 mM 8-bromo-cAMP, potentiated TH-promoter activity when compared to treatment with the respective agents without ethanol. These results suggest that chronic ethanol has a prominent effect on both basal and cAMP-regulated TH expression. Using deletion analysis of the cis-acting regulatory sequences of the TH-promoter, the regions responsible for both basal and cAMP-mediated ethanol induction were characterized. Ethanol-induced changes in TH expression may be a critical aspect of central nervous system adaptation to chronic ethanol exposure.

LONG TERM EFFECT OF PRENATAL METHADONE EXPOSURE ON NEUROPEPTIDE EXPRESSION IN RAT HYPOTHALAMUS. J. W. Nemitz. W VA School of Osteopathic Medicine, Lewisburg, W VA, 24901.

Previous work provided evidence that prenatal methadone exposure results in a decrease in mRNA expression for proenkephalin (ENK), oxytocin (OT), and arginine-vasopressin (AVP) in hypothalamic nuclei of the neonatal rat. The present study examined the mRNA expression of these neuropeptides in hypothalamic nuclei of older rats that were prenatally exposed to methadone.

Adult, female, Sprague-Dawley rats made physically dependent to methadone (9mg/kg/day) by an osmotic minipump (Alzet), were mated and the pregnancies brought to term. Offspring were sacrificed by decapitation between ages six months to one year after birth. Frozen serial coronal sections (20 um) obtained at the level of the hypothalamus were processed for in situ hybridization using ^{35}S-oligonucleotide probes (DuPont). Results indicate that OT and AVP mRNA levels are increased in the retrochiasmatic supraoptic nucleus (RSO) of the hypothalamus of prenatally methadone exposed rats as compared to controls. Differences were not observed in the paraventricular (PV) and supraoptic (SO) nuclei. Results for ENK mRNA expression will also be presented. These data suggest that prenatal methadone exposure can result in selective long lasting changes in neuropeptide expression for a hypothalamic nucleus. Supported by WVSOM funds.

mRNA EXPRESSION PROFILES AFTER OPIATE TREATMENT IN CELL CULTURE & THE RAT CNS. SA Mackler & JH Eberwine. Dept of Pharmacology, Univ of Pa School of Medicine, Phila PA 19104

Opiate use alters the amounts of several proteins. The present studies use the *in vitro* amplification of RNA from limited amounts of tissue (aRNA;PNAS87:1663) to define the composite of relative changes in mRNA abundance which result from opiate stimulation or withdrawal of stimulation.

NG108-15 cells were exposed to 10nM DADLE or 10nM DADLE followed by 100uM naloxone for varying time periods to achieve maximal delta opiate receptor down- and up-regulation, respectively. PolyA+ RNA was isolated and synthesized into 32-P labeled aRNA. This was hybridized to blots containing several cDNA clones and comparisons made among the individual autoradiographic bands. Both receptor stimulation & withdrawal of stimulation resulted in increased signals for the proto-oncogenes fos & jun and decreased signals for K+ channels. Naloxone increased the signal for the Na+ channel & DADLE use increased the signal for the G protein stimulatory alpha subunit.

Male adult rats received subcutaneous pellet administration of either morphine or a placebo for three days. Coronal sections of the striatum underwent *in situ* transcription of the polyA+ RNAs, which were processed for aRNA synthesis. These aRNAs were also used to screen similar cDNA-containing gel blots. Morphine treatment again decreased the signals for the K+ channels & increased the signals for fos, jun, & Gs alpha. There was also an increased signal for the Na+ channel.

These studies demonstrate several changes in gene expression as a consequence of opiate use and provide hypotheses for testing the molecular mechanisms of addiction.

EFFECTS OF PRENATAL MORPHINE ON ADULT SEXUAL BEHAVIOR AND ON BRAIN CATECHOLAMINES IN RATS. Ilona Vathy. Dept. Psychiatry, Albert Einstein Coll. Medicine, Bronx, NY 10461.

Female rats exposed to morphine sulphate (MS) in utero (5-10 mg/kg twice a day on days of 11-18 of gestation) were substantially inhibited in their adult sexual behavior when compared to saline-exposed (S) controls. In contrast, males exposed prenatally to MS had shorter post-ejaculatory intromission latencies and exhibited increased mounting and intromitting activity relative to controls. Examination of the catecholamine content in the preoptic area (POA) and in the hypothalamus (HYP) also revealed that prenatal MS treatment affects males and females differently. Norepinephrine (NE) and dopamine (DA) content in the HYP of S and MS-treated females were essentially identical; however, NE and DA levels in the POA of MS-treated females were decreased about 60%. NE content in the HYP of MS-treated males was increased about 50% relative to that in S-exposed animals while the DA content was not affected. In addition, the DA content was decreased (30%) and the NE content increased (30%) in the POA of MS males when compared to controls. These results suggest that prenatal MS exposure, which differentially affects adult male and female sexual behavior, also alters the content of catecholamines in the HYP and POA in a sexually dimorphic fashion. CP55940 HAS THC-LIKE DISCRIMINATIVE STIMULUS EFFECTS IN RATS. L.H. Gold, R.L. Barrett, R.L. Balster and B.R. Martin*. Dept. of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

CP55940, a phenyl-cyclohexanol derivative, is a potent bicyclic analog of Δ9-tetrahydrocannabinol (THC) which has been used as a probe for a cannabinoid recognition site in neural tissue. In the present study, CP55940 was evaluated in rats trained to discriminate THC (3.0 mg/kg, ip) from vehicle in a two-lever operant procedure. In addition, catalepsy was measured using an adaptation of the mouse ring-test. Dose-effect relationships were established for the training drug (THC 0.01-10.0 mg/kg, ip) and CP55940 (0.003-0.3 mg/kg, ip) at 30 and 90 min after injection. CP55940 substituted completely for THC at both time periods at a dose (0.1 mg/kg) that had minimal effects on rate of responding. CP55940 was about 10-30-fold more potent than THC, consistent with its greater affinity for the cannabinoid site. Doses of THC (>3.0 mg/kg) and CP55940 (>0.1 mg/kg) that reduced response rates by greater than 50% were associated with substantial increases in immobility. A study of the duration of drug effects revealed that both CP55940 (0.1 mg/kg) and THC (3.0 mg/kg) produced diminished levels of THC-lever responding by 360 min post-injection. These results support the use of this potent cannabinoid as a probe for the neural substrate mediating the behavioral responses to THC.

Pharmacological Characterization of Stably Expressed Rat and Human Marijihuana Receptor Clones

*Christian C. Felder, *Jeffrey S. Veluz, *Holly L. Williams, Ted B. Usdin, *Lisa A. Matsuda, Laboratory of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892

Both rat and human cannabinoid receptor clones were stably expressed in mammalian fibroblast cells. Activation of the cloned receptor with various natural and synthetic cannabinoid ligands demonstrated rank order potency and efficacy for the inhibition of forskolin-stimulated cAMP accumulation similar to previously published data using cells containing native cannabinoid receptors. Other second messenger pathways were tested for possible cannabinoid receptor-mediated activation. Cannabinoid receptor activation stimulated calcium influx independent of IP_3 and intracellular calcium release. Potent cannabinoid agonists, CP55,940 and HU-210 (1,1-dimethylheptyl-7-hydroxy-delta-6-tetrahydrocannabinol), and the inactive enantiomer HU-211, stimulated arachidonic acid release at concentrations above 10uM in cells expressing the cannabinoid receptor and in untransfected control cells. These results suggest that cannabinoid ligands stimulate arachidonic acid release through a non-receptor mediated mechanism and only at elevated concentrations. No functional difference was observed between the rat and human cannabinoid receptor for the second messenger pathways tested.

TETRAHYDROCANNABINOL EFFECTS ON BRAIN STIMULATION REWARD AFTER SUBACUTE HALOPERIDOL OR AMPHETAMINE. M. Borrero* and B. Hine. U. of Puerto Rico Sch. Pharm., San Juan, PR 00936.

Using a brain stimulation reward (BSR) procedure that has demonstrated threshold decreases and response rate increases after low morphine doses (Psychopharm. 102:309, 1990), we have found non-uniform changes in BSR thresholds after low doses of Δ^9-tetrahydrocannabinol (THC) in Lewis and SD rats (The FASEB Journal 5: A703, 1991). Since the BSR threshold lowering effect of THC only in Lewis rats, reported by Gardner, has been related to facilitation of mesolimbic dopamine (DA) release by THC (Psychopharm. 96: 142, 1988; 102: 156, 1990), we tested the hypothesis that THC would lower BSR thresholds, and/or increase response rates, in SD rats that were sensitized to DA agonists. Twelve days after withdrawal from osmotic pump infusion of haloperidol (0.4 mg/rat/day for 14 days), significant increases in BSR rates occurred in male SD rats, and this treatment attenuated the threshold increases seen after 0.5 and 1.0 mg/kg THC doses; THC-induced threshold decreases were not seen at other doses, nor did they occur reliably in female SD rats receiving similar THC challenge doses 11 days after withdrawal from a week of daily d-amphetamine sulfate injections, a procedure reported to increase mesolimbic DA utilization in female rats (Robinson: Brain Res. 343: 374, 1985). The basis for the reported strain-specific BSR threshold lowering effect of THC is not apparent and requires further investigation to clarify the conditions that permit unequivocal designation of THC as a rewarding drug. EFFECTS OF PEDUNCULOPONTINE TEGMENTAL NUCLEUS LESIONS ON MORPHINE INDUCED CONDITIONED PLACE PREFERENCE AND ANALGESIA IN THE FORMALIN TEST. M.C. Olmstead and K.B.J. Franklin. Dept. Psychology, McGill University, Montreal, Canada, H3A 1B1

The pedunculopontine tegmental nucleus (PPTg) receives projections from limbic structures associated with reward systems, and it has been suggested that the region is a critical site in neural systems subserving the rewarding effects of morphine. There is also evidence that analgesia in the formalin test depends on the neural systems that mediate the rewarding properties of drugs. Bechara and Van der Kooy (1989) demonstrated that PPTg lesions block the rewarding properties of morphine: we predicted a correlation between attenuation of morphine induced reward and analgesia in these animals. We have confirmed that excitotoxin lesions of the PPTg block development of conditioned place preference to morphine. In the same animals, morphine induced analgesia was reduced, but not eliminated. The reduction of reward and/or analgesia was not significantly correlated with the loss of cholinergic cells in the PPTg, suggesting that the neural substrates mediating morphine reward and analgesia involve the PPTg, but are not dependent on the cholinergic cells in the region. Further studies demonstrated that PPTg lesioned animals display reduced pain scores when tested in the absence of analgesics. During behavioral testing and handling, we observed that sham and lesioned animals differ in their motor abilities. For example, sham and lesioned animals differed in measurements of spontaneous motor activity and catalepsy in both morphine and drug free trials. Furthermore, neurological tests revealed that PPTg lesioned animals exhibit motor abnormalities, including problems with postural support and muscle tone. We believe that the hyperactivity and motor abnormalities that PPTg lesioned animals exhibit may interfere with the expression of pain in the formalin test, resulting in reduced pain scores compared to shams.

MORPHINE REDUCES THE AVERSIVENESS OF NOVEL QUININE SOLUTION. L.A. Parker. Department of Psychology, Wilfrid Laurier University, Waterloo, Ontario, Canada, N2L 3C5.

The ability of morphine (2 mg/kg, sc) to modify the palatability of .05% quinine solution and 20% sucrose solution was assessed in Sprague-Dawley rats using the Taste Reactivity (TR) test. The TR test is a direct measure of the palatability of tastants. Morphine suppressed the aversive TR responses of chin rubbing, gaping and paw treading elicited by quinine on the first 10 minute test trial without modifying general activity level (horizontal and vertical). The effects of morphine on the palatability of sucrose solution were minimal.

ANABOLIC STEROIDS DISRUPT LATENT INHIBITION. M.J. Kelley[1]*, R.B. Messing[1,2], E. Nwokolo[1] and S.B. Sparber[1]. [1]Pharmacology Dept., [1]Univ. of Minnesota, [2]Minn. Dept. Health, Mpls. MN 55455.

Latent inhibition (LI) was studied in male rats by exposures to a Skinner box prior to administering grid shock in the box. Control rats were exposed to a nesting cage followed by shock in the Skinner box. Conditioned-freezing behavior 24-hr after shock was the dependent variable. In the first experiment, testosterone (13.5 mg/kg), or an equimolar dose of nandrolone or olive-oil vehicle were administered seven times over 17 days, prior to and concurrent with the LI procedure (N = 36). A second multi-dose experiment assessed LI 10-months after the administration of anabolic steroids during "adolescence" (N = 73). Both experiments showed a LI effect with vehicle ($p < .01$) but not the testosterone groups. Nandrolone administered 10-months earlier also disrupted LI but had a marginal effect when concurrent with LI testing. Andogenic (testosterone and nandrolone) and estrogenic (metabolism of testosterone) effects may be differentially involved in acute versus enduring influences on LI. Supported in part by USPHS grant DA011979 and MMF grant SMF68-90.

GABA LEVELS IN DIALYSATE OF RAT PERIAQUEDUCTAL GRAY DURING MORPHINE ADMINISTRATION. Y.F.Jacquet, E.Yablonsky-Alter and R.L.Napolitano*, Nathan Kline Institute, NY, 10962, CCNY Med. Sch., NY, 10031, and Bioanalytical Systems, W. Lafayette, Ind., 47906.

The role of GABA in opiate-induced analgesia remains unclear. Intraperitoneal (IP) administration of GABAergic drugs was found to potentiate morphine analgesia,while intracerebral (IC) injections of morphine into the morphine-sensitive CNS site, the periaqueductal gray (PAG), were reported to reduce morphine analgesia. The present study investigated GABA levels in dialysates obtained from the rat PAG during morphine administration. A microdialysis probe (BAS) was inserted into chloral hydrate anesthetized male rats (B.W. approx. 230 g) mounted on a Kopf stereotaxic; dialysates were collected in 30-min samples (after discarding the first 60-min dialysate) during perfusion of Ringers at 1 uL/min. Morphine was given IP (10 mg/kg) or IC (15 ug/uL) through the probe following a 2-hr control period, and collection continued for another 1.5 hrs. GABA was evaluated using the BAS HPLC electrochemical detection method. All rat brains were examined histologically to determine probe placement. Changes in GABA levels following morphine administration were found to be correlated with variations in placement site. Decreases in GABA levels were found when probes were located within the PAG, while more variable results were seen in other sites.

568.12

EFFECTS OF D-SERINE ON EEG, OVERT BEHAVIOR AND DISCRIMINITIVE STIMULUS EFFECTS OF PCP IN RATS. J. E. Moreton, L. Robles, J. M. Witkin, L. G. Sharpe and F. C. Tortella. Univ. Maryland Sch. of Pharmacy, Baltimore, MD, 21201, Neuropharmacol. Br., Walter Reed Army Inst. Res., Washington, DC, 20307 and NIDA Addiction Res. Ctr., Baltimore, MD, 21224.

The potential antagonist action of D-serine, a selective agonist for the glycine/NMDA receptor, against the EEG and behavioral effects of PCP, a noncompetitive NMDA antagonist, was investigated. In rats bearing chronic cortical EEG electrodes and iv and icv cannulae PCP (1.25 mg/kg, iv) produced a behavioral syndrome characterized by head weaving, locomotion, and ataxia. Five min pretreatment with D-serine (1 μM, icv) tended to reduce these PCP-induced behaviors, but the effect was not significant, nor dose-dependent (2 μM). Simultaneous recording of EEG frequency spectra revealed a PCP-induced dual-peak response centered about 2-3 Hz and 7-8 Hz which was also unaltered by D-serine. D-serine alone produced no significant EEG or behavioral changes. In rats trained to discriminate 1.5 mg/kg PCP ip versus saline on a FR 20 schedule of food presentation, PCP produced 95% responding on the PCP-correlated lever. This effect was mimicked by (+)-MK801 but not significantly altered by a two min pretreatment with D-serine (0.5-2 μM, icv). Collectively, these results fail to support a PCP antagonist effect by D-serine. Confirmatory icv PCP studies are in progress. (Supported in part by grant DA03173)

AN INTERACTION BETWEEN OPIOID AND NORADRENERGIC SYSTEMS IN THE MODULATION OF PULSATILE LUTEINIZING HORMONE SECRETION BY DELTA-9-TETRAHYDROCANNABINOL. L.L. Murphy , P. Keller* and M. Kohli*. Department of Physiology, Southern Illinois University, School of Medicine, Carbondale IL 62901.

We have previously demonstrated that naloxone (NAL), an opiate receptor blocker, can reverse the ability of delta-9-tetrahydrocannabinol (THC), the major psychoactive component of marijuana, to inhibit pulsatile luteinizing hormone (LH) secretion in the ovariectomized female rat. Because the effects of endogenous opioids on LH-releasing hormone (LHRH) secretion and, thus, LH release, may be mediated through hypothalamic noradrenergic systems, we attempted to block the NAL reversal of THC-induced LH inhibition by pretreatment with norepinephrine receptor blockers. Approximately 4 weeks post-ovariectomy, blood samples were drawn from adult Sprague-Dawley rats, via indwelling intra-atrial cannulae, every 10 min for 60 min pre- and 120 min post-vehicle (control) or THC (0.5 mg/kg b.w., iv) treatment at time 0 for LH determinations. Either the β-receptor antagonist, yohimbine (YOH, 0.5 mg/kg, iv), or the α-receptor antagonist, prazosin (PRZ, 0.5 mg/kg, iv), was administered 30 min prior to THC or its vehicle, and 50 min before NAL (2 mg/kg b.w., iv) treatment. Neither YOH nor PRZ altered pulsatile LH secretion in vehicle-exposed animals treated with NAL, and YOH pretreatment did not alter the ability of NAL to reverse THC action. However, pretreatment with PRZ prevented NAL reversal of THC-induced suppression of pulsatile LH release. These results suggest that THC may augment hypothalamic opioid activity which, in turn, could inhibit noradrenergic stimulatory inputs onto the LHRH secreting neurons. (Supported by DA 05042)

EFFECTS OF ANALGESIC DOSES OF MORPHINE ON REGIONAL CEREBRAL BLOOD FLOW IN THE RAT. H. Zhang*, E.A. Stein and T.C. Trusk. Departments of Psychiatry and Cell Biology and Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226

The widespread distribution of opioid receptors and peptides in the central nervous system suggests an important role for this system in numerous brain functions including analgesia and regulation of numerous physiologic parameters. Included among these functions may be as mediators in an intrinsic central neurogenic control of cerebral circulation. The present study examined the effects of morphine on neuronal activity as reflected by alterations in regional cerebral blood flow (rCBF). rCBF was measured according to the method of Sakurada et al with the radioactive iodoantipyrene technique and quantitative autoradiography in awake, restrained rats. Morphine was delivered subcutaneously (2 and 4mg/kg) and rCBF measured 15 min later. Tail flick latencies increased at 2 mg/kg to 47% MPE and 100% at 4 mg/kg. The results showed that morphine caused a global dose-dependent increase in RCBF in 39/51 structures analyzed. Mean change in rCBF at 2 and 4 mg/kg were 27% and 71% respectively. At 4 mg/kg, morphine resulted in an increase in $PaCO_2$ of approximately 6 mm Hg, while not changing PaO_2, heart rate or blood pressure. Naloxone (10 mg/kg) was ineffective in changing either rCBF or physiologic parameters when delivered alone but was able to completely reverse the effects of 4 mg/kg morphine. These results suggest that opioid receptor stimulation by morphine may increase both functional neuronal activity as well as influence an intrinsic central neurogenic control of the cerebral circulation as well. (Supported by NIDA grant DA 05012)

RAPID DETERMINATION OF DRUG DISCRIMINATIVE STIMULUS EFFECTS UNDER A CTA PROCEDURE. T.M. Richardson*, E.A. Walker and A.M. Young. Psychology Dept., Wayne State University, Detroit MI 48202

Conditioned taste aversion (CTA) procedures allow efficient characterization of discriminative stimulus effects of drugs. This study developed a method for generating cumulative dose-response curves (DRCs) using multiple trial tests. Rats (n=8) were trained to discriminate 3.2 mg/kg morphine (MS) and saline (SAL) by giving either MS or SAL 15 min prior to 30-min access to a 0.1% saccharin solution, followed by post-session injections of 75 mg/kg LiCl or SAL, respectively. A control group (n=8) received identical pre-session injections, but always received SAL post-session. Five subjects from each group received single trial tests in which an acute dose of a test drug was given 15 min prior to 30-min access to saccharin. Generalization was measured by differences in the dose needed to suppress drinking in the conditioned and unconditioned groups. MS (tested at doses of 0.1-10 mg/kg) and buprenorphine (0.001-0.1 mg/kg) evoked dose-dependent generalization with MS, whereas ketamine (0.1-32 mg/kg) suppressed drinking at identical doses in both groups. Three subjects from each group received multiple trial test sessions, in which each trial consisted of a 15-min pretreatment interval and 5-min access to 5 ml of saccharin. SAL and increasing doses of a test drug were given before successive trials. Multiple trial tests generated DRCs similar to those from single trial tests. MS (0.1-10 mg/kg), buprenorphine (0.001-0.32 mg/kg) and nalbuphine (0.032-32 mg/kg) evoked generalization with MS, whereas ketamine (0.1-32 mg/kg), U50,488H (0.1-5.6 mg/kg) and *d*-amphetamine (0.1-1.6 mg/kg) did not. In conclusion, multiple trial testing in the CTA procedure allows rapid, pharmacologically-specific evaluation of discriminative stimulus effects of drugs. (APA Minority Fellowship Program and by USPHS grants DA03796 and K02-DA00132.)

569.1

LONG-TERM LITHIUM TREATMENT ENHANCES K^+-INDUCED NA,DA AND 5-HT RELEASES IN THE RAT MEDIAL PREFRONTAL CORTEX: AN IN VIVO MICRODIALYSIS STUDY. T.Koyama, Y.Odagaki*, T.Ohmori, T.Inoue* and I.Yamashita*. Dep. of Psychiatry and Neurology, Hokkaido Univ. Sch. of Med., Sapporo, Japan.

The effects of long-term lithium treatment on extracellular NA, DA and 5-HT were examined in the rat medial prefrontal cortex using the in vivo brain microdialysis method. Potassium (K^+) in the perfusion Ringer induced substantial increases in NA, DA and 5-HT outputs in a concentration-dependent manner within the range of K^+ tested(30-120mM).

Maintenance of rats on a diet containing lithium carbonate(0.23%) for 7 days resulted in significant increases in the K^+(60mM)-induced NA, DA and 5-HT releases. Previously we reported that chronic lithium treatment induced significant increases in the accumulations of DOPA and 5-HTP after NSD 1015, aromatic l-amino acid decarboxylase inhibitor, administration, and the concentrations of HVA, DOPAC, 3-MT and 5-HIAA in various brain regions.

Taken together these results are suggestive that lithium treatment enhances the activity of presynaptic monoaminergic neurons.

569.2

LITHIUM INCREASED NEURONAL EXCITABILITY WITHOUT CHANGING ENDOGENOUS LEVELS OF MONOAMINES IN RAT HIPPOCAMPAL SLICES. J.-C. Lacaille, S. Cloutier*, F. Lebel* and T.A. Reader. Centre de recherche en sciences neurologiques et département de physiologie, Université de Montréal, Montréal, Québec, Canada H3C 3J7.

Lithium is an effective mood-stabilizing agent. To study its mechanism of action, we have examined the acute effects of lithium (Li^+), choline (Ch^+), and sodium (Na^+) on field potentials and on the endogenous levels of monoamines in hippocampal slices *in vitro*. Population EPSPs (pEPSP) and population spikes (pSPIKE) were monitored in the pyramidal cell layer of the CA1 region prior to and after 20 minutes of superfusion with Li^+, Ch^+ or Na^+ (1-30 mM; n=62 slices). Li^+, Ch^+ and Na^+ produced a dose-dependent decrease in pEPSP amplitude (30.7-60.7% of control). Ch^+ and Na^+ also caused a dose-dependent decrease in pSPIKE amplitude (21.7-51.7% of control). In contrast Li^+ produced a dose-dependent increase in pSPIKE amplitude (121.4% of control). Following these electrophysiological experiments, slices were collected and immediately frozen. A second set of slices (n=162 slices) were similarly exposed to Li^+, Na^+ and Ch^+ (with field potential monitoring of slice viability) and then frozen. Slices were thawed 1-5 hours later, homogenized, centrifuged and endogenous levels of monoamines assayed in the individual slices by HPLC with electrochemical detection. Li^+ and Na^+ had no effect on endogenous levels of norepinephrine, epinephrine, dopamine and serotonin ($p>0.05$). Ch^+ had complex effects on dopamine levels ($p<0.05$) but did not affect other monoamines. These results suggest a specific acute effect of lithium on neuronal excitability but not on endogenous levels of monoamines.

CHRONIC, BUT NOT ACUTE, LITHIUM ALTERS A MYRISTOYLATED ALANINE-RICH C KINASE SUBSTRATE (MARCKS) IN RAT HIPPOCAMPUS. R.H. Lenox, D. Watson*, J. Ellis, and J. Patel. Neurosci. Res. Unit, Dept Psychiatry, UVM, Burlington, VT 05405 & ICI Pharmaceuticals Group, Wilmington, DE 19897.

Previous studies in our laboratory have observed a reduction in PKC mediated phosphorylation of an 83kDa protein(s) in the hippocampus of rats chronically treated with lithium. Western blot analysis has identified this 83kDa protein as a major PKC substrate known as MARCKS. Because the therapeutic action of lithium in patients is known to exhibit a delay in the onset of therapeutic action and a persistence of efficacy beyond abrupt discontinuation, we have extended these studies to rats exposed to acute lithium and those withdrawn from chronic lithium. Four matched groups of Sprague-Dawley rats were examined: (1) control diet; (2) chronic lithium diet for three weeks; (3) acute lithium (5 meq/kg IP; 2hrs); and (4) 36 hours following withdrawal of chronic lithium. We observed a significant reduction of MARCKS and of PKC mediated phosphorylation of the 83kDa protein in the hippocampi of rats receiving chronic lithium, including those in the withdrawal paradigm. The acute lithium treatment did not produce these changes, even though equivalent brain lithium levels were attained. Our findings parallel the clinical therapeutic efficacy of lithium and suggest the possible involvement of MARCKS in its mechanism of action. (Supported by RO1-MH41571)

ACUTE ADMINISTRATION OF THE PUTATIVE ANTIDEPRESSANT NEFAZODONE DOES NOT ALTER REGIONAL RAT BRAIN CRF CONCENTRATIONS. K.C. Dole, M.J. Owens, G. Bissette, M.A. Vargas, and C.B. Nemeroff. Depts. of Psychiat. and Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710

Corticotropin-releasing factor (CRF), a CNS neurotransmitter, is believed to integrate the endocrine, autonomic and behavioral responses to stress. Moreover, there is evidence that CRF of both hypothalamic and extrahypothalamic origin is hypersecreted in major depression. Because it is plausible that antidepressants may alter CRF neuronal activity and because serotonergic agonists have been shown to increase hypothalamic-pituitary-adrenal (HPA) axis activity by direct effects on CRF neurons, we have investigated the effects of nefazodone, which interacts with both 5-HT uptake sites and 5-HT_2 receptors, on brain CRF concentrations and plasma ACTH and corticosterone levels.

Male Sprague-Dawley rats were administered increasing doses of nefazodone (1 - 100 mg/kg s.c.). CRF concentrations were measured in the hypothalamus, median eminence, and locus coeruleus. After data were obtained from the dose-response experiment, animals were treated acutely with nefazodone (33.3 mg/kg), and CRF concentrations were measured in 10 discrete brain regions including the prefrontal cortex, bed nucleus of the stria terminalis, median eminence, hypothalamus, piriform cortex, amygdala, hippocampus, raphe, cerebellum, and locus coeruleus. Nefazodone was without effect on plasma ACTH or CRF concentrations at any dose. Plasma corticosterone levels were significantly elevated only at a dose of 100 mg/kg of nefazodone. The results suggest that, at least at the dose and time point studied here, nefazodone does not cause major alterations in CRF neuronal function or HPA axis activity. (Supported by MH-42088).

DIFFERENTIAL EFFECTS OF DESMETHYLIMIPRAMINE (DMI) ON THE BRAIN NUCLEUS LOCUS COERULEUS (LC) CULTURED AT TWO DEVELOPMENTAL PERIODS. Cheryl F. Dreyfus. Dept. Neuroscience & Cell Biology, R.W.J. Med Sch / UMDNJ, Piscataway, NJ 08854

DMI is a widely used tricyclic antidepressant drug that specifically inhibits the high affinity NE uptake system, and has been reported to decrease TH activity in the adult lc in vivo. To define drug actions during development, we examined effects on the lc developing within a well-defined culture system. In previous work, lc has been explanted from two developmental stages, embryonic day 12 (E12) and day 18 (E18). E12 and E18 lc grown in culture exhibit distinct developmental capabilities. E12 lc expresses significantly less tyrosine hydroxylase (TH) /cell than E18 lc. (TH is the rate limiting enzyme in NE biosynthesis.) Moreover, E12 lc cells are less mature morphologically than E18 neurons.

In the present study, we took advantage of the distinct E12 and E18 maturational stages evident in culture. Initially, we monitored NE uptake and the ability of DMI to inhibit this process. Both E12 and E18 cultures exhibited high-affinity uptake that was blocked by DMI. To define effects of the drug on TH activity, E12 and E18 explants were grown for one week and then exposed to DMI (1uM or 10uM) for an additonal seven days. In contrast to effects on NE uptake, distinct differences were now apparent in the two culture groups. TH activity in E12 cultures was unaffected by DMI treatment. However, TH in the E18 groups was markedly inhibited by the drug. This effect appears to be selective. Drug treated E18 explants exhibit extensive neuritic outgrowth and are indistinguishable from controls. These data suggest that specific DMI responsive periods exist during brain development. Mechanisms underlying these differences in responsivity remain to be defined. (Support: NIH grant DA 05132)

EFFECTS OF CHRONIC ANTIDEPRESSANT ADMINISTRATION ON RECEPTOR REGULATION IN GUINEA PIGS. A.W. Schmidt and J. Heym. Pfizer Central Research, Groton, CT. 06340.

In rats, downregulation of β adrenergic receptors after chronic administration of antidepressants (ADs) has been well documented. Both tricyclic ADs and 5-HT reuptake blockers have been shown to produce this effect. In addition, 5-HT2 receptor downregulation has been demonstrated after chronic tricyclic AD treatment, but results are inconsistent for 5-HT reuptake blockers. To date no reports are available on the effects of chronic AD treatment on 5-HT1D receptors. Since mice and rats lack 5-HT1D receptors, the present study was conducted in the guinea pig to compare the effects of chronic AD administration on the regulation of 5-HT1D, 5-HT2 and β adrenergic receptors. The tricyclic AD, desmethyl-imipramine (DMI), a norepinephrine reuptake inhibitor, or the 5-HT reuptake inhibitor fluoxetine was given to guinea pigs at a dose of 10 mg/kg i.p. once a day for fourteen days. After a wash out period of 24 hours, animals were sacrificed and brains removed, dissected and stored frozen. Binding assays were performed according to standard literature procedures. The number of 5-HT1D receptors in guinea pig caudate were unchanged in both drug-treated groups. A significant downregulation of cortical β adrenergic receptors was found in both drug-treated groups, while only the DMI-treated guinea pigs showed a significant reduction in the number of cortical 5-HT2 receptors. The effects of chronic AD treatment on 5-HT2 and β adrenergic receptor regulation in the guinea pig appears similar to those found in the rat.

569.7

EFFECTS OF TANDOSPIRONE ON ASSOCIATIVE LEARNING IN MICE. A. Shemer, J Clemente & D Quartermain, Pfizer Inc. & NYU Medical Center. New York. Effects of tandospirone 5mg\kg s.c. buspirone 1mg\kg s.c. & diazepam 1mg\kg s.c. on acquisition and retention were studied in a CER paradigm using a drink suppression task. Drugs were administered before conditioning, before test or before both conditioning & test. All 3 drugs disrupted suppression dose dependently when given before conditioning, but d-amphetamine 2mg\kg s.c. before test reversed the impairment. State dependency was observed with buspirone only. Tandospirone & buspirone both produced a reversible disruption of retrieval but did not impair acquisition, however the state dependency suggests that the drugs produce different internal states. Diazepam alone impaired conditioned suppression when administered before test, an indication that its mechanism of action may differ from that of the 5HT1a agents. In a passive avoidance task tandospirone administered before training produced deficits in retention at test 1, 3 & 7 days later. This effect was reversed by d-amphetamine before test, supporting the hypothesis that retrieval, not learning, is effected by 5HT1a receptor activation.

569.8

IMIPRAMINE BINDING AND EFFECTS OF REPEATED TREATMENT IN ADULT FEMALE RATS. S. Maswood*, J. Williams and L. Uphouse, Department of Biology, Texas Woman's University, Denton, Texas, 76204.

Although imipramine is one of the most widely investigated antidepressants, experimental studies have been performed primarily in the male rodent. However, in the human population, females are the major consumers of antidepressants. The present research was initiated to examine the effects of imipramine in a female rodent with the ultimate objective of comparing these findings to those reported for the male population. In the first study, binding of ^{3}H-imipramine, plus or minus desipramine as a competitor, to frontal cortex of estrous, proestrous and diestrous rats was examined. In general, binding profiles resembled those reported for males. However, the K_d for ^{3}H-imipramine binding in the female frontal cortex was larger than reported for the male and, although not statistically significant, the K_d and B_{max} of estrous rats tended to be lower than that of proestrous and diestrous rats. In the second experiment, female rats were injected i.p. with 10 mg/kg imipramine or saline daily for 21 days. Such treatment regimens are often employed in male rats in order to ascertain the neurochemical changes responsible for the drug's therapeutic action, which require 2-3 weeks. Disruption of the estrous cycle occurred rapidly following imipramine treatment. During the 21 days of treatment, most of the saline-treated rats had 4 consecutive estrous cycles. In contrast, imipramine-treated rats showed only 2 episodes of vaginal estrus, indicative of disruption of estrous cyclicity. These results raise the possibility that the alteration of the reproductive cycle could occur following treatment with other antidepressants.

569.9

SEROTONIN FUNCTION AND THE MECHANISM OF ANTIDEPRESSANT ACTION **P.L. Delgado, H.L. Miller*, R.S. Salomon*, J. Licinio*, L.H. Price, G.R. Heninger, J.H. Krystal, D.S. Charney. West Haven VAMC and Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508**

Brain serotonin (5-HT) content is dependent on plasma levels of the essential amino acid, tryptophan (TRP). We have previously reported that rapid TRP depletion more frequently reversed antidepressant response to monoamine oxidase inhibitors and 5-HT reuptake inhibitors than to desipramine (DMI). This study further investigates the relationship of relapse during TRP depletion to antidepressant type in non-refractory depressed patients randomly assigned to treatment with either DMI or fluoxetine (FLU). METHOD: In an ongoing study, 25 drug-free depressed (DSM-III-R) patients were randomly assigned to receive antidepressant treatment with either desipramine or fluoxetine. All patients were either treatment naive (N=15) or had had previously successful antidepressant treatment (N=10). 19 of the 25 patients had therapeutic responses by predetermined criteria to antidepressant treatment (DMI 7/10; FLU 12/15) and 16 (6 DMI responders and 10 FLU responders) went on to TRP depletion testing. TRP depletion testing involved two 2-day tests, a 16-amino acid drink and a follow-up day, in a double-blind, placebo-controlled (TRP depletion and control testing), crossover fashion. On one test the drink was supplemented with L-TRP (control) and on the other test no TRP was added (TRP depletion). Behavioral ratings (Hamilton Depression Scale (HDRS)) and plasma (for TRP levels) were obtained prior to, during and after testing. Relapse was defined as a 50%increase in HDRS with total >20. RESULTS: Total and free TRP decreased 70-80% 5 hrs. after the TRP-free drink. While 5/10 FLU responders relapsed, none of the DMI responders relapsed (one DMI-treated patient experienced a partial relapse). No patient experienced significant depressive symptoms during control testing. Implications: Rapid depletion of plasma TRP transiently reverses antidepressant response to FLU but not DMI. Given the random, balanced patient assignment, depressive relapse during TRP depletion appears to be more related to antidepressant type than to patient variables. Antidepressant response to FLU appears to be more dependent on 5HT availability than that of DMI. This data suggests that antidepressants may mediate their therapeutic effects through different mechanisms.

MAZINDOL IN TREATMENT-REFRACTORY DEPRESSION **H.L. Miller*, S.M. Stine, P.L. Delgado, R.M.Salomon* and D.S. Charney. West Haven VAMC and Dept. of Psychiatry, Yale University School of Medicine, New Haven, Ct. 06508**

Mazindol is a potent dopamine and norepinephrine reuptake inhibitor which has not previously been examined for antidepressant activity in humans. This study examines the efficacy of mazindol in patients with treatment-refractory major depression. **Method:** 7 depressed patients (4 males and 3 females, ages 34-68) received placebo for the first two weeks of the study, then were treated with mazindol, at doses ranging from 1-4 mg, for 6 weeks. The study was single-blind. Severity of depression was measured weekly with the 25-item Hamilton Depression Rating Scale (HDRS). All 7 patients continued to be depressed throughout the placebo period and proceeded to active treatment. **Results:** 2 of the 7 patients (29%) treated to date had a therapeutic response to mazindol ($\geq$ 50% decrease in HDRS and total $\leq$ 10). The drug was well tolerated; common side effects included insomnia, headaches, and urinary hesitation. **Conclusions:** 30% of this treatment-refractory population improved with mazindol treatment. Mazindol may have greater antidepressant efficacy in patients less refractory to treatment.

CHRONIC FLUOXETINE TREATMENT UP-REGULATES DOPAMINE RECEPTORS IN MESOLIMBIC FOREBRAIN. J.E. Margulies, A.B. Lynn*, L.S. Brady and R.P. Hammer, Jr., Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. Med., Honolulu, HI 96822 and Sect. Functional Neuroanat., NIMH, Bethesda, MD 20892.

Fluoxetine is a clinically effective antidepressant compound which blocks serotonin reuptake. However, the extended time course for clinical efficacy suggests that this compound may produce direct or indirect effects on other neurotransmitter systems, as well. Fluoxetine (5 mg/kg) was administered daily i.p. for 8 weeks in Sprague-Dawley rats, after which animals were decapitated, brains frozen and sectioned, and adjacent sections incubated in appropriate buffer solutions containing either 1.6 nM [^{3}H]SCH 23390 or 0.5 nM [^{3}H]spiperone, washed, dried, and exposed to X-ray film. These binding conditions reveal D_1 and D_2 receptors, respectively; the radioligand concentrations were calculated to be 1.5 x K_d in our hands. Nonspecific binding was determined in the presence of 1 μM (+)butaclamol, and an additional adjacent series of tissue sections was prepared for digital subtraction of nonspecific D_2 binding. The results were analyzed using quantitative densitometry. Receptor binding was assessed in mesolimbic and nigrostriatal terminal regions. D_1 labeling was increased selectively in rostral portions of the nucleus accumbens (NAc), but not in the olfactory tubercle nor the striatum. Specific D_2 binding also increased in NAc, but not in the striatum. The results suggest that chronic fluoxetine treatment could increase dopaminergic response selectively in the mesolimbic fields involved in motivational activity. Thus, dopaminergic activity in endogenous reward centers might be involved in depression. Supported by USPHS Awards HD01161, DA06645 and RR03061 to RPH.

G-PROTEIN α-SUBUNIT mRNA LEVELS IN RAT CORTEX ARE REGULATED BY CHRONIC LITHIUM BUT NOT CARBAMAZEPINE TREATMENT. P.P. Li, Y.K. Tam*, L.T. Young, and J.J. Warsh. Clarke Institute of Psychiatry, Toronto, Ontario, Canada, M5T 1R8.

While lithium and carbamazepine (CBZ) are effective in the treatment of bipolar affective illness, their mechanism of action is still unknown. Recent evidence suggests that lithium might exert its therapeutic effect by modulating the function of GTP-binding (G) proteins associated with CNS second messenger systems. We have therefore examined the effects of chronic lithium or CBZ treatment on rat cerebral cortical mRNA levels for Gs and Gi α-subunits. Groups of male Wistar rats were fed one of three diets for 21 days: control, 0.2% LiCl or 0.25% CBZ for 4 days followed by 0.5% CBZ. Total cellular RNA was extracted from cerebral cortex by the guanidine isothiocyanate/cesium chloride centrifugation method. Northern blots were performed using the EcoR I fragment of rat Gsα, Gi1α and Gi2α cDNAs subcloned into pGEM-2 (provided by Dr. R. Reed). The yield of total cellular RNA did not differ significantly between the control (1.02 ± 0.01 mg RNA/g tissue), lithium-treated (0.97 ± 0.03; n=5) and CBZ-treated animals (0.99 ± 0.01; n=5). Northern blot analysis revealed that chronic lithium treatment decreased Gsα mRNA abundance by 30% ($p < 0.05$) in cerebral cortex. Similarly, there was a 25-30% reduction ($p < 0.05$) in the Gi1α and Gi2α mRNA levels. In contrast, the prevalence of these mRNAs was unaffected by chronic CBZ treatment. Neither of these drug treatments altered β-actin mRNA levels. These data represent the first demonstration of a potential modulatory role of lithium on the dynamics of G protein α-subunit biosynthesis at the level of gene expression. Furthermore, our data support the notion that G protein(s) may be a molecular target for the therapeutic effects of lithium which is not shared by CBZ. Supported by the OMHF, MRC (Canada) and NARSAD.

EFFECTS OF PUTATIVE 5-HT_{1A} ANTAGONISTS ON DORSAL RAPHE UNIT ACTIVITY IN BEHAVING CATS. C.A. Fornal, F. Marrosu, K. Tada*, C.W. Metzler and B.L. Jacobs. Prog. Neurosci., Dept. of Psychol., Princeton Univ., Princeton, NJ 08544.

Somatodendritic 5-HT_{1A} autoreceptors are thought to play an important role in regulating the discharge activity of central 5-HT neurons. Recently, we have shown that blockade of the 5-HT autoreceptor with systemic spiperone produces an increase in the firing rate of 5-HT dorsal raphe nucleus (DRN) neurons in awake cats, suggesting that 5-HT autoreceptors exert a tonic inhibitory influence on the activity of 5-HT neurons under physiological conditions. The present study examines the effects of three other putative 5-HT_{1A} antagonists (BMY-7378, NAN-190, and (-)propranolol) on DRN unit activity. 5-HT neurons were recorded and identified using methods previously described (Fornal et al., Am. J. Physiol. 259:R963-R972, 1990). Drugs were administered via a jugular catheter. In contrast to the effects of spiperone (0.25-1 mg/kg), intravenous administration of BMY-7378 (0.02-0.1 mg/kg), NAN-190 (0.02-1 mg/kg), and (-)propranolol (1-3 mg/kg) suppressed the activity of DRN neurons and failed to block the inhibitory action of 8-OH-DPAT, a selective 5-HT_{1A} agonist. In addition, the suppression of DRN unit activity produced by BMY-7378, NAN-190, and (-)propranolol was antagonized by spiperone. These results indicate that these putative 5-HT_{1A} antagonists act as agonists rather than antagonists at the 5-HT_{1A} autoreceptor site.

569.14

SINGLE-UNIT RESPONSES OF N. RAPHE DORSALIS AND CENTRALIS SUPERIOR NEURONS TO 5-HT_{1A} DRUGS IN BEHAVING CATS. K. Tada*, C.A. Fornal, F. Marrosu, C.W. Metzler and B.L. Jacobs. Prog. Neurosci., Dept. of Psychol., Princeton Univ., Princeton, NJ 08544.

The somatodendritic 5-HT_{1A} autoreceptor regulating the impulse activity of central 5-HT neurons represents an important target site of action for a variety of psychotherapeutic agents. Our previous studies suggested that the sensitivity of the 5-HT_{1A} autoreceptor may vary across different raphe cell groups. The present study examines the effects of 5-HT_{1A} agonist and antagonist drugs on unit activity in the dorsal raphe nucleus (DRN) and nucleus raphe centralis superior (NCS) in behaving cats (methods described in preceding abstract). Intravenous administration of the selective 5-HT_{1A} agonists 8-OH-DPAT and ipsapirone produced a dose-dependent inhibition of both DRN and NCS unit activity. However, 8-OH-DPAT and ipsapirone were more potent in suppressing the activity of DRN neurons (ED_{50} for 8-OH-DPAT = 1.2 μg/kg; ED_{50} for ipsapirone = 4.6 μg/kg) than NCS neurons (ED_{50} for 8-OH-DPAT = 3.0 μg/kg; ED_{50} for ipsapirone = 23.8 μg/kg). The 5-HT_{1A} autoreceptor antagonist spiperone (1 mg/kg) produced a marked, and similar, increase in the firing rate of both DRN and NCS neurons. Overall, these results provide evidence for a differential sensitivity of DRN and NCS neurons to 5-HT_{1A} agonists and suggest that 5-HT neurons in both raphe nuclei are under tonic feedback inhibition.

5-HT_{1A} AUTORECEPTOR AGONISTS INDUCE HIPPOCAMPAL RHYTHMIC SLOW ACTIVITY (RSA) IN FREELY MOVING CATS. F. Marrosu, C.A. Fornal, K. Tada*, C.W. Metzler and B.L. Jacobs. Prog. Neurosci., Dept. of Psychol., Princeton Univ., Princeton, NJ 08544.

Ascending serotonergic projections from the midbrain raphe nuclei have been implicated in the regulation of hippocampal electrical activity. Previous studies have shown that serotonin derived from the midbrain raphe nuclei inhibits the activity of hippocampal pyramidal cells. Recently, we have found a subgroup of serotonergic neurons whose activity appears to be inversely correlated with the occurrence of hippocampal RSA during waking behaviors. These findings have prompted us to examine the effects of 5-HT_{1A} autoreceptor agonists (8-OH-DPAT and ipsapirone) on hippocampal EEG activity in freely moving cats. Intravenous administration of low doses of 8-OH-DPAT (10-20 μg/kg) and ipsapirone (40-100 μg/kg) induced clear RSA in the hippocampal EEG. The onset of the effect (~20 sec) coincided with a general suppression of serotonergic unit activity recorded in the midbrain raphe nuclei. These data suggest that preferential activation of somatodendritic 5-HT_{1A} autoreceptors produces RSA in cats and support the hypothesis that central serotonergic neurons inhibit the generation of hippocampal RSA.

BEHAVIORAL EFFECTS OF CAFFEINE IN RATS TREATED ACUTELY VERSUS CHRONICALLY WITH FLUOXETINE (PROZAC). A.P. Leccese, M.L. Van Etten* and M.G. Smith*. Psychology Department, Kenyon College, Gambier, OH 43022.

Anecdotal evidence from humans receiving the antidepressant fluoxetine suggested that this drug interacts with the commonly used methylxanthine, caffeine, to induce subjectively unpleasant levels of stimulation. A first experiment investigating the impact of caffeine upon rats given acute fluoxetine found that acute fluoxetine induced a reduction in most measured behaviors, while all caffeine increases in behavior were merely superimposed over acute fluoxetine-induced decreases in behavior. In the second experiment, rats were injected ip once daily for 15 days with 0.0 or 5.0 mg/kg fluoxetine. On the 15th day, fluoxetine injections were followed later by ip injections of 0.0, 5.0 or 10.0 mg/kg caffeine 30 min prior to placement within an automated activity device that measured a number of variables relating to locomotion, stereptypy and anxiety. There was no significant effect of fluoxetine nor a significant fluoxetine-caffeine interaction on any measure. There was a main effect of caffeine only upon total distance and number of stereotypy. However, despite the failure to achieve significance, rats given chronic fluoxetine followed by saline showed a trend towards elevated behavior. Increasing doses of caffeine generally caused further elevations of chronic fluoxetine-induced increases in behavior.

PHARMACOLOGICAL ACTIONS OF A-75200, A NOVEL α_2 ANTAGONIST/NOREPINEPHRINE (NE) REUPTAKE INHIBITOR AND POTENTIAL ANTIDEPRESSANT AGENT. A.A. Hancock, J.Y. Lee, R.E. Zelle, S.A. Buckner, D. Stanisic, M.E. Brune, R.B. Warner, J.F. McKelvy, and J.F. DeBernardis

Abbott Laboratories, Abbott Park, IL 60064

A-75200, (±)-(1'R*,3R*)-3-phenyl-1- [(1',2',3',4'-tetrahydro-5',6'-methylene dioxy-1-naphthalenyl) methyl]pyrrolidine-methanesulfonate, exhibits potent antagonism of α_2 adrenergic receptors (R) (K_i = 1.2 nM) plus the ability to inhibit the neuronal reuptake of NE in the CNS (IC_{50} = 0.84 μM). In vitro, A-75200 antagonized α_2 R in canine saphenous vein (pA_2 = 8.2) and rat vas deferens (pA_2 = 7.4), with much weaker effects at α_1 R (pA_2 = 6.6, rabbit aorta). A-75200 also blocked presynaptic α_2 R to release [^{3}H]NE from guinea pig hippocampal slices. In vivo, A-75200 blocked CNS α_2 R (ED_{50} = 0.35 mg/kg i.v., in antagonizing clonidine-induced mydriasis). The agent lacked anticholinergic or antihistaminergic activity. Cardiovascular studies indicated that A-75200 had minimal effects on hemodynamic parameters such as cardiac output, heart rate, stroke volume or total peripheral resistance, and did not induce orthostatic hypotension. A-75200 is a racemic mixture, and biochemical assays showed that one enantiomer antagonized α_2 R more potently while the other enantiomer had better affinity for NE uptake sites. This unique pharmacological profile suggested that A-75200 should have antidepressant activity, and behavioral tests in animals support this hypothesis.

569.18

BEHAVIORAL PHARMACOLOGY OF ABBOTT-75200, A POTENTIAL ANTIDEPRESSANT COMPOUND W. J. Giardina, D. M. Ebert*, C. T. Wismer*, J. F. DeBernardis* and J. F. McKelvy. Abbott Laboratories, Abbott Park, Il 60064

ABBOTT-75200, (±)-(1'R*,3R*)-3-phenyl-1 [(1',2',3',4'-tetrahydro-5',6'methylenedioxy-1-naphthalenyl) methyl] pyrrolidine methane sulfonate, is a potent alpha-2 antagonist and an inhibitor of norepinephrine reuptake. Because this unique profile suggests potential antidepressant activity, A-75200 was evaluated in an antidepressant screening procedure using olfactory bulbectomized (OB) rats. Sham operated (SO) and OB rats were placed in activity monitors for 11 days on a 13 hour light - 11 hour dark cycle. OB rats were markedly more active than SO rats during the dark phase. Six injections of A-75200 (10.0 mg/kg, i.p., once daily) reduced the dark phase activity of OB rats to a level equal to that of SO rats. Imipramine (10.0 mg/kg, i.p., once daily) was effective after 8 injections. A-75200 did not affect locomotor activity, rotarod, seizure threshold or nociception, and showed weak activity in the thirsty rat conflict test. The efficacy of A-75200 in the OB rat supports its potential for antidepressant activity .

GENERATIONAL GENETIC EFFECTS OF IONIZING RADIATION (I.R.)$_2$ CNS' ENERGETICS METABOLISM. E. Egaña & M.T. Ramirez. University of Chile; Faculty of Medicine; Institute of Experimental Medicine; Laboratory of Neurochemistry; Santiago 7 - Chile.

It is well known both in human & experimental that I.R. damage seriously the CNS at its successive stages (preimplantation, embryon, fetus, neonatal, puberty & adult). It describes effects acute and chronic. Our Institute has created an generational (genetic) model of I.R. We studied several CNS' parameters which have been analyzed in three successive generations. In this paper our attention was focused on the alteration of CNS' mitochondrial energetic. First generation: Wistar rats adult ♂&♀were exposed to low-dose rate 0.10-0.25 Gy three times a week to reach 10 Gy as total-dose; this crossed to get the 2nd gen. & this was treated in the same manner to get the 3rd gen. In each gen. many parameters were evaluated some of them at intrauterine life. During pregnancy the ♀ continued being exposed as also neonatals, lactants, juvenils and adults; that means exposure all life. Mitochondria crude preparation from 5 CNS' areas: cortex, hippocampus, hypothalamus, cerebellum & midbrain. Site I & II of the respiratory chain; electron transport & Ca^{2+} influx measured polarigraphically with adhoc electrodes. Results showed alterations in most mitochondrial parameters in all generations, particularly P/O & Ca^{2+} influx.

EXPRESSION OF THE NEUROFIBROMATOSIS TYPE 1 GENE PRODUCT IN THE CHICK EMBRYO L. Baizer, G. Ciment, and G. Schafer* Neurological Sci. Institute, Good Samaritan Hospital, and Department of Cell Biology and Anatomy, Oregon Health Sci. Univ., Portland, OR. 97209.

Neurofibromatosis type 1 (NF-1) is among the most common inherited disorders, and primarily affects tissues derived from the neural crest. Symptoms of this disease include café-au-lait spots, which appear to result from abnormal differentiation and/or proliferation of melanocytes, and neurofibromas, benign tumors consisting of Schwann cells, as well as other cell types. Insight into a possible mechanistic basis for this disorder was provided by the recent molecular cloning and sequence analysis of the NF-1 gene product, which appears to be similar in structure and function to the GTPase Activator Protein (GAP), which may act as a tumor suppressor.

To investigate the possible role of the NF-1 gene product in regulation of the proliferation and differentiation of neural crest cells during development we have isolated cDNAs for chicken NF-1. Chick embryo brain cDNA libraries were screened at low stringency with probes derived from the human NF-1 cDNA. Several positive clones have been isolated and amplified and their nucleotide sequences determined. Comparison of the predicted amino acid sequences for the chick and human gene products suggests that the entire protein is highly conserved, implying that plays an important role in cellular regulation. When radiolabelled and used as a probe on RNA blots the cDNAs hybridize to a low-abundance mRNA of approximately 13-14 kb, similar to the size of the human gene product. These cDNAs will be used as probes to examine the time-course and distribution of NF-1 mRNA expression in the chick embryo.

CELLULAR EXPRESSION OF p53 AND T-ANTIGEN IN HYBRID JCV-SV40 TRANSGENIC MICE. H.G.Ressetar*, O.Prakash, R.Frisque*, H.Webster and G.Stoner. NIH, Bethesda, MD 20892, Alton Ochsner Med. Fdn., New Orleans, LA 70121, and Penn State Univ., University Park, PA 16802

The p53 gene is considered to be an anti-oncogene which controls normal cell proliferation. Elevated levels of p53 have been reported in SV40 polyomavirus-transformed cells. We previously reported pathology in transgenic mice carrying hybrid polyomavirus constructs generated by exchanging the T-antigen-coding regions of SV40 and JC polyomaviruses. Using immunostaining methods to detect p53 and SV40 or JC virus (JCV) large T-antigens, we now report coexpression of p53 and T-antigen in tissues from these mice. A mouse carrying SV40 regulated JCV T-antigen-coding sequences exhibited p53 and JCV T-antigen-expressing cells within a choroid plexus papilloma, but did not express either of the proteins in a coexisting thymoma. Two mice carrying JCV regulated SV40 T-antigen-coding sequences displayed thymic depletion with p53 and SV40 T-antigen-positive cells present in the thymus of one mouse. This mouse also exhibited brain neoplasia and an abdominal lymphoma, with both tissues containing SV40 T-antigen and p53-positive cells. These results suggest that viral regulatory control over T-antigen expression influences p53 levels in pathologic tissue.

HSV-1 VECTOR MEDIATED GENE TRANSFER OF LOW AFFINITY NERVE GROWTH FACTOR RECEPTOR, $p75^{NGFR}$, AND RECEPTOR MUTANTS. M.V. Chao*, D. S. Battleman*, S. Regunathan and A. Geller. The Department of Cell Biology and Anatomy and Division of Neurobiology, Cornell University Medical College, New York, N.Y. 10021, and The Dana Farber Cancer Institute, Boston, MA 02115

The ability to study the genetic regulation and functional role of cloned nervous system genes has traditionally been limited by the inability to stably transfect post-mitotic nerve cells in culture. The recent development of defective Herpes Simplex Virus (HSV-1) vectors has provided a useful method of stable gene transfer into central and peripheral nerve cells without observable cytopathic effects (Science 241, 1667, 1988; Proc. Natl. Acad. Sci., 87, 1149,1990; Biochem. Pharm., 40, 2189, 1990).

Here we report the construction of three viral vectors containing the 2.3 kb cDNA of the low affinity nerve growth factor receptor, pHSV-NGFR, and two mutant constructs, pHSV-X1 and pHSV-5A. pHSV-X1 encodes for a intracellular truncation mutant, containing a premature termination signal shortly after the transmembrane domain coding sequence. pHSV-5A, in contrast, contains a large deletion in the ligand binding domain coding sequence. These constructs have been efficiently introduced and stably expressed in both PC12 cells and fibroblasts. Current work includes establishing stable expression in primary nerve cell culture in order to examine the functional role and molecular interactions of $p75^{NGFR}$ in neurons.

570.5

RETROVIRUS VECTOR WITH HERPES SIMPLEX VIRUS THYMIDINE KINASE GENE AND WILD-TYPE RETROVIRUS KILL GLIOMA CELLS IN CULTURE AND IN VIVO. Y. Takamiya,* M.P. Short, D. Ezzeddine,* X.O. Breakefield and R.L. Martuza. Neuroscience Ctr., Mass. General Hosp., Charlestown, MA 02129, and Neuroscience Prog., Harvard Med. Sch., Boston, MA 02115.

Retroviral vectors can selectively deliver "transgenes" to tumor cells in the nervous system. Tumor cells infected with retrovirus vectors bearing the herpes simplex virus thymidine kinase (HSV-TK) gene are killed by treatment with nucleoside analogues, such as ganciclovir (GCV) (Moolten & Wells, J. Natl. Cancer Inst., 1990; Ezzeddine et al., New Biol., 1991). To increase the efficiency of delivery of the HSV-TK gene to tumor cells, we infected C6 glioma cells, bearing the HSV-TK gene under the MoMLV LTR (C6VIK cells) with ecotropic wild-type retrovirus (MoMLV). These genetically modified tumor cells (C6VIK-WT) release both wild-type retrovirus and retrovirus bearing the HSV-TK gene. In culture, C6VIK-WT cells were 300-fold more sensitive to the toxic effects of GCV than C6VIK cells. The increased sensitivity of C6VIK-WT cells may reflect multiple integrations of the HSV-TK gene and the debilitating effects of wild-type retrovirus infection. Co-culture of C6VIK-WT cells with C6BAG cells (labelled with the lacZ gene) caused the latter to become sensitive to GCV treatment. Regression of tumors was also noted in nude mice inoculated subcutaneously with C6VIK-WT and C6BAG cells following treatment with GCV. These findings suggest that the efficiency of retrovirus-mediated gene delivery and the sensitivity to toxic agents can be increased in tumor cells using helper wild-type virus.

570.6

GENE TRANSFER INTO CULTURED SENSORY NEURONS USING HERPES VIRUS VECTOR: EXPRESSION OF BACTERIAL LAC Z USING A MAMMALIAN NEURONAL PROMOTER. J.K. Andersen, D.A.Garber*, C.A.Meaney*, and X.O.Breakefield. Neuroscience Center, Massachusetts General Hospital East, Charlestown, MA, 02129; and Neuroscience Program and Genetics Department, Harvard Medical School, Boston, MA 02115.

A recombinant herpes simplex virus type 1 (HSV) has been engineered by insertion of the rat neuronal specific enolase (NSE) promoter-bacterial lacZ cassette into the thymidine kinase gene of a wild-type KOS HSV genome. This recombinant virus, which is replication-defective in neurons, has been used to infect neuron-enriched, primary cultures of rat neonatal dorsal root ganglion cells at MOIs ranging from 10 to 0.001. After 3 and 10 days, the cells were fixed and stained for beta-galactosidase (ß-gal) activity using X-gal as a substrate. At low MOIs, some apparently healthy blue cells were observed, indicating that the NSE promotor is active in some of these cells and that gene delivery can be effected with little apparent toxicity to cells. This vector does not express lacZ in cultured Vero cells infected in a similar manner. This finding, together with the fact that the NSE-lacZ plasmid construct was active after transfection into cultured mouse neuroblastoma cells, support the conclusion that this promoter remains neuronal-specific within the herpes genome. The virus is currently being assessed by stereotactic injection into rat CNS for its ability to give efficient and stable gene transfer into the mammalian nervous system.

A POTENTIAL NEW METHOD OF DELIVERY OF AN EXPRESSED GENE TO CENTRAL NEURONS OF THE ADULT RAT

W.S. Rosenberg, X.O. Breakefield and O. Isacson; Neuroregeneration Laboratory, McLean Hospital and Depts. of Neurosurgery, Neurology and Neuroscience, Massachusetts General Hospital, Harv. Med. Sch., Boston

A number of methods have been used to deliver expressible genes to cells. Viral vectors can deliver such genes with a high degree of efficiency. Retroviral vectors are believed to have an absolute requirement for DNA replication to integrate into the host genome, and thus could not mediate gene delivery to postmitotic neurons. To explore whether retroviral vectors may integrate into neurons under certain conditions, we engrafted the right striata of male Sprague-Dawley rats with a mouse fibroblast cell line that constitutively produces retroviral vector containing the reporter gene *E. coli* lacZ (vector provided by Dr. C. Cepko). Rats were perfused 10 days postoperatively with paraformaldehyde. Sections of brains (40 μm) were reacted with 5-bromo-4-chloro-3-indolyl-ß-D-galactoside (X-gal), yielding an insoluble blue reaction product when metabolized by ß-galactosidase. Analysis revealed marked ß-galactosidase activity in clusters of large (approximately 20 μm diameter) cells with neuronal morphology. Prominent gene expression was found bilaterally in the ventral forebrain (ventral pallidum), certain thalamic subnuclei and the substantia nigra pars compacta. We hypothesize that the high efficiency of integration may have been caused by the production of helper virus by the grafted cell line, combined with ongoing DNA repair/replication in neurons. We have thus demonstrated the potential utility of an implanted retroviral vector packaging cell line for the delivery of a gene to adult neurons of the CNS.

570.8

Alterations in Levels of Choline Acetyltransferase in Somatostatin Transgenic Mice. M.L. Oster-Granite, C.F. Hohmann, S.L. Kinsman, and J.T. Coyle, Departments of Psychiatry, Physiology, and Neuroscience, The Johns Hopkins University School of Medicine, and The Kennedy Institute, Baltimore, Maryland.

Various studies of normal and mutant (e.g., *dwarf*) mice during development have indicated a dynamic interaction between the cholinergic and somatostatinergic systems in the forebrain. Furthermore, somatostatinergic regulation of cholinergic activity has been reported in cortical structures. We investigated the effect of increased somatostatin levels in the brains of transgenic mice on the expression of cholinergic markers.

These mice express a transgene consisting of the mouse preprosomatostatin gene, 9 kb of 5' sequences, and 1.5 kb of 3' sequences, in addition to their own endogenous preprosomatostatin gene. Preprosomatostatin mRNA levels in heterozygous mice from this line are elevated in hypothalamus (3 fold), neocortex (1.7 fold), and brainstem (1.8 fold), but are not elevated appreciably in hippocampus or striatum (1.2 fold), when compared to nontransgenic controls.

We assayed levels of choline acetyltransferase in various brain regions of homozygous transgenic mice. Levels of choline acetyltransferase were elevated an average of 1.5 fold in neocortex, striatum, and hippocampus, but were not elevated in the remaining brainstem-ventral forebrain sample.

These data lead us to suggest that a complex interaction exists between somatostatin gene expression and cholinergic innervation in the forebrain. Current studies are analyzing cholinergic markers in other lines of somatostatin transgenic mice with different patterns of expression of preprosomatostatin.

570.9

FETAL GROWTH RETARDATION IN TRANSGENIC MICE OVEREXPRESSING SOMATOSTATIN, S.L. Kinsman* and M.L. Oster-Granite, Kennedy Research Institute and Depts. of Neurology and Physiology, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Because of its early expression during ontogeny, the neuropeptide somatostatin (SS) is considered to play an important role in fetal growth and development To study the developmental roles of somatostatin we produced mice that overexpress SS. Using transgenesis to introduce extra copies of a 15kb mouse genomic fragment, which included the preprosomatostatin (PPSS) coding region and 9kb of 5' sequences, we produced mice with extra functional copies of this neuropeptide gene. Three lines of adult SS transgenic mice have up to three-fold elevations in PPSS message levels from hypothalamus, striatum, hippocampus, and brain stem. Brain regions that did not express PPSS signal in control tissue, such as cerebellum, were also negative in transgenic tissue. These mice were used to generate lines of transgenic mice that were homozygous for the PPSS transgene. Their homozygous state was confirmed by demonstrating 100% transmission of the transgene when these mice were mated to non-transgenic mice. Litters of homozygous transgenic mice from one of these lines were used to study the effects of the transgene on fetal growth. The homozygous SS transgenic mice showed a 10% reduction in size compared to non-transgenic controls on embryonic day 15 (body weight 384.0 ± 7.5 mg (n=64) vs. 427.1 ± 7.6 mg (n=16) ; $p < 0.05$). Preliminary Northern blot analysis of total RNA from embryonic day 15 embryos heads showed at least two-fold overexpression of PPSS message. These studies show that an unaltered 15kb mouse genomic construct containing the PPSS coding region could be used to produce transgenic mice that overexpress SS during prenatal stages. Homozygous transgenic mice exhibit a reduction in body size evident in the fetal period. This indicates a novel role for SS expression in the regulation of fetal growth and development. Future experiments will study the relationship between the degree of growth retardation and the level and distribution of SS overexpression. The mechanism by which SS overexpression exerts this growth reduction remains to be elucidated.

570.10

Immunochemical localization of somatostatin in transgenic mouse. S.B. Plano, S.L. Kinsman, M.L. Oster-Granite, J.T. Coyle, and C.F. Hohmann. Depts. of Psychiatry and Neuroscience, The Johns Hopkins University School of Medicine, and The Kennedy Research Institute, Baltimore, Maryland.

Previous studies on transplants of trisomy 16 [Ts16] and euploid tissue into mouse neonatal cortex showed differences in the numbers of Somatostatin (Smst)-expressing neurons in cortex. Since the gene encoding preprosomatostatin (Smst) is located on mouse chromosome 16, the increase in Smst expressing cells could be the result of the increased gene dosage. Alternatively, such increases may reflect altered developmental regulation. To determine whether the increase in somatostatinergic cells results from an increase in the gene dosage of Smst alone, we studied transgenic mice which have extra copies of a genomic fragment including the entire Smst gene.

We examined paired transgenic (n=8) and nontransgenic control (n=8) adult mice histologically using immunocytochemistry according to the ABC method. The survey of the somatostatin-like immunoreactivity (SOMLI) was conducted blindly. Transgenic and control animals revealed similar patterns of SOMLI, with similar numbers of cells being specifically stained. Previous neurochemical and molecular biology studies showed an approximately 60% elevation of Smst peptide and mRNA levels in cortex of these transgenic animals. Subtle differences in the number of Smst cells between transgenic and control animals may become apparent only upon completion of the quantitative cell counts of these tissue sections. The findings here suggest that the observed increases in Smst expression in these transgenic mice cannot be completely accounted for by increases in the number of somatostatinergic cells.

EPILEPSY: BASIC MECHANISMS III

571.1

NMDA-RECEPTOR MEDIATED ELECTRICAL EPILEPTOGENESIS IN THE ORGANOTYPIC CULTURE OF RAT HIPPOCAMPUS. C. Shin, Y. Tamaki, L. Butler* and J. Wilson*, Epilepsy Research Laboratory, Duke and VA Medical Centers, Durham, N.C. 27705.

Post-traumatic epilepsy develops after brain injury through the process of epileptogenesis. Mechanisms underlying the long-term plasticity in epileptogenesis can best be studied in a chronic *in vitro* preparation. Organotypic slice culture combines the long survivability with preserved neuronal cytoarchitecture and intrinsic connectivity. We sought to establish epileptogenesis in this preparation and study its mechanism.

Hippocampal slice cultures (7-15 DIV) were prepared according to the methods of Gähwiler (*TINS*, 1988) and studied in standard aCSF (95/5, O_2/CO_2) at 36°C. Extracellular fields were recorded in CA1 pyramidal layer. Schaffer collaterals were stimulated with 1-second trains of rectangular pulses (0.1 msec, 60 Hz, 500 μA) every 10 minutes.

Initially seizures were not always evoked, but, with subsequent stimulations, seizures could be reliably elicited with initial tonic discharges followed by phasic bursts. Progressive lengthening was seen over 1-2 hours (N=10), resembling the evolving seizure pattern of kindling model. D-APV (50 μM), an NMDA antagonist, blocked the development of seizures (N=7). The inactive stereoisomer, L-APV (50 μM), was without effect.

We have demonstrated that the electrical stimulation induces seizures reliably and gradually. This process of *in vitro* epileptogenesis appears to be mediated in large part through NMDA receptors. It offers a unique opportunity to study the long-term consequences of seizures and NMDA receptor activation in this chronic *in vitro* preparation.

571.2

HIGH POTASSIUM INDUCED SEIZURES IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS. Y. Tamaki, L. Butler*, J. Wilson*, and C. Shin, Epilepsy Research Laboratory, Duke and VA Med. Ctr., Durham, N.C. 27705

In adult rat hippocampal (HPC) slices, modest elevation of extracellular K^+ (up to 8.5 mM) results in spontaneous seizures (SZs) in a small proportion of these slices (Traynelis and Dingledine, 1989). Many reports document more epileptiform activity in organotypic HPC cultures than in acute adult HPC slices. We therefore used the organotypic HPC cultures to study the mechanism underlying SZs induced by high K^+ medium.

Organotypic cultures were prepared from 6-day-old rat HPC according to the methods of Gähwiler. Extracellular field recordings were made from the CA1 and CA3 pyramidal layers in standard aCSF (95/5, O_2/CO_2) at 36°C.

In 30 out of 35 cultures (10-15 DIV), spontaneous SZs were induced in both CA1 and CA3 after 2-19 minutes of 8.3 mM K^+. During the first 15-25 min of high K^+ application, 3.6 ± 0.8 (mean ± SEM) SZs per 10 min were recorded with an average duration of 39.1 ± 6.1 sec. The SZs recurred as long as high K^+ was maintained (1.5-2.5 hrs; n=7; 15.8 ± 2.4 SZs/hr, 37.6 ± 6.7 sec/seizure). In 11 cultures, D-APV (50 μM) was added for 20 min after 20 min of high K^+. The number of high K^+ induced SZs decreased significantly during D-APV application: before, 4.3 ± 0.7 vs. during, 1.8 ± 0.5/10 min ($p < 0.004$, Wilcoxon). The duration of SZs decreased slightly: before, 30.6 ± 5.2 vs. during, 24.6 ± 3.0 sec ($p > 0.1$, Wilcoxon). L-APV (50 μM) did not suppress the SZs and was not significantly different from control high K^+ bath.

Application of high K^+ medium reliably induced spontaneous SZs in the organotypic HPC cultures. The NMDA antagonist, D-APV, stereoselectively suppressed the number of SZs by 60% but not the duration of each SZs. This suggests that NMDA-receptor mechanisms may mediate events leading up to the initiation of SZs induced by high K^+.

571.3

PAROXYSMAL INHIBITORY POTENTIALS MEDIATED BY $GABA_B$ RECEPTORS IN DISINHIBITED HIPPOCAMPAL SLICE CULTURES. Massimo Scanziani, Beat H. Gähwiler, Margaret Schlumpf, and Scott M. Thompson. *Brain Research Institute, Univ. of Zurich, 8029 Zurich Switzerland*

What is the role of $GABA_B$ receptors in the regulation of hippocampal excitability? The $GABA_B$ antagonist CGP 35 348 blocked the late IPSP in CA3 cells, without causing epilepsy, unlike $GABA_A$ antagonists. Epileptic activity induced by 40 uM bicuculline was changed by low concentrations of the glutamate antagonist CNQX (2uM) into a cycle of epileptic bursts alternating with paroxysmal inhibitory potentials (PIPs), consisting of an EPSP followed by a long-lasting (1-2 s) hyperpolarization. PIPs were as large as 30 mV, were prolonged by the GABA-uptake blocker nipecotic acid, were reduced by the opioid-agonist FK 33-824, and reversed near E_{K^+}. CGP 35 348 abolished the PIPs, indicating that they are mediated by $GABA_B$ receptors. Unlike control $GABA_B$ IPSPs, the amplitude of the PIP was reduced by the NMDA-receptor antagonist D-APV. Regular stimulation elicited a cyclical pattern of responses consisting of gradually increasing PIPs followed by an epileptic burst, which then reset the cycle. Similarly, low concentrations of bicuculline (2uM) alone increased the amplitude of control $GABA_B$-mediated synaptic potentials 2-3 fold. Like the PIP, these responses were D-APV-sensitive and could be cyclical. Unlike control, however, application of CGP 35 348 under these conditions lead to intense epileptic discharge. Amplification of $GABA_B$-mediated inhibition may be a self-protective mechanism, preventing epileptogenesis after partial disinhibition.

571.4

A REVERSIBLE LOSS OF DENDRITIC SPINES ACCOMPANIED BY A DECREASE IN EXCITABILITY IN A MODEL OF CHRONIC EPILEPSY IN VITRO. Michael Müller*, Beat H. Gähwiler, Esther Peterhans and Scott M. Thompson. *Brain Research Institute, University of Zürich, 8029 Zürich, Switzerland.*

Chronic epilepsy was induced in mature rat hippocampal slice cultures by adding bicuculline methochloride (BMC) or picrotoxin to the medium for 3 days. After 3 days, there was vacuolation of the soma, the number of spines in HRP injected cells was considerably reduced, and dendritic swellings appeared. The damage affected CA1, CA3 and granule cells. Intracellular recordings showed a significant reduction in spontaneous synaptic activity. However, IPSPs could still be evoked and were similar to those in untreated cultures. GABA immunohistochemistry suggested that interneurons were intact in treated cultures. Acute addition of BMC to control cultures resulted in spontaneous, long-lasting (>5 s) ictal bursts followed by spontaneous and evoked interictal bursting (<1 s). In treated cultures, however, ictal bursts were never observed, although interictal bursts were still evoked. Moreover, Timm's staining of treated cultures suggested either a loss of mossy fiber terminals, or a depletion of zinc. BMC-treated cultures returned to normal medium for 1 week appeared to have recovered: high levels of spontaneous activity were observed, HRP injected cells possessed normal spines, and acute application of BMC resulted in spontaneous ictal bursts. The data suggest that chronic epileptiform activity causes a transient decrease in excitability, perhaps as a result of reversible morphological changes.

571.5

THE EFFECTS OF EXTRACELLULAR POTASSIUM ON EPILEPTIFORM BURST DYNAMICS IN CULTURED MONOLAYER NEURONAL NETWORKS. B.K. Rhoades and G.W. Gross. Dept. of Biological Sciences, Univ. of North Texas, Denton, TX 76203.

Neuronal cultures from embryonic mouse CNS tissue form networks whose native, spontaneous activity is characterized by consolidation of spikes into coordinated, patterned bursting. This activity may be regarded as epileptiform with regards to its coarse-grained synchrony at multiple sites across the networks, its pharmacological responses to convulsant and anticonvulsant drugs, and its responses to the external ionic milieu. Dissociated cell cultures of 100-200 neurons and underlying glial cells were established from the whole spinal cord, ventral spinal cord, and olfactory bulb, taken at embryonic day 14. For explant cultures, transverse spinal cord slices (400μm) were transferred to culture at the same age. The culture substrate was a multimicroelectrode plate, with 64 photoetched electrodes forming a $1mm^2$ extracellular recording matrix. Extracellular K^+ levels were varied by KCl additions to the bathing medium. Each culture was tested in the native activity state and in a disinhibited state produced by 30μM bicuculline. In the native state, increasing extracellular potassium promoted burst consolidation and burst periodicity. Disinhibition produced a more periodic pattern of bursting and more uniform burst amplitudes and durations. In the disinhibited state, increasing extracellular potassium promoted burst periodicity, increased burst rate, decreased burst duration, and decreased burst amplitude. In both states increasing extracellular potassium promoted synchronization of bursts across the network. These results held for both dissociated cell and explant tissue slice cultures. The results also parallel those reported for induced epileptiform bursting in the adult hippocampal slice, and support the cultured monolayer neuronal network as an *in vitro* model of epileptic activity. (Supported by grants from the Texas Advanced Research Program and the Hillcrest Foundation of Dallas, founded by Mrs W.W. Caruth, Sr.)

571.6

COOPERATIVE PHENOMENA IN NEURONAL NETWORKS: DYNAMICAL MODELS OF EPILEPTIFORM ACTIVITY IN SMALL NEURONAL ENSEMBLES. J.M. Kowalski*, G.L. Albert*, B.K. Rhoades, and G.W. Gross. Depts. of Physics* and Biological Sciences, Univ. of North Texas, Denton, TX 76203.

A new class of neuronal network models is being developed (Kowalski & Gross, 1990) where the basic structural units are neurons of Hodgkin-Huxley type and synaptic interactions are represented by a simple model of the neurotransmitter release and subsequent generation of postsynaptic microcurrents. Each neuron is governed by a scalar equation for membrane potential, a subsystem of kinetic equations for ionic variables, and equations describing neurotransmitter kinetics at synaptic junctions. The model can accommodate a wide range of network interconnection schemes and types of interactions, and allows parametric changes in ionic gradients and conductances. Networks composed of non-endogenous bursters bifurcate into approximately synchronous and phase-locked bursting states. Local network disinhibition results in the emergence of activity patches which may grow, decay, or remain stationary. The model qualitatively mimics some observed effects of extracellular $[K^+]$ on epileptiform bursting in neuronal cultures from embryonic mouse CNS tissue (Rhoades & Gross, this conf.). Simulations with excitatorally interconnected networks match the experimental results from pharmacologically disinhibited cultures; in that increasing extracellular $[K^+]$ decreases both burst and interburst durations. The inclusion of inhibitory interactions may reveal the more complex $[K^+]_o$ effects observed in non-disinhibited cultures. With the further elaboration of network substructure, we expect the model to also show rapid state transitions to synchronized bursting and the local emergence and network spread of coordinated activity patterns. (Funded by grants from the Texas Advanced Research Program and the Hillcrest Foundation of Dallas, founded by Mrs W.W. Caruth, Sr.)

571.7

SPONTANEOUS SYNAPTIC POTENTIALS IN CULTURED SPINAL CORD NEURONS DURING DEVELOPMENT OF EARLY CONVULSANT ACTIVITY PRODUCED BY TETANUS TOXIN. G.K. Bergey and P.J. Franaszczuk*. Departments of Neurology and Physiology, University of Maryland School of Medicine, Baltimore, Maryland 21201

Tetanus toxin is distinct from other convulsants in acting at a presynaptic locus to produce a gradual onset of paroxysmal depolarizing events (PDE) following a dose dependent period (Bergey et al., 1983, 1987). To investigate the changes in synaptic activity occurring during the evolution of convulsant activity, an algorithm was developed for continuous detection of spontaneous postsynaptic potentials (Franaszczuk and Bergey, submitted). Intracellular recordings from dissociated mouse spinal cord neurons in culture (4-10 wk of age) following the addition of tetanus toxin (100-1000 ng/ml final con). Typically 200-600 PSPs/min were detected during the period prior to the onset of established convulsant activity. During this time period the absolute numbers of spontaneously occurring EPSPs increased while the amplitudes of the observed spontaneously occurring EPSPs variably remained constant or diminished. The numbers of spontaneously occurring IPSPs decreased and the amplitudes of the observed IPSPs invariably decreased. Spontaneously occurring large IPSPs disappeared during the period preceding organized convulsant activity. Following toxin addition, spontaneous EPSPs became clustered in advance of the onset of organized convulsant activity (PDE).

Tetanus toxin provides a model for evolution of convulsant action resulting from increased network excitation produced by reduced synaptic inhibition and increased numbers of excitatory synaptic events. No evidence exists to suggest augmentation of monosynaptic excitation in this model.

571.8

IMMATURE RAT CA1 SHOWS AN INCREASED PROPENSITY FOR NON-SYNAPTIC EPILEPTIFORM ACTIVITY. S.N. Roper*†, A. Obenaus and E.E. Dudek. Mental Retardation Research Center, †Division of Neurosurgery, UCLA School of Medicine, Los Angeles, CA 90024.

Immature hippocampal slices show an increased propensity for epileptiform activity in several in vitro preparations. In the absence of synaptic activity, the low-$[Ca^{2+}]$ model produces synchronous bursts of population spikes that are enhanced by osmotically reducing the size of the extracellular space (Dudek et al., Neurosci. Lett. 120:267-270, 1990). Hippocampal slices (N=10/group) were obtained from rats aged 7-10 days (1 week), 11-14 days (2 weeks), 20-23 days (3 weeks), and >60 days (adult). Extracellular recordings were made from the CA1 area of the hippocampus in a low-$[Ca^{2+}]$ solution, low-$[Ca^{2+}]$ diluted 20% with H_2O, and low-$[Ca^{2+}]$ with 20 mM mannitol. Slices from all age groups, except 1 week, generated bursts in the control low-$[Ca^{2+}]$ solution (2 weeks 60%, 3 weeks 80%, adults 40%). In low-$[Ca^{2+}]$ diluted 20% with H_2O, 90%, 80%, and 40% of slices showed bursting in the 2-week, 3-week, and adult groups, respectively. In both of the low-$[Ca^{2+}]$ solutions, burst duration was two-fold greater in the 2- and 3-week old groups compared to adults. This study suggests that CA1 hippocampal neurons from 2- and 3-week-old rats are more susceptible than adults to low-$[Ca^{2+}]$-induced epileptiform activity; this implies that the increased propensity of immature hippocampus for seizure activity is not dependent on synaptic mechanisms. Supported by NIH grant HD05958.

571.9

GIANT IPSC'S RECORDED IN HIPPOCAMPAL PYRAMIDAL CELLS IN THE PRESENCE OF EXCITATORY AMINO ACID BLOCKERS.

K.L. Perkins, H.B. Michelson, and R.K.S. Wong. Center for Neurobiology and Behavior, Columbia University, 722 W. 168th St., NY, NY 10032; Dept. of Pharmacology, SUNY/HSC, 450 Clarkson Ave., NY, NY 11203.

Whole-cell voltage clamp recording from pyramidal cells in transverse slices of guinea pig hippocampus in the presence of 4-aminopyridine(75 uM) revealed large synaptic events which were in part composed of a giant (500-2000 pA, varying among slices) outward current. These giant outward currents(ipsc's) continued to occur spontaneously 1 to 4 times per minute in the presence of CNQX (10uM) and CPP (10 uM). The intracellular solution consisted of (mM) potassium gluconate 120, Hepes 10, EGTA 10, and NaCl 10. The giant ipsc's had at least two components. One component reversed at the same potential as the spontaneous unitary ipsc's; therefore it probably is a GABA-mediated chloride current. The other component reversed at a more negative potential.

The giant ipsc's presumably reflect the synchronous firing of inhibitory interneurons. The amplitude of the giant ipsc's was 25-85 times the amplitude of the unitary ipsc's. This number can be used to estimate the number of inhibitory interneurons innervating a single pyramidal cell in a hippocampal slice.

(Supported by NIH and by a NSF Graduate Fellowship to KLP.)

MEMBRANE CURRENT IN HIPPOCAMPAL NEURONS DURING ELECTRICALLY PROVOKED ELECTROGRAPHIC SEIZURES.

G. Czéh, P.G. Aitken, G.G. Somjen, Dept. Cell Biology, Duke Univ. Med. Center, Durham NC 27710

Interictal epileptiform discharges have in the past been studied in much greater detail than the neuron discharges occurring during actual seizures. We have previously suggested (Somjen et al., J. Neurophysiol., 53: 1079, 1985) that in hippocampal neurons, ictal events are generated by a sustained inward current in the neuron soma. The present experiments used conventional sharp elecrode recording in current clamp mode, and whole cell patch in voltage clamp mode, to further investigate ictal events in CA1 pyramidal cells. Rat hippocampal slices were maintained in an interface chamber with slightly elevated bath K^+ (5.0 mM). Population responses were monitored by extracellular electrodes. Orthodromic stimulation (2-10 sec trains, 0.1 msec, 80-150 μA, 10-50 Hz) provoked electrographic seizures consisting of tonic-sustained as well as clonic-intermittent discharges. The current required to hold membrane potential at hyperpolarized levels reversibly increased during both tonic and clonic phases of a seizure. Voltage-current (V-I) plots shifted, indicating depolarization and decreased input impedance. The findings are consistent with sustained inward current caused by increased ion conductance in membrane regions near the patch electrode during seizure discharge. (Supported by grants NS 17771, NS 18670, NS 06233).

HYPOXIA MODULATES THE EPILEPTIFORM ACTIVITIES INDUCED BY MAGNESIUM-FREE MEDIUM IN SLICES OF RAT HIPPOCAMPUS - ENTORHINAL CORTEX.

H. Kojima and M. Kowada*. Dept. of Neurosurgery, Akita Univ. Sch. of Med., Akita, 010 Japan.

Combined slices of rat hippocampus (HC) and entorhinal cortex (EC) exhibit electrographic seizures when exposed to medium containing no added magnesium (0-Mg medium). These seizures are eventually replaced by interictal bursts (IIBs). It has been previously reported that the IIBs, arising in CA3, disturb the seizure generation in EC. We have hypothesized that the suppression of IIBs in CA3 promotes seizures in EC. Here we describe that mild hypoxia, suppressing IIBs in CA3, promotes seizure generation in EC.

Extracellular recordings were made in area CA3 and EC of HC/EC slices of male Sprague-Dawley rats using a submersion chamber. The bath PO_2 was monitored with a Clark-type oxygen electrode in some cases (n=13). In the 0-Mg medium, seizures appeared first but eventually they gave way to IIBs in both regions. After the seizures were completely replaced by IIBs, mild hypoxia was introduced by switching the oxygenation gas from $95\%O_2+5\%CO_2$ (bath PO_2=551mmHg) to $30\%O_2+65\%N_2+5\%CO_2$ (bath PO_2=211mmHg). In all the slices tested (n=19), the IIBs were suppressed in CA3 and the seizures reappeared in EC during the hypoxic period. In regular artificial cerebrospinal fluid, orthodromic population spikes in CA3 were almost completely suppressed by the mild hypoxia whereas those in EC were less affected (n=10).

In conclusion, hippocampal area CA3 is more susceptible to hypoxia than EC and the suppression of IIBs in CA3 by mild hypoxia promotes seizures in EC.

571.12

BICUCULLINE-INDUCED INTERICTAL BURSTING DECREASES THE DURATION OF STIMULUS-INDUCED ICTAL BURSTING IN THE RAT HIPPOCAMPAL SLICE.

Debbie S. Barr* and Wilkie A. Wilson, Depts. of Pharmacology and Medicine, Duke Univ. and V.A. Medical Centers, Durham, N.C.

We demonstrated previously that in a 0-Mg^{+2} model of electrographic seizures (EGS's) in the rat hippocampal slice, interictal (II) activity suppressed ictal activity; application of the $GABA_B$ agonist baclofen (2-4 uM) inhibited II bursting and reversed this effect. We now show similar results using stimulus-induced EGS's in the in vitro hippocampal slice.

EGS's were induced in the slice preparation by repeated stimulus trains (Science, vol 245:648-651, 1989); then the $GABA_A$ antagonist bicuculline (10 uM) was added to the bath to initiate II bursting. EGS duration was reduced markedly in 11 of 12 experiments. Baclofen (1 uM) was then applied to the bath in the presence of bicuculline to suppress all II activity. Application of baclofen allowed partial to near complete recovery of EGS duration in 9 of 10 slices. In 8 of these experiments, interictals were simulated electrically in the presence of bicuculline and baclofen, and EGS duration was once again significantly diminished.

II bursting is viewed clinically as a symptom of epileptiform activity. These studies suggest that II bursting may actually exert negative feedback control of ictal burst duration.

GAD mRNA INCREASES IN NEURONS FROM CHRONIC EPILEPTIC FOCI INDUCED IN RATS BY INTRAHIPPOCAMPAL TETANUS TOXIN.

J.G.R.Jefferys, A.Najlerahim*, S.F.Williams* and R.C.A.Pearson. Dept. Physiology & Biophysics, St. Mary's Hosp. Med. Sch., London W2 1PG, and Dept. Biomedical Sci. Sheffield Univ., UK.

Intrahippocampal tetanus toxin induces chronic epileptic foci in both injected and contralateral hippocampi[1]. Epileptic activity recurs intermittently for at least 6 weeks, usually remitting by 8 weeks[2]; it is associated with impaired GABAergic inhibition. The low dose of toxin used (ca. 6-12 mouse LD_{50}) causes no gross histopathology.

Here we used in situ hybridization (ISHH) of mRNA for GAD to determine the continued presence and condition of inhibitory interneurons[3]. Slices were prepared for recording in vitro from 2 rats at each survival time (1, 2, 4, 8 weeks), and epileptic responses were recorded from slices from both hippocampi in every case. ISHH revealed no loss of inhibitory neurons in any hippocampal subregion in the toxin injected rats. In the vehicle-injected rats the amount of GAD mRNA per neuron fell in the hilus and CA3 up to 2 weeks after injection, recovering thereafter. In contrast, inhibitory neurons in the toxin-injected group did not show this dip in GAD mRNA, and at 4 weeks, showed a significant increase, which reached double the control value in hilar neurons.

The increase in GAD mRNA in these epileptic rats indicates plastic, possibly adaptive responses to recurring epileptic discharges.

INHIBITION IN PRIMARY AND SECONDARY CHRONIC EPILEPTIC FOCI INDUCED BY INTRAHIPPOCAMPAL TETANUS TOXIN.

Ruth M. Empson* and John G.R. Jefferys. Dept. Physiology & Biophysics, St. Mary's Hosp. Med. Sch., Imperial Coll., London W2 1PG, England.

Injecting tetanus toxin into one hippocampus of a rat induces chronic epileptic foci in both hippocampi[1], which remain epileptogenic for at least 6 weeks. We know that GABA release is depressed 2 weeks after bilateral injections of the toxin[2]. Here we compare inhibitory function in the primary and independent, secondary, "mirror" foci.

Hippocampal slices were prepared 10-16 days after injection of 12 mouse LD_{50} into one hippocampus and used for two studies in vitro:-

1. The Ca^{++}-dependent, K^+-evoked release of ^3H GABA was depressed for slices from the injected hippocampus, in accord with previous acute and chronic studies[2]. In contrast, it remained normal in the contralateral slices, although they generated similar epileptic activity.

2. In control slices, both fast and slow IPSPs are reliably recorded from CA3 pyramidal cells following afferent stimulation. Both were consistently abolished within the primary focus in slices from injected hippocampi. In contrast, fast and slow IPSPs were present in a minority of CA3 cells from the focus in the contralateral hippocampi (respectively 4 and 8 of 17 cells).

The secondary focus thus differs from the primary in retaining some inhibitory function, in spite of producing similar epileptic discharges.

RHYTHMIC SLOW ACTIVITY AND OSMOTIC CHANGE IN CA3 PYRAMIDALE OF RAT HIPPOCAMPUS. E.P. Osehobo* and R.D. Andrew. Anatomy Department, Queen's University, Kingston, Ontario K7L 3N6

Osmolality inversely affects epileptiform activity both clinically and in brain slices (Andrew, R.D., *J. Neurol. Sci. 101*, 7-18). Rhythmic slow activity (RSA) encodes memory in lower mammals and represents a non-pathological oscillation of cortical neurons. We examined the effect of osmolality on the duration and frequency of RSA which consists of a 4-10 Hz oscillation (theta rhythm) overriding a periodic slower depolarization (SD). RSA was induced by 40 μM carbachol and intracellularly recorded in CA3 neurons. Artificial CSF (ACSF) elevated to +40 mOsm with mannitol slowed SD frequency (16 of 16 cells). Conversely -40 mOsm ACSF increased SD frequency (9 of 13). Glycerol however (+40 mOsm) had no effect (4 of 4), indicating that the frequency effects were osmotic in origin. There was no consistent change in theta frequency (n=9) but overriding action potentials were often reduced or arrested in hyperosmotic ACSF (8 of 12). The lack of osmotic effect on theta, which is intrinsically generated by CA cells (and synaptically synchronized) fits with previous data showing no endogenous or synaptic CA3 changes in ± 40 mOsm ACSF. On the other hand, changes in SD frequency and action potential firing may reflect elevated accumulation and slower clearance of K^+ from the reduced extracellular space induced by hyposmotic ACSF. Conversely, hyperosmolality may reduce $[K^+]_{out}$, lowering SD frequency. This hypothesis will be investigated further.

571.16

OSMOTIC EFFECTS UPON FIELD POTENTIALS: EXCITABILITY CHANGE OR SIMPLY RESISTIVE CHANGE? S.J. Quackenbush*, J. Goh and R.D. Andrew. Depts. of Anatomy & Pharmacology, Queen's University, Kingston, Ontario K7L 3N6

Lowered osmolality leads to increased seizure susceptibility both clinically and in brain slice preparations (Andrew, R.D. *J. Neurol. Sci. 101*, 7-18). The field EPSP (fEPSP) and population spike (PS) amplitude recorded in CA1 stratum pyramidale or radiatum are inversely proportional to artificial CSF (ACSF) osmolality. In -40 mOsm ACSF, the orthodromic PS evoked from CA3 radiatum increased by 46 ± 11% at maximal stimulation but increased by 107 ± 39% at sub-maximal stimulation (n=6). The antidromic PS increased by 43 ± 12% and 67 ± 16% (n=9) at max and sub-max stimulation respectively. A +50 mOsm increase using D-glucose *decreased* control ortho PS amplitude by 45 ± 21% at max stim and 69 ± 24% at sub-max stim (n=6). The antidromic PS also decreased by 28 ± 2% and 41 ± 4% (n=9), max and sub-max respectively. The consistently greater sub-max changes suggest that the increased field potentials in hyposmotic media result from neuronal recruitment and not simply from increased extracellular resistance presented by cell expansion. Furthermore unlike the CA1 fEPSP, the preceding CA3 afferent volley was not significantly altered in -40 and +50 mOsm ACSF nor at max and sub-max stim (n=5). With a purely resistive change, both fields should be equally affected. We propose that axons and their glia are less susceptible to volume changes than somatic and dendritic regions.

571.17

EPILEPTIFORM DISCHARGES INDUCED BY TETRAETHYL-AMMONIUM (TEA) IN THE RAT HIPPOCAMPAL SLICE. Y. Fueta and M Avoli. MNI and McGill Univ. Montreal, Quebec, H3A 2B4.

TEA is a K' channel blocker and a convulsant drug in the CNS. We have shown that 4-aminopyridine (4-AP), which blocks a different K' channel, induces epileptiform discharges and synchronous GABA-mediated depolarizing potentials in the CA3 subfield of the rat hippocampal slice (J Neurophysiol, 65:771,1991). Therefore intra- and extracellular recordings were performed to study whether TEA could disclose similar patterns in the CA3 subfield. Like 4-AP, TEA induced interictal-like epileptiform field potentials, which were associated with an intracellular burst of action potentials, were blocked by the non-NMDA antagonist CNQX in a dose-dependent manner, and were resistant to CPP, which is an NMDA receptor antagonist. However TEA did not disclose any GABA-mediated depolarization, although inhibitory mechanisms appeared to be operant. Our data show that TEA induces epileptiform discharges mediated through non-NMDA receptors, but it is not capable of modifying GABA-mediated transmission in a way similar to that reported for 4-AP.

571.18

4-AMINOPYRIDINE-INDUCED SPREADING DEPRESSION EPISODES IN CA3 AREA OF IMMATURE HIPPOCAMPAL SLICES AND THEIR RESPONSE TO EXCITATORY AMINO ACID ANTAGONISTS. C. Psarropoulou*, V. Tancredi and M. Avoli. MNI, McGill University, Montreal, QC, Canada H3A 2B4

Perfusion with 4-aminopyridine (4-AP, 50μM) induced the appearance of spontaneous epileptiform activity and spreading depression (SD) episodes in CA3 hippocampal subfield of slices obtained from 2-30 day-old rats. SD was observed in 34% of all slices tested, a percentage increasing to 50% when only 11-20 day-old slices were considered and declining to 23% for 21-30 day-old slices. SD appeared in all CA3 strata concurrently, having the largest amplitude and duration in the pyramidal layer. Under these conditions, SD was also recorded in CA1, preceding or following that in CA3 area. The negative field potential accompanying SD had an amplitude of 18.1±1.1mV (mean±SEM, n=31), duration ranging from 20-250 s and it occurred every 4.5-33 min. SD was blocked by the application of the NMDA receptor antagonist CPP (2-10μM, n=10), but not by CNQX (5μM, n=6) which is a non-NMDA receptor antagonist. These results demonstrate that: 1) SD episodes can be generated in immature tissue under conditions that do not provoke them in adult tissue and 2) excitatory amino acid receptor subtypes are differentially involved in their generation.

IRON INDUCES "EPILEPTIFORM" ACTIVITY IN RAT HIPPOCAMPAL SLICES. **RA Palovcik, BM Uthman, C Koch, and BJ Wilder. Neurol. Dept. VAMC and Univ. of Florida, Gainesville, FL 32608.**

Intracerebral iron deposits have been suspect as a cause of posttraumatic epilepsy.

"Epileptiform" activity induced by iron occurred after bath application of $FeCl_3$ to achieve a 5 x 10^{-5} M solution. Lower doses (2.5 x 10^{-5} M $FeCl_3$) only increased single unit firing rates. Alterations of $[K^+]_o$ from 3.0 mM to 6.25 mM had no effect on iron-induced "seizure-like" activity but enhanced spontaneous background activity. Bursts of "seizure-like" activity were often followed by periods of depressed activity, similar to an epileptic post-ictal stage.

Most slices had an apparent CA3 to CA1 direction of spike propagation although phase reversal and uncoupling of large "epileptiform spikes" at the two sites often occurred during periods of maximum firing.

Iron application often doubled CA1 recorded population spike amplitude elicited by stimulation of the Schaffer collateral-commissural pathways in stratum radiatum. The acute excitatory and convulsive effects of iron may therefore contribute to its long-term epileptogenicity.

GENETIC CONTROL OF OSCILLATING BRAIN EXCITABILITY IN INBRED GERBIL STRAINS. J.W. Collins and W.B. Iturrian, Pharmacology, University of Georgia, Athens, GA 30602.

The spontaneous seizures of the gerbil model of epilepsy do not occur randomly, but rather show a periodicity across days. Each individual has its own rhythm suggesting that seizure diathesis involves an oscillator of brain excitability. We show a genetic basis for such long term control mechanism by selective breeding. The Black Inbred UGA gerbil was derived from animals that seizure with an intertest interval (iti) of 7 days. The commercial inbred Mon/Tum do not kindle at this iti. F_1 hybrids and parental lines were sensory kindled by handling at itis of 1,3,4,7 or 14 days. The most effective regimen was highly strain dependent with Mon's preferring a 3 or 4 day while BI show 7 days and F_1 are intermediate. A 14 day iti markedly increased severity in all previously kindled gerbils. This kindling is a sensory dependent phenomenon independent of previous seizure and number of tests but varies as a function of iti. Once kindled, seizure susceptibility persists for months. A postictal phase lasts 3-4 days but habituation is the more important refractory state. An overlap for kindling and refractory regimens causes difficulty in sensory kindling Mon and non-inbred gerbils. Although the neurological mechanism(s) for kindling, habituation and postictal protection are unknown, all are controlled by genetically regulated oscillators that can either increase or decrease brain excitability.

572.1

EFFECTS OF BETA AMYLOID (B1-28 & B25-35) ON HIPPOCAMPAL SLICE CULTURES. M.R. Harrigan*, D.D. Kunkel and A.T. Malouf. Dept. of Neurological Surgery, University of Washington, Seattle, WA 98195

Beta amyloid alters neuronal viability in dissociated hippocampal cultures, and may play a direct role in the etiology of Alzheimer's Disease (Whitson et al., *Science* 243, 1488-1490). We are analyzing the effects of B1-28 and B25-35 on rat hippocampal slice cultures; a culture system that maintains the organotypic structure and synaptic connectivity of the intact hippocampus. Slice cultures were exposed to 30uM B1-28 for 2-14 days, and individual CA3 pyramidal neurons were filled with Lucifer yellow or neurobiotin. No gross differences in the overall health of the cultures or morphology of individual cells were observed between B1-28-treated and control cultures. Cumulative length and number of branch points of apical dendrites were quantified using the Eutectics image analyzer. A small increase in number of branch points was observed. Slice cultures were exposed to 50ng/ml NGF + B1-28 (30uM or 100uM), since NGF was reported to enhance the potency of beta amyloid (Yankner et al., *PNAS* 87, 9020-9023). Small increases in length and number of branches of the apical dendrites were observed after exposure to 30uM B1-28 + NGF. We are presently examining the effects of B25-35 (100uM) on hippocampal slice cultures. B25-35 has been reported to be more potent than B1-28 (Yankner et al., *Science* 250, 279-282). Cultures exposed to B25-35 for 24 hr appear less healthy than untreated controls. Cumulative dendritic length and number of branch points are being quantified. Beta amyloid appears to have small effects on the viability of neurons in hippocampal slice cultures.

AMYLOID β-PROTEIN IMMUNOREACTIVITY IN SPLEEN, LYMPH NODE AND OTHER NON-NEURAL TISSUES USING A NEW AβP ANTISERUM.

C. Lemere*, H. Yamaguchi*, C. Joachim-Morris, D. Selkoe, Harvard Medical School, Boston, MA 02115.

AβP-immunoreactive deposits have previously been observed in certain non-neural tissues (e.g., skin, intestine) in numerous patients with Alzheimer's disease (AD) and about 1/4 of aged controls. Here, we report the presence of occasional vascular AβP-reactive deposits in lymph node, spleen, omentum and mesentery from 4 autopsied AD patients, using a new antiserum to synthetic A P_{1-40} (R1280). Other than occasional vascular staining in lymph nodes, no R1280 reactivity was found in matching non-neural tissues of 2 young and 3 aged controls. Staining was markedly reduced by absorption with synthetic AβP1-40. Affinity purified R1280 (AP-R1280) was compared to the whole antiserum, the flow-through (FT) fraction and the preimmune serum on AD brain, intestine and lymph node. Preimmune serum did not label any AβP deposits. R1280 and AP-R1280 both labeled plaques and blood vessels in brain, but only R1280 labeled the vascular deposits in non-neural tissues. The FT R1280 fraction stained blood vessels in AD brain and also in non-neural tissues.The staining was markedly reduced with AβP absorption. Our results extend the detection of small amounts of AβP-reactive deposits to additional non-neural tissues and further support the hypothesis that AβP deposition can occur independently of neuronal alteration and may be of vascular origin.

572.3

THE APPREP SYSTEM, PROTEIN PROCESSING AND BAP PRODUCTION: CHARACTERIZATION OF APP-REPORTER EXPRESSION M.P.Vitek, J. Jacobsen, J. Sonnenberg, S. Sahasrabudhe, H. Muenkel, M. Spruyt and A. J. Blume. Molecular Neurobiology, Lederle Laboratories, American Cyanamid, Pearl River, NY 10965.

We wish to understand how and why BAP levels increase in AD brain. Using an S1 nuclease protection assay, total APP RNA levels increase 2 to 3 fold ($p<0.01$) in 16 AD vs. 10 normal brains (Jacobsen,etal. Neurobiol. Aging 12(1991)in press) which partially explains the increased BAP levels in AD. The remainder may be due to protein processing of the Amyloid Peptide Precursor (APP) into BAP. To test this, we have reconstituted a marked APP substrate with BetA-endoPeptidase (BAPase) enzymes. APP must be cut at the ends of its internal BAP domain by amino-BAPase (N-BAPase) and carboxy-BAPase (C-BAPase) activities which may change in AD. Alternatively, the Dutch and London mutations found in the BAP region of APP may alter these BAPase activities. To measure BAPase activities and resolve the contribution of substrate mutations, we have engineered analogs of **APP** to contain **REP**orter epitopes flanking the BAP domain. Proteolytic cleavage of APPREP is followed by immunological detection of reporters associated with protein fragments whose lengths reflect cleavage location. We have expressed and specifically detected APPREP with antibodies to the Kunitz Protease Inhibitor domain of APP and to Substance-P. Further characterization of APPREP with additional antibodies, aminoacid sequencing, peptide mapping and HPLC analysis are in progress.

MOLECULAR CLONING OF A NOVEL AMYLOID PROTEIN IN ALZHEIMER'S DISEASE.

K. Ueda, H. Fukushima*, E. Masliah, D. Otero*, K. Horsburgh*, J. Kondo*a, Y. Ihara*b, and T. Saitoh. Dept. of Neurosciences, Sch. of Med., University of California, San Diego, La Jolla, CA 92093-0624, aMitsubishi Kasei Co., Res. Ctr., Japan, and bInst. of Brain Res., University of Tokyo, Tokyo, Japan.

Although β/A4-protein was found to be a major constituent of amyloid in Alzheimer's disease (AD) brain, other components might also be found in AD amyloid. Recently, we have discovered a new component of amyloid from AD brain and cloned the corresponding cDNA. Amyloid was purified in the presence of SDS, solubilized in formic acid, digested with cyanogen bromide, then with endopeptidase and analyzed by HPLC. Analysis of the amino acid sequence showed, in addition to the β/A4-protein fragment, a peptide with unknown sequence. We named this peptide NAC signifying New Amyloid Component. This sequence was used to raise a rabbit antiserum, which stained the amyloid core of neuritic plaques on brain sections and a 40kD protein in Western blots. Oligonucleotides were generated from this sequence to amplify the cDNA from human brain cDNA library using PCR. A 247-nucleotide DNA was amplified. DNA sequencing showed this PCR product to contain a nucleotide stretch which encodes the exact peptide sequence of NAC. The amino acid sequence deduced from the DNA sequence demonstrated a striking feature of NAC, i.e., five K#K##V sequences in this 82-amino acid stretch. Furthermore, a 10-amino acid homologous sequence is found to be repeated in it. The characterization of NAC should shed light on the amyloidogenesis in AD and may help in the search for the etiology of this disease.

BIOLOGICAL ACTIVITY OF THE SECRETED FORM OF AMYLOID β/A4 PROTEIN PRECURSOR II: FUNCTIONAL ANALYSIS OF APP FRAGMENTS.

L.A. Flanagan[a], J.-M. Roch[a], M. Sundsmo[a*], L.M. Refolo[b*], N.K. Robakis[b], and T. Saitoh[a]. [a]Dept. of Neurosciences, 0624, Univ. of California, San Diego, La Jolla, CA 92093 and [b]Dept. of Psychiatry, Mt. Sinai School of Medicine, New York, NY 10029.

The secreted form of APP-695 affects the growth regulation of fibroblasts (Cell 58:615-622, 1989). Using proteins made in E. coli or purified from human brain, we are testing N-terminal fragments of APP for growth regulating activity. Several plasmids which drive the synthesis of various fragments of the extracellular domain of APP-695 were constructed using a prokaryotic expression vector. These fragments were purified from bacterial lysates and were tested for the ability to support the growth of A1 fibroblasts, a cell line which produces very low levels of APP and depends on the presence of exogenous APP in the medium for normal growth. Lysates of bacteria carrying only the expression vector were used as negative controls. Whereas some fragments showed no growth stimulating activity, others were active. Our results suggest that this biological activity of the secreted form of APP-695 is contained within a region 40 amino acids in length. Experiments using peptides corresponding to the region of interest are now under way to further define the site of activity. In addition, a fragment of the secreted form of APP from human brain is being studied. This 35 kD fragment, recognized by antibodies to N-terminal epitopes, is increased in Alzheimer (AD) cortex (Neurosci. Lett. 100:340-346, 1989). Investigation of this fragment may yield information on the processing and the biological activity of APP in AD. The purification of this peptide is in progress.

572.6

EXPRESSION OF ALZHEIMER'S AMYLOID PROTEIN BY HUMAN NEUROGLIOMA CELLS: SYNTHESIS, DISTRIBUTION, AND SECRETION.

T.J. Raub*[1], S.L. Kuentzel*[1], R.A. Altman[2], D.E. Lowery[2], and B.D. Greenberg[2]. [1]Drug Delivery Research and [2]Molecular Biology, Upjohn Laboratories, Kalamazoo, MI 49001.

Using antisera against full length AAP695 expressed by baculovirus, we followed synthesis and secretion of AAP in human brain neuroglioma cells (ATCC HTB 148) to determine the site of proteolysis preceeding secretion. These cells were found to express mostly AAP695, some AAP770 and no AAP751 by PCR. Pulse-chase with [35S]met followed by immunoprecipitation, SDS-PAGE and autoradiography reveals a prominent 120-kDa species that is accumulated at 15°C and is Endo H sensitive. After warming to 20°C, a family of proteins appears at 145-165 kDa that are not Endo H sensitive and are sulfated at 20°C suggesting that immature AAP has moved from ER to late Golgi. Shift to 37°C results in rapid and constitutive secretion of a 135-kDa species into the medium. Chase from the immature to the secreted form, which is not detected intracellularly at 20°C, 37°C or in the presence of weak bases, takes 2 h. Immunofluorescence microscopy of permeabilized cells shows that AAP is located mostly in a perinuclear compartment that also labels with wheat germ agglutinin. AAP is not colocalized with cathepsin B nor is it detected at the plasma membrane. These results indicate that AAP is a late Golgi membrane glycoprotein that is cleaved in a neutral, post-trans Golgi compartment enroute to the cell surface.

Participation of the Amyloid A4 Precursor Protein in Lymphocyte Activation

Yoo-Hun Suh, Woong Choi*, Jae-Bum Kim*, Sung-Soo Kim*, Jong-Inn Woo* and Chan Woong Park*

Dept. of Pharmacology, Seoul National University College of Medicine and Dept. of Molecular Biology, Neuroscience Research Institute, Seoul National University, Seoul 110-460, Korea

Amyloid deposition in senile plaques and the cerebral vasculator is a marker of Alzheimer disease. It is encoded as part of a larger precursor(Pre A4) that maps to chromosome 21. Three mRNA-bands have now been accounted for by the demonstration of three alternative splicing products.

The precursor proteins(Pre $A4_{695}$, Pre $A4_{751}$, and Pre A_{770}) of Alzheimer disease A4 amyloid protein are integral, N-glycosylated membrane proteins of unknown function.

Here we report that normal human lymphocytes express pre A4 mRNA and protein. Pre A4 is detectable on the surface of lymphocytes. Lymphocyte Pre A4 surface abundance is increased by cell activation. We conclude that Pre A4 is a lymphocyte surface molecule that may participate in cell activation.

Phagocytosis and Vascular Deposition of Alzheimer Amyloid in Rat. S.A. Frautschy, G.M. Cole and A. Baird, Dept.of Cellular and Molecular Biology, Whittier Institute, 9894 Genesee, La Jolla, Ca.92037 and Dept. of Neurosciences, UCSD, La Jolla, Ca. 92093

Deposits of extracellular β amyloid occur in plaques and vessels in Alzheimer's disease(AD), but they are not found in normal rodent aging, nor have they been induced. In order to develop an animal model for β amyloidosis, we injected amyloid cores from AD brains and, contralaterally, similarly isolated control lipofuscin fractions into cortex and hippocampus of adult rats. Rats were sacrificed 2 d (n=2), 7 d (n=2) and 30d (n=10) and 60d (n=2) after injection and sections were silver or Congo red stained or immunostained for β amyloid. Amyloid and lipofuscin moved medially and laterally from the injection site and persisted for at least 2 months. The astroglial and microglial responses indexed by glial fibrillary acidic protein and OX-42 immunostaining were similar on the amyloid and control sides. By 7d much of the amyloid was in or near phagocytes which appeared to migrate to the vessels and the ventricles. At 30d, there was clear vascular β protein immunostaining. These results show that in the rat, AD amyloid deposits in the neuropil can be aggressively phagocytosed and deposited in vessels.

Studies in transfected cells have shown that the secreted form of Alzheimer amyloid precursor protein (APP) is generated by cleavage of full-length, membrane-bound APP on the N-terminal or C-terminal side of lys^{16} of the β amyloid peptide (βAP). Since βAP is deposited in amyloid fibers, cleavage within βAP cannot lead to amyloid formation. We examined secreted APP purified from medium conditioned by untransfected PC-12 cells which had been differentiated to a neuronal phenotype by NGF. Analysis of the C-terminal peptides obtained after CNBr digestion indicated that cleavage occurs between βAP lys^{16} and leu^{17}. In addition, a portion of the original secreted APP reacted with a monoclonal antibody directed against βAP leu^{17}-asp^{23}, suggesting that a portion of secreted APP may be capable of forming amyloid. Investigation of the site of this alternative cleavage is in progress.

DISTRIBUTION AND ULTRASTRUCTURE OF CEREBROVASCULAR AMYLOID IN AGED SQUIRREL MONKEYS. L.C. Walker and D.L. Price. Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Balto., MD 21205.

Cerebrovascular amyloidosis occurs in the context of several neurological disorders, including Alzheimer's disease. Aged squirrel monkeys (*Saimiri sciureus*) often develop cerebrovascular amyloidosis that is similar in distribution to that of humans. In immunocytochemical studies of animals 18-23 years of age, we have found that: vascular amyloid deposition can be pronounced in the late teens; the incidence and distribution of vascular (and nonvascular) amyloid vary markedly among animals of similar age; and the focal clustering of lesions, which is particularly apparent in mildly affected brain areas, suggests selective involvement of the branches of a common blood vessel. Ultrastructurally, various vascular abnormalities are evident, and foamy, debris- and lipid-laden macrophages often abut amyloidotic vessels. These findings indicate that cerebral amyloid angiopathy in aged squirrel monkeys can selectively affect certain vessels, that the pattern of lesions varies among individuals, and that macrophages may play a role in the processing of mural amyloid in cerebral blood vessels.

STRESS-INDUCED ALTERATION OF APP mRNAs. B. Border, S. Pardue*, E.K. Miller*, and M. Morrison-Bogorad. Dept. of Neurology, Southwestern Medical School, Dallas TX 75235

Although amyloid deposition may be related to changes in absolute or relative amounts of different amyloid precursor proteins (APPs), factors regulating their levels in vivo are unknown. We have shown that two in vivo stressors result in rapid changes in specific APP mRNA levels in rat hippocampus. Rats were made hyperthermic by exposure to heat or injection of amphetamine and sacrificed 2 hours after attaining a temperature of 42°C. Hybridization to an 18s rRNA oligonucleotide probe revealed similar levels of hybridization to neurons in the dentate gyrus and CA1-4 regions in all rats, indicating that signal intensity with mRNA-specific probes could be directly compared. Heat shock alone did not change overall levels of the APP mRNAs, whereas they were increased after amphetamine-induced hyperthermia. There was a reduction in levels of the APP_{695} mRNA in heat shocked rats but a strong induction in the amphetamine-treated rats. Our results suggest that there is a several fold change in the relative amounts of different APP mRNAs after heat shock, while amphetamine induction of both total APP and APP_{695} mRNAs show a separate drug effect over and above that produced by heat shock. APP IMMUNOPOSITIVE GRANULES ARE PRESENT IN A SUBSET OF SENILE PLAQUES WITHIN ALZHEIMER'S DISEASE

B.J. Cummings, J.W. Geddes°, W. Van Nostrand*, S. Wagner*, D.D. Cunningham*, and C.W. Cotman. Depts of Psychobiol., Microbiol.* and Neurosurgery° *University of California: Irvine, CA 92717 USA*

Protease nexin-II has been identified as homologous to the end terminal region of the amyloid precursor protein (APP) containing the Kunitz inhibitor domain. We have examined the distribution and co-localization of APP immunostaining using a monoclonal APP antibody and a polyclonal antibody against β/A4 (1-28) protein. We found that this APP antibody is sensitive to fixation and yields the best results in embalmed tissue. No APP positive staining was observed in controls. Within AD brains, the distribution of APP positive plaques varied greatly, e.g. some AD cases showed the strongest staining within the hilus while other cases had no hilar staining. Total plaque number varied across regions examined, but anti-APP, anti-β/A4 or Bielschowsky staining detected an equal number of plaques within each region except parahippocampal cortex, where the number of β/A4 positive plaques was more than three times greater than APP positive plaques. APP positive plaques were composed of aggregates of punctate, granular staining and were co-localized with thioflavin S. APP positive staining was not limited to plaque-like structures: pyramidal neurons of fields CA3 through CA1, curly fibers surrounding and entering plaques and some blood vessels were also stained. Using confocal microscopy and double labeling, we found that all APP positive plaques were also positive for β/A4, but many β/A4 positive plaques did not contain APP. These data are consistent with the possibility that APP is present in immature plaques and is degraded to form β/A4 plaques.

β-AMYLOID PROTEIN POTENTIATES INJURY BY GLUCOSE DEPRIVATION IN NEURONAL CORTICAL CULTURES. A.G. Copani, J. Koh and C. W. Cotman. Department of Psychobiology, *University of California, Irvine, CA 92717 U.S.A.*

Alzheimer's disease (AD) is associated with a generalized decline in cerebral glucose metabolism, which occurs most severely in the temporal and parietal cortex. In the present study, we used an *in vitro* paradigm to examine the possibility that β-amyloid protein deposited in AD plaques may increase neuronal vulnerability to glucose deprivation. Mature murine cortical cultures deprived of glucose for 3-6 hours developed neuronal degeneration estimated both by examination with phase-contrast microscopy and by lactate dehydrogenase assay. This toxicity was increased when cultures were simultaneously exposed to 50 μg/ml synthetic β-amyloid (β 1-42). Cultures treated with β 1-42 in the presence of a physiological concentration (5.5mM) of glucose did not exhibit toxicity in comparison to controls. In a previous study, β 1-42 was reported to enhance glutamate neurotoxicity (J. Koh et al.,1990); thus the increase in hypoglycemic neurotoxicity by β 1-42 may be due to the potentiation of endogenous excitatory amino acid neurotransmitters which have been reported to mediate glucose deprivation injury. Consistent with this idea, the antagonist of NMDA-receptor MK 801 (5μM) largely attenuated the toxicity-increasing effect of β 1-42. The present results suggest that β-amyloid protein could exacerbate the neuronal cell loss in the presence of a defective cerebral energy metabolism occurring in Alzheimer's disease.

SYNTHETIC β-AMYLOID IS NEUROTOXIC *IN VITRO* FOLLOWING AGING OF PEPTIDE. C.J. Pike, A.J. Walencewicz, C.G. Glabe† and C.W. Cotman. Departments of Psychobiology and Molecular Biology and Biochemistry†, *University of California, Irvine, CA 92717 USA.*

Beta-amyloid is an approximately 42 amino acid residue protein and is the major component of the senile plaques found in Alzheimer's disease. We have found that short-term incubation of synthetic β1-42 solution can result in the formation of peptide aggregations. In order to characterize the biological activity of these β1-42 aggregates, we have conducted experiments comparing the effects of freshly solubilized and pre-incubated β1-42 on neuronal survival. Amyloid peptide was added to immature hippocampal cultures (16,000 cells/cm^2) from embryonic (E-18) rats at concentrations of 0, 0.1, 1.0, 10, 50, and 100 μg/ml. After twenty-four hours under these conditions, cultures treated with freshly solubilized β1-42 showed increased neurite-outgrowth at both the 50 μg/ml and 100 μg/ml concentrations but did not show a significant reduction in neuronal viability when compared to controls. Cultures treated with pre-incubated β1-42 displayed significant cell death that approached 100% at the 100 μg/ml concentration. Both the neurite-enhancement and neurotoxicity effects were dose-dependent, showing differences from controls only above the 10 μg/ml concentration. Analysis with SDS-PAGE revealed that freshly solubilized β1-42 migrated primarily as a ~4 kD monomer whereas pre-incubated β1-42 had additional high molecular weight bands. These data suggest that pre-incubation of β1-42 results in both a change in biological activity from neurite-promoting to neurotoxic and the formation of SDS-resistant peptide aggregations. These findings are consistent with the hypothesis that neurodegeneration in Alzheimer's disease is related to insoluble β-amyloid found in senile plaques.

SITE-SPECIFIC NICKING OF ALZHEIMER ß/A4 AMYLOID ALTERS THE AGGREGATION STATE. T. Honda and C.A. Marotta. MGH, McLean Hospital and Harvard Medical School, Boston, MA 02114.

ß/A4 Amyloid peptide (1-28) aggregated to 15kDa on SDS/urea PAGE. While a variety of proteases readily degraded the complex, endopeptidase Arg-C produced a new aggregate of higher molecular weight (16kDa) on denaturing gels without degraded smaller products. The new aggregate was comprised of three peptides: ß/A4(1-28), ß/A4(1-5) and ß/A4(6-28). The same results were obtained by treatment of ß/A4 with other arginine-specific proteases: the gamma subunit of Nerve Growth Factor and clostripain. The results indicate that arginine-specific proteases, including a growth factor processing enzyme, can nick aggregated ß/A4 amyloid and alter the configuration to produce a more complex form. Should partial cleavages, or nicking, of this type occur in the AD brain then proteolytic processes themselves may promote aggregation of amyloid. This mechanism may contribute to formation of the relatively insoluble amyloid core of senile plaques. KAINIC ACID LESIONING SELECTIVELY INCREASES THE AMYLOID PRECURSOR PROTEIN mRNA ENCODING PROTEASE NEXIN II IN GRANULE NEURONS OF THE DENTATE GYRUS. D. A. Willoughby, S. A. Johnson, G. M. Pasinetti, G. Tocco*, I. Najm*, M. Baudry*, and C. E. Finch. Andrus Gerontology Ctr. and *Program in Neurosciences, Dept. of Biol. Sci. Univ. So. Cal., Los Angeles, CA 90089

The ability of the amyloid precursor protein (APP) to inhibit serine proteases depends upon the inclusion of the 168 nt exon 7 sequence in the fully processed mRNA. Alternative splicing of the APP pre-mRNA generates 5 distinct mRNA transcripts. Three of these transcripts contain exon 7 and encode either 751, 770 or 568 amino acid proteins which are functionally and chemically identical to protease nexin II. The APP mRNA which is the predominant form in rodent brain, lacks exon 7 and encodes a 695 amino acid protein. In Alzheimers disease, hippocampal pyramidal neurons show an increased 751/695 mRNA ratio (Johnson et al., 1990, Science 248; 854-857). It is therefore of interest to develop rodent models which show similar changes in APP mRNA in response to experimental lesion. 12 hours after i.p. administration of kainic acid we observed an 80% increase in APP mRNA molecules containing exon 7 in the rat dentate gyrus. In situ hybridization was used to localize the response to the granule cell layer. No change in the prevalence of APP-695 mRNA was detected. No significant change in the APP mRNA content of the CA1, or CA3 pyramidal cell layers was observed. Because granule neurons are resistant to kainate induced cell death, the elevation of exon 7-containing-APP mRNA can occur in neurons independent of cell degeneration. HUMAN MICROGLIA EXPRESS AMYLOID PRECURSOR PROTEIN. D.W. Dickson, S.C. Lee*, L.A. Mattiace, W. Liu*, A. Fishman* & S.H. Yen*. Department of Pathology, Albert Einstein College of Medicine, Bronx, New York 10461.

Microglia are associated with virtually every amyloid deposit in Alzheimer brains. Amyloid is composed of a 4kd molecule (beta/A4) derived from a larger precursor protein (APP) with several alternative transcripts, including one that is identical to protease nexin 2. APP is widely distributed in a number of tissues, and it has trophic effects on some cultured cells. In order to study amyloidogenesis, we raised antibodies to amino, carboxy and beta/A4 domains of APP. In adult brains, the antibody to the carboxy terminus (APPc) immunostained dystrophic neurites in some senile plaques, blood vessels with amyloid angiopathy and microglia in tissue that had been briefly fixed in paraformaldehyde. Microglia stained by APPc were associated with amyloid deposits, but also more widespread in gray and white matter. In fetal brains, APPc stained immature cells and ameboid microglia in the subventricular zone, but few ramified cells. To better characterize these results, microglia were isolated from mixed glial cultures from second trimester fetal brains using shaking and a differential adhesion method. Isolated microglia were immunoreactive with macrophage antibodies, internalized acetylated low density lipoprotein and produced interleukin-1 in response to lipopolysaccharide stimulation. Cultured microglia were immunoreactive with antibodies to all three domains of APP. Double-labeling immunocytochemistry of mixed astrocyte-microglia cultures showed a largely non-overlapping pattern of GFAP and APP staining. Future studies will explore molecular biology of APP synthesis in cultured microglia; however, the initial results suggest that microglia express APP and that microglia may be a source of amyloid in Alzheimer's disease. In fetal brains, APP may play a role in cell growth and differentiation.

573.1

TRANSIENT GLOBAL ISCHEMIA INDUCES EXPRESSION OF SULFATED GLYCOPROTEIN-2 (SGP-2) IN RODENT BRAIN. P.C. May, J. Clemens, K.S. Fuson, E.B. Smalstig* and P. Robison*. Lilly Research Laboratories, CNS Division, Eli Lilly and Company, Indianapolis, IN 46285.

Sulfated glycoprotein-2 (SGP-2), the rodent homologue to a human hippocampal cDNA clone (pADHC-9) elevated in Alzheimer's disease, increases in rat hippocampus (HC) following intrinsic HC lesions or extrinsic deafferentation (May et. al, 1990, Neuron 5:831). To further explore its *in vivo* regulation, SGP-2 expression was examined in rat HC and caudate nucleus (CN) 3 days after 30 min of transient global ischemia induced by 4 vessel occlusion (4VO). Northern blots of total RNA isolated from HC showed significant increases in SGP-2 RNA and GFAP RNA prevalence following ischemia (1.8 fold and 5 fold, respectively; $p<0.05$, ISC vs CTL); slightly greater increases in SGP-2 and GFAP RNA levels (2.2 and 6 fold, respectively; $p<0.05$, ISC vs CTL) were observed in RNA isolated from CN. Protein immunoblots showed marked increases in SGP-2 and GFAP protein in homogenates from 4VO-lesioned HC and CN. As observed above, greater increases in SGP-2 protein were observed in CN samples than HC samples, consistent with the earlier onset of neurodegeneration in CN vs. HC following 4VO. This well characterized animal lesion paradigm should prove useful in defining the role of pADHC-9/SGP-2 in brain and may point to novel mechanisms of neurodegeneration ongoing in AD.

573.2

APP DECREASE IS AN EARLY RESPONSE TO ISCHEMIA IN RODENT BRAIN. P. Robison*, J. Clemens, E.B. Smalstig* and P.C. May. Lilly Research Laboratories, CNS Division, Eli Lilly and Company, Indianapolis, IN 46285.

The function of Amyloid Precursor Protein (APP) in the brain is unknown. We studied APP regulation in caudate nucleus (CN) and hippocampus (HC) after 30 minutes of transient global ischemia induced by four vessel occlusion (4-VO). Previous histological examination of these two tissues at 24 and 72 hours shows that the CN loses neurons before the HC. To document neurodegeneration we used microtubule associated protein (MAP-2), a neuronal somatodendritic marker, glial fibrillary acidic protein (GFAP), a marker for reactive astrocytes and beta-tubulin as a control. Steady state levels of APP were evaluated by western blot analysis of tissue homogenates using an antibody to aa 595-695. In the CN 24 hours after 4-VO, APP and MAP-2 levels were decreased, while GFAP levels were only slightly elevated, consistent with neurodegeneration. Beta-tubulin was unchanged. In the HC at 24 hours post 4-VO, APP was more decreased than in the CN, while MAP-2 was not not affected. GFAP was elevated to the same level as CN. This confirms that neuronal degeneration was not taking place in the HC and that decreased APP precedes neuronal degeneration. Since neuronal degeneration does not appear until 48 hours after a decrease in APP is seen, it will be important to determine whether full length APP is cleaved to a neurotoxic fragment which promotes degeneration.

573.3

AMYLOID PRECURSOR PROTEIN (APP) IN ALZHEIMER'S DISEASE (AD): A COMPARATIVE IMMUNOHISTOCHEMICAL STUDY. M. Gearing, E.R. Unger*, E.R. Shelton*, H.W. Chan* and S.S. Mirra. VA Medical Center and Emory University School of Medicine, Atlanta, GA 30322 and Syntex Research, Palo Alto, CA 94303.

The distribution and modifications of APP in AD are being widely investigated with antibodies to the beta A4 peptide and other APP epitopes. Yet, differences in antibodies and histochemical techniques militate against ready comparison of data from center to center. We tested one approach to possible standardization using an automated slide stainer allowing concomitant staining of up to 60 slides with minimum quantities of immunoreagents under varying conditions (Brigati et al. J Histotechnol 1988;11:165). Multiple tissue sections were simultaneously treated using three immunohistochemical techniques with different enzyme and chromagen combinations: The more commonly used avidin-biotin peroxidase method with chromagens 3,3 diaminobenzidine tetrahydrochloride (DAB) and 3-amino-9-ethylcarbazole (AEC) was compared with the avidin-alkaline phosphatase method using 5-bromo-4-chloro-3-indoyl phosphate-nitro-blue-tetrazolium (McGadey chromagen). A battery of affinity-purified antibodies directed against domain-specific sites of APP as well as antibody to beta A4 (kindly supplied by Dr. Colin Masters) were used to label amyloid in cerebral cortex and striatum from AD and control patients. We found that the alkaline phosphatase method gave the most striking signal. This difference was most clearly seen in the labelling of diffuse plaques in the AD cases, where antibodies to beta-A4 and its components produced intense and frequent label of diffuse plaques in striatum and cortex. The flexibility of this automated system enabled ready control of variables including concentration of antisera and pretreatment of tissues with reagents such as formic acid, proteases, and phosphatases. The automated approach also permitted processing of multiple tissue sections under identical conditions and could potentially facilitate standardization of diagnostic and research methods among laboratories.

IN VIVO EFFECTS OF ß-AMYLOID PROTEIN IN PRIMATES: IMPLANTATION STUDY. D.T. Stephenson[1], M. Podlisny*[2], D. Games*[3], S. Little*[1], J. Lieberburg*[3], D. Selkoe[2] and J.A. Clemens[1]. [1]Eli Lilly & Company, Indianapolis, IN, 46285; [2]Center for Neurologic Diseases, Brigham and Women's Hospital, Boston, MA 02115; [3]Athena Neurosciences, South San Francisco, CA 94080.

Extracellular deposition of ß-amyloid protein (ßAP) is a hallmark of the neuropathology of Alzheimer's disease. Direct, toxic effects of ßAP on neurons have become a recent focus of investigation. Since most of these studies have been confined to in vitro model systems, we chose to study its effects in vivo in a species that exhibits age-related ßAP deposits. The present study was designed to evaluate the effects of ßAP when it is implanted into the brain in a lipophilic, non-toxic vehicle. Adult rhesus monkeys were anesthetized and their heads placed into a sterotaxic instrument. Sterile implants of synthetic ßAP 1-43 prepared in cocoa butter were made stereotaxically through a stainless steel canula into the frontal cortex. The contralateral hemisphere received implants of a control peptide (N-acetyl scrambled ßAP 25-35) or vehicle alone. After 30 days, monkeys were perfused transcardially with periodate-lysine-paraformaldehyde. Cortical blocks were excised, postfixed for 5 hours, processed as cryosections and stained by conventional histological and immunostaining techniques. Evaluation of three monkeys to date has not revealed characteristic AD-like pathology at any of the implant sites. However, the following differences between control and experimental implant sites were observed in these initial experiments: 1) ßAP implants produced larger necrotic lesions than those produced by control implants. 2) axonal spheroids, morphologically abnormal processes and swollen neurites, as revealed by Bielschowsky silver staining, appeared to be more numerous in the ßAP than the control implants. 3) ßAP implants demonstrated more extensive astrogliosis, as observed by immunolocalization of glial fibrillary acidic protein and S-100 protein. Studies in progress are aimed at implanting more animals with varying amounts of the peptide, testing other control peptides and evaluating the lesion sites with multiple antigenic markers to further define the effects of ßAP in the primate brain.

573.5

IN VIVO EFFECTS OF ß-AMYLOID PROTEIN IN PRIMATES: MICRO-INJECTION STUDY. [1]M.Podlisny*, [2]D.Stephenson, [1]M.Frosch, [3]D.Tolan*, [4]J.Lieberburg, [2]J.Clemens and [1]D.Selkoe. [1]Brigham & Women's Hosp., Boston, MA 02115; [2]Eli Lilly & Co., Indianapolis, IN 46285; [3]Boston University, Boston, MA 02215; [4]Athena Neurosciences, San Francisco, CA 94080.

The progressive deposition of ß-amyloid protein (ßAP) is an early pathogenetic event in Alzheimer's disease (AD). Recent studies suggest both neurotoxic and neurotrophic effects of ßAP in vitro. Since ßAP deposition and surrounding neuritic dystrophy occur spontaneously in aging primates, we sought to evaluate the effects of ßAP in vivo by microinjecting ßAP into monkey cortex. Samples of ßAP were injected into multiple neocortical sites of adult rhesus monkeys in a vehicle of either artificial CSF or 35% acetonitrile/0.1% TFA (AN); control samples were identically injected into homologous contralateral sites. The experimental samples were synthetic ßAP 1-40; ßAP 25-35; or sonicated SDS-extracted amyloid cores purified from AD cortex. Control samples were scrambled synthetic ßAP 1-40; scrambled ßAP 25-35; or SDS-insoluble particles purified from control cortex. All injections were at least duplicate, and the animals were allowed to survive for 2-3 weeks, 8-10 weeks or 3-4 months. Monkeys were perfused with periodate-lysine-paraformaldehyde and cortical blocks were excised and post-fixed for 4 hours. Tissue was paraffin-embedded and injection sites were screened by H&E, modified Bielschowsky silver and immunocytochemistry. In our initial analysis of 5 monkeys, we found experimental injection sites with a range of morphologies. The largest lesions showed liquefactive necrosis with cavitation, indicative of general cellular toxicity. To date, we have found a greater number of such cavitary necrotic lesions in peptide injections made in the AN vehicle than in CSF. Other lesions showed focal neuronal loss accompanied by astrocytic gliosis and microgliosis. The cavitary necrotic lesions occured more commonly with experimental peptide injection; however histologically similar changes were found with control peptide. Experiments are currently underway to define the role of the AN vehicle in causing cavitary necrosis and to determine which cellular effects can be attributed to the experimental peptide itself. Cellular changes that are closely reminescent of AD pathology have not yet been seen.

573.6

POSSIBLE CONTRIBUTION OF THE C-TERMINUS OF β AMYLOID PROTEIN PRECURSOR (APP) TO ALZHEIMER PAIRED HELICAL FILAMENTS (PHFs). C.B.Caputo, C.Wischik*, I.R.E.Sobel*, D.A.Kirschner*, P.E.Fraser*, W.F.Brunner*. ICI Pharms. Gr., Wilm. DE 19897, Lab. Mol. Biol., MRC, Cambridge, UK, Children's Hosp. & Harvard Med. School, Boston, MA 02115.

Polyclonal antibody BR188, which recognizes a peptide corresponding to the C-terminal 20 amino acids of APP, was found to react with pronase-treated PHFs isolated from five different Alzheimer brains. This reactivity was blocked by pretreating the antibody with the peptide antigen but not with peptides with unrelated sequences. The antibody immunogold-labeled these PHFs producing a periodic pattern of labeling. Upon extensive extraction of PHFs and electrophoresis of the soluble fraction, a band was obtained which, when subjected to micro-sequencing, yielded a sequence that corresponded to the last 17 amino acids of APP. Further, the 20 aa peptide used as antigen was found to display amyloid-like properties, including a fibrillar morphology by electron microscopy, birefringence with Congo red staining, fluorescence with thioflavin S, proteolytic resistance, and a characteristic X-ray diffraction pattern for cross-beta pleated sheets. Thus, a fragment from the C-terminus of APP may bind to PHFs and provide them with some amyloid-like properties that are not produced by τ protein, the only other confirmed component of PHFs.

573.7

APP GENE EXPRESSION IN SPECIFIC CELL TYPES OF THE RAT CNS. AC LeBlanc, HY Chen *, L. Autilio-Gambetti and P. Gambetti.Inst. Pathol. Case Western Reserve U. Cleveland, OH 44106

Differential amyloid protein precursor (APP) gene expression was investigated in neonatal rat brain cortex, meninges, and primary astroglial, neuronal and microglial cultures. Relative to brain cortex levels, total APP mRNA was higher in meninges (4.5x) and neuronal cultures (1.4x) and lower in astroglial and microglial cell cultures (0.25x). Ribonuclease protection assays revealed that APP_{695} mRNA was predominant in cortex and cortical neuron (~95% of total APP mRNA) while KPI-containing forms were more abundant in meninges, astrocytes and microglia (~70% of total APP mRNA). The ratio of APP mRNA species changed in neurons and astrocytes with time in culture. Northern blot analysis revealed that cortical astrocytes have an additional APP mRNA of 2.7kb. APP assessed on immunoblots closely paralleled APP mRNA expression except in microglial cells where APP was barely detectable. In addition, lower MW C-terminal fragments were detected in intact tissues but not in the cell cultures. These results indicate that (1) APP gene expression in the CNS is subject to cell specific transcriptional and post-transcriptional regulation (2) high turnover of APP or negative translational regulation is unique to microglia (3) astrocytes express an additional 2.7kb APP mRNA (4) abnormal processing or high turnover of APP C-terminal fragments might occur in primary cell cultures (5) neurons and astrocytes maintained in culture undergo changes in alternative splicing of APP mRNA. Supported by NIA MA AGO8155

573.8

NEUROTROPHIC REGULATION OF AMYLOID PRECURSOR PROTEIN (APP) mRNA SPLICING IN RAT BASAL FOREBRAIN. C.A. Sherman[1], K.S. Chen[2], F.H. Gage[2] and G.A. Higgins[1] [1]Mol. Neurobiol., NIA/NIH, Baltimore, MD 21224; [2]Dept. of Neurosci., U.C.S.D., La Jolla, CA, 92093.

The amyloid precursor protein (APP) gene produces several transcripts. These include APP-695, that is largely 'neuron-specific', as well as a family of mRNAs with a Kunitz serine protease inhibitor (KPI-APP) motif which are expressed in many cell types. We have previously shown that KPI-APP transcripts are elevated relative to APP-695 in the CNS of aged rats with cognitive impairments. In the present study, the developing rat CNS was shown to contain the highest amounts of APP-695 mRNA relative to KPI-containing APP transcripts at postnatal day 15, paralleling the temporal expression of the low affinity NGF-R in the basal forebrain. Chronic infusion of human recombinant NGF into the striatum of adult rats resulted in an induction of APP-695 mRNA, reiterating the pattern of APP expression observed in the developing basal forebrain. These results demonstrate that trophic factors such as NGF can regulate APP mRNA splicing *in vivo*.

573.9

EXPRESSION OF THE C-TERMINAL 100 RESIDUES OF THE AMYLOID PRECURSOR PROTEIN IN CULTURED 293 CELLS. S.P. Little*[1], E. M. Johnstone*[1], K. Bales*[1], R. F. Santerre*[1], T. Oltersdorf*[2], N. W. Fox*[1] and H. U. Bryant[1]. [1]Eli Lilly and Company, Indianapolis, Indiana 46285; [2]Athena Neurosciences, Inc., San Francisco, CA 94080.

The expression of the C-terminal 100 (APP-C100) residues of the amyloid precursor protein (APP) may provide a mechanism for studying processing of APP into the 42-43 residue beta amyloid peptide (ßA4) implicated in Alzheimer's disease. Expression of human APP-C100 in mammalian cells reportedly causes "toxicity" and amyloid-like fibrils. We have expressed the APP-C100 in human embryonic kidney cells (293 cells) in a transient assay and compared it to the expression of transfected full length APP. Products were characterized by Western blot analysis using antibody to the carboxy-terminal region of APP-C100 and the amino-terminal region of ßA4. The APP-C100 produced in 293 cells is the same size as the fragment left in cells after protease nexin II cleavage from full length APP (Esch et al., Science 248:1122, 1990), and is only recognized by anti-carboxy terminal antibody and therefore may not contain the amino terminal amino acids of ßA4. Moreover, APP-C100 appears to be a substrate for "APP secretase" whether it is expressed with the natural APP signal peptide or as APP-C100.

573.10

Beta-AMYLOID PROTEIN POTENTIATES H_2O_2-INDUCED NEURON DEGENERATION IN VITRO. R.D. Saunders, C.A. Luttman*, P.T. Keith* and S.P. Little*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

In Alzheimer's disease, the accumulation of neuritic plaques and tangles has been associated with selective neuronal degeneration. The fact the beta-amyloid protein accumulates in these plaques suggests that it may be involved in neuronal degeneration, either by exerting a direct neurotoxicity on neurons or by making neurons more vulnerable to endogenous toxins. Free radicals and oxidants are believed to contribute to neuronal damage in various disease states. We tested the ability of beta-amyloid protein (beta1-43) to increase the vulnerability of cultured hippocampal neurons to H_2O_2-induced degeneration. Neurons were incubated with beta1-43 for 1 to 3 days before addition of H_2O_2. Neurons were incubated with 1, 10, 50, and 100 uM H_2O_2 for 15 min and then examined the next day for evidence of degeneration. In cultures that had not been preincubated with beta1-43, only 50 and 100 uM H_2O_2 induced significant neuronal degeneration. Preincubation with beta1-43 increased the susceptibility of the neurons to damage at 1 and 10 uM H_2O_2. The results suggest that beta-amyloid potentiates the toxicity that oxidants exert on neurons and therefore may increase the vulnerability of neurons to damage mediated by various endogenous toxins.

MECHANISMS OF NEUROTOXICITY OF CARBOXYTERMINAL FRAGMENTS OF THE ALZHEIMER AMYLOID PRECURSOR PROTEIN. A. Kammesheidt, C.F. Hohmann, P. Brandt, K.J. Ivins, A.F. Spanoyannis and R.L. Neve. Dept. of Psychobiology, U. of California, Irvine, CA 92717; Dept. of Psychiatry, Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 21205.

We have shown that the C-terminal 104 amino acids of the Alzheimer amyloid precursor protein (APP-C104) is toxic to neurons in vitro. To facilitate our studies of the neurotoxicity of this and other fragments of APP, we have attached a sequence termed FLAG (MDYKDDDDK) to the N-termini of the fragments. Fusion of FLAG to APP-C104 and to the beta/A4 fragment allows us to track the molecules as they exert their neurotoxic activity in vitro, so that we may study the mechanism by which they cause the degeneration of neuronal cells. Immunocytochemical analysis of SV-T2 fibroblasts stably transfected with FLAG-APP-C104 reveals localization of the recombinant protein predominantly on the surface of the cells. Conditioned medium from the FLAG-APP-C104 transfectants causes NGF-differentiated PC12 cells and primary cortical neuronal cultures to degenerate more rapidly than those exposed to APP-C104 conditioned medium. Purification of FLAG fusion proteins following their expression in bacteria will enable us to study their activity. We are also examining the neurotoxic effects of these APP fragments in vivo. Preliminary results indicate that transplantation of APP-C104 transfectants into mouse brain results in progressive cortical atrophy and neurodegeneration.

573.12

THE NEUROTOXIC CARBOXYTERMINAL FRAGMENT OF THE ALZHEIMER AMYLOID PRECURSOR BINDS SPECIFICALLY TO A NEURONAL CELL SURFACE MOLECULE. M.R. Kozlowski, A.F. Spanoyannis, S.P. Manly*, E. Hall, and R.L. Neve. Dept. of Screening and Biochemical Research, Bristol-Myers Squibb Company, Wallingford, CT 06492 and Dept. of Psychobiology, U. of California, Irvine, CA 92717.

Recent studies have implicated carboxyterminal fragments of the Alzheimer precursor protein (APP) in the processes of amyloidogenesis and neurodegeneration. In particular, the carboxyterminal 104 amino acids of APP (termed APP-C104) exhibits neurotoxic activity in vitro and in vivo. We hypothesized that APP-C104 may cause the degeneration of neurons by interacting with a cell surface receptor. In support of this hypothesis, we have shown that APP-C104 synthesized in vitro binds specifically and with high affinity to the surface of NGF-treated PC12 cells. Both the cell surface binding and the neurotoxicity of APP-C104 are pH dependent with peak activity at pH 7.0-7.2. Neither the binding nor the neurotoxicity is inhibited by tachykinins. Mutational analysis suggests that both the binding and the neurotoxicity are dependent at least in part on the presence of a tyrosine residue that is a potential site of phosphorylation at the carboxyterminus of the fragment.

PROPERTIES OF MEMBRANE BOUND AMYLOID β/A4 PEPTIDE HYDROLASE(APP-SECRETASE) ACTIVITIES. [1]T. Yamamoto, [2]F. Kametani* [1]T. Kato* and [3]D. Allsop*. [1]Lab. of Molecular Recognition, Yokohama City Univ. Yokohama 236,Japan, [2]Dept. of Molecular Biology, [3]Psychiatric Res. Inst. of Tokyo, Tokyo 156, Japan, and [3]Division of Biochemistry, The Queen's Univ. of Belfast, Northern Ireland, UK.

We have recently reported the binding of Alzheimer amyloid β/A4 peptide fragments to rat cortical membranes and the degradation of β/A4 peptide(Brain Res., in press). In this study, we further examined proteolytic cleavage of synthetic β/A4 peptide, 8-15, 8-17 and 8-28 using cerebral membranes from rats. The major degraded products of β/A4 8-17 identified to 8-14(13) and 8-15. We could find no peak corresponding to 8-16, suggesting that β/A4 8-17 was probably cleaved internally at Gln^{15}-Lys^{16}, not Lys^{16}-Leu^{17} by APP-secretase-like protease. 8-14(13) was also formed by other degrading enzyme which newly identified in this study. A wide range of protease inhibitors had little or no effect on these enzymes. EDTA completely inhibited these degradation and reversed by the addition of Ca^{2+} or Mn^{2+}. No degradation were observed of β/A4 8-15 and 8-28 as a substrate. These observations indicate that membrane-bound metaloendopeptidase(s) may act as APP-secretase to the membrane-spanning region of APP including the β/A4 protein, and speculate that the change of C-terminal side of β/A4 may affect on the conformation of protein toward inactive form to normal degrading protease(s).

573.14

EXPRESSION OF β-AMYLOID PEPTIDE mRNA IN TRANSGENIC MICE. K. R. Bales*, E. M. Johnstone*, S. P. Little*, P. E. Setler[1] and R. F. Santerre*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285 and [1]Athena Neurosciences, Inc., San Francisco, CA 94080.

Extracellular plaques and cerebrovascular deposits containing a 4-kilodalton beta-amyloid peptide (β/A4) are pathologic manifestations of Alzheimer's disease (AD). How full length amyloid precursor protein (APP) is processed yielding the shorter β/A4 peptide is unclear. Cleavage of APP within the β/A4 region occurs constitutively, suggesting that deficiencies within this pathway may contribute to β/A4 accumulation. To develop a rodent model of β/A4 deposition and to identify the role of β/A4 accumulation in AD, transgenic mice containing the plasmid pAMYminiAMY were produced. This minigene construction contains 2.9 kilobases (kB) of the human APP promoter, the genomic sequence of β/A4, including the 5.9 kB intron and a SV40 3' polyadenylation sequence. Six germline founder mice were identified and their hemizygous progeny were analyzed. Northern blot analysis of total RNA isolated from the fore- and hindbrain regions and testes showed significant expression of the transgene message. The level of endogenous APP transcript from testes of transgenic animals appeared to be suppressed. No β/A4 protein has been detected by immunoblotting techniques, suggesting that mice are capable of processing the human β/A4 peptide, perhaps constitutively.

LACTOFERRIN IMMUNOCYTOCHEMISTRY IN ALZHEIMER BRAIN TISSUE. T. Kawamata*, S.C. Sung and P.L. McGeer. Kinsmen Laboratory for Neurological Research, Univ. of British Columbia, Vancouver, B.C., V6T 1W5, Canada.

Lactoferrin (LF) is a protein of unknown function which appears in many secretory fluids of the body. It also occurs in Alzheimer Disease (AD) plaques and tangles (Osmand and Switzer, Neurobiol Aging 11:284, 1990). We studied its distribution in brain immunohistochemically, and confirm the report of Osmand and Switzer. However, we also found it to be present in many neurons of elderly brain, as well as in some astrocytes and microglia, but not in baby brain. At the EM level, LF immunoreactivity (IR) occurred primarily in lysosome-like particles, and was frequently associated with lipofuscin. It was also occasionally distributed diffusely in the cytoplasm. In AD, LF-IR was compared with that of Alz-50, ubiquitin, and Tau-2 to assess its association with neurofibrillary tangles and neuropil threads; with C3d, C4d and β-amyloid protein to assess its association with extracellular amyloid; with GFAP to assess its association with astrocytes; and with LCA and HLA-DR to assess its association with microglia. LF-IR was associated with almost all amyloid deposits, with reactive microglia in consolidated plaques, with a majority of extracellular neurofibrillary tangles, but with only a minority of intracellular neurofibrillary tangles and neuropil threads. These data suggest that lactoferrin may be closely associated with the development of amyloidosis in AD.

573.16

MICROGLIA PROCESS AMYLOID PRECURSOR PROTEIN SEGMENTS IN ALZHEIMER'S DISEASE. P.L. McGeer[1], T. Yamada*[1], T. Kawamata*[1], H. Akiyama*[2] and T. Ishii*[2]. [1]Kinsmen Lab, University of British Columbia, Vancouver, B.C., Canada and [2]Psychiatric Res Inst of Tokyo, Tokyo, Japan.

The immunohistochemical distribution of APP was studied in normal and Alzheimer Disease (AD) brain with antibodies to residues 527-540 (R36), 597-620 (R17, 1-24 of BAP) and 681-695 (R37) (Ishii et al., Neuropath Appl Neurobiol 15:135-147, 1989) at light and em levels. Antibodies to segments flanking BAP (R36 and R37) prominently stained dense membrane-bound granules in normal and AD pyramidal neurons, suggesting that APP is concentrated in an intraneuronal organelle and is not a cell surface protein. In Alzheimer disease (AD), R36 and R37 stained the cytoplasm of some dystrophic neurites but did not stain their surface membranes and only sparsely stained extracellular deposits. By contrast, the BAP antibody (R17) did not stain intraneuronal material, indicating inaccessability of the epitope, but did strongly stain extracellular deposits. All 3 antibodies prominently stained intramicroglial material. BAP deposits in microglial cells were seen communicating with extracellular BAP deposits. Since APP mRNa has not been found in microglia, these data suggest that microglia ingest a large carboxy terminal APP segment containing R36, R17 and R37 sequences. BAP may be primarily produced by breakdown of this segment and then be extruded into amyloid deposits where it accumulates.

SHORT BIOTINYLATED OLIGONUCLEOTIDES BIND NON-SPECIFICALLY TO SENILE PLAQUE OF ALZHEIMER'S DISEASE. S.Syrjänen*, O.Heinonen*, H.Soininen, R.Miettinen*, K.Beyreuther[1], L.Paljärvi*, K.Syrjänen* and P. Riekkinen. Depts. of Neurology and Pathology*, Univ. of Kuopio, P.O.B.1627, SF-70211 Kuopio, Finland. Univ. of Heidelberg, Center for Molecular Biology[1], D-6900 Heidelberg, Germany.

We have used in situ hybridization with biotinylated oligonucleotide (antisense) probes and sreptavidin-biotinylated alkaline phosphatase method to detect the amount of amyloid β-protein mRNA in the paraffin embedded and formalin-fixed brain samples of patients affected by Alzheimer's disese and those of non-affected controls. Instead of the expected specific binding to neuronal cytoplasm, the probes did constantly bind to neuritic senile plaques, the strongest binding being in the hippocampus and the cerebral cortex. We have been able to constantly repeat this peculiar phenomenon with other oligonucleotide probes, e.g., the sense probes for β-amyloid protein and those specific for Human papillomavirus (HPV) 18- and c-erb B-2 mRNAs. An identical nonspecific binding of the oliconucleotides was seen also in one skin biopsy derived from a patient with Alzheimer's disease. Intrestingly, this particular skin biopsy presented with a basal cell carcinoma, a tumor frequently encountered in patients with Down's syndrome. Further experiments to correlate the staining pattern of oligonucleotide probes to accumulation of β-amyloid detected by immunohistochemistry are in progress.

573.19

POSITIVE UBIQUITIN IMMUNOREACTIVITY IN CEREBRAL AMYLOID ANGIOPATHY. F.F. Cruz-Sanchez*, C. Marin, I. Ferrer* and E. Tolosa. Neurological Tissue Bank, Service of Neurology, HCP and Dept. of Pathology, HPE, Universitat de Barcelona, SPAIN.

Vascular amyloid deposit, senile plaques (SP) and neurofibrillary tangles (NFT), are encountered in both cerebral amyloid angiopathy (CAA) and Alzheimer's disease (AD). Ubiquitin (UBQ) is a polypeptide related to ATP-dependent abnormal protein metabolism. Immunohistological studies using antibodies for UBQ have demonstrated similar antigenic determinants between (SP) in CAA and AD. In the present study, we describe immunohistochemical findings in the cerebral blood vessels of CAA compared to the AD ones. Formalin fixed paraffin embedded brain tissue from 4 AD and 4 cerebrovascular patients and 2 from elderly patients without neurological disorders were studied. Sections were stained for the polyclonal antibody for UBQ. Wall vessels in CAA cases showed strong UBQ-positivity in subendothelia and/or in the media layers. SP showed strong positivity with a negative central core immunoreactivity. AD brains showed immunoreactivity for UBQ in SP and NFT, but, vessels were negative. Control brains showed few positive SP and NFT and vessels were negative. These results may indicate that vascular amyloid deposit in CAA and AD might have different physiopathogenic mechanisms.

6-HYDROXYDOPA SELECTIVELY DISPLACES [^{3}H]AMPA BINDING: A POTENTIAL MECHANISM FOR HUNTINGTON'S DISEASE. J. J. Cha, L. S. Dure IV, S. Y. Sakurai, J. B. Penney, and A. B. Young. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI 48104-1687.

Severe atrophy of the neostriatum is a main characteristic of Huntington's disease (HD). Intrastriatal lesions with excitatory amino acids (EAA) mimic certain features of HD leading to the hypothesis that EAA's play an etiologic role in HD. However, the EAA hypothesis of HD does not readily account for the striking involvement of the striatum with relative sparing of other structures which also participate in EAA circuitry.

6-HydroxyDOPA (6OH-DOPA), a derivative of the dopamine precursor L-DOPA, has been reported to have neurotoxic properties (Olney et al., **Exp. Neurol. 108**:269, 1990). 6OH-DOPA displaced rat brain [^{3}H]AMPA binding in an autoradiographic assay. Ineffective displacers of [^{3}H]AMPA binding included: dopamine, L-DOPA, D-DOPA, *threo*-DOPS, carbiDOPA, and DOPAC. 6OH-DOPA also displaced 20% of [^{3}H]kainate binding, but did not displace any NMDA-sensitive [^{3}H]glutamate, [^{3}H]MK-801, [^{3}H]SCH-23390 (D1 receptor), or [^{3}H]spiroperidol (D2 receptor) binding. The IC50 of 6OH-DOPA in displacing [^{3}H]AMPA binding was 31.7 µM, as potent as kainate in displacing [^{3}H]AMPA binding.

These data raise the possibility that 6OH-DOPA, or another abnormal L-DOPA metabolite, could act as an excitotoxic agent via action at AMPA receptors. If the genetic defect in HD resulted in production of 6OH-DOPA, neuronal death would be expected to occur in those structures with a coincidence of L-DOPA (as toxin precursor) and postsynaptic AMPA receptors (mediators of 6OH-DOPA-induced cell death), such as the striatum.

NEUROPSYCHOLOGICAL CHANGES ASSOCIATED WITH CT SCAN MEASURES OF NEUROANATOMICAL ATROPHY IN HUNTINGTON'S DISEASE. J.K.A. Roberts, E.A. Loh, S.L. Sally* & E. Mohr*. Dept. of Neuropsychiatry, Royal Ottawa Hospital, Ottawa, Canada, K1Z 7K4. CT scan measures of basal ganglia regions of 15 patients at various stages in the progression of Huntington's disease (HD) were compared with patient's scores on a neuropsychological test battery. Indices of caudate atrophy: Frontal horn of ventricle width and Bicaudate distance were determined from measures taken from digitized CT scans. Lentiform region atrophy was assessed by measures of width of the third ventricle and distance between the third ventricle and insular regions. Cognitive tests were often as well correlated with atrophy of the lentiform regions as more traditionally used measures of caudate atrophy. Of particular interest, measures of attention and perseveration were highly correlated ($P<.05$) with the lentiform measures even after the effects of the choreiform movements were factored out. These data suggest that measurements of the lentiform regions provide additional information on the progress of HD.

574.3

A QUANTITATIVE LAMINAR ANALYSIS OF CEREBRAL CORTICAL DEGENERATION IN HUNTINGTON'S DISEASE. SM Hersch, V Rosenfeld*, C-A Gutekunst, HD Rees, RC Green. Department of Neurology, Emory University School of Medicine, Atlanta, Georgia 30322

The extent and significance of cerebral cortical atrophy occurring in Huntington's disease (HD) and its implications for understanding the symptoms and pathophysiology of the disease are of great interest. One-micron thick plastic sections, stained with toluidine blue, from defined regions of cerebral cortex from the brains of patients with Huntington's disease (HD) are being examined using a Macintosh computer based image analysis system for data acquisition and analysis. Right hemispheres from 10 patients, aged 45-69, with grade 3 or 4 HD were obtained from the Brain Tissue Resource Center of McLean Hospital. Age-matched control tissue was obtained from routine autopsies. Measurements are based on 250µm wide strips of cortex spanning its full depth and include the total area of each strip, the area contained in each layer, the total numbers of neurons, astrocytes, and oligodendrocytes in each layer, and the size of each neuron. These measurements are adjusted for shrinkage and then neuronal densities, glial densities, and volume densities are calculated. This study will survey primary, association, and limbic cortices. Detailed information about the relative involvement of different areas of cortex, different cortical layers, different neuronal types, and gliosis is being collected. Data from the analysis of frontal lobe regions will be presented. (Supported by the Huntington's Disease Society of America).

EVIDENCE FOR NEURONAL DEGENERATION IN THE SUBTHALAMIC NUCLEUS IN HUNTINGTON'S DISEASE. Karen M. Harrington, Robert J. Ferrante and Neil W. Kowall. Dept of Neuropathology and Experimental Neuropathology Laboratory, Massachusetts General Hospital, Boston MA 02114.

Recent anatomical, physiological, pharmacological and pathological evidence suggests that decreased excitation of the internal segment of the globus pallidus (GPi) by the subthalamic nucleus (STN) produces hyperkinetic movement disorders in man and primates. It has been further theorized that the hyperkinetic movement disorder in Huntington's disease (HD) results from selective depletion of inhibitory enkephalinergic striatal projections to the external segment of the globus pallidus (GPe) which in turn leads to pathological disinhibition of inhibitory projections to the STN and thus the physiological equivalent of a STN lesion. Because we did not find evidence of disproportionate depletion of enkephalinergic fibers in the GPe in HD, we theorized that the basis for the hyperkinetic movement disorder may lie in the STN itself. We therefore examined the STN for evidence of neuronal degeneration in HD utilizing a polyclonal antibody against ubiquitin, a sensitive marker for neuronal injury and stress response. In a series of HD cases (n=9) of various grades the maximal number of ubiquitin positive cells in the STN was 147±33 per mm^2. In normal age-matched STN (n=5) the mean maximal density of ubiquitin positive cells was 57±29 per mm^2 ($p<0.05$). Our findings suggest that the STN is affected in HD. The basis for the hyperkinetic movement in HD may, therefore, lie in abnormalities of the STN itself rather than in the striatum or pallidum.

574.5

UBIQUITIN IMMUNOREACTIVITY IS INCREASED IN HUNTINGTON'S DISEASE CEREBRAL CORTEX.

Alida J. Evans and Neil W. Kowall. Neurology Service, Massachusetts General Hospital, Boston MA 02114.

Neurons respond to injury by increasing the synthesis of endogenous stress proteins including ubiquitin which is conjugated to abnormal proteins destined for non-lysosomal proteolysis. In several neurodegenerative diseases including Alzheimer's disease, Parkinson's disease, and Amyotrophic Lateral Sclerosis, neurons contain ubiquitin immunoreactive inclusions. In Huntington's disease (HD), specific subsets of neurons degenerate in the cerebral cortex and striatum without evidence of specific cytopathological alterations by standard histological techniques. We examined the cerebral cortex of 12 HD patients using a polyclonal ubiquitin antibody to determine if abnormal ubiquitin-conjugated proteins are produced in response to neuronal stress or injury in HD. In all HD cases, variable amounts of dot-like immunoreactivity were found in the superficial cortical layers and white matter identical to that seen in controls. In both low and high grade HD, scattered, diffusely ubiquitin positive neurons were found within the cortex and infracortical white matter. In one high grade HD case with severe cortical changes, ubiquitin immunoreactivity was especially prominent within diffusely stained neurons, intracytoplasmic inclusions and axonal spheroids. The presence of ubiquitin immunoreactivity within a subset of neurons in HD cortex suggests that abnormal proteins may accumulate during the degenerative process. The nature of these proteins and their contribution to neuronal degeneration is unknown but their identification may clarify the pathogenesis of HD.

574.6

NEUROPATHOLOGY OF FRONTAL CEREBRAL CORTEX IN HUNTINGTON'S DISEASE. C.E. Peyser, M.V. Wagster, J.C. Hedreen, T.M. Dawson, M. Fotuhi, D. Bredt, S.H. Snyder, S.E. Folstein,* C.A. Ross. Psychiatry, Neuropathology, and Neuroscience Departments, Johns Hopkins, Baltimore, Md. 21205.

Huntington's disease (HD) results in massive degeneration of neurons in the basal ganglia, but neuronal loss in HD cerebral cortex has not yet been clearly established. We therefore counted neurons in individual laminae of the dorsal frontal cortex in 5 HD (Vonsattel grade IV) and 5 age matched control autopsy brains. Significant neuronal loss was found in layer VI (HD 117±29 vs control 207±32, or greater than 40% loss, $p<0.005$), and layer V (30%, $p<0.05$), and possibly layer III (13%, ns), but no change in layer II and IV. Neurons in layer VI project to thalamus, claustrum, and other regions of cerebral cortex, but not to the basal ganglia; thus their loss is unlikely to be the result of retrograde degeneration secondary to striatal pathology. We are currently performing autoradiography for glutamate receptor subtypes and immunocytochemistry for nitric oxide synthetase in order to explore possible neurochemical mechanisms underlying the neuronal loss.

574.7

EFFECTS OF CHRONIC STRIATAL LESIONS ON CORTICAL NEUROPEPTIDES. S. Garside, JCS Furtado and MF Mazurek. Department of Biomedical Sciences, McMaster University Medical Centre, Hamilton, Ontario, Canada.

We have previously reported widespread increases in CCK-LI as well as more localized changes in VIP-LI and NPY-LI in Huntington's disese (HD) postmortem cerebral cortex. It is not clear whether these differences are the result of abnormal feedback from the striatum or the result of independant cortical pathology. To investigate this issue we examined the effect of chronic striatal lesions on cortical peptide levels in the rat. Animals were given unilateral intrastriatal injections of QUIN (240nmols/µl) or saline (1µl) and sacrificed by decapitation 9-12 months later. Two 2mm coronal sections incorporating the lesion were sliced from each brain and photographed. The striatum was removed from the posterior slice and processed for neurochemistry. Striatal SP-LI in QUIN animals was decreased by at least 50% as compared with controls. The lesion size as assessed with Bioquant II encompassed at least 60% of the striatum. CCK, SS, NPY and VIP levels were studied in 8 regions of cerebral cortex. No significant changes were found between QUIN and saline animals.

These results suggest that the widespread neuropeptide changes in HD cerebral cortex are independant of the striatal pathology seen in HD.

574.8

RELATIVE SURVIVAL OF STRIATAL PROJECTION NEURONS AND INTERNEURONS AFTER INTRASTRIATAL INJECTION OF QUINOLINIC ACID. K.D. Anderson and A. Reiner. Dept. Anat. and Neurobiol., Univ. TN, Memphis.

Huntington's disease (HD) is characterized by extensive loss of striatal projection neurons with no evident loss of somatostatin/neuropeptide Y (SS/NPY)-containing or cholinergic interneurons. Several studies have reported that intrastriatal injection of the NMDA receptor-specific excitotoxin quinolinic acid (QA) induces a pattern of neuronal death in rats that mimics HD, favoring the hypothesis that such excitotoxicity is involved in the neurodegenerative process in HD. Other investigators, however, have reported that striatal SS/NPY-containing neurons are vulnerable to QA. We conducted immunohistochemical studies in rats 2 months after injection of 50 nmol QA to determine the relative survival of 4 types of neurons as a function of distance from the injection site: 1) striatopallidal neurons labeled for enkephalin (ENK); 2) striatonigral neurons labeled retrogradely by fluorogold (FG); 3) SS/NPY-containing neurons; and 4) cholinergic neurons. By quantifying the number of cells in 0.2-mm wide concentric zones at increasing distances from the injection site, we were able to assess the relative vulnerability of each type to QA. Within the injection site, cholinergic neurons were normal in abundance, but ENK+, FG+, and SS/NPY+ neurons were sparse. Moving away from the injection site, the abundance of the latter three returned to normal in the sequence: ENK+, FG+, SS/NPY+. Thus, SS/NPY+ interneurons are more vulnerable to QA than are striatal projection neurons. These results indicate that intrastriatal injection of QA does not induce a pattern of neuronal loss in rats that mimics HD, but the results do not necessarily refute the excitotoxin model of HD. MULTINUCLEATED, TAU POSITIVE ASTROCYTES IN PROGRESSIVE SUPRANUCLEAR (PSP) BRAIN TISSUE. T. Yamada*, P.L. McGeer and E.G. McGeer. Kinsmen Lab., Dept of Psychiatry, Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1W5.

We reported earlier on Tau-2 positive oligodendroglial microtubular masses (OMMs) (Yamada and McGeer, Neurosci Letts 120:163, 1990) in some neurodegenerative diseases. We now report the occurrence of significant numbers of Tau-2 positive astrocytes in PSP but not other neurological diseases. Three PSP, 10 Parkinson's disease, 2 striatonigral degeneration, 3 Huntington's chorea, 8 Alzheimer's disease and 5 non-neurological brains were examined immunohistochemically with the following antibodies: Alz-50, Tau-2, anti-PHF and anti-GFAP. Tuft fibers were identified within large glial cells, which surrounded a single large or smaller paired nuclei. They were positive for Tau-2, Alz-50 and anti-PHF. Double immunostaining with Alz-50 and anti-GFAP revealed that they were Alzheimer type I astrocytes. These astrocytes also stained positive with the Bielschowsky silver stain. They were predominantly localized in areas where a mild gliosis and occasional neurofibrillary tangles were seen such as the striatum, thalamus and frontal cortex. By EM paired nuclei without an obvious separating membrane could be seen. Alz-50 was localized to fiber bundles with a diameter of 25nm. These data suggest that there is active differentiation of astrocytes in PSP.

A SIMPLE METHOD FOR ASSESSING NEURONAL NUMBER IN THE HUMAN SUBSTANTIA NIGRA. C. Zarow and H.C.Chui. University of Southern California, Rancho Los Amigos Medical Center, Los Angeles, CA 90089-0191.

We report a simple method of assessing numbers of neurons in the substantia nigra pars compacta (SNpc). Formalin fixed, paraffin embedded blocks of the midbrain were obtained from 9 Parkinson disease (PD), 4 progressive supranuclear palsy (PSP), 17 Alzheimer disease (AD) and 13 age-matched control cases. Blocks were sectioned at 15 µm and stained with cresyl-violet. The number of pigmented cells per section was counted in every 25th section throughout the rostral-caudal length of the SNpc using a Quantimet 970 image analyzer (Cambridge Instruments). The mean number of neurons/section (N_{total}) was calculated for each case. N_{total} was significantly lower in PD (mean =89.2, sd =84.4) and PSP (mean =46.7, sd =17.8) compared to AD (mean =262.8, sd =151.9) and controls (mean =371.3, sd =152.7) (ANOVA, F=10.7). The mean number of neurons/section was also calculated from a subset of sections which contained the third cranial nerve (N_{CN3}), where it exits from the mesencephalon. There were no significant differences between N_{total} and N_{CN3} for any of the four diagnostic groups. Thus, the number of neurons/section in the region of the third nerve provides a reliable estimate of the mean number of neurons/section through the entire SNpc. This method is reliable even when the degree of neurodegeneration is severe. The exit of cranial nerve III (oculomotor nerve) from the brainstem can be identified easily by observation of the ventral surface of the brainstem. This affords an readily identifiable, externally visible, anatomic landmark. (Supported by NIA 1P50AG05142 and the Veterans Administration).

574.11

MOLECULAR GENETIC ANALYSIS OF THE X-LINKED DYSTONIA-PARKINSONISM SYNDROME (XDP). M.B. GRAEBER[1], K.G. KUPKE[1,2*], A.P. MONACO[3*], U. MÜLLER[1*]. Divisions of Genetics[1] and Newborn Medicine[2], Children's Hospital, Harvard Medical School, Boston, MA 02115; Institute of Molecular Medicine[3], John Radcliffe Hospital, Oxford University, Oxford OX3 9DU.

We have performed linkage analysis in 14 Filipino families with XDP, a severe, X-linked neurological disorder of high penetrance which is characterized by adult-onset dystonia and parkinsonism. Previously, the XDP-Locus (DYT3) has been assigned to Xq21 (Neurology 40:1438). Focusing on chromosomal region Xp11-Xq21, we studied 10 marker loci in DNA samples from a total of 94 family members, including 34 affected males. Highest LOD scores were 5.45, 4.52, 7.7, 4.4 for Loci DXS106, DXS159, DXS72, DXS367 at θ_{max}=0.00 and 4.28 for PGK1 at θ_{max}=0.01. Analysis of linkage and linkage disequilibrium suggests that DYT3 lies in proximity to DXS72 with DXS159 and DXS95 being flanking markers (Kupke et al., in preparation). Presently, we are isolating from yeast artificical chromosomes highly polymorphic, $(CA)_n$-based human DNA sequences close to DYT3. Updated lod scores and data obtained with these probes will be presented.

574.12

EFFECTS OF IBOTENIC ACID LESIONS OF THE STRIATUM ON DOPAMINE CELL NUMBER IN THE ADULT RAT SUBSTANTIA NIGRA. R.M.E. Chalmers[1] and A. Fine[2]. [1]Dept. of Anatomy and [2]Dept. of Physiology & Biophysics, Dalhousie Univ., Halifax, Nova Scotia, Canada. B3H 4H7.

Striatal derived factors may influence outgrowth and survival of tyrosine hydroxylase-immunoreactive (TH-IR) cells of the substantia nigra (SN) in vitro (Del Toso, et al. J. Neuroscience, 1988). To examine whether striatal trophic factors may influence continued survival of dopaminergic SN neurons in the adult, we lesioned the striatum in 250g rats by stereotaxic unilateral injection of ibotenic acid, and after six weeks determined the number of TH-IR cells in the SN. TH-IR cells were counted bilaterally in lesion as well as in control animals.

The SN ipsilateral to the lesioned striatum had a consistent 10 to 15% decrease in the number of TH-IR cells when compared to the contralateral SN while intact animals showed a side to side difference of less than 4%. The number of TH-IR cells in the contralateral SN of lesioned animals was comparable to the unlesioned animals (16-18 x 10^3 cells per SN).

The results suggest that the absence of a trophic factor normally supplied by the striatum, but decreased in our lesioned striatum, is necessary for the continued survival or maintenance of TH expression in a population of dopamine cells in the adult SN. (Sponsored by the MRC of Canada)

GENE MAPPING STUDIES IN FAMILIAL ALS. D.H.Donaldson, C. Nusbaum,* P.Sapp,* T.S.Barnes,* R.H.Brown,Jr,* and D. Patterson.* Dept. of Neurology, Univ. of Colorado Health Sciences Center, Denver, CO 80262; Eleanor Roosevelt Institute, Denver, CO 80206; Dept. of Neurology, Mass. General Hospital, Boston, MA 02129.

Multipoint linkage analysis of 23 pedigrees with familial ALS suggests that a gene important in the disease might lie in the region q22.1-22.2 of chromosome 21. Within this region lie the genes for superoxide dismutase, the trifunctional purine biosynthetic enzyme GART, the interferon α/β receptor, and the interferon γ response element. We report the production of new probes for this region prepared from $(CA)_n$-containing cosmids isolated from somatic cell hybrids that contain only this region of chromosome 21. We are constructing contig maps with these cosmids and YACs homologous to chromosome 21-specific DNA probes mapped to this region of 21, using somatic cell hybrids which allow dissection of this region of the chromosome into more than 10 parts.

ALTERATIONS IN DIHYDROPYRIDINE RECEPTOR BINDING KINETICS IN AMYOTROPHIC LATERAL SCLEROSIS (ALS) SKELETAL MUSCLE. R.G. Smith*, F. Kimura*, K. McKinley*, Y. Harati*, and S.H. Appel. Dept. of Neurology, Baylor Col. of Med., Houston, TX 77030.

Immunoglobulin from ALS patients alters the electrophysiological parameters of rat skeletal muscle dihydropyridine-sensitive Ca^{++} channels in vitro. To determine whether Ca^{++} channels in ALS muscle are altered, subsarcolemmal membrane fractions enriched for transverse tubules were prepared from muscle biopsy specimens taken from ALS, disease control, and normal control patients. These fractions were then assayed for the presence of dihydropyridine-sensitive voltage-dependent Ca^{++} channels (DHPR) with ^{3}H-PN-200/100. Results indicate an increased PN-200 binding affinity in ALS muscle (high affinity Kd $\pm$ S.D. = 0.17 $\pm$ 0.06 nM:n=26) compared to normal and myopathic controls (high affinity Kd $\pm$ S.D. = 0.92 $\pm$ 0.17 nM:n=10). In some ALS muscle specimens, there was also up to a 5-fold increase in the number of DHPR binding sites relative to controls, correlating crudely to the degree of denervation noted histologically. However, five non-ALS denervated muscle specimens (from one familial ALS, two spinal muscular atrophy, and two traumatically denervated control patients) yielded elevated Bmax values, but with DHPR Kd values in the control range. Conversely, specimens from four patients with autoimmune motor neuropathies had control range Bmax values, but Kd values indistinguishable from those of ALS muscle. This difference in ALS muscle DHPR Kd is not solely explainable by denervation state, and may reflect changes attributable to immunological alterations of Ca^{++} channels in vivo.

GANGLIOSIDES MODIFY DIABETES-INDUCED CHANGES IN AXONAL ELEMENTAL COMPOSITION. J. Eichberg, C.M. Castiglia*, A.J. Saubermann and R.M. LoPachin. Dept. Biochem. and Biophys. Sci., Univ. Houston, Houston, TX 77204 and Dept Anesthesiology, Med. Sch., Stony Brook, NY 11794..

Ganglioside (GA) treatment corrects certain functional and biochemical deficits caused by experimental diabetes (DB). Previously, we demonstrated that intraaxonal concentrations of K and Cl were increased significantly in tibial nerve of streptozocin-DB rats. We have now assessed the ability of GA (mixed bovine brain) to modify DB-induced alterations of axonal elemental composition. X-ray microanalysis was used to measure concentrations of Na, P, S, Cl, K, Mg and Ca in tibial nerve axons. As reported earlier, DB rats had elevated axoplasmic K and Cl. In DB rats treated with GA (10 mg/kg/day x 30 days) axoplasmic contents (mmol/kg dry weight±SE) of K and Cl were increased relative to both DB and control (CON) levels (e.g. large axon K: CON=1668±51; DB=2131±80; DB-GA=2393±86), whereas axoplasmic Na was decreased (e.g. large axon Na: CON=237±12; DB=240±19; DB-GA=115±12). GA-control rats displayed changes in Na, K and Cl which were in the same direction as those of the DB-GA group, but smaller in magnitude (e.g. large axon K: CON-GA=1891±98; Na; CON-GA=164±18). DB-induced changes in axonal elemental composition might reflect compensatory mechanisms which are enhanced, either directly or indirectly, by GA treatment. Supported by NIH grants ES03830, NS21445 and DK30577.

ACETYL-L-CARNITINE COUNTERACTS EXPERIMENTALLY INDUCED DIABETIC NEUROPATHY **L. Pacifici*[1], A. Bellucci*[1], P. Piovesan*[1], F. Maccari*[1], A. Gorio[2], A.M. Di Giulio[2], M.T. Alderdice[3], L. Ferraris*[1]. [1]Sigma-Tau Institute for Research on Senescence, Pomezia, Rome, Italy; [2]Dept. Pharmacology, School of Medicine, Univ. of Milano, Italy; and [3]Sigma Tau Pharmaceuticals, Gaithersburg, MD 20878, USA.**

Acetyl-L-Carnitine (ALCAR) exerts trophic effects on neurons. Here we report that similar effects were also observed in Sprague-Dawley rats, 3 months of age, in which a chronic diabetic peripheral neuropathy was induced by a single injection of streptozotocin 50 mg/kg i.v. or alloxan 100 mg/kg s.c. By means of a radioimmunoassay, a significant reduction (30-50%) of Met-enkephalin and substance P in the gut of diabetic rats was found. Such a reduction was successfully prevented by ALCAR administration (for 12 consecutive weeks) at the dose of 50 mg/kg/day i.p. or 300 mg/kg/day in drinking water. Treatment with ALCAR also fully prevented both the reduction (20%) in neuromuscular conduction velocity, as recorded on the sciatic nerve soleus muscle preparation, and the decrease (30%) in muscle contraction force. ALCAR also improved the concomitantly reduced motor performance on Rota-Rod test. These data suggest for a potential therapeutic use of ALCAR in the treatment of diabetic peripheral neuropathy and further confirm ALCAR capability to ameliorate behavioral and morphological aspects of degenerative and age-dependent disorders.

THE EFFECT OF DNA METHYLATION ON THE EXPRESSION OF BC-200, A PUTATIVE GENE-REGULATORY ELEMENT IN NEURONS. J.H. Uhm*, N.P. Dooley, J. Nalbantoglu*, H.D. Durham, N.R. Cashman. Montréal Neurological Institute, Montréal, Québec, CANADA, H3A 2B4.

We have hypothesized that selected neurodegenerative diseases are due to altered DNA methylation in neurons with aging (Schwob *et al*, Ann Neurol 1990). Neuron-specific gene expression in various species may be regulated in part by repetitive DNA elements known as ID (identifier) sequences, which are transcribed by Pol III predominantly in brain; the primate ID element is BC-200 (Watson & Sutcliffe, Mol Cell Biol 1987). BC-200 is also expressed in cultured cells representing a variety of lineages. We have investigated the effect of agents that influence DNA methylation on BC-200 expression in four human cell types: two neural cell lines (H4, SK-N-SH), and two non-neural cells (HeLa, primary skin fibroblasts). Cells were grown in medium containing 5-azacytidine (AZA, 3 μM), which inhibits CpG maintenance methylase, or in methylazoxymethanol (MAM, 50 μM), a carcinogenic methylating agent found in the neurotoxic Cycad nut of Guam. Total RNA extracted by guanidinium-thiocyanate-phenol-chloroform was Northern-blotted with ^{32}P-labeled probes for BC-200, 18S RNA, and actin; the latter two RNAs control for lane loading. Autoradiographs were quantitated by densitometry. BC-200 expression was detected in all four cell types, but was not apparently affected by treatment with AZA; this may reflect hypomethylation of this element prior to AZA exposure. In contrast, MAM decreased expression of BC-200 by 33-43% in neural cell lines (H4, SK-N-SH), but not in non-neural cultures. Our data suggest that abnormal DNA methylation can alter BC-200 expression preferentially in neural tissue.

EXPRESSION OF WILD TYPE AND MUTANT HUMAN PRION PROTEINS BY RECOMBINANT BACULOVIRUS INFECTED INSECT CELLS. D. Goldgaber, R. Bhasin, E.A. Barnes* and J. Safar*. Dept. of Psychiatry, SUNY, Stony Brook, NY 11794; Laboratory of Central Nervous System Studies, National Institutes of Neurological Disorders and Stroke, National Institutes of Health.

A host protein encoded by the gene specifying the human scrapie amyloid precursor protein (Prion Protein, PrP^{CJD}, PRIP gene) is linked with the development, and apparently affects the pathogenesis of the transmissible spongiform encephalopathies: Creutzfeldt-Jakob disease (CJD), Gerstmann-Sträussler-Scheinker's syndrome (GSS) and Kuru. At least four point mutations of the human PRIP gene are known to be associated with the occurrence of CJD and GSS. The wild type human PRIP gene and two point mutants, one at codon 102 (Pro to Leu) and one at codon 200 (Glu to Lys) have been expressed in the baculovirus expression vector system. The recombinant proteins were detected in recombinant baculovirus infected insect cells two days post-infection. No PrP proteins were detected in the culture medium of infected cells indicating that the proteins were not secreted. The cell associated recombinant proteins migrated as a triplet of bands with apparent Mr 29-30, 27-28 and 25-26 kDa. The apparent Mr of the highest Mr band was 3-5 kDa lower than the human PrP^{CJD} protein isolated from brains of patients with CJD. Studies on the subcellular distribution and hydrophobicity of the recombinant proteins indicated similar behavior to proteins isolated from human brains. The recombinant proteins produced by the baculovirus expression system provide an abundant source of prion proteins which can be used for comparative study and determination of the role of point mutations in the infectivity of prion proteins.

A CHICKEN PRION-LIKE PROTEIN UNDERGOES TWO POST-TRANSLATIONAL CLEAVAGES. D.A. Harris. Dept. of Cell Biology & Physiology, Washington Univ. School of Medicine, St. Louis, Missouri 63110.

We have previously identified a chicken prion-like protein (ch-PLP) as the major sequenceable protein in purified preparations of an acetylcholine receptor-inducing activity (ARIA) from brain (D.A. Harris, et al., Soc. Neurosci. Abstr., 15:164, 1989). We have prepared stably transfected lines of mouse neuroblastoma (N2a) cells that express recombinant ch-PLP detectable by immunoblotting and immunoprecipitation. A 45kD form of ch-PLP can be released from intact cells by incubation with bacterial phosphoinositol-specific phospholipase C (PIPLC), suggesting that the protein is anchored to the cell surface by a glycosyl-phosphatidylinositol (GPI) linkage. Two forms of ch-PLP having molecular weights of 33-43kD and 10kD are also released into the extracellular medium in the absence of added enzyme. The 10kD fragment is derived from the N-terminal half of the molecule since it reacts with an antibody raised against a synthetic peptide corresponding to pro^{47}-pro^{65} of the ch-PLP sequence. This fragment can be metabolically labeled with ^{3}H-proline but not with ^{35}S-methionine, suggesting that it probably does not extend beyond met^{137}. Ch-PLP is also detectable in a 100,000xg membrane fraction of chicken brain, from which a 45kD form can be released by PIPLC. 33-43kD and 10kD forms are also detectable in a 100,000xg supernatant fraction of brain. We propose that the the ch-PLP molecule undergoes at least two posttranslational cleavages: one within or adjacent to the GPI anchor that releases the 33-43kD form, and a second near the middle of the protein that generates the 10kD fragment. The role of these cleavages in the deposition of amyloid in prion diseases is under investigation.

Ca^{2+}-INDUCED SPONGIFORM VACUOLATION IN SQUID GIANT NERVE FIBERS: A MODEL OF NEURODEGENERATIVE PROCESSES. H.M. Fishman, J. Metuzals* and K.P. Tewari. Univ of Texas Medical Branch, Galveston, *Univ of Ottawa, Ottawa, Canada.

Extensive vacuolation as observed by light and electron microscopy in stressed, isolated giant axons and surrounding Schwann cells of squid resembles spongiform changes seen in tissues of patients with neurodegenerative diseases (ND). Internal dialysis of unstressed axons with dialysates containing Ca^{2+} (100 μM to 10 mM) induced vacuolation similar to that observed in stressed axon preparations with Ca^{2+} externally. These results suggest that neurodegeneration is mediated via a common mode of action involving intracellular Ca^{2+} regulative processes. Membranes involved in Ca^{2+}-induced spongiform changes form a layer as a peripheral portion in fibers and originate from axolemma and endoplasmic reticulum (ER) as well as from adjoining plasmalemma and ER of Schwann cells. The membranes of vacuoles demonstrate regions of membrane damage, especially axolemma. Modified cytoskeletal filaments (10 to 20 nm diameter) are associated with these damaged regions. The large size of the squid giant nerve fibers and the relative ease with which morphological, biochemical and physiological methods are applied and integrated make giant axons of squid a unique preparation in which to study processes associated with degeneration. REDUCTION OF KAINATE-INDUCED SPECTRIN BREAKDOWN BY CALPAIN INHIBITORS. [1]D. Eveleth, [1]J. Estrada*, [2]S.J. Mennerick, [1]D. Lutz, [1]R. Dean, [3]J. Powers and [1]R. T. Bartus. [1]Cortex Pharmaceuticals, Irvine, CA 92718, [2]Washington Univ., St. Louis, MO 63110, [3]Georgia Institute of Technology, Atlanta, GA 30332.

Excitotoxicity is associated with many neuropathologies, including ischemia, stroke, and epilepsy. The mechanism of excitotoxicity is thought to involve elevations of intracellular calcium, which in turn activates a variety of potentially damaging enzymatic events. One such event is the activation of the calcium-dependent protease calpain, which degrades intracellular proteins including the cytoskeletal component spectrin.

Systemic administration of the excitotoxic glutamate analog kainate to rats produces an acute phase of convulsions and seizures followed by extensive cell death in the hippocampus and other brain regions. Cell death is dependent upon the induction of seizures, manifested externally by convulsions, in individual animals. The breakdown of spectrin correlates well with the extent of cell death observed histologically. Administration of Calpain Inhibitor 1 (Ac-Leu-Leu-Nle-H), a potent inhibitor of calpain, reduced the breakdown of spectrin measured 4 days after administration of kainate. The inhibitor also reduced the extent of convulsions associated with kainate toxicity.

These data argue that Calpain Inhibitor 1 interferes with the cascade of events leading to cell death and neurodegeneration following kainate toxicity. Calpain activation, which is reduced by the inhibitor, may be necessary for the initiation or maintenance of the cascade of events leading to cell death. Calpain inhibitors may thus represent a useful therapeutic approach to stroke and other forms of glutamate-related neurodegeneration.

574.22

OVERCOMING CONDUCTION BLOCK IN A CENTRAL DEMYELINATING LESION BY COOLING, BUT NOT BY 4-AMINOPYRIDINE (4-AP). P.A. Felts[1], K.J. Smith[2] and F.J. Liuzzi[1], Dept. of Anat. and Neurobiol., Eastern Va. Med. Sch., Norfolk, Virginia[1] and Depts. of Neurol. and Anat., UMDS, Guy's Campus, London[2].

The symptoms of multiple sclerosis (MS) can sometimes be relieved by a reduction in body temperature, or by the administration of 4-AP, a potassium channel blocking agent. The improvement in symptoms has been attributed to a restoration of conduction to central axons in which conduction has been blocked by demyelination. To examine this possibility in more detail, focal, unilateral demyelinating lesions were produced in the dorsal columns of fifteen adult rats by the intraspinal injection of ethidium bromide under general anesthesia. Two chronically prepared animals were then examined at multiple time points, and the remaining animals were examined acutely. During the period of demyelination (2-6 weeks post-injection) a reduction of lesion temperature from 38°C to 33°C increased the number of axons conducting through the lesion by up to approximately 280%. The newly conducting axons had the long latency expected of demyelinated axons. However, in the same preparations the administration of 4-AP, in a dose sufficient to have caused limb tremors in preliminary experiments with lightly anesthetized animals (1.7-3.4mg/kg, i.v.), had little or no effect on the number of conducting fibers.

In view of these findings, we suggest that the restoration of conduction to blocked axons contributes to the improvement in symptoms observed with body cooling. However, it seems that the improvement caused by 4-AP may result primarily from other effects, perhaps by the facilitation of transmission at central and neuromuscular synapses, thereby augmenting the action of pathways which are already functional. *Supported in part by grants from the NINDS and the National Multiple Sclerosis Society.*

ATTENUATION OF EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (EAE) BY THE 21-AMINOSTEROID TIRILAZAD MESYLATE (U-74006F). S.J. Karlik*, E. Grant*, C. Norley* and E.D. Hall. University of Western Ontario, London, Ontario, and The Upjohn Company, Kalamazoo, MI 49001.

In EAE, a model of multiple sclerosis, there is an autoimmune attack on the CNS causing demyelination, blood-brain-barrier (BBB) disruption, edema, and neurological dysfunction. Macrophage-derived free radicals and lipid peroxidation (LP) have been postulated to play a role in EAE. Thus, we tested the protective efficacy of the LP inhibitor U-74006F in a guinea pig EAE model. Vehicle or U-74006F (1, 3, or 10 mg/kg) was administered i.p once daily from days 0-12 after innoculation with whole CNS tissue in Freund's adjuvant. Disease was evaluated by a clinical grading scale and by magnetic resonance imaging (MRI). Gadolinium MRI enhancement was used to determine BBB compromise. U-74006F reduced the incidence of clinical symptoms from 81% in the untreated animals to 44 and 56% with 3 and 10 mg/kg, respectively. The maximum MRI scores were significantly decreased, and the incidence of gadolinium-enhanced scans (BBB opening) was attenuated from 63% to 36-44%. These results support a role of LP in the pathogenesis of EAE.

574.24

EFFECT OF GM_1 ON EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS IN FEMALE LEWIS RATS E.L. Orr and N.C. Stanley Dept. of Anatomy & Cell Biology. Texas College of Osteopathic Medicine. Ft. Worth, TX 76107.

Experimental autoimmune encephalomyelitis (EAE) is a model for CNS associated autoimmune disease (eg., multiple sclerosis). Fluctuations in clinical signs of EAE parallel changes in histamine in certain regions of the CNS. Agents known to alter histamine levels or release from neurons or CNS-associated mast cells attenuate the course and severity of EAE. Since the ganglioside GM1 has been reported to inhibit histamine release from basophils and mast cells, we investigated the effect of GM1 on the clinical course and severity of EAE. In all experiments adult female Lewis rats were inoculated to induce EAE and assessed for clinical symptoms beginning on day 7 postinoculation (pi). Parameters assessed were: day of onset of clinically significant disease (score of 4+), peak clinical score, day the peak score occurred, and duration of clinically significant disease (number of days at a score of 4+). In our initial experiments, the effect of intraperitoneal injections of GM1 (30mg/kg/day) or equal volumes of saline from days 6 pi through day 10 pi on the clinical course of acute (experiment 1) and recurrent (experiment 2) EAE were investigated. Compared to Controls, only a slightly shorter duration of acute EAE was observed in GM1 treated rats and no effect was observed in the clinical course or severity of recurrent EAE. The last experiment assessed the effect of prolonged, continuous administration of GM1 or saline (delivered subcutaneously using Alzet minipumps) on acute EAE. Pumps were implanted on day 6 pi and delivered an average daily dose of 30 mg GM1/kg for 25 days (i.e., through day 31 pi). Again, no significant differences between experimental or control rats were observed for any of the clinical parameters assessed. We conclude that GM1 has no effect on the clinical course or severity of EAE in female Lewis rats.

DELAYED PHENCYCLIDINE-INDUCED ALTERATIONS IN LOCAL CEREBRAL GLUCOSE UTILIZATION IN RAT BRAIN. X.M. Gao, O. Shirakawa, C.A. Tamminga. Maryland Psychiatric Research Center, University of Maryland at Baltimore, Baltimore, MD. 21228

Phencyclidine (PCP) is a psychotomimetic drug which produces psychotic symptoms in humans, closely resembling clinical manifestation in schizophrenia. PCP has been observed to produce delayed, reversible intracellular vacuolizations after a single dose (Olney Science 244:1990). Because this action might be related to the long lasting psychotic manifestations of PCP, we studied the delayed regional metabolic alterations in rat brains following the administration of PCP, using glucose autoradiography. PCP (8.6 mg/kg) was administered 3,6,and 12 hours prior to the 14C-2DG experiment. At 6 hours intracellular vacuolizations were observed with PCP on thin light microscopic sections in the posterior cingulate cortex, hippocampus, and subiculum. The rCMRglu was decreased selectively in parallel limbic regions with vacuolizations (e.g. posterior cingulate, retrosplenial cortex, amygdala, ventral tegmental area)($p<0.05$), and, in addition, in auditory regions ($p<0.001$) and in visual cortex ($p<0.05$). However, no metabolic changes remained either in the neocortex or in the extrapyramidal areas, and vacuolizations were not present. Glucose metabolism was decreased in the lateral habenula, an action opposite to that produced by antipsychotic drugs. The overall distribution of altered glucose utilization observed in this study, is distinct from the acute actions of PCP (Tamminga et.al. Synapse 1:1987) in its restricted limbic effects. This may be a more precise animal model for psychosis because of the extended time course of the psychotomimetic action of PCP. Moreover, we have previously observed an altered distribution of regional metabolism in schizophrenia precisely in limbic areas, similar to the effects of delayed PCP.

575.2

CEREBRAL METABOLIC ACTIVITY AND ABNORMAL EYE MOVEMENTS IN SCHIZOPHRENIC PATIENTS. D.E. Ross*, G.K. Thaker, H.H. Holcomb, N.G. Cascella, P.Morris*, S. Cassady, C.A. Tamminga. Maryland Psychiatric Research Center, University of Maryland at Baltimore, Baltimore, MD 21228.

Schizophrenic patients have abnormal smooth pursuit and saccadic eye movements, and it is likely that these defects are associated with abnormalities in supra-brain stem oculomotor areas. We hypothesize that these abnormal eye movements are associated with abnormal metabolism in the frontal eye fields (FEFs) and/or supplementary motor area (SMA).

To test this hypothesis, we examined regional cerebral metabolic rates of glucose utilization (rCMRglu) with PET/FDG in these areas and correlated them with measures of eye movements in schizophrenic patients (N=13). For the analysis of PET images, regions of interest for the FEFs and SMA were defined by stereotactic atlas coordinates reported by Fox et al. (J. Neurophysiol. 54: 348-369, 1985). 12 of the 13 subjects had an MRI scan of the brain which was used to determine the PET slices of interest. Eye movements were tested with infrared oculography, and tasks included smooth pursuit and an antisaccade paradigm. One measure of the latter is distractibility, which is defined as the percentage of trials in which the patient makes a reflexive saccade inappropriately toward the target. The results show that saccadic eye movement distractibility correlates with decreased metabolism in the frontal eye fields ($r=0.58$, $p=0.05$) and supplementary motor area ($r=0.64$, $p=0.02$). Distractibility did not correlate significantly with metabolism in non-oculomotor areas. Other oculomotor measures did not correlate significantly with metabolic values. These preliminary results may indicate that increased saccadic eye movement distractibility in schizophrenic patients results from a failure of FEFs and SMA to inhibit lower centers of oculomotor control.

575.3

HIPPOCAMPAL EFFERENTS TO THE NUCLEUS ACCUMBENS MODULATE SENSORIMOTOR GATING OF STARTLE IN THE RAT. S.B. Caine, M.A. Geyer and N.R. Swerdlow*. Departments of Psychiatry and Neuroscience, UCSD School of Medicine, La Jolla, CA 92093-0804.

"Prepulse inhibition" (PPI) occurs when the startle response to a startling stimulus is reduced by the prior presentation of a weak lead stimulus. PPI is an operational measure of sensorimotor gating that can be studied in both humans and rats. Schizophrenic patients exhibit deficits in PPI. In the rat, infusion of the cholinergic agonist carbachol into the dentate gyrus (DG), but not into the neocortex, disrupts PPI. Because the nucleus accumbens (NAC) is an important neural substrate of PPI, the present study examined the modulation of PPI by hippocampal efferents to the NAC. Male Sprague-Dawley rats were surgically equipped with bilateral steel cannulae aimed above the DG, ventral subiculum (VS) or CA1 of the hippocampus. Starting a week later, carbachol was infused into each site and startle amplitude was measured following 50 presentations of a startle pulse (118 db[A]) either alone or 60, 120 or 500 msec after a weak prepulse (80 dB[A]). The normal inhibition of startle by the prepulse was reversed by carbachol dose dependently (0.1,0.2,0.4 ug/side) in the DG, VS and CA1. The magnitude of the disruption of PPI was CA1>DG>VS, ventral hippocampal infusions having a longer duration of action than dorsal hippocampal infusions. Coinfusion of atropine (0.4 ug/side) restored PPI, indicating that carbachol disrupted PPI via a receptor-mediated mechanism. In a separate experiment, infusion of atropine alone (0.2,0.4,0.8 ug/side) failed to alter PPI.

Other studies in our laboratory indicate that the ventral pallidum and pedunculopontine nucleus are also important neural substrates of PPI. The results presented here suggest that the hippocampus may modulate sensorimotor gating through efferents to the NAC- ventral pallidal- pedunculopontine circuitry, and that pathology within the hippocampus may play a role in the deficits in sensorimotor gating observed in schizophrenic patients.

575.4

CHRONIC HALOPERIDOL AND CLOZAPINE TREATMENT AT THE CENTRAL AMYGDALA NUCLEUS. M.C. Schiess. Dept. Pharmacology, Univ. Texas Med. Branch, Galveston, TX 77550

The dopaminergic cell bodies of the ventral tegmental area (A_{10}) project to the central nucleus of the amygdala. Hyperactivity of the dopaminergic system at this level may be responsible for the dysfunctional emotional symptomatology of schizophrenia. *In vitro* intracellular recording from the amygdala slice was used to assess the effects of chronic neuroleptic treatment. At 25 weeks of 1 mg/kg/ day s.c. haloperidol, all rats displayed vacuous chewing movements, catalepsy and stereotypy. After six weeks chronic treatment with clozapine at 25 mg/kg/day i.p. all rats displayed passivity and apathy. Haloperidol and clozapine did not produce significant changes from control in passive membrane properties; depolarization blockade was not induced. Haloperidol produced a heightened response to superfusion with muscarine and quisqualate. Clozapine dramatically altered the central nucleus response to dopamine (1 μM) superfusion; producing membrane depolarization, an increase in spontaneous firing, a blockade of the s-AHP and a broadening of the action potential. These data suggest that clozapine's antipsychotic efficacy may be mediated by a modulation of dopaminergic transmission at the amygdala level and that haloperidol's antipsychotic efficacy may be mediated by a modulation in excitatory transmission. (Supported by Scottish Rite Schizophrenia Research Program)

DOPAMINERGIC DYSFUNCTION IN SCHIZOTYPAL PERSONALITY DISORDER. Larry J. Siever MD, Farooq Amin MD*, Oren Kalus MD*, Robert Trestman MD*, Emil Coccaro MD*, Ren-Kui Yang PhD*, Peter Knott PhD, Kenneth L. Davis MD. Dept. of Psychiatry, Mt. Sinai School of Medicine, NYC, NY 10029

In order to evaluate dopaminergic activity, suggested to be associated with psychosis in schizophrenia, in patients with schizotypal personality disorder (SPD), who have attenuated symptoms related to schizophrenia, plasma and cerebrospinal fluid (CSF) concentrations of HVA were determined by HPLC in SPD patients (n=21) and controls (19 other personality disorder [OPD] patients and 14 normal controls) in the AM after an overnight fast and 3 days of low monoamine diet. An overlapping group of patients were evaluated by CT-scan and neuropsychologic testing utilizing the Wisconsin Card Sort (WCST) and Trails B in order to evaluate pre-frontal function. Both plasma and CSF HVA concentrations were significantly increased in the SPD patients compared to OPD patients and normal controls ($p<0.05$), and both were correlated with the number of psychotic-like symptoms ($p<0.01$). Both frontal horn and lateral ventricular-brain-ratio were increased in the SPD patients compared to the two comparison groups ($p<0.05$) and lateral VBR was negatively correlated with psychotic-like symptoms ($p<0.05$). Plasma HVA was correlated negatively with frontal horn size and both WCST perseverative errors (increased in SPD) and Trails B performance ($p<0.05$). These results suggest a bidirectional relationship between dopamine activity and pathophysiology of SPD with increased dopaminergic function associated with the psychotic-like symptoms of SPD.

575.6

THE USE OF MAGNETIC RESONANCE IMAGING (MRI) TO QUANTIFY CORTICAL CEREBROSPINAL FLUID: A COMPARISON OF THREE METHODOLOGIES. M.L. Kesler, D.S. O'Leary, G.A. Cohen*, O. Stibolt*, and N.C. Andreasen. NIMH-CRC, Psychiatry Department, University of Iowa, Iowa City, IOWA 52242.

In a preliminary study by our group (see O'Leary *et al.*, this conference), 54 male patients with schizophrenia were found to have significantly more cortical CSF than 33 male controls in frontal and temporal regions. A visual rating method was used to rank MRI scans by the amount of cortical CSF seen within the subarachnoid space.

To validate the visual rating method and to begin to understand the etiology of increased cortical CSF, two computerized methods were used on coronal MRI slices (forward of the anterior horns of the lateral ventricles). Using image analysis software developed in our laboratory, inner cranial and cerebral surfaces were semi-automatically traced, and the surfaces were used to define three-dimensional volumes. Ratios of peripheral CSF volume to total cranial volume were calculated and were found to be significantly correlated with the visual ratings for the same subjects ($n=29$, $r=.70$, $p<.001$). Additional tracing data suggests that the increased cortical CSF results, in part, from sulcal widening.

A segmentation algorithm was used to classify MRI voxel intensities as gray matter, white matter, or CSF for each subject's series of frontal lobe slices. Ratios of the number of voxels classified as CSF to the total number of voxels classified were calculated. These ratios were found to be significantly correlated with the visual ratings ($n=15$, $r=.57$, $p<.05$) and with the tracing ratios ($n=16$, $r=.67$, $p<.01$). Gray matter and white matter volume changes which correlate with increased cortical CSF are being explored.

The comparison of three different methodologies used to evaluate MRI scans serves to validate each, and each may prove useful in generating hypotheses concerning brain changes in schizophrenia and schizophrenic subtypes.

575.7

DECREASED CRANIAL AND CEREBRAL VOLUME IN SCHIZOPHRENIA: A MAGNETIC RESONANCE IMAGING STUDY. M.A. Flaum*, D.S. O'Leary, V.W. Swayze II*, R. Alliger*, O. Stibolt* and N.C. Andreasen. Mental Health Clinical Research Center, University of Iowa, Iowa City, IA 52242.

Objectives: To assess volumes of various brain structures using MRI in a group of schizophrenics as compared with healthy control subjects.

Methods: The groups were selected so as to be highly comparable for the following variables: age, gender (all male), race and parental socioeconomic status. All patients (N=54) met DSM-III-R criteria for schizophrenia, and had no concurrent medical illness or history of substance abuse. Controls (N=33) were recruited from the community and were in good medical and psychiatric health. All subjects were scanned on a 1.5 Tesla GE Signa MR scanner, with 5 mm coronal slices and a 2.5mm gap. All tracings were performed by a single rater, blind to diagnosis, using a semi-automated method. Intra-rater reliability was consistently high, and inter-rater reliability was acceptable (kappa >0.70) for all structures except for the amygdala and thalamus. Subarachnoid CSF volume was estimated based on subjective ratings using a 0-5 scale.

Results: Using two tailed t-tests, schizophrenics were found to have significantly smaller cranial volume, right and left cerebral volume, and right and left thalamic volume than controls. Ratings of subarachnoid CSF were higher in the schizophrenic sample. Third ventricle volume was significantly larger in the schizophrenic group. All of these differences remained significant ($p<0.05$) after cranial volume and age were covaried. There were no significant differences in the volumes of the following structures: lateral ventricles, caudate, putamen, globus pallidus, hippocampus, amygdala or cerebellum.

Conclusions: The finding of smaller cranial and cerebral volume in schizophrenia was replicated, even after carefully controlling for socioeconomic factors, suggesting an early developmental defect. The findings of smaller cerebral volumes and increased subarachnoid CSF, even after cranial volume is covaried, suggest that an atrophic process may also be considered.

575.8

COGNITIVE FUNCTION AND CEREBRAL SPINAL FLUID MEASURES IN SCHIZOPHRENICS AND NORMALS: A MAGNETIC RESONANCE IMAGERY STUDY. D.S. O'Leary, M.L. Kesler, M.A.Flaum*,O. Stibolt*, & N.C. Andreasen. Mental Health Clinical Research Center, University of Iowa, Iowa City, IA 52242.

The relationships of cognitive functions and putative measures of cerebral atrophy were studied in schizophrenic and normal males 50 years of age or younger. Visual ratings of cerebral spinal fluid (CSF) surrounding Frontal, Parietal/Occipital, and Temporal lobes were made by two raters blind to diagnosis on coronal MRI films. Volumes of ventricles were obtained using semi-automated tracings (see Flaum et al., this conference). Neuropsychological tests were administered to obtain summary scores for IQ and other cognitive domains. Schizophrenics (n=54) met DSM-III-R criteria and had no concurrent medical illness or history of substance abuse. Controls (n=33) were recruited from the community.

Schizophrenics had significantly higher ratings of CSF surrounding the Frontal and Temporal lobes and had significantly larger Third Ventricular volumes than normals. These findings remained when age was covaried. IQ showed no relationship to any CSF measure. In both normals and patients, significant correlations were found between CSF measures and long- and short-term verbal memory, visual memory, and attentional measures. The effects of age differed in schizophrenics and normals but significant correlations remained in both groups when age effects were controlled. Future studies will investigate whether increased CSF reflects changes in gray or white matter using semiautomated segmentation techniques (see Kesler *et al.* this conference for discussion of computer methods of MRI analysis).

575.9

ALPHA$_2$ ADRENERGIC BLOCKADE WITH YOHIMBINE DISRUPTS AUDITORY SENSORY GATING IN RATS. K.E. Stevens, J. Meltzer, S.L. Stryker* and G.M. Rose. Department of Pharmacology, UCHSC and Medical Research, VAMC, Denver, CO 80262

In unmedicated rats and normal humans, midlatency auditory evoked potentials recorded in response to the second of a closely-spaced pair of clicks are reduced compared to the first. Amphetamine treatment of rats or humans disrupts this "gating" in a manner similar to that seen in schizophrenics. Animals studies using selective antagonists have implicated alterations in both noradrenergic and dopaminergic neural transmission in this phenomenon. To more directly assess the role of noradrenergic transmission in impaired sensory gating, the presynaptic alpha$_2$ adrenergic antagonist, yohimbine, was administered. Several doses were injected, i.p., and the effect on gating of the N40 waveform was determined at various times post injection. At a dose of 1 mg/kg, both 20 and 45 minutes post injection, the ratio of the second to the first response was elevated compared to controls. This disruption was achieved by both a decrease in the response to the first click and an elevation of the response to the second. To determine if dopaminergic blockade could effect this alteration in gating, the selective D1 antagonist, SCH23390, was co-administered with yohimbine. Preliminary data indicate that, rather than ameliorating the effects of yohimbine, D1 blockade actually exacerbates the gating deficit. (Supported by P50 MH44212-02)

YOHIMBINE CAUSES A TRANSIENT IMPAIRMENT IN P50 AUDITORY SENSORY GATING. L.E. Adler, L. Hoffer*, H.T. Nagamoto, M.C. Waldo*, R. Perkins*, and R. Freedman. Department of Psychiatry, University of Colorado Health Sciences Center, and Veterans Affairs Medical Center, Denver, CO 80262

Previous research using the auditory P50 response in a paired click paradigm has shown that schizophrenics have a chronic inability to gate auditory sensory stimuli. That is, the electrophysiological response to the second click is not reduced compared to the first click, as it is in normal individuals. This is taken as an indication of reduced sensory gating. Manic patients share this deficit when acutely ill, but the disruption is transitory and returns to normal when they are euthymic. Similar transient disruptions of gating of the P50 waveform in humans and the N40 waveform in rats can be induced by amphetamine. However, it is unclear whether this is due to increasing CNS noradrenergic and/or dopaminergic neuronal transmission

This pilot study used yohimbine, a presynaptic alpha$_2$ adrenergic antagonist to increase CNS noradrenergic neuronal transmission in 6 normal control subjects. Yohimbine caused a transient impairment of P50 auditory sensory gating during the first 30 minutes post ingestion, followed by a rapid return to baseline levels. The data suggest that increasing CNS noradrenergic neuronal transmission may transiently impair P50 auditory sensory gating in human subjects. This work was supported by grants 5K01 MH00728-03 and P50 MH44212-02.

INCREASED PHOSPHORYLATION OF GAP-43 AND OTHER SYNAPTIC PROTEINS IN SCHIZOPHRENIC BRAINS. N. I. Perrone-Bizzozero, L.I. Benowitz, E.D. Bird, S.E. Lewis*, L. Boling*, P. Holtzman*, S. Matthysse* and S.L. Rogers Department of Biochemistry, University of New Mexico, Albuquerque, N.M., 87131 and McLean Hosp., Harvard Univ., Belmont, MA, 02178.

The growth of axons and formation of synaptic connections are associated with the expression of the neuronal membrane phosphoprotein, GAP-43. To examine whether GAP-43 levels were altered in conditions of abnormal brain function such as in schizophrenia, we compared the levels of GAP-43 and other synaptic proteins in postmortem brain tissues derived from 5 control and 5 schizophrenic subjects. Following *in vitro* phosphorylation reactions in the presence of either Ca^{2+} or cAMP, synaptic phosphoproteins from primary visual (A17), and visual association (A20) areas were analyzed by two-dimensional gel electrophoresis and fluorography. Quantitative analysis revealed that levels of phosphorylation of GAP-43 in both areas 17 and 20 of schizophrenic brains were about 3-fold higher than in control brains. A similar increase was observed for other Ca^{2+}-dependent and cAMP-dependent synaptic phosphoproteins, whereas the levels of phosphorylation for tubulin and another major synaptic protein showed no change. Preliminary analysis of the frontal cortex (A10/11) in schizophrenic brains also showed increased levels of GAP-43 phosphorylation, suggesting that the anomaly observed in the previous studies is not limited to visual cortical areas. Finally, the fact that haldol-treated rats did not show any significant increase in GAP-43 phosphorylation suggests that our findings in schizophrenic brains are not the result of neuroleptic treatment and that an altered expression of GAP-43 and other synaptic proteins may correlate with some aspect of the disease. *Supported by the Scottish Rite Schizophrenia Research Program*

^{3}H-DTG BINDING IN POST-MORTEM BRAINS OF SCHIZOPHRENICS. H.Shibuya, M.Mori* and M.Toru*. Dept. of Neuropsychiatry, Sch. of Med., Tokyo Medical and Dental Univ., Tokyo 113 JAPAN

The pharmacological profile of sigma receptor in Wistar male rat and human were studied using ^{3}H-1,3,-(2-o-tolyl)guanidine(^{3}H-DTG). Futhermore, sigma receptor binding in the postmortem brains of 10 controls and 12 schizophrenics were assayed. None-specific binding was determined in the presence of 10^{-5}M haloperidol. 100mM Na^+ significantly decreased ^{3}H-DTG binding in rat brain homogenate but not in human brain cortex. K^+, Mn^{++}, Mg^{++}, Ca^{++} made no obvious difference in the binding between two species. 1μM Glu, Asp or Gly significantly increased ^{3}H-DTG binding in the human brain cortex but not in the rat brain.

In schizophrenics, sigma receptors in the frontal cortices, the temporal cortices, the parietal cortices and the occipital cortices showed no obvious difference compared to those in controls. There was no significant difference in sigma receptor binding between on-drug groups and off-drug groups in schizophrenics. These findings suggest that sigma receptor might not play important roles in the pathogenesis of schizophrenia.

575.13

REGIONAL CORTICAL SURFACE AREA MEASUREMENTS IN MONOZYGOTIC TWINS DISCORDANT FOR SCHIZOPHRENIA SUGGEST A LEFT HEMISPHERE BASIS FOR THE DISEASE. R.L. Green*, M.J. Tramo, W.C. Loftus*, C.E. Thomas*, P.J. Brown*, J.B. Weaver*, and M.S. Gazzaniga, Program in Cognitive Neuroscience and Dept. of Psychiatry, Dartmouth Med. School, Hanover, NH 03756

In order to consider whether behavioral differences in monozygotic twins discordant for schizophrenia (MZDS) are associated with neuroanatomical differences, we measured the surface area of 27 cortical regions via three-dimensional computer-generated reconstructions of magnetic resonance (MR) images. Four pairs of female MZDS were studied. Patients met DSM-III-R criteria for the diagnosis of schizophrenia. Monozygosity was determined by red blood cell marker assays and a standardized questionnaire. Contiguous 3mm-thick T1-weighted MR images were obtained in the coronal plane. For each of the 27 regions of interest (ROIs), differences in surface area (SA) within twin pairs and differences in SA between unrelated twin pairs were compared using a repeated measure ANOVA and Bartlett's test to compare variances. In a prior study (Gazzaniga et al. 1991), 15 of 27 ROI SAs in the left hemisphere of five normal female MZ twin pairs showed significantly less variance. In the MZDS group, only one ROI showed significantly less variance in the left hemisphere. In marked contrast, the right hemisphere of the five normal MZ twin pairs showed only four areas of significantly less variance. In the MZDS group significantly less variance was seen in three of these same regions.

These preliminary results are consistent with the view that: 1) schizophrenia reflects disease of the left hemisphere; and 2) the pathogenesis of the disease goes beyond abnormalities of neurotransmitter function and involves disorganization of cortical structures. (Supported by NARSAD, and ONR N00014-89-J-3035.)

SENSORIMOTOR GATING OF THE STARTLE REFLEX (SR) IS MEDIATED BY VENTRAL PALLIDAL EFFERENTS TO THE PEDUNCULOPONTINE NUCLEUS. N.R. Swerdlow*, S.B. Caine and M.A. Geyer. Departments of Psychiatry and Neuroscience, UCSD School of Medicine, La Jolla, CA 92093

The SR is inhibited or "gated" when a startling stimulus is preceded 30-500 msec earlier by a weak click or "prepulse". This "prepulse inhibition" (PPI) provides an operational measure of sensorimotor gating. PPI is impaired in schizophrenic patients, and this loss of startle gating may be a psychophysiologic correlate of deficient inhibitory processes that cause sensory and cognitive "flooding" in schizophrenia.

Our previous findings indicate that PPI is modulated in rats by neural circuitry connecting the hippocampus, nucleus accumbens and ventral pallidum (VP). Davis (J Neurosci 1982) reported that the "primary" control of the SR occurs in a 5-neuron circuit that links the sensory receptor through the pontine reticular formation to the motor effector. We examined how limbic/motor circuitry that modulates PPI might influence activity in this "primary" startle circuit.

In a replication of our published work, infusion of picrotoxin into the VP disrupted PPI of acoustic startle. PPI, but not startle itself, was profoundly impaired in rats after electrolytic lesions of VP efferent terminal regions in the pedunculopontine nucleus (PPN). PPI was not significantly impaired by electrolytic lesions of the dorsomedial thalamus. Limbic/motor information that modulates PPI appears to access the "primary startle circuit" via ventral pallidal efferents to the PPN. By linking forebrain and reticular formation substrates that modulate the SR, we have identified circuitry that controls a specific quantifiable behavioral abnormality in schizophrenia.

ABNORMALITIES IN NAAG AND NAALADase LEVELS IN SCHIZOPHRENIC BRAIN. G. Tsai, B.S. Slusher, R.E. Carter*, L. Passani, F. Casanova, J. Kleinman, J.T. Coyle. Depts. of Psychiat., Pharmacol., Neurosci., Johns Hopkins School of Med., Balto. MD 21205 and Neuroscience Center at St. Eliz., Washington, D.C. 20032.

Recent studies suggest that disturbed glutamatergic neurotransmission may play a role in schizophrenia. An important contribution to this hypothesis is the observation that phencyclidine (PCP), a potent psychotomimetic drug, acts at the NMDA-type glutamate receptor. The endogenous neuropeptide, N-Acetyl-Aspartyl-Glutamate (NAAG), has been proposed to act as a mixed agonist-antagonist at the NMDA receptor. To determine whether NAAG is involved in the neurochemical alterations of schizophrenia, NAAG and its catabolic enzyme, N-Acetylated Alpha-Linked Acidic Dipeptidase (NAALADase), were measured in eight different regions of freshly frozen schizophrenic, neuroleptic control and normal control brains. Preliminary results indicate abnormalities in NAAG levels and NAALADase activity in schizophrenics compared to normal controls. NAAG levels were increased in frontal and parietal cortices, but decreased in putamen. NAALADase activity was decreased in temporal and frontal cortices, hippocampus and amygdala. The alterations of NAAG in the putamen and of NAALADase in the frontal cortex, hippocampus and the amygdala were also observed in the neuroleptic control group, suggesting that these changes may be the effects of drug treatment. These results support the hypothesis that glutamate may be involved in schizophrenia and underscore the importance of studying the metabolism of NAAG, a potential NMDA ligand, in the pathophysiology of schizophrenia.

575.16

IN VIVO ^{1}H MAGNETIC RESONANCE SPECTROSCOPY (MRS) OF THE HIPPOCAMPUS/AMYGDALA COMPLEX IN SCHIZOPHRENIA H.A. Nasrallah, T.S. Skinner *, P. Schmalbrock*, A. Obringer* and P.M.L. Robitaille*, Departments of Psychiatry and Radiology, Ohio State University, Columbus, Ohio 43210

Several postmortem and brain imaging studies provide evidence for pathology of the medial (limbic) temporal lobe in schizophrenia. This includes hypoplasia and histoarchitectural abnormalities in the hippocampus of schizophrenic patients, suggestive of neurodevelopmental disruption of neuronal migration. We conducted an in vivo MRS study of the medial temporal lobe in schizophrenics and controls to generate hypotheses about the putatively abnormal neurochemical functions of this region in schizophrenia.

Eleven schizophrenic patients (by DSMIII-R) and six healthy volunteers consented to participate in the study. ^{1}H MRS was conducted using a GE Signa (1.5T).

Proton spectra were acquired from a 2 X 2 X 3 cm^3 voxel localized in the right/left hippocampus regions, using a modified STEAM sequence with a TE of 50 msec. Signal intensities of N-acetyl aspartate (NAA), creatine, and choline relative to a standardized noise measure were obtained. Preliminary analysis reveals no significant differences in the intensities of the creatine or choline resonances between the controls and schizophrenics bilaterally. However, mean NAA intensities from the right (but not the left) hippocampus were 30% lower in the schizophrenic group (p .05). Implications of these findings for the neurobiology of schizophrenia will be discussed.

575.17

REDUCED SEN (VISUAL ERP) INDEXES PROCESSING IMPAIRMENTS IN SCHIZOPHRENIC ADULTS. R.J. Strandburg, J.T. Marsh, W.S. Brown*, R.F. Asarnow*, D.Guthrie*, J. Higa* Dept. of Psychiatry, UCLA, Los Angeles CA 90024-1759.

ERPs were recorded from 19 normal and 18 schizophrenic adults during performance of a visual discrimination task, the Span of Apprehension (Span) which may detect vulnerability factors in schizophrenia. An RT condition preceded the Span. Identical stimuli (12 letter arrays) were presented in both conditions. Subjects responded to the visual arrays in the RT condition and discriminated between the presence of either a T or F in the Span condition. EEG was recorded from 17 scalp sites and ERPs spanned a 2 second epoch. Difference potentials (Span-RT) were computed to isolate Span endogenous negativity (SEN) associated with Span discrimination. Topographic fields were computed at the peak of SEN.

Schizophrenics produced significantly less SEN than normals. SEN differed in topography and time course from the exogenous components (N1, P2) it overlaps. SEN is similar to NA (Ritter et al 1983), which is associated with attentional effort during pattern recognition. Results suggest thatschizophrenics are impaired in allocation of adequate attentional resources for Span processing. This deficit is manifest early (220 msec) in discriminative processing. SEN results are similar to those obtained from normal and schizophrenic children.

575.18

CHARACTERIZATION OF A GROWTH PROMOTING AGENT FOR HUMAN NEUROBLASTOMA CELLS DERIVED FROM SCHIZOPHRENIC CSF. S.Shirabe*[1,2], J.P.Schwartz[2], and J.R.Stevens[1].1) NIMH, St. Elizabeths Hosp., Washington DC 20032, & 2) CNB, NINDS, NIH, Bethesda MD 20892.

We have identified a factor in schizophrenic (Sch) but not control CSF which promotes the growth of the human neuroblastoma cell line SH-EP. Once transformed, the cells themselves produce the factor. Further characterization has shown that the biological activity is destroyed by treating with $CHCl_3$, heat (at 56°C, 60°C or 90°C), and protease (proteinase K or trypsin), but not destroyed by 24 hr incubation at 4°C or RNAse. Growth of the cells for 24 hr in serum-free medium increased the biological activity approx. 100-fold compared to regular 10% FCS containing media. On a Percoll density gradient of culture media, the activity migrated to 1.081 -1.107 g/ml, using a gradient designed to fractionate viruses and subcellular particles, but not proteins or nucleic acids. Two additional changes in the properties of Sch-transformed cells include 1) decreases of vimentin and neurofilament by Western blotting (in agreement with previous immunohistochemistry results) and 2) loss of response to EGF stimulation.

AFFECTIVE ILLNESS AND RELATED DISORDERS

ANXIETY RESPONSES TO IV MCPP IN HEALTHY SUBJECTS AND PATIENTS WITH PANIC DISORDER. A.W. Goddard, D.S. Charney, M. Germine, G.R. Heninger, and S.W. Woods. Yale Univ. Dept. of Psychiatry, New Haven, CT 06519.

Patients with panic disorder (PD) have been reported to have an increased sensitivity to oral doses of the 5-HT agonist, m-chlorophenylpiperazine (MCPP). However a previous study by our group failed to find patient vs healthy subject behavioral differences following administration of higher doses of intravenous (IV) MCPP. The current study used a lower dose of IV MCPP, 0.05mg/kg, to determine whether the different findings were due to a dose effect. METHOD: Twenty nine PD patients and 22 healthy subjects participated in two study days, separated by at least one week. They received either a bolus infusion of normal saline or a solution of 0.05mg/kg MCPP, according to random assignment. Within challenge measurements included visual analog scale (VAS) anxiety, DSM III-R somatic panic symptoms, and blood pressure and heart rate. RESULTS: Baseline VAS anxiety on the active challenge day was 41±28 mm for the PD group and 4±11 mm for the healthy subject group. These baseline values were virtually the same for the placebo study day. Inspection of the data revealed that the peak anxiety response occurred at 30 min. post infusion. The MCPP minus placebo change from baseline anxiety at 30 min was 26±30 mm for the PD group and 17±27 mm for the healthy group. This difference was not significant on student t-test analysis, $p<0.3$. DISCUSSION: These data replicate the results of our previous study, suggesting that MCPP fails to discriminate between PD and healthy subjects on measures of anxiety. While 5-HT may play an important role in mediating human anxiety responses in general, it is unlikely that anxiety associated with PD specifically is the result of 5-HT receptor hypersensitivity. The effects of different routes of MCPP administration remain to be investigated.

EFFECTS OF SODIUM LACTATE INFUSIONS ON CISTERNAL LACTATE AND CARBON DIOXIDE MEASURES IN NONHUMAN PRIMATES. Jeremy D. Coplan, M.D. Leonard A. Rosenblum, PhD, Steven Friedman PhD, Trina B. Bassoff, MA, Jack M. Gorman, M.D. From: New York State Psychiatric Institute,Biological Studies Unit, Columbia University and Primate Behavioral Facility, SUNY HSCAB. To further understand lactate induced panic in patients with panic disorder, we evaluated the central effects of sodium lactate infusions as measured by cisternal lactate and gas measurements in a sample of nonventilated nonhuman primates under ketamine anesthesia. Despite the development of the characteristic peripheral biochemical effects of infused sodium lactate, no increases of central lactate or carbon dioxide was observed. The study therefore supports previous findings of non permeability of the blood brain barrier to lactate but conflicts with another nonhuman primate study suggesting a central increase in lactate during infusions. These discrepant data may be accounted for by type of anesthetic agent used, ventilation effects and concentration of lactate infused. Available studies, however, are consistent regarding the absence of central hypercarbia during lactate infusions, a factor hypothesized to be an important trigger of an abnormally sensitive "suffocation alarm mechanism" in panic disorder. The study thus supports theories of lactate panic based on cognitive and/or brainstem misevaluation of peripheral somatic sensations.

576.3

INCREASED SENSITIVITY OF THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS TO GLUCOCORTICOID FEEDBACK INHIBITION IN A TRANSGENIC MOUSE MODEL OF DEPRESSION TREATED WITH ANTIDEPRESSANTS.

N. Barden, M-C. Pepin and F. Pothier* Molecular Psychogenetics, CHUL Research Centre and Laval University, Ste-Foy, Québec, Canada G1V 4G2

We have created transgenic mice which bear a glucocorticoid receptor mRNA antisense transgene as an animal model for depression. These animals have decreased brain glucocorticoid binding activity and elevated serum cortisol and ACTH levels. Depressive illness is often characterized by an increased cortisol secretion which is refractory to glucocorticoid suppression. This apparent lack of glucocorticoid feedback inhibition could be explained by decreased glucocorticoid receptor (GR) gene expression in the brain. Normalization of HPA axis regulation follows successful antidepressant (AD) therapy of depression. To test the hypothesis that ADs might restore glucocorticoid sensitivity to brain areas by increasing GR gene expression, we have treated transgenic mice with desipramine (20mg/kgBW) and observed the effects on GR mRNA, glucocorticoid binding and corticosterone secretion. The glucocorticoid binding activity of different tissues from AD-treated and control transgenic mice was measured using [^{3}H]-dexamethasone. When transgenic mice were treated with desipramine, we observed up to a 4 fold increase in the glucocorticoid binding activity of different brain regions. The GR mRNA concentration of different tissues was determined by Northern blot analysis using a ^{32}P-labelled RNA probe complementary to a 1.8 kb fragment of the GR cDNA and a ß-actin cRNA probe for standardization. The GR mRNA concentration in the brain of AD-treated transgenic mice was twice that of non-treated transgenic animals.. Moreover, the serum corticosterone of AD-treated transgenic mice was within the concentration range of normal mice. These results suggest that ADs can restore the sensitivity of the HPA axis to glucocorticoid feedback inhibition by increasing the concentration of brain GR.

576.4

[^{3}H]-IMIPRAMINE BINDING IN PLATELETS OF NEVER-MEDICATED DEPRESSED PATIENTS. J.A. Franks*, D.L. Knight, K.R.R. Krishnan, T.A. Slotkin and C.B. Nemeroff. Duke Univ. Med. Ctr., Durham, NC 27710.

The serotonin uptake site in brain is labeled by [^{3}H]-imipramine with binding characteristics virtually identical to the imipramine binding site in platelets. Several previous studies demonstrated that the number of [^{3}H]-imipramine binding sites in platelets is decreased in drug-free depressed patients. However a recent study has suggested that the reduction in platelet [^{3}H]-imipramine binding sites found in these studies is due to prior treatment of patients with antidepressant drugs (Mellerup and Plenge, Acta Psychiatr. Scand. 1990). To test this hypothesis, platelet [^{3}H]-imipramine binding was evaluated in 12 depressed patients who had never received antidepressant drug therapy, and compared to that of age- and sex-matched controls. Patients fulfilled DSM-IIIR criteria for major depression and ranged in age from 22 to 81 years. Total [^{3}H]-imipramine binding was assayed at seven concentrations (0.25-8 nmol) of drug. Nonspecific binding was defined as binding persisting in the presence of 50 µmol desipramine. The number of platelet [^{3}H]-imipramine binding sites was significantly decreased by 33% in the depressed group vs controls. Bmax for the depressed group was 753.8 ± 78.2 vs control Bmax of 1120.9 ± 63.6. The Kd values were not significantly different between the two groups. This decrease in platelet [^{3}H]-imipramine binding site number observed in depressed patients is not the result of prior antidepressant drug therapy. (Supported by NIMH MH-40159).

576.5

LACK OF SIGNIFICANT MONTHLY VARIATION IN PLATELET [^{3}H]-IMIPRAMINE BINDING KINETICS IN CONTROLS OR PATIENTS WITH MAJOR DEPRESSION. D.L. Knight, K.R.R. Krishnan and C.B. Nemeroff. Depts. Psychiatry & Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710.

Specific high affinity binding sites for [^{3}H]-imipramine (IMI), that label the serotonin transporter, have been described in brain and platelets. In studies reported by our group and others, drug-free depressed patients have exhibited a reduced number (Bmax) of platelet IMI binding sites when compared to normal controls. Other groups have reported a seasonal variation in platelet IMI binding kinetics that masked any group differences in IMI Bmax. With our large database (104 controls, 178 depressed patients, 88 non-depressed psychiatric patients), we examined the possibility of monthly variations in platelet IMI binding site density or affinity using one-way ANOVA. We observed no significant monthly variation in platelet IMI binding Bmax or Kd in controls or patients with major depression. There were small statistically insignificant peaks of IMI binding in Febuary and August with the lowest binding found in July. Bmax values for depressed patients were significantly below the monthly mean of normal control Bmax values at every time point examined. There were no differences betwcen control and depressed Kd values in any month. The present results, by demonstrating no monthly variation in controls or depressed populations, indicates that seansonality is not a confound in the use of platelet IMI binding as a biological marker of major depression. (Supported by NIMH MH-40159).

576.6

CLONIDINE STIMULATION OF GROWTH HORMONE AND CORTISOL IN OBSESSIVE-COMPULSIVE DISORDER. W.A. Hewlett*, K. Martin, and S. Berman. Department of Psychiatry, Stanford University, Stanford, CA 94305.

Clonidine stimulates the release of growth hormone via an alpha-2 adrenergic mechanism. Altered alpha-2 adrenergic functioning has been suggested to occur in Obsessive Compulsive Disorder (OCD) and the growth hormone response to clonidine stimulation has been reported as blunted in the setting of OCD. In an attempt to replicate this finding, a clonidine challenge test was conducted on 19 subjects with a DSMIIIR diagnosis of OCD and 18 control subjects. Two baseline blood samples were obtained prior to IV administration of clonidine (2 μg/kg.) Blood samples were then collected at 15 minute intervals for one hour and subsequently at 2 and 4 hours post administration. Plasma samples were frozen at -70°C prior to assay for growth hormone. Cortisol levels were also assayed as a nonspecific endocrine measure of stress. Clonidine induced a six-fold increase in plasma growth hormone levels in both patients and controls. There was no difference in the amount of stimulation between these populations. Cortisol levels dropped by 15% during the period of clonidine-induced growth hormone stimulation and there was no significant difference between patients and controls in this decrement. These results would indicate that there is no difference in.alpha-2 adrenergic functioning between OCD patients and control subjects.

EFFECTS OF LITHIUM ON TYROSINE HYDROXYLASE GENE EXPRESSION IN PC12 CELLS. **G. Allan and N.G. Bazan. LSU Eye Center and Neuroscience Center, New Orleans, LA 70112.**

Lithium is an effective drug for the treatment of some manic disorders, but its precise mechanism of action has not yet been determined. It has been shown to affect the inositol lipid cycle via inhibition of inositol-1-phosphatase, and to affect the coupling of G-proteins. Recent evidence showing that lithium augments c-*fos* expression in PC12 cells has led to the suggestion that lithium might also act at the level of gene expression. The control enzyme of catecholamine biosynthesis, tyrosine hydrolase (TH), has been shown to be a target of the AP-1 translational activator complex. PC12 cells were treated with nerve growth factor (NGF) and/or lithium and TH mRNA levels were determined by Northern analysis. Lithium (0.1 mM and 1 mM) elevated TH message levels in NGF-treated cells after 5 and 6 days, but not after 8 days. TH mRNA levels in undifferentiated cells were not affected. Ten millimolar lithium decreases TH mRNA levels with respect to controls in both differentiated and undifferentiated cells after 5 and 8 days of exposure. These data suggest that chronic lithium treatment can affect TH gene expression in this cell line, but, at the highest concentration, might have nonspecific effects. We are currently studying this system in more detail, since it provides a model to study its action in neural cells. (Supported by NINDS NS23002).

AN HYPOTHESIS OF THE NEUROBIOLOGY OF THE ATTENTION DEFICIT HYPERACTIVITY DISORDER (ADHD) SYNDROME. **W. A. Weinberg and R. A. Brumback. Dallas Children's Hospital, Dallas, TX and University of Oklahoma, Oklahoma City, OK.**

Children and adolescents not doing well in school and/or home are often labeled as suffering from ADHD. However, ADHD is a symptom complex resulting from multiple specific etiologies. We have developed an hypothesis in which ADHD syndrome is explainable as genetically-based dysfunction of specific brain areas. Depression relates to loss of right parietal-temporal cortex control of locus ceruleus and median raphé nuclei with resultant reduced bioamine neurotransmission to cerebral cortex bilaterally. Disturbed control of hypothalamic circadian functions results in associated abnormalities of biologic rhythms and sleep. Primary disorder of vigilance relates to loss of controlling modulation by inferior parietal lobule on reticular activating system resulting in dearousal sleep. In narcolepsy, inferior parietal lobule control is intact, but genetically-abnormal reticular activating system aberrantly influences both cerebral hemispheres with resultant sleep attacks and hypovigilance. Although abnormal functioning of left mesial temporal cortex can alone present as mania, more commonly interactions between hemispheres determine clinical symptoms of affective illness. Disorder of right hemisphere not only generates depression, but its influence on left hemisphere can result in mixed symptoms (depression and mania) or (less commonly) pure mania. Occasionally, primary dysfunction of left mesial temporal (limbic) cortex can induce right cerebral hemisphere dysfunction presenting clinically as mixed symptoms or as pure major depression. Individual variation in higher cortical cognitive functions may be apparent as learning disabilities. In right parietal cortex learning disability syndrome, stressing dysfunctional cortical areas in an unfavorable learning environment results in inattention, secondary hypovigilance, and promotion of affective illness. Although most symptoms of conduct disorder are secondary to underlying affective illness, dysfunction of anterior-inferior right frontal cortex results in primary conduct disorder (sociopathy). Comorbidity and concurrent diagnoses are explainable as a consequence of interactions between affected brain centers.

LYMPHOCYTE DNA-SYNTHESIS AND GLUCOCORTICOID-RECEPTOR PLASTICITY IN MAJOR DEPRESSIVE DISORDER. N.Wodarz*, C.Konradi, R.Rupprecht*, J.Kornhuber*, P.Riederer*. Dep. of Psychiatry, Clin. Neurochem., Univ. of Würzburg, Füchsleinstr. 15, W-8700 Würzburg, Germany.

Abnormalities of hypothalamic-pituitary-adrenal (HPA) axis integrity, as well as alterations in immune function have repeatedly been associated with the syndrome of depression. We investigated in 12 drug-free patients with severe major depressive disorder (according to DSM-III-R) and 13 age-matched non-hospitalized healthy individuals the lectin-induced lymphocyte DNA-synthesis (Concanavalin A, Phytohemagglutinin A, Pokeweed Mitogen), i.e., an in-vitro measure of cell-mediated immunity, and the sensitivity of the lymphocyte glucocorticoid receptor. In contrast to previous reports, the basal lectin-driven lymphocyte DNA-synthesis did not differ between patients and controls. But a weaker sensitivity to in-vitro adrenocortical hormones might be indicative of an impaired plasticity of glucocorticoid receptor regulation in a subgroup of depressed patients. The elucidation of the exact mechanism may yield insights into the pathophysiology of major depressive disorder.

ADRENAL ACTIVITY DOES NOT MEDIATE ALARM PHEROMONE REACTION IN THE FORCED SWIM TEST. P.J. Bilitzke and E.L. Abel. Depts. of Psychology, Ob/Gyn and Fetal Alcohol Research Center, Wayne State Univ., Detroit, MI 48201.

Rats tested in fresh water in a forced swim test are more immobile than rats tested in soiled water which presumably contains an alarm pheromone. This study was done to see if the adrenal glands are somehow involved in this phenomenon. Male Long-Evans rats, 110-120 days of age, were tested in the forced swim test after adrenalectomy or after SHAM surgery. Plexiglas cylinders were filled to a height of 25cm with fresh tap water (26±1°C.) ADX did not affect the behavior of rats in fresh or soiled water nor did it affect production of alarm pheromone or reaction to it. The results suggest that adrenal function does not mediate the response to, or production of alarm pheromone.

576.11

AN ANIMAL MODEL OF PANIC DISORDER: PSYCHOPHARMACOLOGIC EVIDENCE. J.H. Hannigan, E.L. Abel and P.J. Bilitzke. C.S. Mott Center, Wayne State Univ., School of Medicine, Detroit, MI 48201.

Rats forced to swim with no possibility of escape initially swim vigorously but soon show considerable immobility. In contrast, animals tested in water soiled by another rat exhibit almost no immobility. We hypothesized that behavior in soiled water resembles a panic-like response which will respond to drugs with anti-panic effects. The present results supported this hypothesis by showing that buspirone, diazepam and imipramine had no significant effects on immobility when rats were tested in fresh water. In soiled water, diazepam was still ineffective; imipramine increased immobility slightly; and buspirone increased immobility to the level of animals tested in fresh water. Since the selective serotonin agonist buspirone has relatively greater anti-panic effects clinically than diazepam or imipramine, we concluded that our variation of the forced swim test may be a useful animal model for studying mechanisms of panic and treatment of panic disorder.

ABSENCE OF HABITUATION TO ALARM PHEROMONE IN THE FORCED SWIM TEST. E.L. Abel and J.H. Hannigan. C.S. Mott Center, Wayne State Univ., School of Medicine, Detroit, MI 48201.

Rats were tested for 8 consecutive days in a forced swim test in either fresh water or soiled water. On day 9, some rats previously tested in fresh water were tested in soiled water, and vice versa. On days 10 and 11, all rats were tested in their original water condition. On day 12, escape from a water maze was measured for all rats, plus a group of naive animals. Rats were more immobile in fresh than in soiled water on all days. Rats tested repeatedly in fresh but not soiled water increased immobility over days. When switched between water conditions, rats behaved like rats that had been tested previously in each condition, with no evidence that prior testing influenced immobility in either condition. Rats that had been tested continuously in fresh water had the longest escape latencies and were the only group to differ from naive controls.

CALCIUM CHANNEL ANTAGONISTS INDUCE NEURONAL DEATH IN CORTICAL CULTURE.

J. Koh, and C.W. Cotman. Dept. of Psychobiol. University of California, Irvine, CA 92717 USA

Organic calcium channel antagonists (OCCA) have been shown to protect neurons from ischemic or excitotoxic injury, possibly by limiting Ca influx through the voltage-gated calcium channels. However, the important possibility that OCCAs alone may possess neurotoxic potential has not been examined. In the present study, we report that 2 d exposure of mouse cortical cultures to nifedipine (10-100 μM), verapamil (3-30 μM), diltiazem (10-100 μM), or flunarizine (1-10 μM) produces selective neurotoxicity in a concentration-dependent manner. Interestingly, neurotoxicity produced by nifedipine or verapamil is largely attenuated by 1-10 μM cycloheximide (CHX), an inhibitor of protein synthesis. Furthermore, extensive neuronal degeneration developing in low Ca media is also similarly blocked by CHX. Although other possibilities cannot be excluded, these findings suggest that a decrease in intraneuronal Ca levels may trigger synthesis of proteins mediating neuronal death, similar to what has been proposed to occur in growth factor deprivation neuronal injury. Regardless of the exact mechanisms involved, more study regarding neurotoxicity of OCCAs seems warranted since these compounds are currently clinically used in patients with certain cardiovascular problems.

577.2

POSTMORTEM STABILITY OF mRNA FOR GLUCOCORTICOID AND MINERALOCORTICOID RECEPTOR IN RODENT BRAIN.

Daniel M. Wetzel, Martha C. Bohn, and Robert W. Hamill. Dept. of Neurology, & Dept of Neurobiology and Anatomy, University of Rochester Medical Center, Monroe Community Hospital, Rochester, NY 14620.

In preparation for experiments with human tissue we determined the relative postmortem stability of the respective mRNA's for glucocorticoid (GR) and mineralocorticoid (MR) receptor in rodent brain using semi-quantitative *in situ* hybridization (ISH). Groups of 3 rats were killed by CO_2 asphyxiation and their brains removed immediately (O hr) or following, 12 hr or 24 hr delays. Rat carcasses in the 12 hr group were maintained at RT until brain removal; rat carcasses in the 24 hr group were maintained for 12 hours at RT followed by an additional 12 hr at 4°C. Specific hybridization of GR anti-sense ^{35}S-RNA-probe to tissue mRNA encoding the (GR) was detected using film and emulsion autoradiography. The most intense labelling was in the dentate gyrus followed by the CA1 hippocampal region. Less, but still detectable, signal was apparent over CA3-CA4 pyramidal cell regions. Positive hybridization of the MR anti-sense ^{35}S-RNA-probe was detected throughout the CA1-4 pyramidal cell fields of the hippocampus and the granular cells of the dentate gyrus. Film images demonstrated that even in the 24 hr postmortem delay group intense specific signal is present in sections hybridized with both anti-sense GR and MR probes. The distribution of the detected mRNAs changes little with postmortem time and there is no overall increase in non-specific background. These initial experiments with rat brain demonstrate that the mRNA for both GR and MR, as detected with ISH, are stable up to 24 hours following death. (Supported by NIH grants AG03644 and NS20832).

577.3

CORTICOSTERONE EXACERBATES HIPPOCAMPAL CALCIUM-DEPENDENT SPECTRIN PROTEOLYSIS IN VIVO. E Elliott[1] P Vanderklish*[2] J Chang*[1] G Lynch[2] and R Sapolsky[1]. [1]Dept Biol Sci, Stanford Univ, Stanford, CA 94305 and [2]CNLM, Univ of CA, Irvine, CA 92715.

Corticosterone (CORT), a steroid with enhanced secretion during stress, increases hippocampal neuronal vulnerability to excitotoxins, hypoxia-ischemia, and metabolic poisons. One hypothesis for this CORT endangerment is an exacerbation of the glutamate/NMDA/calcium cascade. This would result in the activation of calcium-dependent proteases such as calpain, the preferred substrate of which is spectrin, a prominent component of the membrane cytoskeleton. We investigated whether CORT increases hippocampal spectrin proteolysis induced by the excitotoxin Kainic Acid (KA).

Adrenalectomized (ADX) rats, half with daily CORT replacement (3 mg/100 g bw), were infused with KA in the hippocampus and sacrificed 6 hours later. Spectrin and its proteolytic fragments were compared in the 2 groups by immunoblot assay. CORT treatment increased KA-induced hippocampal spectrin proteolysis 124%. This may be energetic in nature as CORT decreases hippocampal neuronal glucose transport. To test this, ADX and ADX+CORT rats were injected ip with 0.75 gm mannose every 3 hr for 24 hr before and after KA infusion. This mannose supplementation eliminated the CORT-induced increase in spectrin proteolysis. The CORT exacerbation of spectrin degradation would be expected to disrupt membrane-associated events and intracellular transport and could explain the hippocampal neuronal vulnerability and toxicity evident following CORT exposure.

577.4

SELECTIVE DEGENERATION OF THE RAT OLFACTORY NERVE AND OLFACTORY-RELATED CORTICAL AREAS DURING THE DEVELOPMENT OF ETHANOL DEPENDENCE

T.D. Corso[1], E.J. Neafsey[2] and M.A. Collins[3], [1]Neurosci. Prgm., Depts. [2]Anat. and [3]Biochem., Loyola U. Med. Center, Maywood Ill. 60153

Adult male rats were maintained at high blood ethanol concentrations (300-500mg%) for 4 days via an indwelling stomach catheter (adaptation of the Majchrowicz dependence technique) and then sacrificed. Using the deOlmos cupric-silver stain, neuronal degeneration was histologically found in the dentate gyrus (granule layer), the entorhinal cortex (layer 3), the perirhinal cortex (layer 3), the piriform cortex (layer 2) and the olfactory amygdala, confirming the findings of Switzer et al. (Anat. Rec. 1982: 202:186a). In addition, we detected neuronal degeneration in the insular cortex (layers 2&3), the lateral orbital cortex (layer 2), and striking degeneration of the olfactory nerve terminals in the olfactory bulb. We have also found that adding a 36 hour withdrawal did not increase the observed degeneration (cell counts), implying that the degeneration was a direct effect of the ethanol and not secondary to withdrawal seizures.

577.5

BRAIN SAM-DEPENDENT N-METHYLATIONS OF β-CARBOLINES AND THEIR TETRAHYDRO FORMS: POTENTIAL BIOACTIVATION ROUTES TO NEUROTOXINS.

M.A. Collins, E.J. Neafsey and K. Matsubara*, Biochem. and Anatomy Depts., Loyola Univ. Med. Center, Maywood, Ill. 60153.

S-Adenosylmethionine (^{3}H-SAM)-dependent N-methylation of β-carboline (BC) and 1,2,3,4-tetrahydro-BC (THBC) alkaloids was examined in undialyzed subfractions of guinea pig and rat brain, using HPLC/radiodetection. Simple THBCs were methylated solely on the 2[β]-nitrogen by cytosolic activity possibly identical to aza-heterocyclic N-methylating activity reported by others. However, simple BCs such as harman or norharman underwent both 2[β]- and 9[indole]-N-methylations in sequential fashion by activity in the nuclear subfractions. Importantly, the 2,9-dimethyl-BC products displayed dopaminergic neurotoxic effects that surpassed the 2-methyl-BCs and approached MPP+, the parkinsonian "street drug" toxin. Since THBCs and BCs are endogenous constituents, their respective N-methylations by differing brain methyl-transferases could lead ultimately to cationic 2,9-[indole]-methylated BC toxic factors which are trapped within the brain. Supported by NS23891 and LUMC.

SPINAL KINETICS OF LIPOSOME-ENCAPSULATED 1-ß-D-ARABINO-FURANOSYL CYTOSINE IN RATS.

J. D. Jang, S. Kim* and T. L. Yaksh. Dept of Anesthesiology and Internal Medicine* University of California at San Diego, La Jolla, CA 92093

Maintenance of therapeutic concentrations of anti-neoplastic agents in the CNS for extended periods of time is efficient method for the delivery of the cell cycle specific antimetabolites in cancer chemotherapy. Multivesicular liposomes composed of bilayer lipid membrane have been reported as slow release reservoirs for hydrophilic drugs.

We studied the intraspinal kinetics of liposome-encapsulated (liposomal) 1-ß-D-arabino-furanosyl cytosine (Ara-C) in rats. Liposomes were observed in lumbar and cisternal CSF for 7 days after intrathecal (IT) injection of liposomal Ara-C (1mg/50ul) through a chronic lumbar IT catheter. The IT T1/2 of the liposomal Ara-C was 154 hr in contrast to T1/2 of 0.3 hr for free Ara-C. T1/2 of IT inulin-C^{14} in CSF was 0.5 hr. This suggests liposomes are cleared more slowly than bulk CSF flow. No toxicity on general behavior with IT liposomes was observed.

CSF sample	Ara-C		T2/1(hr)	R
Lumbar	free		0.28	.96
	liposomal	pellet	154*	.97
		super	80*	.84
Cisternal	liposomal	pellet	58.3*	.9
		super	54*	.85

R = Correlation coefficient, * = Second order kinetics, free = unencapsulated drug, pellet = drug in liposome, super = free drug in supernatant.

577.7

COLCHICINE-INDUCED DEGENERATION OF CHOLINERGIC SEPTOHIPPOCAMPAL NEURONS AS DEMONSTRATED BY THE LOSS OF NGFr-IMMUNOREACTIVITY.

Sheryl R. Ginn and Gary M. Peterson. Department of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858-4354.

Neuronal somata in the medial septum (MS), which are immunoreactive for choline acetyltransferase (ChAT), are also immunoreactive for the nerve growth factor receptor (NGFr). Similarly, the pattern of innervation of the hippocampus by cholinergic afferents is matched by the pattern of NGFr-immunoreactive (NGFr) fibers. Thus, NGFr-immunoreactivity appears to be a reliable marker for cholinergic somata and axons in the septohippocampal system. The present study was conducted to determine if ICV injections of colchicine, which reduce the number of ChAT-immunoreactive somata in the MS and the numbers of acetylcholinesterase (AChE)-positive fibers in the hippocampus, produce a similar change in the numbers of NGFr-immunoreactive somata and fibers. Colchicine (2.5 μl of 0.2%) was injected into each lateral ventricle of female Sprague-Dawley rats; the rats were allowed to survive for 1 week before aldehyde perfusion. The brains were cut through the MS and the hippocampus, and sections in these areas were stained immunocytochemically for NGFr using 192 IgG (generously provided by Eugene M. Johnson, Jr). ICV colchicine resulted in a 48% reduction in the number of NGFr-immunoreactive somata in the MS, compared to control. Within the hippocampus the intensity and numbers of NGFr-immunoreactive fibers were greatly reduced. These results are similar to what has been reported for ChAT-immunoreactive somata in the MS and AChE-positive fibers in the hippocampus, and support the conclusion that ICV colchicine induces degeneration of cholinergic neurons in the septohippocampal system.

577.8

NEUROTOXIC EFFECTS OF CHRONIC GABA INFUSION INTO THE NUCLEUS BASALIS WERE NOT ATTENUATED BY CO-INFUSION OF THE $GABA_A$ RECEPTOR ANTAGONIST, SR95531.

M. Majchrzak, G. Ballough and B. Will. L.N.B.C., U.P.R. 419 du CNRS, Centre de Neurochimie , 67000-Strasbourg, France.

Previous studies have demonstrated that unilateral GABA infusion into the Nucleus Basalis (NB) of rats produces pronounced gliosis in the NB and various surrounding structures, as well as cholinergic deafferentation in the ipsilateral frontoparietal cortex (Will et al., 1988; Majchrzak et al., 1990). This investigation was undertaken to examine whether the neurotoxic effects of chronic GABA infusion are directly mediated by the $GABA_A$ receptors. A total of 42 male Long-Evans rats (250-300g) was randomly divided into 6 treatment groups with 7 animals per group. Each rat received a unilateral, intra-NBM infusion of either "SR-0.5" (i.e., SR95531; 0.5 μg/μl/h), "SR-0.05" (0.05 μg/μl/h), "GABA100" (100 μg/μl/h), GABA100 + SR-0.5 (0.5 μg SR + 100μg GABA per μl/h), GABA100 + SR-0.05 (0.05 μg SR + 100μg GABA per μl/h), or the vehicle (ultrafiltered saline; 1 μl/h) for a period of 24 hours. It has been demonstrated that SR95531 (i.e., "GABAzine") is a potent competitive $GABA_A$ receptor antagonist. Animals were monitored for alterations in spontaneous activity (i.e., actography) and spontaneous turning (i.e., bucket rotation). Rats were sacrificed 8 days following the initiation of infusions. Brain sections were examined using AChE and cresyl violet histochemistry, and GFAP immunocytochemistry. These results demonstrate that co-infusion of SR-0.5 or SR-0.05 with GABA100 did not attenuate GABA-induced neurotoxicity and/or behavioral abnormalities. On the contrary, it was observed that SR alone or co-infused with GABA produced a similar or greater extent of cortical deafferentation, gliosis and GFAP immunoreactivity than GABA alone. It is concluded that GABA-induced neurotoxicity and behavioral abnormalities are not abolished or even attenuated by co-infusion of the $GABA_A$ antagonist, SR95531, at least not at the dosages employed.

577.9

SERIAL EVALUATION OF THE NEUROPATHY ASSOCIATED WITH THE ANTI-AIDS COMPOUND ddC IN THE RABBIT.

M.Litwak, T.Anderson*, C.Brosnan, A. Davidovich*, and J.Arezzo. Albert Einstein Coll. of Med., Bronx, N.Y. 10461 and Hoffmann La-Roche, Nutley, N.J. 07110

The nucleoside, 2',3'-dideoxycytidine (ddC) is a potent inhibitor of HIV but has been associated with a dose-dependant peripheral neuropathy in clinical trials. Previous studies in the rabbit have established that high doses (50 - 250 mg/kg/day) of ddC, administered for 18 weeks, produced a profound neuropathy characterized by both myelin and axonal dysfunction. This severe neuropathy most likely reflected an end stage process clinically characterized by paralysis in the hindlimbs and paresis in the forelimbs. The present study was designed to establish the earlier stages and progression of ddC neuropathy. We studied 40 New Zealand white rabbits that were equally divided into a control and a treated group. ddC was administered by gavage at a dose of 35 mg/kg/day. Histopathology was serially examined at 8, 12, 16, 20, 24 wks (electrophysiologic measures were recorded at these timepoints plus at baseline).

Beginning at wk 16, the proximal segments of the sciatic nerve and the associated ventral roots showed myelin splitting and intramyelinic edema. At 20 wks, clinical signs of weakness appeared. At 24 wks, a significant reduction in axonal cross sectional diameter was evident in the sciatic and distal tibial nerves. The principal electrophysiological change was seen at 24 wks in the peroneal F-Wave, which was delayed by approximately 45% of it's baseline latency. These findings confirm a ddC induced proximal motor fiber myelinopathy and a distal axonopathy, and demonstrate the effectiveness of the rabbit as a model for ddC neuropathy.

577.10

BEHAVIORAL DEVELOPMENT OF INTACT AND NEONATALLY CAPSAICIN TREATED RATS.

J. Manzo, P. Carrillo*, L. Cornejo*, M. Salas* and P. Pacheco. CIB, Univ. Veracruzana, Xalapa, Ver.; IIB-UNAM, México, D.F. 04510.

Capsaicin (CAP) neonatally injected damages small primary sensory neurons related with thermo-nociceptive activity. This study analyzes the development of scratching, still, grooming, rearing, sniffing, digging, and searching behaviors in intact and neonatally (day 2pp) CAP treated (50mg/Kg s.c.) rats. The frequency of these behaviors was scored every other day from day 3 to day 90 of life. Eye opening day, body weight and physical appearance were also recorder. RESULTS: Control: Still behavior frequency (BF) prodominated over others BFs during the first 7 days of life and progressively diminished until day 13th, when rearing and digging BFs started to increase. Sniffing, grooming and searching BFs suddenly increased from day 9, however, the latter showed a fast decrement on day 13th. Scratching BF was slightly apparent showing a gradual, small increment. On days 14-15 eye opening occurred. CAP-treated: The frequency of all behaviors but scratching was similar as controls. Scratching BF increased significantly on day 13th and was maintained at a higher level than control throughout the study. Eye opening occurred before (days 10-14) and these rats presented head wounds. CONCLUSION: Thermo-nociceptive stimuli (activity carried by CAP sensitive fibers) influence the time of eye opening and the intensity of scratching behavior.

SUPPRESSION OF HIPPOCAMPAL SLICE EXCITABILITY BY 2-, 3-, AND 4-METHYLPYRIDINE. S.B. Fountain and T.J. Teyler, Dept. Psychol., Kent State Univ., Kent, OH 44242 and Dept. Neurobiol., N.E. Ohio Univs. Coll. of Med., Rootstown, OH 44272.

Neurophysiological assessments in rats have shown that 2-, 3-, and 4-methylpyridine have effects on sensory function and cerebral excitability, causing effects similar to those produced by depressant agents. The present study assessed the effects of 2-, 3-, and 4-methylpyridine on rat hippocampal slice excitability. Slices were prepared using standard techniques and maintained at the interface of a pool of artificial CSF and an O_2/CO_2 atmosphere. Stimulating and recording electrodes were positioned in the Schaffer collaterals and CA1 cell body layer, respectively. When a stable waveform was recorded, an input/output (I/O) profile was obtained by administering a series of increasing stimulus intensities. Paired-pulse tests of inhibitory processes were also conducted. Tests of excitatory and inhibitory systems in area CA1 of the hippocampal slice were conducted over a period of 3 hr postexposure. Following exposures of 100 μM 2-, 3-, or 4-methylpyridine, evoked population EPSP and population spike responses recorded in the cell body field of hippocampal area CA1 were slowly suppressed over the course of 3 hr, whereas no effects on local inhibitory processes or latency of evoked responses were detected. No significant differences were observed between agents.
(Supported by US EPA and Johns Hopkins Center for Alternatives to Animal Testing.)

577.12

EFFECTS OF BILIRUBIN ON TRANSMEMBRANE ELECTRICAL AND PROTON GRADIENTS OF RAT CORTICAL SYNAPTOSOMES, AND ON RECONSTITUTED NICOTINIC ACETYLCHOLINE RECEPTOR FUNCTION. E.L.M. Ochoa, T. Nguyen*, R.P. Wennberg*, and T.Takashima*, Neonatology, University of California at Davis, Davis CA. 95616.

Bilirubin IXa, 4Z, 15Z (BR) depolarizes synaptosomes, releasing trapped tetraphenylphosphonium$^+$ ion (TPP$^+$). The intervening mechanisms (unknown) are acutely relevant to neonatal bilirubin encephalopathy. Equilibrium distribution values of ouabain-sensitive $^{86}Rb^+$ transport, and TPP$^+$ influx were monitored in rat cortical synaptosomes isolated by iso-osmotic Percoll-sucrose gradient centrifugation. Potassium (35 mM) or 4 μM human serum albumin (HSA) / 40 μM BR produced a rapid (1-2 min) efflux of both trapped cations. Steady-state pH gradients were estimated using the weak base methylamine in two media: (a) Krebs-Ringer, (b) Ca^{2+} and Na^+-free, 1 mM ouabain. Potassium released trapped methylamine in both conditions, but HSA/BR only showed this effect in synaptosomes incubated in Krebs-Ringer. Possible post-synaptic effects of BR were explored using purified *T.californica* nicotinic acetylcholine receptor (nAchR) reconstituted into Asolectin or dioleoylphosphatidylcholine-phosphatidic acid-cholesterol vesicles (60:20:20 molar ratio). BR (10-40 μM) did not modify: (1) the passive or the carbamylcholine (Carb)-stimulated (20-100 μM) $^{86}Rb^+$ influx, (2) the 5 - 10 μM Carb-induced first-order decrease in the Carb-stimulated $^{86}Rb^+$ transport, (3) the cation efflux from $^{86}Rb^+$-loaded *pure* Asolectin vesicles, (4) the equilibrium binding of ^{125}I-α-bungarotoxin, or, (5) the affinity shifts associated to nAChR desensitization. BR (50-100 μM) decreased the rate binding of toxin by 20% with respect to controls, and 10 μM pigment shortened (3-fold) the time course of receptor desensitization to 5 μM Carb. We conclude that BR truly depolarizes the synaptosomal plasma membrane, since intra-synaptosomal mitochondria have little or no Rb^+ permeability, and their membrane potential is independent of $[K^+]_{out}$. The pigment requires media containing Na^+, and Ca^{2+} to dissipate proton gradients, suggesting a BR–induced release of transmitter-filled vesicles (known to accumulate the base). Finally, BR displays little interaction with the nAChR. The observed effects on rate of toxin binding and receptor desensitization may be mediated through BR–vesicular lipid matrix interactions. *Supported by NIH Grant R01HD25241-01A2.*

MICROWAVE-INDUCED BRAIN HYPERTHERMIA ALTERS LOCAL CEREBRAL GLUCOSE UTILIZATION (LCGU). B.L. Cobb, G.A. Mickley and T.J. Nemeth, Armstrong Laboratory, Brooks AFB, TX 78235-5301

Alterations in LCGU in response to hyperthermia induced by fever or ambient temperature rise have been examined in some detail (Morimoto et al., Brain Res., 381, 1986, 100-106; McCulloch et al., J. Neurochem., 39, 1982, 255-258). Less is known about the patterns of LCGU produced by microwave radiations. In order to map these patterns, rat's basal brain temperature (Mean = 38.1$\pm$.1^{o}C) was raised 2^{o}C ($\pm$ <0.1^{o}C), in 9.4$\pm$1.97 minutes, through either head-only exposure to 5.6 GHz microwaves or hot-moist air (temperature control group). Hyperthermia was maintained for 45 minutes during which LCGU was assessed using the autoradiographic 2-Deoxyglucose method of Sokoloff et al. (J. Neurochem., 28, 1977, 897-916). Other rats were sham irradiated, and therefore experienced no brain temperature rise. Compared to normothermic controls, both microwaves and hot-moist air generally raised the LCGU of most brain areas sampled (e.g., somatosensory cortex and selected thalamic nuclei). However, microwave exposure produced rates of LCGU sometimes higher (e.g., in septal nuclei) or lower (e.g., in hypothalamic nuclei) than those recorded in hyperthermic controls. These data suggest that, while raising brain temperature generally enhances LCGU, distinct nuclei-specific alterations in metabolism may be observed during brain hyperthermia produced by 2 different sources. These phenomena may reflect either variable temperature gradients within the brain or unique cerebral functional alterations that vary with the source of thermal energy.

EFFECTS OF ^{60}Co IRRADIATION ON LOCOMOTOR ACTIVITY IN THE RAT. H.D. Davis, S.B. Kandasamy, V. Bogo and A.H. Harris. Armed Forces Radiobiology Research Institute, Behavioral Sciences Department, Bethesda, Maryland 20889-5145.

Male Sprague-Dawley albino rats were exposed to bilateral doses of 0 Gy (control), 0.5 Gy, 1.0 Gy and 3.0 Gy ^{60}Co radiation at 1.0 Gy/min. Irradiation occurred with 4 hours of light remaining in the animals' 12:12 hour light-dark cycle. Immediately after irradiation, rats were placed in automated monitors that measured locomotor activity (ambulation and vertical activity) for the next 24 h. The 0.5-Gy and 1.0-Gy irradiated rats showed about 75% of the cumulative ambulation of control rats throughout the experiment, while the 3.0-Gy group showed about 55% of cumulative ambulation of control rats. Deficits were significant during the periods of time when control rats showed enhanced activity: the first hour of exposure to the monitor (introduction to a novel environment) and the dark portion of the light-dark cycle (the normal period of high activity in the rat). Deficits in ambulation were not significant during periods when control rats showed low activity. Measurements of vertical activity showed a similar pattern of radiation-induced decrements. Future studies will examine the roles of neural and peripheral mechanisms in radiation-induced behavioral decrements.

577.15

HIGH ENERGY ELECTRON AND PROTON IRRADIATION OF RAT BRAIN INDUCES DEGENERATION DETECTABLE WITH THE CUPRIC-SILVER STAIN. R.C.Switzer III, V. Bogo*[1], and G.A. Mickley[1]. Dept. of Pathology Univ. of Tennessee Med. Ctr., Knoxville, TN 37920, [1]Armed Forces Radiobiol. Res. Inst., Bethesda, MD. 20889.

Different types of ionizing radiation can produce behavioral effects in laboratory animals but neuronal morphologic changes that correlate with these effects have not been detected using conventional histopathologic techniques. Since the silver-degeneration staining methods (eg Nauta, Fink-Heimer, and deOlmos' cupric-silver (CuAg)) impregnate disintegrated cell components that exist long after the cell has died, we used the CuAg method to detect degeneration induced by proton irradiation and levels of electron radiation that are known to influence behavior (Radiat. Res., 118: 341-352, 1989). Male rats (521g mn wt.) were irradiated with either 18.6 Mev electrons (N=20) or 155 Mev protons (N=16) at doses of 22-100 Gy @ 20 Gy / min (1Gy=100 rad). Six other rats, 319 g mn wt., were irradiated with 2-8 Gy of protons. All rats were sacrificed 4 days after exposure. CuAg stained sections from both electron and proton irradiated rats displayed diffuse and wide spread astrocyte-like degenerative profiles (DP) which were counted from 29 different cerebral areas for each brain to yield a total score that included the few neuronal profiles observed. A linear dose response was found for the low dose proton irradiated rats while the plot for the higher doses for both the electron & proton groups suggests a plateau effect with about the same DP scores. Control rats (6) averaged 1/5th of the median DPs found in those irradiated. It is concluded that: 1) the CuAg stain is able to reveal neuronal / glia degeneration due to these radiation levels; 2) degeneration vs dose is linear in the range of 2 - 8 Gy of protons.

BRAIN GLUTATHIONE S-TRANSFERASE (GST) ACTIVITY AND ISOENZYME PROFILES IN THE GUNN RAT. J.A. Johnson*, A. El Barbary*, S.E. Kornguth, J.F. Brugge and F.L. Siegel, Depts. of Pediatrics, Physiological Chemistry, Neurology and Neurophysiology, the Environmental Toxicology and Waisman Centers, University of Wisconsin, Madison, WI 53706.

GSTs are a multifunctional group of dimeric enzymes (α, μ or π-class) involved in the metabolic detoxication of electrophilic compounds and the intracellular binding and transport of hydrophobic molecules. GSTs were isolated from cerebrum, cerebellum and brainstem of Jj (non-jaundiced) and jj (jaundiced) Gunn rats, and the level of each subunit was determined by reverse-phase HPLC. Subunit 7 (π) was the major subunit in brainstem, whereas in the cerebrum, subunits 6 (μ) and 7 were expressed equally. The GST subunit pattern and GST activity in cerebrum and brainstem were the same in both Jj and jj rats. The primary subunits present in cerebellum were 3 (μ), 7, 6 and 11 (μ). In jj cerebellum, there was a 4-fold increase in subunits 2 (α) and 4 (μ) and a 2.5-fold increase in 8 (α) and 11 compared to Jj rats. There was a corresponding 1.5-fold increase in the total cytosolic GST activity in jj cerebellum. Immunohistochemical studies on cerebellum of normal and Jj animals showed that subunit 3 was present in Bergmann glia, but heterogeneously distributed among other astrocytes and Purkinje cells. Purkinje cells were strongly GST-positive in the flocculus and lateral hemispheres, but lightly-stained or GST-negative in the vermis. Thus, the increased GSTs in jj cerebellum could result from induction and/or toxicity-induced selection for GST-containing cells. These data imply that GSTs may be important in modulating the neurotoxicity of bilirubin. (Supported by NIH grants DC00398, NS24669, HD03352.)

ALTERATIONS IN PROTEIN SYNTHESIS BY ISOLATED ASTROCYTES EXPOSED TO LEAD. L. Shemancik*, D. Cory-Slechta and J.N. Finkelstein*, Env. Health Sci. Center and Strong Children's Res. Center Univ. of Rochester, Rochester NY. 14642

Prenatal and perinatal lead exposure has long been associated with significant behavioral impairments. The cellular and molecular mechanisms of these effects and the specific interactions between individual cell types in the CNS and added Pb have not been completely elucidated. The current study was undertaken to determine the nature of the response of isolated astroglial cells to exogenously added Pb. The effects of Pb and other metals were studied in 14-18 day primary astrocytes isolated from neonatal rat cerebral cortex. The cultures were >95% GFAP positive. These cells were then incubated with varying concentrations of lead acetate for up to 7 days. At varying times, cells were pulse labeled with ^{3}H-leucine and analyzed by SDS-PAGE followed by autoradiography. During the first 24 hours, cells exhibited protein synthesis patterns consistent with a classical stress response. After 12 hours, Pb exposed cells began to synthesize a unique protein species with an apparent molecular weight of 23-24 kDa. This protein persisted throughout the 7 day treatment period. The synthesis of this protein was dependent on the dose of Pb in the culture media and was not observed when cells were cultured with other metals including Zn, Cd, Mn, or Ca^{++} controls. Subcellular fractionation suggested that this protein was localized to the cytosolic fraction of cells. The relationship between this astroglial protein and those observed in whole brain or kidney from lead-exposed animals remains to be elucidated. (Supported in part by ES 07026, ES 01248, and HL 36543)

578.2

LACK OF EFFECT OF CHRONIC LEAD TREATMENT ON BIOAMINE METABOLITE CONCENTRATIONS IN RHESUS MONKEY CEREBROSPINAL FLUID (CSF). S. A. Ferguson*, G. W. Kraemer*, R. E. Bowman, M. H. Ebert*, and D. E. Schmidt. National Center for Toxicological Research, Division of Reproductive and Developmental Toxicology, Jefferson, AR; Harlow Primate Laboratory, University of Wisconsin, Madison; Vanderbilt University School of Medicine, Nashville, TN.

Concentrations of norepinephrine (NE), 3-methoxy-4-hydroxyphenylglycol (MHPG), 3,4 dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), and 5-hydroxy-indoleacetic acid (5-HIAA) were measured in the CSF of developing rhesus monkeys treated orally with moderate levels of lead acetate (n=4) or sodium acetate (n=4). Blood lead levels peaked at 62 μg/dl at 1.5 months of age and were maintained at 14 μg/dl from 20-56 months of age. Cisternal CSF samples were collected monthly from 5-41 months of age and every 1-3 months until 56 months of age. Bioamine metabolite concentrations were assayed by high-performance liquid chromatography. As is typical of rhesus monkeys, HVA and 5-HIAA concentrations decreased with age. NE and MHPG levels remained fairly stable across time. Concentration of DOPAC began to decrease at approximately 40 months of age. However, no measure interacted with lead treatment and overall concentrations for the five measures were not significantly different between control and lead-treated monkeys. As measured in cisternal CSF, bioamine metabolites were not altered by chronic low-level lead treatment.

578.3

Sensitive Measurements of Lead Toxicity in Cultured Astroglia by Interactive Laser Cytometry. M.E. Legare*, R. Barhoumi,* R.C. Burghardt* and E. Tiffany-Castiglioni. Department of Veterinary Anatomy and Public Health, Texas A&M University. College Station, TX 77843.

Low levels of lead (Pb) are proposed to damage cells at subcellular sites, including several calcium (Ca^{2+}) homeostatic pathways, mitochondria, and gap junctions. Sensitive measurements for damage at these sites were carried out with an ACAS 570 Interactive Laser Cytometer. Astroglial primary cultures were prepared from neonatal rat cerebral hemispheres. After 10-20 days in culture the cells were treated daily with medium containing 1 μM or less of Pb acetate and were subcultured before examination with the laser cytometer. Intracellular calcium ($[Ca^{2+}]_i$) levels were measured with an Indo-1 label. In preliminary experiments astroglia responded to ionomycin by a rapid 50% increase in $[Ca^{2+}]_i$ followed by partial recovery towards basal levels. Pb-treated astroglia showed a blunted Ca^{2+} spike in response to ionomycin. In a control experiment, cells were bathed with Ca^{2+}-free medium. Astroglia not treated with Pb had no response to ionomycin. By contrast, Pb-treated astroglia showed a marked Ca^{2+} spike followed by recovery. This finding indicates that Pb alters the handling and storage of $[Ca^{2+}]_i$. Other parameters measured included cell-cell communication via gap junctions, which was unaffected by Pb treatment, and mitochondrial permeability, which was reduced after one week of Pb treatment but not after three weeks.

578.4

SELECTIVE TOXICITY TO CENTRAL CATECHOLAMINERGIC NERVOUS SYSTEM IN POSTNATALLY LEAD EXPOSED RAT. J.H. Ryu*, J.H. Cheong*, J.H Jung*, U.T. Oh and K.H. Ko. Department of Pharmacology, College of Pharmacy, Seoul National University, Seoul 151, Korea.

Possibility whether postnatal lead ingestion can cause selective toxicity to central catecholaminergic nervous system in rats was tested. Three groups of Wistar rats; 1) Control, 2) Low dose and 3) High dose groups, were prepared. Right after parturition from dams rat pups received drinking water containing either 0% (control), 0.05% (low dose) or 0.2% (high dose) of lead acetate. At 2, 4, 6 and 8 weeks of age, tyrosine hydroxylase (TH) activity and Na-K ATPase activity were measured in 4 areas of rat brain; Telencephalon, Diencephalon, Midbrain and Pons-Medulla. TH activities were assayed by modified method of Reinhard *et al.* (1986) using ^{3}H-[3,5]-L-tyrosine as substrate. TH activity was determined as a criterion of lead poisoning to central catecholaminergic nervous system and ATPase activity as a criterion of nonspecific lead poisoning to any kinds of tissues. In lead exposed rats, TH activities were higher but Na-K ATPase activities were lower than those observed in age-matched control animals. Selective toxicity of lead poisoning to central catecholaminergic nervous system was evaluated by the changes of TH activities without concomitant changes of ATPase activities. Brain areas where selective toxicity of lead seems to be induced were pons-medulla (2 weeks of age) and telencephalon (6 weeks of age) in low dose group, and midbrain (4 and 6 weeks of age) in high dose group.

578.5

THE EFFECTS OF ALUMINUM INGESTION ON SPATIAL MEMORY IN THE RAT. T.L. Brown, P. Stewart*, J.P. Ryan. Department of Psychology, State University of New York at Plattsburgh, Plattsburgh, NY 12901

The study tested the hypothesis that spatial memory deficits in laboratory rats may be induced by oral administration of a daily solution comprised of aluminum chloride and sodium citrate. Aluminum (AL3+) is capable of bonding with citrate to form a neutral AL3+ citrate complex that may pass through internal membranes including the blood-brain barrier. Thirty-six Long-Evans hooded rats were divided randomly into one of three experimental conditions for sixteen weeks. The control group received a daily oral aqueous solution comprised of water and sodium citrate. The low and high groups received either 100 or 1,000 ppm aluminum chloride, dissolved in a sodium citrate solution. Each animal was rotated regularly into metabolic cages for a twenty-four hour period. The animals were then behaviorally tested in the Morris water maze to assess spatial memory impairments. Brain aluminum content (BAC) was analyzed by Electrothermal Atomic Absorption Spectrophotometry. Aluminum in the urine and feces was analyzed by Flame Atomic Absorption Spectrophotometry. There was a significant difference of BAC in neuronal tissue between the high group and control group, but no significant differences in spatial learning and memory between groups. Although aluminum can enter the brain in the presence of citrate there appears to be no significant correlation between BAC, other variables, and behavioral deficits. Long-term intake of aluminum-citrate and subsequent behavioral testing of the aged rat may clarify the role of AL3+ in AD.

EFFECTS OF ALUMINUM ON THE PHOSPHATASE ACTIVITY OF RAT SYNAPTOSOMAL $(Na^+ + K^+)$-ATPase. M.L. Caspers, P.S. Jacques* and M.J. Fu* Dept. of Chem. Univ. of Detroit Mercy, Detroit, MI 48221.

The presence of aluminum in the CNS has been linked to several neurological disorders, including Alzheimer's disease. $AlCl_3$ inhibits the release of ^{32}P from ATP catalyzed by the $(Na^+ + K^+)$-ATPase of cerebral cortical synaptosomes in a dose dependent manner. At 25 μM $AlCl_3$, the enzyme from adult rats is inhibited 14.5% and this increases to 46.8% at 100 μM $AlCl_3$. Sodium citrate (100 μM), added after pre-incubation with $AlCl_3$(100 μM), fails to reverse the inhibitory effect of $AlCl_3$, however it can prevent inhibition of $(Na^+ + K^+)$-ATPase when added simultaneously with $AlCl_3$. Lineweaver Burk analysis of enzyme activity with varying concentrations of ATP indicates a reduction in the V_{max} but not the K_M of the $(Na^+ + K^+)$-ATPase in the presence of $AlCl_3$, suggestive of noncompetitive inhibition. A comparison of the enzyme in synaptosomes prepared from young or aged rats shows that the V_{max} is significantly elevated in aged rats. The susceptibility of the $(Na^+ + K^+)$-ATPase to 100 μM $AlCl_3$ is greater (72% inhibition) in the aged group. Disruption of the $(Na^+ + K^+)$-ATPase in neurons may underlie, at least in part, the neurotoxicity associated with an elevated aluminum content in the CNS. ALUMINUM-INDUCED NEURODEGENERATION IN THE RABBIT RETINA. K.R. Fry, A.L. Chapman, K.A. Shaw and C.B. Watt. Alice R. McPherson Laboratory of Retina Research, Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX 77381.

Study of the effects on the nervous system of long-term exposure to aluminum has been hampered by the unavailability of an appropriate animal model. Recent studies in this laboratory (Fry et al, Neurosci. Lett. 124:216-220, 1991) have examined aluminum-induced neurofibrillary changes in rabbit retinal ganglion cells as a potential long-term model system for aluminum neurotoxicity. The current study examines the dose-response and temporal relationships of the disorder. Adult New Zealand White rabbits were injected intravitreally with concentrations of $AlCl_3$ ranging from 0.05% to 2.0% and allowed to survive for periods ranging from 1-3 months. The retinas were then prepared for light level immunocytochemistry using either a ganglion cell-specific or a neurofilament-specific antibody. The results of the study indicated that the extent of neurofibrillary change is directly related to both the dosage of aluminum and the time post-injection. At low aluminum dosages (<1%), the vast majority of ganglion cells undergoing neurofibrillary degeneration were located in the retinal periphery suggesting a specific susceptibility of ganglion cells in these regions to aluminum. At higher aluminum dosages (1% and above), the distribution of ganglion cells undergoing neurofibrillary degeneration more closely followed the normal total ganglion cell distribution, suggesting a more generalized toxicity. Examination of total ganglion cell populations indicated that there is a loss of ganglion cells which also appears to be directly related to the dosage of aluminum as well as the time post-injection. Interestingly, the loss of ganglion cells occurs primarily in the central retina, suggesting that some mechanism other than the neurofibrillary disorder may be responsible for ganglion cell death. NEUROBEHAVIORAL EFFECTS OF SUBCHRONIC DIETARY ALUMINUM IN MICE. M. S. Golub, C.L. Keen*, M.E. Gershwin*. Dept Internal Medicine, Univ. California, Davis Sch. Med. Davis, CA 95616.

Female Swiss Webster mice (n=12/grp) were fed purified diets containing 25 (control) or 1000 µg Al/g diet (Al as Al lactate). Weight, food intake and gross neurotoxic signs were monitored regularly. At 45 and 90 days a modification of the NTP neurotoxicity screening battery was administered and spontaneous motor activity was determined using automated method for 1 24-hr period. At necropsy, brain and liver Al and trace metals (Fe, Mn, Cu, Zn) concentrations were determined by AAS and lipid peroxidizability was measured by generation of thiobarbituric acid reactive substances (TBARS) in vitro. Al was associated with a slight acceleration of weight gain during the second half of the 90-day period; no effect on food intake and no mortality or morbidity were observed. Relative to controls, mice fed 1000µg Al/g diet had lowered locomotor activity (p=.015), hindlimb grip strength (p=.012) and air puff startle responsiveness (p=.024) at the 90 day time point. Temperature sensitivity (tail flick test), negative geotoaxis, forelimb grip strength and footsplay were not affected. Al was increased 3-fold in both brain and liver (p<.001) but not in femur. Essential trace elements were not altered and there was no effect on TBARS measures. These results demonstrate a specific pattern of neurobehavioral deficit caused by subchronic dietary exposure to Al lactate and suggest the value of further testing using more sensitive endpoints and/or longer exposure periods and higher doses. (Supported by ES04190).

EFFECT OF $ZnCl_2$ ON ^{54}Mn-UPTAKE BY SYNAPTOSOMES OF MOUSE BRAIN. J. Estévez*, R. Katiyar*, E. Bonilla, H. Martínez. Instituto de Investigaciones Clínicas. Universidad del Zulia. Apartado 1151. Maracaibo, Venezuela.

The accumulation of Mn in brain decreases when given together with zinc in mice (Khandelwal S. et al. Bull Environ Contam Toxicol 32:10,19-84). We studied the in vitro effect of Zn^{+2} on ^{54}Mn uptake by synaptosomes. Male albino mice were killed by cervical dislocation and their brains removed immediately. Striatum (ST), olfactory bulb (OB) and hypothalamus (HT) were dissected out. Synaptosomes were obtained by the technique of Hajos F.(Brain Res 93:485,1975). Isolated synaptosomes were suspended in 0.3M sucrose and assays were performed in two different ways as follows: a) 200ul of the synaptosomal preparation were added at 37ºC for 15 min to a solution containing 0.05 M tris-buffer, pH 7.4, 0.02 uCi of $^{54}MnCl_2$ and increasing concentrations of $ZnCl_2$ (10^{-1} to 10^{-4}M). The final volume of the incubation mixture was 0.5 ml. b) On other assays $ZnCl_2$ was added after a 15-min preincubation of the above mixture. Incubations were ended by suction through a Skatron cell harvester. The radioactivity contained in the filters were counted in a gamma counter. With a concentration of 10^{-4}M $ZnCl_2$ the ^{54}Mn uptake was completely inhibited in OB. For ST and HT a concentrations of 10^{-3}M was needed to obtain a similar inhibition. On the contrary, after preincubating the synaptosomes with ^{54}Mn the maximun concentration of Zn^{+2} used (10^{-1}M) displaced only 49.5±3.9%, 33.7±4.7% and 31.7±3.7% of the ^{54}Mn taken up by OB, ST and HT, respectively. The inhibitory effect of Zn^{+2} on Mn uptake by synaptosomes seems to be due to a higher binding affinity for Zn^{+2} than Mn. The results obtained after preincubation seem to indicate that ^{54}Mn is apparently bound in an insoluble or high affinity state to intra synaptosomal structures(i.e.synaptic vesicles) and/or molecules(i.e.ATP).

578.10

MANGANESE TOXICITY: MUSCARINIC RECEPTOR BINDING IN THE MOUSE BRAIN. E. Bonilla, V. Villalobos*, F. Castro*, J. Estévez*, J.O. Dávila*. Instituto de Investigaciones Clínicas, Universidad del Zulia and Inbiomed-Fundacite, Apartado 1151, Maracaibo, Venezuela.

Cholinergic neurons seem to be resistant to the toxic effect of manganese, since the activity of choline-acetyltransferase was not affected in any of 7 brain regions studied in rats after eight months of treatment with manganese. We now report the effect of chronic administration of manganese on the binding parameters of ^3H-quinuclidinyl benzilate (^3H-QNB) in different brain regions of mice. Experiments were carried out on male albino mice divided into two groups. Mice in one group were injected i.p. with manganese chloride (5mg Mn/kg/day) five days per week during nine weeks. The control group was treated similarly with saline. Mice were killed by cervical dislocation two days after the end of the intoxication. Brains were extracted immediately and the following regions dissected out: striatum, hippocampus and frontal cortex.

The binding of ^3H-QNB to homogenates of mouse brain was performed according to the method of Yamamura and Snyder (Proc. Nat. Acad. Sci USA 71:1725, 1974). The Bmax values (means ± S.E.M.) of ^3H-QNB in the three brain regions of controls and Mn-treated mice were as follows: a) striatum: 344.2 ± 45.2 and 371.0 ± 90.8 fmol/mg protein; b) frontal cortex: 194.5 ± 21.1 and 232.0 ± 13.3; c) hippocampus: 219.1 ± 23.6 and 239.0 ± 30.8. The Kd's found were: a) striatum: 1.46 ± 0.3 and 1.32 ± 0.45 nM; b) frontal cortex: 0.80 ± 0.20 and 0.71 ± 0.15; c) hippocampus: 0.86 ± 0.10 and 0.93 ± 0.17.

The results of the present study clearly show that chronic manganese administration does not alter the binding constants of ^3H-QNB to the muscarinic cholinergic receptors in mouse brain.

578.11

AN IMMUNOCYTOCHEMICAL STUDY OF THE EFFECTS OF TRIMETHYLTIN ON PEPTIDERGIC NEURONS WITHIN THE HIPPOCAMPUS. L. L. Addington*, K. LeVee*, R. H. Baisden and M. L. Woodruff. J. H. Quillen Col. of Med. East Tenn. St. U., Johnson City, TN 37614.

It is well established that trimethyltin (TMT) causes loss of projection neurons in the CA3c and CA1 subfields of Ammons horn and the temporal part of the dentate gyrus. The effects of TMT on hippocampal neurons containing specific neuropeptides has been less well documented. Immunocytochemistry visualized vasoactive intestinal polypeptide (VIP), somatostatin (SS), and cholecystokinin (CCK) in the hippocampus of male Long-Evans rats exposed to 6 mg/kg TMT. When compared to controls cell counts revealed a significant loss of neurons showing VIP- and SS-like immunoreactivity in rats exposed to TMT. CCK appeared to be less affected by the toxin. These effects resemble those produced by cerebral ischemia (Johansen et al., Acta Neuropathol. 73:110-114, 1987) and may be interpreted to indicate that loss of SS neurons, which presumably excite inhibitory GABAergic neurons, may contribute to loss of CA1 pyramids after TMT. (Supported by NIH Grant ES 04070-05 to MLW)

578.12

TRIMETHYLTIN (TMT) AND GLUTAMINE-EVOKED RELEASE OF GLUTAMATE FROM HIPPOCAMPAL AND CAUDATE SLICES OF RAT BRAIN. A.C. Scallet, G.W. Lipe*, J.C. Matthews[1] and J.F. Bowyer. National Center for Toxicological Research, Jefferson, AR 72079 and [1]University of Mississippi, University, MS 38677

We have previously reported that although the hippocampal neurotoxin trimethyltin (TMT) produced comparable increases of hippocampal glutamine in both 7 and 17 month old rats, it produced passive avoidance deficits, hippocampal neuronal necrosis and gliosis only at 17 months. Glutamate levels measured in whole hippocampal extracts were reduced in the older rats, while their glutamate receptors (KA sub-type) were increased. Although TMT had little effect on total glutamate content "in vivo", there might be a selective effect on extracellular release. Therefore, we superfused glutamine and TMT through hippocampal and caudate slices and measured glutamate in the effluent. Glutamine (up to 1mM) produced a dose-related increase in glutamate release of at least 15-fold, while addition of TMT (up to 13 uM) only slightly increased this release. Since potassium increased the glutamine effect, but in a non-concentration-related fashion, we are at present uncertain of the exact mechanism of the glutamine effect. However, our results are consistent with the possibility of an indirect action of TMT to produce neurotoxicity secondary to glutamine-evoked release of glutamate.

578.13

BISMUTH DISTRIBUTION IN MOUSE CNS AFTER INTRAPERITONEAL DOSING. M.R. Poston, J.F. Ross and G.T. Lawhorn*. Miami Valley Laboratories, Procter & Gamble Co., Box 398707, Cincinnati, OH 45239-8707.

Routes of entry and distribution of metals into the CNS have toxicologic significance. To determine the distribution of bismuth (Bi), adult female Swiss-Webster mice were injected ip once with dH2O (n=10) or 2500 mg/kg Bi subnitrate (n=22) as a 10% suspension in dH2O to establish a Bi depot. Four weeks later, mice were anesthetized and perfused with aldehyde fixatives; brain and spinal cord were processed for frozen and paraffin sectioning. Bi was coated with silver using autometallography and visualized as silver grains. Sections were counterstained with toluidine blue.

Control sections had negligible Bi. In dosed mice, somata of brainstem upper motor neurons (in red, lateral vestibular, gigantocellular reticular and lateral reticular nuclei) had dense intracytoplasmic granulation. Similar, but less dense granulation was observed in somata of cranial and spinal motor nerves and large projection neurons (mitral and purkinje cells). Small cells in primary projection zones of spinal and cranial sensory nerves had lighter, intracellular accumulations. Gray matter adjacent to circumventricular organs had multifocal aggregates not clearly associated with neuronal somata. White matter had few grains except for fornix and corpus callosum near the subfornical organ. Choroid plexus epithelium had diffuse grains throughout, while meninges had both diffuse grains and aggregates. There were several gradients of Bi, including a ventral (higher)/ dorsal (lower) gradient in olfactory bulb, and a ventral/dorsal gradient in cerebellum. These patterns suggest mechanisms for entry and distribution of Bi into CNS that may apply to other metals.

578.14

REGIONAL BISMUTH LEVELS AFTER PARENTERAL DOSING IN MICE AND FERRETS. J. F. Ross and G. T. Lawhorn*. Miami Valley Laboratories, Procter & Gamble Co., Box 398707, Cincinnati, OH 45239-8707.

Bismuth (Bi) neurotoxicity (encephalopathy) occurs rarely during long term oral treatment with Bi-containing medications. Signs of neurotoxicity (hyperreactivity, myoclonus, ataxia, tremors, convulsions) like those in humans are produced by ip injection(s) of Bi subnitrate (BSN) into mice (Ross et al., NeuroToxicology 9(4):581-6, 1988). Here we measured regional brain Bi levels of animals under different subchronic exposure conditions.

BSN or the sodium salt of Bi subgallate (NaBSG) or dH2O (n=4-6) was injected ip into female mice (BSN, NaBSG) or ferrets. Parts of CNS and PNS were dissected and Bi level measured by atomic absorption spectrometry/hydride generation after wet ashing with acid. BSN (2500 mg/kg) was dosed once and regions analyzed 28 days later (mice; n=9) or dosed (100-200 mg/kg) up to four times during eight weeks (ferrets; n=11). NaBSG was dosed (20 mg/kg/day) to mice (n=10) five days/week for 13 weeks. Regional Bi levels were indexed to the hypothalamic Bi level and compared by analysis of variance followed by Student's t-test or a rank sum test adjusted for multiple comparisons.

Bi distribution was independent of type of Bi dosed, the dosing regimen or the species tested. In the CNS, levels were highest in meninges (15 ppm). Relatively high levels of Bi were also found in lumbosacral spinal cord (10 ppm), hypothalamus (6-9 ppm), olfactory bulb (4-7 ppm) and brainstem (2-3 ppm). Significantly lower levels were found in cerebellum, striatum and cerebral cortex (all ~1-2 ppm). The data complement autometallographic studies (see M. R. Poston et al., this meeting) and indicate that Bi is inhomogeneously distributed in the nervous system, and concentrates in sites consistent with the signs of neurotoxicity.

578.15

ORGANIC AND INORGANIC MERCURY ALTER SYNAPTOSOMAL CALCIUM CONCENTRATIONS. M.F.Hare, M.F.Denny*, W.D.Atchison. Dept. Pharm./Tox. & Neurosc. Prgm., Mich. State Univ., E. Lansing, MI 48824.

Methyl mercury (MeHg) increases the release of neurotransmitters and intracellular calcium ($[Ca^{2+}]_i$) in mammalian nerve terminals. The Ca^{2+} pool(s) responsible for the elevated $[Ca^{2+}]_i$ and transmitter release are unknown. Less is known about the effects of inorganic mercury (Hg^{2+}) on nerve terminal $[Ca^{2+}]_i$ and transmitter release. Ruthenium red (RR), a polysaccharide dye, decreases MeHg-induced acetylcholine release from synaptosomes and $^{45}Ca^{2+}$ efflux from isolated rat brain mitochondria. We therefore examined the ability of RR to prevent elevations in synaptosomal $[Ca^{2+}]_i$ by MeHg and Hg^{2+}. In fura-2 loaded synaptosomes, MeHg and Hg^{2+} (10 μM each) increased $[Ca^{2+}]_i$ by 55 and 121 nM respectively in media containing 200 μM Ca^{2+}. Neither effect was altered by pretreatment with 20 μM RR. This concentration of RR had no effect on $[Ca^{2+}]_i$. Alterations in $[Ca^{2+}]_i$ and transmitter release by MeHg and Hg^{2+} may be mediated by an increase in the permeability of the plasma membrane to Ca^{2+}. To test this possibility we took advantage of the effect of Mn^{2+} on fura-2 fluorescence. Mn^{2+} decreases fura-2 fluorescence upon binding. Since synaptosomes contain no Mn^{2+}, decreases in the intrasynaptosomal fluorescence signal must result from divalent cation influx. Addition of 1 mM Mn^{2+} decreased the fluorescence signal at the 340 nm excitation wavelength by 70.9% after 4 min. This decrease was not altered by pretreatment of the synaptosomes for 6 min with either 10 or 25 μM MeHg. Pretreatment with 10 μM Hg^{2+} prior to Mn^{2+} addition decreased the 340 excitation signal by 79.9%. These preliminary data suggest that increases in $[Ca^{2+}]_i$ by MeHg may result from an action on intracellular, RR insensitive Ca^{2+} pool(s), whereas Hg^{2+} may increase $[Ca^{2+}]_i$ by actions on both the plasma membrane and intraterminal Ca^{2+} pools. Supported by NIEHS grant ES03299.

ALUMINUM TREATMENT IMPAIRS THE ABILITY OF ASTROGLIA TO PROTECT MOTONEURONS AND CORTICAL NEURONS FROM GLUTAMATE EXCITOTOXICITY. J.B. Sass* and B.H.J. Juurlink. Dept. of Anatomy, University of Saskatchewan, Saskatoon, Canada, S7N 0W0.

Aluminum has been implicated as a neurotoxin in a number of neurological disorders, including Amyotrophic Lateral Sclerosis, Alzheimer's disease, and senile dementia. Glutamate may, under pathological conditions, act as an excitotoxin. In experiments designed to examine synergistic interactions between aluminum (Al) and glutamate we demonstrated that Al-treatment of astrocytes impaired their ability to protect neurons from glutamate excitotoxicity. Astroglial cells were isolated from newborn CD1 mice and cultured on coverslips for 2 weeks. Motoneurons were isolated from E15 CD1 mouse embryos and cultured on coverslips for six days. Astroglial and neuronal cultures were then treated with aluminum citrate at a final concentration of 100 µM for 3 days. Control or Al-treated astrocytes were co-cultured with the control or Al-treated motoneurons; these co-cultures were treated with glutamate at a final concentration of 50 µM. Cell viability was determined 24h later using the fluorescein diacetate-propidium iodide fluorescent technique (Jones and Senft. 1985. J Histochem Cytochem, 33:77). Glutamate did not affect the viability of control or Al-treated neurons when co-cultured with control astrocytes; however, glutamate caused death of all neurons (both control and Al-treated) when neurons were co-cultured with Al-treated astrocytes. These experiments have been repeated using cortical neuron cultures with similar results. Our observations demonstrate that sublethal levels of aluminum will severely impair the ability of astroglial cells to protect neurons from glutamate excitotoxicity, rendering normally subtoxic levels of glutamate lethal to neurons. This suggests that impaired astroglial function may play a causal role in diseases involving neuronal degeneration. We are currently comparing glutamate uptake in control and Al-treated astrocytes.

AN *IN VITRO* ASSAY OF IRON INDUCED NEURONAL MEMBRANE DAMAGE: PROTECTION BY ANTIOXIDANT LAZAROIDS. H.M.Scherch*, P.F.Vonvoigtlander, and E.D.Means. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

Membrane damage related to lipid peroxidation has been implicated in the pathophysiology of a variety of diseases. The Upjohn Company has developed a series of compounds, known as the lazaroids, aimed at preventing the propagation of the lipid peroxide chain reaction. Several of these compounds have been tested in an *in vitro* model of Fe^{++} induced lipid peroxidation.

Fetal mouse spinal cord neuronal cultures were treated with various lazaroids at concentrations ranging from 0.3 to 100 µM. The cultures were then exposed to 200 µM ferrous ammonium sulfate for 30 min to induce lipid peroxidation. Membrane damage and cell viability were determined by ^{3}H-α aminoisobutyric acid uptake. Of the 21-aminosteroids, U-74006F showed significant improvement above control, and U-74500A was highly efficacious with an 86.5% increase in viability above control at 10 µM. The 2-methylamine chroman, U-78517F, was the most potent of the compounds tested. It displayed a maximum increase of 98% above control at 1 µM, and was used as an internal standard for all compounds tested.

This assay provides a neuronal culture method of detecting compounds that protect against Fe^{++} induced lipid peroxidation and subsequent membrane dysfunction and death.

SCAVENGER ENZYMES IN SUPEROXIDE DISMUTASE TRANSGENIC MICE. **S. Przedborski, V. Jackson-Lewis, V. Kostic, E. Carlson, C. J. Epstein & J.L. Cadet. Columbia University, Dept. of Neurology, New York, N.Y. 10032**

Oxygen-based free radicals have been implicated in the pathogenesis of several neurological disorders. Transgenic (Tg) mice with increasedCu/Zn-superoxide dismutase (SOD) activity, one of the key enzymes of the cellular scavenging system, is an animal model of critical importance to test the effects of free radicals in vivo. In the present study, we measured Mn-SOD, catalase and glutathione peroxidase (G-Px) activities in cytosolic and particulate fractions in various brain regions of SOD-Tg and their non-Tg littermates. Cytosolic fractions exhibited a 3-fold increase in Cu/Zn-SOD activity and a 2-fold increase in catalase activity in Tg compared to non-Tg littermates; the activities of both enzymes correlate significantly ($r=.71$, $df=29$, $p=0.0001$). In contrast, there was no change in G-Px in SOD-Tg mice compared to non-Tg animals. Particulate fractions showed a 4-fold increase in Cu/Zn-SOD activity which correlated significantly ($r=.80$, $df=29$, $p=0.0001$), with a 1.8-fold increase in Mn-SOD activity in Tg compared to non-Tg mice. In contrast, the two groups of mice showed no significant differences in catalase and G-Px activities. These findings indicate that increases in brain Cu/Zn-SOD activity in Tg mice are associated with significant increases in other scavenger enzymes. These results provide more information on the free radical scavenging capacity of the SOD-Tg mice and indicate that SOD-Tg mice may be able to buffer any excess H_2O_2 produced in response to enhanced dismutation of superoxide radicals in these animals.

CEREBELLAR GRANULAR CELL MODELS FOR TESTING OF PROTECTION AGAINST NEUROTOXICITY. G.J.Fici*, J.S. Althaus, and P.F.VonVoigtlander. The Upjohn Company, Kalamazoo, MI 49001

A novel *in vitro* method for testing various lipid peroxidation inhibitors' (lazaroids) ability to protect cerebellar granular cells has been developed. These neurons possess excitotoxin receptors and have been used in studies involving excititory amino acids. We have postulated that they would be susceptible to injury induced by buthionine sulfoximine (BSO), an inhibitor of γ-glutamylcystein synthetase, and ferrous ammonium sulfate (FAS), an initiator of lipid peroxidation. This study reveals BSO (10-1000μM) after 24 hrs produces a dose-dependent reduction of glutathione (GSH) in the intact cells, as determined by HPLC with electrochemical detection, along with a reduction of cell viability as measured by amino-isobutyric acid (AIB) uptake. Data will also be presented which shows the importance of glutathione in FAS toxicity. In addition, our results show that pretreatment with lazaroids can block these toxic insults. It is hoped that the described toxicity models will reveal mechanisms of lazaroid-mediated neuronal protection.

578.20

LIPID HYDROPEROXIDES IN CEREBRUM AND CEREBELLUM OF RAT BRAINS. Eli Kaplan. Research Service, VA Medical Center Minneapolis, MN 55417.

As a prelude to studies on the metabolism of arachidonic acid in the brains leading to the formation of lipid hydroperoxides, studies were done to determine if rapidly frozen tissues could be used as a control. Male, S/D rats, 150-200g, were fasted overnight prior to perfusion with 5% heparin in K-R bicarbonate buffer, pH 7.6. Cerebrum and cerebellum were quickly excised, dropped into liquid N_2 and kept at -70°C for 5 days. In the 2nd set of experiments the brain tissues were quickly excised, homogenized in same buffer and lipids extracted using Bligh-Dyers method. The frozen tissue was homogenized and lipids extracted in a similar manner. The lipid classes were separated by SPE, and individual lipid hydroperoxides identified and quantitated by reverse phase HPLC column chromatography using acetonitrile:0.02 M PO_4 buffer as mobile phase. The eluant was monitored at 235 and 215 nm. 15-, 12-, 9-, and 5- hydroperoxy-eicosatetraenoic acid (HPETE) were observed in both sets of experiments. The quantity of all the HPETEs in the frozen group was 3 times greater than in the freshly homogenized cerebrum and cerebellum. 12- and 9-HPETEs were found in the largest quantity in both groups. The quantity of HPETEs in the cerebellum appeared to be greater than the cerebrum. It is apparent that tissues, frozen in liquid N_2, produce large quantitites of HPETEs, and can not be used as a control.

578.21

REACTIVE OXYGEN SPECIES DETECTED BY MICRODIALYSIS IN BRAIN EXTRACELLULAR FLUID INCREASE DURING SEIZURES. M.E. Layton*, T.L. Pazdernik, S.R. Nelson and F.E. Samson. Dept. of Pharm., Tox. and Therap. and R.L. Smith Res. Ctr., Kansas Univ. Med. Ctr., Kansas City, KS 66103.

Reactive oxygen species (ROS) such as hydroperoxides (ROOH) may form free radicals responsible for excitotoxic neuropathology. Free radicals damage critical components of membranes, DNA and proteins when normal cellular defenses are overwhelmed. Intracerebral microdialysis sampling permits the analysis of biochemical constituents in the brain cell microenvironment in awake animals. To determine if hydroperoxides are present in brain extracellular fluid, we analyzed the microdialysis perfusates from the piriform cortex of rats (N=6) prior to and after a systemic injection of kainic acid (16 mg/kg; i.p.). Perfusates were collected during control and seizure phases and analyzed in a hydroperoxide-dependent chemiluminescence assay. Hydroperoxides were detected under control conditions and increased substantially during the seizure episode. Pretreatment of perfusate samples with catalase (20 U/ml) reduced chemiluminescence to blank levels, indicating that hydrogen peroxide (HOOH) was the major hydroperoxide detected in brain extracellular fluid during seizures. These results suggest that the conspicuous brain damage in the piriform cortex following kainic acid-induced seizures may be mediated by free radicals. Supported in part by U.S. Army DAMD 17-90-C-0041 and ESO7079.

NEUROTOXICITY: ENVIRONMENTAL

579.1

EFFECT OF HYDROGEN SULFIDE ON MEMBRANE AND SYNAPTIC CONDUCTANCES IN DORSAL RAPHE *IN VITRO*. Samuel B. Kombian, R.J. Reiffenstein and W.F. Colmers. Dept of Pharmacology, Univ. of Alberta, Edmonton, AB, Canada T6G 2H7.

Hydrogen sulfide (HS^-) is suspected to cause asphyxiation and death by an action on respiratory neurons in the brainstem. Dorsal raphe (DR) nucleus neurons share many properties with these respiratory neurons. We studied the effects of HS^- on DR cells in transverse slices of brainstem *in vitro*.

Intracellular voltage and current clamp recordings were made with 2M KCl-filled microelectrodes. Focal (bipolar) stimulation of the nucleus evoked synaptic responses: fast, excitatory amino acid (EAA) and $GABA_A$ currents were followed by an IPSC (5-HT_{1A}), then by a slower EPSC (α_1 adrenoceptor). HS^- produced a dose-dependent inhibition of both IPSC (ED_{50}≈105 μM) and EPSC (ED_{50}≈50 μM). 200 μM HS^- inhibited the IPSC by 88.5±6.8% (n=4), while completely abolishing the EPSC. Four different responses to HS^- were observed: 1) an outward current or hyperpolarization caused by an increase in membrane conductance over the voltage range -115 to -40 mV (E_{Rev}=85.5±3.8 mV, n=4), partially blocked by 100 μM Ba^{++} (n=1) and completely blocked by Ba^{++} plus 2 mM Cs^+ (n=3); 2) a voltage-independent inward current (n=6) which was sensitive to strophanthidin (3-10 μM, n=6) [Cs^+ and Ba^{++} unmasked this in cells having an outward current]; 3) a biphasic response (n=8), first an inward current (sensitive to strophanthidin, n=1) then an outward current (sensitive to Ba^{++}+Cs^+, n=1); 4) no response (n=4). After washing out HS^-, a voltage-independent, strophanthidin-sensitive outward current appeared briefly.

These results indicate that in DR, HS^-: 1) activates a potassium conductance in some cells, 2) inhibits the Na^+-K^+ ATPase in most cells, 3) removal of HS^- allows the pump to reactivate, and 4) inhibits synaptic transmission. Hydrogen sulfide's effects on respiration may be caused by any or all of these actions.

EFFECTS OF VARIOUS PCB DOSES ON THYROID STATUS AND CHOLINE ACETYLTRANSFERASE (ChAT) ACTIVITY IN 15 DAY OLD RATS. M. Sharma, L.M. Juarez de Ku, M.A. Baratian, R.B. Amiri and L.M. Meserve. Dept. Biol. Sci., BGSU, Bowling Green, OH 43403-0212.

Polychlorinated biphenyl (PCB) is a common pollutant, the ingestion of which is harmful to a number of physiological systems in adult animals. Previous studies in our lab have found addition of 250ppm (PCB (Arocohlor 1254), to the maternal diet during pregnancy and lactation to depress both thyroid status and choline acetyltransferase (ChAT) activity in the hippocampus and basal forebrain of 15 day old rats. The present study was done to determine whether the maternal ingestion of lesser amounts of PCB (125, 62.5ppm) results in a proportionally lesser depression of thyroid status and ChAT activity. Thyroid status was determined by measuring circulating T_4 and T_3 levels with RIA. ChAT activity was estimated quantitatively by the ability of a homogenate to incorporate ^{14}C-labelled acetyl-CoA into acetylcholine and qualitatively by immunohistochemistry. All PCB doses significantly depressed thyroxine (T_4) levels but had insignificant effects on triiodothyronine (T_3). Quantitation of ChAT activity revealed a linear dose response with less ChAT activity in the hippocampus and basal forebrain as the PCB doses increased. Fewer neuronal processes of PCB fed animals stained positively for ChAT than in controls. Thus, there seems to be a significant physiological influence of maternal PCB ingestion at doses lower than 250ppm (125, 62.5ppm).

579.3

USE OF NEUROTOXICITY DATA TO SET REGULATORY STANDARDS FOR ENVIRONMENTAL TOXICANTS Eve Andersen, Clement Intl. Fairfax VA.

Animal and human experimental data have been used by government agencies such as the Environmental Protection Agency (EPA) to determine safety limits for human exposure to chemicals in the everyday environment.

The methodology for deriving these limits is well established. The literature is reviewed to determine the study which shows the effects at the lowest dose level. The effects can be behavioral, developmental, structural, or biochemical. When available, human experimental data are preferred, otherwise animal data are used. Ideally an acceptable study will reveal no observable adverse effects at one dose level (NOAEL), and lowest observable adverse effects (LOAEL) at a slightly higher dose level. When necessary, the experimental doses are converted to account for chronic daily exposure. Uncertainty factors, when appropriate, are applied to account for interspecies differences between animals and humans, sensitive human subpopulations, and other factors.

This methodology has been used to set environmental standards for metals (chromium, manganese, mercury), solvents (bromomethane, hexane, toluene, xylene), pesticides (cresol, diazinon, endrin, parathion) and other substances. The methodology can only be used when experimental data exist that show a positive dose-response effect with a lower limit, so some neurotoxicants, such as lead, are not regulated with this system. The methodology can also be used to set standards for chemicals which are not neurotoxic.

Regulatory limits are mandated by the Toxic Substances Control Act, Resource Conservation and Recovery Act, Safe Drinking Water Act, Clean Air Act etc. Other agencies such as the National Institute for Occupational Safety and Health, the Occupational Safety and Health Administration, and the American Conference of Governmental Industrial Hygienists also set standards and regulations for occupational settings using less rigorous methodologies.

579.4

THE NEUROTOXICITY OF CHEMICALS FROM ACUTE EXPOSURES. R. M. Mastrangelo* and C. Rabe. Clement Int., Fairfax, VA 22031.

A review was conducted to determine what neurotoxic effects occur from short-term exposures to chemicals and to evaluate the use of short-term exposure neurotoxicity data as criteria for adding chemicals to or deleting chemicals from the Section 302 SARA Title III Extremely Hazardous Substance (EHS) list.

Effective doses for chemicals including organophosphates and pesticides were compared to their Level of Concern (LOC) and/or acute exposure limit (AEL) values. LOCs, which have been derived specifically for chemicals on the EHS list, and AELs are levels at which acutely exposed individuals should not experience adverse effects. Acute exposure effective doses were compared to these values only for chemicals with neurotoxic effects that impair a person's ability to escape in an emergency, inflict injuries that impair escape, or that are serious and irreversible. Based upon these comparisons, it was found that humans exposed to either hydrogen sulfide, lindane, or endrin, at their current LOC values, are not protected against such neurotoxic effects. The pesticides diazinon, dieldrin, Nexion™, methamidophos, and tri-o-cresyl phosphate also exhibit these effects, but are not on the EHS list. Finally, bromotrifluoromethane, carbon dioxide, fluorocarbon 12, heptane, hexane, isophorone, perchloroethylene, and petroleum distillates each have AELs that are protective against these neurotoxic effects but those for carbon monoxide, toluene and trichloroethylene are not protective. None of these chemicals with AELs are on the EHS list.

The results show that the EHS list can be revised using acute exposure neurotoxicity data and that this endpoint is more sensitive than acute lethality, which is the current toxicity criterion used to include chemicals on the list and to derive their LOC values.

579.5

IN VITRO TOXICITY OF N-BUTYL BENZENESULFONAMIDE: A NEWLY DISCOVERED NEUROTOXIN. V.R. Nerurkar*, I. Wakayama*, T. Rowe*, R. Yanagihara* and R.M. Garruto. Laboratory of Central Nervous System Studies, NINDS, NIH, Bethesda, MD 20892.

N-Butyl benzenesulfonamide (NBBS), a plasticizing agent used in the production of plastic resins and in the synthesis of an agricultural herbicide, produces a dose-dependent, progressive spastic myelopathy characterized by neuroaxonal degeneration in New Zealand white rabbits (Strong M.J. et al., Lancet, 330:640, 1990; Strong M.J. et al., Acta Neuropathol, 81:235, 1991). Using conventional assays for cell viability (trypan blue dye exclusion, LDH, MTT) and cell growth and function (^{3}H-thymidine incorporation, immunostaining), we studied the effects of NBBS on C6 glioma and Neuro-2a, two continuous cell lines of glial and neuronal origin, respectively. Micromolar (μM) concentrations of NBBS inhibited cell growth and produced morphological changes and altered cell function in these cell lines. A lower concentration of NBBS was required to inhibit DNA synthesis in Neuro-2a cells (10 μM) than in C6 cells (100 μM), suggesting that neuronal cells are more sensitive than glial cells to NBBS toxicity. Thymidine incorporation by subconfluent, actively growing C6 glioma cells was affected more than confluent cell monolayers. The effect of NBBS on DNA synthesis in C6 cells occurred as early as 24 hrs at a concentration of 10 μM (18% inhibition of thymidine incorporation), with 30% inhibition at 72 hrs. At an NBBS concentration of 250 μM, DNA synthesis was strikingly inhibited (70%) at 72 hrs. C6 cells exposed to 100 μM and 250 μM NBBS exhibited markedly reduced or absent immunoreactivity with antibodies against S-100 protein and glial fibrillary acidic protein. Our data indicate a cell type-specific neurotoxicity of NBBS and support our in vivo studies in rabbits. Studies are underway to determine the effects of NBBS on primary cultures of neuronal cells.

TRIADIMEFON SELECTIVELY INHIBITS DOPAMINE UPTAKE, IN VITRO. Q.D. Walker, M.H. Lewis, and R.B. Mailman. Curriculum in Toxicology, Brain and Development Research Center, University of North Carolina School of Medicine, Chapel Hill, NC

Triadimefon [1-(4-chlorophenoxy)-3,3-dimethyl-1-(1H-1,2,4-triazol-1-yl)-2-butanone] is an agricultural triazole fungicide that induces "stimulant-like" effects when administered to rodents. Previous reports from this laboratory indicated that low doses of triadimefon caused increased locomotion and rearing in rats. At higher doses, more intensely stereotyped behaviors (e.g., head weaving and backward locomotion). We have also reported that triadimefon administration generally decreases dopamine concentrations in striatum, and increases them in olfactory tubercles. The fungicide was found not to have direct effects on D_1 or D_2 dopamine receptors. These initial investigations led to the hypothesis that triadimefon acts like an indirect-acting dopamine agonist, either inhibiting dopamine uptake or inducing dopamine release. The present studies investigated this further.

The first experiment examined whether triadimefon would inhibit the uptake of dopamine, serotonin, or norepinephrine. This assay was run in crude synaptosomal preparations and measured uptake of each radiolabeled neurotransmitter. Using striatal synaptosomes, triadimefon dose-dependently inhibited the uptake of ^{3}H-dopamine with an IC50 = 20 μM, about one-fifth the potency of GBR 12909, a selective blocker of dopamine uptake. Triadimenol, a mammalian metabolite of triadimefon and a commercial triazole fungicide, was 2-3 fold less potent than triadimefon in its ability to inhibit the uptake of ^{3}H-dopamine. Triadimefon did not alter the uptake of either ^{3}H-serotonin or ^{3}H-norepinephrine into synaptosomes prepared from frontal cortex (IC50's > 100 μM). The second experiment used slices of rat striatum to assess the ability of triadimefon to release dopamine. Amphetamine (1 μM), used as a positive control, doubled the basal efflux of preloaded ^{3}H-dopamine. Conversely, 31 μM triadimefon had no effect on release. Together, these data suggest that triadimefon is a relatively selective inhibitor of dopamine uptake with potency sufficient to explain its behavioral and neurochemical effects.

ACRYLAMIDE ALTERS THE DISTRIBUTION OF MAP1 AND MAP2 IMMUNOREACTIVITY IN RAT BRAIN. N.B. Chauhan*, M.I. Sabri, P.S. Spencer. Center for Research on Occupational and Environmental Toxicology, Oregon Health Sciences University, Portland, OR 97201.

Microtubule-associated proteins (MAPs) play an important role in the formation and maturation of neurites. Two MAPs (kinesin and dynein) mediate microtubule-based fast axonal transport which is retarded in rodents receiving the occupational chemical acrylamide (AC), a cause of axonal degeneration and cerebellar dysfunction in animals and humans. To study actions of AC on brain MAP immunoreactivity, rats were given 0.03% AC in drinking water for two weeks, systemically perfused with paraformaldehyde, brains dissected and 10-μm-thick paraffin sections prepared for MAP immunocytochemical localization according to Sternberger's PAP technique. Control MAP1 immunoreactivity was observed in neuronal perikarya, axons and dendrites of cortical pyramidal and Purkinje cells; in hippocampus, staining was limited to axons. AC caused significant loss in the immunoreactivity of hippocampal axons and of Purkinje cells, while staining in the cortical pyramidal cells was less affected. Control MAP2 immunoreactivity labeled axons and dendrites of cortical and hippocampal pyramidal cells, Purkinje cell processes and the cerebellar granular layer. AC reduced MAP2 immuno reactivity in cortical dendrites, cerebellum and hippocampal neurites. In summary, AC differentially disrupts the specific spatial distribution of MAP1 & 2 immunoreactivity in regions of rat brain involved in motor and memory functions. [Supported by NIH Grant, NS 19611]

EFFECTS OF PERINATAL EXPOSURE TO SPECIFIC POLYCHLORINATED BIPHENYL (PCB) CONGENERS ON LOCOMOTOR ACTIVITY OF RATS. S.L. Schantz and D.K. Ness*. Institute for Environmental Studies and Dept of Veterinary Biosciences, Univ of Illinois at Urbana-Champaign, Urbana, IL 61801.

Individual PCB congeners vary greatly in toxic potency. Those with 0 or 1 *ortho* chlorines, 2 *para* chlorines and at least 2 *meta* chlorines can assume a coplanar configuration similar to TCDD and are extremely toxic. Those with 2 or more *ortho* chlorines cannot assume a coplanar configuration and are believed to be considerably less toxic. However, recent evidence suggests the structure-activity relationship may be different for neurotoxicity. That is, *ortho*-substituted PCBs may be more neurotoxic than coplanar PCBs. Perinatal exposure to low-doses of complex PCB mixtures has been shown to alter activity in rodents, monkeys and humans. Therefore, we compared the effects of perinatal exposure to a coplanar PCB, an *ortho*-substituted PCB and a complex PCB mixture on activity in rats. Time-pregnant Sprague-Dawley rats were treated orally with 33',44'-tetrachlorobiphenyl, 22',55'-tetrachlorobiphenyl, Aroclor 1242 or corn oil vehicle on days 10-16 of gestation. Litters were culled to eight pups each on day two and weaned on day 21. One male and one female from each litter were tested for horizontal motor activity in an automated open-field. Activity of animals exposed to the high dose of the coplanar PCB or the high dose of the PCB mixture was suppressed compared to that of controls ($p < .01$) and compared to that of their respective low dose groups ($p < .05$). Activity of animals exposed to the noncoplanar PCB was not suppressed.

579.9

EFFECTS OF EXPOSURE TO TRIPHENYL PHOSPHITE (TPP) ON THE CNS OF THE CHICK (GALLUS DOMESTICUS) D. Tanaka, Jr., S.J. Bursian and E. Lehning, Depts. of Anatomy and Animal Science and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI 48824.

Although it is clear that chicks are resistant to Type I organophosphorus delayed neurotoxicants for as long as 8-10 weeks post-hatch, it has not been as well established that they are similarly resistant to Type II neurotoxicants. In order to assess the neuropathological effects of a Type II compound on the developing CNS, we injected subcutaneously 1184mg TPP/kg body weight in 1-, 2-, and 3-week-old chicks. The chicks were killed after 21 days and their brains processed with the Fink-Heimer silver method for degenerating axons and terminals. The brains of 1-week-old chicks contained no degeneration. In 2-week-old chicks the amount of degeneration varied, ranging from small numbers of degenerating axons in the lower brainstem to large numbers of degenerating axons and terminals in medullary, cerebellar, midbrain, and forebrain regions. In 3-week-old chicks degeneration was also noted at all brain levels. These results indicate that the CNS of the chick is susceptible to TPP and that adult-like degeneration patterns may result from exposure as early as 2 weeks post-hatch.

Interactions Between Chronic Physostigmine and Repeated Soman Exposure in Rats and Monkeys. S. A. Miller[1*], D. W. Blick[2], S. Z. Kerenyi[1*], M. R. Murphy[1], and S. L. Hartgraves[1]. [1]Directed Energy Div., Armstrong Laboratory and [2]Systems Research Laboratories, Inc. Brooks AFB, TX 78235.

We previously showed that chronic infusion of pyridostigmine (PYR) did not increase the toxicity (symptoms, lethality) of daily exposure to the irreversible cholinesterase inhibitor, soman, but did have a small, but reliable, protective effect against soman-induced Primate Equilibrium Platform (PEP) performance deficits in monkeys.

In contrast to PYR, physostigmine (PHY) readily crosses the blood-brain barrier, and thus may be more efficacious in protecting against the CNS effects of repeated soman exposure. In rats with and without chronic PHY infusion, we measured weight, symptoms, brain acetylcholinesterase (AChE), and lethality as a result of five daily repeated soman injections. In monkeys, we tested the protective effects of PHY infusion at several different rates on 5-day repeated soman-induced changes in serum cholinesterase (ChE) and PEP performance.

We found that, like PYR, chronic PHY had a small protective effect against lethality (rats), and performance decrements (monkeys) induced by repeated daily exposure to soman. No adverse interaction between the PHY and repeated soman was seen, even when PHY alone produced serum ChE inhibition levels averaging 60%.

This work was supported in part by the U.S. Naval Medical Research and Development Command.

579.11

Behavioral Toxicity of Organophosphate Nerve Agents: Efficacy of Exogenous Cholinesterases as Blood-borne Scavengers in Primates. D. W. Blick[1], B. P. Doctor[2*], A. D. Wolfe[2*], S. A. Miller[3*], G. C. Brown,[1*] and M. R. Murphy[3] [1]Systems Research Laboratories, [2]Walter Reed Army Institute for Research, and [3]USAF Armstrong Laboratory, Brooks AFB, TX 78235

We previously showed that adding an anticonvulsant (diazepam) to the therapy for high-dose soman exposure after pyridostigmine pretreatment increased survival and reduced deficits in Primate Equilibrium Platform (PEP) performance in rhesus monkeys during the first few days after such exposure. However, all of these chemical countermeasures failed to protect against complete prostration lasting 1.5 to 4 hrs, and delayed/residual deficits lasting up to 3 weeks.

We have now shown that high levels of exogenous cholinesterases (fetal bovine serum acetylcholinesterase, AChE, or equine serum butyrylcholinesterase,BChE) can provide complete protection against both symptoms and performance decrements produced by soman dosages 4-5 times the LD_{50}, even in the absence of any other pretreatment or therapy. Four monkeys were pretreated with each esterase. Soman (27-32 μg/kg) was given in 3 spaced injections and performance tested for 30 min after each injection. Serum esterase assays verified the stoichiometric inhibition caused by the soman and allowed titration of the next injection. No PEP deficits were seen in animals pretreated with AChE; however, 3 animals with BChE showed minor PEP deficits after the 3rd soman injection. No delayed/residual deficits were seen in any animal.

Performed under USAF Contract F33615-89-C-0547/40B.

579.12

EFFECTS OF SCOPOLAMINE (SCP) ON STRIATAL NEUROCHEMICAL LEVELS IN RATS INTOXICATED WITH SOMAN. B.R. Capacio*, T.-M. Shih, L. Cook*, T. Koviak*, T. Sewell* and N. Adams*. U.S. Army Med. Res. Inst. Chem. Def., APG, MD 21010

The antimuscarinic compound SCP, which is known to affect striatal neurochemistry, has been reported to prevent convulsions induced by the cholinesterase inhibitor soman. Evidence suggests that convulsions associated with soman intoxication contribute to brain neuropathology as a result of excitotoxic mechanisms. The purpose of this investigation was to determine the effects of SCP (0.125 mg/kg, im) on striatal amino acid and catecholaminergic parameters in rats intoxicated with a neurotoxic dose of soman (100 μg/kg, sc). The time course (0-2 hr) for concentrations of aspartate (ASP), glutamate (GLU), γ-aminobutyric acid (GABA), glycine (GLY), lysine (LYS), norepinephrine (NE), dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC), and homovanillic acid (HVA) were determined after soman, SCP and soman + SCP. Soman administration produced decreases in ASP and LYS concentrations which returned to control levels by 30 min. Soman + SCP blocked the decrease in ASP and produced a 30% increase in LYS which returned to control levels at 30 min. Soman did not significantly affect levels of GLU, GABA or GLY. Striatal concentrations of NE and DA were not altered by soman, but, the DA metabolites (HVA and DOPAC) increased to twice that of control. SCP blocked the effects of soman on DOPAC and HVA levels. The limited effects of soman on amino acid levels support findings that soman produces less damage in the striatum than in other brain areas. Furthermore, the data suggest that the anticonvulsant effects of SCP may be partially attributed to its influence on DA metabolism in addition to its well known anticholinergic activity.

DOWN REGULATION OF MUSCARINIC RECEPTORS IN RATS DUE TO EARLY POSTNATAL EXPOSURE TO PARATHION. C.L. Dvergsten*, R.B. Meeker, and James F. Howard, Department of Neurology, University of North Carolina, Chapel Hill, NC 27599.

Parathion (PTN), an organophosphorous pesticide, is a potent inhibitor of acetylcholinesterase (ACHE). We are currently investigating the acute and long-term effects of ACHE inhibition in the developing brain due to parathion. Acute studies indicated: 1) a dose-dependent and transient inhibition of brain ACHE and 2) an increased susceptibility of the brains of 12-day-old rats (IC_{50}=1.5 mg/kg) versus adult rats (IC_{50}=2.5 mg/kg) to the anti-ACHE properties of PTN. Based on these observations we produced a prolonged dose-dependent inhibition of brain ACHE by giving rat pups daily injects of PTN from postnatal days 8-21. Growth retardation was dose dependent and varied between 6-30%. Growth was inhibited only during the first 5-6 days of exposure, thereafter the growth rate paralleled controls. Daily injections of 1.5 mg/kg PTN reduced whole brain ACHE activity by 50-70% throughout the exposure period. ACHE histochemistry indicated ACHE was inhibited in a variety of brain regions including the caudate-putamen, hippocampus and cerebral cortex. ^{3}H-QNB binding in whole brain homogenates from 21-day-old rats injected daily for 13 days with 1.5 mg/kg PTN showed that PTN reduced B_{max} by about 20% but the K_D was unchanged. Hill analyses of competition binding studies with acetylcholine indicated agonist binding properties were unaffected by PTN. Thus, prolonged exposure of young rats to PTN and the resulting inhibition of ACHE produced a decrease in the number of muscarinic receptors but did not influence the binding of acetylcholine to the receptor.

METABOLISM OF THE NEUROTOXIC PYRROLIZIDINE ALKALOIDS FROM *TRICHODESMA INCANUM*. S.L. Glowaz*, R.J. Bowers*, K. Kashihara and R.J. Huxtable, Department of Pharmacology, Arizona Health Sciences Center, Tucson, AZ 85724.

Contamination of grain with the seeds of the pyrrolizidine alkaloid-containing plant, *Trichodesma incanum*, caused an outbreak of human poisoning in central Asia in 1950. Poisoning in both humans and animals differ from other pyrrolizidine alkaloid intoxications inasmuch as *T. incanum* has been reported to have a primary neurotoxic action. *T. incanum* contains the alkaloids, trichodesmine and incanine. These alkaloids are structurally similar to the *Crotalaria spectabilis* alkaloid, monocrotaline. However, monocrotaline is associated primarily with hepatic and pulmonary toxicities rather than neurotoxicity. Its toxicity results from hepatic metabolism to reactive pyrrole intermediates. We have compared the metabolism of the pyrrolizidine alkaloids, heliotrine (hepatotoxic only), monocrotaline (hepatotoxic and pneumotoxic), and trichodesmine and incanine (neurotoxic) by isolated rat liver microsomes. Incubation with 0.5 mM monocrotaline for 10 min yielded 9 ± 2 nmol.mg^{-1} protein of a highly reactive alkylating pyrrole, as measured by trapping through thioether bond formation with thiopropyl sepharose resin, and 19 ± 5 nmol.mg^{-1} protein of nonalkylating pyrroles. By comparison, 0.5 mM trichodesmine/incanine mixture (3:1 ratio) yielded 21 ± 4 nmol.mg^{-1} protein of alkylating pyrrole and 23 ± 2 nmol.mg^{-1} protein of nonalkylating pyrrole. No alkylating pyrrole was trapped from incubations with heliotrine. It appears, therefore, that the organ-specific toxicity of pyrrolizidine alkaloids correlates with the quantity of reactive alkylating pyrrole generated, as determined by an *in vitro* trapping system.

ACUTE EFFECT OF Karwinskia humboldtiana (Kh) ON SOME MOTOR REGIONS OF THE CENTRAL NERVOUS SYSTEM. G.G. Ortiz*, I. González-Burgos*, G. Tapia-Arizmendi and A. Feria-Velasco. Morphology Lab., Fac. Cienc. Biol., Univ. de Guadalajara; and Exptl. Path. Div., Unidad Invest. Biomed. Occte., I.M.S.S. Guadalajara, Jal.

Kh is a shrub that grows in Mexico and U.S.A. Ingestion of Kh fruit produces ascendent flaccid paralysis and death. Distal peripheral demyelination is observed in large motor nerves which degenerate. Structural alterations have been reported in cerebellum, pons and spinal cord. With the purpose to explore the effect of Kh in other brain regions, 2g/Kg of Kh endocarp were orally administered to 24 male Wistar rats, and after 6,12,48 and 72 hr, their brains were fixed with buffered-2% paraformaldehyde by intracardiac perfusion under general anesthesia. Sections of sensory-motor cortex (Cx), CA1 region of hippocampus (Hp) and caudo-putamen (CP) were studied under a light microscope, after being stained with aniline dyes. Widening of Virchow-Robin spaces and shrinkage with hyperchromasia of pyramidal cells were seen in Cx throughout the study. Neuronal death was observed in all regions since 6 hr after Kh administration, increasing at 12 and 48 hr, mainly in Hp, where the lesions remained until 72 hr after Kh administration. Hp was the most affected region.

It is concluded that Kh has an acute neurocytotoxic effect on Hp and to a lesser extent on Cx and CP. These findings could be related in part, to the non-paralytic motor disturbances observed in the first week after Kh ingestion.

3-NITROPROPIONIC ACID - EXCITOTOXIC LESION OF THE HIPPOCAMPUS INDUCED BY AN INHIBITOR OF CHEMICAL ENERGY METABOLISM. M. Riepe*, A.C. Ludolph*, M.I. Sabri, P.S. Spencer, C.N. Allen. Center for Research on Occupational and Environmental Toxicology, Oregon Health Science University., Portland, Oregon 97201

3-Nitropropionic acid (3-NPA), a widespread fungal and plant toxin, and inhibitor of mitochondrial Complex II is of pathogenetic significance in human and animal diseases. The pattern of damage in the basal ganglia and the hippocampus *in vivo* mimics excitotoxic lesions. In mouse cortex explant cultures, 3-NPA induces vacuolization and chromatin clumping, which are preceded by cellular energy depletion and partly attenuated by glutamate antagonists (MK-801). In contrast, 3-NPA (0.1 to 10 mM) does not induce currents mediated by ionotropic glutamate receptors in whole-cell patch clamp recordings of cultured hippocampal neurons. Diazoxide (0.1 mM), an agonist of ATP-dependent potassium channels, induced a hyperpolarizing current in the same system. We propose that the hyperpolarization observed in cells treated with 1 mM 3-NPA alone is due to an increased potassium conductance following impaired energy metabolism similar to observations in ischemic cells. A further energy depletion by 3-NPA possibly causes a depolarization of the cell membrane that gates the toxic action of endogenous excitatory agents. LINDANE INHIBITS NEURITE INITIATION AND ELONGATION AND DECREASES INTRACELLULAR FREE CALCIUM ION CONCENTRATIONS IN CULTURED RAT HIPPOCAMPAL NEURONS AND MOUSE N1E-115 NEUROBLASTOMA CELLS. C. Ferguson*, L. Cabell-Kluch*, D. Shugarts*, T. Audesirk and G. Audesirk. Biology Department, U. Colorado at Denver, Denver, CO 80217-3364.

Several studies suggest that neurite initiation and elongation may be modulated by intracellular free calcium ion concentrations and/or calcium fluxes across the plasma membrane. Departures from optimal intracellular calcium concentrations, both increases and decreases, appear to lead to decreased neurite initiation (J. Frank abstract, this meeting), as does blocking calcium influx through voltage-sensitive calcium channels (Audesirk, et al., 1990). The organochlorine pesticide lindane has been reported to increase intracellular calcium concentrations in short-term experiments (less than an hour). We cultured embryonic rat hippocampal neurons and mouse N1E-115 neuroblastoma cells in lindane concentrations ranging from 0.1 to 100 uM. Neurite initiation and elongation were measured after 48 hours in culture. Lindane significantly inhibited neurite initiation at concentrations as low as 1 uM (hippocampal neurons) and 0.5 uM (N1E-115 cells). Lindane significantly inhibited neurite elongation at concentrations as low as 25 uM in both cell types. Contrary to previous reports using short-term exposure, digital imaging microscopy with fura-2 showed that long-term exposure to lindane (24 hours or more) decreased intracellular free calcium ion concentrations in a dose-dependent manner.

MAGNETIC COIL STIMULATION OF STRAIGHT AND BENT PERIPHERAL NERVE IN-VITRO: EFFECT OF CHANGING STIMULUS PROFILE AND POLARITY. P.J. Maccabee, V.E. Amassian, L.P. Eberle* R.Q. Cracco and A.P. Rudell. SUNY-Health Science Center at Brooklyn, Brooklyn, N.Y. 11203

A 9-11 cm segment of amphibian nerve was placed in a relatively large flat-bottommed plastic trough containing Ringer's solution. The distal end of the nerve emerged from the solution for monophasic recording. A 5 x 10 cm figure '8' magnetic coil [MC] was positioned beneath the trough, with the long axis of the junction centered under and parallel to the nerve. The direction and waveform of the energizing pulses [polyphasic, phase II 80% of phase I; biphasic, phase II 20% or 35% of phase I] was selectively changed by a mechanical switch.

Suprathreshold biphasic pulses elicited a single response corresponding to the (-) going spatial derivative of the electric field, just distal to the anterior divergence of the coils. Reversing the current shifted the latency by 0.65-1.0 ms, corresponding to approximately 30 mm at the measured conduction velocity. This second site at the figure '8' is posterior to its middle region. These locations were confirmed by direct electrical stimulation. For the two current directions, the responses were stable in latency at all stimulus output intensities.

Polyphasic MC pulses of either polarity resulted in stimulation at the spatial derivative site closest to the recording electrodes; the responses differed in latency by approximately 200 μsec possibly reflecting the period between 1st and 2nd phases. Presumably, excitation by the 1st or reversed polarity 2nd phase of the polyphasic pulse at this site leads to collision with impulses generated at the more distant site.

Bending the nerve from 30° to 90° or more created a low threshold stimulation site at or near the bend.

These findings may help explain MC excitation of axons in the CNS.

EFFECTS OF CONTROLLED AMBIENT LIGHT AND CIRCADIAN FACTORS ON THE PUPILLARY LIGHT REFLEX IN HUMANS. W.B. Pickworth, J.S. Fosnaugh* and E.B. Bunker*, NIDA, Addiction Research Center, Baltimore, MD 21224

Measures of pupillary size and the light reflex are safe and noninvasive methods to quantify and characterize the mechanism and site of drug action. In this study, we measured the effect of variations in the ambient light level and time of measurement on pupil diameter and the dynamic light reflex. Light levels of: >.1,4,40,100 and 200 ftcd were used every 3 hr between 6 AM and 9 PM in 14 adult males. Measurements were made with a Fairville Medical Optics pupilometer. The diameter of the dark-adapted pupil at >.1 ftcd averaged 6.4 mm, whereas the diameter in the 200 ftcd condition averaged 2.3 mm. Time of day effects were significant but small and a significant interaction between light level and time suggests that the pupil size is influenced differently by the ambient light over the course of the day. Constriction amplitude decreased with ambient light from 2.1 mm (>.1 ftcd) to .2 mm (200 ftcd) while constriction and dilation velocities decreased from 7.7 to 2.8 and 4.3 to 2.8 mm/sec respectively. A patch over the counterlateral eye increased the size of the pupil and measures of the light reflex. Such baseline data may be useful in describing the normal variations in these increasingly popular measures.

NONINVASIVE MEASUREMENT OF NERVE ELECTRICAL MEMBRANE PROPERTIES IN HUMANS USING VARIABLE PULSE-WIDTH MAGNETIC STIMULATORS. D. Rudiak* & E. Marg, Sch. of Optometry, U. Calif., Berkeley, 94720.

Using strength-duration protocols, magnetic stimulators can make nerve membrane measurements, but without the pain of electrical stimulation. If threshold units $\propto$ induced charge density (e.g., $\sqrt{\text{Energy}}$), threshold is linearly related to pulse width. The membrane time constant (T) can be computed from the slope (m) and y-intercept (b) of a linear regression through the data. T = .582 b/m and is typically 125-150 μsec in peripheral nerve and motor cortex. Assuming "typical" values for membrane capacitance (e.g., 1 $\mu F/cm^2$) and threshold depolarization voltage (15-20 mV), membrane leakage resistance and current density may also be computed, yielding 125-150 ohm-cm^2 and .6-.9 A/m^2. Another possibly useful quantity, the ratio of membrane to total current density, may be computed from absolute thresholds. Typical values are .25-.50. This ratio is relatively uniform in cortex but highly variable in peripheral nerve. Variability is related to tissue inhomogeneity, e.g., conductance changes. Studies in normal vs. pathological populations are now needed to establish the clinical utility of these measurements.

NEW INTRAMUSCULAR ELECTRODES AND MICROPROCESSOR CONTROL OF ELECTRICAL STIMULATION TO IMPROVE HEMIPARETIC GAIT. A. Prochazka, L. Davis* & M. Gauthier*, Div. Neurosci., University of Alberta, Edmonton AB, T6G 2S2, CANADA

There are two major impediments to the widespread use of functional electrical stimulation to improve motor function in paralysed patients: i) unreliability of electrodes; ii) unreliability of sensors and controllers. We have tested a robust intramuscular electrode similar to that developed recently in Cleveland by J.T.Mortimer. Two Cooner 632 insulated stainless steel wires are coiled tightly around a length of 4/0 prolene monofilament and terminated with a knotted monofilament barb which acts as an anchor. The last 25 mm of each wire is bared, so that 50 mm of wire coiled into a 10 mm length interfaces with muscle. Implantation is done with a jacketed translumbar aortogram needle under fluoroscopy control. 5 electrodes implanted in psoas, gluteus medius muscles and peroneal nerve in 2 incomplete quadriplegics have remained electrically stable and functional for a year. We have also developed a portable microprocessor controller which uses signals from underfoot force sensors to control multichannel stimulation during gait. The system compensates for transducer drift and can be monitored and parametrically adjusted from an IBM AT host. *Supported by Canadian MRC.*

TEMPERATURE CHANGES IN DEPTH ELECTRODE DURING MR SCANNING. J. Zhang, C.L. Wilson, M. Levesque, E. Behnke* and R. Lufkin,* Brain Research Institute and Department of Neurosurgery and Department of Radiology, UCLA, Los Angeles, CA 90024.

Surgical therapy for complex partial epilepsy requires precise identification of the seizure focus. Magnetic resonant imaging (MRI) compatible depth electrodes have been implanted stereotaxically in the temporal lobes for prolonged stereoelectroencephalography (SEEG) recording to assist in focus identification. Post-implantation MRI scans offer accurate localization of electrode sites; however, eddy currents in a metallic electrode induced by the radiofrequency magnetic field applied by the MRI scanner may heat the electrode. Electrode heating may raise the local brain tissue temperature, possibly to a dangerous extent. We therefore examined electrode temperature changes in a 1.5-T MRI scanner.

A bundle of five Nickel-Chromium electrodes (NiCr, Nickel 80%, Chromium 20%) were attached around a miniaturized precision thermistor (model 44003A, YSI Inc.) which was connected to a ohmmeter by copper wires. Masking tape was wrapped around the electrode bundle to prevent heat dissipation. The bundle of electrodes was then placed between two saline bags in a GE Signa 1.5-T MRI scanner with the electrode axes in parallel with the scanner axis to obtain maximal heating effect. The electrode temperature increased by 0.07°C after scanning for 3 minutes with multi-echo sequences (TR/TE = 800/20).

We conclude that MRI scanning will not cause a significant NiCr electrode temperature rise.

RESPONSE OF ESSENTIAL WRIST TREMOR TO SINUSOIDAL SOMATOSENSORY FEEDBACK. R. J. Elble and C. A. Higgins*. Southern Illinois University School of Medicine, P.O. Box 19230, Springfield, IL 62794-9230.

Sinusoidal forcings at 4 to 15 Hz were delivered by a computer-controlled torque motor to the wrists of 11 normal adults and 10 patients with advanced essential tremor. Wrist angle and forearm EMG were recorded. Our normal adults exhibited a second-order underdamped wrist response with a natural frequency of 5.5 Hz. The wrist response of our patients exhibited 66% greater resonance at forcing frequencies of 4 to 6 Hz, which was the frequency range of their tremor. The increased resonance in our patients was attributable to intermittent frequency entrainment of essential tremor by the mechanically-induced somatosensory feedback. The wrist response of our patients and controls did not differ at frequencies greater than 7 Hz. The marked entrainment of motor units by essential tremor precluded normal reflex modulation of forearm EMG by wrist forcings at frequencies greater than 6 Hz. Consequently, the forearm EMG response of our patients was less than control values at frequencies greater than 6 Hz. Furthermore, forcings at frequencies greater than 12 Hz tended to suppress essential tremor. Essential tremor is a centrally generated oscillation that can be enhanced or suppressed by somatosensory feedback. (Supported by NINDS grant NS20973.)

PATTERNS OF MUSCLE ACTIVATION DURING GAIT IN SUBJECTS WITH DOWN SYNDROME (DS). M.Cioni, A.Cocilovo*, F.Comeau*. OASI Inst.(IRCCS) Troina, Inst. Physiology, Catania Univ.,Italy Neurobiology Res. Centre, Hop. Enfant J., Québec, Canada.

In order to explore the basic mechanisms underlying the disturbed and delayed motor development in DS, we have analyzed the muscle activations and movement patterns during free gait of 12 young subjects of different age with DS as well as of 10 normals subjects. Gait movements have been monitored by an electrogoniometer and surface EMG was recorded from four leg muscles (hamstrings, quadriceps, tibialis ant., triceps s.).Three patterns of muscle activation have been identified: the first one showed EMG characteristics similar to those observed in the normals, the second pattern was characterized by the precocious activation of triceps surae and was observed in most DS subjects, the third pattern was mainly represented by the activation of the triceps surae at the beginning (0-35%) and at the end (70-100%) of the gait cycle.Our results show the presence of a different phenotypical expression of walking patterns in DS and of a specific delay in the functional development of the triceps surae.Moreover they suggest a key role for this muscle and its neural control in the delayed development of gait observed in this syndrome.

TREMOR REDUCTION BY MICROINJECTION OF LIDOCAINE INTO THE THALAMUS OF MOVEMENT DISORDER PATIENTS. G.D. Sher*, J.O. Dostrovsky, R.R. Tasker*, A. Lozano, A. Parrent* and F.E.B. Wells*. Departments of Physiology and Neurosurgery, University of Toronto, Toronto, Ontario, M5S 1A8, Canada.

Thalamotomy has long been used in the treatment of intractable tremor. The optimal site for the lesion is believed to be in the region immediately anterior to the tactile relay in the thalamic ventrobasal complex where cells respond to joint movement and/or fire in synchrony with the tremor (tremor cells) and where microstimulation blocks or reduces the tremor. However, it is unclear whether these criteria predict the optimal lesion site and also whether stimulation-induced tremor reduction (TR) is due to disruption and block of neural activity or to activation of neural elements. The present study utilized microinjections of the local anesthetic lidocaine hydrochloride (1-2ul of 1 or 2% solutions) in order to obtain further information related to these points. Injections of lidocaine, at sites where joint activated units and/or tremor cells were recorded and/or where microstimulation evoked TR, produced marked or complete TR in 2 Parkinsonian and 4 other movement disorder patients; TR occurred within 3 min., was maximal at 5 and persisted for up to 20 min. The TR effects were confirmed by marked reductions of EMG recordings of 4 muscle groups on the contralateral forearm. In all cases speech and voluntary movements were unaffected during lidocaine block, and there was no loss of tactile sensibility. These findings suggest that stimulation-induced TR may be due to block or disruption of neural activity. Furthermore, since lidocaine block mimics the effects of a lesion, it allows one to determine the sequelae of lesioning prior to permanent ablation and thus may serve as a very useful additional tool in functional stereotactic neurosurgery. (Supported Canadian MRC and Parkinson Foundation)

ABNORMAL BLOOD FLOW RESPONSES TO VIBRATION IN PATIENTS WITH WRITER'S CRAMP. L.W. Tempel, J.S. Perlmutter. Departments of Neurology and Radiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

We evaluated sensorimotor processing in patients with writer's cramp using positron emission tomography (PET) and $H_2^{15}O$. We studied 6 right-handed patients (3 female) 24-72 yrs of age (mean 50). All had unilateral writer's cramp. These were compared to 8 right-handed normals (6 female) 20-72 yrs of age (mean 41). Data were analyzed using subtraction image analysis. Vibration produced a consistently localized and robust peak response (ml/(100gmin) +/- SD) in primary sensorimotor cortex (S1) contralateral to hand vibration in normals (right hemisph: 13.11 +/- 3.25;left hemisph: 12.57 +/- 1.18). This response was significantly reduced in patients with writer's cramp ($p < .001$) whether vibrating the unaffected (7.87 +/- .62) or affected (10.40 +/- 2.07) hand. Coordinates for the SMA locus were determined from the averaged responses in an independent data set of 14 normals 20-69 yrs of age (mean 39). It was in high medial frontal cortex contralateral to the vibrated hand. This locus then was used to objectively search the data from the patients and the other 8 normals. Right and left SMA responses in normals were not significantly different from each other (right hemisph: 6.52 +/- 1.47; left hemisph: 6.46 +/- 1.45). There also was no significant right-left (or "unaffected-affected") difference in writer's cramp patients (unaffected hemisph: 4.30 +/- 1.70; affected hemisph: 4.66 +/- 1.09). Both SMA responses were significantly less than in normals ($p < .01$). These data indicate that patients with unilateral writer's cramp have bilateral brain dysfunction. Abnormal responses in S1 and SMA are consistent with dysfunction of the cortico-striato-pallido-thalamo-cortical circuit.

580.10

ELECTROMAGNETIC MAPPING OF DYNAMIC BRAIN ACTIVITY: SPATIO-TEMPORAL ANALYSIS AND ANATOMICAL CONSTRAINTS. J. Mosher*, J.S. George, P.S. Lewis*, R. Leahy*, M. Singh*. Los Alamos National Lab., M-715, Los Alamos, NM 87545 & Univ. Southern California, Los Angeles, CA

Neural electromagnetic measurements offer the prospect of high resolution, noninvasive mapping of dynamic patterns of activity of the human brain. However, localization of neural sources from external magnetic field or potential measurements requires the solution of an ill-posed inverse problem. We have developed an approach based on MUSIC (MUltiple SIgnal Classification) algorithms that systematically exploits spatio-temporal correlations in the measurement matrix. The method also incorporates anatomical information, derived from volumetric magnetic resonance imaging, to constrain the locations of candidate sources. The *signal subspace* of the electromagnetic measurements is estimated by performing an eigenvalue decomposition on the correlation matrix of the time series data. Because theoretical and experimental evidence suggests that the dominant sources observed in noninvasive electromagnetic measurements are cortical dendritic currents, in our application the *source region* is limited to cortex. A scan metric is computed at each spatial location in the source region by projecting the field of a current element at that location onto the signal subspace, to identify sources that produce fields that lie within the signal subspace. Locations that produce a peak in the 3-D distribution of the metric are accepted as probable neural sources. If greater accuracy in localization or a description of the timecourse of component sources is required, sources identified by the algorithm may be used as location estimates for multiple dipole fitting procedures. We have applied these procedures to experimental neuromagnetic data from somatosensory studies to resolve the sources activated by electrical stimulation of the thumb, ring finger or the simultaneous stimulation of both. We have also resolved neuromagnetic sources associated with early cortical activation in response to a small sinusoidal grating presented to single quadrants of the visual field. Our MUSIC-based algorithm provides a powerful and systematic approach to estimate a spatio-temporal ensemble of sources, while incorporating anatomical information to improve the accuracy and efficiency of electromagnetic imaging of brain function.

580.11

BEHAVIOR-RELATED CHANGES IN HIPPOCAMPAL THETA ACTIVITY RECORDED FROM OCCIPITAL TRAJECTORY DEPTH ELECTRODES. **J.L. Thompson, K.J. Meador, D.W. Loring*, G.P. Lee*, D.W. King*, B.B. Gallagher, A.M. Murro*, J.R. Smith* and H.F. Flanigin*. Departments of Neurology and Surgery, Medical College of Georgia, Augusta GA 30912.**

In previous studies of temporal lobe epilepsy (TLE) patients, we have shown that hippocampal theta activity recorded from vertex trajectory depth electrodes changes as a function of behavior. In this study of nine patients with unilateral TLE, theta activity recorded from an occipital trajectory hippocampal depth electrode (contralateral to the seizure focus) was compared across four behavioral conditions: resting eyes closed (RC), resting eyes open (RO), eyes open with auditory word activation (AW), eyes open with visuospatial activation (AP). Theta activity decreased significantly during AW and AP compared to RC ($p=0.0195$& $p=0.002$,respectively) and during AP compared to RO ($p=0.0195$).

In contrast, vertex trajectory patients showed a significant decrease in theta during RO compared to AW, and no significant differences between AW & RC or AP & RO. The differences between the vertex and occipital groups in behavior-related theta activity changes may be due to: group differences, small size of the occipital group, or an electro-physiologically important difference in electrode placement. Occipital trajectory electrodes allow comparison between contact points along a line from the amygdala through anterior hippocampus to posterior hippocampus. It is interesting to note that no significant behavior-related changes in theta activity were observed in the amygdala and, that theta changes within the hippocampus varied from anterior to posterior suggesting that precise electrode placement is an important consideration.

ENHANCED CORTISOL RESPONSE TO FENFLURAMINE IN MAJOR DEPRESSION. R.T. Malison*, L.H. Price, P.L. Delgado, D.S. Charney and G.R. Heninger. Department of Psychiatry, Yale University School of Medicine., New Haven, CT 06519.

Alterations in central serotonergic neurotransmission have been implicated in the pathophysiology of major depression. We studied central serotonin (5HT) function in major depression by comparing the neuroendocrine response to pharmacologic challenge with the potent 5HT releasing agent fenfluramine (FEN) both between depressed (n=21) and healthy (n=17) subjects and within a depressed subset (n=12) later treated with desipramine (DMI). Serum cortisol (COR), prolactin (PRL), and growth hormone (HGH) were measured at baseline, and at 30 min intervals between 2 and 5 hrs after an oral dose of FEN (60 mg). Results showed a significantly ($p<.05$) increased mean (± SEM) peak change in COR in depressed (6.61 ± .91 µg/dl) as compared to healthy (2.64 ± 1.62 µg/dl) subjects. This enhanced COR response to FEN was significantly attenuated and appeared to normalize following DMI treatment (6.94 ± 1.42 vs 3.33 ± .85 µg/dl, $p<.05$). No significant differences in PRL or HGH responses were noted. These findings lend support to the hypothesis of altered 5HT function in depression which normalizes with antidepressant treatment.

580.13

ELECTROPHYSIOLOGIC ANALYSIS OF CEREBRAL CORTICAL DYSFUNCTION IN FELINE MODELS OF NEURONAL STORAGE DISEASE. S.U. Walkley and C.E. Schroeder, Dept. Neuroscience, Kennedy Center, Albert Einstein College of Med., Bronx, NY 10461.

The pathogenetic mechanisms underlying brain dysfunction in Tay-Sachs disease and other neuronal storage disorders are poorly understood. Two abnormalities of neurons known to commonly occur in cerebral cortex in gangliosidosis and to a lesser degree in other storage disorders are (i) ectopic dendritogenesis and associated asymmetrical synapse formation on axon hillocks of pyramidal neurons, and (ii) axonal spheroids predominating on GABAergic neurons. We evaluated the relative contributions of these cytopathologic features to cortical dysfunction using feline models of GM1 gangliosidosis (GM1) and Niemann-Pick disease type C (NPD). To date we have studied 1 GM1 cat (9 mo. old), 1 NPD cat (7 mo. old), and 4 normal cats (9 mo. and older). Laminar profiles of field potentials, current source density, and multiunit activity, elicited by 90 dB, 100 µsec, contralateral clicks, were sampled from primary auditory cortex under pentobarbital anesthesia using multicontact electrodes. In the GM1 cat, response latencies in laminae III-IV were elevated by 2-7 ms and response durations by 4-10 ms over normal values, whereas in the NPD cat elevations were minimal. In both diseases the amplitude and spatial extent of supragranular activation was greater than normal. Attenuation of cortical response amplitudes in lamina III at high stimulation rates was 20-40% greater than normal at rates above 10 Hz; 100% attenuation was reached at 40 Hz, vs. 200 Hz for normals. Control data suggested a minimal contribution from subcortical pathology and neural fatigue processes. While there is clear evidence for neurophysiologic abnormalities in the cerebral cortex of GM1 and NPD cats, the relative contributions of increased excitatory and decreased inhibitory influences remain to be elucidated. (NS18804, MH06723, NS10967, AR37095)

EXPERIMENTAL THERAPY OF HUMAN GLIOMA BY MEANS OF A GENETICALLY ENGINEERED VIRUS MUTANT. R. L. Martuza[1], A. Malick[1*], J. M. Markert[1*], K. L. Ruffner[2*], D. M. Coen[2*]. [1]Molecular Neurogenetics Laboratory, Dept. Surgery (Neurosurgery) Mass. General Hospital, Boston, MA 02114; [2]Dept. Biological Chemistry and Molecular Pharmacology, Harvard Medical School, Boston, MA 02115.

Malignant gliomas are the most common malignant brain tumors and are almost always fatal. A thymidine kinase negative mutant of herpes simplex virus-1 (*dl*sptk), that was attenuated for neurovirulence, was tested as a possible treatment for gliomas. In cell culture, *dl*sptk killed two long-term human glioma lines and three short-term human glioma cell populations in a dose-dependent fashion. In nude mice with implanted subcutaneous and subrenal U87 human gliomas, intraneoplastic inoculation of *dl*sptk caused significant growth inhibition. In nude mice with intracranial U87 gliomas, intraneoplastic inoculation of 10^3 and 10^5 plaque forming units (pfu) dlsptk prolonged survival in a dose-dependent fashion ($p<0.05$). Moreover, at the highest tested dose (10^5 pfu), 2/7 (29%) animals were alive, healthy, and neurologically normal at 19 weeks. After sacrifice, histological sections revealed no residual tumor. We are testing genetically engineered viruses like *dl*sptk and others that are attenuated for neurovirulence for use as novel antineoplastic agents for malignant brain tumors.

SYMPOSIUM. "LIPID MEDIATORS" IN SYNAPTIC TRANSMISSION AND SIGNAL TRANSDUCTION OF NEURONAL CELLS: PHYSIOLOGICAL AND PATHOLOGICAL IMPLICATIONS. G.Z. Feuerstein, SmithKline Beecham Pharmaceuticals and N. Bazan, Louisiana State University School of Medicine (Chairpersons); D. Piomelli*, Institut National de la Sante et de la Recherche Medicale; T.V.P. Bliss*, National Institute for Medical Research.

Lipids are the major constituent of all plasma membranes and possess vast diversity of composition and dynamic plasticity in structure and function. While much of our past efforts have been spent on understanding the structural significance of membrane lipids, their supportive role in enzyme and receptor function and a source of autocrine and paracrine autacoids (e.g., prostaglandins, leukotrienes), recent evidence emerges to suggest that certain lipids might have a role in preparation of external signals across the cell membrane toward intracellular targets. Activated PLA_2 via voltage or receptor operated membrane signals results in phospholipid remodeling and production of platelet-activating factor and selected eicosanoids which results in intracellular events such as elevated $[Ca^{2+}]_i$, IP_3, PKC and immediate gene-expression. Functional consequences of archidonate metabolites such as those produced by the 5 or 12-lipoxygenase enzyme include modulation of neurotransmitter release. At the neural system function, evidence has been raised in support of a role for eicosanoids in the evolution of the phenomenon of long term potentiation and its physiological and pharmacological implications. While this field is clearly at its infancy, it provides new dimensions for basic research and new therapeutic strategies in modulation of normal and pathological aspects of brain function.

SYMPOSIUM. NEURAL GRAFTING AND PARKINSONS DISEASE. A. Björklund, Univ. of Lund, Sweden (Chairperson); M.R. De Long, Emory University; S.B. Dunnett, Univ. of Cambridge, U.K.; D.M. Gash, Univ. of Rochester; O. Lindvall, Univ. of Lund, Sweden.

The session will deal with recent progress in the understanding of the pathophysiology of the dopamine-denervated striatum and the mechanisms by which neural grafts can ameliorate symptoms in experimental parkinsonism in primates and in Parkinsons disease in man. M.R. De Long will focus on changes in neuronal activity in the primate basal ganglia following MPTP treatment, which results in an increased tonic and phasic output from the globus pallidus and excessive inhibition in the thalamus. S.B. Dunnett will review recent studies on the behavioral recovery induced by dopamine-rich nigral grafts in 6-hydroxydopamine-lesioned marmosets, and the topographic and behavioral specificity of these effects. D.M. Gash will deal with trophic effects, and trophic substances, elaborated by neural grafts or by the host brain in response to the grafting process, and the ability of such trophic mechanisms to rescue damaged neurons or stimulate sprouting in the nigrostriatal system. O. Lindvall will summarize recent data emerging from ongoing clinical trials using fetal nigral transplants, and discuss the shortcomings of the present techniques and the problems which have to be addressed in order to develop the neural transplant approach into a useful clinical therapy in PD patients.

VISUAL SYSTEM: CORTICAL MECHANISMS

585.1

SPONTANEOUS CALCIUM TRANSIENTS IN DEVELOPING NEOCORTICAL NEURONS.

L. C. Katz and R. Yuste. Dept. of Neurobiology, Duke University, Durham, NC 27710 and Lab. of Neurobiology, Rockefeller University, NY, NY 10021.

Spontaneous activity in the developing visual system plays a critical role in the activity-dependent modification of cortical circuits. Since synaptic activation causes postsynaptic calcium influx, video-based optical recording of neuronal $[Ca^{2+}]_i$ can be used to monitor activity over extensive cortical regions, with single cell resolution (Yuste & Katz, *Neuron* 6:333, 1991). Using fura-2, we have now recorded spontaneous $[Ca^{2+}]_i$ changes in slices of somatosensory and visual cortex of neonatal rats. During the first postnatal week the majority of neurons in all cortical layers exhibit spontaneous transients that result in 5-10 fold increases in $[Ca^{2+}]_i$. These events are non-periodic and occur in complex spatial and temporal patterns. Individual transients last 3-20 sec and occur at intervals ranging from 12 sec to 10 min.

Transients are totally blocked by 1mM Ni^{2+}, indicating that the entry of extracellular Ca^{2+} is probably involved. Although glial cells also show calcium transients (Cornell-Bell *et al.*, *Science* 247:471, 1990), and we cannot exclude their involvement, most of the events we observed occurred in neurons, as distinguished by their apical dendrites and large cell bodies. Transients are blocked by 100 µM APV but are unaffected by 20 µM CNQX. Their pharmacology suggests that they probably represent NMDA receptor-mediated responses to spontaneously released glutamate.

$[Ca^{2+}]_i$ transients have been associated with intracellular regulation of other messenger systems and the control of gene expression. In addition, optical recording of these spontaneous calcium events and others changes in $[Ca^{2+}]_i$ elicited by different stimulation paradigms can be used to unravel the spatial and temporal dynamics of the activity of neuronal networks.

585.2

NEURONAL GROUPS REVEALED BY OPTICAL RECORDING OF CALCIUM TRANSIENTS IN SLICES OF DEVELOPING NEOCORTEX.

R. Yuste, A. Peinado and L. C. Katz. Lab. of Neurobiology, Rockefeller University, NY, NY 10021 and Dept. of Neurobiology, Duke University, Durham, NC 27710.

Correlations in the spontaneous activity of neighbouring neurons may play a critical role in the developmental refinement of cortical connectivity. By imaging slices of rat visual and somatosensory cortex with the Ca^{2+} sensitive dye fura-2, during the first postnatal week, we have observed frequent spontaneous calcium transients in individual cells (see previous abstract). When larger areas (~1 mm^2) were imaged, we found that discrete regions of neurons frequently changed $[Ca^{2+}]_i$ in synchrony, defining spherical, multicellular groups of 50-100 µm in diameter. These synchronous transients last 4-8 sec, appearing without any clear temporal relation to one another. Groups occur in both tangential and coronal slices, in visual and somatosensory cortices, and in all cortical layers, being more frequent in the upper layers. In tangential slices, groups of co-active cells tile the cortex without significant overlap. Groups are present at birth, and remain similar in size and properties throughout the first postnatal week.

To explore possible relationships between co-active groups and patterns of thalamic innervation, we combined Ca^{2+} imaging with fluorescent anterograde labelling of the "barrel field" in slices of somatosensory cortex. Rhodamine was injected in the Ventrobasal nucleus of the thalamus and the resulting pattern of "barrels" imaged in a tangential slice through layer 4. In preliminary experiments, groups, which are smaller than individual barrels, occur both inside and outside the barrels without any clear relationship to them.

In numerous cases, groups were observed at identical locations several minutes apart. This, combined with the lack of overlap with neighbouring groups, suggests that they may represent modular units in the developing brain.

585.3

INTRACELLULAR STUDY OF VISUAL RESPONSE PROPERTIES AND OSCILLATORY BEHAVIOR OF KITTEN AREA 17 NEURONS AT THE PEAK OF THE CRITICAL PERIOD.

D. DEBANNE*, V. BRINGUIER*, D. SHULZ*, A. BARANYI & Y. FREGNAC. (Spon:A.Baranyi) Lab. de Neurobiologie et Neuropharmacologie du Développement Université Paris XI, 91405 Orsay Cedex, FRANCE

Intracellular recording techniques were used *in vivo* in anesthetized (Altesine) and paralyzed (Flaxedil) kittens to study the physiological properties, visually evoked PSP's underlying functional selectivity, and oscillatory behavior of visual cortical neurons.

77 cells have been recorded intracellularly (10 to 110 min.) in 7 to 15 week-old kittens, with 70 MΩ glass micropipettes filled with K+methyl-sulfate 2 M. Stability of recordings was improved by minimal craniotomy (1 to 2 mm), bilateral pneumothorax and eventually cystema drainage.

1) The membrane potential (-63 +/- 7 mV), spike amplitude (54 +/- 11 mV), and membrane resistance (25 +/- 9 MΩ) were similar to those usually found in adult visual cortex. However, the rather high proportion of bursting neurons which exhibit Ca2+ spikes (28 %) contrasts with their relative low representation in *in vitro* slices of kittens of the same age (Frégnac et al., 1990).

2) "Simple" (n=24) and "complex" (n=19) cells were visually characterized before and during impalement with static and dynamic stimuli. Most of the recorded simple cells exhibit an EPSP-IPSP sequence in response to the extinction of the stimulus in the ON subzone, and to the presentation of the stimulus in the OFF subzone of the RF. This suggests that the spatial segregation of ON and OFF subzones in simple cells is achieved by selective inhibition applied to a "complex" excitatory connexion scheme.

3) 8 to 30 Hz subthreshold oscillations of the membrane potential were observed in many cases during dynamic stimulation and less often during static stimuli. In the absence of visual stimulation, depolarization of the same neurons did not elicit such subthreshold oscillatory patterns. These observations suggest that in most cells, oscillatory behavior in kitten visual cortex is not an intrinsic voltage dependant property but could be mediated by synaptic input of either cortical or subcortical origin.

POSTSYNAPTIC MEMBRANE POTENTIAL REGULATES POTENTIATION AND DEPRESSION OF VISUALLY EVOKED SYNAPTIC POTENTIALS IN KITTEN CORTICAL NEURONS RECORDED IN VIVO.

A. BARANYI, D. DEBANNE*, D. SHULZ* & Y. FREGNAC (SPON:Y. Frégnac) Lab. Neurobiologie du Développement, Univ. Paris XI, 91405 Orsay, FRANCE

It has been shown from in vivo extracellular recordings in cat visual cortex that changes in covariance between pre- and postsynaptic activity can potentiate or depress visual responses (Frégnac et al. Nature 333: 367, 1988). The effects of pairings between visual triggered PSP's with concomitant depolarizing or hyperpolarizing current injection in the target cell were studied to study the role of membrane potential of the postsynaptic neuron in inducing changes in synaptic efficacy.

77 stable intracellular recordings were made in area 17 of 7-15 week old kittens, using 2M K+methyl sulfate filled glass micropipettes. Visual compound PSP's in response to ON and OFF stimulation in 2 different positions of the receptive field (RF)were recorded in "simple" and "complex" cells of area 17. 24 cells were submitted to 40 low frequency (0.25 Hz) pairings where short depolarizing (S+, +1.5 to +4 nA) or hyperpolarizing pulses (S-, -1 to -4 nA) were associated to the presentation (ON) or extinction (OFF) of an optimal stiumulus in a given position of the RF. Visual responses averaged on 20-50 trials were compared before and after pairing at the same postsynaptic membrane potential. An increase (by more than 20%) of the paired compound PSP amplitude was observed in 8 out of the 12 S+ pairings. A decrease (by more than 20%) in PSP's amplitude was observed in 14 out of the 28 S- pairings. Input resistance and resting potential were usually unchanged. Spatial input specificity and temporal associativity were assessed by studying other parts of the receptive field which were stimulated out of phase from the paired position. After pairing, the distribution of the PSP's amplitude of the paired characteristic was significantly different from that of the unpaired characteristics in both positions of the RF.

These results demonstrate that the same visually evoked compound PSP can be potentiated or depressed by the temporal association of afferent stimulation with a local control of the membrane potential of the postsynaptic cell.

SIMULATING EXERIENCE-DEPENDENT DEVELOPMENT OF ORIENTATION AND SPATIAL FREQUENCY TUNING IN CAT V1 WITH A REVERSE-HEBB MODIFICATION RULE. R. E. Soodak, The Rockefeller University, New York, NY 10021.

In a previous report (*Visual Neurosci.*, **6**) I showed that a reverse-Hebb synaptic modification rule led to experience-dependent enhancement of orientation tuning in simulations of simple cells in cat V1. In this presentation I will show that the model can be extended to account for experience-dependent enhancement of spatial frequency tuning as well. All structural parameters of the model, i.e. positions of ganglion cells in the retinal mosaic, cortical magnification factor and spread of geniculate afferents tangential to the cortical surface, were constrained by published anatomical and physiological data. In the general form of the synaptic modification rule, fractional change in synaptic weight, dW/W, is defined as a time weighted average, by a function H(t'), of the input-output cross-correlation, $X_{io}(t')$, where t' is the time interval between input and output. For the case of sinusoidal stimuli, as employed in these simulations, fractional change in synaptic weight is determined by the amplitudes of the pre- and post-synaptic activities, and a cosine term containing the phases of the pre- and post-synaptic activities and a phase variable defined by the Fourier transform of H(t') at the input frequency. The reverse-Hebb condition results when this phase variable has a value of 180 deg. In simulated development, the increase in slope of the low spatial frequency cutoff is more pronounced than that of the high frequency cutoff, in agreement with the data of Derrington and Fuchs (*J. Physiol.*, **316**, 1-10).

NERVE GROWTH FACTOR-RECEPTOR-IMMUNO-REACTIVITY IN CENTRAL VISUAL PATHWAYS OF THE DEVELOPING RABBIT BRAIN. Dennis Rickman, Nicholas Brecha and David Dawbarn*. Depts of Anatomy & Cell Biology and Medicine, Jules Stein Eye Institute and CURE, UCLA School of Medicine and VAMC-Wadsworth, Los Angeles, CA; University of Bristol, U.K.

Nerve growth factor (NGF) is a target-derived molecule which is crucial for the survival of, and neurite outgrowth from, sympathetic and primary sensory neurons. Recently it has been suggested that NGF plays a role in the development and maintenance of neurons in the central nervous system as well. In the developing rabbit retina, the low- affinity NGF-receptor (NGF-R) appears to be expressed transiently in Muller cells during the perinatal period. Here, using a mouse monoclonal antibody (ME 20.4) to the human low-affinity NGF-R, we examined the expression of NGF-R-immunoreactivity (NGF-R-IR) in central visual pathways of the developing rabbit brain. At embryonic day 25 and postnatal days 5, 7 and 10, NGF-R-IR was observed in the optic tract, the lateral geniculate nucleus of the thalamus, the nucleus of the optic tract, and the superficial (retinorecipient) layers of the superior colliculus. In addition, NGF-R-IR was observed in the medial and dorsal terminal nuclei of the accessory optic tract. No NGF-R-IR was observed in these central visual nuclei in the adult rabbit brain. These results suggest that NGF-R is expressed transiently during the perinatal period and may play a role in the innervation of central visual targets.

NGF PREVENTS THE EFFECTS OF MONOCULAR DEPRIVATION. N. Berardi, G. Carmignoto, L. Domenici, V. Parisi*, T. Pizzorusso* and L. Maffei Neurofisiologia (CNR) and Scuola Normale Superiore, Pisa, 56100, Italy.

Monocular deprivation (MD) during the critical period of mammalian visual cortex development shifts the ocular dominance (OD) distribution of visual cortical neurons towards the non deprived eye. This effect is ascribed to competition between the thalamic afferents. We tested the hypotesis that this competition is for a neurotrophic factor such as NGF by assessing whether an exogenous supply of NGF could prevent MD effects. 20 hooded rats were monocularly deprived for one month from eye opening. 7 rats were left untreated, 9 rats were treated with ßNGF (intraventricular injections, 2 µl, 1-1.6 µg/µl), 4 rats were treated with cytochrome c. We found that in NGF treated rats the OD distribution in area 17 is similar to that in normal adults. By contrast MD shifts the OD distribution both in untreated and in cytochrome c treated rats. NGF treatment does not affect such spontaneous discharge and selectivity for stimulus parameters of cortical cells. We conclude that NGF prevents the effects of MD in the rat visual cortex.

585.8

EVIDENCE FOR A ROLE OF NGF IN NEURONAL PLASTICITY OF THE CAT VISUAL SYSTEM. G. Carmignoto, R. Canella*, P. Candeo* and M.C. Comelli* Fidia Research Laboratories, 35031 Abano Terme (PD), Italy.

Monocular deprivation in kittens causes the almost total loss of excitability of visual cortical neurons by stimulation of the deprived eye. We report that intraventricular administration of NGF through a cannula-mini-pump system in kittens subjected to monocular deprivation for 15 days prevents, virtually completely, the shift of ocular dominance of area 17 neurons toward the open eye. Conventional single unit recordings show that in NGF-treated animals (n=3; 208 cells) 57.1±12.1% of recorded neurons in area 17 were binocularly responsive compared to 9.6±0.6% and 6.3±1.7% in kittens treated with cytochrome c (n=3; 172 cells) or untreated (n=3; 148 cells), respectively. Receptive field properties of neurons in NGF-treated kittens did not show any abnormalities. Autoradiographic experiments utilizing ^{125}I-NGF are in progress to detect the possible presence of NGF binding sites in visual system-related nuclei. A specific role of NGF on visual cortical plasticity is proposed.

ORIENTATION AND DIRECTION SENSITIVE CELLS IN THE LGND AND STRIATE CORTEX OF DARK REARED CATS. Audie G. Leventhal, Kirk G. Thompson, Yifeng Zhou, Steven J. Ault Anat. Dept., Univ. of Utah Sch. of Med., Salt Lake City, UT 84132

LGNd and striate cortical (area 17) cells of cats reared in darkness from birth were studied quantitatively using gratings, bars, and spots generated under computer control. Statistical tests designed specifically to analyze orientation and direction were employed. These procedures revealed a higher percentage of orientation and direction selective cortical cells in dark reared cats than reported previously and provide evidence that dark rearing does not affect these properties of LGNd cells.

In dark reared animals, the orientation and direction sensitivity of LGNd relay cells and area 17 cells did not differ quantitatively or qualitatively. Most LGNd cells and cortical cells were orientation sensitive, 79% and 71% respectively, and many were also direction sensitive, 36% and 46% respectively. Dark reared area 17 cells exhibited mean orientation and direction biases of .17 and .11, respectively compared with mean values of .19 and .10, respectively for LGNd cells. Also, in both the LGNd and in area 17, cells were more selective when the test stimuli were gratings rather than bars and, in both areas cells exhibited clearer direction and orientation sensitivity when tested with relatively low and high spatial frequency gratings, respectively. The orientation and direction sensitive responses of LGNd cells were two times stronger and three times less variable than those of cortical cells.

Our results indicate that innate, subcortical orientation and direction sensitivity coupled with early visual experience contribute to the high degree of selectivity found normally in visual cortex.

585.10

RECOVERY FROM THE EFFECTS OF EARLY BINOCULAR DEPRIVATION IN THE CAT STRIATE CORTEX. S. V. Szapiel and T. N. Wiesel, Laboratory of Neurobiology, The Rockefeller University, N.Y., N. Y. 10021.

The effects of 3 months of binocular visual deprivation at birth by eyelid suture followed by opening of one eye and 3 months of recovery, were studied in the striate cortex of 6 cats by extracellular, single-unit recordings and in one animal also by optical recording of intrinsic signals. A total of 253 cells were recorded in anesthetized and paralyzed animals and their receptive field properties were analyzed using oriented stimuli. The majority of cells (65%) were driven solely by the opened eye and only 5% solely by the closed eye. This indicates a significant shift in eye preference associated with the recovery period, since as previously shown (Hubel and Wiesel, 1965) at 3 months after binocular deprivation without recovery, there is an equal number of monocular cells dominated by either eye. Analysis of orientation tuning in the current study revealed that 38% of all cells (96/253) exhibited normal orientation tuning, similar to a finding of 40% in the Hubel and Wiesel study. Of the remaining cells in their study, 27% were non-drivable and 32% were unoriented whereas, we found few cells which could not be driven, and a large number of poorly oriented or unoriented cells. This suggests that the high proportion of non-drivable cells found before recovery now seem to be drivable but show poor or no orientation specificity. These results may indicate that at least partial recovery of visual function is possible after the critical period. (Supported by NIH grants EY00305 and EY05253).

585.11

ACTIVITY-DEPENDENT PRUNING OF LONG-RANGE TANGENTIAL CONNECTIONS IN AREA 17 OF STRABISMIC CATS. Siegrid Löwel and Wolf Singer. Max-Planck-Institut für Hirnforschung, Deutschordenstr. 46, D-6000 Frankfurt 71, F.R.G.

A prominent feature of visual cortical circuitry is the system of long-range horizontal connections. These develop postnatally and acquire their selectivity through a pruning process. We examined whether this pruning is influenced by visual experience and in particular whether it is affected by the decorrelation of neuronal responses as it occurs with strabismus. In 4 cats, divergent strabismus was induced surgically at the age of 2-3 weeks. At age 2-3 months, intrinsic cortical connections were labelled with fluorescent tracers and ocular dominance (OD) columns were visualized using 2-DG autoradiography. Regions of increased 2-DG uptake extended in a columnar fashion through all cortical layers and formed a pattern similar to the OD-system seen in layer IV after intraocular injections of [^{3}H]proline. Clusters of retrogradely labelled cells extended up to 5mm from the injection site. Comparison of the two patterns in flat-mount sections revealed that labelled cells were predominantly confined to regions of the same OD as the respective injection sites, indicating that in strabismic cats the tangential fibers interconnect preferentially columns with the same OD. In normally reared cats, tangential connections were not confined to 2-DG territories labelled after monocular stimulation. These data suggest that 1) pruning of tangential connections is influenced by visual experience and 2) selection criterion for the stabilization of pathways is the correlation of activity in interconnected elements.

585.12

REMAPPING OF THE PROJECTION OF THE VISUAL FIELD ON THE SUPERIOR COLLICULUS AFTER NEONATAL ROTATIONAL SQUINT IN THE WALLABY (*MACROPUS EUGENII*). R.F. Mark, L.R. Marotte* and X.-M. Sheng. *
Centre for Visual Science, Developmental Neurobiology Group, Research School of Biological Sciences,Australian National University, Canberra ACT 2601, Australia.

For a short period after the eyes open different parts of the mammalian visual system are variably dependent upon visual experience for their normal development. Abnormal experience such as neonatal squint (misalignment of the eyes) produces changes in the receptive field properties of neurones of the cerebral cortex. The superior colliculus is not so susceptible.

In 7 wallaby pouch young one eye was surgically rotated about the visual axis just prior to eye opening. The animals were grown to maturity and maps made by electrophysiology of the projection of the visual field of each eye upon the contralateral superior coiliculus. In 3 additional mature animals a similar rotation was performed after anaesthesia immediately prior to mapping. In this latter group the projection of the visual field was as would be expected from the degree of rotation. In all of the early rotation group the projection of the visual field was distorted towards a complicated map in which elevation was in accord with eye rotation but azimuth was represented in the original orientation on the colliculus. This may indicate some developmental compensation in the colliculus towards restoring spatially correct vision from the misaligned eye.

NEUROBIOLOGY OF AFFECTIVE ILLNESS AND RELATED DISORDERS

586.1

REDUCED TYROSINE HYDROXYLASE IMMUNO-REACTIVITY IN LOCUS COERULEUS OF SUICIDE VICTIMS A. Biegon , Lawrence Berkeley Laboratory, Univ. of California, Berkeley, CA 94720

As part of a search for presynaptic noradrenergic markers in suicide and depression, we have investigated the fate of noradrenaline synthetising enzymes in suicide victims. Antibodies against tyrosine hydroxylase (TH), the rate limiting enzyme in norepinephrine synthesis, and dopaminre beta hydroxylase (DBH), the last enzyme in the synthesis, were used for immunohistochemical stainimg of human brain locus coeruleus sections obtained postmortem. Brains of 6 suicide victims and 6 age- and sex matched controls were obtained from the medical examiners' office. All subjects were drug- and neuropathology free at time of death and had no psychiatric history (controls) or none besides depression (suicide victims). Sections (40µ) were cut on a whole body cryostat, thaw mounted onto glass slides and postfixed in 10%formalin prior to staining. Mean cell number, cell density and immunreactivity (stain density) over individual cells (~100cells/subject) were quantified by a computerized image analysis system. Mean TH stain density, in optical density x 100 units, was significantly lower in the suicides (controls: 28.8±6.8, suicides: 19.9±5.8, $p<0.025$, Student's t-test for paired values). There was no significant difference between suicides and controls in DBH immunoreactivity , mean cell size or mean cell density. The results suggest that a presynaptic noradrenergic deficit does indeed exist in suicides, expressed as reduced levels of TH in the locus coeruleus.

586.2

BINDING TO SEROTONIN UPTAKE SITES IN PREFRONTAL AND TEMPORAL CORTEX OF SUICIDE VICTIMS. R.A. Henteleff, V. Arango and J.J. Mann. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

We have previously reported increased postsynaptic 5-HT$_2$ binding in the prefrontal cortex of suicide victims (*Arch. Gen. Psychiatry, 43:954-9, 1986; Arch. Gen. Psychiatry, 47:1038-47, 1990).* Conflicting reports exist in the literature as to whether binding to the serotonin transporter on serotonin nerve terminals is reduced in brain cortical regions of suicide victims. Using the selective radioligand ^{3}H-paroxetine, we sought to determine whether binding is altered in membrane homogenates from the prefrontal cortex (Brodmann area 9, PFC) and the temporal pole (Brodmann area 38, TC) of suicide victims compared to controls. All cases had negative toxicological screens. Subjects were matched for postmortem delay, age, gender, and where possible race (PFC N = 11 pairs; TC N = 7 pairs). P$_2$ pellets (5 mg/tube) were preincubated (30 min, 23°C) in 50 mM Tris-HCl buffer, pH 7.4 and then incubated (60 min, 23°C) in same buffer containing 120 mM NaCl, 5 mM KCl and 6 concentrations of ^{3}H-paroxetine (0.1-3.2 nM). Nonspecific binding was determined by 10 µM sertraline. In the suicide group binding was significantly reduced in the PFC (93.1 ± 12.3 *vs.* 150.8 ± 33.3 fmol/mg protein, $p = 0.026$) but not in the TC (127.2 ± 11.5 *vs.* 153.3 ± 23.7 fmol/mg protein, $p > 0.05$). K_D did not differ between groups in either area. Binding in both groups was positively correlated with age in TC ($r = 0.69$, $p = 0.007$, N = 14). A negative correlation with postmortem delay (range 7 to 22 hours) was found in TC of both groups ($r = -0.53$, $p = 0.05$, N = 14). We conclude that 5-HT uptake sites are reduced in the PFC but not in the TC of suicide victims, consistent with the hypothesis that there is a serotonergic deficiency associated with suicide. (Supported by PHS grants MH40210 and MH46745.)

586.3

QUANTITATIVE AUTORADIOGRAPHY OF 5-HT$_{1A}$ BINDING IN SUICIDE. V. Arango, W.E. Miller, M.L. Miller, M.D. Underwood, R.W. Smith and J.J. Mann. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

We have previously reported increased 5-HT$_2$ binding in the prefrontal cortex of suicide victims. Several subtypes of 5-HT$_1$ receptors have now been identified in human brain including the 5-HT$_{1A}$ site which appears to be involved in the actions of certain psychotropic agents. Using quantitative autoradiography we sought to determine whether 5-HT$_{1A}$ binding is altered in the brain of suicide victims by studying five Brodmann areas (11, 24, 8, 9 and 46) in the frontal cortex of suicide victims and controls, with negative toxicological screens. Subjects were matched for postmortem delay, age and gender (N = 10 pairs). Slide-mounted coronal sections (20µm) from the right hemicerebrum were incubated with 2nM ^{3}H-8-OH-DPAT and nonspecific binding determined by 1µM 5-HT. Sertraline blocked binding to 5-HT uptake sites. Tissue sections were exposed to Ultrofilm for 8 weeks and analyzed using a PC-based image analysis system (Imaging Research, Inc). 5-HT$_{1A}$ receptor distribution across cortical layers was similar in both groups forming five isodensity bands corresponding to layer I, layer II, outer layer III, layers III-IV, and layers V-VI. The gyrus had a higher level of binding than the sulcus. Layer II had the highest level of binding, approximately sixfold that of layers III-IV, which had the lowest. The suicide group differed from the control group in only one of the five brain areas. In the sulcus of area 46, layer II had 29% more 5-HT$_{1A}$ binding in the suicide group (Suicide: 31.1 ± 4.1 fmol/mg tissue; Control: 26.6 ± 4.2 fmol/mg tissue; $p < 0.05$). The binding was positively correlated with age ($r = 0.44$ to 0.66; $p = 0.003$ to 0.05) but not with postmortem delay. Females had greater 5-HT$_{1A}$ binding than males. We conclude that 5-HT$_{1A}$ binding is increased in some brain regions of suicide victims. Further studies should investigate other brain areas and other 5-HT$_1$ receptor subtypes and control for the effects of age and gender. (Supported by PHS grants MH40210 and MH46745.)

586.4

REDUCED PLATELET [^{3}H]-PAROXETINE AND [^{3}H]-IMIPRAMINE BINDING IN MAJOR DEPRESSION. C.B. Nemeroff, D.L. Knight, and K.R.R. Krishnan. Depts. Psychiat. & Pharmacol., Duke Univ. Med. Ctr. Durham, NC 27710

Considerable evidence has accumulated to implicate serotonergic neuronal dysfunction in the pathophysiology of major depression. One such line of evidence is the reduction in the density of binding sites for [^{3}H]-imipramine ([^{3}H]-IMI), a marker of the presynaptic 5HT uptake site, in postmortem brain tissue and platelets of patients with major depression. However, not all investigators have confirmed the reduction in [^{3}H]-IMI binding site density in drug-free depressed patients. This may be at least partly due to the fact that [^{3}H]-IMI is not the ideal ligand to label the presynaptic 5HT transporter as it binds to a variety of other neurotransmitter receptors. For all of these reasons we have used a very selective 5HT uptake inhibitor, [^{3}H]-paroxetine ([^{3}H]-PAR), to label the 5HT transporter to study the platelet binding kinetics of the 5HT transporter in drug-free depressed patients and age- and sex-matched controls. In the same platelet samples, we also measured [^{3}H]-IMI binding. Seven concentrations of [^{3}H]-IMI and [^{3}H]-PAR were used in these experiments and Scatchard analysis of these data were performed. The diagnostic groups studied were: (1) young normal controls, n=14, (<50 yrs); (2) elderly normal controls, n=14 (>60 yrs); (3) young major depression, n=14 (<50 yrs); (4) elderly major depression, n=14 (<60 yrs.) The number (Bmax) of high affinity binding sites for both [^{3}H]-PAR and [^{3}H]-IMI was significantly reduced in the depressed patients when compared to their age-matched controls. No change in Kd was observed. In addition, there was a significant correlation between the Bmax for [^{3}H]-PAR and [^{3}H]-IMI ($p < 0.005$). These findings represent the first study in which both [^{3}H]-PAR and [^{3}H]-IMI binding was measured in identical platelet samples. The results support a role for 5HT systems in the pathophysiology of depression. (Supported by NIMH MH-40159).

THE FOUR-ARM MAZE: AN IMPROVED MODEL FOR OBSESSIVE-COMPULSIVE DISORDER? E. Yadin and C. Thompson*. Department of Psychiatry, The Medical College of Pennsylvania, Philadelphia, PA 19129, USA.

The sensitivity of the traditional spontaneous alternation paradigm to serotonergic manipulation has been previously demonstrated. The present study used a modification of the spontaneous alternation task, the four-arm maze, as an improved model for the repetitive nature and indecisiveness seen in obsessive-compulsive disorder (OCD) in humans. Food-deprived rats were run in a black Plexiglas maze with 4 identical arms, equipped with white end-panels. All arms were baited with a small amount of chocolate milk. Each rat was placed in the center and allowed to explore the maze until 12 arm entries were completed (or a maximum time of 10 min). Chocolate milk was replenished after each choice. The percent of repeated arm entry patterns was recorded as well as the latency to complete 12 entries. After a stable baseline of arm entries was achieved the effects of manipulating the serotonergic system were tested.

Both the nonselective 5-HT agonist 5-MeODMT (1.25 mg/kg) and the more selective 5-HT_{1A} agonist 8-OH-DPAT (2 mg/kg) disrupted alternation patterns in the 4-arm maze, a change that was reversed by the nonselective antagonist methiothepin (0.1 mg/kg). A course of chronic treatment (2x5 mg/kg for 21 days) with the selective 5-HT uptake blocking agent fluoxetine had a protective effect on the 5-MeODMT-induced disruption of alternation behavior, whereas chronic treatment with the benzodiazepine chlordiazepoxide did not.

THE PHOSPHOLIPID THEORY OF DEPRESSION: IMPLICATIONS FOR TRH FUNCTION IN CNS. J. R. Hibbeln* and A. Sattin. DVA Sepulveda-UCLA Medical Center, Sepulveda, CA 91343-2099.

Many confirmed biological findings in depressed patients not explained by amine theories are compatible with increased activities of phospholipase A_2 (PLA_2; Hibbeln *et al, Biol. Psychiat.*, 25: 945, 1989). By altering membrane phospholipid composition and fluidity diverse enzymes and regulatory proteins may be affected. The theory explains depression-related altered activity of Na-K-ATPase, β_2- and α_2-adrenergic receptors, MAO, uptake of NE and 5-HT, and imipramine binding. PLA_2 reduction of tyrosine and tryptophan hydroxylase activity is consistent with amine theories. The theory explains the antidepressant effects of tricyclic antidepressants, Li^+, electroconvulsive shock (ECS) and some other antimanic agents. PLA_2 activation may reduce the binding of TRH and cortisol to their respective ligands, explaining the reduced responses to TRH and dexamethasone seen in many depressed patients. ECS activates phospholipase C→ arachidonic acid→ PGE_2 (prolonged elevation), an anticonvulsant which inhibits PLA_2. Reduced PLA_2 activity might increase TRH receptor efficacy in CNS (as in pituitary) wherein TRH synthesis and release are also augmented, in hippocampus, after ECS (Knoblach *et al, Abstr. Soc. Neurosci.*, 16: 1098, 1990). This apparent concerted augmentation of TRH function might be opposed by receptor down-regulation but the functional resultant remains unknown. Both ECS and TRH are anticonvulsant. These interactions are believed to contribute to the uniquely antidepressant properties of Electroconvulsive Treatment which is also anticonvulsant in humans.[suppt: DVA Res. Svc.]

ELEVATED CEREBRAL CORTEX G_s-ALPHA IMMUNOREACTIVITY IN BIPOLAR AFFECTIVE DISORDER. L.T. Young, P.P. Li, S.J. Kish, K.P. Siu* and J.J. Warsh. Clarke Institute of Psychiatry, Toronto, Canada, M5T 1R8.

Evidence implicating postreceptor disturbances in affective disorders, including bipolar affective disorder (BAD), together with the recent observations that lithium acts on the coupling of neuroreceptors to effector responses at the guanine nucleotide binding (G)-protein level suggest that abnormalities in G-protein function may occur in BAD. To test the hypothesis that G-protein levels are altered in brain of BAD patients we estimated the relative abundance of G-protein subunits in postmortem brain obtained from patients (N=7) who had been diagnosed with BAD (confirmed by chart review) and age and sex-matched controls (N=7). G-protein subunit immunoreactivities were determined in membranes prepared from postmortem prefrontal cortex (Brodman's area 10) using SDS-PAGE and immunoblotting with specific polyclonal antisera against specific G-protein subunits: $G_{s\alpha}$, $G_{i(1\&2)\alpha}$, $G_{o\alpha}$ and G_{β}. Immunoreactive bands were detected by enhanced chemiluminescence and quantitated by laser densitometry. Brain samples from BAD and matched control subjects were processed in a yoked design on the same blots to control for intrablot assay variation. Prefrontal cortical $G_{s\alpha}$ subunit (52 kDa species) immunoreactivity was significantly elevated (34%, p=.01) in BAD subjects compared with age and sex-matched controls. In contrast, no significant differences were found in the other G-protein subunits measured. Significantly increased (>80%, p<.05) mean $G_{s\alpha}$ immunoreactivity was also found in occipital cortex but not in cerebellum (22 %) obtained from the same subjects. On the basis that increased $G_{s\alpha}$ immunoreactivity reflects increased $G_{s\alpha}$ subunit concentration, and that increased levels may enhance functional responses to receptor activation, the present findings suggest that disturbances in G_s-mediated signal transduction may be involved in the pathophysiology of BAD.

GABA BLOCKADE IN THE REGION OF THE DORSOMEDIAL HYPOTHALAMUS (DMH) OF RATS: A POSSIBLE MODEL FOR PANIC ATTACKS. A. Shekhar, Dept. of Psychiatry, Indiana Univ. Med. Ctr. Indianapolis, IN 46202.

Blocking GABA neurotransmission in the region of the DMH of rats elicits a constellation of responses which include increases in heart rate (HR), respiratory rate (RR), blood pressure (BP), locomotor agitation, aversive responses and "anxiety" similar to severe anxiety states like panic attacks in humans. The present study was aimed at testing if this response can be blocked by treatment with standard human anti-panic drugs like imipramine. Rats were implanted with bilateral microinjection cannulae in the DMH and arterial and venous catheters. Rats were then randomized to either daily placebo injections or imipramine (15 mg/kg) injections intraperitoneally for 7 days. All treatments were double-blind and the physiological responses to BMI injection (25 ng/250 nl) into the DMH were recorded at baseline and on days 2, 7 and 10. The BMI response was almost completely blocked by systemic imipramine while the placebo treatment had no significant effect. These results support the hypothesis that GABA blockade in the DMH may be a model for severe anxiety states. (Supported by R29 MH45362-02).

PYRITHIAMINE-INDUCED THIAMINE DEFICIENCY RESULTS IN DECREASED Ca^{2+}-DEPENDENT RELEASE OF GLUTAMATE FROM RAT HIPPOCAMPAL SLICES. O. Le*, M. Héroux and R.F. Butterworth, Lab. of Neurochemistry, André-Viallet Clin. Res. Center, Hôpital St-Luc (Univ. of Montreal), Montreal, Quebec, Canada H2X 3J4.

Pyrithiamine-induced thiamine deficiency encephalopathy results in decreased brain glutamate content (Butterworth and Héroux, J. Neurochem. 52, 1079, 1989). In order to evaluate the effects of thiamine deficiency on the release of neurotransmitter glutamate, electrically-stimulated release of glutamate was studied in superfused hippocampal slices from symptomatic pyrithiamine-treated rats as well as in pair-fed controls. Stimulation-evoked release of glutamate was reduced by 42% ($p<0.02$) in the presence of 1.2 mM Ca^{2+}. These changes were accompanied by parallel decreases of activity of the thiamine-dependent enzyme α-ketoglutarate dehydrogenase (αKGDH) in hippocampi from symptomatic animals. These findings suggest an effect of thiamine deficiency on the glutamate content of nerve terminals in the CNS. Such decreases could result from decreased synthesis of neurotransmitter glutamate as a consequence of diminished activities of αKGDH. Glutamatergic dysfunction could play an important role in the pathogenesis of thiamine-deficiency encephalopathy (Supported by grants from MRC Canada and ABMRF).

DOES DOPAMINE ACTIVATE POTASSIUM CHANNELS OF MULLER CELLS? F.A.M. de-Azeredo and M.F.Ribeiro*,Laboratorio de Biociencias, Depto de Neurobiologia, Universidade Federal Fluminense, Caixa Postal 100229, Niteroi, RJ, 24000, Brazil.

In the retina, during spreading depression (SD), large spatial buffering K+ currents have been predicted to occur where the Muller cells are well suited to transfer K+ from the retina to the vitreous humor and the extracellular space. Recently, Karwoski,Lu and Newman (Science,244:578,1989) have reported that Ba2+ block K+ channels of Muller cells reducing the release of this ion to the vitreous humor during light stimulation. We then tested the action of Ba2+ on the velocity of propagation (VP) of SD and its influence on the the effect of a dopamine D1 agonist, SKF 38393. SD can be mechanically elicited at the isolated eye cup preparation of the chick retina and the wave followed with a stereomicroscope. VP is very sensitive to changes in the composition of the superfusate and it can measured based on the time elapsed between two parallel lines located at the ocular which correspond to 2 mm at the preparation. When SKF 38393 (10 uM) is added to the superfusate there is a significant increase in VP which is inhibited by SCH 23390,a D1 antagonist. VP also returns to control levels when the eye cup is superfused with normal physiological solution (PS). However, if the preparation is superfused with SKF 38393 after being initially bathed with Ba2+ (50 uM) no significant increase in VP is observed. Ba2+ when added at the bathing fluid at the begginning of the superfusion does not change the VP and if does the effect seems to be very slow. Returning to superfusate the retina with PS no residual effect of Ba2+ is observed. We suggest that Muller cell has a D1 dopamine receptor which regulates K+ channels responsible for the spatial buffering of this ion in the retina.

SUBSTANCE P, SOMATOSTATIN AND MET-ENKEPHALIN REGULATE THE SAME K- CHANNEL IN CULTURED NORADRENERGIC NEURONS FROM THE LOCUS COERULEUS. *B.Velimirovic, K.Koyano, S.Nakajima and Y.Nakajima. Dept. of Anat. and Cell Biol. and Dept. of Pharmacol., Univ. of Illinois, College of Medicine at Chicago, Chicago, IL 60612.*

We reported that substance P (SP) excites noradrenergic neurons of the locus coeruleus by suppressing a K-conductance (Koyano et al.,Biophysical J. 59:391A,1991), whereas somatostatin (SOM) or methionine enkephalin (MENK) inhibits them by enhancing a K-conductance (Inoue et al.,J. Physiol. 407:177,1988; North et al.,Proc.Natl.Acad.Sci.USA 84:5487,1987). All these K-conductances showed inwardly rectifying properties. The SP response and SOM (or MENK) response seem to be mediated through different G proteins. We performed experiments to determine whether the same K-channel molecule is modulated by SP and by SOM (or MENK). The whole-cell patch clamp technique was used on cultured rat locus coeruleus neurons. Application of SP during a SOM (or MENK) response produced a larger conductance reduction than when SP was applied alone. In some neurons SP alone did not cause an obvious response, yet, SP was able to abolish the K-conductance that was induced by SOM or MENK. When SOM (or MENK) was applied soon after SP application, SOM (or MENK) induced a smaller conductance increase than when it was applied alone. Similar results were obtained in neurons preloaded with GTPγS. These results indicate that it is the same inwardly rectifying K-channel molecule which is responding (closing or opening) to SP and to SOM (or MENK). The SP action that closes the K-channel seems to be stronger than the SOM (or MENK) action that opens it. Supported by PHS grants AG06093 and DA05701.

Hormonal Regulation of K^+ Channels in Human T Lymphocytes. L.C. Schlichter*, P.A. Pahapill* and P.S. Pennefather, Department of Physiology, University of Toronto, Ontario, Canada, M5S 1A8.

In cell-attached patch-clamp recordings of intact human T cells we found voltage-activated K^+ channels in about 60% of patches. The I-V relation was inwardly rectifying and had a slope conductance of 9.4 pS to 23.8 pS. From the reversal potentials under various ionic gradients the cell resting potential was -51 $\pm$ 1 mV in normal NaCl saline and about 0 mV when the bath contained 150 mM KCl saline. Ensemble currents constructed from single channel recordings showed sigmoid kinetics of current activation and a monoexponential decay phase. These kinetics were well fitted by a Hodgkin-Huxley type n^4j kinetic model with time constants very similar to the whole-cell current of disrupted cells. K^+ channel activity at the resting potential increased about 10 fold when the temperature was raised from 22° to 30°C and the single-channel conductance increased. This voltage-dependent K^+ channel was inhibited by a rise in internal Ca^{2+} concentration produced by mitogens or ionomycin in the presence of external Ca^{2+}. Several agents that raise cyclic AMP levels in T lymphocytes caused an increase in K^+ channel activity in cell-attached patches (8BrcAMP, dbcAMP, cpt cAMP, forskolin, isoproterenol, isobutyl methyl xanthine, histamine and prostaglandin E_2). The cAMP-analogues had no effect on intracellular Ca^{2+}, as measured by Fluo-3 fluorescence. Supported by grants from MRC and NCIC (Canada).

STIMULATION OF ATP-SENSITIVE K^+ CHANNEL ACTIVITY BY ADP IN EXCISED PATCHES FROM CULTURED MOUSE PANCREATIC B-CELLS. W.F. Hopkins and D.L. Cook*, Depts. of Physiology/Biophysics and Medicine, Univ. of Washington and VA Medical Center, Seattle, WA 98108.

ATP and ADP are known to compete in regulating ATP-sensitive potassium channels (K(ATP)) in insulin-secreting cells, yet little is known about the receptor mechanisms for this effect. We have obtained concentration-response data for ADP on K(ATP) channel activity in excised, inside-out patches from cultured adult mouse B-cells. At millimolar concentrations, ADP inhibited K(ATP) channel activity, as has been described (Cook and Hales, 1984). Furthermore, we found that 10 mM ADP inhibited channel activity by 94 $\pm$ 3% (sem, N=7 patches) suggesting that it is a full rather than partial agonist for inhibition of K(ATP) channel activity. At micromolar concentrations, however, ADP stimulated K(ATP) channel activity in the absence of ATP. ADP (100 μM) enhanced channel activity by 221 $\pm$ 82% (N=15), while 10 μM ADP stimulated channel activity by 19 $\pm$ 7% (N=6). The stimulatory effect of ADP did not run-down with repeated applications, and was not mimicked by the non-hydrolyzable ADP analogue, ADP-ß-S (100 μM). In 20% of patches in which K(ATP) channels were blockable by 10 mM ADP, the excitatory effect of 100 μM ADP was not seen. These results suggest that ADP competes with ATP by binding to an ADP-site which opens the channel while ATP (and high concentrations of ADP) binds to a separate site which closes the channel. This competition may be the basis for channel regulation by ADP levels in the 10-100 μM range thought to exist in cells.

GLYBURIDE-SENSITIVE K^+ CHANNELS IN CULTURED RAT HIPPOCAMPAL NEURONS: ACTIVATION BY CROMAKALIM AND ENERGY DEPLETING CONDITIONS. D.M. Politi and M.A. Rogawski. Neuronal Excitability Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892.

Previous studies in our laboratory have shown that cromakalim activates a tetraethylammonium-sensitive K^+ current in cultured embryonic rat hippocampal neurons. This phenomenon was further characterized using whole-cell voltage-clamp and single channel recording techniques. Glyburide (1-25 μM), an antagonist of ATP-dependent K^+ channels, produced a depression of the cromakalim-activated current, but did not affect resting or voltage-activated K^+ current in the absence of cromakalim. Exposure of the cells to energy depleting conditions [oligomycin (0.24 μg/ml) and 2-deoxy-D-glucose (10 mM)] also activated an outward current. Single channel recordings in the cell-attached configuration showed that cromakalim (100 μM) stimulated the opening of flickery single channels having a unitary conductance of ~26 pS and a prolonged burst duration (mean open time ~131 ms); similar channel openings were observed in patches from cells exposed to energy-depleting conditions. Preliminary studies with inside-out patches showed currents with a conductance of 26 pS in physiological solutions and 50 pS in symmetrical K^+ solutions; these channels are being further characterized for ATP sensitivity. Nevertheless, the observation that cromakalim and energy depleting conditions activate the same glyburide-sensitive channel supports the concept that the K^+ channels whose opening is stimulated by cromakalim are of the ATP-sensitive type.

Ca^{2+}-dependence of I_D in hippocampal pyramidal neurons. K.Krnjević,[1] V. Crépel* and Y. Ben-Ari. INSERM U29, Hôpital Port-Royal, 75014 , Paris, France and [1]Anaesthesia Research Dept., McGill University, Montréal, H3G 1Y6, Canada.

A fast-activating, slowly inactivating K current, which is generated by depolarizing pulses from a relatively negative membrane potential (< -60mV), was first identified (and named I_D) by Storm (1988, Nature 336:379). As originally described, I_D was insensitive to TEA, but was readily blocked by low concentrations of 4-AP (30 μM). Its persistence in the presence of 200 μM Cd^{2+} led to the conclusion that I_D is not Ca^{2+}-activated.

In experiments on CA3 pyramidal cells, in slices (from Wistar rats) kept submerged at 33° and in the presence of tetrodotoxin, we have repeatedly recorded a current having the characteristics of I_D: a very slowly decaying (time constant > 1s) outward current, evoked either by depolarizing pulses from V_H ~ -80mV, or more often as an off-current following large hyperpolarizing pulses from V_H ~ -50mV. Also in agreement with Storm (1988), this current was largely abolished by 30-40 μM 4-AP, but not by 1-10 mM TEA.

However, when the superfusing medium was changed to a low Ca^{2+} (0.2-0.5 mM) solution - with 0.2-0.5 mM Cd^{2+} or 4 mM Mn^{2+} added - we consistently observed a major suppression of I_D, comparable to the effect produced by 30 μM 4-AP. Neither 4-AP nor low Ca^{2+} solutions produced any major depression of the early transient outward current (I_A).

The sensitivity of I_D to Ca-deficient solutions (with Cd^{2+} or Mn^{2+} added) suggests that Ca^{2+} does play a role in the generation of I_D.

THE DIVALENT CATION BINDING SITE ON POTASSIUM CHANNELS. T. Begenisich and S. Spires. Department of Physiology, University of Rochester, Rochester, NY 14642.

External divalent cations produce significant alteration in the kinetics of delayed rectifier potassium channels of squid (*Loligo pealei*) axons. The activation of the K channel current is slowed and the rate of deactivation is increased. These effects are produced by the physiologically important cation, Ca^{++}, but the kinetic alterations are more pronounced when Zn ions are used as probes. The modifications produced by low concentrations (2 to 5 mM) of Zn ions are qualitatively similar to but much larger than those produced by much larger concentrations of Ca ions. At normal pH values (7.5), these Zn concentrations produce a 3- to 4-fold slowing of the activation time constant: much too large to be consistent with any reasonable voltage shift produced by interaction with surface charges. The pK for hydrogen ion inhibition of the Zn effects is near 7.4. Treatment of the cells with histidine- or sulfhydryl-modifying reagents does not alter the Zn effects, however, Zn ions have almost no effect on the K channel kinetics after treatment with the amino-specific reagent trinitrobenzenesulfonicacid (TNBS). The external divalent cation binding site on the squid delayed rectifier K channel probably contains one or more important amino residues: lysine or a terminal amine.

To see if these properties of the divalent cation binding site are characteristics general to K channels we performed experiments on a K channel with a known sequence: the A-type K channel from Shaker *Drosophila*. The baculovirus vector expression system was used to insert A-type K channels from Shaker into the cell membranes of caterpillar cells (*Spodoptera frugiperda*). The caterpillar cells have no endogenous ion channels. Electrophysiologic studies were performed using standard voltage-clamp techniques. The interaction of Zn with the divalent cation binding site of the Shaker A-type channel produces some effects similar to those seen in squid: the activation and inactivation kinetics are slowed by Zn; and hydrogen ions compete with Zn ions for the binding site. However, there is a major difference: treatment of the cell with TNBS does not render the Zn inactive.

IMMATURE RAT MYOMETRIAL CELLS AND HUMAN UTERINE FIBROID CELLS IN CULTURE PREDOMINANTLY EXPRESS TRANSIENT OUTWARD K^+ CURRENTS

S.D. Erulkar, J. Ludmir*, B. Ger* and R. DePino*. Depts. of Pharmacol. and Obstet. and Gynecol., Univ. of Penn. Med. School, Philadelphia, PA 19104.

Whole cell patch clamp techniques were used to record K^+ currents from myometrial cells isolated from immature (23-25 days postpartum) rat uterus and human myomatous (fibroid) tissue. IRB approval has been given.

Immature rat myometrial cells responded to depolarizing voltage steps from holding potentials of -80mV to +30mV with fast outward currents that decayed with two time constants (6.87±0.98 (sem) msec and 75.77±15.92 msec (n=18)). When the animals are injected prior to cell isolation with 17β-estradiol, the probability of expression of these currents is reduced from 78.6% (n=42) in control cells to 29.8% (n=47) in cells from estrogen-injected animals. Cells from progesterone-injected animals showed little difference from control.

Fast transient outward currents have also been recorded predominantly in human myomatous cells (56.5%, n=23 in myomatous cells compared to 5.9%, n=34 in normal cells). Human myomatous cells, therefore, may reflect dedifferentiated myometrial cells.

ANALYSIS OF CURRENT-VOLTAGE RELATIONS OF THE DELAYED RECTIFIER CHANNEL (I_K) BY THE SINGLE VACANCY MODEL OF ION TRANSLOCATION. J.R. Clay. NIH, Bethesda, MD 20892

The I_K channel in squid axons is known to be multiply occupied by 2 or 3 K ions, based on tracer flux measurements (Begenisich and DeWeer, 1980; JGP **76**:83). The other measure of ion permeation is the net flux, i.e., the current-voltage (IV) relation, which for I_K is well described by the Goldman-Hodgkin-Katz flux equation (Clay, 1984; Biophys J **45**:481). Inferences about multiple occupancy cannot be drawn from the net flux. Nevertheless, the IV and tracer flux results taken together are suggestive of a paradox inasmuch as the GHK equation is based on independent movement of ions across the membrane. The paradox can be resolved by the single vacancy model of ion translocation in which the channel is either fully saturated or has, at most, a single vacancy (Kohler and Heckmann, 1979; JTB **79**:381; Schumaker and MacKinnon, 1990; Biophys J **58**:975). A 3 binding site version of the model in the low ionic strength (physiological) regime gives IV relations for I_K which are essentially equivalent to GHK for $-200 < V < 200$ mV. The model is also consistent with the tracer flux results. In other words, the resolution to the paradox is that the I_K channel may indeed obey the independence principle for ion vacancies rather than ion occupancies.

Evidence for the presence of a slowly inactivating potassium current in prefrontal pyramidal cells.

C. Hammond and F. Crepel, laboratoire de Neurobiologie, université Paris XI, URA CNRS 1121, Orsay, France.

Potassium currents of the I_A family, such as I_D, have been described in a variety of preparations and particularly in hippocampus (Storm '88). Their characteristics make them good candidates for participating in delayed integration of synaptic currents. We present here data showing the presence of a I_D-like current in pyramidal cells of the rat prefrontal cingular cortex, using an in vitro slice preparation and single electrode voltage clamp as well as current clamp recordings. Pyramidal cells were identified as regular firing or bursting cells and their morphology was studied following intracellular injection of Lucifer yellow. In a fraction of these cells, a depolarizing pulse to -40mV from a holding potential of -95mV evoked the fast outward I_A current followed by a slower outward current which declined during the 3s pulse. This slower outward current was inactivated at a holding potential of -60 mV. The voltage and time dependences of its activation and inactivation kinetics together with its sensitivity to low concentrations (40 μM) of 4-AP, suggest that this slowly inactivating outward current is similar to I_D.

Characterization of the biosynthesis, processing and assembly of the drk1 K^+ channel α-peptide expressed in *Xenopus* oocytes and mammalian cells. J. S. Trimmer and A. Kleinklaus Dept. of Biochemistry & Cell Biology, SUNY Stony Brook, Stony Brook, NY 11794-5215.

The biochemical properties of the drk1 K^+ channel α-peptide expressed from the cloned cDNA (Frech et al., Nature 340:642, 1989) in transient expression systems have been studied. Using two distinct anti-drk1 sera, we have identified the drk1 α-peptide in *Xenopus* oocytes microinjected with drk1 cRNA that express large, voltage-sensitive K^+ currents identical to those previously reported. This drk1 α-peptide is a broad band centered at an M_r of 118 kD; the endogenous drk1 α-peptide in adult rat brain has an M_r of 130 kD. The drk1 cDNA sequence predicts a core peptide of 95.3 kD, thus the drk1 α-peptide in both *Xenopus* oocytes and rat brain has undergone extensive postranslational modification. To investigate these processes in mammalian cells, the drk1 α-peptide was expressed in a human embryonic kidney cell line and was found to have an M_r=113 kD. Pulse chase studies in these cells show a conversion of the initial M_r = 95 kD product to the final M_r = 113 kD product. These results show that post-translational processing makes a significant contribution to the final structure of the drk1 α-peptide in rat brain, *Xenopus* oocytes and cell lines.

XENOPUS MYOCYTES DIFFERENTIATING IN VITRO EXPRESS SEVERAL CLASSES OF TRANSIENT POTASSIUM CHANNELS. U. Ernsberger and N.C. Spitzer. Department of Biology, UCSD, La Jolla, CA 92093.

Currents through voltage-dependent potassium channels affect the amplitude and duration of action potentials and consequently regulate events which are secondary to membrane depolarization. Thus, developmental changes of potassium currents play an essential role in the differentiation of excitable cells. We are investigating the development of transient, A-like potassium channels in *Xenopus* myocytes differentiating in vitro. Single channel recordings are performed in the cell-attached and inside-out configuration of the patch clamp technique with myocytes grown in the presence of other differentiating cell types, in particular neurons.

Channels were identified by their steady-state inactivation, which was complete at -60 mV in the inside-out configuration. Upon depolarization from more negative holding potentials, the channels were activated, showing faster activation with more depolarized potentials. Inactivation during depolarizing voltage steps was indicated by the decay of ensemble average currents. In some patches the current decay could be best fitted with 2 exponentials, in others with one. Time constants of current decay were variable, but clustered around 10 and 200 ms in the inside-out as well as the cell-attached configuration. However, in excised patches, channels giving rise to rapidly decaying currents were observed less often than in cell-attached patches. These results indicate the presence of several classes of transient potassium channels.

The density of channels in cell-attached patches of myocyte surface membrane increased during the first day in vitro. However, activation times and decays of ensemble average currents were similar for channels at both developmental stages. The lack of change of kinetic properties suggests that an increase in the density of potassium channels rather than the expression of new classes of channels contributes to the developmental increase in density of transient potassium currents.

ACTIVATION OF DIFFERENT PROTEIN KINASE C ISOENZYMES IN IMMORTALIZED LHRH NEURONS. W.C.Wetsel, H. Rivera*, and I. Merchenthaler. Lab. of Molecular and Integrative Neuroscience, NIEHS, Res. Tri. PK., NC 27709.

An immortalized, hypothalamic, neuronal cell line (GT1-7) has recently been developed which biosynthesizes and secretes LHRH (Mellon et al., Neuron 5:1, 1990). In vitro, LHRH nerve terminals in the median eminence are highly responsive to phorbol 12,13-dibutyrate (PDBu). The purpose of our study was to determine which protein kinase C (PKC) subspecies were present in the GT1-7 cells, whether these cells were responsive to PDBu, and which of the PKC subtypes were most susceptible to down-regulation following continuous stimulation with this agent. In order to determine the presence of the different PKC isoenzymes, polyclonal antisera specific for each of the 8 PKC subtypes were developed. Immunocytochemical and Western Blot analyses revealed that pKCα,-βI,-βII,-γ,-δ,-ε,-ε' and -ζ were present in the GT1-7 cells in different amounts. When PDBu (50 to 400 nM) was added to the media for 30 min, LHRH secretion was stimulated in a dose-response manner. Activation of secretion for 2 hours with 200 nM PDBu stimulated LHRH secretion 7.7-fold over that of an unstimulated control. At the same time, PKCα, -β_I, and -β_{II} were found to translocate from the cytosol to the membrane. Translocation of the other 5 PKC isoenzymes during the 2 hr period of stimulation was not readily apparent. These data indicate that LHRH secretion is rapidly stimulated by phorbol esters. In addition, these immortalized LHRH neurons contain at least 8 different isoforms of PKC and some of these species appear to be differentially reactive to PDBu. Our findings suggest that these 8 PKC isoenzymes may differentially participate in a variety of functions in LHRH neurons that may be critical for reproduction.

FURTHER STUDIES OF MODELS OF VASOPRESSIN SYNTHESIS. M.D. Fitzsimmons, M.M. Roberts, and A.G. Robinson. Dept of Endocrinology Univ. of Pittsburgh PA 15261.

Previously (*Neurosci Abs*, 20: 1143), we discussed the merits of mathematical models of vasopressin (AVP) synthesis based exclusively on one of three mechanisms (transcription, translation, or mRNA decay), concluding that a strictly transcriptional model best fit the available data with respect to the dynamics of pituitary AVP content and hypothalamic AVP mRNA levels. In order to prevent net changes in pituitary content, these models presume hormone synthesis is always just sufficient to replace released AVP. Subsequently, we have observed that young adult male rats synthesize considerably more than they release, with the difference reflected in a straight line, age-dependent pituitary AVP accumulation (elsewhere in this volume). This excess synthesis proceeds in spite of weight restriction but can be prevented by inducing hyponatremia.

By incorporating constant, age-dependent AVP synthesis into the transcriptional model (mRNA half-life=1.9 days), we have successfully accounted for three quantitative shortcomings of the original model. This modification accelerates the rate of pituitary AVP content recovery after chronic stimulation and explains why content recovers beyond baseline levels; both predictions are observed experimentally. This modification also explains the unexpectedly slow pituitary AVP recovery under hyponatremic conditions (which blocks the age-dependent synthesis). Finally, assuming that transcriptional mechanisms regulate both stimulated and age-dependent AVP synthesis, the modified transcriptional model predicts significantly lower peak mRNA levels (relative to baseline) resulting from chronic stimulation. These new predictions correspond much more closely to mRNA levels observed by us and others. The results from the modified transcriptional model suggest that AVP synthesis is controlled in response both to stimulation for release and to other, as yet uncharacterized age-dependent influences.

The transcriptional model has proved to be a valuable tool for designing experiments investigating AVP synthesis. In turn, these results have led to more realistic and quantitatively accurate models of neurohypophyseal regulation.

NEURAL PATHWAYS INVOLVED IN OSMOTICALLY-STIMULATED THIRST AND VASOPRESSIN SECRETION - A STUDY UTILISING C-FOS IMMUNOREACTIVITY AND NEURONAL TRACERS B.J. Oldfield, +R.J. Bicknell, D.K. Hards* and M.J. McKinley*. Howard Florey Institute, University of Melbourne, Parkville, Australia, 3052. +Institute of Animal Physiology and Genetic Research, Babraham, Cambridge, U.K.

In order to help delineate the neural circuitry subserving osmotically-stimulated thirst and vasopressin (AVP) secretion we have utilised elevated levels of C fos protein to identify neurons activated following iv infusion of hypertonic solutions. These studies have been combined with the retrograde labelling of neurons projecting to the supraoptic nucleus - a site responsible for the production of AVP. Twenty three Sprague Dawley rats were used and on day 1 all had femoral veins cannulated. Eight of these also had stereotaxically-placed, bilateral injections of 30nl of rhodamine-labelled microspheres into the supraoptic nuclei. Three days latter, 1.5 ml of either hypertonic (1.5 M) or isotonic (0.15 M) saline was infused iv over 10 minutes. After a further 90 minutes, all rats were perfused intracardially with 4% paraformaldehyde. Elevated levels of fos protein in the brain were detected immunocytochemically. In animals receiving the hypertonic stimulus, fos immunoreactivity was found in neurons of the lamina terminalis i.e., the subfornical organ (SFO), median preoptic nucleus (MnPO) and organum vasculosum lamina terminalis (OVLT) as well as in magnocellular neurons in the paraventricular and supraoptic nuclei. These areas were essentially free of immunoreactive neurons in control rats. In double labelling experiments, at least 20% of fos immunoreactive neurons in the SFO, MnPO, and OVLT projected to the supraoptic nuclei. These results taken together highlight the population of neurons in the forebrain which are responsive to osmotic challenges and the trajectory of some of their projections.

CHRONIC HYPONATREMIA PREVENTS SPROUTING OF OXYTOCINERGIC AXONS IN LONG-TERM PARAVENTRICULAR NUCLEUS (PVN) LESIONED RATS. J. Dohanics, G. E. Hoffman, and J. G. Verbalis, Depts. of Medicine and Physiology, University of Pittsburgh, Pittsburgh, PA 15261

Destruction of the PVN causes acute changes in hypothalamic morphology. Of these the most striking is the virtual disappearance of CRF-41 axons from the external zone of the median eminence (EZ-ME), accompanied by decreases of vasopressinergic (AVP) and oxytocinergic (OT) fibers in the internal zone of the median eminence (IZ-ME). However, 6 wks following PVN lesions, strong sprouting of OT, but not CRF-41 or AVP, fibers occurs in the EZ-ME. We investigated if similar sprouting also occurs in chronically hyponatremic rats following PVN lesions, since AVP and OT synthesis and secretion is inhibited in such rats. Hyponatremia was induced in adult male rats fed a liquid diet as their only food source and infused with DDAVP (5 ng/h) via subcutaneous osmotic minipumps. Immediately after implantation of the minipumps, PVN lesions were made using a triangle-shaped rotating knife. One wk or 6 wks after surgery rats were perfused and hypothalamic sections stained for AVP-neurophysin (AVP-NP) and OT-neurophysin (OT-NP) immunoreactivities. In normonatremic/sham-operated rats strong AVP-NP staining was present both in the EZ-ME and IZ-ME, while OT-NP staining was present only in the IZ-ME. One wk after PVN lesions both AVP-NP and OT-NP staining was virtually absent from the EZ-ME and reduced in the IZ-ME. As expected, 6 wks after PVN lesions the EZ-ME in normonatremic rats exhibited strong OT-NP immunoreactivity, while AVP-NP staining remained unchanged. However, no such increase in OT-NP staining occurred following PVN lesions in rats who were maintained hyponatremic for 6 wks following the lesions. These results suggest that chronic hyponatremia inhibits not only synthesis and secretion of AVP and OT, but also causes a more generalized decreased synthetic activity of magnocellular neurons which impairs cellular processes involved in cytoskeleton remodeling in response to PVN lesions.

EFFECTS OF DOPAMINE RECEPTOR AGONISTS UPON OXYTOCIN AND VASOPRESSIN SECRETION IN MONKEYS. J.A. Amico, S.M. Pomerantz, L.M. Layden*, and J.L. Cameron, Depts. of Medicine, Physiology, and Psychiatry, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Administration of the dopamine receptor agonist apomorphine (Apo) causes a dose-dependent increase in plasma oxytocin (OT) concentrations and dose-specific behavioral changes in monkeys (Soc Neurosci Abstr 20:471.8, 1142, 1990). To further explore the pharmacological mechanisms of Apo effects upon neurohypophysial hormone secretion, we administered graded doses of the respective D_1 and D_2 receptor agonists, CY 208-243 and LY 163502, to monkeys and monitored plasma concentrations of OT and vasopressin (AVP). Five female rhesus, 2 male rhesus and 2 male cynomolgus monkeys were implanted with chronic indwelling venous catheters and outfitted with standard jacket/tether/swivel systems to allow remote blood sampling. Blood samples were collected at 15 and 1 min prior to and at intervals 1 to 120 min after injection. Apo (50-400 μg/kg) and LY 163502 (10-100 μg/kg) elicited a dose-dependent stimulation of OT and AVP secretion. In contrast CY 208-243 (100-400 μg/kg) significantly increased OT and AVP secretion only at the 400 μg/kg dose. Low doses of Apo (50-100 μg/kg) and LY 163502 (10 μg/kg) elicited yawning and high doses of Apo (200-400 μg/kg) and LY 163502 (50-100 μg/kg) elicited stereotypy. No behavioral effects of Cy 208-243 (100-400 μg/kg) were observed. The magnitude of the secretory responses varied among animals, was similar in male and female monkeys, and was greater for AVP vs. OT. We conclude that Apo and LY 163502 elicit dose-related stimulation of OT and AVP secretion coupled with dose-specific behavioral changes in male and female monkeys. Apomorphine's effects upon OT and AVP secretion in primates may be mediated primarily by D_2 receptors.

588.6

RESPONSE OF THE MAGNOCELLULAR SYSTEM (MCS) TO HYPOVOLEMIA AND CHOLECYSTOKININ (CCK) DURING PREGNANCY AND LACTATION. E.Koehler*, G.McLemore*, J.Summy-Long, Dept. of Pharmacol., Hershey Med. Ctr., Penn.State Univ., Hershey, PA 17033

Oxytocin(OT) and vasopressin(VP) systems show a decreased sensitivity to osmotic stimulation during lactation(L). We examined further the responsiveness of the MCS to hypovolemia & CCK. Virgin(V),pregnant(d 20;P) & L(d 6) albino rats were injected s.c.(35ml/kg) with polyethylene glycol (PEG MW 20,000; 70-1200 mg/ml),4 hrs before killing to induce hypovolemia. In other studies, V, P & L rats were injected i.p.(4ml/kg) with CCK(100 ug/kg) 5 min before killing. Controls received isotonic saline (SAL),or no needle stick(NS). OT and VP were measured by RIA. During hypovolemia, the exponential relationship(linearized by log transformation) between volume depletion & plasma [OT] was different ($p<0.03$;partial F-tests) such that P>V>L whereas that for VP was unchanged(V=P=L). CCK increased plasma[OT] (pg/ml;NS vs SAL vs CCK)in V(9±1 & 9±1<35±4),P(10±1 & 12±1<26±3)& L(6±1 & 5±1<17±3). The OT response to CCK, however, was reduced in lactation(L<V & P, $p<0.01$ 2-way AOV).Plasma VP increased slightly after CCK (NS & SAL<CCK,$p<0.05$ 2-way AOV) but was not different among V,P & L rats. Thus,during lactation,the OT response to CCK, osmotic and hypovolemic stimuli is reduced, while late in pregnancy the OT system shows an enhanced response to hypovolemia.(Supported by grant # HD 25498).

OROPHARYNGEAL REGULATION OF WATER BALANCE IN POLYDIPSIC HYPONATREMIC SCHIZOPHRENICS.

M.B. Goldman, V.E. Ehrhardt*, G. L.Robertson*, R.C. Marks*, L. Blake*, D. Hedeker*, D.J. Luchins. Dept of Psychiatry, Univ. of Chicago, Chicago, IL 60637; Ill. St. Psych. Inst., Chicago, IL 60612.*

Objective: To assess oropharyngeal regulation of water balance in normals (Ns), and polydipsic schizophrenics with (PHSs) and without (PNSs) episodic hyponatremia.

Methods: Ns (n = 12) received two 2 hr 3% NaCl infusions (0.1 ml/Kg/min). 35" post-infusion each received either 10 ml/Kg water or nothing. Plasma vasopressin (pAVP), desire for water (DFW), and relevant stimuli were measured at 15,30,40,45,50,55,60,65 min. post-infusion. Matched PHSs (9) and PNSs (6) only ingested water post-infusion.

Results: pAVP dropped immediately in Ns following water (30"=4.8±.9 pg/ml, 40"=2.6±.7) vs nothing (30"=5.1±1.8, 40"= 5.1±2.3) prior to changes in stimuli. pAVP also fell immediately in both PHSs (30"=1.2±.8, 40"=.7±.3) and PNS (30"=3.1 ±1.9, 40"=1.6±1.2), and their responses resembled Ns. In contrast, desire for water dropped acutely in Ns (30"=1.9 +2.6 cups, 40"=1.3±2.2) and remained level; while PNSs had high basal DFW (5.6±1.7) which fell acutely (40"=1.8±2.1) but rapidly rebounded (55" 3.4 ±2.9). PHSs (30"1.8±2.6) showed no change over time.

Conclusions: Defects in oropharyngeal regulation of water balance are unlikely to account for our previously described defects in AVP regulation in PHSs; but may contribute to the possibly different etiologies of polydipsia in PHNs and PHSs. ENDOTOXIN REGULATION OF TRH AND CRH GENE EXPRESSION IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS (PVN) IS MEDIATED BY INTERLEUKIN-I.

I. Kakucska*, B. D. Clark* and R. M. Lechan. Dept. of Medicine, Div. of Endocrinology and Infectious Disease, New England Medical Center, Boston, MA O2111

Lipopolysacharide (LPS), a bacterial endotoxin, elevates the plasma concentration of ACTH and suppresses TSH release. Although the effect of LPS on ACTH secretion is thought to be mediated primarily by interleukin-I (IL-I) on hypothalamic CRH secretion, little is known about the mechanism by which TSH is suppressed. To determine whether IL-I could have a central action on TRH production and thereby mediate the effect of LPS on TSH, we studied male S.D. rats after either intraventricular (icv) injection of recombinant human IL-Iß (1-100 ng) or saline or systemic treatment with LPS (E coli 055:35, 25 µg/kg, ip) 30 minutes after an icv injection of saline or the interleukin-I receptor antagonist (IL-Ira, 250 µg). Brains were fixed six hours later by perfusion with 4% paraformaldehyde and coronal sections were processed for *in situ* hybridization histochemistry using ^{35}S-labelled antisense RNA probes for CRH and TRH mRNA. Autoradiographs of the PVN were analyzed under darkfield microscopy by computer image analysis. Intraventricular IL-I induced a marked increase in CRH mRNA by 294% ($p<0.05$) but significantly decreased TRH mRNA by 52% ($p<0.05$) at a dose of 1 ng. LPS also increased CRH mRNA by 216% ($p<0.05$) and reduced TRH mRNA by 58% ($p<0.05$) compared to saline controls. This response could be inhibited (CRH) or prevented (TRH) by pretreatment with IL-Ira whereas the inhibitor alone had no significant effect. These studies indicate that IL-I is capable of exerting a central action on both CRH and TRH gene expression in the PVN and may mediate the effects of LPS on anterior pituitary secretion by acting through central IL-I receptors.

588.9

EFFECTS OF DIETARY PROTEIN INTAKE AND AMINO ACIDS ON TSH SECRETION.

I.Gutberlet*, D.Hellhammer, J.Beyer*, H.Lehnert. Dept. of Internal Medicine-Endocrinology, University of Mainz, 6500 Mainz and Dept. of Physiological Psychology, University of Trier, 5500 Trier, FRG.

In previous studies we have investigated the effects of meals and precursor amino acids on prolactin and cortisol secretion. In this study, we analyzed the effects of dietary protein and amino acids on basal and stimulated TSH secretion in normal volunteers. TSH levels were determined in seven different experimental situations: administration of placebo, tyrsoine (5 and 10 g orally), tryptophan (5 g orally), prazosin (1 mg orally), prazosin and 10 g tyrosine combined and administration of an amino acid mixture (15 g, with 5.7 g of large neutral amino acids competing with tyrosine for blood brain barrier transport). TSH secretion was determined 90 minutes following nutriant/drug intake and following TRH stimulation (200µg). Basal levels of TSH were significantly elevated following the combined administration of l-tyrosine and the amino acid mixture (2.66 +/- 1.75 vs. 1.09 +/- 0.82 µE/ml). The TRH-stimulated TSH secretion was again most dramatically increased following l-tyrsoine plus amino acid mixture (14.05 vs. 7.40 µE/ml). Tyrsoine alone also significantly augmented TSH release following TRH stimulation. Prazosin administration did not alter TSH secretion. These data indicate that dietary protein intake enhances TSH secretion, most likely through tyrosine or its derivatives stimulating TRH release. In addition, other constituents of protein, such as phenylalanine, appear to contribute.

REGULATION OF DBI PEPTIDE AND MITOCHONDRIAL BENZODIAZEPINE RECEPTOR (MBR) EXPRESSION BY ADRENOCORTICOTROPIN (ACTH) IN RAT ADRENAL GLAND

S. Cavallaro, M. Massotti**, I. Mocchetti*, K. Krueger, S. Casalotti, A. Guidotti and E. Costa. F.G.I.N.; *Dept. of Anatomy and Cell Biology, Georgetown University School of Medicine, Washington, DC 20007; **ISS, Rome, Italy.

MBR and DBI are highly enriched in steroidogenic cells such as adrenocortical, Leydig, and glial cells. In these cells DBI acts on MBR and stimulates steroidogenesis (Endocrino.: 123: 2075, 1988; Papadopoulos V., Neurosc. Abst., 1991). We have investigated whether ACTH regulates MBR and DBI expression in rat adrenal gland, testes, cerebellum and C6-2B glioma cells. Seven days after hypophysectomy the amount of DBI-like immunoreactivity (DBI-LI) and DBI mRNA in rat adrenal glands decreased by almost 80%. Similarly binding of the specific MBR ligand, [^{3}H]4'Cl-diazepam, to crude adrenal homogenates, and MBR mRNA, decreased by 60-70%. The administration of ACTH, (15U/Kg, twice daily) reduced the decrease in adrenal DBI-LI, DBI mRNA, MBR binding sites and MBR mRNA caused by hypophysectomy. The regulation of DBI and MBR expression by ACTH specifically occurred in adrenal gland and was absent in testes and cerebellum. Addition of 10^{-7}M ACTH to 6C-2B glioma cells cultured in serum-free medium failed to change the content of DBI-LI and DBI mRNA.

588.11

THE ENDOGENOUS POLYPEPTIDE DBI AND OTHER DRUG LIGANDS OF MITOCHONDRIAL BENZODIAZEPINE RECEPTORS (MBR) STIMULATE STEROIDOGENESIS BY C6-2B GLIOMA CELL MITOCHONDRIA.

V. Papadopoulos*, P. Guarneri, K.E. Krueger, A. Guidotti, and E. Costa. *Dept. of Anatomy and Cell Biology and F.G.I.N., Georgetown University School of Medicine, Washington, DC 20007.

Mitochondrial preparations of C6-2B cells convert 22(R)-hydroxycholesterol to pregnenolone by a mechanism blocked by aminoglutethimide. Immunoblotting confirmed the presence in C6-2B cell extracts and intact mitochondria of relatively high levels of cytochrome P-450 cholesterol side-chain cleavage enzyme. Furthermore, MBR and diazepam binding inhibitor (DBI), that are operative in mitochondrial steroidogenesis regulation are abundant in C6-2B cells. Pregnenolone synthesis in C6-2B mitochondria is stimulated by nanomolar concentrations of Ro5-4864, PK11195, or DBI as well as by triacontadecaneuropeptide (TTN; DBI_{17-50}) a naturally occurring processing product of DBI. In contrast, clonazepam and the octadecaneuropeptide (ODN; DBI_{33-50}) which exhibit a low affinity for MBR were ineffective in stimulating pregnenolone synthesis. Thus C6-2B cells exhibit a significant steroidogenic activity that appears to involve MBR and DBI as endogenous regulators.

588.12

PURIFICATION AND CHARACTERIZATION OF DIAZEPAM BINDING INHIBITOR (DBI) PROCESSING PRODUCTS.

E. Slobodyansky, C. Eskalante and B. Martin* Fidia-Georgetown Institute for the Neurosciences, Georgetown University, Washington, D.C. 20007, *NIMH, Bethesda, MD 20892

DBI is a protein with multiple biological actions that is located in selected neurons, glia, steroidogenic cells, and in pancreatic islets. DBI tryptic digestion yields several fragments including an 18 amino acid residue, ODN (DBI_{33-50}). Synthetic ODN a) elicits a flumazenil sensitive proconflict response in rats; b) inhibits glucose induced insulin secretion from pancreatic islets; c) displaces [^{3}H] flumazenil but not [^{3}H] 4'chlorodiazepam from brain crude synaptic membrane prepara-tions. Reverse phase HPLC of rat brain extract reveals several immunoreactive peaks with ODN antibodies (ODN-IR). The most abundant of them, TTN (DBI_{17-50}) was purified (Slobodyansky, J. Neurochem. 53:1276, 1989). It elicits a set of DBI responses different from those of ODN. a) It displaces [^{3}H] 4' chlorodiazepam but not [^{3}H] flumazenil; b) it elicits mitochondrial steroidogenesis; c) in rats it produces a flumazenil resistant proconflict response. Another ODN-IR peak emerges with the same HPLC retention time as ODN. This peptide was purified by reverse phase HPLC and by a Sepharose-ODN antibody column. The sequence of the first 15 amino acids is identical to that of ODN but the carboxy terminus sequence is not completed.

SHAGGY-ZESTE WHITE 3 AND THE DEVELOPMENT OF ECTOPIC SENSILLA IN THE WING OF *DROSOPHILA*.
S.S.Blair. Dept. Zoology, U. Wisconsin, Madison, WI 53706.

Mitotic recombination coupled with enhancer-trap marking techniques were used to follow the development of ectopic sensilla induced by the mutation *shaggy/zeste white 3* during wing development in *Drosophila*. This gene codes for a serine-threonine kinase thought to be involved in the transduction of positional signaling during the specification of sensilla in the developing imaginal discs. The mutation acted to induce the development of ectopic sensillar precursors during the period of normal sensillar development, as marked using sensillar specific enhancer trap lines. The timing of the appearance of these ectopic precursors depended upon the position of the clone, being markedly delayed in the posterior of the wing. Neurons were formed by ectopic precursors and almost always extended axons in the normal direction, despite their abnormal positions. Localized expression of *achaete-scute* genes are thought to play a primary role in the positioning of sensilla. Interestingly, ectopic sensilla were formed outside the regions of normal *achaete-scute* expression. Using marked clones, it is apparent that the mutation can induce ectopic anti-*achaete* immunoreactivity. Thus, *shaggy/zeste white 3* may play a role in the localization of *achaete-scute* expression in the developing wing.

FUNCTION OF THE *DROSOPHILA SINGLE-MINDED* GENE AND DEVELOPMENT OF THE CNS MIDLINE.
J. R. Nambu, J. O. Lewis*, and S. T. Crews. Dept. of Biology, Molecular Biology Institute, UCLA, Los Angeles, CA 90024.

The midline nerve cells of the *Drosophila* embryo possess unique anatomical, developmental, and morphological properties; they play an important role both in the formation and function of the CNS. We are characterizing the development and function of these cells via molecular, genetic, and cell biological approaches. The *single-minded* (*sim*) gene is specifically expressed in the midline cells and we have shown via genetic analyses that *sim* is required for proper midline cell differentiation and activation of "downstream" midline genes. It has been determined that *sim* is a member of the basic-helix-loop-helix family of transcription factors, strongly suggesting that *sim* acts to directly regulate midline gene transcription. We investigated the effect of ectopic *sim* expression on midline development and gene expression by generating transformant flies in which the expression of *sim* protein is driven by the hsp70 promoter. This heat-shock/*sim* construct allows us to induce ectopic *sim* expression during different developmental stages. Early induction of *sim* protein results in defective nervous system formation as well as ectopic expression of midline genes. The data indicate that *sim* is capable of directing other cell types to exhibit midline-like properties and may function as a master regulator of the midline lineage.

THREE CLASSES OF NEURON IN THE MEDIAN NEUROBLAST LINEAGE OF THE GRASSHOPPER.
K.J. Thompson and M.V.S. Siegler. Dept. of Biology, Emory Univ., Atlanta, GA 30322

Our concern is the manner in which neuronal diversity is generated within a family of lineally related neurons. Each segmental ganglion of the grasshopper Schistocerca contains a midline group of neurons that are bilaterally symmetrical in their branching and that innervate bilaterally symmetrical targets. The neurons are unpaired (by contrast with motor neurons, for example) and arise during embryogenesis from segmentally iterated unpaired median neuroblasts (MNBs). The midline group of the third thoracic ganglion contains about 100 neurons. We show that the group is divided into three distinct classes of neuron [Thompson & Siegler (1991) J. Comp. Neurol. 305:659]. Based on differences in the shape and position among neurons of the different classes, we predict that the classes are produced sequentially during embryogenesis, in the following order: 1) octopamine-containing efferent modulatory neurons; 2) GABA-immunoreactive spiking local interneurons with an auditory function; 3) GABA-immunoreactive spiking intersegmental interneurons with a role in flight. In ongoing studies we are determining the relative numbers of the different neuronal types within the population and the rate at which the MNB progeny are produced. This will allow us to predict when, given a sequential model, each of the neuronal classes arises during embryogenesis.

589.4

TEMPORAL CHANGES OF PRECURSOR CELL PATTERNS IN DORSAL ROOT GANGLIA (DRG) AND SYMPATHETIC GANGLIA (SG) OF THE QUAIL EMBRYO.
R. S. Duff*, C. J. Langtimm, M. K. Richardson and M. Sieber-Blum. Department of Cellular Biology and Anatomy, Medical College of Wisconsin, Milwaukee, Wisconsin 53226.

We have performed *in vitro* clonal analyses to elucidate changes in the temporal and spatial patterns of pluripotent and apparently committed precursor cells in DRG and SG. Previous *in vitro* clonal analysis of quail neural crest differentiation indicated that all sympathoadrenal cells and some sensory neurons originate from pluripotent neural crest cells (M. Sieber-Blum, Science **243**, 1608, 1989). Our present data suggest the following. 1) All four classes of pluripotent and apparently committed cells found in the migrating neural crest are also present in young DRG and SG. 2) The proportion of pluripotent cells decreases with progressing age of the embryo. 3) Both types of ganglia contain an at least bipotent, possibly "neurogenic", precursor that persists at least half-way through the incubation period, albeit at a 10-fold lower concentration in the SG than in the corresponding DRG. 4) There is a subset of early-differentiating sensory neurons in the DRG, explaining and confirming previous studies by us and others. These data support the notion that the life-span of pluripotent cells within the neural crest as well as in DRG and SG correlates well with the timing of proven and putative location-specific environmental cues influencing the ultimate phenotype generated by these pluripotent cells. Supported by USPHS grant HD21423 and a Research Grant from the Familial Dysautonomia Foundation (M. S-B.) and NIH Training Grant GMO 7892-09 (R.S.D.).

589.5

PARTIAL RESTRICTION IN THE DEVELOPMENTAL POTENTIAL OF LATE EMIGRATING AVIAN NEURAL CREST CELLS.
Kristin B. Artinger* and Marianne Bronner-Fraser. Developmental Biology Center, University of California, Irvine, Ca. 92717

Trunk neural crest cells migrate along two major pathways: (1) a ventral pathway whose cells form neurons, glia and chromaffin cells and (2) a dorsolateral pathway whose cells form melanocytes. Neural crest cells fill their derivatives in a ventral to dorsal order, with the last emigrating cells moving dorsolaterally (Serbedzija *et al.*, 1989, Develop. 106: 806). Here, we test whether late emigrating neural crest cells are more restricted in developmental potential than early migrating cells. In culture, early migrating ("young") neural crest cells differentiate into pigmented and catecholamine-containing cells, among other derivatives, by 7 days. "Older" neural crest cells were prepared from stage 20 - 21 embryos, when the last neural crest cells are emigrating from the neural tube. When "older" neural crest cells were cultured for 10 - 14 days, pigment cells were detected but no catecholamine-containing cells were found. Because the culture system may lack important differentiation factors, "older" neural crest cells were injected into young chick embryos during the early stages of neural crest migration (stages 16 - 18). Cells were labelled with the vital dye, DiI, prior to injection to aid in their visualization. Injected embryos were allowed to develop for 2 - 3 days. Embryos that were injected with "young" neural crest cells contained DiI-labelled catecholamine-positive cells. In contrast, no DiI-labelled catecholamine-positive cells were observed in embryos injected with "older" neural crest cells. These results suggest that late emigrating neural crest cells have a more restricted developmental potential than early migrating neural crest cells. (supported by USPHS HD-25138)

589.6

CLONAL PATTERNS OF NEURON PROLIFERATION AND DISPERSAL IN THE BRAIN STEM OF THE CHICKEN EMBRYO.
Sharon G. Hemond and Joel C. Glover, Inst. of Physiology, Univ. of Oslo, 0317 Oslo, Norway.

The purpose of this study was to determine the importance of lineage in the determination of neuronal phenotype in the brain stem of the chicken embryo. We used the recombinant retrovirus LZ10 to introduce the marker gene lacZ into single progenitor cells in the brainstem proliferative zone. The virus was pressure-injected into the fourth ventricle on embryonic day (E)2. On E4-5 or E9 the embryos were sacrificed, and the brain stems were fixed and reacted in wholemount to detect the lacZ gene product, β-galactosidase.

On E4-5, clusters of labelled cells were observed in wholemount, and their positions noted. They were then examined in transverse sections. On the basis of an adopted set of criteria, 83 such clusters were defined as clones. These were distributed to all rostrocaudal levels and mediolateral locations and contained from 1 to 29 cells (mean = 5). 79/83 clones extended radially from the ventricular zone (77 had ventricular attachment = 93%). 4/83 were non-radial but contained only a few (1 - 4) cells. 21 of the 79 radial clones included outlier cells. These clones were located predominantly in the lateral region.

On E9, 10 clusters that satisfied our criteria for classification as clones were observed after sectioning. They contained from 3 to 14 cells (mean = 8). 6/9 had cells or attachments in the ventricular zone. 2/9 were radial, 3/9 had a radial component with outliers, and 4/9 were non-radial. The degree of cell dispersal, as measured by mediolateral extent in cell diameters, was greater at E9 than at E4-5. Mapping cell positions shows that most of the E9 clones contribute to several different brainstem nuclei.

Neural progenitors appear to differ in their mitotic rates at these stages. Clonally-related cells are spatially restricted during early migration but disperse to contribute to different functional neuron groups later. This suggests that lineage relationships at these stages are not of primary importance in the determination of neuronal phenotype in the developing brain stem.

589.7

MULTIPLE RETROVIRAL VECTORS ARE USED TO STUDY CLONAL DISTRIBUTION IN THE CHICK RETINA. D. M. Fekete, J. Perez-Miguelsanz*, and C.L. Cepko. Department of Genetics, Harvard Medical School, Boston, MA 02115

Lineage analysis of mouse and Xenopus retina has shown that clonally-related cells form radially-arrayed, cohesive columns. We now report results from lineage analysis in the chick showing a different spatial distribution of clonally-related cells generated at early times in development. Three different replication-defective avian retroviruses are used in paired combinations to co-infect chick retinas between embryonic day 3 (E3) and E7. Retinas are harvested between E14-E19 and processed for the presence of the retrovirally-encoded protein products: ß-galactosidase or alkaline phosphatase are detected by enzyme histochemistry while viral gag protein is detected immunohistochemically. Clones derived from infections at E3 are arrayed as clusters of 5-50 radial columns that are separated by unlabelled cells. Each radial column is composed of 10-50 cells that are often flanked by individual early-born cells (horizontal, photoreceptor or ganglion cells). Clones in the central retina have fewer radial columns than clones in the periphery. The dispersed pattern formed by each clone is evident using all three retroviral vectors. Such a pattern is consistent with an initial period of tangential mixing (or migration) of progenitor cells followed by radial expansion of clones to form separate cohesive columns.

ARE GANGLION CELLS THE DEFAULT PHENOTYPE FOR RETINAL NEUROEPITHELIAL CELLS IN THE RAT? T. A. Reh and I. J. Kljavin†. University of Washington, Dept. of Biological Structure, Seattle WA, 98195 and †University of Calgary, Neurosciences Research Group, Calgary, Alta. Canada.

To determine the mechanisms that control the determination of cell phenotype in the developing central nervous system, we are using dissociated cell cultures of rodent retina. In this experiment, we asked whether the environment of a retinal neuroepithelial (NE) cell can influence its phenotype, by culturing rat retinal or cerebral cortical cells from different embryonic and postnatal ages at high density ($10^6/cm^2$) and plating 10-100 mouse retinal cells onto the rat monolayers. After three or four additional days of culture, the cells were fixed and the mouse neurons and glial were identified with monoclonal antibodies M2 and M6, respectively. We found that 82 % of the E11 or E12 mouse retinal cells, plated onto cerebral cortical monolayers, differentiated into ganglion cells, and none of these cells differentiated into rods. By contrast, when the same aged mouse cells were plated onto rat retinal cells only 27 % differentiated into ganglion cells and 18% differentiated into rods. These data indicate that the microenvironment can influence the commitment of the multipotent NE cells, and in the absence of these retinally derived microenvironmental cues, the NE cells differentiate into ganglion cells. NIH RO1 NS28308.

NONCOMPARTMENTAL CELL LINEAGE IN RAT NEOCORTEX: A STUDY USING A RETROVIRAL LIBRARY/PCR RESCUE TECHNIQUE. C. Walsh and C.L. Cepko, Dept. of Genetics, Harvard Med. Sch., Boston, MA.

Whereas cell lineage compartments correspond to patterned gene expression in the developing vertebrate hindbrain, developmental compartments in the forebrain have been elusive. We have addressed this question using a new technique which allows definition of clonal relationships regardless of the migration patterns of sibling cells.

A library of 95 retroviral vectors was made, all carrying the histochemical marker gene, lacZ. Each vector contained a unique, 30-600 bp fragment of genomic DNA, as a genetic "tag". This viral mixture was injected into the forebrain of fetal rats, to label cortical progenitor cells and their progeny. The brains of adult animals were then sectioned, reacted for ß-galactosidase, and the labeled cells plotted on drawings. Labeled cells were then removed from the tissue sections and processed using the polymerase chain reaction (PCR) to analyze the genetic tags. Sibling cells share the same tag, while cells in different clones essentially always contain distinct tags.

Clonally related cortical neurons varied widely in their degree of separation from one another. About 50% of multicellular clones formed clusters of 2-5 cells from 50-800µm across. These clusters, similar to the pattern previously described (Walsh and Cepko, 1988, Science 241:1342), cross functional subdivisions of the cortex such as "barrels" of the somatosensory cortex. Surprisingly, the other 50% of multicellular clones spread for 1 millimeter or more, with several clones crossing major cytoarchitectonic subdivisions of the neocortex. The most widespread clones covered more than half of the antero-posterior or medial-lateral dimensions of the neocortex. Thus, the neocortex shows no simple compartmental or segmental development. Furthermore, the control of some aspects of cell number and phenotype may be independent of later specification of the neocortex into cytoarchitectonic zones. VENTRICULAR ZONE HETEROGENEITY IN THE DEVELOPING RAT FOREBRAIN. S. E. Acklin and D. van der Kooy. Univ. Toronto, Toronto, Canada.

In the developing mammalian telencephalon there is evidence to suggest that some aspects of the fates of forebrain cells are predetermined while they are still proliferating in the ventricular zone (Krushel et al. 89, Soc. Neurosci. Abstr. 241.4; Fishell et al. 90, Devel. Biol.141,70-83; Barbe&Levitt, 91, J. Neurosci. **11**, 519-533). We hypothesized that such early predetermination might manifest itself in heterogeneous proliferation kinetics among individual cell lineages within the ventricular zone. In order to investigate cell cycle kinetics within individual cell lineages we devised a novel double labeling technique which combines retroviral identification of clonal populations within the ventricular zone with simultaneous radioactive labeling of all dividing cells. The retrovirus used (Psi 2 Bag alpha) introduces a histochemical marker gene directly into the genome of an infected progenitor cell; this marker is inherited undiluted by all the daughter cells and therefore serves to identify individual clones. The radioactive thymidine label is also taken up by all dividing cells, but then is successively diluted by half with every further division. By counting the number of silver grains (3H-thy) in all retrovirally labeled cells of a given clone it is possible to draw conclusions concerning (1) cell cycle kinetics (2) mode of proliferation (exponential vs steady state), and (3) cell death, for each clone analyzed. In our experiments the retroviral label was injected directly into the lateral ventricles of E 17 rat embryos in utero, and simultaneously the radioactive thymidine was administered systematically to the mother. After a survival time of 48 hours, serial sections through the embryonic rat forebrains were analyzed. Within the developing cerebral cortex, the results revealed a segregation into four spatially distinct proliferating cell populations. The individual populations differed in cell cycle kinetics, mode of proliferation as well as in the amount of cell death that occurred. The proliferative zone of the developing striatum shows similar differences in cell cycle characteristics among individual cell lineages, however the spatial segregation of the these different populations was not as prominent as in the cortex. We speculate that some aspects of the adult mammalian cortex might already be predetermined within the various proliferating cell populations in the embryonic ventricular zone.

CLUSTERS OF COUPLED CELLS IN THE VENTRICULAR ZONE OF NEOCORTEX J. L. Lo Turco and A. R. Kriegstein. Dept. of Neurology and Neurological Sciences, Stanford Univ. Sch. of Med., Stanford, CA 94305.

Cell to cell interactions may participate in determining the fates of cells in the central nervous system. We have used whole-cell patch clamp recordings to characterize physiological interactions between cells in the fetal rat neocortex. Cells in the ventricular zone had much lower input resistances and generated much larger currents in response to GABA than did neurons in the cortical plate. When Lucifer Yellow was injected into ventricular zone cells we found that large numbers of cells (15-90) were dye-coupled into radially oriented columns, whereas neurons in the cortical plate were not dye-coupled. To determine the nature of this coupling, both HRP and Lucifer Yellow were simulataneously injected into cells. While Lucifer Yellow filled a large number of cells, HRP staining was confined to single cells. In addition, manipulations that uncouple gap junctions (halothane, acidification, and arachidonic acid) increased the apparent resistance of ventricular zone cells. These experiments indicate that cells in the ventricular zone are coupled together by gap junction channels.

The number of cells in clusters decreases as neurogenesis proceeds in rat cortex (E15=60±20, E17=32±12, E19=7±4 cells), and mitotic figures at the ventricular surface are not coupled to cells in clusters. This suggests that during proliferation cells are first coupled to clusters and then uncouple before they enter M-phase. We are currently exploring with Brdu when during development cells decide to uncouple from clusters. We have also begun to characterize how cell clusters respond to neurotransmitters that may be released into developing cortex. Cells in clusters depolarize upon the application of GABA, glutamate and norepinephrine. We conclude that proliferating cells in the ventricular zone interact directly with each other through gap junction channels and can respond to transmitters well before the formation of synapses.

GABAERGIC CORTICAL NEURONS EXPRESS THEIR TRANSMITTER PHENOTYPE DURING MIGRATION AND EARLY CORTICAL PLATE FORMATION IN DEVELOPING MONKEY. D.L. Meinecke, M.L. Schwartz, and P. Rakic. Section Neurobiology, Yale Sch. Med. New Haven, CT 06510.

Recent evidence suggests that the restriction of cell phenotype in the cerebrum may occur early in development before neurons attain their final destination. For example, the commitment of fetal neurons to projection or local circuit subclasses may occur prior to the completion of their migratory phase, since it has been shown that some of these cells have callosal axons (Schwartz et al. '91, PNAS: 88). Additionally, patch clamp analysis shows that some neurotransmitter receptors also emerge before postmitotic cells settle in their laminar positions (Lo Turco et al.'91, Science). Here we report the early expression of GABA in cells of the developing monkey telencephalon. GABA antisera were used to immunolabel frontal and occipital lobes at stages when cortical neurons are generated (embryonic ages E41-E90; birth is at E165). GABA positive cells were present in the cortical plate in both frontal and occipital lobes at all ages examined, including E41 when the cortical plate is as yet only 2-3 cell layers wide. GABA-containing neurons were also present in the ventricular and subplate zones, and some of these cells had ultrastructural features typical of migrating neurons. Since GABA is commonly associated with inhibitory local circuit neurons, the present results indicate that their phenotype is determined early in neurogenesis independent of prospective synaptic interactions, and before they reach their final positions. Supported by NIH grants.

INTRAMUSCULAR INJECTION OF WGA YIELDS SYSTEMIC DISTRIBUTION ADEQUATE FOR IMAGING OF AXONAL TRANSPORT IN INTACT ANIMALS. A. G. Filler, H. R. Winn*, L. E. Westrum, P. Sirrotta*, K. Krohn*, and T. W. Deacon§. Dept. Neurol. Surg. and Dept. Nuc. Med., Univ. of Wash., Seattle, WA 98195, and §Dept. Anthro., Harvard University, Cambridge, MA 02138.

To explore the possibility of PET or MR imaging of axonal transport in humans, a series of preliminary biodistribution studies were undertaken in rats to learn whether tracer concentrations in nerve and among other tissues could achieve imageable relative distributions. The underlying principle is an extension of techniques in which retrograde transport from small intramuscular injections of wheat germ agglutinin (WGA) are used to selectively label and distinguish spinal cord neurons innervating closely juxtaposed muscles.

Concentrated [^{125}I]-WGA injected percutaneously into rat forearm or hindlimb muscle in various microliter quantities using methacrylate to seal the puncture site was allowed three to ten days to distribute after which animals were sacrificed, perfused, and 25 different tissues including blood, lymph nodes, liver, lung, muscle, ipsilateral and contralateral peripheral nerve, spinal root/dorsal ganglia, and various spinal cord segments were collected, weighed, and assayed in a gamma counter.

Excluding the injection site (as could be done in a clinical image) WGA concentrations (as counts per min./mg) in ipsilateral nerve and ganglia were up to five to ten times greater than that in any other tissue in the same animal when injection technique and dose were optimized. Spinal cord segment concentrations were greater than in any non-neural tissue except liver.

These results clearly show that biodistributions of axonal tracers can be achieved which may permit clinical imaging of phenomena involving axonal transport in humans if MR or PET dectectable labels can be delivered in adequate quantities. Direct application of axon transport imaging in the evaluation of nerve compression, spinal cord injury, and neuropathy as well as other reapplications of a variety of transport related basic neuroscience techniques into the clinical realm are possible.

IMPLEMENTATION OF AN ULTRAVIOLET (UV) LASER AS LIGHT SOURCE FOR FLUORESCENCE CONFOCAL SCANNING MICROSCOPY. Brun Ulfhake (1), Ulf Arvidsson (1), Kjell Carlsson (2) and Karin Mossberg (2). Department of Anatomy, Karolinska Institutet ,S-104 01 Stockholm (1), and Physics IV, The Royal Institute of Technology S-100 44 Stockholm (2), (Sweden)

We here describe the use of an UV laser as light source for confocal microscopy. We used a *Spectra-Physics 171-18* laser providing three lines in UV, namely *334, 351* and *364* nm . These lines can be used simultaneously or individually. With this instrument it is possible to use fluorophores not previously available for fluorescence confocal imaging as e.g. *Fluoro-Gold* and *AMCA* (7-amino-4-methyl coumarine-3-acetic acid). In this study we show confocal laser microscopical imaging of fluorescent motoneurons labeled by retrograde transport of Fluoro-Gold and AMCA- fluorescent axon terminals labeled with antiserum against various immunogenes. These two fluorophores may be recorded *simultaneously, or separately* by using filters that suppresses the emission of one of the fluorophores.

Measurements performed in reflected and fluorescent light indicated that the *resolution* along the optical axis *improved* by about *25%* when UV light (351nm) is used instead of visible light (514 nm). This figure is close to that expected on theoretical basis. There are, however, also serious problems related to the use of UV-light. Firstly, the objectives must be selected based on their *UV transmission properties*. Secondly, *chromatic aberration* may cause a substantial *focal shift* between illuminating and emitted light. Remedies for these technical problems are presented and discussed.

590.3

DYNAMIC INTRACELLULAR CALCIUM COMPARTMENTS: THREE DIMENSIONAL CONFOCAL MICROSCOPY OF FLO-3 IN PC12 CELLS. L.R. Mills and J.K.Stevens, Volume Investigation Lab. Playfair Neuroscience Unit,The Toronto Hospital, 399 Bathurst St. Toronto. ON Canada M5T 2S8

A confocal microscope (Biorad MRC-600) and an ICAR 80.8 Volume Investigation workstation were used to study the three dimensional distribution of the calcium indicator dye flo-3 in NGF activated PC12 cells. In addition to its expected cytoplasmic distribution flo-3 was also found to label the nucleus and a variety of subcellular organelles. Labelling with rhodamine 123 identified one class of organelle labelled by flo-3 as mitochondria, other organelles are as yet unidentified. In cells loaded with flo-3 in the presence of serum at 37 degrees, rest calcium levels were significantly higher in the mitochondria than in the cytoplasm: on average calcium levels in the cytoplasm were 74+8 nM (n=21 cells), compared to 129+11 nM (n=20 cells), in the mitochondria. Experimental perturbation of intracellular calcium levels using the calcium ionophore A23187 or removal of extracellular calcium indicate that flo-3 can act as a calcium indicator in all compartments examined. Furthermore, calcium dynamics appears to be different in different subcellular compartments.

590.4

IN-VIVO IMAGING OF INTRACELLULAR ION CONCENTRATIONS IN RAT BRAIN NEOCORTEX: A FEASIBILITY STUDY. U.Dirnagl, A. Villringer, A.Them*, G.Sixt*, K.M.Einhäupl*. Dept.of Neurology, University of Munich, 8000 Munich 70, F.R.G.

We tested the feasibility of in-vivo loading and imaging of brain cells in situ with ion-sensitive dyes. Anesthetized and ventilated Wistar rats were equipped with a closed cranial window (dura mater removed), and the brain surface was superfused with the pH-sensitive dyes BCECF-AM ($\lambda_{ex\text{-}max}$=488nm) and/or the Ca^{2+}-sensitive dye Calcium Crimson-AM ($\lambda_{ex\text{-}max}$=590nm; both dyes from Molecular Probes, 10 μM in artificial CSF). Loading and washout time was 30 minutes each, with a flow rate of 4ml/h. Images were generated using a confocal laser scanning microscope (CLSM, Biorad MRC-600) with an Ar/Kr-laser (488/568/ 647 nm) as a light source. Image formation was triggered to respiration. Leakage of dyes was assessed through the loss of intracellular signal over time and with spectro-fluorimetrical determination of dye concentrations in the outwash CSF. At the end of the experiment, calibration of intracellular pH (pH_i) was attempted by clamping pH_i to extracellular pH (pH_e) with iso-osmotic buffers titrated to pH 6 and 8 respectively (nigericin/high potassium method). Autofluorescence of the brain was low. On optical sections dye related signal was retrieved up to 200 μm beneath the cortical surface, single dye loaded cells could be visualized down to 50 μm. Double labelling allowed simultaneous imaging of pH_i and Ca^{2+} related signal. The rate of photobleaching was low, and leakage of the dyes was less than 15 % per hour. Motion artifacts and changes in brain geometry with experimental manipulations (f.e. clamping) impeded the accuracy of the measurements. In these experiments we have shown that 1) loading with AM-dye-esters, 2) CLSM imaging, and 3) pH_i/pH_e-clamping of brain cells in situ is feasible.

590.5

INTRINSIC OPTICAL IMAGING OF THE CAT DORSAL HIPPOCAMPUS FOLLOWING INTRAVENOUS COCAINE ADMINISTRATION R. M. Harper, D. M. Rector*, G. R. Poe*. Department of Anatomy and Cell Biology and the Interdepartmental Neuroscience Program, UCLA School of Medicine, Los Angeles, CA, 90024-1763.

Cocaine induces marked changes in neuronal discharge of limbic structures, including pronounced dimunition or cessation of firing in amygdala regions, an effect maintained for periods of 60-150 min. We wished to relate electrophysiological activity with local metabolic actions of cocaine, and thus assessed the time course of local metabolism in the dorsal hippocampus following intravenous cocaine delivery using a coherent-image technique. Electrodes were placed to record EEG, eye movement and diaphragmatic activity in three cats under surgical anesthesia, and a 1.6 mm diameter image probe was placed over the dorsal hippocampus. After recovery, a 2.5 mg/kg intravenous cocaine dose was administered following a baseline recording, and the time course of successive frames of reflected 700 nm optical activity was assessed over a 60 min recording period. Frames were collected together with digitized cortical and hippocampal EEG. Images were averaged over 1 min epochs, and a pre-cocaine epoch was subtracted from all subsequent epochs to eliminate background activity. A multiplication also was performed to amplify the differences, and ANOVA procedures for each individual pixel were used to determine the significance of the comparisons using an alpha of .05. Cocaine induced a profound overall diminution in reflected light from the dorsal hippocampus; this decline began as early as 1 min, with the maximal decline varying, depending on the preadministration state of the animal; typically maximal declines occurred at 2 min post administration, with recovery to baseline levels requiring approximately 15 minutes.

Supported by DA-04913-3. D.R. is supported by NIDR DE 07212. G.P. is supported by a Howard Hughes Medical Institute Predoctoral Fellowship.

590.6

DYNAMIC SPATIAL PATTERNS OF OPTICAL ACTIVITY FROM THE CAT DORSAL HIPPOCAMPUS FOLLOWING INTRAVENOUS COCAINE ADMINISTRATION D. M. Rector*, G. R. Poe*, R. K. Harper, and R. M. Harper. Department of Anatomy and Cell Biology, Interdepartmental Neuroscience Program, UCLA School of Medicine, Los Angeles, CA, 90024.

We observed intrinsic optical properties of tissue from the dorsal hippocampus of the cat using an optical probe and reflected 700 nm light. The probe consists of a 1.6 mm diameter coherent image fiber bundle coupled to a 128 by 128 pixel CCD, cooled with liquid nitrogen to reduce thermal noise. In three cats under surgical anesthesia, electrodes were placed to record cortical EEG, and the image probe was lowered to the surface of the dorsal hippocampus. Diaphragmatic leads were placed to record respiratory and ECG activity. After surgical recovery, recordings of cortical and hippocampal EEG were digitized simultaneously with the hippocampal optical activity. Images were digitzed at the peak of the ECG R-wave to eliminate cardiac artifact. Each fiber in the probe was 25 um in diameter, which allowed the simultaneous visualization of optical activity in 10,000 individual regions, each covering an area of 450 um^2. One fiber was approximately represented as a pixel on the video image. Previous studies indicate that optical activity at 700 nm correlated with regional blood flow and local metabolism. Images were collected 10 min prior to, and 30 min after 2.5 mg/kg intravenous cocaine adminstration. Animations were created by displaying successive images which illustrated changes in optical activity for the area of tissue under each fiber. Individual pixels of the image alternated between light and dark levels at a steady rate over time before administration of cocaine. As early as one minute after cocaine, the light and dark alternation of individual pixels accelerated, with an average level that was darker than precocaine conditions. The change in pattern created banding patterns on the image and an overall diminution of light reflected from the surface of the dorsal hippocampus.

Supported by DA 04913-3. D.R. is supported by NIDR DE 07212. G.P. is supported by a Howard Hughes Medical Institute Predoctoral Fellowship.

COMPUTER ANALYSIS AND VIDEO-DEMONSTRATION OF THREE-DIMENSIONAL MORPHOLOGY OF NEURONS OF APLYSIA . H. KOIKE, Y. UMITSU*, M. IMANISHI* & H. SHIBUTANI*. Dept. Neurophysiol., Tokyo Metropolitan Institute for Neurosciences, Fuchu, Tokyo 183, JAPAN.

A computer constructed realistic three-dimensional image of neurons will be presented on a video-screen. The neuron in the abdominal ganglion of Aplysia juliana was stained by an intra-cellular injection of cobaltic-lysine in combination with the silver-intensification procedure. The ganglion was serially sectioned (2-3μm) for the light-microscopy using an adhesive tape method (Umitsu, 1990). The video microscopic images of the serial sections (around 200) were sequentially acquired to a computer (Hamamatsu Photonics C2000). The acquired images were processed as 16-bit gradient natural images without any human handlings such as tracings or binary slicings. These images were reconstructed by our computer programs to produce hypothetical pictures of the stained neuron viewed from any angles other than actually observed. By presenting these calculated pictures of different view angles sequentially on the video screen, full rotation of the three-dimensional natural-looking image of the neuron was produced satisfactorily. We also precisely determined the volumes, surface areas and lengths of the cell body, axons and neurites of the stained neurons three-dimensionally.

590.8

AUTOMATIC GRAIN COUNTING. J. Nissanov, S. Mani*, and O.J. Tretiak*. Imaging and Computer Vision Center, Drexel University, Philadelphia, PA 19104.

While exposed silver grains are often dark objects on a lighter background, automatic grain counting techniques which segment the image on the basis of gray value alone are inaccurate. We report on an algorithm with improved performance which exploits the size as well as the gray value discrepancy between the grains and the background objects.

This algorithm convolves the original image with a low-pass filter followed by subtraction of the filtered image from the original. This high-pass result is then automatically thresholded to separate the grains from the background.

The performance of variants of this algorithm was measured on 42 images taken through a 100X objective. We compared the computer and visual grain count for 4 different low-pass filters, average, median, high, and F75, each at 5 different kernel sizes. The best results (r^2= 0.870) was achieved with a 7 X 7 median filter. (Supported by NIH grant # 5 P41 RR01638).

REGENERATION

591.1

THE SPECIFICITY OF MOTOR AXON REGENERATION DECREASES WITH AGE. T.M.Brushart. Depts. of Neurology and Orthopaedics, Johns Hopkins, and Curtis Hand Center, Baltimore, MD 21218.

The superior results of peripheral nerve repair in children have been attributed to CNS plasticity (Almquist '83), allowing better use of inappropriate peripheral connections. However, the specificity of peripheral axon regeneration itself may also be age dependent. These experiments examine the effects of age on Preferential Motor Reinnervation, the tendency for regenerating motor axons to reinnervate a distal motor branch in in preference to a sensory one. Both femoral nerves of juvenile (3 wks) and aged (1 yr) rats were sharply transected and sutured with proper alignment (40 nerves), 90° rotation of the distal stump (40 nerves), or enclosure of a 1/2 mm interstump gap within silicone tubing (40 nerves). After 12 wks of regeneration, HRP was used to identify motoneurons regenerating correctly down the motor branch (20 nerves/group) or incorrectly down the sensory branch (20 nerves/group). Significantly more motoneurons were labeled from the motor branch ($p < .01$) except in the aged animals with rotated repairs ($p = .07$). The difference between mean motoneuron counts from the sensory and motor branches, an indication of specificity, was significantly greater in the juvenile animals ($p < .0001$) regardless of repair type. The specificity of motor axon regeneration, and especially the ability to overcome repair malalignment, thus decreases with advancing age in the rat.

591.2

THE DEVELOPMENTAL HISTORY OF SUPRASPINAL PROJECTIONS TO THE LUMBOSACRAL CORD IN THE NORTH AMERICAN OPOSSUM, DIDELPHIS VIRGINIANA. POSSIBLE RELEVANCE TO DEVELOPMENTAL PLASTICITY. George F. Martin and Xiao Ming Xu. Dept. of Cell Biology, Neurobiology and Anatomy, The Ohio State Univ., Columbus, OH 43210.

In order to study the origins of supraspinal projections to the lumbosacral cord in developing opossums, we have used the retrograde transport of Fast Blue (FB). When injections were made into the caudal cord at postnatal day (PD)1, 12-13 days after conception, labeled neurons were present within the brainstem where they were most numerous within the reticular formation of the pons and the coeruleus complex. A few neurons were also labeled in the bulbar reticular formation and raphe, and in some cases, within the vestibular complex. By PD3, labeled neurons were much more numerous and present in most of the brainstem areas labeled by comparable injections in adult animals. A notable exception was the red nucleus which could not be labeled with certainty until approximately PD13. We have shown that rubral axons are able to grow around a lesion of their spinal pathway during development and it is our hypothesis that all brainstem-spinal axons are capable of comparable plasticity. If the potential for plasticity is based on maturation at the time of injury, we predict from the above results that the critical period for reticulospinal and vestibulospinal plasticity, if it occurs, ends earlier than that for the rubrospinal axons. (Supported by NS-25095 and NS-10165).

591.3

A SUBSTANTIAL FRACTION OF RETINAL GANGLION CELLS SURVIVE THE TRANSECTION OF THE RABBIT'S OPTIC NERVE. Jutta Schnitzer and Leo Peichl. MPI für Hirnforschung, Deutschordenstr. 46, W-6000 Frankfurt/Main, Germany

Cutting the optic nerve of adult mammals leads to degeneration of retinal ganglion cells (GC). Our study shows, however, that even 1-2 years after cutting the optic nerve of rabbits, a substantial fraction of the GC (about 10%) survive. We confirmed completeness of the cut by the failure of retrograde transport of HRP to the surviving GC, or by the absence of GC axons in the optic nerve anterograde to the cut. The surviving GC bodies and axons in the retina were detected by neurofilament-labeling and by reduced-silver stain. Lucifer Yellow injections revealed some alpha, bi-stratified and nonclassified GC.

Ultrastructurally the surviving axons appeared healthy; most were myelinated in the medullary rays (MR). Some oligodendrocyte cell bodies in the 'lesioned' retina were covered with myelin. Thus, after degeneration of about 90% of the axons, oligodendroglia myelinate 'aberrant' cellular elements. The proportion of myelinated vs. unmyelinated axons in the MR was higher in the 'lesioned' than in the control retina. Whether the enhanced proportion of myelinated axons is caused by 'aberrant' myelination, or whether myelinated axons survive to a higher extent, is still open. It remains to be shown why some GC are capable of surviving and whether they could regenerate their axon in a 'suitable' environment.

591.4

RETINAL GANGLION CELL AXON REGENERATION FAILURE IN GOLDFISH. A.D. Springer Department of Cell Biology and Anatomy, New York Medical College, Valhalla, NY 10595.

Retinal ganglion cell (RGC) axon regeneration occurs in goldfish after the optic nerve is crushed. This ability in nonmammalian vertebrates, and its absence in mammals, can be interpreted as reflecting species differences in regenerative capacities. However, failures of axon regeneration in mammals have been shown recently to be due, at least in part, to inhibitory factors present at the site of nerve damage.

Microenvironmental factors in the goldfish visual system also can interfere with RGC axon regeneration. RGC axons were transected intraretinally. At various post-surgical times, the eye was removed and cobaltous-lysine was placed on the optic nerve to backfill the RGCs. RGCs having undamaged axons were filled throughout the retina. However, there were very few labeled RGCs in the retina peripheral to the slit. The possibility that the sectioned axons had regenerated into the optic nerve, but that the corresponding cells could not be filled readily, was ruled out. In a control study, RGCs were easily filled several weeks after damaging their axons by crushing the optic nerve.

To determine the origin of the inhibition, small pieces of retina were explanted into poly-lysine coated dishes. Neurite outgrowth was quantified 8 days following explantation. A supernatant, prepared from the contents of the eye, inhibited neurite outgrowth completely when added to the media at the time of explantation. Thus, following severe retinal, but not optic nerve trauma, an inhibitory factor enters the microenvironment of the damaged RGC axons.

REGENERATION OF THE AMPHIBIAN OPTIC NERVE THROUGH AN AUTOLOGOUS PERIPHERAL NERVE GRAFT. F. Scalia and S. Roca*
Dept. Anat./Cell. Biol., SUNY-HSCB, Brooklyn, NY 11203.

The nerve-graft method of Aguayo and coworkers was used to conduct regenerating optic nerve axons to their normal targets in R. pipiens, by joining the ocular stump of the left optic nerve to the right optic tract with a length of peroneal nerve. The optic nerve was severed close behind the eye. One end of the nerve graft was passed through the optic foramen toward the eye, and secured in apposition to the optic nerve stump. The other end was inserted into the contralateral optic tract close to the optic chiasma. By 17 wks p.o., the frogs were actively locating and capturing meal worms presented to either eye. Prior to sacrifice, the affected eye was injected with 3H-labeled amino acids to trace the central projections of the regenerated nerve. At sacrifice, segments of the autologous nerve bridge were also excised and post-fixed in osmium tetroxide. The radiolabeled optic axons were observed to enter the optic tract from the graft and to terminate in the normal targets of the optic projection. The projection to the contralateral tectum was organized into its normal pattern of lamination. In the nerve graft, the radiolabel was confined within its perineurial compartments, where the EM material showed the optic fibers to be associated with a profusion of Schwann cells either individually, as myelinated axons, or as bundles of unmyelinated axons. Supported by PHS grant No. EY05284.

591.6

COMBINED NGF INFUSIONS AND HIPPOCAMPAL GRAFTS INDUCE FUNCTIONAL RECOVERY IN THE LESIONED SEPTOHIPPOCAMPAL PROJECTION.

M. H. Tuszynski and F. H. Gage. Department of Neurosciences, University of California-San Diego, La Jolla, CA. 92093

Septohippocampal (S-HC) lesions induce degeneration of septal cholinergic neurons and impair spatial memory in rats. Previous studies have shown that fetal neuronal grafts that span a fimbria-fornix lesion cavity (bridging grafts) induce partial reinnervation of the host hippocampus by promoting fiber regrowth from the host septum. We sought to determine whether NGF infusions combined with fetal hippocampal bridging grafts to the bilaterally lesioned S-HC projection of the Fischer 344 rat could restore host circuitry and induce *functional* recovery. Animals underwent bilateral fimbria-fornix lesions, placement of E18 fetal hippocampal bridging grafts in the lesion cavity, and 9 week intraventricular infusions of NGF (total NGF dose 60 ug). Control animals received either lesions alone, lesions plus NGF infusions, or lesions plus fetal hippocampal bridging grafts (total n=38). After a total eight month survival period, functional performance was assessed in a Morris water maze and a habituation task. Animals receiving combined NGF infusions and grafts showed significant, partial recovery on the habituation task and in the water maze. Morphologically, all animals receiving transient 9 week NGF infusions had long-term recovery of 80% of septal cholinergic neurons ($p<0.001$), independent of the presence of a bridging graft. Only animals with grafts spanning the lesion cavity showed hippocampal reinnervation. Thus, long-term but transient NGF infusions combined with bridging grafts promote partial anatomical and functional recovery in the adult brain. More complete restoration of the septohippocampal pathway is needed for complete functional recovery.

FUNCTIONAL EFFECTS OF LOCALLY APPLIED EXTRACELLULAR MATRIX WITH AND WITHOUT NGF AND bFGF FOLLOWING SPINAL CORD TRANSECTION. B.B.Walters, J.R.Encarnacion*, T.E.Melin*, and S.N. Schwirck*. Div. of Neurosurgery, Univ. of North Carolina at Chapel Hill, NC 27599-7060.

67 Sprague-Dawley rats underwent an open midthoracic procedure under methoxyflurane anesthesia within 36 hours of birth. 12 had laminectomies alone (LAMI), 17 had intradural transection and one segment myelectomy (TRANS), 17 had myelectomies with implantation of approx. 7 µl of Matrigel (ECM), 14 had implants containing approx. 3.5 µg of 2.5S NGF, and 7 had implants containing approx. 15 µg of bFGF. The animals were evaluated by the combined behavioral score of Wrathall (Exp. Neurol. 88: 123, 1985) 3 times weekly for 15 weeks in blinded fashion. The LAMI animals performed significantly better ($p<10^{-10}$, ANOVA) than all other groups on weeks 3-15. ECM outperformed TRANS during weeks 5, 6, and 8 ($p<0.05$ to <0.001) while bFGF outperformed TRANS during weeks 5-13 ($p<0.01$ to <0.001 except week 11). bFGF also outperformed ECM during weeks 5, 7, 9, 12 and 13 ($p<0.05$ to <0.01). In contrast, NGF performed the same as TRANS through week 6 and then performed more poorly ($p<0.05$ to <0.001). NGF performed more poorly than ECM after week 4 ($p<0.05$ to <0.001) and more poorly than bFGF after week 2 ($p<0.01$ to <0.001). Quantitative histological correlates of these results will be presented. Supported by the American Paralysis Association.

SURVIVAL AND AXONAL GROWTH OF RETINAL GANGLION CELLS IN ADULT RATS IS ENHANCED BY THE USE OF 'CONDITIONED' SCIATIC NERVE GRAFT. M. Bähr , G.W. Eschweiler* and H. Wolburg+. Max-Planck Institut für Entwicklungsbiologie and Neurologische Universitätsklinik Tübingen, +Pathologisches Institut der Universität Tübingen, Spemannstr. 35/1, W-7400 Tübingen, Germany

We have examined the influence of normal and precrushed ('conditioned') sciatic nerve grafts on the survival and axonal growth of retinal ganglion cells (RGCs) in adult rats. Normal sciatic nerves (group A) or sciatic nerves which had been crushed one week before transplantation (group B, 'conditioned' grafts) were used as grafts. The nerves were removed and sutured to the proximal stump of intraorbitally axotomized optic nerves. Neuronal survival and axon growth were determined by counting the numbers of surviving DiI prelabeled RGCs, cresylviolet stained RGCs and the numbers of axons which had grown into the grafts three and six months after transplantation. Counting of axons was performed by combined use of light- and electronmicroscopy.

We observed that the use of conditioned grafts (group B) significantly enhanced RGC survival and axonal regrowth as compared to normal grafts at 3 months after transplantation. Six months after grafting, RGC survival (as determined in DiI stained retinae) and axonal growth were not significantly different in both groups. When cresylviolet stained retinae were analysed, significantly more RGCs survived in group B compared to animals with normal grafts. These results suggest that the functional status of a peripheral nerve used for grafting in the CNS influences neuronal viability and axonal reelongation especially during the first 3 months after grafting. Long-term RGC survival, however, may be determined by functional reconnection of regenerating RGC axons rather than by the graft itself.

RAT PERIPHERAL NERVE REGENERATION ACROSS 18-mm GAPS AND SCHWANN CELL MIGRATION: INFLUENCE OF FIBRONECTIN. S.B. Bailey[1], M.E. Eichler[2], A. Villadiego*[2], K.M. Rich[2,3], Departments of [1]Otolaryngology, [2]Neurosurgery, and [3]Neurobiology, Washington University School of Medicine, St. Louis MO 63110

Silicone chambers, filled with sterile saline solutions of fibronectin (FB, 500 µg/ml), laminin (LN, 500 µg/ml), the combination of fibronectin-laminin (FB/LN, 500 µg/ml each), cytochrome-C (1 mg/ml cyto-C, control), or nerve growth factor (NGF, 1mg/ml), were sutured between the severed ends of sciatic nerves to form gaps of 18 mm, a distance chosen to stress the rat regenerative capacity. After 4 months, the various experimental groups were examined to determine the success of regeneration. Although NGF slightly increased cable formation -- the initial step for regeneration, all the groups had at least a 60% incidence of cables across the 18-mm gaps. The number of myelinated axons in the sural nerve distal to the repair was increased with either FB or FB/LN. HRP-labeling demonstrated that significantly more sensory and motor neurons in the FB or FB/LN groups had extended axons through the cables.

A possible reaction that may improve peripheral nerve regeneration is the augmentation of Schwann cell migration. As above, sterile saline solutions of FB, LN, FB/LN, NGF, or cyto-C were added to silicone chambers forming 5-mm gaps to determine the immediate effect, within the first 10 days, on Schwann cell invasion of the cables. Quantification revealed a greater influx of Schwann cells into the regenerate segment of the FB/LN group than of control.

Thus, although NGF does improve short-term regeneration in rat sciatic nerve, fibronectin provided a greater, over-all effect in the stressed system and affected the early influence of Schwann cells.

591.10

FLUNARIZINE IMPROVES LONG-TERM REGENERATION AFTER SCIATIC NERVE INJURY K.M. RICH, M.E. EICHLER, J.P. HOLLOWELL
Depts. of Neurosurg. & Neurobiol., Wash. Univ. Sch. Med., St. Louis, MO

The diphenylpiperazine, flunarizine, improves long-term regeneration in newborn rats after sciatic nerve crush. Experiments were done to determine whether prolonged neuronal protection with flunarizine during the period of axonal regeneration would be beneficial and result in long-term improvement in regeneration. Two groups of newborn rats were studied in parallel; the first group (experimental) received systemic administration of flunarizine, while the second group (control) received injections with vehicle only. Newborn rats (PND-1) were injected subcutaneously with flunarizine (25 mg/kg) every 12 hours. A unilateral sciatic nerve crush at the midthigh was performed under hypothermia anesthesia on PND-2 with continuation of flunarizine injections. On PND-3, 24 hours after nerve injury, the dose was increased to 50 mg/kg every 12 hours and continued for 28 days. The rats were then allowed to survive for an additional 3 months after the last flunarizine injection (4 months after injury). Total myelinated axonal counts of the sural nerves showed a 50% decrease on the lesioned side in the control group (947 ± 45 vs. 473 ± 48) compared with only a 26% decrease in the flunarizine-treated group (942 ± 72 vs. 700 ± 72). At the time the sural nerves were removed, the rats underwent injection with HRP in the sciatic nerve distal to the crush site and retrograde labeling studies were done to determine the number of neurons that survived and regenerated distal to the crush lesion. The control and flunarizine-treated groups respectively showed 1406 ± 346 vs. 4716 ± 811 in lumbar DRG and 194 ± 35 vs. 599 ± 132 in the ventral horn of the lumbar spinal cord. Differences between corresponding control and experimental lesioned groups were statistically significant, $P<0.05$, Student's t-Test, independent variables. Flunarizine treatment after sciatic nerve crush provides significant neuronal protection allowing enhancement of peripheral nerve regeneration.

INTERLEUKIN-1 RECEPTOR ANTOGONIST RELEASED FROM A POLYMERIC GUIDANCE CHANNEL IMPEDES PERIPHERAL NERVE REGENERATION. P. Aebischer[1], V. Guénard[1], C.A. Dinarello[2]*. [1]Brown University, Providence, RI and [2]Tufts University and New England Medical Center Hospital, Boston, MA.

Schwann cell-mediated nerve growth factor (NGF) effects play a key role in regenerative processes in the PNS. Upon injury, interleukin-1 (IL-1), a cytokine released by macrophages, triggers NGF synthesis by Schwann cells. Activated macrophages also release IL-1 receptor antagonist (IL-1ra), a true antagonist which binds to IL-1 receptors without inducing any IL-1 effects. Ethylene vinyl acetate (EVA) copolymer tubes releasing controlled amounts of either IL-1ra or deactivated IL-1ra (dIL-1ra) combined with bovine serum albumin (BSA) were tested in the mouse transected sciatic nerve model across a 4 mm nerve gap. Channels releasing BSA only were used as controls. Four weeks postimplantation, cables bridged the nerve stumps in all the tubes. Regardless of the channel type, at any point along the tubes, regenerated cables were morphologically similar. The regenerated tissue consisted of an epineurial-like sheath enclosing blood vessels and nerve microfascicles containing unmyelinated and myelinated axons with their associated Schwan cells. However, cables extending through BSA-IL-1ra-releasing channels contained significantly less unmyelinated and myelinated axons as compared to cables regenerated through BSA- and BSA-dIL-1ra-releasing channels. This study demonstrates that a true antogonist to IL-1 receptors impedes peripheral nerve regeneration and suggests that macrophages modulate peripheral nerve regeneration by releasing stimulatory and/or inhibitory molecules.

LOW ENERGY LASER IRRADIATION ALTERS IMMUNO-FLUORESCENCE OF CHOLINE ACETYLTRANSFERASE (ChAT) IN REGENERATING RAT FACIAL NEURONS. J.J.Anders, R.Borke and S.Woolery*. Dept. of Anatomy and Cell Biology, USUHS, Bethesda, MD 20814.

The authors have shown that low energy He-Ne laser irradiation (632nm, 8.5mW, 90 min) increases the rate of facial nerve regeneration after crush injury. ChAT decreases during the first week post-crush and returns to normal levels by 20 days in motoneurons (Curtis and Borke, Anat. Rec., 226:24A, 1990). The purpose of this study was to determine if irradiation could effect ChAT changes during nerve degeneration and regeneration. The facial nerve was crushed unilaterally in anesthetized rats for 90 s. The wound was irradiated transcutaneously, daily. Rats were fixed by intracardiac perfusion on days 5 and 11 and sections were processed for immunofluorescence. Fluorescence levels of ChAT were quantified using a Biorad Confocal Imaging System. A significant increase ($p<.05$) in ChAT fluorescence intensity/μm^2 was detected in motoneurons of irradiated versus nonirradiated injured rats at 5 and 11 days. Whether this increase in ChAT correlates with a decrease in the initial degenerative events or signifies an earlier return of acetylcholine systhesis is being determined.

AUDITORY SYSTEM: CENTRAL PATHWAYS V

592.1

MIDBRAIN AUDITORY PHYSIOLOGY IN TWO SPECIES OF MORMYRIDS. J.D. Crawford. Parmly Hearing Institute, Loyola U., Chicago, IL 60626.

All of the African mormyrid fishes have specialized ears consisting of a gas-filled bladder within each labyrinth, and the direct coupling of an otolithic organ (sacculus) to this bladder. Even though several mormyrid species are now known to use acoustic signals in communication, little is known about the processing of sounds by the ear and brain in these animals. As a part of an ongoing study of the processing of temporally modulated communication signals, I have conducted a single-unit survey of the midbrain auditory nucleus in two species of mormyrids: *Pollimyrus isidori*, a species known to use sounds in communication, and *Brienomyrus niger*, a related fish but one which is not known to produce sounds.

Microelectrodes were used to record from single neurons while fish were submerged in a calibrated, water-filled, tank. Recording sites were marked with 15 µm diameter deposits of metal from the recording electrode. Response areas (RAs) were constructed by presenting an array of 20 tone bursts (105 to 1500 Hz) over a 60 dB range. From the RA, each neuron was classified on the basis of characteristic frequency (CF), best sensitivity (BS), and degree of frequency tuning (Q_{10dB}). Both fish were found to be highly responsive to low frequency tones, with the most common characteristic frequencies around 235 Hz. Other CF classes had single excitatory zones located in the vacinity of 150 Hz and 450 Hz respectively, and another class had broad RAs including two excitatory zones. The majority of neurons were phasic, producing large onset responses with much less sustained activity during a 200 ms tone burst (50 ms rise/fall). Tonic units were much less common, and typically had low BSs and were relatively sharply tuned. In *P. isiodri* some neurons had quite complex response properties in that they rarely responded to tones even at high levels, but gave robust responses to clicks. Preliminary experiments with click trains suggest that certain neurons in *P. isidori* may be selective for particular inter-click-intervals. (NIH DC00020-02 & DC00293-06).

"GLYCINE RECEPTOR" IMMUNOSTAINING SITES MARK CLASSES OF AUDITORY AND VESTIBULAR CELLS. J.C. ADAMS ENT Dept., Mass. Eye & Ear Infirmary Boston, MA 02114.

A monoclonal antibody(BM) raised against strychnine binding sites recognizes sites that do not bind strychnine nor contain much glycine. One example is that of inclusion bodies within the cytoplasm of auditory and vestibular neurons. These cells are in the MNTB, primary vestibular neurons, octopus cells, spherical cells in the VNLL, and spherical cells located caudal and ventral to the LSO. Three of these cell classes are immunoreactive for glycine. Octopus cells and Scarpa's ganglion cells are not. One trait shared by cells containing inclusion bodies is the sparsity of immunoreactive sites for the "glycine receptor" on their surfaces. This suggests that the inclusion bodies are probably not sites where the receptor is made. The role of the inclusion bodies is obscure, but their presence can be used for identifying cell classes. For example, with the inclusion body as the defining trait of octopus cells: humans have very many; cats have many; rodents have few. This is another example of a closer similarity of cat and human auditory systems as contrasted with rodents.

Sound-localization deficits induced by lesions in the owl's auditory space map. H. Wagner. Max-Planck-Institut für biologische Kybernetik, Spemannstrasse 38, D-7400 Tübingen, FRG

Barn owls possess a map of auditory space. The map is synthesized in the external nucleus of the inferior colliculus (ICx) and then projected to the optic tectum (OT). Azimuth is mapped from antero-medial to postero-lateral, while elevation is mapped vertically.

To find out whether the map plays a role in the localization of acoustic stimuli, head movements of owls were recorded before and after lesioning ICx and/or OT. After focal electrolytic lesions, I observed increased response latencies, reduced turning amplitudes and an increased number of turns away from the sound source. These deficits occurred at azimuths expected from the physiological data obtained at the lesion site before passing current. The deficits extended over a range of some 20 degrees and were obvious from 3 to 20 days after the lesion. After this transient phase, mean response latency remained increased in 1 of 6 cases, and the number of turns with very short latencies was reduced in 2 cases. Thus, this is the first unambiguous demonstration, for sound localization, of a deficit covering a locally well-circumscribed area within a hemisphere. Since the major lesion deficits were transient, two lesions, one on each side of the brain, were made in each of the three animals. Since the behavioral deficit induced by the second lesion disappeared in the same way as did the deficit induced by the first lesion, the possibility is excluded that the animals learned to respond tactically. The deficits were also not due to motor impairment, because immediately after the lesion, the animal responded normally to stimulation from outside the well-circumscribed region of the lesion.

LATENT NEURONAL ACTIVITY IN HUMAN AUDITORY CORTEX Z.L. Lü*, S.J. Williamson and L. Kaufman. Neuromagnetism Lab., Depts. of Physics and Psychology and Center for Neural Science, N.Y.U., New York, NY 10003**.

The auditory event-related response detected magnetically about 100 msec following the onset of a tone burst with a long interstimulus interval (ISI) reveals a component of neuronal activity that overlaps in time with the response in primary auditory cortex (N100m). We call this activity the 'latent' component (L100m) since it requires a much longer ISI than N100m to reach a full response amplitude when stimuli are presented at a fixed rate. Amplitudes of L100m and N100m were measured at their separate magnetic field extrema with interstimulus intervals ranging from 0.8 to 16 sec. The resulting ISI-dependence for each could be well fit by an exponential curve using a least square criterion. Statistically significant fits showed that suppression of the response amplitude caused by the preceding stimuli decreased exponentially with ISI, with the time constant for L100m being about 1.5 sec longer than for N100m, the latter ranging from 1.5 to 3.5 sec across individuals. The locations of the neuronal activity that produce L100m and N100m were deduced from the field pattern by a least squares fit of 2 current dipoles. By comparison with MRI, both were found to lie on the supratemporal plane with the source of N100m lying in primary auditory cortex and the source of L100m lying about 1.5 cm more posterior and 1 cm more inferior than that of N100m. The second location was identified as the auditory association cortex.

592.5

DISRUPTION OF INTERHEMISPHERIC INTEGRATION OF COMPLEX AUDITORY INFORMATION FOLLOWING FOCAL HEMORRHAGE INTO THE POSTERIOR BODY OF THE CORPUS CALLOSUM M.J. Tramo, F.E. Musiek, and M.S. Gazzaniga
Program in Cognitive Neuroscience and Division of Audiology, Dartmouth-Hitchcock Medical Center, Hanover, NH 03756

In subhuman primates, the posterior body of the corpus callosum contains interhemispheric projections of auditory cortical neurons in the supratemporal plane and posterior superior temporal cortex (Pandya & Seltzer 1986). To our knowledge, in only one human has the posterior body of the callosum been selectively sectioned (Dimond et al. 1977), but the extension of the surgical lesion (and possibly the pathological lesion) into the left hemisphere precludes a clear interpretation of the unusual auditory findings in this case. Evidence that a segment of the posterior callosum mediates interhemispheric auditory integration in humans has been derived from dichotic studies of patients with partial callosotomies extending from the splenium forward (Geffen 1980; Musiek et al. 1985) and of patients with left hemisphere lesions lying deep in the periventricular parietal or parieto-occipital white matter (Damasio & Damasio 1979).

We report a case of focal hemorrhage into the posterior body of the callosum caused by delayed post-traumatic rupture of a pericallosal artery aneurysm. Thin-section sagittal and coronal MR permitted the precise localization of callosal damage and documented the limited extent of intrahemispheric involvement. Pure tone thresholds were within normal limits in each ear. Consonant-vowel (CV) phonemes presented monaurally 50dB above sensation level were correctly repeated in 30/30 trials in each ear. When CV phoneme pairs were presented dichotically, 30/30 vs. 0/30 presented to the right ear vs. left ear, respectively, were reported. When monosyllabic homophone pairs were presented dichotically, 25/30 vs. 3/30 presented to the right vs. left ear were reported. In none of the 60 trials were both right and left ear stimuli reported. Other notable findings included: no extinction to double simultaneous visual or tactile stimulation; normal naming of line drawings presented tachistoscopically in the left visual field; normal tactile naming in the left hand; and mild left hand dyspraxia.

These findings indicate that: 1) the posterior body of the corpus callosum mediates the interhemispheric integration of phonemic information; and 2) the topography of callosal auditory projections is homologous in humans and nonhuman primates.

HOMOTONIC SEGREGATION IN THE ORIGIN OF BILATERAL ASCENDING PROJECTIONS FROM THE FERRET LATERAL SUPERIOR OLIVARY NUCLEUS. C. K. Henkel and J. K. Brunso-Bechtold, Dept. of Neurobiology and Anatomy, Bowman Gray Sch. of Med., Winston-Salem, NC 27157-1010.

In this study of the adult and early postnatal ferret lateral superior olivary nuclei (LSO), it was observed that cells giving rise to the ipsilateral and contralateral ascending projections were segregated spatially within areas of similar frequency representation. This homotonic segregation was far more striking in the ferret LSO than the heterotonic variation that has been previously reported. The cellular region of the intermediate limb of the LSO was divided arbitrarily into eight parallel lanes from core to margin. Labeled projection cells on the ipsilateral and contralateral side with respect to tracer injections in the inferior colliculus were mapped and their position plotted as a function of the lanes they occupied. There was a clear tendency for ipsilateral projection cells to occupy marginal lanes and contralateral projection cells to occupy core lanes. Approximately two-thirds of the ipsilateral projection cells were found in the two inner and outer lanes compared to only one-third of the contralateral projection cells. The distribution curves varied from case to case and limb to limb, probably in part due to the irregular orientation of the limbs of the LSO with respect to standard anatomical planes. Some homotonic segregation in the LSO was evident at birth indicating that this rule of organization may be in place at least four weeks prior to the onset of hearing. Cells marked by other phenotypic traits reveal similar homotonic segregation. Glycine- and GABA-immunoreactive cells were most frequent in the marginal lanes. Similar immunoreactive cells ringed the nucleus in the developing ferret. No homotonic gradient of immunoreactive puncta in the LSO was apparent suggesting that the output but not necessarily the input to the LSO may be segregated. Further studies are underway to address these hypotheses. Supported in part by NIH grant DC00335.

592.7

AN ANIMAL BEHAVIORAL MODEL OF HALLUCINATIONS IN RATS. P.J. Jastreboff[1] and J.F. Brennan[2]. [1]Dept Surgery, Univ Maryland Sch Medicine, Baltimore, MD 21201; and [2]Dept Psychology, Univ of Massachusetts/Boston, MA 02125.

An animal model of phantom auditory perception has been tested on salicylate-induced auditory sensation in rats (Behavioral Neurosc. 102:811-822, 1988) and involves continuous exposure of rats to background noise or light with offset of the background serving as a conditioned stimulus (CS). The model has been expanded to accommodate visual and auditory hallucinations by introducing complex background of pulses of tone or light of random length presented randomly, with the offset of the background serving as CS. Pulses of light/tone of different traits superimposed on this background resulted in modality-specific changes in behavior consistent with our previous findings.

The additional use of scopolamine (0.5-, 0.75- and 1.0 mg/kg/day, s.c.), which has been reported in humans to induce visual but not auditory hallucinations, produced changes in extinction among groups trained with visual modality, but not with the auditory modality, in a dose-dependent manner. These results are consistent with the postulate that scopolamine induces visual hallucinations in rats, detected by our paradigm. This offers a possibility for creating a behavioral animal model for schizophrenia. (NIH NIDCD Grant DC00445).

592.8

IDLING 10-HZ RHYTHM IN THE HUMAN AUDITORY CORTEX? R. Hari. Low Temperature Laboratory, Helsinki University of Technology, 02150 Espoo, Finland.

The 10-Hz alpha rhythm in the visual cortex and the corresponding mu rhythm in the somatomotor area are considered 'idling' rhythms of the sensory systems; they are blocked by visual and tactile stimuli, respectively. We have recorded magnetic spontaneous activity with a 24-channel superconducting quantum-interference device (SQUID) gradiometer to find out whether the human auditory areas also display an idling rhythm [1,2].

Magnetic 8–10 Hz rhythm was observed over the temporal regions. It was damped by auditory stimuli but it did not decrease when the eyes were opened or when the fist was clenched. The field patterns over the auditory cortex could be satisfactorily explained by equivalent current dipoles, situated within 2 cm from the source of the 100-ms auditory evoked response, generated in the supratemporal auditory cortex. During light drowsiness, when the occipital electric alpha became discontinuous and 'spread' to more anterior scalp locations, the temporal magnetic 10-Hz rhythm accentuated and resembled the frontocentral electric activity. Since currents at the superior surface of the temporal lobe would produce the maximum potentials in the frontocentral midline, the 'spread' of electric 'alpha' during drowsiness might reflect activity of the temporal-lobe 10-Hz generators.

The results suggest that each sensory projection cortex has its own idling rhythm.

TOPOGRAPHY OF INTENISTY ENCODING BY SINGLE NEURONS IN CAT PRIMARY AUDITORY CORTEX. M.L. Sutter and C.E. Schreiner. Coleman Laboratory, Dept of Otolaryngology, University of California, San Francisco, CA 94143-0732.

The topography of the sharpness of amplitude tuning (monotonicity) of single neurons was studied within the isofrequency domain of high frequency (CFs > 4 kHz) primary auditory cortex (AI). To pool data across animals, the multiple unit monotonicity (Schreiner et al. 1988: ARO abstracts 11: 36) and excitatory bandwidth maps were used as topographical frames of references (Sutter and Schreiner 1991: J. Neurophysiol. 65). The multiple unit monotonicity map consisted of two non-monotonic (sharply tuned for amplitude) areas along the isofrequency (roughly dorsal-ventral) domain of AI. Non-monotonic response profiles were more common in single unit (56%) than multiple unit (36%) recordings. In ventral AI, the spatial distribution of single neuron monotonicity ratios (response at highest tested intensity divided by response at best intensity) paralleled the shape of the multiple unit spatial distribution. In dorsal AI, pooled single neurons displayed no clear topographical order with respect to amplitude tuning. At the two non-monotonic regions, a sharp decrease in the scatter of intensity thresholds for single neurons was observed, implying that non-monotonic multiple unit areas are a result of tightly overlapping intensity receptive fields for single units. These data indicate that parcelling AI into dorsal (AId) and ventral (AIv) regions, as supported by the excitatory bandwidth topography, is justified; however, physiological properties of the ventral non-monotonic area lying at the AId/AIv border need to be considered in more detail.

The ventral multiple unit non-monotonic area roughly aligns with the area of sharply frequency tuned units described by Schreiner and Mendelson (1990: J. Neurophysiol. 64: 1142-1160). This region, with low intensity thresholds, narrow intensity tuning, and narrow frequency tuning might correspond to an intensity fovea for low intensity narrow-band stimuli, just above the background noise. BRAINSTEM INFUSION OF KYNURENIC ACID REDUCES SPONGIFORM LESIONS IN GERBIL COCHLEAR NUCLEI, SUGGESTING AN EXCITOTOXIC ORIGIN. M.D.McGinn and B.T. Faddis*. Dept. of Otolaryngology, University of California, Davis CA 95616

We hypothesized that spongiform lesions in gerbil cochlear nuclei are the result of chronic excess of an excitatory amino acid neurotransmitter. For eight days we used osmotic minipumps to infuse a magnesium-free 50 mM solution of kynurenic acid, a non-specific glutamate antagonist, through brainstem cannulae whose tips were unilaterally placed near cochlear nuclei. Sequential methacrylate sections showed that lesions were significantly reduced in the cochlear nuclei ipsilateral to the cannulae when compared with the untreated side. The greatest reduction in spongioid lesions was located near the cannulae tips, apparently reflecting diffusion gradients. The results suggest that the reduction of lesions is due to blockade of amino acid receptors in the cochlear nuclei.

592.11

REORGANIZATION IN AUDITORY CORTEX OF ADULT CATS WITH UNILATERAL RESTRICTED COCHLEAR LESIONS. D. R. F. Irvine, R. Rajan, L. Z. Wise and P. Heil. Dept. of Psychology, Monash University, Clayton, Vic. 3168, Australia.

In a previous study (Robertson & Irvine, J. Comp. Neurol. 282:456-471, 1989), restricted cochlear lesions in adult guinea pigs were found to result in a reorganization of the representation of the lesioned cochlea in the contralateral auditory cortex. One question raised by this result concerns the effect of this reorganization on the representation of the normal (ipsilateral) cochlea in that cortex. This question was examined in adult cats in which restricted unilateral cochlear lesions were produced by direct mechanical trauma. Following a 2-6 month post-lesion recovery period, the animals were reanesthetized, the extent of the peripheral hearing loss in the lesioned ear was established by means of the compound action potential audiogram, and the frequency organization of primary auditory cortex (AI) contralateral to the lesioned ear was determined using conventional microelectrode mapping techniques. In the representation of the lesioned contralateral cochlea the region deprived of its normal input by the lesion was partially occupied by an expanded representation of the frequency at the edge of the lesion, but the ipsilateral frequency map in this region showed a normal frequency progression. Evidence on the thresholds at their new characteristic frequencies of neuronal responses in the enlarged contralateral representation indicated that the expanded representation reflected a reorganization of cortex rather than simply residual drive at frequencies unaffected by the lesion. The lack of change in the ipsilateral frequency map results in a loss of the normal registration between the two frequency maps, and has implications for the mechanisms underlying auditory cortical reorganization.

PRESYNAPTIC MECHANISMS: ION CHANNELS

593.1

5-HT INCREASES Ca^{++} INFLUX DURING ACTION POTENTIALS IN *APLYSIA* SENSORY NEURONS BY SPIKE BROADENING AND BY DIRECT CALCIUM CHANNEL MODULATION. H. Blumenfeld, L.S. Eliot, B.W. Edmonds, E.R. Kandel and S.A. Siegelbaum. Columbia Univ., H.H.M.I., N.Y., N.Y. 10032.

Aplysia sensory neurons contain "N-like" Ca^{++} channels which participate in transmitter release, and dihydropyridine-sensitive "L-like" Ca^{++} channels which do not contribute to release (Edmonds et al., 1990). 5-HT produces presynaptic facilitation of the *Aplysia* sensory-motor neuron synapse, and increases the sensory neuron $[Ca^{++}]_i$ transient during action potentials. The increase in the $[Ca^{++}]_i$ transient is due to two processes: 1) Indirect modulation whereby $S\text{-}K^+$ channel closure and resulting spike broadening increase influx through both N and L channels, and 2) A direct increase in L Ca^{++} current. Since only N Ca^{++} current contributes to presynaptic facilitation (Edmonds et al., 1990), we have used fura-2 $[Ca^{++}]_i$ measurements with or without nitrendipine to assess the relative contributions of N and L currents to the $[Ca^{++}]_i$ transient and its modulation by 5-HT.

5-HT caused a 77 ± 14% increase (mean ± SEM; $n = 10$; $p<0.001$, two tailed t-test) in the amplitude of $[Ca^{++}]_i$ transients in the cell body produced by action potentials. However, in the presence of 10 μM nitrendipine (which blocks the 5-HT-induced increase in L current by 87 ± 4%), 5-HT caused only a 28 ± 8% increase in $[Ca^{++}]_i$ transient amplitude ($n = 9$), significantly different both from control ($p<0.01$) and from 5-HT alone ($p<0.01$). This 28% increase presumably reflects increased Ca^{++} influx via the N channels due to spike broadening. In nitrendipine, the amount of spike broadening produced by 5-HT was roughly correlated with the increase in $[Ca^{++}]_i$ transient amplitude. As shown in the accompanying abstract (Eliot et al., 1991), a similar increase in Ca^{++} influx is seen in presynaptic sensory neuron processes in 5-HT + nitrendipine, supporting its role in presynaptic facilitation.

IMAGING $[Ca]_i$ TRANSIENTS AT *APLYSIA* SENSORIMOTOR SYNAPSES: CONTRIBUTIONS OF DIRECT AND INDIRECT MODULATION TO PRESYNAPTIC FACILITATION. L.S. Eliot, H. Blumenfeld, B.W. Edmonds, E.R. Kandel and S.A. Siegelbaum. Ctr. Neurobiol & Behav, HHMI, Columbia Univ., N.Y., N.Y. 10032.

The accompanying abstract (Blumenfeld et al., 1991), demonstrated that 5-HT increases Ca transients in *Aplysia* sensory neurons both by direct modulation of the L-type Ca current and by action potential broadening, which indirectly enhances influx through both L- and N-type Ca currents. Here, we examine the contributions of these two mechanisms to the increase in Ca influx in synaptic terminal regions.

Serotonin produced a 39 ± 9% ($N = 5$) increase in the $[Ca]_i$ transient in regions of the sensory neuron making contact with a postsynaptic motor neuron, and facilitated the EPSP by 47 ± 16%. Nitrendipine reduced this increase by 65%, but did not reduce facilitation of the EPSP. In separate cultures, nitrendipine by itself reduced the Ca transient to 80 ± 5% of control ($N = 5$). Subsequent 5-HT addition increased the Ca transient by 27 ± 6% and facilitated the EPSP by 109 ± 46% over nitrendipine alone. These results indicate that direct modulation of the L-type current contributes roughly 2/3 of the enhancement of Ca influx by 5-HT, but this does not contribute to facilitation. The remaining enhancement of Ca influx occurs through N-type Ca channels as an indirect consequence of spike broadening. There was a significant correlation between enhancement of the Ca transient in the presence of nitrendipine and facilitation of the EPSP ($R = .737$, $p < .05$, $N = 8$) fit by a 2.4 power relation, consistent with the view that enhanced Ca influx via the N-type channels contributes to presynaptic facilitation. These experiments also provide some evidence that the two classes of Ca channels are differentially localized.

SYNAPTIC PLASTICITY OF A DUAL-ACTION POTENTIAL MEDIATED BY METABOLITES OF ARACHIDONIC ACID IN *APLYSIA*. E. Shapiro, Howard Hughes Medical Institute, New York, NY 10032

In the abdominal ganglion of *Aplysia*, an identified cluster of interneurons called L32 cells makes a dual-action synaptic potential onto L14 cells, motor neurons controlling the defensive release of ink. The dual-action consists of a fast early depolarizing phase followed by a slower hyperpolarization. Previous work has suggested that both phases of the dual-action may be mediated by stimulation of arachidonic acid (AA) metabolism to produce the active 12-lipoxygenase products 12-hydroperoxy-5,8,10,14-icosatetraenoic acid (12-HPETE) and 8-hydroxy-11,12-epoxy-5,9,14 icosatrienoic acid (8-OH). I have begun to examine plasticity of this dual-action response in order to gain insight into the regulation of signalling by the AA cascade.

The L32-L14 dual-action synapse displays quite variable strength. Within the same L32 cluster different individual cells may produce almost pure excitation or almost pure inhibition on the same L14 follower cell. Similar to other dual-action responses, the L32-L14 dual-action is frequency-dependent. At low frequencies of stimulation (< 1Hz) the early excitatory phase predominates, while at higher frequencies of stimulation, the depolarizing phase undergoes synaptic depression, and the slow inhibitory phase predominates. When L32 cells are tetanized (e.g. 20Hz stimulation for 20 sec) the slow IPSP component of the synaptic response elicited by a short train of spikes (20 Hz for 1 sec) exhibits post-tetanic potentiation. In each ganglion up to seven L32 cells converge on L14. I am currently testing whether activity in one L32 cell may affect the synaptic response of L14 to other L32 cells.

ADENOSINE MEDIATES SYNAPTIC DEPRESSION IN *APLYSIA*. S.M. Fredman. Department of Physiology, Meharry Medical College, Nashville, TN 37208.

Low frequency stimulation of the A-B neuron synapse in the cerebral ganglion of *Aplysia* produces a long-lasting depression. Only 5 spikes presented at 3 min intervals results in a 49±14% ($n=10$) reduction in EPSP amplitude. I have obtained evidence that this depression may be mediated by the neuromodulator adenosine. Synaptic depression was assessed by measuring EPSP amplitudes in B neurons evoked by stimulating A neurons at 3 min intervals and by changes in potentiated EPSP amplitudes (Slow Developing Potentiation, SDP; Fredman, 1988) produced by 2 sec 20 Hz trains in the A neurons.

Adenosine agonists increased depression. Bath application of 100 μM adenosine (ADO) or 150 nM of the A_1 agonist, N^6-cyclohexyladenosine reduced SDP and increased synaptic depression. ADO antagonists decreased depression. Application of 100 μM DPSPX reduced depression and increased SDP. ADO antagonists with phosphodiesterase activity had two effects. At low concentrations, both 100-400 μM IBMX and 200 μM theophylline reduced or blocked synaptic depression. At high concentrations (1-2 mM) they increased it. The latter effect suggested that depression might be mediated by cyclic AMP. Both bath application of DB-cAMP and direct injection of cAMP into A neurons reduced SDP. Adenosine deaminase (1 mg/ml) which hydrolyses ADO significantly reduced depression, indicating that endogenous ADO may contribute to depression of the synapse. These results suggest that at the A-B neuron synapse in *Aplysia*, depression may be mediated by presynaptic adenosine autoreceptors acting via a cAMP dependent-mechanism. Thus, as in the mammalian CNS, adenosine may also modulate synapses in *Aplysia*.

PRESYNAPTIC CALCIUM CONCENTRATION MEASURED BY THE EFFECTS OF CALCIUM BUFFERS ON CALCIUM-ACTIVATED POTASSIUM CHANNELS THAT COLOCALIZE WITH ACTIVE ZONES IN SACCULAR HAIR CELLS OF *RANA PIPIENS*. W.M. Roberts. Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403.

We have proposed that the entry and action of Ca^{2+} in frog saccular hair cells is confined to the immediate vicinity of a 250 nm-diameter cluster of ion channels at the center of each synaptic active zone [Roberts, Jacobs & Hudspeth, *J. Neurosci.* (1991) **10**:3664]. Each active zone is purported to contain ~90 Ca^{2+} channels that can pass a 50 pA Ca^{2+} current, and ~40 K_{Ca} channels that open when the cell is depolarized and the local $[Ca^{2+}]_i$ exceeds ~10 μM. To test this model, I introduced Ca^{2+} buffers through whole-cell recording pipettes and examined how the concentration and association rate constant of the buffer affected the K_{Ca} current. At concentrations of 1 mM, EGTA had little effect, whereas BAPTA, which binds Ca^{2+} >10 times more rapidly, reduced K_{Ca} channel activation. This difference indicates that 1 mM-EGTA was too slow to intercept a significant fraction of the Ca^{2+} as it diffused the short distance between the clustered Ca^{2+}- and K_{Ca} channels, and implies a diffusion distance <300 nm. K_{Ca} channel activation was reduced by 500 μM BAPTA during small depolarizations that evoked submaximal Ca^{2+} currents, but the buffer saturated during larger Ca^{2+} currents. This saturation indicates that local $[Ca^{2+}]_i$ exceeded 500 μM during large depolarizations. Thus, diffusible buffers reduced the local steady-state $[Ca^{2+}]_i$ only when present at high concentration, and the buffer's binding rate was a crucial factor in its effectiveness close to the site of Ca^{2+} entry.

CALCIUM DYNAMICS IN MOUSE MOTOR NERVE TERMINALS REVEALED BY FURA-2 RATIO IMAGING. Z.-P. Fang and N. Robbins. Dept. of Neurosciences, Case Western Reserve Univ., Sch. of Med., Cleveland, OH 44106.

Until now, the amplitude and time course of changes in free calcium concentration in mammalian nerve terminals has been estimated only indirectly by measuring MEPP frequency or EPP amplitude. Therefore, it was of interest to determine cytosolic calcium dynamics more directly; particularly those transients which occur during physiological pattern of neuronal activity. We studied cytosolic calcium dynamics in mouse motor nerve terminals by direct measurement with the calcium indicator fura-2. The nerve-muscle preparation was perfused in normal Krebs solution at room temperature. After the dye was injected into preterminal axons in soleus muscles, it rapidly diffused into the nerve terminals (Fang & Robbins, *Neurosci. Abstr.* **15**:484, 1989). Fluorescence signals at two excitation wavelengths, detected by a photomultiplier tube or a video camera, were ratioed to generate average terminal calcium concentration data. During a tetanus of 10-20 Hz (the natural firing rate in the soleus), $[Ca^{++}]_i$ increased from a resting level of 100-200 nM to a plateau level of 500-1000 nM in about 10 seconds. At the end of the tetanus, $[Ca^{++}]_i$ decayed exponentially to the resting level with a time constant of 10-20 seconds. When a higher stimulation frequency of 50-100 Hz (typical of fast twitch muscle) was used, $[Ca^{++}]_i$ reached plateau levels as high as 1500 nM or more in 3-5 seconds, and recovery could take more than 20 minutes. These data in soleus muscle will be compared to those in fast twitch muscles which have different firing patterns. Supported by NIA grant AG08886.

CALCIUM-EVOKED [^{3}H]ACETYLCHOLINE RELEASE FROM CALCIUM-NAIVE RAT HIPPOCAMPAL SYNAPTOSOMES: INFLUENCE OF MUSCARINIC CHOLINERGIC AUTORECEPTORS AND CATION CHANNELS. T.W. Vickroy, C.J. Schneider* and J.M. Hildreth*. Depts. Physiol. Sci. and Neuroscience, Univ. Florida, Gainesville, FL 32610.

Studies were carried out to delineate presynaptic mechanism(s) which regulate the ability of calcium (Ca^{2+}) to promote [^{3}H]acetylcholine ([^{3}H]ACh) release in a novel model system. Rat hippocampal synaptosomes were prepared, labelled with [^{3}H]choline and superfused under Ca^{2+}-free conditions (zero Ca^{2+} plus 50μM EGTA) at 37°C. Infusion of buffers containing Ca^{2+}, Sr^{2+} or Ba^{2+} produced a four to twelve-fold increase in the rate of [^{3}H]ACh efflux. Tetrodotoxin, an inhibitor of voltage-activated Na^+ channels, caused near-complete blockade of cation-stimulated [^{3}H]ACh release thereby indicating an integral role for voltage-activated Na^+ channels in this exocytotic event. Pharmacological studies with Ca^{2+} channel blockers demonstrated that the response to Ca^{2+} (and Ba^{2+}) was sensitive to selected agents, including (IC_{50}'s in parentheses) ω-conotoxin GVIA (0.9nM), $CdCl_2$ (1.6μM), $CoCo_3$ (300μM), $MgCl_2$ (<20mM) and $LaCl_3$ (<1mM). The dihydropyridine Ca^{2+} channel antagonist nifedipine (10μM) was without effect, consistent with the profile for N-type voltage-sensitive Ca^{2+} channels. Membrane depolarization with elevated extracellular potassium (up to 30mM) selectively enhanced the secretagogue action of Ca^{2+}. In addition, pretreatment with potassium channel blockers, including (EC_{50}'s in parentheses) charybdotoxin (3nM) 4-aminopyridine (10μM) and tetraethylammonium (800μM), nearly tripled the maximal response to Ca^{2+}. Pretreatment with muscarinic cholinergic agonists (carbachol or oxotremorine) significantly reduced Ca^{2+}-stimulated [^{3}H]ACh release in an atropine-sensitive manner. Together, these results demonstrate that Ca^{2+}-naive synaptosomes are a useful model for studies of presynaptic receptors and ion channels which regulate Ca^{2+}-dependent neurotransmitter release in CNS tissues. A STUDY OF SYNAPTIC FACILITATION IN CA1 PYRAMIDAL CELLS USING WHOLE CELL RECORDING AND STIMULATION OF ONE OR A FEW PRESYNAPTIC FIBERS J.F. Storm & M. Raastad, Inst. of Neurophysiology, Pb 1104 Blindern, N-0317 Oslo, Norway.

Paired-pulse facilitation (PPF) is a widespread form of short-term synaptic plasticity, which may be due to residual Ca in the presynaptic terminal following the first impulse. We have used whole-cell recording to study PPF in CA1 cells in rat hippocampal slices (in 10 uM bicuculline). Two electrical stimuli (stim.1 and 2, 30-60 ms apart) were given to radiatum fibres once every 1-2 s, each eliciting a postsynaptic excitatory current (EPSC1 and 2). Strong stimuli from a glass pipette (30-50 um tip) elicited regular EPSCs (peak amplitude 10-50 pA; no failures). Each EPSC2 was larger than EPSC1, reflecting PPF of the summed EPSC from many synapses. In contrast, weak stimuli from a small pipette (2-6 um tip; to stimulate a single presynaptic fiber; Raastad, Storm, Andersen, Soc. Neurosci Abstr. 16, 674, 1990; Raastad, this meeting), elicited small EPSCs of highly variable amplitude (typically < 10 pA) intermixed with no detectable response (failures). Now, PPF was only seen as fewer failures; the mean amplitude of non-zero EPSCs did not change. When medium pipette sizes (5-20 um) or stimulation strenghts were used (to stimulate a few fibres), there were still some failures, but when records with failures were omitted, the mean EPSCs showed clear PPF (Fig.: A). And: when records with failures in EPSC1 but not in EPSC2 were averaged, EPSC2 was as big as when EPSC1 did not fail (Fig.: B). Hence, the failures of EPSC1 were not mainly stimulation failures. This suggests that: (1) stimuli that release or do not release transmitter cause the same degree of facilitation; (2) PPF is due to a presynaptic mechanism (probably fewer release failures, e.g. due to residual Ca); (3) each synapse releases only 0-1 quantum per impulse even during PPF (since PPF did not increase the apparent single fibre EPSC amplitude); and (4) if the residual Ca hypothesis is correct, the release failures are probably not due to variations in presynaptic Ca influx (since EPSC1 failures were not correlated with a smaller EPSC2).

A METHOD FOR RELIABLE ACTIVATION OF A SINGLE EXCITATORY SYNAPSE IN CA1 PYRAMIDAL CELLS
M. Raastad, Inst. of Neurophysiology, Pb 1104, N-0317 Oslo, Norway.

A reliable single synaptic input is a useful tool for a detailed study of synaptic mechanisms. By stimulating with a small (2-4um) glass pipette filled with extracellular solution, positioned 100-200um off-centre in the dendritic tree, and using a random stimulation-strength pattern, it is possible to demonstrate regular activation of a single synaptic afferent to CA1 cells.

CA1 cells in submerged hippocampal slices from rats were patch-clamped deep in the tissue without cleaning. 200us long stimuli varying randomly between 0 and 2mA, were delivered at 1Hz. Above threshold, there was a good linear correlation between the stimulus strength and the amplitude of extracellular field potential. In contrast, there was no correlation between the size of the excitatory postsynaptic current (EPSC) and stimulus strength above threshold (T in fig.A). The mean amplitude and the variability remained constant. In conclusion, only one synapse was activated within this range of stimuli. Below the threshold the amplitudes were distributed normally around zero (failures, dotted in fig.B), whereas above threshold the amplitudes were distributed around two values, either around zero or around a given mean amplitude, with a considerable variability (EPSCs, continuous line in fig.B). The mean amplitude varied considerably between synapses.

Above threshold, paired pulses 30ms apart, reduced the number of failures (facilitation), but the mean amplitude of the EPSCs was not affected, confirming that only one synapse was regularly activated, and suggesting that these synapses release either no or one quantum.

PRIMARY CULTURES OF NEURONS FROM RAT HIPPOCAMPUS RELEASE CORTICOTROPIN RELEASING FACTOR (CRF)
D.L.Birkle. Dept. Pharmacology & Toxicology, West Virginia University, Morgantown, WV 26506

CRF-containing cells have been localized in a number of brain areas outside the hypothalamus, including the hippocampus and frontal cortex. Changes in CRF levels in these sites occur in response to psychoactive drugs, stress and anxiety. However, the factors that regulate CRF release from extrahypothalamic sites have not been identified. Primary cultures of hippocampal neurons were prepared from fetal rat brain (E17), and grown in poly-lysine coated 35 mm wells. Cells were treated at day 3 with ARA-C, and used on culture day 12. Cells were incubated 1 hr in physiological buffer (basal period), then re-incubated 1 hr in fresh buffer containing 50 mM K^+. CRF immunoreactivity (CRF-IR) in the incubation media was measured by radioimmunoassay. Basal levels of CRF-IR were 154 ± 3 pg/10^8 cells (n = 12). Depolarization with K^+ caused a 100% increase in CRF-IR to 300 ± 4 pg/10^8 cells. Cultures of neurons from specific brain regions will provide a useful model system for studying the regulation of CRF release. Supported by Pharmaceutical Manufacturers Association and the National Science Foundation.

PHORBOL ESTERS INCREASE THE FREQUENCY OF SPONTANEOUS EXCITATORY POSTSYNAPTIC CURRENTS IN THE HIPPOCAMPUS BY A PRESYNAPTIC, CALCIUM-DEPENDENT MECHANISM. K.D. Parfitt and D.V. Madison, *Dept. of Molecular & Cellular Physiology, Stanford Univ. Sch. of Med., Stanford CA 94305-5426.*

Phorbol esters, which are activators of protein kinase C, induce a synaptic potentiation in the hippocampus that may share many common mechanisms with LTP. Using whole-cell voltage clamp techniques to study synaptic transmission in area CA1 of 500 uM-thick hippocampal slices, we have found (Parfitt & Madison, Soc. Neurosci. Abstr. 1990) that phorbol esters are capable of potentiating stimulus-evoked synaptic transmission even when induction of LTP is blocked by postsynaptic dialysis, suggesting a presynaptic mechanism for the phorbol potentiation. Using the same techniques, we have recorded spontaneous excitatory postsynaptic currents (EPSCs) in pyramidal neurons in the presence of tetrodotoxin and picrotoxin. Thus, these events are the product of non-action potential-dependent excitatory transmitter release. We have observed an approximate 8-fold increase in the frequency of spontaneous EPSCs during bath application of phorbol diacetate (PDAc, 10 uM), with no change in the amplitude distribution of these events. This phorbol ester-induced increase in frequency of spontaneous EPSCs is significantly attenuated by voltage-dependent calcium channel (VDCC) blockers, such as cadmium, dihydropyridines, or omega conotoxin. These VDCC antagonists did not affect the basal frequency or amplitude of spontaneous EPSCs. A glutamate antagonist known to act postsynaptically, 6-cyano-nitroquinoxaline-2,3-dione (CNQX, 100 nM), shifted the amplitude distribution to the left without significantly diminishing the frequency of spontaneous events. Taken together, these results strengthen our hypothesis that phorbol esters potentiate synaptic transmission by enhancing the opening of presynaptic voltage-dependent calcium channels, thereby augmenting transmitter release.

593.12

DIFFERENTIAL MODULATION OF INHIBITORY TRANSMISSION IN THE HIPPOCAMPUS BY CARBACHOL, ADENOSINE, BACLOFEN, SEROTONIN AND NOREPINEPHRINE. G.A. Cohen, V.A. Doze and D.V. Madison, *Department of Molecular & Cellular Physiology, Stanford School of Medicine, Stanford, CA 94305.*

Carbachol (CARB), baclofen (BACLO), serotonin (5-HT), norepinephrine (NE), and 2-Cl-adenosine (ADEN), all reduce the polysynaptic evoked inhibitory postsynaptic potential (ipsp) in area CA1 of the rat hippocampus.

Intracellular recording and whole cell patch clamping were used to monitor evoked ipsps and miniature ipscs, respectively, in rat CA1 pyramidal cells. We studied the effects of the listed neurotransmitter agonists on polysynaptic-evoked ipsps, monosynaptic evoked ipsps (KMeSO4 and QX-314 in the intracellular electrode; CNQX and APV in the extracellular ACSF), and spontaneous miniature ipscs (KCl and QX-314 in the patch electrode; CNQX, APV and TTX in the ACSF).

CARB (10uM), or BACLO (10uM) inhibited the monosynaptic ipsp more than 60%. At 1uM, BACLO reduced the monosynaptic evoked ipsp 30%. 5-HT, NE, or ADEN (all 10uM) had no effect on the monosynaptic evoked ipsp. CARB (10uM) reduced the frequency of spontaneous miniature ipscs more than 50%, while the overall shape of their amplitude distribution was not changed. Baclo (10uM) caused a 10% reduction in frequency, and had no effect at 1uM. 5-HT, NE, or ADEN (10uM) had no effect on spontaneous miniature ipscs.

These results show that different neurotransmitters that reduce inhibitory transmission may exert this effect by acting at different sites in the synaptic circuitry. 5-HT, NE, and ADEN appear to inhibit interneurons at a somatic location or by inhibiting excitatory synaptic activation of interneurons. At low concentrations BACLO does not directly decrease spontaneous GABA release but may still act at the interneuron terminal (e.g., by decreasing calcium currents). CARB directly reduces GABA release from interneuronal synaptic terminals.

SEROTONIN III

594.1

GLIAL BUT NOT NEURONAL ACTIVATION OF Na^+/K^+-ATPase BY SEROTONIN IN THE RAT BRAIN. J. Hernández, R. Mercado* and G. Chagoya*. CINVESTAV-IPN. A.P. 14-740, México, D.F. 07000 México.

In-vitro and in-vivo experiments from our and other laboratories have shown a regulatory role of serotonin (5-HT) on the activity of Na^+/K^+-ATPase in rat brain. We further observed that the Vmax of the enzyme kinetics was significantly elevated by 5-HT, only in cerebral cortex homogenates, but not in synaptosomes or microsomes, where glial membranes are not predominant.

The possibility of a selective activation of the glial enzyme by 5-HT was tested in enriched glial or neuronal fractions isolated from rat brain and also in cultured astrocytes or neurons.

The results clearly indicate that 5-HT selectively activates the glial enzyme with significant response - curves from 10^{-7} to 10^{-3} M. No activation of the neuronal enzyme was observed at physiological 5-HT concentrations. Potassium activation curves and (^{3}H) Ouabain binding in glial enriched fractions and cultured astrocytes, suggest that 5-HT may act by exposing more active sites of the enzyme. Our results suggest that regulation of glial Na^+/K^+-ATPase by a neurotransmitter may play an important role in maintaining the cationic balance for neuronal function.

594.2

THE 5-HT_2 ANTAGONIST RP 62203 SELECTIVELY BLOCKS SEROTONINERGIC INHIBITION IN THE RAT PREFRONTAL CORTEX. R. Godbout, J. Mantz*, J. Glowinski* and A.M. Thierry*. Collège de France, INSERM U. 114, 75231 Paris cedex 05, France.

The electrical stimulation of the median raphé nucleus (MRN) inhibits the spontaneous firing of medial prefrontal cortical (PFC) neurons, and this effect is likely mediated by 5-HT_2 receptors (Mantz et al., *Brain Res.*, **524**: 22-30, 1990). Biochemical and autoradiographic studies have shown that RP 62203, a novel naphtosultam derivative, is a potent and selective antagonist of 5-HT_2 receptors. To further characterize the selective influence of RP 62203 on 5-HT neurotransmission in the PFC, we analysed the effect of i.p. administration of RP 62203 on: 1) the 5-HT inhibitory responses induced by MRN stimulation and 2) the dopaminergic (DA) inhibitory responses elicited by stimulation of the ventral tegmental area (VTA). A single dose was administered and 1 PFC cell was tested in each of 10 ketamine-anesthetized rats. In 8 of the 10 PFC cells inhibited by both MRN (dur = 87.0±5ms; lat = 10.4±2ms) and VTA (dur = 114.0±18ms; lat = 6.0±2ms), RP 62203 blocked MRN-induced inhibitory responses in a dose-dependent and reversible fashion; in contrast, it failed to affect the inhibition elicited by VTA stimulation. These results show that RP 62203 selectively blocks 5-HT but not DA neurotransmission in the rat PFC and further support the involvement of 5-HT_2 receptors in this effect.

594.3

INHIBITION OF PLATELET SEROTONIN UPTAKE BY PHORBOL ESTER: DOES PROTEIN KINASE C ACTIVATION DOWN-REGULATE THE SEROTONIN TRANSPORTER? **G.M. Anderson*, W.C. Horne*, L.M. Hall*, B.A. Shaywitz, D.J. Cohen*. Child Study Center, Yale University School of Medicine, New Haven, CT 06510.**

Treatment of human platelets with 4-beta-12-0-tetradecanoylphorbol-13-acetate (beta-TPA), an activator of protein kinase C (PKC), resulted in a mean 34% decrease (N=16, p=.0001) in the V_{max} of serotonin (5-HT) uptake. A smaller effect on K_m was also observed (mean 15% decrease, N=16, p <.0005). 4-Alpha-TPA was without effect on either the V_{max} or K_m of platelet 5-HT uptake. Treatment with the calcium ionophore A23187 produced a smaller, non-significant, decrease in V_{max}, while dibutyrylcyclic AMP treatment had no effect. Phorbol ester (beta-TPA) did not cause a decrease in [^{3}H]-imipramine binding in intact platelets. Experiments in which sodium/proton antiporter or the chloride/bicarbonate exchangers were inhibited suggest that about one-third of the TPA effect may be due to change in the transmembrane sodium gradient.

The data indicate that PKC activation may down-regulate the activity of the 5-HT transporter in platelets. Most of the effect of PKC activation appears to be independent of a reduction in the number of 5-HT transporters at the platelet surface or alterations in ion gradients. The apparent regulation of 5-HT uptake by PKC raises the possibility that the transporter may be receptor-regulated as has been demonstrated for several other transport systems.

594.4

COLOCALIZATION OF PROGESTIN RECEPTORS AND SEROTONIN IN RAPHE NEURONS OF MACAQUE. C. L. Bethea, Div. of Reproductive Biology and Behavior, Oregon Regional Primate Res. Ctr., Beaverton, OR 97006.

Serotonin (5HT) neurons play a significant role in the regulation of several endocrine systems. Dysfunction of 5HT neurons has also been implicated in various affective disorders, including depression. We have shown that progesterone (P) increases prolactin secretion in estrogen-primed monkeys, and that lactotropes do not contain progestin receptors (PR). Since stimulation of 5HT increases prolactin secretion, we questioned whether P could act on 5HT neurons to increase prolactin secretion. Pontine and medullary tissue blocks were obtained at autopsy of a female Japanese macaque. 5HT neurons were immunohistochemically identified in dorsal and ventral pontine raphe groups, as well as in a more caudal medullary group using an antibody to 5HT-BSA conjugate (Incstar) and an avidin-biotin alkaline phosphatase bridging technique (Vector Labs, ABC-AP Kit). Development in Substrate Kit III yielded blue 5HT positive (+) neurons. PR expressing neurons were identified with B39, a monoclonal antibody against PR and an avidin-biotin peroxidase bridge with development in DAB (Vector Labs, ABC-HP Kit). The blue AP reaction product for 5HT localizes in the cytoplasm of neurons while the brown DAB reaction product for PR localizes in the nucleus of neurons. All 5HT+ neurons in both raphe groups exhibited PR+ nuclei when the whole cell was visible in the section. Many PR+ nuclei were also observed in 5HT negative neurons in adjacent areas. These data indicate that the midbrain 5HT neurons are progestin target cells and suggest that P can modulate the function of 5HT neurons. Supported by HD17269, HD18185, RR00163.

594.5

INCREASED EXTRACELLULAR CONCENTRATION OF SEROTONIN IN THE RAPHE NUCLEI AFTER UPTAKE INHIBITION MEASURED WITH IN VIVO MICRODIALYSIS. SECONDARY EFFECTS ON 5-HT_{1A} AUTORECEPTORS F. Artigas*, A. Adell, R. Cortés, P. Celada*. Department of Neurochemistry, C.S.I.C. E-08034 Barcelona, Spain

Extracellular serotonin (5-HT) occurs in the raphe nuclei in concentrations similar to other brain areas rich in nerve terminals. We have examined the effects of several drugs and ions affecting 5-HT neuronal activity on this extracellular pool in the raphe using the technique of intracerebral microdialysis. Dialysate 5-HT was significantly increased (400%) by K^+ ions but it was insensitive to removal of Ca^{2+} ions from the dialysis fluid. The treatment with reserpine (5 mg/kg, 24 h) did not change dialysate 5-HT. However, it increased after a single injection of p-chloroamphetamine in both saline- and reserpine-treated animals (550% and 350%, respectively). 8-OH-DPAT, a 5-HT_{1A} agonist, locally applied through the dialysis cannula placed in the raphe did not change extracellular 5-HT in this area but it reduced it in the frontal cortex of animals with two cannulae. These results and the low density of 5-HT nerve endings in the raphe suggest a somatodendritic release of the amine. The treatment with 5-HT uptake inhibitors increased several-fold extracellular 5-HT in the raphe. Given the high density of 5-HT_{1A} receptors in the dorsal raphe nucleus, we have examined the effects of repeated treatment with two 5-HT uptake inhibitors used as antidepressants (fluoxetine and clomipramine, 10 and 20 mg/kg daily, respectively) on its density using autoradiography with ^{3}H-8-OH-DPAT as ligand. Preliminary results showed that two weeks of treatment with either drug did not alter 5-HT_{1A} receptor density.

ACUTE AND LONG TERM EFFECTS OF CERICLAMINE, A SELECTIVE 5HT UPTAKE INHIBITOR, ON THE FIRING OF DORSAL RAPHE NEURONS. T. Jolas*, J. Adrien*, L. Lanfumey, S. Hai-Dahmane* and M. Hamon*, (SPON: European Neuroscience Association)
INSERM U288, CHU Pitié-Salpêtrière, 75013 Paris, France.

Under acute treatment, serotonin (5HT) uptake inhibitors reduce the discharge frequency of 5HT neurons in the Dorsal Raphe nucleus (DRN) by triggering a negative feedback through somatodentritic 5HT_{1A} autoreceptors. Under chronic treatment, these drugs have been claimed to be less effective, due to a desensitization of the latter receptors. Further assessment of such changes was made using Cericlamine (JO 1017, Jouveinal Labs), a new highly selective 5HT uptake inhibitor with potent antidepressant properties.

Acute treatment: Extracellular recordings were performed in male Sprague-Dawley rats under chloral hydrate anaesthesia. Cericlamine (0.25-10mg/kg i.v.) induced a dose-dependent decrease in the firing frequency of DRN 5HT neurons (IC_{50}=0.45mg/kg), which could be reversed by the 5HT_{1A} antagonist Tertatolol (2mg/kg i.v.). In contrast, the same doses of Cericlamine had no effect on the discharge frequency of noradrenergic neurons in the Locus Cæruleus.

Chronic treatment: 24 h after completion of a 14 day-treatment with Cericlamine (16mg/kg i.p. twice daily), the potency of this drug to depress the firing rate of DRN 5HT neurons recorded *in vivo* was significantly less than in controls (IC_{50}=1.53mg/kg). Moreover, the inhibitory effect of the 5HT_{1A} agonist 8-OH-DPAT (10-50nM) on the firing rate of DRN 5HT neurons recorded *in vitro* (in brain stem slices) was significantly smaller in treated rats (IC_{50}=10nM) than in controls (IC_{50}=18nM).

These data support that the desensitization of somatodentritic 5HT_{1A} autoreceptors might be a common effect of 5HT uptake inhibitors when administred chronically for alleviating depression.

INFLUENCE OF 5,7-DHT HYPOTHALMIC LESION ON ANTEROGRADE TRANSPORT OF 5HT MEASURED BY IN SITU SYNTHESIZED α-METHYL SEROTONIN M. Diksic and A. Takada*. Department of Neurology and Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, Quebec, H3A 2B4, CANADA

α-methyl serotonin (α-M5HT), a chemical and functional analogue of serotonin synthesized in situ, was used to measure anterograde transport of 5HT along the medial forebrain bundle (MFB) of 5,7-DHT stereotaxicly lesioned rats.

Lesions were produced in the brains of 250g Sprague-Dawley rats by injecting 3μg of 5,7-DHT (free base) in 250 nL of saline at the following coordinates: -3.14 (post); 1.0 (lat); 8.1 (vent) (Paxonos and Watson). In a control rat, 250 nL of saline alone was injected. Five days later, 500-800 μCi of [^{3}H] labelled α-MTrp was injected. In each animal, it was possible to compare the rate of transport in the lesioned and the contralateral MFB.

Destruction of the terminals by 5,7-DHT increased the rate of anterograde transport of 5HT by at least 30%. Destruction of the terminals also resulted in a tenfold increase in the amount of 5HT transported anterogradely. The amount transported was estimated from the area under the curve, obtained by plotting the radioactivity ratio in the MFB and that found in the hypothalamus on the non-lesioned side, as a function of the distance from the dorsal/medial raphe plane.

Our data support the notion that there is a presynaptic receptor/autoreceptor that controls the rate and the amount of anterogradely transported 5-HT. We also conclude that anterogradely transported 5HT has some physiological relevance, as there would otherwise be no need for presynaptic control of the rate and amount of 5HT transported from the cell bodies towards terminals.

HYPOINNERVATION OF SEROTONIN NEURONS IN THE FOREBRIAN OF ALCOHOL-PREFFERING (P) RATS. Li, T.-K., Lumeng, L., Pu, C.F., Farber, S., and Zhou, F.C.
Depts. of Anatomy and Medicine, Indiana University School of Medicine and VAMC Indianapolis, IN 46202 USA

We have previously found that the levels of serotonin (5-HT), and 5-hydroxyindole-acetic acid (5-HIAA) content are decreased in the hippocampus, accumbens, striatum, cortex, and thalamus of selectively bred alcohol-preferring P rats, compared with the alcohol-nonpreferring NP rats. This study shows that the number of 5-HT fibers and 5-HT neurons are low in P rats compared with NP rats. 5-HT immunofibers were lower in cingulate cortex, and medial nucleus accumbens, layer III-V of anterior frontal cortex, CA4 and fascicularis cinarium of dorsal hippocampus and dentate gyrus of ventral hippocampus, hypothalamus and striatum (unpaired Student's t-tests, n>4) of the P rats. 5-HT neurons were counted in serial sections through the entire ascending raphe nuclei. Overcounting in adjacent sections was corrected with use of Abercrombie's formula. There were significantly fewer 5-HT neurons in the median raphe in P (1542±76) than in NP (1975±81) rats (n=5 each), while no significant difference was observed in the B9 group (P=1359±132, NP=1489±151). This result indicates that the lower content of 5-HT and the decreased 5-HT fiber density seen in P rats may be partially due to decrease number of 5-HT neruons in the median raphe. Antipeptide antibodies against rat brain tryptophan hydroxylase Azmitia, E.C.[1,2], Yu, I.J.[2], Akbari, H.M.[1], Chen,Y.[1] and Marshak, D.R.[2]
[1]Dept. of Biology, New York University, Washington Square East, N.Y., N.Y. 10003 and [2]Cold Spring Harbor Laboratory, Cold Spring Harbor, N.Y. 11724

N- and C-terminal segments from rat tryptophan hydroxylase were selected with no homology to tyrosine or phenylalanine hydroxylase. The peptides were coupled to KLH and injected into adult rabbits. Radio-immuno assay of the immune serum up to 1/8000 showed higher binding (5-18X) than the pre-immune serum. Immunoblotting against whole cell extracts (30-75 ng) from pineal and midbrain raphe tissue from adult rats were run on 12.5% SDS-PAGE and transferred to nitrocellulose. Both antibodies at 1/100-1/2000 revealed specific bands. A single band (approximate M.WT. 48,700) was seen for the rat pineal and midbrain raphe using the C-terminal peptide derived antibody (WOH-412). Staining with the N-terminal region antibody (WOH-66) showed 3 specific bands (approximate MW 52,500, 48,400, and 47,800) for the pineal and single band (MW 47,800) for the midbrain raphe. The specificity was further characterized by using immunohistochemical staining of rat brain sections. The staining with WOH-66 showed specific staining in all the classical raphe nuclei at dilutions as low as 1:7000 using glutaraldehyde, paraformaldehyde or picric acid as fixatives. In addition labelled cells were seen in the pineal gland and in the area postrema. The perikarya, dendrites and axons, but not the nuclei, were stained by WOH-66. The rare ependymal cell in the fourth ventricle was positively stained. No staining was seen in the locus coeruleus, substantia nigra or in the hypothalamus. No staining was seen with antibody WOH-412. The multiple bands seen with the pineal extract after immuno-blot with WOH-66 but not WOH-412 indicate post-translational modification or alternative splicing at the C-terminus. EVALUATION OF POTENTIAL NEUROTOXIC EFFECTS OF AMPHETAMINE-RELATED ANORECTIC AGENTS ON BRAIN SEROTONIN AND DOPAMINE IN THE RAT. M.S. Kleven, W.L. Woolverton, and L.S. Seiden. Department of Pharmacological and Physiological Sciences, The University of Chicago, Chicago, IL 60637.

Amphetamine, N-methylamphetamine, and several related analogs have neurotoxic effects on brain dopamine (DA) and/or serotonin (5-HT) neurons. In this study, possible long-lasting neurochemical effects of several structurally dissimilar anorectic agents currently available for clinical use were examined. Saline or phentermine (25, 50 or 100 mg/kg), phenmetrazine (31.3, 62.5, or 125 mg/kg), phendimetrazine (31.3, 62.5, or 125 mg/kg), or benzphetamine (75, 150, or 300 mg/kg) were administered s.c. to separate groups of rats (n=6-9/group) twice daily for four consecutive days and levels of DA and 5-HT were assayed after a two week survival period. Doses used were approximately 5, 10, and 20 time the anorectic ED50 for suppression of milk intake obtained in separate groups of rats presented sweetened condensed milk. The four day regimen of phentermine and benzphetamine produced significant, dose-related decreases in DA levels in striatum (to 73.6±8.3 and 66.5±3.1% of control, phentermine and benzphetamine, respectively). Depletions of 5-HT were also observed in hippocampus (to 50.5±4.9% and 71.8±6.1%) and cortex (to 70.7±13.0 and 76.3±8.9) following repeated phentermine and benzphetamine injection. In contrast, comparable monoamine depletions were in general, not observed following repeated administration of phenmetrazine or phendimetrazine, nor did any of the drugs cause substantial depletions of 5-HT in striatum or hypothalamus. The results indicate that, like amphetamine, the α,α-dimethyl homolog phentermine and the N-dialkyl homolog benzphetamine may be neurotoxic to DA and 5-HT neurons. In contrast, the phenylmorpholine derivatives, phenmetrazine and phendimetrazine probably lack such effects. (Supported by NIDA Grant DA-00085 and RSA MH-10562 [L.S.S.])

PROLONGED ADMINISTRATION OF D-FENFLURAMINE IS NOT ASSOCIATED WITH ANY LONG LASTING EFFECT ON NEOCORTICAL 5HT INNERVATION. M. Kalia Dept. Pharmcol, Jefferson Med Col., Thomas Jefferson Univ., Philadelphia. PA 19107.

Previous studies from this laboratory revealed that in the rat, orally administered D-Fenfluramine for short periods (up to 4 days) produced short-lived and reversible immunocytochemical changes in neocortical 5HT innervation. (*Kalia, M., Brain Res. 1991)* In this report additional questions have been addressed: How long does the depletion of 5HT from the neocortex last following cessation of treatment? Is this effect reversible?. We selected two oral doses, (8mg/kg/day and 16 mg/kg/day) which were administered for 21 & 30 days. The animals were examined at 3 different post-treatment time points: 18 hrs, 30 days and 60 days. Immunocytochemical methods, identical with those described previously were used to evaluate the brains postmortem. A predictable reduction in immunocytochemical staining of neocortical 5HT nerve networks was seen 18 hrs following cessation of treatment. The 5HT immunocytochemical staining 30 and 60 days post-treatment was indistinguishable from pair-fed controls. When the results of 18 hour post-treatment were compared with existing data from 4 day treated animals, we found qualitative differences. Chronic treatment with D Fenfluramine produced fewer "thick" immunoreactive 5HT fibers and the fine fibers were very distinct and finely beaded. These results confirm our hypothesis that the predictable reduction in neocortical 5HT immunoreactivity is a function of transient depletion of 5HT and is not associated with any long-term change in the 5HT innervation of this region.

CIRCUITRY AND PATTERN GENERATION II

595.1

MUTATIONS AFFECTING PERIODIC BEHAVIOR IN *C. ELEGANS*. Dennis WC. Liu and James Thomas*, Department of Genetics University of Washington, Seattle, WA 98195.

Defecation is a periodic behavior in *C. elegans*, occurring about every 45 seconds in well-fed, adult wild-type worms. The cycle periodicity (CP) may be under the control of a neuronal pattern generator. Wild-type worms will stop defecating in the absence of food and CP is correlated with the rate at which the pharynx pumps in food; pumping defective mutants defecate less often. Extensive screens for constipated (Con) mutants yielded only one mutation in one gene (*dec-1*) which caused lengthening of the defecation CP (Thomas, Genetics 124:855-872, 1990). We reasoned that Con screens might fail to reveal many mutants with long cycles and should miss mutants with shorter than normal CP.

To isolate short and long-cycle mutants we undertook a direct screen for animals with altered CP, after EMS mutagenesis. CP was timed in individual animals, and a mutant candidate was picked: 1) if it repeated the behavior twice or more in one minute, 2) if it repeated the behavior less often than once per minute.

The screen has led to the identification of three classes of mutations which affect CP by causing; 1) long cycles, 2)short cycles , and 3) variable CP. Most of the mutations we have isolated are of the first class. An example is the *sa73* mutation, which causes an average period of 100 seconds. We have isolated one mutation in the second class, *sa92*, which causes a CP of about 30 seconds. Finally we have isolated a mutation *(sa96)*, which causes animals to have a variable CP ranging from 10-150 seconds. Thus far, none of the mutations map to the same loci and we are carrying out epistasis analysis.

We are currently examing the effects of these mutations on other rhythmic behaviors such as egg-laying and locomotion. In order to identify the cells which are responsible for controlling periodic behavior, we are using a microsope-focused laser to kill neurons in wild-type worms.

595.2

STIMULATION OF THE SECOND THORACIC ROOTS AFFECTS THE SWIMMERET, THE WALKING AND THE ABDOMINAL POSITIONING SYSTEMS OF THE CRAYFISH. A. Chrachri and D.M. Neil. University of Glasgow, Department of Zoology, Glasgow G12 8QQ Scotland, U.K.

In crayfish, the rhythmical activity of the swimmeret system is strongly modified by stimulating the second thoracic roots (STR). This stimulation increases the frequency of the swimmeret rhythm and the frequency of spikes within bursts, it also increases the total amplitude of membrane potential oscillations of certain swimmeret neurons. Sometimes, an increase in the intensity of stimulation inhibits the swimmeret rhythm.

Recently, we have found that stimulation of STR affects not only the swimmeret system but also the abdominal positioning and the walking systems. The STR effects are most of the time comparable to that of spontaneous activity in these systems often obtained during the same experiment. In the present study we have also been able to record intracellularly from a number of abdominal interneurons. Most of these interneurons respond to the stimulation of the STR with a long-lasting depolarization, while others with only a short-lasting membrane depolarization and/or EPSPs. These properties may explain the variety of the STR effects.

In conclusion, axons in the STR seems to have access to a wide range of abdominal interneurons, some with specific effects (i.e. activation or inhibition of the swimmeret rhythm), while others seems to have a multiple motor output properties. At least some of these interneurons seems to induce effects that are established slowly and are of long duration suggesting that the stimulation of the STR might involve command neurons. Finally, intracellular recording from the same interneuron in two different ganglia suggests that they are descending interneurons.

MODULATION OF IDENTIFIED STOMATOGASTRIC NEURONS IN PRIMARY CELL CULTURE. G.G. Turrigiano and E. Marder, Dept. of Biology, Brandeis Univ., Waltham, MA 02254

We have begun to use current and voltage clamp techniques to study the properties of identified stomatogastric neurons in primary cell culture. Gastric mill and pyloric neurons from the stomatogastric ganglion of the spiny lobster *Panulirus interruptus* are identified electrophysiologically, ganglia are enzymatically treated, neurons are dissociated by aspiration into micropipettes, and plated onto uncoated Nunclon culture dishes in defined medium. Over the course of several days these neurons regenerate neurites, and regain the ability to produce action potentials, to oscillate in the presence of TEA, and to respond to neuromodulators. The DG neuron, a likely target of octopamine *in situ*, is modulated by octopamine in culture: octopamine acts in part by reducing the magnitude of an A-type current in this neuron. The PD neuron in culture is excited by the muscarinic agonist pilocarpine, inhibited by dopamine, and is not affected by serotonin; these responses are similar to those exhibited by PD *in situ*. These preliminary results suggest that pyloric and gastric mill neurons are expressing the same complement of receptors in culture as *in situ*, and are retaining some of their physiological properties. 595.4

MECHANISMS SUBSERVING CONSTRUCTION OF A NOVEL MOTOR-PATTERN GENERATING NETWORK BY A MULTIACTION INTERNEURON. A. J. Simmers*, P. Meyrand* and M. Moulins. Lab. de Neurobiologie et Physiologie Comparées, Univ. de Bordeaux I, CNRS, Arcachon, 33120 FRANCE.

We have recently reported that in the stomatogastric nervous system (STNS) of lobsters (*Homarus gammarus*), the rhythmic discharge of an identified modulatory neuron (PS) is able to construct *de novo* the central pattern generator (CPG) for swallowing-like behavior from neurons belonging to other functional CPGs (Nature, 1991, in press). Thus, when PS is active, neurons otherwise operating independently as integral elements of different neuronal networks are reconfigured into an completely new functional circuit.

We report here on the cellular mechanisms underlying this network reconfiguration. A study of direct effects of PS on individual STNS neurons has revealed three major types of postsynaptic action. First, PS acts directly on many neurons via conventional short-term synapses that evoke discrete excitatory or inhibitory postsynaptic potentials (PSPs). Second, PS can exert long-term influences that far outlast the discharge of the interneuron itself. These modulatory influences involve the suppression of intrinsic bursting properties in certain STNS neurons, while in others, a sustained membrane depolarization is produced. Third, PS may act on the same target neuron via both short and long-term influences, giving rise to transient PSPs in combination with the modulation of bursting properties.

Our results show how a neuronal network can be dynamically assembled from neurons of disparate origin by the multiple actions of a single interneuron; conventional synapses serve to coordinate different individuals to the cell own firing pattern, while modulatory influences appear to dictate both functional membership in the new circuit and the duration of its existence.

595.5

LOCAL INTERACTIONS OF DESCENDING INPUTS WITH RHYTHMICALLY ACTIVE NEURAL NETWORKS. M.P. Nusbaum. Neurobiology Research Center and Dept. of Physiol. & Biophysics; Univ. of Alabama, Birmingham; Birmingham, AL 35294.

The pyloric and gastric mill networks in the crustacean stomatogastric ganglion (STG) are influenced by descending modulatory inputs from anterior ganglia. These inputs extend axons for long distances to arborize in the STG neuropil, but little is known about events occurring locally in these STG arbors. I am therefore recording intra-axonally, at the entrance to the STG, from descending Stomatogastric Nerve Axons (SNAXs) in the crab, *Cancer borealis*. These recordings are electrotonically close to the STG neuropil, enabling recordings of discrete PSPs to be made from a SNAX.

Individual SNAXs are identifiable in successive preparations, based on their interactions with STG targets. Each SNAX that influenced the STG networks was also found to receive local synaptic feed-back from these networks. This feed-back must occur locally, in the STG neuropil, since it persisted in the isolated STG. All recorded feed-back was via IPSPs and/or electrical coupling.

SNAX 1, for example, can initiate or enhance the pyloric and gastric mill rhythms. This SNAX received short latency electrotonic EPSPs and chemically-mediated IPSPs from gastric mill neuron LG. The pyloric network also affected SNAX 1. During pyloric or gastric mill rhythms, this feed-back imposed a rhythmic inhibition on SNAX 1. This rhythmic inhibition was sufficiently strong to suppress impulses in a tonically stimulated SNAX 1, thereby transforming its activity from tonic to rhythmic. These results suggest that endogenous, spontaneous descending activity may also be locally reconfigured.

595.6

COMMAND OF FEEDING IN *APLYSIA*: IMPLICATION OF A NETWORK OF IDENTIFIED INTERGANGLIONIC INTERNEURONS IN THE BUCCAL AND CEREBRAL GANGLIA. S.C. Rosen, K.R. Weiss and I. Kupfermann. Cntr. for Neurobiol. and Behav., NYS Psychiatric Inst., New York, NY 10032; Dept. of Physiol. and Biophys., Mount Sinai Sch. of Med., New York, NY 10023.

Identified cerebral to buccal interneurons (CBIs 1-4) can initiate and regulate "feeding" motor programs. CBI-2, in particular, effectively drives a motor program that produces rhythmic, biting-like movements of the buccal mass. CBI-2 is a phasic, command-like cell that fires in periodic bursts when stimulated with constant, intracellular current. Its phasing is due to feedback inhibition and excitation generated by a buccal central pattern generator (CPG). CBI-2 acts both "permissively" and "instructively" since it: (a) produces a rhythmic, motor program even when phasic feedback is blocked and the cell fires tonically; and (b) drives salivary duct and lip (C11) motor neurons independent of CPG activity. In order to further elucidate CBI-2's functions, we examined two interganglionic buccal neurons that are antiphasically active in the program driven by CBI-2 and are monosynaptically connected to it. B17 is a postsynaptic cell that receives powerful, slow excitatory input from CBI-2. B17, in turn, produces direct PSPs in multiaction interneurons (B4,B5) and in buccal and cerebral motor neurons (B15,B16,C4,C5,C11,C12). B17 itself drives a motor program. 5(6)-Carboxyfluorescein dye fills indicate that B17 has bilateral axons in the buccal and cerebral ganglia and in buccal nerves 3. B19 is a presynaptic cell that evokes a complex, slow inhibitory and excitatory PSP in CBI-2. The PSP contributes to CBI-2 phasing across cycles of the program. B19 stimulation phase advances the CBI-2 driven program. B19 also directly excites cerebral and buccal motor neurons (many of which are reciprocally driven by B17). B19 has a single, ipsilateral axon that projects to the cerebral ganglion. The data indicate that command-like functions for feeding involve interganglionic CPG neurons that exhibit feedforward and feedback connections. Many of the dynamic properties of the neural circuitry can be simulated by a simple computer model.

595.7

TWO POPULATIONS OF RHYTHMICALLY FIRING TRIGEMINAL COMMISSURAL INTERNEURONS STUDIED DURING FICTIVE MASTICATION IN THE ANAESTHETIZED RABBIT. J.P. LUND & R. DONGA. Cent. rech. sci. neurol. Univ. de Montréal, Montréal, CANADA, H3C 3J7.

In rabbits anaesthetized with urethane, paralyzed with gallamine triethiodide and artificially ventilated, we have previously shown that trigeminal (V) commissural last-order interneurons in the left V sensory nuclei and adjacent cell groups can be antidromically identified by stimulating the right V motor nucleus (NVmot). When fictive mastication is induced by stimulation of the sensorimotor cortex (SMC) in this preparation, some of these interneurons fire rhythmically (Donga & Lund, J. Physiol. 423: 74P). We have now found that rhythmically firing interneurons (n=20) can be sub-divided into two distinct categories based on whether they received short-latency excitatory inputs (SLEIs) from the SMC (n=11) or not (n=9), using post stimulus time histogram analysis. Approximately equal numbers in both groups fired during the two main phases (jaw opening and jaw closing). 7 neurons in the SLEI category were only rhythmically active during stimulation of the contralateral SMC, 2 had ipsilateral SMC inputs only while the other 2 fired to stimulation of either SMC. The mean of the modal latencies to stimulation of the contralateral SMC was 8.3 ms (n=9) compared to 9.6 ms (n=4) for the ipsilateral SMC. It was concluded that rhythmical firing of most SLEI interneurons resulted from phasic inhibition of tonic SLEIs by other parts of the masticatory central pattern generator (CPG). It also appears that the rhythmical firing of neurons that did not receive SLEIs was due to phasic excitation from other CPG neurons. In some cases, phasic inhibition also occurred. Supported by the Canadian MRC.

595.8

A NEURALLY-INSPIRED MODEL FOR TEMPORAL AND SPATIAL PATTERN LEARNING. James L. Adams, Division of Neurobiology, Barrow Neurological Institute, 350 W. Thomas Road, Phoenix, AZ 85013.

In this model, pairs of adjacent excitatory synapses, receiving randomly-assigned input, function as local processing units. A hypothetical neuron is divided into multiple spatial/temporal levels with multiple synaptic pairs per level. During learning, a trigger event initiates a process which passes sequentially from the cell body to the tips of the dendrites. As the process passes each level, it records the ratios of the current input signal strengths at each synaptic pair on that level. After recording, whenever a given pair of synapses is presented with stimuli in the same ratio as during recording, that pair produces its maximum postsynaptic effect. Other ratios yield lesser effects. Thresholding is applied at each neuronal level to reduce noise.

Initial simulations tested the model with three neurons of 122 levels and 12 synaptic pairs per level recording three simple musical pieces of up to 73 notes in length. After recording and while each piece was input numerically note by note, the neuron which had recorded it responded continuously and vigorously and the other two neurons remained nearly inactive. Each neuron also responded to the playing of a fragment of its recorded piece or to the playing of the piece at a somewhat different rate.

The model is non-Hebbian in that the reinforcement of individual synapses does not depend upon, nor reflect, the amount of overall postsynaptic depolarization of the cell. It also does not require that the input be highly active. Once recording is triggered, the process simply records the activation ratios of each synaptic pair. Several physiological, biochemical, and molecular biological mechanisms are envisioned which could perform the operations of this model.

Supported by NIH grant 5T32 07309.

595.9

A NEURAL NETWORK MODEL OF CHEMOTAXIS IN SIMPLE NERVOUS SYSTEMS. S. R. Lockery and T. J. Sejnowski. Salk Institute, La Jolla, CA 92037.

Some properties of neural circuits can be predicted by training a model network to reproduce the activity of input and output neurons in the biological network. However, in most systems, more is known about the animal's behavior than about the activity of individual neurons. Using chemotaxis as a model behavior, we trained neural networks in which the desired output was the movement of the animal. The gradient was a one-dimensional gaussian-shaped distribution of an attractant. The network had two sensory units and two motor units. The velocity and position of the animal were represented by two additional units. Activation of the sensory units was determined by the position of the animal. Sensory units were separated in space, allowing the animal to compute the local gradient. Sensory units excited motor units which determined the animal's velocity up or down the gradient. The position unit integrated the activity of the velocity unit. This network could be trained successfully using recurrent backpropagation to find and remain at the center of the gradient from arbitrary initial positions. The model can be made more realistic by including interneurons and known connections. Additional constraints on the neural circuit should allow the model to predict the contribution of real neurons to observed behaviors.

SEROTONIN ENHANCES POSTINHIBITORY REBOUND IN OSCILLATOR INTERNEURONS OF THE LEECH SWIM CIRCUIT. P.S. Mangan and W. Otto Friesen. Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22901

Application of micromolar concentrations of serotonin (5-HT) elicits recurrent swim episodes in isolated leech ventral nerve cords (Willard, J. Neurosci. 1:936-944, 1981). Investigation has shown that endogenous 5-HT induces or enhances postinhibitory rebound (PIR) in swim motor neurons (Friesen et al., in preparation). Motor neuron PIR occurs in two forms. In inhibitor cells, PIR is induced by 5-HT, is prolonged, and is of low amplitude (< 5mV). In excitor cells, 5-HT enhances existing PIR which is higher amplitude (up to 10 mV) and occurs with a faster time course than inhibitor cell PIR. We report here that serotonin enhancement of PIR occurs also in oscillator interneurons 28, 208, and 115 of the leech swim circuit.

We examined interneurons exposed either to normal saline or saline with 50 μM 5-HT. Cells were injected with constant, hyperpolarizing current (1 s, -2.0 to -0.5 nA). PIR was monitored following release from inhibition. As in motor neurons, PIR was of two types. Cell 115 PIR occurred as a brief peak, analogous to excitor motor neurons, while PIR in cells 28 and 208 was more prolonged, as in inhibitor motor neurons. In either case, PIR amplitude was less than 3mV. Serotonin enhancement of time dependent, non-linear cellular properties, such as PIR, in oscillator cells could facilitate oscillatory activity in the reciprocally inhibitory interactions prevalent in the leech swim oscillator network. We conclude that, because changes in PIR of oscillator interneurons are small relative to PIR in swim motor neurons, the interactions and activity of motor neurons, which have reciprocally inhibitory connections with oscillator network cells, may be critical to the serotonin-enhanced expression of swimming in the isolated leech nerve cord. Supported by grants NS08781 (P.S.M.) and NS21778 (W.O.F.).

596.1

SYNCHRONIZATION OF INTERNEURONS IN THE HIPPOCAMPUS. H.B. Michelson and R.K.S. Wong. Dept. of Pharmacology, State Univ. of New York, Health Science Center, Brooklyn, N.Y. 11203.

Synchronized inhibitory post-synaptic potentials (IPSPs) can be recorded in guinea pig hippocampal pyramidal and granule cells in the absence of glutamate-mediated excitation. These synchronized IPSPs are recorded in the slice in 4-aminopyridine (4-AP, 75 μM), CNQX (10 μM) and CPP (10 μM). Direct recordings from inhibitory interneurons confirmed that a population of these cells were firing simultaneously to generate the synchronized IPSPs in principal cells.

Picrotoxin (50 μM) initially suppressed the rhythmic synchronized IPSP in principal cells. A second, different hyperpolarizing event subsequently emerged. This synchronized event had a slower time-to peak (303.3 ± 15.4 ms), was blocked by saclofen, and occurred at a lower frequency than the picrotoxin-sensitive event.

Picrotoxin (50 μM) blocked the burst events in a subpopulation of interneurons, indicating that excitation between this group of interneurons was mediated by GABA. Some interneurons continued to burst in the presence of picrotoxin. These bursts occurred simultaneously with the slower synchronized IPSP in principal cells. We conclude that GABAergic interneurons can become synchronized by at least two non-glutamate dependent processes: excitation mediated by the $GABA_A$ receptor, and a process independent of amino acid transmission. EPILEPTOGENESIS FOLLOWING CORTICAL INJURY. D. A. Prince and G.-F.Tseng, Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, CA 94305.

We developed an in vitro model of chronic epileptogenesis by taking advantage of the hyperexcitability and epileptogenesis known to develop in chronically isolated in vivo. Partially isolated neocortical islands were prepared in P5-P42 rats. 17-122 days later, slices were prepared through the previous lesion. Orthodromic stimuli in lesioned but not control cortex evoked long and variable latency field potentials that had the characteristics of epileptiform events. Discharges were maximal in layer 2-3 and propagated into deeper layers and across the slice. Bath application of APV blocked the long latency discharges. Intracellular recordings showed that epileptiform field potentials were accompanied by polyphasic EPSPs without prominent inhibitory events. In both postnatally and adult-lesioned animals biocytin-filled layer V pyramidal neurons showed remarkable elaboration of recurrent axonal collaterals extending to supragranular layers. Some neurons showed the typical picture of recurrent axonal sprouting described in immature isolated cortex by Cajal and Purpura and Housepian (Exp. Neurol. 4:377, 1961). These preliminary results suggest that chronically undercut cortex studied in vitro is an excellent model for examination of development of chronic epileptogenesis after brain injury. Alterations in pyramidal cell membrane properties, development of new excitatory connectivity, and depression in inhibitory synaptic electrogenesis may play a role in the abnormal discharges generated by this tissue. Supported by NIH grants NS06477 and NS12151 from the NINDS, and a Pimley Postdoctoral Fellowship.

FORNIX LESIONS ALTER EPILEPTIFORM ACTIVITY IN HIPPOCAMPAL SLICES. *P.A. Rutecki.* Sec. of Neurophysiol., Dept. of Neuro., Baylor Col. of Med., Houston, TX 77030.

Chronic (10-90 day), unilateral fornix lesions in rats result in hippocampal slices that have a propensity for epileptiform activity in 5 mM $[K^+]_o$ saline. To assess effects of fornix lesions on local CA3 synaptic circuitry, epileptiform discharges were produced by 50 μM picrotoxin (picro) or by 8.5 mM $[K^+]_o$ saline and recorded using extracellular techniques. The duration and frequency of occurrence of epileptiform discharges in slices from control animals and from hippocampi ipsi- and contralateral to the lesion were compared. In picro, no difference in the rate of discharges in the three groups was observed, but the duration of the discharges was significantly ($P \leq 0.05$) longer in slices ipsi- and contralateral to the lesion compared to control slices (120.7±8.4, 116.9±7.6, and 93.9±5.0 ms respectively). In 8.5 mM $[K^+]_o$ saline, discharges from slices ipsilateral to the lesion were longer than those from contralateral slices (80.0±3.7 vs. 63.6±3.3 ms) and occurred at a faster rate than those from control animals (0.68±.06 vs. 0.45±.09 Hz). The effects of the NMDA antagonist APV (50 μM) on convulsant induced bursting was studied. On average, APV slowed the rate of picro induced bursting in slices from lesioned animals by greater than 50%, but did not affect control slice discharge rate. APV tended to shorten burst duration, but this did not reach statistical significance. In 8.5 mM $[K^+]_o$ saline, APV slowed significantly the epileptiform discharges in slices ipsilateral to the lesion, but did not significantly change the rate in slices taken from control or contralateral hippocampi. The duration of high $[K^+]_o$ bursts was shortened by APV in all three groups. These results suggest that deafferentation of the hippocampus by fornix lesioning altered the response of the CA3 region to convulsants and enhanced the NMDA-mediated component of epileptiform activity. (Supported by NIH grant NS-28580 and the Klingenstein Fund.)

AMYGDALA KINDLING ALTERS PROTEIN KINASE C (PKC) ACTIVITY AND THE LEVEL OF A 17 KD PKC SUBSTRATE IN DENTATE GYRUS S.J.Chen,E.Klann,M.A.Desai,J.D.Sweatt, and P.J.Conn
Div. of Neurosci., Baylor Coll. of Med., Houston, TX 77030 and Dept. of Pharm., Emory U., Atlanta, GA 30322.

Kindling is a model of epilepsy and neuronal plasticity in which repeated electrical stimulation of certain CNS structures gradually leads to development of generalized clonic convulsions. Evidence suggests that PKC plays an important role in various forms of neuronal plasticity, including LTP in the hippocampus and activity-dependent cortical development. To investigate the possible role of PKC in kindling-induced epileptogenesis, we determined the effect of amygdala kindling on PKC activity in various regions of rat brain. We first assayed for changes in kinase activity by assaying post-hoc phosphorylation of endogenous proteins. We observed that kindling markedly elevated basal ($-Ca^{2+}$) and Ca^{2+}-stimulated phosphorylation of an endogenous protein in dentate gyrus which we have termed P17. Increased phosphorylation of P17 was observed 2 hours after the last stimulus-induced seizure and did not occur in limbic regions other than the dentate gyrus. P17 phosphorylation was decreased in dentate gyrus 24 hours after seizure. Assay of the amount of P17 protein revealed a transient increase in P17 protein 2 hours after the last seizure. Addition of a competitive peptide inhibitor (PKC_{19-36}) for C kinase greatly inhibited the phosphorylation of P17 while a peptide inhibitor ($CaMKII_{273-302}$) for CaM kinase II has no effect on P17 phosphorylation, suggesting that P17 is a fairly selective substrate for PKC. PKC activity, assayed in vitro using an exogenous peptide substrate, also showed a transient increase in both basal and Ca^{2+}-stimulated activity in kindled dentate gyrus, 2 hours after kindling stimulation. These results document a kindling-associated alteration in PKC activity. Interestingly, these observations also suggest that there is a coordinate up-regulation of PKC and the level of one of its substrates in the kindled dentate gyrus.

POSTICTAL CHANGES IN GABA METABOLISM IN SUBSTANTIA NIGRA C.F. Baxter, C.G. Wasterlain, C.C. Oh and R.A. Baldwin Epilepsy and Neurochem. Labs, VAMC, Sepulveda, CA 91343 and Dept. of Neurology, Psychiatry and BRI, UCLA Sch. Med., Los Angeles, CA.

Seizures are invariably followed by profound behavioral depression and by enhanced inhibitory post-synaptic potentials, but the responsible mechanisms are unknown. We investigated GABA metabolism in the substantia nigra (SN) of rats kindled by stimulation of medial septum. SN GABA concentration was 93±11 μmole/g prot in untreated controls, 87±11 μmole/g prot. in naive rats subjected to septal stimulation, 107±7 μmole/g prot in kindled unstimulated rats, and 138±11 μmole/g prot in kindled rats stimulated to a stage 5 seizure 60 minutes before SN tissue was sampled (Gp 4). The corresponding rate of GABA synthesis in SN of these 4 groups of rats was respectively 57±8, 69±14, 68±7, and 116±20 μmole/g prot/hr. Only the GABA metabolism in SN of Gp 4 was significantly different from controls. The increase of GABA concentration and synthesis in SN was observed post-ictally; 5 to 60 min after all seizure activity had ceased, the rate of GABA synthesis in SN was 160 μmole/g prot/hr compared to 68 μmole/g prot/hr pre-ictally. These changes may provide a potential explanation for the post-ictal depression and enhancement of inhibitory processes. Supported in part by funds from the V.A. Research Service and by grant NS13515 from NINDS.

596.6

LONG-LASTING DECREASES OF TYPE II CALMODULIN KINASE EXPRESSION IN KINDLED RAT BRAINS. J.M. Bronstein, P. Micevych, P. Popper, G. Huez, D.B. Farber, and C.G. Wasterlain. Depts of Neurology, Anatomy, and Ophthalmology, UCLA School of Medicine and Dept of Biological Chemistry, ULB, Brussels, Belgium.

The kindling model of epilepsy is associated with long-lasting changes in Type II Calmodulin kinase (CaM kinase) activity and immunoreactivity. In order to determine the mechanism of these alterations, we measured gene expression of CaM kinase using in situ hybridization in septally kindled rat brains and paired controls using a 35-S labeled riboprobe for the CaM kinase beta subunit. We found the mRNA concentrated in the hippocampus and other limbic structures in a similar pattern of staining observed immunohistochemically. Kindling resulted in significant decreases in hippocampal CaM kinase mRNA: 30% in CA1, 34% in CA2, 35% in CA3, 41% in CA4, and 29% in the dentate gyrus. Hybridization was also decreased by 21% in the cerebral cortex but not in the lateral septum. These changes are similar in distribution and direction as those measured immunohistochemically. These data suggest that altered CaM kinase activity and immunoreactivity associated with kindling reflect long-lasting alterations in gene expression of this synaptic protein and provides further evidence for its possible importance in the kindling phenomenon.

596.7

KINDLING REDUCES THE SENSITIVITY OF PRE- BUT NOT POSTSYNAPTIC $GABA_B$ RECEPTORS IN THE BASOLATERAL AMYGDALA (BLA). E.K. Asprodini, D.G. Rainnie, & P. Shinnick-Gallagher, Dept. of Pharmacology, Univ. of Texas Medical Branch, Galveston, TX 77550.

Kindling results in an enhancement of excitatory and a loss of inhibitory responses elicited by stimulating the stria terminalis (ST) in BLA neurons. Since excitatory transmission is negatively regulated by $GABA_B$ receptors on excitatory terminals, we tested whether alterations in presynaptic $GABA_B$ receptors contributes to the kindling-induced enhancement in excitatory responses using standard intracellular recordings. Superfusion of baclofen (0.1nM-100μM) depressed ST evoked synaptic responses in control (C) and kindled (K) BLA neurons. The EC_{50} for this action of baclofen was shifted 100-fold from 5nM in control to 500nM in kindled neurons (C:n=29; K:n=23). When $GABA_A$ and postsynaptic $GABA_B$ receptors were blocked with bicuculline (bic, 30μM), CNQX (10μM, to block the bic-induced bursting), and intracellular GTP-γ-S (10mM), baclofen (20nM) reduced the evoked slow EPSPs to a greater extent in control than in kindled neurons (C:55.2±4.9%, n=3; K:10±5.6%, n=4; $p<0.01$). Baclofen (20nM) had no effect on NMDA (n=3) or AMPA (n=3) responses recorded with a GTP-γ-S filled electrode. The EC_{50} for postsynaptic $GABA_B$ receptors was 1μM in control and in kindled neurons (C:n=31; K:n=24). 2-OH-Saclofen (2-OH-sac, 100μM) blocked baclofen-induced hyperpolarizations in control (n=7) and kindled (n=10) neurons; however, in 2-OH-sac baclofen (100nM) still reduced EPSP amplitude by 45.7±3.4% in control and by 28.8±5.6% in kindled neurons.

These data suggest that the kindling-induced changes in baclofen sensitivity presynaptically cannot be due to a loss of $GABA_A$ inhibition, or an effect on postsynaptic glutamate or $GABA_B$ receptors. The differential change in the sensitivity of $GABA_B$ receptors, and the response to 2-OH-sac may indicate distinct subpopulations of $GABA_B$ receptors whose long-lasting response to the kindling stimulus is different. Supp. by NS 24643.

FINE STRUCTURE AND SYNAPTIC CONNECTIONS OF THE MOSSY CELLS IN THE RAT AND MONKEY FASCIA DENTATA: M. Frotscher, L. Seress*, W. K. Schwerdtfeger* and E. Buhl*. Inst. Anatomy, Univ. Freiburg, D-7800 Freiburg, FRG

The functional role of the mossy cells in the hilar region of the fascia dentata is poorly understood. In this study commissural mossy cells in rats were identified by retrograde horseradish peroxidase (HRP) tracing combined with Golgi impregnation and, alternatively, by retrograde fluorescent tracing (Fast Blue, FB) combined with intracellular Lucifer Yellow (LY) staining. For an electron microscopic analysis the retrogradely HRP-labeled and Golgi-impregnated commissural mossy cells were gold-toned, and the LY-stained neurons were photoconverted. Mossy cells in the fascia dentata of primates (Papio anubis, Macaca mulatta, Saimiri sciureus) were, like mossy cells of rats, either Golgi-impregnated and gold-toned or intracellularly injected with LY but not retrogradely labeled. No major differences were found between mossy cells of rats and monkeys. Giant mossy fiber boutons formed synapses not only with the large excrescences on proximal dendritic portions of the mossy cells but also with peripheral mossy cell dendrites lacking excrescences. Impregnated or intracellularly labeled mossy cell axons traversed the hilus and penetrated the granular layer. These data demonstrate that the mossy cells are commissural/associational neurons that are controlled by the granule cells. This massive excitatory input from the granule cells may cause their degeneration in epileptic disorders.

ADENOSINE KINASE AND ADENOSINE DEAMINASE INHIBITION IN RAT PREPIRIFORM CORTEX CONFERS PROTECTION AGAINST BICUCULLINE METHIODIDE-INDUCED SEIZURES G. Zhang and T. F. Murray, College of Pharmacy, Oregon State University, Corvallis, OR 97331.

Our previous studies have demonstrated the proconvulsant effects of the adenosine receptor antagonist 8-*p*(sulfophenyl)theophylline and the anticonvulsant effects of the adenosine transport blocker dilazep, suggesting that adenosine may function as an endogenous antiepileptic substance in rat prepiriform cortex (PPC). The aim of this study is to examine the influence of an adenosine kinase inhibitor and an adenosine deaminase inhibitor on bicuculline methiodide (BMI)-induced generalized seizures in this brain area.

All drug solutions were unilaterally microinjected into the PPC. We found that focal injection of the adenosine kinase inhibitor, 5′-amino-5′-deoxyadenosine (ADADO), protected rats from BMI seizures in a dose-dependent fashion (ED_{50}=2.6±0.8 nmol). A dose of 68.4 nmol of ADADO afforded complete protection against BMI seizures. In contrast, the adenosine deaminase inhibitor, 2′-deoxycoformycin (DCF), elicited anticonvulsant effects with less potency and lower efficacy showing a maximal response of 30% protection. When a dose of ADADO which was inactive when administered alone was co-administered with DCF, the DCF dose-response curve was dramatically shifted to the left with an increased maximal effect. These findings suggest that accumulation of endogenous adenosine may effect seizure suppression, and further that adenosine kinase may play a pivotal role in the regulation of extracellular levels of adenosine in the CNS. (Supported by USPHS Grant NS23227).

EPILEPTIC DISCHARGES TRIGGER SLOW EPSPS IN IMMATURE AND ADULT NEOCORTEX. L.S. Benardo. Dept. of Pharmacology, S.U.N.Y.-H.S.C.A.B., Brooklyn, NY 11203.

Slow EPSPs can be triggered in rat layer V somatosensory neocortical neurons by repetitive stimulation as early as postnatal day 6. The role of such events in epilepsy is unknown. Blocking $GABA_A$-mediated IPSPs causes epileptic discharge by releasing local recurrent excitation. Whether similar release phenomena occur for slow EPSPs was tested by exposing slices to picrotoxin (25-50 uM) to induce epileptic discharge by blocking fast IPSPs. This maneuver allowed triggering of slow EPSPs at lower stimulus intensities, with fewer stimuli. Epileptic discharge occurred spontaneously and triggered slow IPSP-EPSP sequences (most prominent at depolarized potentials), similar to those elicited by electrical stimulation. Seizure discharge in younger animals has a characteristic ontogeny, being most robust at 15-30 days of age. As expected the amplitude and duration of slow EPSPs seen under these conditions varied in relation to ontological changes in epileptic events. Atropine and atenolol in combination, blocked slow EPSPs triggered by epileptic discharge. Eserine or cocaine enhanced slow EPSPs generated by epileptic events. This supported the notion that these slow EPSPs were also subserved by cholinergic and noradrenergic transmission. A non-conventional mechanism for synaptic transmisssion is postulated to account for triggering of slow EPSPs by epileptic discharges. (Supported by CIDA NS01386-01)

596.11

RELATIONSHIP OF IMMEDIATE EARLY GENE EXPRESSION TO ELECTROENCEPHALOGRAPHIC (EEG) CHANGES DURING PENTYLENETETRAZOL SEIZURES IN THE RAT. **P. Lanaud[1], A. Depaulis[2]*, C. Bugnon[1]* and M. Vergnes[2]*. [1]Laboratoire d'Histologie-Embryologie-Cytogènètique Faculté de Médecine, 25000 Besançon, France, and [2]Centre de Neurochimie, 67084 Strasbourg Cedex, France.**

Pentylenetetrazol (PTZ) was given to rats at 3 doses to evoke qualitatively distinct seizures, based on behavioral and EEG changes. Using in situ hybridization to examine mRNA encoding immediate early genes (IEG) in brain sections, we evaluated the relationship between the seizure characteristics and regional changes in IEG expression.

At 30 min after i.p. saline (control) or PTZ (20, 40 or 80 mg/kg), mRNA encoding c-fos, c-jun, jun-B and zif/268 was evaluated. No IEG expression above basal and no EEG modification occurred after saline. After 20mg/kg, spike and wave discharges (6-7 c/s) regularly appeared on the EEG, concomitant with behavioral arrest but no modification of IEG expression was observed. At 40 mg/kg, myoclonic and clonic seizures occurred concomitant with spike discharges (3-4 c/s) and significant increases in expression of all four IEGs occurred in neocortex, hippocampus, piriform cortex and amygdala. After 80 mg/kg, severe tonic-clonic seizures were associated with a general increase of IEG expression throughout the forebrain.

Our results suggest that PTZ-evoked increases in IEG expression in brain can be detected only with convulsive seizures and not with nonconvulsive spike-and-wave discharge. Moreover, selective regional changes in IEG expression occurred with a moderate dose of PTZ; increased IEG expression had relatively little regional selectivity after the high dose. Some of the changes in IEG expression with the high PTZ dose may reflect direct effects unrelated to seizure activity.

596.12

FUNCTIONAL CAPILLARY DENSITY IS REDUCED IN BRAIN OF PATIENTS WITH MERRF (MYOCLONUS EPILEPSY, RAGGED-RED FIBER SYNDROME) L. Ribeiro, S.F. Berkovic, H. Kuwabara, F. Andermann, A. Gjedde. Montreal Neurological Institute, Montreal, Quebec H3A 2B4 Canada.

MERRF is a disorder of the mitochondrial respiratory chain, sometimes associated with a mutation in mitochondrial tRNA. The energy state in muscle of these patients is abnormal, but the cerebral metabolic consequence are poorly understood. Our previous studies using magnetic resonance spectroscopy and PET showed globally reduced cerebral metabolism for glucose and oxygen with no evidence of intracerebral acidosis. Here we applied our technique for measuring functional capillary density (D_{cap}) in these patients to further elucidate the cerebral metabolic profile in MERRF. We analysed 3 patients with MERRF, and 5 normal volunteers. The global averages were (means±SEM; CBF, cerebral blood flow; CMR_{glc}, cerebral metabolic rate for glucose; T_{max}, maximal transport rate for glucose; K_t, half-saturation constant):

Variable	Unit	Control (n=5)	MERRF (n=3)
CBF	(ml/hg/min)	31 ± 2	40 ± 5*
K_t^*	(ml/hg/min)	9.6 ± 0.6	7.3 ± 0.6*
CMR_{glc}	(μmol/hg/min)	32 ± 2	17 ± 1**
D_{cap}	(mm^{-2})	255 ± 17	157 ± 13**
T_{max}	(μmol/hg/min)	82 ± 8	52 ± 14*
K_t	(m*M*)	2.3 ± 0.2	3.2 ± 0.5*

*$P < 0.05$, **$P < 0.005$

The data show that, despite elevated CBF, there is a marked reduction in CMR_{glc} together with a parallel reduction in D_{cap}. While it is possible that reduced capillary density limits the diffusion of glucose and oxygen, it is more likely that the reduction of D_{cap} and CMR_{glc} are chronic consequences of the intracellular mitochondrial defect.

597.1

ANXIOLYTIC-LIKE EFFECTS OF THE NON-COMPETITIVE NMDA ANTAGONIST MK-801 ON CONFLICT BEHAVIOR IN THE RAT. Z.C. Xie and R.L. Commissaris. Dept. Pharmaceutical Sci., Coll. Pharmacy & AHP, Wayne St. Univ., Detroit, MI 48202.

The present study determined the effects of the non-competitive NMDA antagonist MK-801 on behavior in the conditioned suppression of drinking (CSD) paradigm, a repeated measures conflict task. In daily 10-minute sessions, water-restricted rats drank from a tube which was occasionally electrified (0.25 mA shocks signaled by a tone). Trained subjects (4 weeks of CSD testing) exhibited stable baselines for both punished (41 $\pm$ 5 [Mean $\pm$ SEM] shocks received/session and unpunished (14.0 $\pm$ 0.7 ml/session) responding. Phenobarbital (5 - 40 mg/kg, IP) or chlordiazepoxide (2.5 - 20 mg/kg, IP) administration with a short (10- or 30-minute) pre-treatment resulted in a dose-dependent increase in punished responding, whereas (+) MK-801 did not increase punished responding when administered using a 10-minute or 4-hour pretreatment. However, at a 24-hour pretreatment (+) MK-801 (0.01 - 0.4 mg/kg, IP) produced a dramatic and dose-dependent increase in punished responding. The "inactive" isomer (-) MK-801 did not produce an anxiolytic-like effect in the CSD paradigm at any pretreatment interval. These data suggest that the anti-convulsant (+) MK-801 also may possess anti-anxiety effects in humans. (Supported in part by MH 47181.)

597.2

EFFECTS OF ANTI-SEIZURE AGENTS ON CONFLICT BEHAVIOR IN THE RAT. T.J. Hill, D.J. Fontana and R.L. Commissaris Dept. of Pharmaceutical Sci., College of Pharmacy, Wayne State University, Detroit, MI 48202.

Traditional anti-seizure agents recently have been used in psychiatry for the treatment of a number of disorders, including anxiety disorders. The present study examined the effects of acute treatment (10- to 120-minute pretreatment) with several anti-seizure agents in the conditioned suppression of drinking (CSD) conflict paradigm, an animal model for the study of "anxiety" and anti-anxiety agents. The agents tested were diazepam (DZ), phenobarbital (PhB), carbamazepine (CBZ), phenytoin (DPH), valproate (VPA), and ethosuximide (ESI). Consistent with their anxiolytic effects in man, DZ (1.25-20 mg/kg) and PhB (5-40 mg/kg) produced dose-dependent and robust (maximal effect 50 - 70 shocks above control) increases in punished responding. CBZ (2.5 - 40 mg/kg) and VPA (50 - 200 mg/kg) produced dose-dependent increases in punished responding, but the maximal effect was less than that seen with PhB or DZ. Neither ESI (25 - 100 mg/kg) nor DPH (0.6 - 20 mg/kg) increased punished responding. Thus, not all anti-seizure agents exert anxiolytic-like effects on conflict behavior. (Supported in part by MH 47181.)

597.3

BEHAVIORAL EFFECTS OF INTERACTIONS AMONG D1 AND D2 DOPAMINE RECEPTOR AGONISTS AND ANTAGONISTS. J. L. Katz and J. M. Witkin. Psychobiology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224, U.S.A.

The effects on schedule-controlled operant behavior of the D1 receptor agonist, SKF 38393, and the D2 agonist, quinpirole, were assessed alone and in combination with selective dopamine-receptor antagonists. Squirrel monkeys (*Saimiri sciureus*) were trained to press a response key under fixed-interval and fixed-ratio schedules of food reinforcement. Quinpirole increased rates of responding under the fixed-interval schedule at doses (0.1 - 1.0 mg/kg) that decreased rates of responding under the fixed-ratio schedule. Under the fixed-interval schedule, the D2 antagonists, spiperone (0.003 - 0.006 mg/kg) and to less of a degree haloperidol (0.003 - 0.01 mg/kg), and the D1 antagonist, SCH 23390 (0.03 mg/kg), shifted the quinpirole dose-effect curve to the right. At the highest doses of the antagonists the maximal effects of quinpirole were decreased. However, only the D2 antagonist, spiperone, antagonized the effects of quinpirole under the fixed-ratio schedule. The D1 agonist, SKF 38393, dose-dependently (1.0 - 10.0 mg/kg) decreased rates of responding under both schedules. Those effects were not antagonized by any doses studied of either spiperone (0.003 mg/kg) or SCH 23390 (0.003 - 0.3 mg/kg). SCH 23390 produced a dose-related enhancement of the effects of SKF 38393.

597.4

DIFFERENTIAL EFFECTS OF D_1 AND D_2 ANTAGONISTS IN COMBINATION WITH THE D_2 AGONIST (+)-PHNO IN SQUIRREL MONKEYS. Sharon Rosenzweig-Lipson, Sara Johnson*, and Jack Bergman. Harvard Medical School/NERPRC, Southboro, MA.

Behavioral effects of the dopamine D_2-selective agonist (+)-PHNO were determined alone and after pretreatment with the D_2-selective antagonist eticlopride, the D_1-selective antagonist SCH 39166, and the nonselective dopamine antagonist clozapine in squirrel monkeys responding under a 30-response fixed-ratio schedule of stimulus-shock termination. When administered cumulatively, (+)-PHNO (0.001 - 0.3 mg/kg) produced dose-dependent decreases in rates of responding, with ED_{50} values ranging from 0.002 to 0.014 mg/kg for individual monkeys. Eticlopride (0.001 - 0.006 mg/kg) produced graded rightward shifts in the dose-response curve for (+)-PHNO; ED_{50} values for (+)-PHNO were increased by as much as 30-fold for individual monkeys. In contrast, SCH 39166 did not antagonize the behavioral effects of (+)-PHNO at any dose. Instead, increasing doses of SCH 39166 (0.01 - 0.1 mg/kg) produced leftward and downward shifts in the dose-response curve for (+)-PHNO. Clozapine (1 - 5.6 mg/kg) also resulted in graded leftward and downward shifts in the dose-response curve for (+)-PHNO. These results show that the rate-decreasing effects of (+)-PHNO can be surmountably antagonized by the D_2 antagonist eticlopride but are modified differently by the D_1 antagonist 39166 and the atypical neuroleptic clozapine. (Supported by USPHS grants DA03774, DA00499, MH07658, and RR00168).

597.5

EFFECTS OF CHRONIC MDMA (METHYLENEDIOXYMETHAMPHETAMINE) ADMINISTRATION ON RHESUS MONKEY PERFORMANCE IN AN OPERANT TEST BATTERY (OTB). M.G. Paule, M.P. Gillam*, and R.R. Allen*. Div. Reprod. Development. Toxicol. & Computer Based Systems, Inc., National Center for Toxicological Research, Jefferson, AR 72079-9502.

MDMA profoundly depletes serotonin (5-HT) in nerve terminals in primate brain following several repeated doses. The present studies were conducted in adult male monkeys (n=3) to determine the effects of such 5-HT depletion on complex brain functions including learning, short-term memory and attention, time perception, color and position discrimination, and motivation to perform for food. Daily (M-F) performance in a multiple schedule OTB was used to model these functions with response rate, accuracy, and percent task completed serving as indicators of functional ability. Each dose of MDMA [0.0 (saline), 0.1, 0.3, 1.0, 3.0, 5.6, 10.0 and 20.0 mg/kg] was given intramuscularly twice daily for 14 consecutive days in ascending order. Although there were clear acute effects of MDMA (generally at $\geq$ 1.0 mg/kg) to disrupt performance of all tasks 45 min after administration, marked tolerance to these effects was demonstrated. OTB performance generally returned to predrug values a few weeks after chronic treatment ended, when 5-HT systems are presumably severely depleted. Thus, 5-HT systems would not appear to be of fundamental importance for the performance for these specific brain functions.

597.6

THE LACK OF SEDATIVE PROPERTIES OF CI-988, A SELECTIVE CCK_B RECEPTOR ANTAGONIST. Lakhbir Singh, Ryszard J. Oles and Geoffrey N. Woodruff. Parke-Davis Research Unit, Addenbrookes Hospital Site, Hills Road, Cambridge CB2 2QB, U.K.

Previously it has been reported that the selective CCK_B receptor antagonist CI-988 (previously PD 134308) produces anxiolytic-like action in a number of animal models of anxiety (Hughes *et al.*, 1990; Singh *et al.*, 1991). We now show that CI-988 does not induce sedation/ataxia or potentiate the action of CNS depressants.

Chlordiazepoxide (CDP) or CI-988 were administered i.p. 40 min before test to male TO mice (25-30g). CDP dose-dependently (1-30 mg/kg, i.p.) impaired rotarod performance and increased sleeping time induced by sodium pentobarbitone (60 mg/kg, i.p.) with minimum effective dose (MED) of 10 mg/kg. CDP also potentiated the ability of ethanol to impair rotarod performance. In contrast, CI-988 up to 30 mg/kg which is 300-3000 fold higher than the anxiolytic dose was found to be inactive in all these tests.

Thus, it is suggested that CI-988 should have a better side-effect profile in man than the benzodiazepines.

SPROUTING IN THE NEUROMUSCULAR SYSTEM: EARLY SIGNALING BY IGF1 FROM INACTIVATED MUSCLE FIBERS. Caroni, P. and Schneider, C*. Friedrich Miescher Institute,P.O.Box 2543,CH-4002 Basel

Upon lesion- or toxin-induced paralysis processes in the inactive muscle fibers and in nearby cells are initiated to bring about restoration of muscle activity. Among these is the local stimulation of nerve growth.Insulin-like growth factors (IGFs) can induce neurite growth in vitro, and contents of IGFs mRNA in muscle correlate with the presence of nerve growth inducing activity in fast skeletal muscle (Ishii, PNAS (1989)86:2898-2902). We are therefore investigating the possible roles of IGFs in neuromuscular regeneration, including intramuscular nerve sprouting.We found that: 1.)embryonic motoneurons in vitro respond to IGFs in the subnanomolar range with a vigorous neurite growth and ramification reaction; 2.) non-lesioning application of IGFs to adult rodent skeletal muscle in vivo specifically elicits processes that are observed in denervated or paralyzed muscle, including a marked nerve sprouting reaction (Caroni and Grandes, JCB (1990) 110:1307-1317); 3.) in the adult rat, paralysis leads to rapid (detectable after 15h) and transient (peak at about 48h) induction of IGF1 mRNA in muscle fibers (in situ hybridization data; DIG-alkaline phosphatase method), followed by a slower and persistent increase of IGF1 and IGF2 mRNA in muscle fibers and in muscle interstitial cells. For comparison, increase in muscle fiber N-CAM mRNA was detectable 3d after paralysis; 4.) adult rat motoneurons in vitro express IGF1-receptor mRNA (method as above). Since elevated IGF1 levels are sufficient to trigger sprouting and intramuscular cell proliferation, and since muscle fiber IGF1 mRNA levels are rapidly elevated upon paralysis, IGF1 is likely to initiate restorative responses in paralyzed skeletal muscle, possibly including a direct stimulation of nerve sprouting.

INSULIN, IGF-I, IGF-II AND NGF ACTIVATE A COMMON BIOCHEMICAL PATHWAY DURING NEURITE GROWTH: ROLE OF NEUROFILAMENT AND TUBULIN GENE EXPRESSION. D.N. Ishii, C. Wang*, Y. Li*, B. Wible*, and K.J. Angelides. Physiol. Dept., Colorado State Univ., Ft. Collins, CO 80523; Physiol. & Molec. Biophysics Dept., Baylor Univ., Houston, TX 77030.

We tested the hypothesis that insulin, insulin-like growth factors (IGFs) and nerve growth factor (NGF) can all increase the expression of genes encoding major structural proteins of axons, particularly 68 and 170 kDa neurofilament (NF) genes, in human neuroblastoma SH-SY5Y cells. We also studied whether more than one transmembrane signal might be involved.

Insulin, IGF-I, and IGF-II increased 68 and 170 kDa NF mRNA content relative to total RNA, poly(A)$^+$ RNA, and histone mRNA during neurite formation. Insulin and IGFs had little effect on stability of NF mRNAs, whereas insulin increased transcription of 68 and 170 kDa NF mRNAs. Similar effects are reported for NGF (Lindenbaum et al., 1988). In contrast, our previous studies showed that insulin, IGF-I, and NGF all stabilize α- and β-tubulin mRNAs, but have no detectible effect on transcription. We conclude that insulin, IGF-I and IGF-II can selectively increase NF gene expression, and that insulin, IGFs and NGF can activate two branches of a common biochemical pathway regulating neurite formation. SEPTAL DENERVATION OF THE HIPPOCAMPUS IS REQUIRED FOR SYMPATHETIC AXON INGROWTH. B. N. Saffran and K. A. Crutcher. Department of Neurosurgery, University of Cincinnati, Cincinnati, OH 45267.

Sympathetic sprouting into the rat hippocampal formation (HF) after a medial septal lesion (MSL) may occur as a result of accumulation of NGF. Intraventricular infusion of NGF in the absence of septal denervation, however, does not elicit sympatho-hippocampal sprouting even though there is proliferation of vascular sympathetic fibers (Brain Res. 492: 245). Furthermore, NGF infusion in the presence of a MSL results in reduced sympathohippocampal sprouting, perhaps due to competition with perivascular collaterals (Brain Res. 525: 11). We tested whether intraventricular NGF infusion would promote sympathetic sprouting into the HF from autologous superior cervical ganglion transplants in the presence or absence of a MSL. Female SD rats received 2 week infusions of NGF beginning at the time of transplantation of the SCG to the HF. Four rats received a MSL, six did not. Animals were killed at 2 (n=2) or 4 (n=8) weeks after surgery and the brains were examined for sympathetic ingrowth (SPG method), septal denervation (AChE histochemistry) and NGF content (2-site ELISA). Although extensive ingrowth was found in septal-denervated regions of the HF, no ingrowth was observed in animals without evidence of septal denervation (n=4). Furthermore, in animals where there was partial septal denervation (n=2), sympathetic axons were found only in denervated areas. In NGF-infused animals, contralateral sympathetic hyperinnervation of the internal carotid artery occurred. In 7 animals with transplants and NGF infusion, fibers extended from the transplants through the fimbria and corpus callosum to surround the ventricle where the cannula was placed. These results indicate that infused NGF stimulates sympathetic fiber outgrowth from transplanted ganglia but does not permit sympathetic sprouting in the HF in the presence of septohippocampal fibers. STAUROSPORINE NEUROTROPIC EFFECTS IN PC12 CELLS ARE INDEPENDENT OF PROTEIN KINASE C. D. Rasouly[a*], D. Lester[b*], Y. Matsuda[c*] and P. Lazarovici[a], [a]Dept. of Pharmacology, Hebrew University, Jerusalem, Israel, [b]Dept. of Membrane Res., Weizmann Institute, Rehovot, Israel and [c]Kyowa Hakko Kogyo Co. Ltd., Tokyo, Japan.

Nerve growth factor (NGF) is a polypeptide orchestrating a number of sympathetic neuronal phenomena including differentiation and survival. In PC12 cells, NGF induces differentiation expressed by neurite-outgrowth and neuronal network formation.

We have found that Staurosporine (St), an alkaloid known to inhibit Protein Kinase C (PKC) in vitro, induces neurite outgrowth in PC12 cells within 6 hours at non toxic, 10-30nM, concentrations. Appearance of neurites induced by St was similar to that induced by NGF but differed in the ruffling property. Down regulation of PKC (assessed by protein phosphorylations, ^{3}H-St binding and fluorescent phorbol ester imaging) by TPA (500nM/24 hrs) or inhibition of kinases by K-252a family of compounds, had no effect on neurite outgrowth in PC12 cells. This suggests that the neurotropic effect of St (at doses that inhibit PKC) is unrelated to the inhibition of PKC.

Elucidation of these mechanism(s) has clinical implications and is important in exploring NGF action in the nervous system.

IMMUNOCHEMICAL EVIDENCE FOR NGF-LIKE MOLECULE(S) IN THE CENTRAL NERVOUS SYSTEM OF LYMNAEA. R.L. Ridgway, G.C. Hauser, N.I. Syed and A.G.M. Bulloch. Neuroscience Research Group, Dept. of Med. Physiol., Univ. of Calgary, Calgary, Alberta, Canada T2N 4N1.

We have recently reported that murine 2.5S Nerve Growth Factor (NGF) stimulates neurite outgrowth in vitro of identified motor neurons and interneurons of the pond snail, Lymnaea stagnalis (Ridgway et al., J. Neurobiol., in press). Antisera generated against NGF was found to block not only the sprouting activity of 2.5S NGF but also of Lymnaea brain-conditioned medium (CM), raising the possibility that endogenous NGF-like molecule(s) might be active in the molluscan CNS. Here we examined this possibility further using immunoblotting and immunoaffinity chromatography methods.

Culture medium conditioned with Lymnaea central ganglionic rings (2/ml) for 72 h was concentrated ~30-fold via 10kD cut-off (Amicon YM-10) filtration membranes, subjected to gel electrophoresis, and then transferred to nitrocellulose for immunoblot analysis. Prominent polypeptide bands with relative molecular weights (M_r) of ~140, ~100, ~62, ~27, and ~15kD (under reducing conditions) were identified using 3 different antisera to NGF; some bands may represent proteolytic fragments of a larger protein. Chromatography of concentrated CM via an anti-NGF affinity column resulted in the elution of several polypeptides, the most prominent being at M_r ~15kD. In preliminary bioassays, the elution volume was found to contain neuritogenic activity on Lymnaea Pedal A (Pe.A) cluster motor neurons. These results, together with those of the companion abstract (Bulloch et al.), strongly support the hypothesis that molecule(s) resembling mammalian NGF are present in the CNS of Lymnaea. Supported by AHFMR and Canadian Centre of Excellence in Neural Regeneration and Functional Recovery.

GLUTAMATE MODULATES A NGF-like PROTEIN AND A NGF-like mRNA IN THE LYMNAEA CNS. A.G.M. Bulloch, R.L. Ridgway, K.C. Harrington and W. Tetzlaff. Neuroscience Research Group, University of Calgary, Faculty of Medicine, Calgary, Alberta, Canada, T2N 4N1.

This study continues our recent examination of neurotrophic molecules in the nervous system of the snails Lymnaea and Helisoma. We recently reported that glutamate enhances the release and/or production of factors that are responsible for the conditioning of medium required for neurons to sprout in vitro. We have also shown that a mammalian neurotrophic factor, Nerve Growth Factor (NGF), can induce sprouting by specific Lymnaea neurons. In the adjacent presentation (Ridgway et al.) we show that Lymnaea brain-conditioned medium (CM) contains a NGF-like immunoreactive molecule. Here we demonstrate that the concentration of this molecule in CM can be enhanced by glutamate. One of the key questions arising from these observations is the nature of the mechanism by which glutamate enhances CM (e.g., does it increase the synthesis and/or release of conditioning factors by CNS tissues?). In this study we have assayed the CNS of Lymnaea and Helisoma for NGF-like mRNAs using a P^{32}-cDNA probe derived from the human NGF sequence. Northern blots of RNA from both Lymnaea and Helisoma have shown that this probe hybridizes with a 1.35 kB mRNA under low stringency conditions. Furthermore,the level of this NGF-like mRNA is increased by axotomy and also by the presence of glutamate during the conditioning period. These results suggest that the molluscan nervous system contains a NGF-like protein and a NGF-like mRNA, both of which can be modulated by glutamate. Supported by the Canadian Centre for Exellence in Neural Regeneration and Functional Recovery.

Mn^{2+} INDUCES NEURON-LIKE MORPHOLOGICAL CHANGES IN PC12 CELLS. W.H.Lin*, K.A.Marcucci* and J.A.Roth, Dept. of Pharmacology and Therapeutics, School of Medicine and Biomedical Sciences, SUNY at Buffalo, Buffalo, NY 14214

Divalent cations in the culture medium have been shown to affect the attachment of PC12 cells to the substratum. However, their effect on the process of neuronal differentiation have not been characterized. When cells were treated with 0.3 - 2.0 mM of $MnCl_2$, we observed morphological changes similar to those induced by NGF treatment, i.e. flattening of cell bodies and extension of neurites. These responses were dose-dependent and observable within 6 hours after treatment. The effects of Mn^{2+} were enhanced in medium containing 1% serum and in the presence of NGF. Of the other divalent cations examined, only Co^{2+} was able to simulate the effects of Mn^{2+}. When compared to the morphological changes observed with forskolin, the Mn^{2+}-treated cells were appreciably flatter, with cell body diameters up to 30 μm. While forskolin alone induced neurite outgrowth maximally in only 60% of the cells, co-incubation with submaximal concentration of $MnCl_2$ increased the response rate to over 90%, with a profound increase in the size of the cell bodies. In addition, Mn^{2+} was also able to induce similar responses in a mutant PC12 cell line deficient in protein kinase A activity. These observations suggest that Mn^{2+} induces neurite outgrowth in PC12 cells through a mechanism independent of cAMP. Questions remain as to whether NGF and Mn^{2+} share a common signal transduction pathway which results in morphological differentiation of PC12 cells. ELEVATED POTASSIUM MAINTAINS NEURITE STABILITY IN A PC12 MUTANT CELL LINE AFTER NGF WITHDRAWAL. KENNETH K. TENG AND LLOYD A. GREENE*. Department of Pathology and Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University, New York, N.Y. 10032.

We have isolated a clonal PC12 mutant, designated as Clone 41 (C41), with heightened responses to NGF. Compared to wild type PC12 cells, the C41 line extends neurites in significantly greater abundance in the presence of NGF. Biochemically, NGF-differentiated C41 cells differ from their PC12 counterparts in showing more pronounced changes in cytoskeletal proteins. In characterizing the C41 line, we observed that elevated K^+ (20-80mM) can maintain neurites for at least 3 weeks after NGF withdrawal; however although they are maintained, the neurites do not continue to elongate. Without either NGF or K^+, the neurites degenerate. Cells in which NGF is replaced with K^+ also retained a "primed" state characterized by capacity for rapid NGF-dependent neurite regeneration. The K^+-induced effect is inhibited by Ca^{+2} channel blockers (Verapamil and/or Nitrendipine). This neurite-stabilizing effect is accompanied by an alteration in several cytoskeletal components. Amongst these, phospho-β-tubulin decreases to undifferentiated levels while the microtubule associated proteins MAP1.2 and chartins remain highly phosphorylated as in NGF-treated controls. The data presented here suggest that depolarization may stabilize neurites in the absence of neurotrophic factors, at least in part by affecting the cytoskeleton.

598.9

INDUCTION OF GROWTH CONE COLLAPSING ACTIVITY IN CULTURED ASTROCYTES BY FGF AND INTERLEUKIN 1. Alan R. Johnson*, James W. Fawcett*, Roger J. Keynes and Geoffrey M.W. Cook*. Physiological Laboratory and Department of Anatomy, University of Cambridge, Downing Street, Cambridge, U.K.

Mature astrocytes and astrocytes derived from injury-induced glial scars may be inhibitory for axon growth. We have explored astrocyte-growth cone interactions by assessing the capacity of detergent extracts of cultured astrocytes to cause growth cone collapse *in vitro*. Astrocytes prepared from neonatal rat brains were cultured for 2 weeks, purified, and subsequently homogenised in 2% CHAPS in PBS in the presence of protease inhibitors. The detergent extracts were then incorporated into liposomes and added to cultures of embryonic chick and rat dorsal root ganglia for 1 hour. Detergent extracts of untreated astrocyte cultures produced only modest levels of growth cone collapse; extracts prepared from cultures of Schwannoma cells also lacked activity. Some cultures were treated with bFGF and Interleukin 1 for 24 hours before extraction, and now posessed potent growth cone collapsing activity. It is known that both these molecules can produce reactive-type changes in astrocytes. Similarly, axons growing directly on monolayers of astrocytes exhibited a collapsed growth cone morphology, while axons growing on Schwannoma cells had fully spread growth cones. These observations raise the possiblity that reactive astrocytes possess surface-bound molecules that inhibit axon regeneration.

A NEURITE PROMOTING ACTVITY FROM AN IMMORTAL SCHWANN CELL CLONE. L.M. Bolin and E.M. Shooter, Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA,94305

Regeneration of the peripheral nervous system requires the precise reformation of synaptic connections between motor and sensory neurons and the tissues that they subserve. Schwann cells are essential to this process. To explore the Schwann cell - neuron interaction, we have established primary cultures of adult rat Schwann cells from crushed sciatic nerves. From these primary cultures, we have isolated a spontaneously immortal Schwann cell clone (iSC), whose conditioned media (CM) contains a neurite pro-moting activity that is not active on PC12 cells. Embryonic chick ganglia explants were incubated with CM to determine the neuronal specificity of this activity. This activity is not selective for a general class of neurons, neurites are elicited from CNS (spinal cord, brain and retina) and PNS (dorsal roots and sympathetic chain ganglia). We have characterized this activity after elution from a cation exchange column. In a dilution of 1:50, this eluant retains its neurite promoting activity with embryonic neurons. Neither the column profile nor the types of embryonic neurons supported by this eluant are consistent with it being CNTF. This activity does not bind to heparan and antibodies to bFGF do not inhibit neurite promotion. Although poly-adenylated RNA from iSC gives a positive signal when probed with cDNA for NGF, blocking antisera to NGF does not inhibit neurite formation. This Schwann cell clone has been transformed at a time of trophic activity and may provide new information on the regenerative milieu.

PURIFICATION AND BIOCHEMICAL CHARACTERIZATION OF RAT AND BOVINE CNS MYELIN ASSOCIATED NEURITE GROWTH INHIBITORS NI-35 AND NI-250. C.E. Bandtlow* and M.E. Schwab, Brain Research Institute, University of Zurich, 8029 Zurich, Switzerland.

Rat and bovine CNS myelin contain two proteins of 33-35 kDa and 250 kDa which exert potent inhibitory effects on extending neurites (neurite growth inhibitor NI-35 and NI-250). SDS-PAGE eluted NI-35 and NI-250 revealed several active spots in the pI range of 4-6 on 2D-gels. NI-35 and NI-250 are hydrophobic proteins; so we further purified this material on a C4 reverse phase HPLC column. The chromatograms, showing two major protein peaks (I and II) were identical for both, NI-35 and NI-250. Peaks I and II, derived from NI-35 or NI-250 migrated at 33 kDa on SDS-PAGE. The amino acid compositions of peak I and II were determined and found to be very similar. Initial N-terminal and internal amino acid sequence data of peak II derived from NI-35 were identical to the corresponding sequences of peak II of NI-250. The amino acid sequences available so far show no homologies to known proteins.

These results show that NI-35 and NI-250 are closely related proteins and that NI-250 is most likely a complex containing the 35 kDa protein. NI-35 is microheterogenous consisting of 2 subforms differing slightly in their hydrophobicity.

598.12

LOCAL CONTROL OF NEURITE OUTGROWTH OF DORSAL ROOT GANGLIA AND SPINAL CORD NEURONS BY ACTH ANALOG ORG 2766, BIM 22015 AND NGF. S.J. Lee, T.S. Lee and F.L. Strand. Department of Biology and Center for Neural Science, New York University, Washington Square, New York, New York 10003.

The dorsal root ganglia and spinal cord of 14-15-day old Sprague-Dawley rat embryos were removed and plated into the center chamber of three compartment culture dishes.[1] The center chamber neurons were maintained for 3-14 days with 100ng/ml 7S nerve growth factor (GIBCO). The left compartments contained the peptide analogs, Org 2766 or BIM 22015, while the right chambers contained the NGF, as a control. The neurite outgrowths can be seen extending from the center compartment to the side chambers containing NGF. This extension can also be seen in side chambers containing peptide analogs (100ng/ml) without NGF. The local withdrawal of NGF in the side chambers prevented further neurite elongation but maintained their survival for 5-7 days. Peptide withdrawal from the side chambers also caused cessation of outgrowth but the survival rate is questionable. Neuronal survival of DRG and spinal cord cultures was also determined after peptide treatments.

Nerve growth factor is required for survival, differentiation and neurite outgrowth. Treatment of the DRG and spinal cord neurons with ACTH analogs *in vitro* seemed to delay neuronal cell death, a characteristic of normal development in the mammalian nervous system.[2] The effects of Org 2766 and BIM 22015 on neurite outgrowth have been compared and preliminary studies show that they may possess neurotrophic properties in the culture system. TISSUE SPECIFIC EXPRESSION OF VGF8a, A GENE INDUCED BY NGF

ROBERTA POSSENTI, NADIA CANU, EUGENIA TRANI, ANDREA LEVI, Institute of Neurobiology, CNR, Viale Marx 15, Rome Italy, GIANLUCA FERRI, University of Cagliari, SERGIO NASI Nucleic Acid Center CNR Rome.

We have analyzed the tissue specific expression of VGF, a secretory protein similar to secretogranin proteins, that is highly induced by NGF in PC12 cell line. Immunohistochemistry, in situ hybridization, northerns and RNAse protection have been used to identity the protein and the mRNA in different tissues. In particular, we have focused our attention on neuronal and endocrine tissues. Previous work has shown the expression of VGF in localized area of the brain (van Den Pol et A J. Neurosci. 1989, 9, 4122). The protein, as well as the mRNA, is present in a sub-population of cells of Dorsal Root Ganglia, Sympathetic Ganglia, Trigeminal Ganglia, Spinal Cord, Adrenal Medulla, Adenohypophysis, and in some neurons of the Myoenteric Plexus. We could not detect the protein or its mRNA in muscle, liver, spleen and other tissues. Furthermore, we have studied the regulatory regions of the VGF8a gene and the tissue specific expression of the promoter in different cell lines. Nuclear extracts from different cell lines show distinct patterns of band shifts and foot printings which map to two different region. CAT activity with partial deletion of the promoter shows that the region to -78 can act as a minimal promoter, albeit without NGF inducibility.

599.2

SELECTIVE EFFECTS OF NERVE GROWTH FACTOR DEPRIVATION ON DORSAL ROOT GANGLION CELLS IN EMBRYONIC RATS.

K.G. Ruit and W.D. Snider, Department of Neurology, Washington University School of Medicine, St. Louis, MO 63110.

Although embryonic dorsal root ganglion (DRG) neurons in general are known to require nerve growth factor (NGF) for their survival and function, the degree to which the numerous classes of these neurons depend on NGF is unsettled. We have assessed the effects of embryonic NGF deprivation by labelling the characteristic central axonal arborizations of the various classes of DRG neurons. Embryonic rats (E15) received individual, *in utero* systemic injections of goat anti-mouse NGF serum. The embryos were then taken by Caesarean section on E18 and perfusion fixed. The central axonal arborizations of DRG neurons were visualized utilizing the lipid-soluble tracer DiI placed either within individual DRGs or in the skin covering the dorsum of the embryo.

NGF deprivation in this prenatal period was selective with regard to which classes of sensory neurons were affected. Embryonic exposure to NGF antibodies prevented the ingrowth of the fine cutaneous (pain, thermoreceptive) primary afferents which occupy Rexed's lamina I and the most superficial part of lamina II in the dorsal horn. On the other hand, the "flame-shaped" axonal arborizations characteristic of the thicker hair follicle afferents, which occupy normally laminae IV, III, and only the inner part of lamina II in the dorsal horn, not only survived but now sprouted into the unoccupied superficial laminae. In many cases, their terminals reached nearly to the surface of the spinal cord. The central arborizations of other classes of primary afferents, including Type I muscle afferents, appeared unaffected by NGF deprivation during the E15-E18 period.

We conclude that DRG neurons differ in their requirement for NGF, and that the small diameter cutaneous afferents are the most sensitive.

599.3

COMPARISON OF RABBIT FACIAL NERVE REGENERATION IN NGF-CONTAINING TUBES TO AUTOLOGOUS NERVE GRAFTS.

P. Lee, J. Spector, A. Derby[1], G. Frierdich[2], G. Neises[3] and D. Roufa[2]. Dept. of Otolaryngology, Washington University, [1]Dept. of Biology, UM-STL and [2]Searle R&D & [3]Monsanto, St. Louis, MO 63198.

Previous reports suggest that NGF enhances rabbit facial nerve regeneration. We compared facial nerve regeneration in NGF or Cytochrome C (Cyt. C)-containing silastic tubes to autologous nerve grafts. A 4-5 mm segment of the buccal division of the rabbit facial nerve was removed, the nerve ends were inserted into a 10 mm tube and sutured to create an 8 mm nerve gap. For nerve graft repair, an 8 mm autologous segment of the buccal nerve was removed, rotated 180° and sutured to bridge the nerve gap. Five weeks post-implantation, the animals were processed for morphological evaluation. NGF treated nerves recovered significantly higher percentage of their preoperative number of myelinated fibers than Cyt. C treated nerves (46% vs 18%). The number of myelinated fibers at the nerve grafts midpoint was significantly greater than at the NGF tube midpoint. However, the number of myelinated fibers reaching the distal nerve stump was proportionately greater in NGF treated nerves than in nerve grafts. In nerve grafts, the percentage of intrafascicular myelinated fibers was inversely related to the amount of myelin debris and the majority of fibers (66%) were extrafascicular. Thus, although nerve grafts contain larger number of myelinated fibers than NGF-containing tubes, functional recovery and elimination of aberrant reinnervation may not be superior to entubation repair with NGF.

599.4

INHIBITION OF NGF-STIMULATED NEURITE OUTGROWTH BY AMINE-MODIFIED α_2-MACROGLOBULIN.

D.J. Liebl and P.H. Koo*. Neurosciences Program and Dept. of Microbiology and Immunology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272

Alpha-2-macroglobulin (α_2M) is a rather ubiquitous protein in extracellular spaces of mammals. It is an inhibitor of endopeptidases and a carrier for a number of cytokines/hormones such as β-nerve growth factor (NGF) (P.H. Koo and R.W. Stach, J. Neurosc. Res. 22:247, 1989). The objective of this study is to determine whether α_2M and its modified forms may affect the biological activity of NGF. Alpha-2-M was purified from human plasma and then modified by either methylamine or trypsin. Our results clearly show that methylamine-modified α_2M (MA-α_2M) exerted a dose-dependent inhibition on the NGF-stimulated neurite outgrowth by embryonic chicken dorsal root ganglia whereas normal α_2M and trypsin-modified α_2M had little or no effect. MA-α_2M is not toxic to neurons and the inhibition can be overcome by higher NGF concentrations. As determined by gel filtration, native polyacrylamide gel electrophoresis and SDS-urea gel electrophoresis, both normal α_2M and MA-α_2M carry >90% of NGF noncovalently. Although MA-α_2M carries about twice as much NGF, much higher doses of normal α_2M had little or no effect on the biological activity of NGF. This suggests that amine-modified α_2M may inhibit neurite growth via an active process not involving passive absorption of NGF.

599.5

NGF FACILITATES THE RECOVERY OF NIGRO-STRIATAL DOPAMINERGIC NEURONS AFTER A LESION INDUCED BY MPTP.

M. Hadjiconstantinou[1,2,3], M.J. Eaton, J.G. Fitkin[2,3*], and N.H. Neff[2,3]. Depts. of Psychiatry[1] and of Pharmacology[2] and the Neuroscience Program[3]. The Ohio State Univ. Col. of Med., Columbus, OH 43210.

Nerve growth factor (NGF) promotes the development and survival of sympathetic and sensory neurons in the periphery, however, it is reported to be neurotrophic for cholinergic but not catecholaminergic neurons of the brain. We administered NGF 7S ICV for 2 weeks to mice pretreated with MPTP, 30 mg/kg i.p. for 7 days, and found that NGF facilitated the recovery of the nigrostriatal dopaminergic neurons. In our model, administration of MPTP results in about a 60% decrement of striatal dopamine (DA), tyrosine (TH) activity, and DA uptake, which is accompanied by loss of TH-immunopositive cells in substantia nigra. The administration of NGF 24 hr after completing the MPTP treatment restored DA, TH activity and DA uptake in a dose-dependent manner. Moreover, NGF restored the number of TH-immunopositive cells in substantia nigra of MPTP-treated mice. NGF had no effect on the above neurochemical parameters in control animals.

CHRONIC TREATMENT WITH NGF ALTERS MONOAMINE METABOLISM IN RATS WITH LESIONS OF THE NBM.

Leon J. Thal and Ad J. Dekker, Dept. of Neurology VAMC, San Diego and Dept. of Neurosciences, UCSD, CA92037.

Rats received bilateral lesions of the nucleus basalis magnocellularis by infusion of ibotenic acid (28 nmoles in two injections per side). Fourteen days later, osmotic minipumps, releasing human recombinant NGF (0.3 µg/day) were implanted subcutaneously. Pumps were replaced every 14 days. After 6 weeks the rats were sacrificed and the levels of monoamines and their metabolites were determined in the frontal and parietal cortex and hippocampus. Treatment with NGF led to a 50% reduction in the levels of 5-HIAA in cortical areas and DOPAC in the hippocampus. NGF did not affect the levels of DOPA, NE, MHPG, DA, HVA and 5HT in any of the brain regions studied. These results suggest that chronic treatment with NGF influences the turnover of serotonin and dopamine in selected brain regions. These non-cholinergic effects may play a role in the amelioration of behavioral deficits by NGF in rats with lesions of the nucleus basalis.

NERVE GROWTH FACTOR PREVENTS TOXIC NEUROPATHY. M. E. Moran*, S. C. Apfel, J. C. Arezzo, and J. A. Kessler. Albert Einstein College of Medicine, Bronx, N.Y. 10461

Nerve Growth Factor regulates the survival and function of subpopulations of dorsal root ganglia sensory neurons in vitro and in vivo. We have previously demonstrated the ability of NGF to prevent the small fiber sensory neuropathy caused by administration of the experimental anti tumor agent taxol. In this study we sought to determine whether NGF is also capable of preventing the large fiber sensory neuropathy caused by the widely used anti tumor agent cisplatin. Cisplatin was administered intraperitoneally to adult mice at a dose of 10 mg/kg once a week for eight weeks. The animals were concurrently injected subcutaneously with either NGF (5 μg/g) or control buffer three times a week. After the eight week administration period peripheral nerve function was examined using carefully selected behavioral, biochemical, and electrophysiological techniques. Cisplatin administration impaired proprioception as measured by the ability to balance on a rotating dowel ($p<0.005$), reduced sensory ganglion levels of the peptide transmitter calcitonin gene related peptide ($p< 0.02$) and slowed nerve conduction in the tail ($p <0.006$). NGF coadministration prevented all of these abnormalities, indicating that the factor was effective in averting cisplatin induced neuropathy. We are currently testing the ability of NGF to prevent other diseases of the peripheral nervous system. These observations suggest that clinical trials of the growth factor are now warranted.

599.8

CHROMATOLYTIC-LIKE ALTERATIONS AND ABERRANT NEUROFILAMENT PHOSPHORYLATION IN SENSORY NEURONAL PERIKARYA FOLLOWING NGF ANTISERUM INJECTION. B.G.Gold, D.R. Austin*, W.C. Mobley^ and T. Storm-Dickerson*. Center Res. Occup. and Environ. Toxicol., Oregon Health Sci. Univ., Portland, OR 97201 and ^Depts. of Neurol. and Pediat., UCSF, San Francisco, CA 94143.

The mechanism by which the neuronal perikaryal response to injury (axon reaction) is initiated is unknown. Our previous study utilizing nerve growth factor (NGF) antiserum injections for 2 weeks (Gold et al., J. Neurosci. 11:943,1991) demonstrated that loss of NGF triggers two components of the axon reaction (i.e., somatofugal axonal atrophy and nuclear eccentricity). In the present study, three-week-old male rats were given daily injections of goat-antimouse NGF antiserum (0.5 μl/gm) into the left footpad for 4 weeks; age-matched controls received normal goat serum. At 7 weeks of age, the rough endoplamic reticulum was displaced to the periphery of the cell body in some (5-10%) L4-L6 DRG neuronal perikarya. Eccentric nuclei demonstrated prominent nuclear membrane infoldings. Some neurons showed accumulations of lysosomes and lipofusin granules. Axonal atrophy, present only at the level of the DRG at 2 weeks, was observed in the distal portion of the dorsal roots, demonstrating its somatofugal progression. Preliminary immunocytochemical studies (peroxidase-antiperoxidase method) revealed light to modest immunoreactivity in neuronal perikarya (approx. 10%) to phosphorylated neurofilament (pNF) epitopes (antibodies 6-17 and 7-05). The results suggest that interruption of target-derived supply of NGF initiates chromatolytic-like alterations and aberrant expression of pNF epitopes in DRG neurons. Supported by NS26265.

NERVE GROWTH FACTOR (NGF) CHANGES IN RAT EXPERIMENTAL DIABETIC NEUROPATHY.

R.Hellweg*[1], H.D.Hartung*[2], C.Hock*[2], M.Wöhrle*[3], and G.Raivich[1].
[1]Max-Planck Institute for Psychiatry, Munich/Martinsried, [2]University of Munich, [3]University of Giessen, F.R.Germany

NGF-responsive peripheral neurons with small and unmyelinated fibers are affected at an early stage of diabetes mellitus. As revealed by NGF enzyme-linked immunoassay, streptozotocin (STZ)-induced destruction of insulin-producing pancreatic islets, which causes diabetes mellitus led to up to a 3-fold increase of NGF levels in most NGF-producing tissues (Iris, heart atrium and ventricle, spleen, vas deferens), but to a 50% decrease in the NGF-dependent sympathetic superior cervical ganglion[1]. This decrease in the superior cervical ganglion was reversed by successful pancreatic islet allotransplantation. Since NGF is known to exert its effects after retrograde axonal transport together with NGF receptor, we have studied this axonal transport in the rat sciatic nerve 8 weeks after the induction of diabetes with STZ. The overall retrograde transport of NGF decreased to 50% of untreated controls ($p<0.001$ in a 2-sided Student' t-test), and the amount of retrogradely transported NGF in the STZ-treated animals was negatively correlated with the individual blood glucose concentration ($r=0.68$, $p<0.002$).

Taken together, our results could suggest a pathophysiological role for NGF in diabetic neuropathy which may be due to a decreased neuronal capacity of NGF uptake and retrograde transport. Thus, prevention of diabetes-related NGF deprivation in NGF-dependent peripheral neurons could play an important role in the future therapy of diabetic neuropathy.

THE EXPRESSION OF NERVE GROWTH FACTOR RECEPTOR AND HEAT SHOCK PROTEIN mRNA IN ALS SPINAL CORD. J. L. Seeburger, S. Tarras, M.E. Lewis, E. Robbins, and J.E. Springer, Dept. of Neurology, Hahnemann University, Philadelphia, PA 19102, and Cephalon, Inc. 145 Brandywine Pkwy, West Chester, PA 19380 (MEL and ER).

The trophic actions of nerve growth factor (NGF) are necessary for the development and maintenance of neural crest derived sensory, sympathetic and basal forebrain cholinergic neurons. Recently it has been shown that alpha motor neurons may also utilize NGF. These neurons express nerve growth factor receptors (NGFR) developmentally and in response to mechanical injury to peripheral axons. Because of these findings, we were interested in the role of NGF in the alpha motor neuron response to pathological degenerative processes. We also analyzed whether alpha motor neurons may express heat shock protein (HSP) mRNA, which may identify vulnerable cells. An in situ hybridization procedure was used to localize alpha motor neurons expressing NGFR and HSP mRNA in postmortem spinal cords from patients with amyotrophic lateral sclerosis (ALS). Cervical, thoracic, and lumbar sections were processed with a radioactive 2.5 kb cRNA probe complimentary to rat NGFR mRNA, or a 30-mer oligonucleotide probe complimentary to HSP mRNA. Additional sections were processed using cresyl violet or silver degeneration staining procedures. The expression of NGFR mRNA in the ventral horn was greatest at those spinal cord levels which exhibited the most extensive cell loss and agyrophilia, and which were associated with the most extreme clinical symptomatology. In addition, HSP mRNA was localized primarily to a few ventral horn cells in all segments analyzed. We hypothesize that as the disease process advances, some motor neurons start to re-express growth related proteins in an attempt to compensate for the progressive degenerative state. This is supported by EMG and histochemical evidence demonstrating the reinnervation of denervated muscle via collateral sprouting in ALS patients. Supported by PHS grant AG-08969 (JES).

FLUORESCENT AUTOMATED SEQUENCING OF PCR AMPLIFIED DNA CORRESPONDING TO THE PROTEIN CODING REGION OF THE HUMAN B NERVE GROWTH FACTOR GENE.

C. J. Drebing, J. Hopkins*, A. S. Khan*, J. M. Sikela and R. F. Freedman. Schizophrenia Research Center, Veterans Administration Medical Center and University of Colorado Health Sciences Center, Denver, CO 80262.

PCR primers with added restriction enzyme sites were synthesized that flanked the protein coding region of the human β nerve growth factor (NGF) gene (Ullrich et.al., Nature, 1983). After the primers were used to PCR amplify normal and schizophrenic human genomic DNA, the resultant double-stranded DNA was restriction-digested and ligated into Bluescript. The circularized vector with NGF insert was transfected into competent E. coli. Resulting white colonies were screened for NGF insert by amplifications of DNA with universal and reverse M13 primers. The positive NGF PCR products were purified using Centricon 100 filters and used for DNA sequencing. Sequence analysis was carried out with fluorescent-labeled universal and reverse primers, using the Applied Biosystems, Inc. cycle sequencing linear amplification protocol. Sequencing reactions were analyzed on an ABI 373 DNA Sequencer. Automated DNA sequencing of the NGF gene as described here has the potential to identify changes in the primary sequence of NGF that may be associated with specific disease states. This work was supported by the VA Medical Research Service and USPHS Grant No. P50 MH44212-02.

DELETION ANALYSIS OF MOUSE NERVE GROWTH FACTOR

C. C. Drinkwater, U. Suter, & E. M. Shooter Dept of Neurobiology, Stanford University School of Medicine, Stanford CA 94305

Nerve growth factor (NGF) is a trophic peptide responsible for the survival, development, maintenance and regrowth of neural-crest derived sensory and sympathetic neurons as well as basal forebrain cholinergic neurons. Binding sites and mRNA for NGF have been detected throughout the developing avian and mammalian central nervous system, indicating that NGF may affect other cell types early in development. The primary structure of NGF from several different species has been determined by amino acid and nucleotide sequencing, however, as yet, resolution of the three-dimensional structure has not been completed. NGF is initially synthesized as a 33.8 kDa precursor, from which the mature form is cleaved by one or more trypsin-like enzymes. In mouse, active NGF appears to comprise a non-covalently bound homodimer of 118 residue chains, each with three internal disulfide bridges. In an attempt to define a minimal structure of NGF with biological activity, a series of deletion mutants were constructed, using DNA *in vitro* mutagenesis. These mutants were expressed in COS-7 cells and analysed for biological activity. The yields of two mutants were significantly reduced in comparison to wild type recombinant NGF, and no activity could be detected in a neurite outgrowth assay. Though the third mutant, in which amino acids 3-14 were deleted, was produced in relatively high amounts, it was not correctly processed to the mature, active form. Treatment with trypsin does not appear to activate this mutant precursor. Therefore, this region may be critically involved in the specific processing of NGF from its precursor. We are currently examining this region in greater detail by further *in vitro* mutagenesis.

A RAT CELL LINE PRODUCING RECOMBINANT HUMAN NERVE GROWTH FACTOR (rhNGF)

L Olson[1], C Wetmore[1], P Lönnerberg[2], H Persson[2], M Eriksdotter-Nilsson[1], A Kylberg[3], T Ebendal[3]

[1]Dept. of Histology & Neurobiology, Box 60 400, and Dept of Medical Chemistry II, Laboratory of Molecular Neurobiology, Karolinska Institute, Stockholm, Sweden, and [3]Dept of Developmental Biology, Uppsala University, Box 587, Biomedical Center, S-751 23 Uppsala, Sweden.

By grafting genetically modified cell lines that secrete neurotrophic factors to the CNS, the problems of long term delivery of trophic proteins across the blood brain barrier can be overcome. In the present experiments we wished to obtain a cell line which secreted rhNGF and could be grafted to Sprague-Dawley rats without immunosuppression. The coding portion of the human NGF gene was therefore introduced (using MRE(4X)-OVEC vector) into a rat cell line immortalized from E15 Sprague-Dawley rat muscle tissue through 47 passages. Clones were tested for NGF production (approximately 0.5-1.0 ng/ml of conditioned medium) by a biological assay using fibre outgrowth from embryonic sympathetic ganglia, as well as a two-site enzyme immunoassay for NGF. Pieces of collagen gel containing rhNGF-secreting or parental cells were grafted to unilaterally fimbria-fornix lesioned adult Sprague-Dawley rats. Grafts of these cells survived well and rescued axotomized cholinergic neurons in the medial septum, as compared with non-transfected, parental cell lines. These studies indicate that cell lines established from the recipient strain survive grafting without immunosuppression and can secrete amounts of biologically active NGF sufficient to exert tropic effects on damaged CNS neurons in vivo.

A FUNCTIONAL DOMAIN OF THE LOW AFFINITY NGF RECEPTOR (LNGFR).

S.Myers*, S.Dostaler*, D.Weaver*, P.Richardson†, R.Riopelle and K. Dow. Apps Medical Research Centre, Kingston General Hospital & Queen's University, Kingston, Ontario, Canada K7L 2V7, and †McGill University, Montreal, Quebec, Canada H3G 1A4.

Regions of the cytoplasmic domain of LNGFR which might interact with G protein subunits were identified by comparison with the cationic amphiphilic tetradecapeptide mastoparan, which catalyzes nucleotide exchange on G proteins similar to that of receptors. The program PRISM was used to identify αhelical regions and BIOGRAF was used to construct and minimize these regions using an AMBER force field with the αhelix constrained and the amino acid side chains free to find their most stable conformations. Synthetic peptides were tested for effects on trophic factor induced survival/differentiation responses of rat PC12 cells, chick DRG neurons and chick ciliary neurons. A peptide representing residues 370-383 of human LNGFR accelerated the neurite growth response to NGF of PC12 cells and DRG neurons but not the survival effect of CNTF on ciliary neurons. Mastoparan and a hybrid peptide had no effect. Millimolar Mg^{2+} and benzalkonium chloride blocked the effect of the peptide on PC12 cells, and, of three bacterial toxins tested, only diphtheria was inhibitory. The LNGFR may modulate the biological effect of NGF on responsive cells mediated by the high-affinity NGF receptor by influencing an effector system coupled to a diphteria toxin sensitive G protein.

RECEPTOR RADIOAUTOGRAPHY AND IN SITU HYBRIDIZATION FOR NGF RECEPTORS IN PRIMARY SENSORY NEURONS.

V.M.K. Verge, J. Grondin, R.J. Riopelle and P.M. Richardson. McGill University, Montreal & Queen's University, Kingston, Canada.

Individual neurons in adjacent sections of rat lumbar DRG, nodose ganglia, and trigeminal ganglia have been examined by receptor radioautography for high-affinity NGF receptors (HNGFR) and in situ hybridization with an oligonucleotide probe for the low-affinity NGF receptor (LNGFR). In normal lumbar DRG, all neurons with HNGFR plus some additional neurons have relatively high levels of LNGFR mRNA. In nodose ganglia, many neurons lacking HNGFR have abundant LNGFR mRNA. Intrathecal infusion of NGF increases expression of the LNGFR gene in lumbar DRG of otherwise normal rats and, for neurons with HNGFRs only, counteracts a sharp down-regulation of LNGFR mRNA which follows sciatic nerve transection. The observations are consistent with the hypotheses that i) the HNGFR consists of the NGF-inducible LNGFR plus some unidentified component, ii) the previously reported down-regulation of the HNGFR following peripheral injury results from interruption of NGF support for the LNGFR, iii) LNGFRs in some sensory neurons lacking HNGFRs could constitute one component of BDNF receptors.

599.16

A RAPID AND HIGHLY QUANTITATIVE SOLUTION HYBRIDIZATION METHOD FOR DETECTING NERVE GROWTH FACTOR RECEPTOR MESSENGER RNA.

R.C. Elliott, C.E. Inturrisi, C.F. Dreyfus, and I.B. Black. Cornell Univ. Med. Coll., N.Y., NY, and UMDNJ/Robert Wood Johnson Med. Sch., Piscataway, NJ.

Currently the most sensitive method of detecting a specific species of messenger RNA (mRNA) from total cellular RNA is by nuclease protection assay (NPA). Though highly sensitive, the accuracy of the NPA is limited by variations in efficiency per sample in 1) ethanol precipitation, 2) dissolution and gel-loading of hybridized fragments, and 3) densitometric analysis. Furthermore, NPA analysis of mRNA is slowed by the extended time often necessary for autoradiography and the limited number of samples allowable on a standard electrophoresis apparatus.

We report the application of a solution hybridization technique (SHyT), described by Franklin et al. (Molec. Brain Res. (1991) in press), to quantitate levels of mRNA for nerve growth factor receptor (NGF-R) derived from rat brain. With the SHyT, protected riboprobe fragments are TCA precipitated, harvested over glass-fiber filters, and quantititated immediately by scintillation spectroscopy. Utilization of the SHyT led to a marked increase in sample reproducibility, linearity over two orders of magnitude, and approximately a twofold increase in assay sensitivity. Moreover, direct counting of samples and the lack of sample number limitation allowed RNA analysis of multiple experimental groups in days instead of weeks. Hence the SHyT provides a significant increase in the efficiency and accuracy of mRNA analysis compared to previously described methods.

CALCIUM ANATGONISTS PREVENT SMOOTH MUSCLE HYPERTROPHY AND NEURAL PLASTICITY ASSOCIATED WITH BLADDER OUTLET OBSTRUCTION.

J.B. Tuttle, M.E. Albo*, D.J. Creedon, W.D. Steers. Univ. of Virginia Sch Med, Urology and Neuroscience, Charlottesville, VA 22908

Calcium influx has been implicated as an initial signal triggering smooth muscle hypertrophy and growth factor production. Rats with bladder outlet obstruction were maintained for 3 weeks on verapamil (V) (75mg/kg/da PO) and diltiazem (D) (100mg/kg/da PO). Both drugs significantly prevented the increase in bladder weight following obstruction [397mg (no drug) to 277mg (V) and 237mg (D), ($p<0.05$)]. Bladder tissue from obstructed rats maintained on calcium antagonists contained less smooth muscle. The calcium antagonists also reduced the neuronal hypertrophy of pelvic ganglion cells (525um^2 to 411um^2 ($p<0.001$)) and nerve growth factor levels (45.2pg to 23.1pg (V)). Calcium antagonists did not prevent the increased voiding frequency (1.25 vs 1.18 (V) and 0.98 (D) hr^{-1}) associated with obstruction. Prazosin (10mg/kg/da) did not affect bladder enlargement (396mg) or neuronal hypertrophy (522um^2). However, this alpha-1 adrenergic blocker prevented the increase in voiding frequency (0.89hr^{-1}, $p<0.05$). These data suggest that calcium is involved in the muscle growth and neural plasticity associated with obstruction. Furthermore, alpha adrenergic antagonists abolish symptoms of bladder hyperactivity independent of the relief of obstruction.

GLUCOCORTICOIDS REGULATE mRNA EXPRESSION FOR NEUROTROPHIC FACTORS IN THE RAT BRAIN

Gisela Barbany*, Nils Lindefors[2] and Håkan Persson Deparment of Medical Chemistry, Laboratory of Molecular Neurobiology 2 Department of Pharmacology, Karolinska Institute, S-10401 Stockholm, Sweden

The hippocampus is the major target region for glucocorticoid action in the nervous system. Adrenalectomy results in a nearly complete cell loss of hippocampal granule cells 3 to 4 months after surgery. In the present study we investigated the effect of glucocorticoids on neurotrophic factor mRNA expression. In the rat brain NGF mRNA expression in the hippocampus was found to be significantly decreased 3 days after adrenalectomy compared to sham-operated animals. Corticoid replacement by daily s.c. dexamethasone injections (1mg/kg) restored NGF mRNA levels to normal. The same effect was seen for BDNF and NT-3 mRNAs. Sham animals recieving s.c. dexamethasone injections showed no significant changes in neurotrophic factors mRNA expression.

The effect of adrenalectomy on neurotrophic factor mRNA expression in the cortex was also assesed and the results showed a decrease in the level of mRNA for all three factors. As in the hippocampus, the increase in the cortex was also prevented by dexamethasone replacement. The effect of a single dose of dexamethasone (5mg/kg) administered i.p. to intact animals on the expression of neurotrophic factors was also analysed. NGF mRNA in the cortex was significantly increased after a single i.p. injection of dexamethasone . The mRNA for NT-3 showed only a sligth increase and BDNF mRNA was the same as in control animals recieving vehicle injection.

MORE REGENERATED AXONS IN THE DISTAL STUMP OF TRANSECTED SCIATIC NERVE TREATED WITH GLIAL MATURATION FACTOR ß. K. Harman*, J. Katnick*, R. Lim, J.C. de la Torre. Univ. of Ottawa, Ontario Canada KIH 8M5

Sixteen female Sprague-Dawley rats were anaesthetized and prepared for bilateral sciatic nerve transection. The transection and entubulation repair involved: pre-treating the nerve with 15% polyvinyl alcohol:chlorpromazine solution, to reduce post-transection extrusion of the nerve tip; rapid cooling with fluorimethane spray, to render the nerve firm; transection with an ultrafine-edged razor blade. In each animal, the 2 mm (± 0.25 mm) interstump gap created was filled with either collagen only (COL) or a collagen / neurotrophic (COL/NTF) factor mixture. Each NTF held the prospect of exerting a stimulatory or protective effect on regenerating axons when applied at the transection and repair site and were chosen because they were as yet untested in the sciatic nerve. The concentration of each NTF/ml collagen was: 4-aminopyridine (4-AP) 0.2 mg; lipid angiogenic factor (LAF) 2.0 mg; leupeptin (LEU) 0.2 mg; ß-GMF 20 ng. After six weeks the number of regenerated myelinated axons in the distal stump were counted using our line-sampling quantification technique, and compared to the controls (COL). We found that nerves treated with 4-AP, LAF and LEU had both greater and fewer axons. However, in the distal stumps of the nerves treated with ß-GMF, there were consistently more axons (48-52%). We therefore conclude that ß-GMF may stimulate regeneration in the peripheral nervous system. The implantation of a COL/NTF mixture in our entubulation preparation provides a useful and quantifiable technique for screening potential enhancers of peripheral axon growth.

MODULATION OF 2-DEOXYGLUCOSE UPTAKE IN CULTURED ASTROCYTES. D.L. Davies and T.M. Ross*. Dept. of Anatomy, Univ. of Arkansas for Med. Sci., Little Rock, AR 72205.

Reactive differentiation of astrocytes is a key component of the cerebral response to injury. As part of an endeavor to define the metabolic changes associated with cellular differentiation, 2 deoxyglucose (2DG) uptake was measured in cultures treated with agents known to induce morphologic reconfiguration or impede proliferation. Secondary rat astrocytic cultures were treated with dibutyryl cyclic AMP (dBcAMP), a cerebral tissue extract with morphogenic properties or ethanol levels sufficient to diminish proliferation. The 2DG uptake was measured using the method of Brooks and Yarowsky (1985, J. Neurochem. 44:473-479). Increased 2DG uptake was detected in control cultures at 3 and 6 hrs after replenishing the nutrient medium, but uptake values returned to baseline at 24 hr. Treatment with either dBcAMP (1mM) or cerebral extract (1mg/ml) enhanced 2DG uptake at 3, 6 and 24 hrs. These changes in 2DG were noted prior to qualitative changes in astrocytic morphology. The increase in 2DG uptake induced by treatment with dBcAMP and cerebral extract (0.5 mg/ml) was sustained at 24 and 48 hrs of treatment. Simultaneous exposure to 0.2% or 0.5% (w/v) ethanol augmented this response to dBcAMP and cerebral extract at 24 hr. These data suggest that metabolic changes requiring glucose consumption preceed alterations in astrocytic morphology and may have a role in reactive differentiation.

NEURONAL SURVIVAL OF CEREBELLAR GRANULE CELLS *IN VITRO* IS REGULATED BY LEVELS OF INTRACELLULAR CALCIUM. T.Koike. Department of Natural Science, Saga Medical School, Nabeshima, Saga 84001, JAPAN.

We have previously proposed a calcium set-point hypothesis for the degree of neuronal dependence on trophic factor *in vitro* (T.Koike et al. PNAS, 86:6421, 1989), and provided evidence for this hypothesis in sympathetic neurons (T.Koike and S.Tanaka, ibid, 88, in press,1991). Here, as an extension of this study, we examined the relationship between intracellular calcium ([Ca2+]i) and survival of cerebellar granule neurons. The granule neurons isolated from 7-day-old postnatal rats undergo massive degeneration around DIV 5, which appears to mimic neuronal death due to unavailable trophic factor that occurs in development. Chronic depolarization with high potassium prevents this cell death. The neurons were grown in various concentrations of potassium for 1 or 2 days, loaded with fura-2 (2µM), and their [Ca2+]i levels were measured using digital fluorescence imaging. Neuronal survival was determined by measuring release of lactate dehydrogenase activity into medium or counting the number of viable neurons. By combining these two data we generated a correlation curve between [Ca2+]i and neuronal survival similar to that for sympathetic neurons; the result indicates that neurons with [Ca2+]i =30nM at 5mM K did not survive and the compete survival occurred at 150nM (at 25mM K). Moreover, NMDA is known to mediate neuronal survival of granule cells. We found that NMDA elicited a sustained level of [Ca2+]i which is pertinent to neuronal survival. These results demonstrate the feasibility of this hypothesis in neurons from the central nervous system as well as in peripheral neurons.

NICOTINIC AGONISTS, PHORBOL ESTERS AND GROWTH FACTORS ACTIVATE TWO DISTINCT MYELIN BASIC PROTEIN KINASES IN BOVINE CHROMAFFIN CELLS. B. Pavlovic-Surjancev*, A.L. Cahill, R.L. Perlman. Depts. of Pediatrics and Pharmacol. and Physiol. Sciences, The University of Chicago, Chicago, IL 60637

Insulin-like growth factor I (IGF-I) increases protein kinase activity against microtubule associated protein-2 and myelin basic protein (MBP) in bovine chromaffin cells (Cahill and Perlman, J. Neurochem., in press). To characterize the MBP kinases in chromaffin cells, we separated chromaffin cell proteins by electrophoresis on SDS-polyacrylamide gels into which MBP had been incorporated, allowed the proteins to renature and then assayed MBP kinase activity by incubating the gels in solution containing [γ-^{32}P]ATP. We have identified six MBP kinases, with M_r of 116, 80, 60, 53, 46 and 42,000. The MBP kinases of M_r 46,000 and 42,000 (PK46 and PK42) were activated by treatment of the cells with the nicotinic agonist dimethylphenylpiperazinium (DMPP), phorbol 12,13-dibutyrate (PDBu) or IGF-I. The involvement of protein kinase C (PKC) in the activation of PK46 and PK42 was examined. Down regulation of PKC by incubation of the cells with PDBu abolished the activation of both PK46 and PK42 by DMPP, PDBu and IGF-I. Staurosporine, a PKC inhibitor, prevented the activation of PK46 and PK42 by DMPP and PDBu, but did not block the activation of these kinases by IGF-I. Thus, chromaffin cells appear to contain two MBP kinases that can be activated by both PKC-dependent and PKC-independent mechanisms. These kinases may participate in protein kinase cascades activated by various agonists. (Supported by research grants from NIH and NSF)

CHOLINERGIC DIFFERENTIATION OF CULTURED RAT SYMPATHETIC NEURONS BY FACTORS APPLIED TO DISTAL NEURITES. D. R. Ure, R. B. Campenot, and A. Acheson. Dept. of Anatomy and Cell Biology, Faculty of Medicine, Univ. of Alberta, Edmonton, Alta., Canada T6G 2H7.

The development of cholinergic properties in rat sympathetic neurons in vivo is believed to occur in response to factors derived from target tissues. Although the cholinergic switching event in mass cultures occurs in response to a variety of factors, only one model, the rat sweat gland innervation, has directly supported the theory of target-mediated cholinergic differentiation. The results of our studies using a variety of factors applied to rat sympathetic neurons in a compartmented culture system also support that theory. When 600 units/ml leukaemia inhibitory factor (LIF; Dal.a cell line proliferation assay), 50% heart cell conditioned medium, or 50% dermal fibroblast conditioned medium are supplied to only distal neurites from Days 7-21 in culture, a many-fold increase in specific choline acetyltransferase (ChAT) activity and a decrease in tyrosine hydroxylase immunoreactivity are observed. The increase in ChAT activity is time- and concentration-dependent. Our results suggest that LIF and the factor(s) in conditioned media could act as target-derived differentiation factors in vivo.

NOT ALL CNS TRANSPLANTS CAN RESCUE AXOTOMIZED CLARKE'S NUCLEUS NEURONS. B.T. Himes[1], P. Baker*[1], M.E. Goldberger[1], and A. Tessler[1,2] Dept. of Anatomy and Neurobiology, The Medical College of Pennsylvania[1], and VA Medical Center[2], Philadelphia, PA.

Axotomy of Clarke's nucleus (CN) results in a 50% loss of CN neurons in neonatal rats and a 30% loss in adults 2 months postoperatively. This retrograde degeneration is a reaction to the loss of target derived neurotrophic factors. Grafts of fetal spinal cord, cerebellum, or neocortex all prevent lesion-induced cell death and maintain normal numbers of CN neurons for at least two months following surgery (Himes et al.'90, Soc. Neurosci. Abst. 16:818). These three areas of embryonic CNS produce a neurotrophic factor, neurotrophin-3 (NT-3). NT-3 provided by the grafts may be responsible for the survival of axotomized CN neurons. We therefore transplanted into P2 rats an area of the CNS that does not contain NT-3, the striatum (Maisonpierre et al.,'90 Neuron 5:501-509). Grafts of E14 striatum were placed into a spinal cord hemisection cavity at T8. The transplants survive, although they are not well integrated with the host spinal cord. CN in the L1 spinal cord segment was analyzed 2 months postoperatively. The mean number of surviving CN neurons ipsilateral to the lesion is reduced by 50% (n=3). This cell loss is equivalent to that seen in the neonate after hemisection alone. Transplants of striatum appear to be unable to rescue axotomized CN neurons, perhaps because they do not provide NT-3.

LAMININ B2 mRNA IS UP-REGULATED IN SENSORY NEURONS AND SCHWANN CELLS DURING PERIPHERAL NERVE REGENERATION. J. M. Le Beau[1] and F. J. Liuzzi[2]. Diabetes Institute[1] and Dept. of Anatomy and Neurobiology[2], Eastern Virginia Medical School, Norfolk, VA. 23501

Laminin, a large glycoprotein consisting of three polypeptide chains, is an extracellular protein that has been implicated in promoting Schwann cell-neuron interactions. Laminin functions as a potent stimulator of neurite extension and can enhance neuronal survival *in vitro*. *In vivo*, its presence on the surface of Schwann cells has been correlated with the advancement of neurites regenerating across a 10 mm gap (Longo et al., Brain Res. 309:105-107). We examined regenerating rodent peripheral nerves and their associated sensory neurons for changes in laminin mRNA expression by *in situ* hybridization with sense or anti-sense laminin B2 RNA probes. Regenerated sciatic nerves showed an up-regulation of laminin B2 mRNA in Schwann cells compared to control sciatic nerve. More suprisingly, we detected laminin B2 mRNA in L4 and L5 DRG neurons and this mRNA appeared to be up-regulated during regeneration. Increased laminin B2 mRNA expression was also observed in the satellite cells of those DRGs after sciatic nerve injury. These findings suggest that neurons, as well as supporting cells, may be capable of regulating the synthesis and secretion of a glycoprotein implicated in their own as well as neighboring cells differentiation, migration and in the case of neurons, neurite elongation. Immunohistochemical studies are currently in progress to determine the relationship between the synthesis and deposition of laminin during peripheral nerve regeneration.

600.8

SCHWANN CELLS PROMOTE SURVIVAL AND MORPHOLOGY OF NEURONS FROM POSTNATAL LOCUS COERULEUS, SUBSTANTIA NIGRA, AND CEREBRAL CORTEX. M.B. Clark and C. Chui. Dept. Anatomy, Univ. MD. Sch. of Med.,Baltimore MD 21201.

We studied dissociated cell cultures from the locus coeruleus, substantia nigra and cerebral cortex of postnatal rats to determine if Schwann cells (SCs) and SC products promote survival and regeneration of specific types of postnatal CNS neurons (NCs). We used an image analysis system to measure several morphometric parameters of NCs to assay for the effects of SCs or SC conditioned medium (SCM) on the regenerative capacity of surviving NCs. NCs were identified by immunostaining for neurofilament (Nf), Tau protein, and tyrosine hydroxylase (TH). Two populations of NCs were identified by their immunoreactivity for Tau and/or NF: Tau positive (Tau+) alone or both Nf and Tau positive (Nf/Tau+). In addition, a third population of NCs which was both TH and Nf immunoreactive (TH/Nf+) was identified in cultures from brainstem nuclei. Neuronal survival of all three populations was increased at least 1.5 fold in the presence of living SCs and in SCM as compared to appropriate controls, including neurons grown in the presence of fibroblasts. Interestingly the greatest effect of SCs and SCM was seen on the NF/Tau+ subpopulation. SCs or SCM increased the number of these NCs by at least 10 fold. Image analysis of NF/Tau+ NCs revealed an increase in somal perimeter, mean number of primary neurites, mean number of processes, total neurite length, and the extent of neuritic field in the prescence of SCs or SCM. Filtration and dialysis experiments appear to indicate that the active components in SCM are ≥ 10kDa. Our results suggest that SCs and soluble SC products support both the survival and regenerative capacities of several specific classes of postnatal CNS neurons. (Supported by NS24252).

SAFETY TESTING OF INTRATHECAL URIDINE AND OROTIC ACID IN RABBITS. C.K. Haun, G. Goubran*, W.K. Engel and I. Tan*, Depts. of Anatomy & Cell Biology and Neurology, USC School of Medicine, Los Angeles, CA 90033.

In an ongoing study of agents with potentially trophic effects upon spinal cord neurons, we have safety-tested intrathecal uridine (U) and orotic acid (OA), two precursors of RNA via the salvage & de novo paths, respectively.

In uM/Kg/d, doses of U ranging from 410 to 1640, and OA, from 440 to 3520, were administered to young male and female rabbits with Alzet osmotic pumps, through a catheter inserted into the spinal subarachnoid space at the L7-S1 interspace. Freshly loaded pumps were reimplanted at two-week intervals for as long as tolerated.

Of the two, OA seemed better tolerated: viz. 3520 uM/Kg/d for over five mos., and one rabbit tolerated 880 uM/Kg/d for over 9 mos., without discernable side effects. U was well tolerated for over 20 wks. at 820 uM/Kg/d; but with 1640 uM/Kg/d, diarrhea and weight loss occurred after 9 wks. The animals continued to maintain normal growth and behavior throughout the treatment periods, but at a reduced rate with the higher dosages of OA & U, respectively 3520 and 1640 uM/Kg/d.

Thus, OA & U will probably be safe, within the dose ranges noted above, for intrathecal administration as potential therapeutic agents for human neurological disorders.

S100β, A GROWTH FACTOR WITH NEUROTROPHIC ACTIVITY, STIMULATES INCREASES IN INTRACELLULAR CALCIUM IN NEURONAL AND GLIAL CELLS. S.W. Barger and L.J. Van Eldik. Depts. of Cell Biology and Pharmacology, Vanderbilt Univ., Nashville TN 37232.

Recent data have suggested that S100β is a bifunctional growth/differentiation factor, stimulating proliferation of glial cells and survival and morphological differentiation of immature neurons. We demonstrate here that dimeric S100β can evoke increases in free, intracellular calcium concentrations ($[Ca^{2+}]_i$) in both glial and neuronal cells. The S100β-induced $[Ca^{2+}]_i$ increase included a rapid, transient component that was independent of extracellular calcium and a sustained, reversible elevation that was dependent on calcium influx. The monomeric form of S100β appeared to lack the ability to evoke this response. The S100β-induced $[Ca^{2+}]_i$ increase was blocked by an inhibitor of phospholipase C, consistent with the ability of S100β to stimulate the hydrolysis of phosphatidylinositol. In at least one neuronal cell type, S100β stimulated increases in $[Ca^{2+}]_i$ synergistically with high K^+. These data demonstrate that while the biological responses of neuronal and glial cells to S100β are quite different, transduction of the S100β signal in both cell types may involve changes in $[Ca^{2+}]_i$. RELEASE OF OTOCYST-DERIVED TROPHIC FACTORS IS DEVELOPMENTALLY REGULATED. L.M. Bianchi and C.S. Cohan, Dept. of Anatomical Sciences, SUNY ay Buffalo, Buffalo, N.Y. 14214

During the early stages of auditory development, the otocyst releases a diffusible trophic factor which promotes the outgrowth of neurites from statoacoustic ganglia (SAG). The present experiments evaluated the developmental time course of this trophic influence by coculturing E4-E15 SAG explants with otocysts of various developmental stages. In the absence of otocysts, little neurite outgrowth was seen from SAG explants at all stages. However, extensive neurite outgrowth occurred when E4-E6 SAG were cultured in the presence of otocysts of the same age. The amount of neurite outgrowth observed in cocultures steadily decreased at later development stages. E7-E9 cocultures produced less outgrowth and E10-E13 cocultures produced the least outgrowth compared to E4-E6 cocultures. Additionally, otocysts from older stages (E9) were unable to promote outgrowth of E4 SAG. Thus, the level of the trophic factor released by the otocysts declines during development. In contrast, the ability of SAG neurons to respond to the trophic factor was maintained throughout development. Neurite outgrowth from E10-E15 SAG was promoted in the presence of the conditioning factor released by younger stage (E4) otocysts. The results of our experiments indicate that there is a developmentally-regulated release of a diffusible chemotrophic factor from the otocyst which influences neurite outgrowth from SAG. AN IMPROVED METHOD FOR POSTNATAL RAT HIPPOCAMPAL CULTURE. **L.T. Happel[1], J.M. Lyles[2], G.D. Clark[2] & C.F. Zorumski[3]. [1,2]Dept. of Neurol., [1]Neurosurg. & [1]Physiol., LSU Med. Ctr., New Orleans, LA 70112 & [3]Depts. of Psych., Anat. & Neurobiol., Wash. Univ., St. Louis, MO 63110.**

Current methods of postnatal rat hippocampal culture lead to inconsistent neuronal survival prompting efforts to improve techniques. Hippocampi from 1-4 d rat pups were sliced transversely and placed in an oxygenated L-15 media containing .2 mg/ml bovine serum albumin and 15 U/ml papain for a 30 minute incubation period. Hippocampal neurons were gently dissociated by trituration in Eagles minimal essential media containing 5-10% (v/v) fetal calf serum, 5-10% (v/v) horse serum, 200 μM glutamine, 50 μg/ml streptomycin, 50 U/ml penicillin, 6 mM glucose, 10 μg/ml insulin, 10 μg/ml human transferrin and 10 ng/ml selenium. The resultant cell suspension was placed in 35 mm culture dishes coated with a reconstituted basement membrane substance, Matrigel (Collaborative Research). Though neurons on standard collagen matrix were still attaching and had few processes within 12 h of plating, neurons on Matrigel had extended processes. Little difference in neuronal yield was noted in dishes coated with Matrigel concentrations of ≥ 1:5. Fewer neurons were noted at ≤ 1:10 Matrigel and even fewer on collagen. Matrigel improves survival and enhances development of hippocampal neurons.

THE DISTRIBUTION OF THE CHICK PRION-LIKE-PROTEIN IN THE NERVOUS SYSTEM OF THE CHICKEN F. A.Johnson, and G.D.Fischbach
Department of Neurobiology, Harvard Medical School, Boston,MA 02115

A protein purified and cloned in our laboratory based on its copurification with the 42kD Acetylcholine-Receptor-Inducing-Activity shares a 33% homology to the mammalian prion protein (Falls et al, CSH Sym, 55 1990). We report here the distribution of this chick prion-like-protein (ch-PLP) in the chicken spinal cord and brain.

A monoclonal antibody raised to a peptide of amino acids 213-224 of ch-PLP labels neurons in both the spinal cord and brain of chickens, and this labelling is significantly reduced by the specific peptide, but not by another peptide. Motoneurons in the anterior horn chicken cord are very intensely labelled. Some neurons in the dorsal and medial gray matter are also labelled, but less intensely. The anti-ch-PLP antibody also labels neurons in the embryonic cord, with labelling in the anterior horn visible as early as E6. Many neurons in the brain are labelled, with intensely labelled neurons visible in the Edinger-Westphal nuclei, oculomotor nuclei, the isthmus nuclei, magnocellular and parvocellular parts, the Purkinje cell layer in the cerebellum, and cells in layer SGFSi of the Optic Tectum. Many of these nuclei, with the exception of the Purkinje cells, are probably cholinergic as they are labelled both by acetylcholinesterase histochemistry and an anti-choline acetyl-transferase antibody (kindly provided by Miles Epstein). We are currently investigating if the labelling in the brain and cord is restricted to cholinergic neurons. This is important in light of the possible trophic activity of this molecule.

SURVIVAL OF LOCUS COERULEUS NEURONS IS PROMOTED BY ELEVATING INTRACELLULAR CYCLIC AMP LEVEL. L.Sklair and M.Segal. Center for Neuroscience, The Weizmann Institute, Rehovot 76100, Israel.

Central noradrenergic (NA) neurons from the locus coeruleus (LC) differ from other neurons in their extensive morphology and outstanding regenerative capacity. The aim of our study was to identify agents that specifically regulate the survival of tissue cultured rat LC neurons. The numbers of NA and total neurons were quantitated using tyrosine hydroxylase (TH) and NSE immunocytochemistry, respectively. Following exposure of LC cultures to cAMP analogs or to forskolin, a dramatic increase, up to to 4 fold, in the number of NA cells was seen. The non-NA cells, in the same culture, were not affected. The increase in the number of TH cells in LC cultures resulted from a selective trophic effect on the survival of NA neurons. Glial cells and calcium were not required for the expression of the trophic effect. NGF, EGF and FGF did not affect the survival of TH neurons. However, the beta-adrenergic agonist isoproterenol (10uM) significantly increased the number of NA neurons. Therefore, cAMP may be the messenger by which norepinephrine exerts its trophic effect on central NA neurons.

A PURIFIED DOPAMINE-RELEASING PROTEIN (DARP) FROM MESENCEPHALIC CELL CULTURES STIMULATES *IN VITRO* DA RELEASE FROM CORPUS STRIATUM AND AN ANTI-DARP REDUCES THE NUMBER OF NEURONS AND NEURITE OUTGROWTH. K. Sachchithanantham, Y. Park*and V. D. Ramirez, Dept. Physiology, University of Illinois, Urbana, Illinois, 61801.

Previously we reported that a partially purified DARP from adrenal gland is a 54 kD glycoprotein that stimulates *in vitro* DA release from corpus striatum. To purify DARP from CNS, mesencephalic cells (M-cells) derived from E17 rat fetuses were cultured. DARP was purified from media of 12 day old M-cell cultures using ammonium acetate/ethanol precipitation and anti-DARP affinity chromatography column. The DARP preparation from ammonium acetate/ethanol precipitation stimulated *in vitro* DA release in a dose-response manner. For instance, a 200 µg dose stimulated DA release from 22.6 ± 3.5 pg/mg/min, basal to 54.5 ± 8.7, peak level, n=9, $p < 0.01$. In contrast, a similar preparation from media alone was not effective (22.1 ± 3.5, vs 23.2 ± 5.5, n=4). After affinity chromatography, highly purified DARP at an estimated protein concentration of 100-200 ng also increased *in vitro* DA release (8.7 ± 1.6, basal level, vs 23.0 ± 3.8, peak, n=6). In addition, a monoclonal anti-DARP (Ig-M type) was added once to 9 day old M-cell cultures. Anti-NGF was used as a control. On day 12, 14 and 16, cell numbers were counted. 35 and 70 µg of Anti-DARP clearly decreased the number of cells as well as neurite outgrowth, while Anti-NGF did not affect either of them. These results suggest that DARP is produced from M-cells in culture, and seems to be a neurotrophic factor for these cells.

600.16

REGULATION OF THE EXPRESSION OF G41, A NOVEL LAMININ-LIKE CDNA CLONE, IN INJURED RAT BRAIN AND IN PC12 CELLS. T.T.Quach, S.A. Tijoe and A.M. Duchemin. Department of Pharmacology, The Ohio State University College of Medicine, Columbus, Ohio, 43210 USA.

G41 clone was isolated from a cDNA library constructed in plasmid pGEM, from poly (A^+) RNA extracted from lesioned rat brain. Sequence comparison of a partially sequenced insert revealed more than 53% homology with the nucleic acid sequence coding for laminin. A cRNA probe was used to study G41 expression in northern blot analyses. An hybridizing band was detected at a position corresponding to approximately 3.8 Kb. In the rat, the strongest signal was found in the brain. We failed to detect G41 expression in kidney, lung, muscle and liver, under identical hybridization conditions. A low level of G41 mRNA was detected in the heart. In preliminary experiments, we found that 2 days after injury to the cerebral cortex of the rat brain the expression of G41 was increased more than 300% in the tissues surrounding the injury site. We also detected high levels of G41 expression in tumors and in PC12 cells. In PC12 cells, NGF negatively regulates the expression of G41 gene: G41 mRNA levels decreased more than 60% after incubation of the cells with 10 nM NGF for 4 hours. These preliminary results suggest that G41 gene is regulated during brain injury and cell differentiation.

GLYCYL-L-GLUTAMINE REGULATES THE EXPRESSION OF ACETYLCHOLINESTERASE ASYMMETRIC FORMS IN CULTURED FETAL CARDIAC MYOCYTES. C.N. Battie, K. Hagler* and W.R. Millington. School of Basic Life Sciences, University of Missouri-Kansas City, Kansas City, MO 64108.

ß-endorphin and other opioid peptides have been identified in rat heart, although their role in cardiac function is poorly understood. We examined whether glycyl-glutamine (Gly-Gln; ß-endorphin$_{30-31}$), a dipeptide formed during ß-endorphin processing, regulates the expression of acetylcholinesterase (ACHE) forms in rat cardiac myocytes as it does in skeletal muscle and sympathetic ganglia. Globular (G) and asymmetric (A) AChE forms are present in the ventricles of neonatal rats; however, neonatal ventricular myocytes cultured in a defined medium for 72h do not synthesize A-forms of AChE. Dissociated cells from ventricles of neonatal rats were preplated in M199 and 0.5% fetal calf serum to remove non-muscle cells, then transferred to laminin- coated culture dishes (1.5×10^5 cells/35mm dish) in a defined medium with or without 10^{-4} or 10^{-6} M Gly-Gln. Gly-Gln did not change the specific activity of cell-associated AChE or the amount of secreted AChE, but Gly-Gln did alter the relative proportions of AChE forms, inducing the expression of asymmetric AChE. A_{12} AChE was barely detectable in control cultures but was clearly present, constituting 15 ± 3% of cell associated activity, in those with the dipeptide. These results suggest that Gly-Gln may have trophic activity towards the postsynaptic cholinergic system in developing rat heart.

600.18

EXPRESSION OF c-FOS IN MONKEY AND HUMAN CEREBELLUM AND HIPPOCAMPUS.
K. A. Maguire-Zeiss, L. M. Nakayama* and R. W. Hamill. Dept. of Neurology & Neurobiology and Anatomy, University of Rochester Medical Center, Monroe Community Hospital, Rochester, NY 14620.

The proto-oncogene c-fos is able to form complexes with the transcription factor c-jun and these dimers bind with high affinity to the AP1 consensus site thereby regulating the expression of a number of genes (ie. beta amyloid precursor protein, tyrosine hydroxylase, SV40). In addition, the expression of the c-fos is regulated by a number of physiological pertubations: induction of c-fos occurs following membrane depolarization and calcium influx, and exposure to nerve growth factor and cholinergic agonists. Since proto-oncogenes represent a third messenger system and participate in key cellular regulatory phenomenon, alterations of which may occur in the brain regions involved with neurodegenerative disorders, we sought to determine whether c-fos might be examined in postmortem human brain. We have used semi-quantitative in situ hybridization (ISH) to localize c-fos messenger RNA (mRNA) in postmortem monkey (M. *nemestrina*) and normal human cerebellum and hippocampus. In order to compare c-fos expression with Fos protein, we utilized immunocytochemical techniques. The data demonstrate detectable c-fos mRNA and Fos protein in dentate gyrus of hippocampus as well as hippocampal subfields, and the purkinje cell layer of cerebellum. Thus, the role of proto-oncogenes in the pathophysiology of human neurological disorders may now be characterized utilizing postmortem human brain. (Supported by NIH grants AG03644 and NS20832).

MODULATION OF CALBINDIN-$D_{28k/29K}$-LIKE GENE EXPRESSION BY RETINOIC ACID IN NEURONAL CELLS OVER-EXPRESSING A RETINOIC ACID RECEPTOR.

A. K.Hall, Y-Z. Wang*, R. K. Gill*, and S. Christakos, New Jersey Medical School, Newark, NJ 07103.

It is a well established fact that the calbindin-D_{28k} gene can be influenced by vitamin D in intestine and kidney. However, attempts to modulate this gene within the brain using vitamin D and its metabolites, even at pharmacological doses, have been unsuccessful. Whilst screening for retinoid-sensitive genes in B104 neuroblastoma cells transiently transfected with an expression vector (pSG5RAR) harboring a human retinoic acid receptor (RAR), we found that retinoic acid ($2x10^{-7}$M for 3 days) enhanced the relative abundance of an mRNA which cross-hybridized with human brain calbindin-D_{28k} cDNA. A 5-8 fold enhancement was observed using both slot blot and Northern blot analyses and this enhancement was detectable only in cells over-expressing RAR mRNA. Cross hybridization was observed in non-transfected cells. However, the signal was weak and no change was observed after treatment with retinoic acid. Western blot analyses using an antibody specific for rat calbindin-D_{28k} indicated the stimulated presence of an immunologically similar protein with an apparent molecular weight of 29,000 in retinoic acid-treated, retinoic acid receptor transfected cells. Collectively, these data suggest that the nuclear retinoic acid receptor can target "calbindin-like" genes in cells derived from the neural crest.

600.20

POSSIBLE INVOLVEMENT OF THE ODC/POLYAMINE PATHWAY IN NEURONAL DEGENERATION.

L. Najm, P. Vanderklish, A. Etebari, G. Lynch and M. Baudry, Neuroscience Program, USC, Los Angeles, CA and CNLM, UC Irvine, CA.

The ornithine decarboxylase (ODC) / polyamine pathway has been involved in cell growth and differentiation in many tissues. ODC activity and levels of polyamines are high during the postnatal period and decrease gradually to adult levels during the fourth week after birth. Kainic acid (KA) produces seizure activity in neonate and adult rats. Despite prolonged seizure activity, young rats (< 21 days old), are less susceptible to the histopathological damage due to KA than adults. In adults, KA-induced seizure activity is accompanied by ODC induction, increased levels of putrescine and spectrin breakdown product (bdp) in hippocampus and piriform cortex. Furthermore, putrescine levels are positively correlated with increased bdp levels and pretreatment of the animals with the irreversible ODC inhibitor DFMO reduces both putrescine and bdp levels. During the postnatal period, KA-induced seizure activity did not produce ODC induction and increased spectrin breakdown before PND 21. On the other hand, chronic DFMO treatment between PND 6 and 11 decreased both polyamine and spectrin bdp levels measured at PND 11. These results indicate that polyamines participate in the *in situ* regulation of calpain activity, both in adult and in developing brain. Moreover they indicate that the seizure-induced triggering of the ODC/ polyamine pathway may represent a critical step in the susceptibility to neuronal injury.

600.21

INHIBITION OF TROPHIC FACTOR-MEDIATED CHOLINERGIC DIFFERENTIATION BY CHRONIC PHORBOL ESTER TREATMENTS IN SYMPATHETIC NEURONS.

C.J. Kalberg and J.A. Kessler Depts. of Neurosci. and Neurol., Albert Einstein Coll. of Med., Bronx, NY 10461.

Cholinergic differentiation of cultured rat sympathetic neurons is promoted by several factors including ciliary neurotrophic factor (CNTF), leukemia inhibitory factor (LIF), and a membrane associated factor (MANS). However, their post-receptor signalling mechanisms are unclear. Here, phorbol 12, 13-myristate acetate (TPA) was used to implicate calcium, phospholipid-dependent protein kinase (PKC) in neurotrophic factor action. Short-term TPA treatment (0.5 μM, 15 min) reduced cytosolic PKC levels by 70% with a corresponding 91% increase in membrane enzyme levels. This redistribution of PKC was followed by down-regulation of total cellular enzyme levels in chronic TPA-treated (30 nM, 1-2 wks) cultures to 14% of control levels. CNTF (0.5 ng/ml) and LIF (0.5 ng/ml) both significantly increased choline acetyltransferase (ChAT) activity by 4.5 and 1.7 fold, respectively. Additionally, neurons grown at double cell density exhibited a 1.9 fold increase in ChAT activity. In cultures depleted of PKC activity by chronic TPA treatment, co-treatment with LIF (0.5 ng/ml), CNTF (0.5 ng/ml) or increasing cell density failed to increase ChAT levels. An inactive phorbol, 4α-phorbol, did not affect PKC levels or trophic factor-mediated increases in ChAT activity. Phosphatidylinositol 4, 5 bis-phosphate (PIP_2) hydrolysis and the generation of inositol triphosphate (IP_3) and diacylglycerol (DAG) is thought to be an initial step in PKC activation. However, LIF or CNTF did not stimulate PIP_2 hydrolysis as compared to carbachol which increased PIP_2 hydrolysis by 268%. These results implicate PKC in neurotrophic factor signalling processes and cholinergic development in sympathetic neurons but activation of PKC is likely to involve alternative sources of DAG such as phosphatidylcholine.

600.22

TCP-TREATED HUMAN SPINAL CORD CULTURES: AN IMMUNOCYTOCHEMICAL AND ULTRA-STRUCTURAL STUDY.

M.C.CALVET*,C.LEVALLOIS*,F.SANDILLON*,J.CALVET** and J.M.KAMENKA***. INSERM U336*,EPHE**,CNRS LP8402-INSERM U249***. ENSCM, 8 rue de l'ecole normale, 34053, Montpellier,cedex 2,France.

Experimental evidence supporting for the excitotoxic theory involving the excitatory neurotransmitters came from cell culture models. NMDA antagonists are considered as potential neuroprotective agents in neurodegenerative disorders related to excitatory mechanisms. The results reported here show that TCP (N,1-(2-thienyl) cyclohexyl) piperidine, a non-competitive NMDA antagonist enhances the survival of human fetal spinal cord cells in cultures. The spinal cords from 7-10 week-old human fetuses were cultured as either dissociated cells or organotypic explants. Both sets were treated at 3 weeks with 2-8.10-6M TCP. After 10 weeks, progressive neuronal necrosis was observed in control whereas TCP-treated cultures survived up to 6 months. In all models, neurons were immunoreactive for GABA, CAT and N. S. enolase. However, the TCP-treated neurons showed at the ultrastructural level a marked increase in the length of the processes, in the number and size of growth cones and in the degree of maturation of synapses. To conclude, TCP appears as a promising drug for the protection and long term survival of neurons.

600.23

PRIMATE SCHWANN CELLS EXPRESS MULTIPLE GROWTH FACTORS IN VITRO.

M.F.D. Notter, D.L. Hurley,[1] D.M. Gash, and J.T. Hansen, Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642 and Department of Anatomy,[1] Tulane University Medical Center, New Orleans, LA 70112

Aged primate Schwann cells have been shown by us to respond to specific mitogens in vitro and express appropriate cell markers such as nerve growth factor receptor after two weeks of culture (Soc. Neur. Abst. 16:341, 1990). In this study we have begun to examine the neuronotrophic factor profile of these cells important in neural regeneration.

Adrenal medullary cells from the same aged Rhesus monkeys were cocultured with sciatic nerve explants in the absence or presence of neutralizing levels of antiserum to nerve growth factor (NGF). After immunostaining for tyrosine hydroxylase and scoring for neuritogenesis, chromaffin cells were shown to extend neurites on the surface of Schwann cells and fibroblasts even in the presence of antiserum to NGF. In order to screen for the presence of other factors a radioactive RNA probe to acidic fibroblast growth factor (afgf) cDNA was generated and used for in situ hybridization with explant cultures of monkey peripheral nerve. Moderate levels of mRNA were expressed in monkey as well as rat Schwann cell cultures when compared to negative and positive expressing cell cultures. Furthermore, immunocytochemistry employed for detecting the presence of insulin-like growth factor-I (IGF-I) in primate Schwann cells revealed positive staining of these cells with only background levels detected in contaminating fibroblasts. Therefore, although primate Schwann cells exhibit NGF receptors indicative of NGF activity in these cells, the presence of afgf and IGF-I in Schwann cells may contribute to axonal repair during injury. (Supported by NIH NS25778).

600.24

NORMAL AND SEAD RAT SCHWANN CELLS ARE IMMUNOREACTIVE FOR INSULIN-LIKE GROWTH FACTOR-1 AND NERVE GROWTH FACTOR RECEPTOR.

E.L. Imperato, M.F.D. Notter, and J.T. Hansen. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Neurotrophic factors, nerve growth factor (NGF) and insulin-like growth factor (IGF-1), are important in peripheral nerve regeneration and are expressed in Schwann cells *in vivo*. In the present study, we determined trophic factor expression in two types of rat Schwann cells, SEAD and normal, after culture. SEAD cells represent a rat clonal cell line established by gene transfer of the E1A gene. Therefore, these cells are permanently growth-stimulated. Normal neonatal rat Schwann cells were harvested from sciatic nerve, cultured, and partially purified. Both cell types were cultured for 2-3 weeks in serum-containing medium. IGF-1 (gift from R. Furlanetto) and NGF-receptor (NGF-rec; 192 IgG) immunocytochemistry was done for both groups of Schwann cells; the normal rat Schwann cells were immunoreactive for NGF-rec and IGF-1. Fibroblasts did not exhibit NGF-rec-like immunoreactivity, but a very faint IGF-1-like immunoreactivity was observed. SEAD cells also were immunoreactive for NGF-rec and IGF-1. In control samples, elimination of the primary antibody showed no immunoreactivity in all cases. This is the first example of *in vitro* staining of IGF-1 in both types of Schwann cells. The results of this study suggest that normal and genetically altered Schwann cells may express important trophic factors. (Supported in part by NS25778).

REGULATION OF SUBSTANCE P IN SYMPATHETIC NEURONS BY ENDOGENOUS IL-1β. M. Freidin*, E.Goldensohn, & J.A. Kessler. Dept. Neurosci. & Neurol., AECOM, Bronx, NY 10461.

The peptide neurotransmitter, substance P (SP), is regulated and distributed differently than coexisting transmitters in sympathetic neurons. Denervation of the rat sympathetic superior cervical ganglion (SCG) elevates levels of the peptide within the ganglion, but not in the nerve terminals or in target organs. Further, the cytokine, interleukin-1β (IL-1β) stimulates levels of SP and preprotachykinin mRNA in SCG culture. These observations suggest that SP may help regulate intraganglionic responses to injury, which in turn may be mediated by endogenous cytokines. To test this hypothesis, cultures of the SCG were treated with recombinant IL-1 receptor antagonist (IL1ra) derived from activated human monocytes. IL1ra largely blocked the increase in SP normally seen in explants and dissociated neuronal cultures grown in the presence of ganglion nonneuronal cells. Levels of SP were the same as controls values when excess IL-1β was added to IL1ra treated cultures, indicating both the specificity and lack of toxicity of IL1ra. Further, IL1ra treatment did not inhibit the stimulation of the peptide by another SP-acitivating cytokine, D-factor. In conclusion, these results suggest that endogenous IL-1β plays a role in mediating the regulation of SP expression in the SCG and supports the hypothesis that the peptide is involved in ganglion responses to injury.

600.26

THE EXPRESSION OF PLATELET-DERIVED GROWTH FACTOR (B-CHAIN) IN THE DEVELOPING BRAIN AND TRANSPLANTED OLFACTORY BULB OF THE RAT. [1]J.N. Kott, [3]A. Sasahara*, [3]M. Sasahara*, [3]R. Ross*, and [1,2]L.E. Westrum. Depts. of [1]Neurol. Surg., [2]Biol. Struct., and [3]Pathol., University of Washington, Seattle, WA 98195.

Platelet-derived growth factor (PDGF) was originally recognized as a major mitogen in human platelets. This growth factor exists as hetero- and homodimers of two separate but related chains (PDGFA and PDGFB). PDGF B-chain has been localized to specific neurons and fibers of the monkey CNS (Sasahara et al., Cell, 64, 1991).

We have examined the distribution of PDGF B-chain-like immunoreactivity (PDGFB-I) in the CNS of rats at various embryonic (E) and postnatal (PN) ages. At E 14, PDGFB-I is seen associated with specific developing fiber systems especially the main and accessory olfactory nerves (ON), but not generally with perikarya. Heavily labeled ON fibers persist through all stages examined and into adulthood. This persistent and particularly heavy reactivity may be related to the fact that ON neurons are continuously generated throughout life and suggests that PDGFB may serve in some way to support the regenerating fibers. While many reactive cell bodies are visible in the periventricular proliferative zone at E14, reactive cells identifiable as neurons by their size and position are not apparent until PN 1.5 when lightly reactive pyramidal and Purkinji cells are seen in the developing hippocampus and cerebellum. The intensity of staining of these neurons as well as that in certain other nuclei gradually increases with age.

As the above findings suggest that PDGFB may have roles in both the development and maintenance of the CNS, we are undertaking studies of the expression of PDGFB-I in donor olfactory bulbs which have been transplanted to the site vacated by removal of a host OB. These data along with general anatomical localization will be presented. (Supported by NIH Grant NS 09678, NS07144 and HL18645. L.E.W. is an affiliate of the CDMRC).

NUTRITIONAL AND PRENATAL FACTORS

601.1

IDENTIFICATION OF NUCLEAR RETINOIC ACID BINDING ACTIVITY AND RETINOIC ACID RECEPTOR TRANSCRIPTS IN A HUMAN NEUROBLASTOMA CELL LINE (LA1-15n). M. Clagett-Dame[1], J.L. Biedler[2*] and T.J. Verhalen[1*]. School of Pharmacy, Univ. of Wisconsin-Madison, WI[1] and Cellular and Biochemical Genetics, Memorial Sloan-Kettering Cancer Ctr., NY.[2]

Retinoic acid (RA) can influence nervous system development and may do so by binding to one or more nuclear receptor proteins. We have identified nuclear RA receptors (RAR's) in a clonal line of human neuroblastoma (NB) cells that differentiate in response to RA. Specific [3H]-RA binding sites were detected in both nuclear and cytosolic fractions with the cytosolic RA binding protein sedimenting at ~2S on sucrose density gradients. In contrast, the nuclear protein sedimented at ~4S on gradients which is consistent with the Mr of ~50,000 deduced from RAR cDNA's. The specific [3H]-RA binding activity in the nuclear fraction was saturable and of high affinity (Kd~0.2 nM). The nuclear [3H]-RA binding protein bound to DNA-cellulose, an activity characteristic of other members of the steroid hormone receptor superfamily. Northern blotting experiments suggest the nuclear protein represents a RAR of the α subtype. The expression of RARα mRNA was unaffected by treatment of cells with RA (100 nM). In contrast, mRNA for RARβ was initially absent but was induced within four hours after treatment of cells with RA. These results support the hypothesis that RAR's are involved in human NB cell differentiation.

601.2

INCREASED REPEATED ERRORS IN RHESUS MONKEYS WITH OMEGA-3 FATTY ACID DEFICIENCY (FAD). S. Reisbick, M. Neuringer and W.E. Connor. Or. Health Sci. Univ., Portland, OR 97201 & Or. Reg. Primate Res. Center, Beaverton OR 97006

Omega-3 fatty acids are major structural components of neural and retinal membranes. In primates, perinatal omega-3 FAD has been associated with lowered levels of omega-3 fatty acids in cerebral cortex and retina, abnormal electroretinograms and delayed development of visual acuity. Altered performance (higher response rates to both S+ and S-) of operant learning tasks has been reported in rats with long-term omega-3 FAD.

In the current study, monkeys with combined pre- and postnatal omega-3 FAD and their controls learned a series of operant visual discriminations using a correction procedure. Monkeys discriminated pairs of visual stimuli including horizontal and vertical stripes in a series of pairs of decreasing size. There were no group differences in speed of learning the pairs (trials to criterion) or in % repeated errors (repeated errors/ total errors x 100) while learning new pairs (first 5 days with a new pair). However, when tasks were well-known (last 5 days to criterion), deficient monkeys made a higher % repeated errors (24.1 $\pm$ 3.3 vs 6.4 $\pm$ 0.7 for the controls: Mean $\pm$ SEM, $p<.01$). Such perseverative errors may reflect deficits in attention or memory, or difficulty in inhibiting a previous response.

THE EFFECTS OF DIETARY N-3/N-6 RATION ON BRAIN DEVELOPMENT IN THE MOUSE: A DOSE RESPONSE STUDY WITH LONG-CHAIN N-3 FATTY ACIDS. P.E.Wainwright, Y.S.Huang*[1], B.Bulman-Fleming, D.Dalby*, D.E.Mills*, P.Redden*[1] and D.McCucheon*. Department of Health Studies, University of Waterloo, Waterloo, Ontario N2L 3G1. [1]Efamol Res.Ins., Kentville, NS B4N 4H8.

A dose-response study was conducted to examine the effects on brain development in mice of maternal dietary ratios of n-3/n-6 fatty acids (FA), where the n-3 FA were supplied as the preformed long-chain compounds. From conception until 12 days after birth, B6D2F$_1$ mice were fed dietary n-3/n-6 ratios of 0, 0.25, 0.5, 1.0, 2.0 and 4.0, with an n-6 content of greater than 1.5% of energy in all diets, and similar levels of total polyunsaturated FA. Biochemical analyses were conducted on pup brains, as well as on samples of maternal milk. There were no obvious effects on overall pup growth and development, apart from a smaller litter size in ratio 1. Covariance analysis indicated that increasing the n-3/n-6 ratio was associated with slightly smaller brains, relative to body weight. Increasing dietary n-3/n-6 ratios generally resulted in an increase in n-3 FA, with a corresponding decrease in n-6 FA. In the milk 18:2n-6 was the predominant n-6 FA, and 20:5n-3 the predominant n-3 FA; in the brain these were 20:4n-6 and 22:6n-3 respectively. The n-3/n-6 ratio of the milk lipids showed a strong linear relationship with the diet, but in the brain the rate of increase tended to decrease beyond 0.5 (phosphatidylcholine, PC) and 0.25 (phosphatidylethanolamine, PE), such that there was a significant quadratic contribution to the relationship. These results indicate that the n-3/n-6 ratio of the phospholipids in the developing mouse brain respond maximally to maternal dietary long-chain n-3/n-6 ratios of between 0.25 and 0.5, which are equivalent to a n-3/n-6 ratio of approximately 0.25 in maternal milk.

COMBINED Mg^{2+} AND Ca^{2+} DEFICIENCY DURING FETAL AND POSTNATAL LIFE INCREASES LEVELS OF THE 28 kDa CALCIUM-BINDING PROTEIN (CALBINDIN) IN BRAIN. S. Bose, B. Cheng, B. Rychlik and M. P. Mattson, Center on Aging and Dept. of Anat. & Neurobiol., Univ. of Kentucky, Lexington, KY.

Rats were maintained on a diet deficient in Mg^{2+} (<0.003%) and Ca^{2+} (< 0.02%), or a control diet (0.065% Mg^{2+} and 0.75% Ca^{2+}), beginning on day 4 of pregnancy and through 3 weeks postpartum. Overall growth of pups from mothers on the Mg^{2+}/Ca^{2+} deficient diet was significantly retarded; in 2 week-old pups body and brain weights were reduced 40-60% and 20%, respectively. The pups of mothers on the Mg^{2+}/Ca^{2+} deficient diet developed seizures and often died within 3-5 weeks of birth. Cell counts in hippocampi revealed a >40% reduction in neuronal density in regions CA1 and CA3, and a 20% reduction in neurons in the dentate gyrus in 2-3 week-old pups of mothers on the Mg^{2+}/Ca^{2+} deficient diet. Immunocytochemical localization of calbindin in brain revealed an increase in both the number of calbindin immunoreactive neurons, and in their relative staining intensities in both hippocampus and cerebral cortex. Western blots of whole brain demonstrated a large increase in calbindin levels in pups from mothers maintained on the Mg^{2+}/Ca^{2+} deficient diet. Since calbindin may play a role in protecting neurons against excitotoxicity (*Neuron*, 6:41), the increased levels of calbindin in Mg^{2+}/Ca^{2+} deficient pups may represent an attempt to compensate for the increased vulnerability to seizures resulting from the Mg^{2+} deficiency. (we thank S. Christakos for anti-calbindin; supported by the International Life Sciences Institute and NS29001).

QUANTITATIVE STUDY OF CELL DENSITY IN NEONATAL RAT BRAINS. S. Zamenhof. Dept. of Microbiology and Immunology, and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024

This work is a continuation of studies of brain parameters quantitatively correlated with behavioral performance. In previous work we have studied one such parameter, brain cell number or brain DNA (Life Sci 18:1391, 1976; Nutr. Res., in press). In the present work we have studied another parameter: brain cell density (D). The rationale is that lower D allows for more voluminous future development of dendritic tree, hence possible superior behavioral performance (Physiol. Behav. 23: 945, 1979). However, lower D could be also caused by lower brain cell number (undesirable), and it is not known which of the two parameters is more important for behavioral performance. We limited our search to those brains which have cell number (DNA) not lower than the mean for the group. Because of the inhomogeneity associated with different cell types, and quantitatively difficult brain geometry, we studied instead the ratio of brain cell number to brain volume (DNA/brain weight, as index of D). We found that among the total of 1948 neonatal rats there were 22 (1.1%) outstanding individuals (0) that had D more than 2 std. deviations (significant) below the mean, while also having DNA not below its mean. Of these 0 individuals, 71% came from the litters that had at least one more such 0 individual (suggesting common factors, such as prenatal nutrition). The mean number of fetuses per litter was n=9.4± 2.5 for the entire group, and 6.3 ± 3.2 for litters with at least one 0 individual (difference significant at $P<0.01$), which suggests that low n is one of the factors contributing to the favorable low brain cell density.

EARLY DEFICITS IN BRAIN WATER RESULT IN REDUCED BRAIN GROWTH. E J Moore* and J Diaz. Dept of Psychology University of Washington, Seattle, WA 98195.

The procedure of artificially rearing rat pups results in brain weight deficits as large as 7-10% compared to mother reared siblings Despite these differences, brain water content is comparable on day 18 and as early as day 10 even with extreme undernutrition, indicating that brain water content is well defended. Given the osmotic density of the formula, the possibility of an acute hyperosmotic insult must be considered, especially since brain weight deficits have been reported after only 24 hours of artificial rearing (Br. Res. Bull., 11, 1983). The purpose of this experiment to test the hypothesis that brain water content cannot be altered acutely

Four day old rat pups were randomly assigned to one of five groups 1) mother reared (MR); 2) gastrostomized, given formula (AR-F); 3) gastrostomized, given only water (AR-W); 4) gastrostomized, given hypertonic saline (AR-S); and 5) removed from mother (ISO). After 24 hours, all animals were sacrificed and wet whole brain weights were recorded. Subsequent dry brain weights were collected.

Brain water content can be altered acutely. Compared to the MR group, brain water content was significantly lower in the AR-F and ISO groups; higher in the AR-W group; and lowest in the AR-S group

Brain water content is well defended over the long term, but even this fundamental rate-limiting factor of brain growth is susceptible to acute early challenges. Accelerated brain growth cannot be maintained without sufficient water. Relative dehydration may thus lead to a deceleration in the long term trajectory of brain growth.

SENSITIVITY TO COCAINE IN RAT PUPS GIVEN PRENATAL COCAINE EXPOSURE. J.S. Meyer, J.D. Sherlock*, and N. MacDonald*. Dept. of Psychology, Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

This study determined whether prenatal exposure to cocaine alters behavioral sensitivity to postnatal cocaine administration. Pregnant Sprague-Dawley rats were divided into 3 groups: Cocaine-treated, Saline-treated, and Untreated. The cocaine group was injected s.c. 2X/day with 20 mg/kg cocaine HCl from gestational day 11 to day 20. Saline controls were pair-fed to the cocaine females, whereas untreated controls were undisturbed. Litters were culled to 8 pups (normally sex-balanced) and were fostered to normal lactating dams on postnatal day (PD) 1. On PD11, subjects were given either saline or cocaine (1.25, 2.5, or 5.0 mg/kg), returned to the nest for 15 min, and then removed for testing. Distress vocalizations and other behaviors were recorded during a 5-min test session. The results indicated that while acute cocaine treatment markedly suppressed distress vocalizations, there was no shift in the dose-response curve as a function of prenatal condition. In contrast, cocaine-induced activation of wall-climbing was influenced by prior cocaine exposure. Both control groups displayed a near-maximal increase in wall-climbing to the lowest cocaine dose, whereas the cocaine-pretreated pups showed little response except for the high (5.0 mg/kg) dose. Thus, prenatal cocaine treatment alters the sensitivity of some but not other behaviors to subsequent cocaine exposure. Supported by NIDA Grant DA-06495.

EFFECTS OF MATERNAL ALCOHOL EXPOSURE ON PERINATAL ORNITHINE DECARBOXYLASE LEVELS. A. CHICZ-DEMET, B.D. NGUYEN*, B.S. STOVEKEN*, S. TEWARI*, E.M. DEMET. Dept. Psychiatry, Univ. California, Irvine, CA 92717 and State Developmental Research Institutes, Costa Mesa, CA 92626

The effects of maternal alcohol ingestion on ornithine decarboxylase (ODC) and organ weights were examined in 8 day old rat pups. Control dams were fed a similar isocaloric diet without alcohol. Elevated ODC levels may reflect stress induced growth processes responsible for a disordering of normal developmental events. Treated animals had elevated ODC levels in 8 brain regions, heart and liver. Decreases were found in whole body, brain, liver, and heart weights although the latter was not significant. Alcohol treated female pups had larger ODC increases in all tissues than their male counterparts, and had greater decreases in whole body, and brain weights. In contrast, no gender differences in body or organ weights were evident in controls. The results suggest a relationship between ODC increases and organ weight decreases and imply a greater susceptibility to prenatal alcohol in female rats.

EFFECT OF PRENATAL ETHANOL EXPOSURE ON ETHANOL TOLERANCE IN ADULT OFFSPRING IS DEPENDENT ON BLOOD LEVEL AFTER CHRONIC ETHANOL EXPOSURE. H.C. Becker and R.L. Hale. VA Medical Center and Medical University of South Carolina, Charleston, SC 29403

We previously found that prenatal ethanol (EtOH) exposure renders adult offspring less tolerant to the motor incoordinating effects of EtOH following chronic exposure to the drug. The purpose of this study was to examine whether this effect is influenced by the degree of chronic EtOH intoxication prior to tolerance testing. Female C3H mice derived from dams maintained on isocaloric liquid diets containing 25% or 0% EtOH-derived calories, or standard lab chow were used as subjects. Offspring were placed in inhalation chambers and exposed to either EtOH vapor or air for 48 hrs. Six hours following withdrawal, all mice were injected ip. with 3 g/kg EtOH and tested for motor coordination on a horizontal dowel. Immediately after fall, a sample of cortex was collected. Results indicated that EtOH-exposed offspring fell off the dowel at significantly lower brain EtOH levels than control offspring following chronic exposure that yielded blood EtOH levels of 185.0 ± 4.7 mg% (i.e., prenatal EtOH offspring exhibited less tolerance). This prenatal treatment difference was not observed with chronic exposure that resulted in blood EtOH levels of 93.1 ± 3.0 and 149.3 ± 1.7 mg%. Blood EtOH levels did not differ among prenatal treatment groups in any of teh exposure conditions. Results from studies varying the duration of chronic EtOH exposure will be presented as well.

A STEREOLOGICAL STUDY OF THE EFFECT OF EARLY POSTNATAL ALCOHOL EXPOSURE ON THE NUMBER OF GRANULE CELLS AND MITRAL CELLS IN THE RAT OLFACTORY BULB. N.E. Bonthius, D.J. Bonthius, R.M.A. Napper and J.R. West. Department of Anatomy, University of Otago, Dunedin, New Zealand.

This study examined the effect of early postnatal alcohol exposure on the total number of olfactory bulb mitral cells and granule cells. Sprague-Dawley rat pups were reared artificially over postnatal days (PD) 4 through 9, a period of rapid brain growth comparable to the human third trimester. Alcohol-exposed pups received a daily alcohol dose of 4.5 g/kg, administered as a 10.2% solution in 2 of the 12 daily feedings. Gastrostomy and suckle control pups were also reared. Pups were sacrificed either on PD 10 (to determine the acute effects) or on PD 105 (to determine the long-term effects). The total number of granule cells and mitral cells from one bulb in each subject were determined using unbiased stereological methods and systematic sampling. Control rats had an average of 2,200,000 granule cells and 53,000 mitral cells on PD10. By PD 105, granule cell number had increased to 5,060,000, while mitral cell number had decreased to 43,000. On PD 10, immediately following the alcohol exposure, the alcohol-exposed subjects had a 33.1% deficit in granule cells and a 36.7% deficit in mitral cells, relative to gastrostomy controls. On PD 105, both the granule cells and mitral cells were still significantly reduced in number, by 19.3% and 26.6%, respectively. These results demonstrate that, while there may be some rebound in neuronal number following alcohol exposure, the deficits induced in some neuronal complements are permanent.

601.11

THE EFFECT OF CHRONIC IN UTERO ALCOHOL EXPOSURE ON DEVELOPING NEURONS IN CULTURE. M. L. Weaver*, C. S. Cretan*, D. A. Ciraulo* and S. Jacobson. Depts. of Clinical Pharmacology and Anatomy and Cell Biology, Tufts Univ., and Dept. of Veterans Affairs Outpatient Clinic, Boston, MA.

The effects of in utero ethanol exposure on the growth of neurons in culture were examined. CD-1 female mice consumed liquid diet containing 3.2 % or 20 % ethanol derived calories (EDC) or a control diet. The mice were maintained on the diet until fetal day 17 when they were sacrificed. The pups were removed, the cerebellum and cerebrum where mechanically separated in incomplete F12 media, and the neuroblasts plated on thermanox coverglasses. Cells were grown for 6-29 days in culture. Cells from animals given control diet developed into mature appearing neurons with a well differentiated dendritic tree. Neurons from animals exposed to the 20% EDC diet had a grossly simplified and abnormal dendritic tree. Neurons from the 3.2% EDC group exhibited stunted growth as demonstrated after the images were digitized and evaluated.

EFFECT OF PRENATAL EXPOSURE TO ETHANOL ON GLUCOSE UTILIZATION IN PRIMARY SOMATOSENSORY CORTEX OF RATS: RESPONSE TO STIMULATING A ROW OF VIBRISSAE. M.W. Miller and D.L. Dow-Edwards. Dept. of Cell Biology, Univ. of Med. and Dent. of N.J.- Sch. of Osteopathic Med., Piscataway NJ 08854, and Dept. of Neuroscience and Cell Biology, Univ. of Med. and Dent. of N.J.- R.W. Johnson Med. Sch., Piscataway NJ 08854.

Prenatal exposure to ethanol produces permanent morphological and physiological changes in the neocortex of adult rats. For example, glucose utilization in all of the cortical laminae of primary motor and somatosensory cortices is depressed 20-30% following prenatal exposure to ethanol. We used [^{14}C]2-deoxyglucose autoradiography to determine whether the ethanol-induced metabolic depression disappeared when cortex was stimulated by sensory activity. The mature offspring of 2 groups of rats were examined: the pups of mothers that were fed a liquid diet containing 6.7% ethanol during the second half of gestation and the offspring of mothers which were pair-fed a nutritionally-matched liquid diet. The mystacial vibrissae of all rats, except for the C row on the right side, were shaved. As in previous studies, glucose utilization in non-stimulated regions of cortex (e.g., right non-barrel somatosensory cortex) was significantly depressed in ethanol-treated rats. Stimulation of the vibrissae produced a significant increase in glucose utilization in the C row barrels in ethanol-treated and control rats. Nevertheless, the substantial ethanol-induced difference in glucose utilization remained. Thus, prenatal exposure to ethanol depresses cortical metabolic activity regardless of the physiological state. Funded by DE 07734 and AA 06916.

EFFECTS OF EXPOSURE TO ETHANOL DURING DEVELOPMENT ON PLAY BEHAVIOR. Janie H. Wilson and Sandra J. Kelly. Department of Psychology, University of South Carolina, Columbia, SC, 29208.

This experiment examined the influence of early postnatal ethanol exposure on play behavior as measured by the number of pins and the involvement of opioid activity in this behavior. Rats were artificially reared and exposed to either 5 or 3 g/kg/day of ethanol from postnatal days 4 through 10. Control groups consisted of rats artificially reared but not exposed to alcohol and rats reared normally by dams. All rats were reared by dams from postnatal day 12 to 21 and tested between 32 and 40 days of age. The rats were habituated alone in the testing chamber for 5 min on two consecutive days and tested on the following 4 days. All subjects were housed in isolation 24 hours before the first test session and remained isolated throughout the testing period. Rats were tested with a nonexperimental same-sex rat of approximately the same weight for 10 min on 4 consecutive days. The experimental rats received subcutaneous injections of either saline, saline followed by naloxone (1 mg/kg), morphine (1 mg/kg) followed by saline, or morphine followed by naloxone before testing. The order of drug treatments was balanced across sex-by-group blocks. All sessions were taped, and the number of pins was recorded.

There was a trend for ethanol exposure to increase pinning. When the results were divided by gender, females pinned more when exposed to 5 g/kg/day dose of ethanol; however, males pinned more when exposed to 3 g/kg/day of ethanol. The effect of drug injections on pinning varied with gender but not with ethanol treatment. It was found that males pinned more than females overall, and all animals increased their pinning behavior over days. In conclusion, exposure to ethanol during the early postnatal period alters the amount of pinning behavior in rats, but this alteration in behavior does not appear to be mediated by the opioid systems. (Supported by NIAAA Grant AA08080)

ABERRANT MITOTIC ACTIVITY IN THE DEVELOPING TADPOLE CEREBELLUM FOLLOWING ACUTE ETHANOL EXPOSURE. N.J. Uray and P.S. Sexton*. Dept. of Anatomy, Kirksville College of Osteopathic Medicine, Kirksville, MO 63501

To explore the mechanisms underlying alterations in cerebellar development that were seen following chronic alcohol administration, we examined the cerebella of tadpoles, after acute exposure to ethanol.

At the ages of 6, 14 and 24 w(weeks) tadpoles of the frog Rana catesbeiana were placed in 1% ethanol and were killed 1,4,8,16,24,48,72, and 168 h (hours) later. Slides of cerebella were examined for mitotic activity. Numerous mitotic figures were present in the ventricular and subventricular zones of both control and ethanol exposed tadpoles at 6 and 14 w, but few were noted in 24 w old animals. In all age groups, ethanol treated tadpoles also contained mitotic figures in the pml (primitive molecular layer) and the subpial zone. Normal tadpole cerebella do not contain dividing cells in the pml or in the subpial position, thus, it is likely that such mitotic activity is a consequence of ethanol exposure. This may represent an aberrant secondary proliferative activity or alternately, ethanol may act as a trigger to synchronize mitotic activity that in normal animals may take days. The latter possibility would imply that external granular layer cells in tadpoles also undergo a secondary proliferation, as in other species. Supported by NIAAA Grant R01 AA97537.

EFFECTS OF TREATMENT OF PREGNANT ALCOHOLIC RATS WITH SEROTONIN$_{1A}$ AGONISTS ON OFFSPRING. M.J. Druse and N.F. Tajuddin. Molecular & Cellular Biochemistry, Loyola U. Chicago, Stritch Sch. Med., Maywood, IL 60153.

Previous studies in this laboratory demonstrated that in utero ethanol exposure results in a serotonin (5-HT) deficiency, which is detected as early as gestational (G) day 15. Because fetal 5-HT is important for normal CNS development, a 5-HT deficiency could contribute to the CNS abnormalities found in ethanol-exposed offspring. In order to test this hypothesis we treated pregnant Sprague-Dawley rats with two 5-HT$_{1A}$ agonists -- 8-OH-DPAT (3.5-4mg/kg/day) and buspirone (4.5 mg/kg/day) during the last trimester of pregnancy. 5-HT and 5-hydroxyindole-acetic acid (5-HIAA) were assessed on postnatal day 5.

These experiments demonstrated that the offspring of ethanol-fed rats had ~40% less 5-HT in the brain stem and cortex and ~30% less 5-HIAA in these regions. Treatment of pregnant alcoholic rats with 8-OH-DPAT had no significant effect on 5-HT or 5-HIAA levels in these regions, although the size of the brain stem 5-HT deficiency was reduced. In contrast, buspirone treatment resulted in brain stem 5-HT levels in ethanol-treated rats that were not significantly different from those of control rats ($p>0.05$). Additional studies will determine whether buspirone treatment of ethanol-fed dams ameliorates other 5-HT abnormalities in offspring.

This research was supported by USPHS-AA03490.

NEUROTRANSMITTER LEVELS IN LIMBIC REGIONS IN STRESSED AND NONSTRESSED RATS EXPOSED TO ALCOHOL DURING DEVELOPMENT. Sandra J. Kelly and Regina R. Dillingham*. Department of Psychology, University of South Carolina, Columbia, SC, U.S.A. 29208.

The effect of alcohol exposure during the early postnatal period on neurotransmitters and their metabolites was examined in stressed and nonstressed rats. Rats were artificially reared and exposed to either 5 or 3 g/kg/day of ethanol from postnatal day 4 through 10. Control groups consisted of rats artificially reared but not exposed to alcohol and rats reared normally by dams. When the rats were between 90 and 95 days of age, half the rats were put into wire mesh close-fitting restrainers for 30 min and then decapitated. The other half of the rats were decapitated within two min of being removed from the animal quarters. The head was immediately dropped into liquid nitrogen and then the brain was removed. The hypothalamus, hippocampal region, septal region and amgdala region were dissected free. The tissue was sonicated in 0.2M perchloric acid and frozen until the time of assay. At that time, the sonicated tissue was thawed and centrifuged for 15 min. Twenty microliters of the supernatant was injected onto a C18 reverse phase column for HPLC with electrochemical detection. The mobile phase was 700 parts 100 mM sodium monophosphate and 300 parts methanol with 0.97 mM octyl sodium sulfate, 1 mM disodium EDTA and 0.26 mM triethylamine (pH 3.2). The supernatant was analyzed for noradrenaline, dopamine, DOPAC, HVA, 5-HT, and 5-HIAA content.

Noradrenaline levels in the hypothalamus in both stressed and nonstressed conditions were increased by exposure to alcohol during the early postnatal period. In the amygdala, the stress-induced change in 5-HIAA was increased and the stress-induced change in HVA was decreased in alcohol-exposed rats. (Supported by NIAAA Grant AA08080 to S.J.K.)

CORTICAL ASTROGLIOSIS INDUCED BY EARLY POSTNATAL ALCOHOL EXPOSURE IN RATS DEMONSTRATED BY CONFOCAL MICROSCOPY OF GFAP IMMUNOFLUORESCENCE. J.T. Leo.* C.R. Goodlett, J.C. Mahoney,* and J.R. West. Dept. of Anatomy, University of Iowa, Iowa City, IA 52242.

Alcohol exposure during the early postnatal brain growth spurt in rats, in a pattern which produces cyclic blood alcohol concentrations with high peaks and low troughs each day, results in an acute reactive astrogliosis in the cerebral cortex. Glial fibrillary acidic protein [GFAP] is increased over 300% in the cortex relative to controls on postnatal day [PD] 10, and numerous, hypertrophied astrocytes are revealed by GFAP immunocytochemistry in cortical layer V. The goal of this study was to determine whether cortical astrogliosis included an increase in glial density in addition to hypertrophy of astroglia. The density (per unit volume) of astrocytes labeled by GFAP immunofluorescence was quantified in layer V of the cortex in alcohol-exposed and control pups on PD 10, via the high resolution in 3 dimensions provided by confocal microscopy. Pups from 5 litters were gastrostomized on PD 4. On PD 4-9, they were given either 4.5 g/kg of alcohol per day (delivered in 2 of 12 daily feedings as a 10.2% v/v solution in milk formula; mean peak BAC=294 mg/dl), or were given a calorically-matched diet free of alcohol. Pups were perfused on postnatal day 10, and 50-µm frozen sections were processed for GFAP immunoreactivity using a biotinylated secondary antibody and FITC-conjugated avidin. Matched sections from control and alcohol-treated pups were evaluated with a Bio-Rad MRC 600 confocal microscope [60x objective, N.A. 1.4], sampling from at least 6 locations in layer V of parietal cortex in each section. Unbiased estimates of glial densities were obtained using a 95 µm-square counting frame through a z-axis depth of 10 µm (taken in 1 µm steps). The mean density of labeled astrocytes was significantly higher in alcohol-exposed pups than controls (mean±sem of 5.9±0.7 and 2.8 ±0.6 cells per 10^5 μm^3, respectively). The mean area of GFAP immunoreactivity in the optical sections was also greater in the alcohol-exposed group. Thus, the astrogliosis induced by alcohol in cortical layer V involved an increased density of astroglia as well as hypertrophy of their somas and processes. DISTRIBUTION OF TAURINE, GABA AND GLUTAMATE IN DEVELOPING CAT CEREBELLUM. P. Lu and J.A. Sturman. Inst. for Basic Research, Staten Island, NY 10314.

Taurine has been shown to be involved in feline cerebellum development by *in vivo* and *in vitro* studies. In order to further understand its role we have examined its distribution in newborn, 8-week-old and adult cat cerebellum, along with that of GABA and glutamate. Antisera to taurine, GABA and glutamate were prepared by immunizing rabbits with the amino acids conjugated to bovine serum albumin with glutaraldehyde, and purified to high specificity as determined by ELISA. Clear developmental differences in the distribution of these amino acids were seen. In newborn cerebellum taurine was present in granule cells and in a band in the inner molecular layer adjacent to the Purkinje cell layer, but was not present in Purkinje cells at their dendrites, which did contain glutamate. GABA was present only in Golgi II cells in the granule cell layer. At 8 weeks after birth, taurine is present in most cerebellar cells, especially Purkinje cells and their dendrites and granule cells, which both contained glutamate as well. Stellate and basket cells contained taurine and GABA, which again was also present in Golgi II cells. In adult cerebellum taurine was located in granule and basket cells and was now virtually absent from Purkinje cells and their dendrites, which contained GABA and glutamate. GABA was also present in Golgi II, stellate and some basket cells. Glutamate was also present in granule and a few Golgi II cells. Thus at birth, Purkinje cells appear to contain only the excitatory amino acid glutamate, which is joined by taurine sometime early in development, which, in turn, is replaced by GABA during maturation.

FELINE MATERNAL TAURINE DEFICIENCY: EFFECT ON NEWBORN VISUAL CORTEX. J.A. Sturman, Y. Xu*, H. Imaki and P. Lu. Inst. for Basic Res., Staten Island, NY 10314.

Cats are dependent on an adequate dietary source of taurine to maintain their body pools and without which they become taurine-depleted. Taurine deficiency has an adverse effect on feline reproduction resulting in excessive fetal wastage and low-birth-weight live kittens. We have previously reported abnormal ontogeny of cerebellum and visual cortex, and now report quantitative morphometric and immunohistochemical evidence of abnormalities in newborn visual cortex. Kittens born alive to taurine-deficient mothers have body and brain weights approximately 70% of similar control kittens (from mothers fed the same diet supplemented with 0.05% taurine) but brain taurine concentrations less than 50% of controls. The thickness of all discernible laminae, except layer I, and total thickness are significantly smaller than control kittens. There was no significant difference in the number of cells (neurons plus glia) under 1 mm^2 of surface, either total or in individual layers, except layer V, which had fewer. Numerical density of cells was greater in layers II-III and IV. Using antibodies raised to amino acids linked to BSA with glutaraldehyde, no cells in visual cortex from taurine-deficient or control showed taurine-like immunoreactivity, although there was extracellular reactivity throughout the region. This was greater in control than in taurine-deficient kittens, and was not present when the antiserum was preabsorbed with antigen. This is not an artefact of the perfusion fixation since neurons in other regions such as frontal cortex, hippocampus and cerebellum showed clear reactivity. Visual cortex neurons did show GABA-like immunoreactivity.

CEREBELLAR CORTEX ALTERATIONS IN TAURINE DEFICIENT MICE. M.C. Márquez-Orozco, A. Márquez-Orozco, V. Gazca-Ramírez* and H. Pasantes-Morales*. Sch. of Med., Inst. Cell Physiol. Natl. UNAM. P.O.B. 70-553. México 04510 D.F. MEXICO.

Adverse effects of taurine deficiency on differentiation and maturation of cat cerebellum are well documented (Sturman et al., J. Neurosci. Res., 13, 405, 1985) but the consequences of taurine deficiency in nervous tissue in other species have not been explored. In rodents, tissue taurine depletion is obtained by treatment with guanidino ethane-sulfonate (GES), a potent blocker of taurine transport. In the present study we describe the effect of GES treatment (1% in drinking water, 4-12 weeks) on the structure of cerebellar cortex of adult mice. Brains were excised and fixed in 10% formaline pH 7.3, 7 µm-sections were stained with hematoxylin-eosin and observed in a photonic microscope. Alterations in Purkinje cells consisting in marked swelling of the soma and the molecular layer were consistently observed since the 4th week of treatment. Subsequently, picnotic and degenerated Purkinje cells appear. Empty spaces corresponding to degenerated glial cells and neuron synaptic terminals also characterize the alteration caused by GES. The observed changes my be the consequence of cell swelling occurring as result of a decrease of intracellular taurine as a large number of recent reports substantiate the involvement of taurine in osmoregulation in brain.

MINIMAL REQUIREMENTS FOR LONG-TERM SERUM-FREE CULTURING OF ELECTRICALLY ACTIVE RAT CEREBRAL CORTEX NEURONS IN A MONOLAYER G.J.A. Ramakers, Netherlands Institute for Brain Research, Royal Dutch Academy of Sciences, Meibergdreef 33, 1105 AZ Amsterdam, The Netherlands.

A method is presented and evaluated for culturing dissociated fetal rat cerebral cortex. These cultures meet the following requirements: they are maintained in a serum-free medium; (2) the cultured cells form a near monolayer allowing optimal access and visibility; and (3) neurons survive up to at least six weeks, while (4) showing a high incidence of spontaneous bioelectric activity. Series of 300 to 400 nearly identical cultures can be routinely produced from two litters of rats, and are amenable to the application of a variety of morphological, biochemical and electrophysiological techniques. The dissociated cells are grown in a central spot on poly-lysine coated round coverslips in the presence of an astroglial coculture. The medium consists of 62.5% DMEM and 22.5% Ham's F12 medium, from which glutamate and aspartate have been deleted, and is supplemented with BSA, insulin, transferrin, lipoic acid, and vitamins A and E. These factors and conditioning of this medium by (astro)glial cells are demonstrated to be essential to meet the above requirements. The medium furthermore contains for the first time ionic conditions similar to those in the brain extracellular space. These cultures appear to be especially useful for studying axonal outgrowth, neuron-glia and neuron-target interactions, myelination, transmitter release and various activity-mediated phenomena. In addition, they provide efficient models to study a wide variety of teratological and toxicological effects of chemical agents on brain development.

LHRH GENE EXPRESSION IN C57BL/6J MICE EXPOSED TO ETHANOL IN UTERO H.C. Scott, R.T. Zoeller, P.K. Rudeen, Department Of Anatomy And Neurobiology, University Of Missouri School Of Medicine, Columbia, MO 65212. The expression of LHRH mRNA was analyzed in fetal C57BL/6J mice exposed to ethanol (ETOH) on gestational day 7 (G7) or on G11. G11 corresponds to the day that LHRH neurons are first detected at the medial olfactory placode. Ethanol exposure on G7 has been shown to cause deformities in the regions where LHRH neurons originate and migrate. Our lab has previously reported that pups exposed to ethanol on G7 had a decrease in the number of LHRH neurons detected by immunohistochemistry on G18 as compared to control pups. Pregnant dams were intubated with a 25% ETOH solution (2.9 g/kg body wt.) or vehicle at 10 a.m. and at 2 p.m. on G7 or G11. Animals were sacrificed on G18 and frozen parasagittal tissue sections cut at 12 µm. In situ hybridization histochemistry localized individual neurons containing LHRH mRNA. The number of neurons expressing LHRH mRNA were counted in six neuroanatomical regions and image analysis was used to quantify the level of LHRH mRNA in neurons in those regions. Data were compared between control pups and pups exposed to ethanol on G7 or on G11. Results show no significant differences in the number of neurons expressing LHRH mRNA on G18 when given ETOH on G7 as compared to control animals. Ethanol exposure does not seem to interfere with LHRH gene expression during development. (Supported by NIAAA grants AA07458, AA05893, and AA00107).

MAMMALIAN GROWTH ENHANCED BY SUPPLEMENTAL LIGHT: FEED EFFICIENCY IS INCREASED. Patricia D. Wade+# & Ira Baum*+. +Rockefeller Univ., 1230 York Ave., N.Y., NY 10021 & #N.Y. Coll. of Pod. Med., 53 E. 124th, N.Y., NY 10035.

We are studying direct (extraocular) effects of light in the visible range on mammalian tissues. At intensities capable of penetrating the head, we have found that such light influences release of a transmitter from mammalian brain tissue in vitro (Wade et al., PNAS 1988, 85:9322). At a certain intensity it also enhances ^{14}C-2-deoxyglucose uptake into the tissue suggesting a possible effect on cell metabolism. Therefore, as a first step toward understanding what role light may have in cell metabolism, we used body growth as a monitor of metabolism and examined the extent of growth in several lighting conditions. This is based on studies in which supplemental environmental light increased body growth and/or body products (e.g., Am. J. Physiol. 1971, 220:233, J. Endocrinol. 1975, 64:549, Science 1978, 199:911).

In the present study mice pups [strain Crl:CD-1(ICR)BR)] were reared with foster mothers from postnatal day 4 to 28 in either: dark, 12h light/12h dark (standard), or 16h light/8h dark (supplemental). Details of the variation in intensity, duration and spectrum will be presented. Growth as measured by body weight (mean pup weight in grams ± S.E.) was slow in the dark (e.g., at day 28, 11.37±1.16, n=15), greater in the standard condition (13.85±0.35, n=20), and greatest in the supplemental condition (15.06±0.45, n=30). Feed efficiency of weight gain as defined by total weight gain of mother and pups together per total food consumed during the experiment was greatest in the supplemental and least in the dark condition. The increase in growth induced by the light indicates an effect on metabolism; whether it is direct and/or indirect is yet to be determined.

AGING PROCESSES V

602.1

A MAGNETIC RESONANCE IMAGING (MRI) STUDY OF BRAIN MORPHOMETRIC CHANGES WITH HEALTHY AGING IN HUMAN MALES. D. Murphy, C.S DeCarli, W. Williams, S.I. Rapoport, M.B Schapiro, B Horwitz. National Institute on Aging, Bldg 10, Rm 6C 414 Bethesda, MD 20892.

Aging is associated wirth an increase in the prevelance in motor abnormalities. We wished to examine the effect of aging on the volume of cerebrospinal fluid (CSF) spaces, and the subcortical nuclei. We used MRI to detremine the volumes (vol) of cerebral brain matter (CBM), subcortical grey matter nuclei (GMN), and the ventricular and sulcal cerebrospinal fluid (CSF) in 27 healthy men aged 19 to 92 years. Ten subjects (YM) were below the age of 35 years (mean age 25.4 ± 4 (S.D)) and 17 (OM) were older than 60 years (mean age 73.2 ± 7.7(S.D)). We studied subjects free of primary brain disease or medical conditions that contibute to it. The MRI studies were performed on a Picker 0.5 Tesla scanner. Axial slices were analyzed, using a T1 (TR 2000 msec, TE 20 msec) sequence with 192 views and 2 repetitions. 18, 7mm thick, contiguous slices were obtained from the foramen magnum to the vertex. The results of the OM were compared to the YM with a students t test after correcting for intracranial vol. OM had significantly ($p<0.05$) less CBM than the YM. The % of intracranial vol occupied (% vol) by the CBM in the OM was 75.94 ± 3.74 (mean ± S.D), and in the YM was 80.67 ± 2.73 (mean ± S.D). The OM had significantly larger ($p<0.05$) CSF vols than the YM in every CSF measure, except the left lateral ventricle. The caudate (CN) and lenticular (LN) nuclei were significantly smaller ($p<0.05$) in the OM than the YM. In the OM the % vol of the CN and LN respectively were 0.72 ± 0.09 (mean ± S.D), and 0.90 ± 0.14 (mean ± S.D). In the YM the CN and LN volumes were 0.92 ± 0.09 (mean + S.D), and 1.22 ± 0.11 (mean ± S.D). This significant difference remained when their vol was expressed as a ratio of CBM vol. The vol of the thalamus did not differ between groups. There was no asymmetry in the vols of the CBM, GMN or CSF in OM or YM. In conclusion, the caudate and lenticular nuclei are significantly more affected by healthy aging than cerebral brain matter, this may account for some of the motor abnormalites in aging.

602.2

AGE-RELATED CHANGES IN WERNICKE'S AREA: A QUANTITATIVE DENDRITIC ANALYSIS. A. B. Scheibel and B. Jacobs. Brain Res. Inst., UCLA, Los Angeles, CA 90024.

This investigation examined age-related changes in the basilar dendrites of supragranular pyramidal cells in Wernicke's area of left and right hemispheres. Tissue was obtained from 10 male (M_{age} = 52.2; *range* = 18-78; *SD* = 17.42) and 10 female (M_{age} = 47.8 years; *range* = 20-79; *SD* = 20.47) subjects. All subjects were neurologically nomal right-handers. Using a modified rapid Golgi technique, 10 pyramidal cells were sampled from each hemisphere (total # of cells = 400; total # of segments = 16,697). These were evaluated according to total dendritic length (TDL), mean dendritic length (MDL), and dendritic segment count (DSC). A distinction was also made between proximal (1st, 2nd, and 3rd order) and the ontogenetically later developing distal (4th order and above) dendritic branches.

Despite considerable interindividual variation, the data clearly revealed an age-related shift in dendritic laterality such that individuals less than 50 years of age tended to have greater TDL values in the LH, while the trend was reversed in individuals older than 50. The data also exhibited both dendritic proliferation and degeneration with aging. There was an age-related decrease in TDL (r = -.44) and especially in MDL (r = -.69, p < .001) with increasing subject age. Age-MDL correlations were negative for all segment orders and revealed a progressive decrease in segment length in more distal branches. Although length measurements decreased with age, there was an age-related increase in the number of dendritic segments (r = .23), especially in the right hemisphere. Additional support for the age-related loss in dendritic material came from a post-hoc analysis of two 9 year old children, who had the highest TDL values of all subjects. These findings parallel the metabolic changes reported by Chugani et al. (*Annals of Neurol., 22:* 487-497, 1987) and the synaptic elimination noted by Huttenlocher (*Brain Res., 163:* 195-205, 1979).

602.3

AGE-RELATED REGIONAL DIFFERENCES IN CEREBELLAR VERMIS OBSERVED *IN VIVO*. N. Raz, K.White*, I.J. Torres*, W.D. Spencer*, and J.D. Acker*#. Dept. Psychology, Memphis State University, Memphis, TN 38152 and #Diagnostic Imaging Center, Baptist Memorial Hospital, Memphis, TN 38119.

We investigated age-related differences in cerebellar vermis. The areas of three vermal regions were estimated from digitized midsagittal MRI scans of 29 healthy Ss and 24 neurologically intact Ss free of vestibular symptoms, seizures, psychoses or alcoholism (age 18-78). The three ROIs included: 1-centralis and culmen; 2-declive, folium, tuber, and pyramis; 3-uvula and nodulus. Ventral pons was used as a control region. After covarying cranial size, we found age-related decline in the vermis area [Λ=.79; $F(3,47)=4.1$, $p<.01$]. This difference was found only for the superior segments of the vermis [$F(1,49)=6.45$ and $F(1,49)=6.75$ for ROIs 1 and 2, respectively, both $p<.015$], but not for uvula-nodulus ($F<1$). Pons was unaffected by age. No sex differences were found. The observed vermal regions of age-related loss correspond to the cerebellar areas with increased metabolic demands. Thus, selective vermal atrophy may stem from age-related decline in tissue oxygenation.

DIFFERENTIAL CELLULAR CHANGES IN THE FRONTOPARIETAL CORTEX AFTER BASAL FOREBRAIN LESIONS IN ADULT AND AGED RATS. C.L. Wellman and D.R. Sengelaub. Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405.

Because aging can be viewed as a regressive process that alters both cell numbers and plasticity of remaining neurons, aging may interact with other degenerative processes to produce unique pathological syndromes. To understand the mechanisms of aging and disorders associated with aging, we are using basal forebrain lesions in adult and aged rats to determine the contribution and potential interaction of age and depletions of cholinergic input on frontoparietal morphology.

Thirteen- and 21-month-old rats received either sham or ibotenic acid lesions of the basal forebrain. Three months after lesioning (at 16 and 24 months; adult and aged, respectively), cellular changes in the frontoparietal cortex were assessed in frozen sectioned, cresylecht violet stained material. Neuronal somas were smaller in aged sham-lesioned rats than in adult sham-lesioned rats, but cortical laminar thickness did not decrease with age. Furthermore, in both adult and aged rats, basal forebrain lesions reduced soma size in specific cortical laminae, resulting in decreased laminar thickness relative to sham-lesioned rats. However, decreases in laminar thickness and soma size were more pronounced in the 16-month-old rats compared to the 24-month-old rats. The pattern of changes also differed between the two ages: changes tended to be more pronounced in the superficial laminae of adult rats, whereas aged rats showed more changes in the deeper laminae. Thus, the magnitude and pattern of regressive changes in frontoparietal cortex after basal forebrain lesion differ in adult and aged rats, indicating that aging interacts with cholinergic depletion to produce unique neural changes.

602.5

DEGENERATIVE CHANGES IN BASAL FOREBRAIN CHOLINERGIC NEURONS IN AGED RATS: A QUANTITATIVE ANALYSIS OF CELLS STAINED FOR ChAT OR NGFr, OR RETROGRADELY LABELLED WITH FLUORESCENT TRACER OR I-125 NGF. S. de Lacalle, J.D. Cooper*, C.N. Svendsen*, S.B. Dunnett and M.V. Sofroniew. Departments of Anatomy and Experimental Psychology, University of Cambridge, England.

The effects of aging on basal forebrain cholinergic neurons were investigated in male Sprague-Dawley rats aged 3-6 or 24-33 months by immunohistochemical detection of ChAT or NGFr, and by retrograde transport of Fluoro Gold (F.G.) or I-125 labelled NGF injected into multiple sites in the cerebral cortex and hippocampus. Cell counts and surface area measurements were prepared for precisely defined subdivisions of the basal forebrain cholinergic system: medial septum (MS), vertical and horizontal diagonal band, and basal nucleus (BN). Values from about one third of the aged rats were not different from those of young adults; the remaining aged rats showed degenerative changes either in the form of cell loss or atrophy in several of the parameters tested. The degree of degenerative change varied considerably among individual rats and among different regions, the MS being affected the least and the BN the most. Some aged rats showed a decline in the ratio of F.G./ChAT labelled cells, suggesting an impaired ability to retrogradely transport tracer, while others showed reduced retrograde labelling with I-125 NGF. These findings suggest that in some but not all aged rats basal forebrain cholinergic neurons decline in number and atrophy in the form of cell shrinkage, reduced ChAT immunoreactivity, and reduced capacity to retrogradely transport tracers and I-125 NGF.

602.6

INCREASING NEURON NUMBER WITH BODY SIZE: A TEST OF THE SELECTION HYPOTHESIS. P.G.R. St. Wecker and P.B. Farel. Dept. of Physiology, Univ. N. Car. at Chapel Hill, NC 27599.

Large bullfrogs have more neurons in the hindlimb motor pool (JCN 261:125, 1986) and in dorsal root and sympathetic ganglia (Soc. Neurosci. Abstr. 15:301, 1989) than small frogs. The possibility that this association is due to counting error was eliminated by 3-D reconstructions of HRP-labeled neurons, which showed that nucleoli are not split in sectioning. A second alternative to neuron addition is that, by selection, only those frogs with many neurons survive to attain large size. Thus, the difference in mean number of neurons between small and large animals may be due to a dropping out over time of those animals with few neurons. This possibility can be tested by counting neurons from the same closed population at different points in time.

Twelve size-matched frogs were randomly divided into two groups shortly after metamorphosis. Six juvenile frogs, with a mean length of 4.0±.1 cm (mean±SEM) and a mean weight of 5.6±.2 g, were killed immediately. At the end of one year, the remaining six animals (mean length 6.7±.2 cm, mean weight 26.6±2.4 g) had substantially more lumbar sympathetic neurons (7756±571 vs 3398±413) and dorsal root ganglion neurons (9930±572 vs 5505±449).

These data show that selection cannot account for the relationship between body size and neuron number. Previous studies of ^{3}H-thymidine incorporation provided no evidence for neuron birth after metamorphosis. The explanation most consistent with these results is that immature nerve cells differentiate with increasing body size.

602.7

THE EFFECTS OF LONGTERM VOLUNTARY ETHANOL CONSUMPTION ON THE AGING OF SYMPATHETIC NEURONS IN THE RAT. P.Jaatinen[1], A. Hervonen[1], H. Alho[1] and K. Kiianmaa[2]. [1]Laboratory of Gerontology, University of Tampere Medical School, Tampere, and [2]Research Laboratories, Alko Ltd., Helsinki, Finland)

The effect of two years' voluntary ethanol intake (mean; 6.5 g/kg/day) on the aging of the nervous tissue was studied in alcohol preferring AA (Alko alcohol) rats. Here we report the ethanol-induced changes in the aging of superior cervical ganglion (SCG) neurons. The initially 3-month-old rats were given access to food, tap water, and 10% ethanol solution (ethanol group) or to food and water only (control group). At 28 months of age the rats were killed, and samples of the SCG were processed for histochemical, morphometric, and electron microscopic studies. The long-term ethanol exposure increased the heterogeneity of the aged neuron population and produced several signs of enhanced neuronal degeneration. The packing density of SCG-neurons (the number of neurons with a large nuclear profile per 90,000μm^2) decreased from 42.7±0.97 (mean±SD) at the age of 3 months to 25.5±1.34 in the controls and 21.0±3.13 in the ethanol group at 28 months. The amount of highly pigmented neurons was 39.3±2.5% in the old control rats and 59.3±4.2% in the old ethanol group. The overall intensity of TH-immunoreactivity and catecholamine histofluorescence was also lower in the ethanol rats than in the controls. The density of fluorescence intensity of the peripheral neuronal network in the submandibular gland (a target tissue of the SCG) was decreased in the ethanol-exposed rats. The monoamine contents of different brain areas did not change due to ethanol exposure. The survival of ethanol and control rats did not differ either. Thus the results may indicate a selective vulnerability of sympathetic neurons rather than a universal accelerated aging due to ethanol exposure.

602.8

PATHOLOGY OF PRE- AND POSTSYNAPTIC ELEMENTS IN AGED MOUSE SYMPATHETIC GANGLIA. R.E. Schmidt, K.G. Ruit, and W.D. Snider. Departments of Pathology and Neurology, Washington University School of Medicine, St. Louis, MO 63110.

Dysfunction of the autonomic nervous system is an increasingly recognized problem in aging animals and man, the pathological basis of which is poorly understood. In this study of young (4 month) and aged (24 month) mice we have examined the ultrastructural appearance of perikarya, dendritic processes, preterminal axons, and synapses within selected sympathetic ganglia as well as the structure of the dendritic arborizations of principal sympathetic neurons using intracellular injections of Lucifer yellow (LY).

Upon ultrastructural examination, numerous large spherical structures derived from terminal presynaptic axons and synapses were located in proximity to neurons within the prevertebral and paravertebral sympathetic ganglia of aged mice. These markedly dilated preterminal axons distorted the perikarya of sympathetic neurons and contained a variety of subcellular organelles which had the ultrastructural appearance of neuroaxonal dystrophy, a process described in a variety of clinical and experimental conditions. Dystrophic axons were rare in young animals, and, in distinction to other animal species and man, both prevertebral and paravertebral sympathetic ganglia were involved. Intracellular injections of LY revealed that the dendritic arborizations of aged sympathetic neurons were significantly smaller with regard to total dendritic length, extent, and branching when compared to those of young animals. These short, stunted dendritic processes also exhibited large, dystrophic swellings along their extent, a phenomenon not observed in young animals. The ultrastructural appearance of these dystrophic dendritic profiles is presently under investigation.

These observations may provide a neuropathological basis for changes in autonomic function observed in aged animals and man.

602.9

CELL SURVIVAL IN DORSAL ROOT GANGLION FOLLOWING SCIATIC NERVE SECTION: A COMPARISON OF ADULT AND AGED RATS. S. Croul*, E. Wolf* and I. Zimmerman. Depts of Pathology and Physiology -Biochemistry. The Medical College of Pennsylvania, Philadelphia, PA 19129.

Previous studies have quantitated the loss of dorsal root ganglion cells from the L5 dorsal root ganglion following sciatic nerve section in adult rats. In this study, we have examined the issue of dorsal root ganglion cell death in adult and aged rats. Fischer 344 rats underwent sciatic nerve section at 2, 12, 24 or 30 months of age. Animals were sacrificed at 1 month following surgery and the number of cells in the L5 dorsal root ganglion counted. we found no difference in cell survival between those age groups. The ability of dorsal root ganglion cells to respond to nerve section does not seem to change with age at this time interval.

603.1

MODIFICATION OF NON-RADIOACTIVE DETECTION OF NEUROPEPTIDES FOR IN SITU HYBRIDIZATION IN RAT BRAIN. N. Nousek-Goebl*, T.C. Cavanagh[+] and D. S. Grega[+]. R&D Division, Boehringer Mannheim Corp. and [+]Indiana Univ. Sch of Med., Program in Medical Neurobiology, Indianapolis, IN 46250

In situ hybridization histochemistry is a powerful tool to localize specific mRNAs to individual cells. This is especially important in the nervous system where the complex structural interactions of diverse neuronal and glial cell types need to be preserved. Non-radioactive detection of hybridization probes is attractive for safety and ease of use. Additionally, localization to subcellular structure is desirable.

This report describes the modification of the detection method for localizing digoxigenin-labeled oligonucleotide probes used for in situ hybridization in the rat nervous system. Ordinarily following hybridization with cellular mRNA, the 3'-end tailed oligo probe is localized using an alkaline phosphatase antibody conjugate and a subsequent color reaction. In the present study, whole anti-digoxigenin sheep polyclonal antibody is used as a primary antibody, followed by a biotinylated anti-sheep secondary. This complex is visualized using an avidin-biotinylated peroxidase or alkaline phosphatase detection system. This detection method results in a reaction product which is more immunocytochemical in appearance. This procedure has been performed with a 48mer to oxytocin which yielded crisp cellular labeling in the PVN and SON. Several other probes are under study.

603.2

A NEW METHOD FOR *IN SITU* HYBRIDIZATION HISTOCHEMISTRY TO PROCESS BRAIN MATERIAL STORED FOR SEVERAL YEARS W.X. Lu* and S. N. Haber, Dept. of Neurobiology and Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642.

We have developed a new protocol for *in situ* hybridization in order to label mRNA in tissue sections that have been in long-term storage and have not been treated to prevent RNase activity. Brains from rats and monkeys were sectioned at 50μ and stored free floating in an ethylene glycol based cryoprotective solution at -20 °C. Rat brain sections were stored in cryoprotective solution for 3 days, 1 month, and 2 months. Control sections were cut and mounted immediately on gelatin coated slides and stored at -80°C. Monkey brains sections were stored in cryoprotective solution for up to 5 years. 48-mer oligonucleotide probes, human preproenkephalin (sequence 130-145), rat preproenkephalin (sequence 388-435) and rat tyrosine hydroxylase (sequence1441-1488), were labeled with ^{35}S-dATP and terminal deoxynucleotidyl transferase. To prevent RNase contamination from mounting the tissue sections onto gelatin coated slides, *in situ* hybridization was performed in sterile culture dishes prior to mounting. Each solution was removed from the dish by aspiration. Prior to the hybridization step, there was no solution in the dish and the sections lay flat on the bottom of the dish. The amount of probe used for each section was 50μl (rat) and 500μl (monkey).

Using this protocol, the results in rats showed better specific labeling with less nonspecific background compared to controls. Excellent resolution was obtained from monkey sections that were stored in cryoprotectant for up to 31 months. As with conventional in *situ* hybridization methodology, the prehybridization treatment step is not necessary to reduce the background. This protocol is an efficient procedure to allow effective labeling of mRNA in brain sections that have been stored for several years in cryoprotectant solution. This protocol is suitable for various species including rat, mouse, monkey, and possibly human. Supported by NIMH MH 45573.

603.3

COMBINED IN SITU HYBRIDIZATION AND IMMUNOCYTOCHEMISTRY FOR THE ANALYSIS OF PEPTIDE AND 5-HT EXPRESSION IN THE RAT BRAIN. G. Wotherspoon*, D. Savery*, S. Averill*, J.V. Priestley and M. Rattray. Departments of Physiology & Biochemistry, UMDS St.Thomas's Campus, London, England.

To study the expression of 5-hydroxytryptamine (5-HT) and peptide mRNA, we have developed a procedure combining immunocytochemistry with in situ hybridization using ^{35}S labelled oligonucleotides. Peroxidase anti-peroxidase immunocytochemistry and immunofluorescence were tested and were applied either preceeding or following in situ hybridization. Combined 5-HT immunocytochemistry and peptide in situ hybridization was obtained using immunofluorescence followed by in situ hybridization. The fluorescence survived a post-hybridization 55°C wash and liquid emulsion autoradiography. Loss of mRNA during immunostaining was prevented by diluting antisera in 0.1% diethylpyrocarbonate treated phosphate buffered saline containing 20 mM vanadyl ribonucleoside complex. Double labelling was not as sensitive as 5-HT immunocytochemistry or in situ hybridization performed alone, but was adequate to allow localisation of 5-HT immunoreactive cell bodies and fibres combined with enkephalin, somatostatin, cholecystokinin, galanin or glutamic acid decarboxylase mRNAs. In most CNS regions 5-HT immunoreactivity and peptide mRNA occurred in separate cell populations, but coexistence was observed between 5-HT and enkephalin in raphe magnus and 5-HT and galanin in raphe dorsalis.

603.4

QUANTITATIVE AUTORADIOGRAPHY OF TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE LOCUS COERULEUS AND THE SUBSTANTIA NIGRA OF RATS TREATED WITH RESERPINE. R. Raisman-Vozari*, V. Blanchard*, M. Savasta M., F. Javoy-Agid, E. Hirsch C., Feuerstein and Y. Agid. INSERM U 289, Hôpital de la Salpêtrière, 75651 Paris and INSERM U 318, CHU 38043 Grenoble, France.

Most of the immunohistochemical studies so far reported were only qualitative, we therefore developed a rapid and sensitive radioimmunohistochemical method for tyrosine hydroxylase (TH) quantification in fresh-frozen rat brain. The present study was performed in the substantia nigra (SNC) and ventral tegmental area (VTA), containing dopaminergic neurons and the locus coeruleus (LC) and subcoeruleus (SubC), containing noradrenergic neurons, of rats treated with reserpine. Autoradiography of TH was performed on 15 μm thick coronal sections from unfixed brain of rats treated either with reserpine (i.p.,10 mg/kg) or vehicle. Sections were incubated with TH monoclonal antibody for 2 hours and the reaction was revealed with a ^{35}S-labelled secondary antibody. TH was quantified in the different brain regions by measuring optical density (O.D.) on film or emulsion autoradiography and compared with adequate TH standards, using computer-assisted image analysis. TH concentrations (expressed in ng/mg prot) measured on films were 40% increased by reserpine in the LC and 20% in the SubC but were unchanged in the SNC and in the VTA. Microscopic examination of TH radioimmunolabeling on emulsion-coated sections showed a heavy labeling appearing as an accumulation of silver grains over cell bodies and also over processes. Grain density per cell, considered as representative of the amount of TH on individual cells, was increased in the LC and subC but not in the SNC. These results support the validity of the radioimmunohistochemical method as a tool for quantifying proteins at cellular level and confirm that TH protein content is differentially regulated in noradrenergic and dopaminergic neurons in response to reserpine.

603.5

KINETIC ANALYSIS OF SECONDARY ANTIBODY BINDING TO FLOATING BRAIN SECTIONS. A METHOD OF QUANTITATIVE IMMUNOCYTOCHEMISTRY. D.G. Morgan, D.G. Berg* and M.N. Gordon. Div. of Neurogerontology, Univ. of Southern California, Los Angeles, CA 90089-0191.

50 μm vibratome rat brain sections were incubated overnight with mouse monoclonal antibody (Ab) towards GFAP. The binding of a secondary (2°) rat monoclonal Ab conjugated to HRP was measured using the soluble HRP substrate tetramethylbenzidine. Assays were stopped with sulfuric acid, and the sections incubated by shaking to evenly distribute the reaction product before A_{450} was measured. Preliminary studies established a standard curve relating A_{450} to the molar concentration of 2° Ab. Tissue sections processed without the primary antibody were used to estimate nonspecific binding of the 2° Ab, and these values were subtracted from the "total" binding to yield specific 2° Ab binding. Rarely did these nonspecific values exceed 10% of the total binding. Specific 2° Ab binding was not affected by section thickness between 30 and 90 μm, confirming earlier observations that Ab penetration into brain sections was limited to the outer few μm.

The time course of 2° Ab association was dependent upon the concentration of 2° Ab. At high concentration, maximal binding was attained by 3 h of incubation, while 6 h of incubation was required for low 2° Ab binding. Values were lower after 23 h of incubation at all concentrations, probably because of dissociation of the primary Ab from the section. An initial saturation analysis indicated a K_d of 7 nM for the 2° Ab. These preliminary experiments validate the utility of this method for evaluating Ab binding kinetics to brain sections, and will allow quantitative analyses of primary Ab binding kinetics in future studies. Supported by AG-7892, AHA-GIA 891079, and AHA-EIA 890173.

603.6

A NEW METHOD FOR THE PREPARATION OF ANTISERUM TO LUCIFER YELLOW. C. Brandon, M.H. Criswell*, and E. Indyk*, Dept. of Cell Biology and Anatomy, The Chicago Medical School, North Chicago, IL 60064.

Intracellular injection of Lucifer Yellow (LY) has proven to be very useful for the study of cell morphology (Stewart, Cell *14*, 71 (1978)). Long periods of fluorescent observation, however, may cause fading, so it is often necessary to generate a visible marker. Photo-oxidation of LY (Maranto, Science *217*, 953 (1982)) can be used to convert it to a visible reaction product, but is tedious when applied to large numbers of cells. Immunocytochemical localization of LY has been used (e. g. Taghert, Dev. Biol. *94*, 391 (1982)), but no detailed information about the conjugate preparation and antibody production has been published. We have developed a new method for the preparation of antisera to LY, and used these sera for the immunocytochemical localization of LY in large numbers of dye-filled cells in vertebrate retina.

Covalent conjugates of the VS isomer of LY were prepared with keyhole limpet hemocyanin (KLH) or rabbit serum albumin (RSA), and used as immunogens in rabbits. Antiserum to the KLH-LY conjugate contained precipitating antibodies against KLH and LY, while antiserum to the RSA-LY conjugate had precipitating activity only against LY. When used for immunocytochemical staining of large retinal pieces containing many LY-filled cells, both antisera yielded well-stained, darkly-filled cells similar to those seen with the Golgi technique; even very fine dendritic processes of retinal ganglion cells could be followed for long distances. We used tissue that was stained *in vitro*, but the immunocytochemical approach may be especially useful for the immunocytochemical identification of cells filled with LY after tissue fixation.

Supported by the USPHS.

INTRACELLULAR INJECTIONS OF BIOTINYLATED LUCIFER YELLOW IN COMBINATION WITH RETROGRADE TRACING IN LIGHTLY FIXED SECTIONS OF THE INFERIOR COLLICULUS (IC). S.J. HILL and D.L. Oliver, Dept. Anatomy, UCONN Health Center, Farmington, CT 06030

Intracellular injections of neurons can be made even when the tissue has been previously fixed by aldehydes (Tauchi & Masland, '85; Einstein, '88; Buhl & Lubke, '89). Such cells can be converted to a permanent non-fluorescent form. In the present study of the rat, we identify cells in the IC that project to the ipsilateral thalamus by injection of rhodamine-labeled latex beads (LumaFluor) in the medial geniculate body and retrograde transport in vivo. After 1-3 days, the brains are perfused with 2.5% paraformaldehyde and 0.2% glutaraldehyde in phosphate buffer (pH 7.3). The IC is cut on a vibratome into 150-300 µM thick sections. Intracellular micropipets (100-200 MΩ, 1.0 mm borosilicate glass with capillary pulled on a Flaming-Brown P80/PC) are filled with 9% Lucifer Yellow dilithium salt (L-0259, Sigma) and 1% biotinylated lucifer yellow (L-2601, Molecular Probes). The rhodamine-labeled cells are observed with epi-fluorescent optics, impaled under visual control, and injected with 5-20 nA of negative current (100 msec duty cycle) until they appear well filled. The biotinylated lucifer yellow is then converted to a permanent stable reaction product by overnight incubation in avidin-HRP (Vectastain) in the presence of 0.1% triton X-100 at 4°C. Incubation in DAB with cobalt and nickel follows (Adams, '81).

This method produces well filled neuronal cell bodies, dendrites, and spines for light microscopic analysis. The non-fluorescent reaction product in these intracellularly filled cells will permit transmitter immunohistochemistry and synaptic fine structure to be studied in combination with neural connections and dendritic morphology.

Supported by grants from NIDOCD (R01-DC00189).

A COMBINATION OF COBALT AND IMMUNOCYTOCHEMICAL LABELING FOR ELECTRONMICROSCOPICAL STUDIES. I. Nagy*, M. Petko*, E. Polgar*, A. Sik*, M. Antal, J. D. Feigenbaum[1]. Dept. of Anat., Univ. Med. Sch. of Debrecen, H-4012, Hungary, [1]Dept. of Anat., Univ. Coll. of London, WC1E 6BT, England.

Combined methods of tracer and immunocytochemical labeling of nervous tissues for electronmicroscopical (EM) investigations described previously have various disadvantages and difficulties. We report here a new and simple EM double labeling technique using cobalt staining and peroxidase-antiperoxidase (PAP) pre-embedding or immunogold (IG) post-embedding immunocytochemical reactions, which can overcome these problems. Primary afferents of the frog spinal cord were labeled with cobalt, and GABA-, or CGRP-like immunoreactivity was shown in profiles adjacent to cobalt positive structures or in cobalt positive boutons, respectively. Our results have shown: 1. The chemical nature of profiles identified by the cobalt labelling can be studied, because the EM appearance of the endproduct of cobalt labeling is different from those of both immunocytochemical reactions. 2. Cobalt and IG labeling can be studied on the same section, because the electron density of cobalt labeling is not influenced by the osmium content of the tissue. 3. Selective and intensive dye and immunocytochemical staining can be achieved.

THE USE OF NICKEL IONS FOR TRACING CENTRAL CONNECTIONS AND PERIPHERAL PROJECTIONS OF THE LEECH NERVOUS SYSTEM. M. Nitabach and E. Macagno. Dept. of Biological Sciences, Columbia University, NY, NY 10027.

We report here on the use of Ni^{++} and Nickel-lysine (Ni-Ly) as dyes both for nerve backfilling and for direct injection of identified neurons in the leech, *Hirudo medicinalis*. The male sex nerve was backfilled with either 5% $NiCl_2$ or 250mM Ni-Ly. After precipitation of NiS and silver intensification, we saw at least 8 neuronal somata in stereotyped ganglionic positions in all cases examined. In addition, we saw ganglionic fiber tracts containing the filled central projections of peripherally located sensory neurons. We also backfilled the male sex nerve in several cases with 30% horseradish peroxidase (HRP). We always saw more backfilled neurons with Ni^{++} or Ni-Ly than with HRP. This suggests that these dyes are more sensitive for backfills than HRP.

As no previous report of direct intracellular iontophoresis of Ni^{++} or Ni-Ly into leech neurons was known to us, we examined the feasibility of these dyes for this purpose. While ~30MΩ 150mM Ni^{++} electrodes could pass positive current when the tip was in the bath, as soon as a neuron was impaled they invariably clogged. In contrast, ~30MΩ 250mM Ni/Ly electrodes could pass 300msec 1-5nA positive current pulses at 1Hz into impaled leech neurons for up to 30min without clogging. This method was used to fill identified cells in both adult and embryonic leeches. These fills were at least as complete as those obtained after intracellular HRP injection. Even very fine ramifications of embryonic sensory neurons' peripheral projections could be seen in the body wall. Interestingly, when Ni^{++} was pressure injected into a Retzius cell, it did not pass into the electrically coupled contralateral Retzius cell.

BIOTINYLATED DEXTRAN AMINE AS AN ANTEROGRADE TRACER FOR SINGLE- AND DOUBLE-LABELING STUDIES. A. Reiner, C.L. Veenman and M.G. Honig. Department of Anatomy and Neurobiology, University of Tennessee - Memphis, Memphis, TN 38163.

The utility of fluorescent dextran amines for anterograde pathway tracing has recently been reported. Fluorescent markers, however, are not always ideal for detailed anatomical mapping studies. We therefore evaluated the efficacy of biotinylated dextran amine (BDA, MW10K) for anterograde labeling in several different preparations. BDA was visualized with an avidin-biotinylated HRP (ABC) procedure followed by a DAB reaction. After iontophoretic injections of BDA into isocortex-like telencephalic regions in pigeons or into visual or somatosensory cortex in rats, we found excellent and abundant labeling of terminals in forebrain, midbrain and hindbrain target areas with one week survival times. Pressure injections of BDA into the ventral horn of embryonic chick spinal cord yielded extensive anterograde labeling of motoneuron axons in peripheral nerves. We also found that BDA labeling could be combined with a second labeling method to differentially label and distinguish two sets of projections. For these experiments, motoneuron and sensory neuron projections into the embryonic chick hindlimb were differentially labeled by HRP injection into the DRGs (visualized using a blue cobalt-DAB reaction) and BDA injection into the spinal cord (visualized with a brown DAB reaction). Taken together, these various studies show that BDA is effective for anterograde pathway tracing and can be used in double-label studies with other labeling methods.

Supported by NS-19620 and NS-28721 (AR) and NS- 26386 (MGH).

ANTEROGRADE NEUROANATOMICAL TRACT TRACING WITH CENTRAL NERVOUS SYSTEM INJECTIONS OF IMMUNOGLOBULIN G: A LIGHT AND ELECTRON MICROSCOPIC EVALUATION. C.F. Phelix and W.K. Paull Div. of Life Sci., Univ. of Texas, San Antonio, TX 78285, Dept. Anat. & Neurobio., Univ. Missouri, Columbia, MO 65212

Normal rabbit serum (NRS) was pressure injected into the forebrain of rats to be tested as an anterograde neuroanatomical tracing substance. Undiluted NRS was stereotaxically injected into the bed nucleus of the stria terminalis (BST) with a 1 µl Hamilton syringe. Postinjection survival times ranged from 24 hr to 14 days. An immunohistochemical method utilizing goat anti-rabbit IgG antibody was used to detect the rabbit IgG within vibratome sections. Visualization of the final reaction product (diaminobenzidine, DAB) was enhanced by a silver/gold postintensification (SGI) method. Rabbit IgG-containing neural structures were examined at both light and electron microscopic (EM) levels. At the injection site neuronal soma, dendrites and axons were filled homogeneously with the SGI-DAB at 24 hr, 48 hr, 7 days and 14 days indicating local neuronal uptake, storage and transport of rabbit IgG. In the hypothalamus many anterogradely filled axons were present and displayed short collateral branches and terminals. EM examination revealed synaptic terminals containing IgG, without signs of trans-synaptic transport after 14 days. Signs of retrograde transport of IgG were never observed. A propensity of neurons to take up, sequester and anterogradely transport IgG is indicated.

603.12

THE USE OF HERPES SIMPLEX VIRUS TYPE 1 FOR NEURONAL PATHWAY MAPPING IN MICE. G.A. Lewandowski, P.P. Sanna and F.E. Bloom. Department of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla, CA 92037.

Herpes simplex virus type 1 (HSV–1) was used as a transneuronal pathway tracer in the CNS. HSV–1 was stereotaxically placed in the caudate putamen of mice and after varying survival times mice were sacrificed by cardiac perfusion with paraformaldehyde fixative. Virus was detected in brain sections by immunohistochemistry with a polyclonal antibody to HSV–1 proteins, and an antibody to mouse macrophage (Mac–1) was used to detect immune responses within the same sections. The retrograde, anterograde and transynaptic transport of the virus was observed. HSV–1 was transported from the caudate along all known major pathways and was detected in regions of the brain including the cortex, globus pallidus, substantia nigra, dorsal raphe nucleus, ventral tegmental area, and thalamus. The immunostaining patterns suggest that the virus was then transported transynaptically from these regions. The Mac–1 staining of the same sections revealed that activation of macrophages follows the same inter–neuronal pathways of the viral infection in a temporal manner.

603.13

MOUSE CORNEAL MODEL OF HERPES SIMPLEX VIRUS (HSV) INFECTION: TISSUE TARGETS AND ROUTES OF SPREAD J.R. Martin[1]*, F.J. Jenkins[2], D.B. Henken[1]* [1]Lab. of Expt'l Neuropath., NIH, [2]USUHS; Bethesda, MD, 20892

In animal models, spread of HSV-1 from epithelial replication sites to the PNS and CNS is known from analysis of individual tissues. To more completely define tissue targets of infection and infer routes of spread, corneas of adult mice were inoculated with 10^6pfu of HSV-1, F strain. One to 13 days later, groups of 4 mice were formalin-perfused. Decalcified head and neck were embedded *en block* in paraffin. At intervals, serial sections were screened for HSV antigen. On days 1 and 2, antigen was limited to cornea and conjunctiva but by days 3 and 4 was also in autonomic ganglia and the trigeminal system. On day 6, antigen reached its maximum extent; infected sites included the trigeminal complex (ganglion, ophthalmic and maxillary branches, root and spinal nucleus and tract) ethmoid sinus and olfactory bulb, visual system, and autonomic ganglia (ciliary, pterygopalatine and superior cervical). By days 8 and 10, antigen was greatly reduced, and day 13 samples were negative. This method shows a broader range of infected tissues and suggests a more complex pattern of HSV spread than has been recognized. Virus appears to reach the intracranial compartment by 4 different neural routes. Inoculum dose may alter the kinetics of virus spread to neural tissues.

603.14

TRACING OLFACTORY PATHWAYS IN THE MOUSE WITH A CORONAVIRUS. E.M. Barnett*, M. Cassell and S. Perlman*. University of Iowa College of Medicine, Iowa City, IA 52242.

Olfactory system pathways in the mouse were studied after intranasal inoculation of Mouse Hepatitis Virus (MHV) strain JHM, a neurotropic murine Coronavirus which is non-pathogenic to humans. Animals were sacrificed 4 and 5 days post inoculation and viral RNA was detected by means of in situ hybridization with a ^{35}S labeled probe. Labeling was seen in the main olfactory bulb and its afferent and efferent connections including: the anterior olfactory nucleus, insular cortex, piriform cortex, the nucleus of the diagonal band, lateral hypothalamus, the nucleus of the lateral olfactory tract, and midbrain raphe nuclei. These results are consistent with transneuronal retrograde, and possibly anterograde, movement of virus. Viral RNA was also labeled in structures such as the endopiriform nuclei, the external lateral parabrachial nuclei, the ventral tegmental area, and medullary raphe nuclei suggesting viral movement across several synapses. These findings suggest that MHV strain JHM may be a useful neural systems tracer in the mouse.

603.15

ß-GALACTOSIDASE EXPRESSING RECOMBINANT PSEUDO-RABIES VIRUS FOR LIGHT AND ELECTRON MICROSCOPIC STUDY OF RETROGRADE TRANSNEURONALLY LABELED CNS NEURONS. A.D. Loewy, P.C. Bridgman & T.C. Mettenleiter. Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110 and Federal Research Center for Virus Diseases of Animals, D-7400 Tübingen, Germany.

Bartha's strain of pseudorabies virus (Bartha PRV) is a neurotropic virus used in veterinary medicine to vaccinate pigs against Aujesky's disease (i.e., the "mad itch"). It has also been shown to be a highly specific retrograde transneuronal cell body marker (Brain Res. 491:274, 1989 and J. Neurosci. 10:2139, 1990). The latter property makes this particular virus a potentially useful tool for neuroanatomy and for other neurobiological studies.

A ß-galactosidase expressing Bartha PRV was constructed and used to transneuronally label the CNS autonomic neurons in rats that project to the sympathoadrenal preganglionic neurons and to the eye. Four days following injections of the ß-galactosidase expressing Bartha PRV, virally infected neurons were visualized with a one step histochemical reaction using the Bluo-Gal substrate (halogenated indolyl-ß-D-galactoside). In some infected neurons, a Golgi-like staining of the primary and sometimes secondary dendrites could be obtained. For electron microscopic studies, the Bluo-Gal substrate produced an electron dense reaction product that was easily identified at both low and high magnification. This virus may be useful for the study of the cell architecture and synaptic organization of transneuronally labeled neurons of functionally defined neural circuits. These results also demonstrate that it is possible to deliver foreign genes into specific chains of neurons in the mammalian CNS by means of the retrograde transneuronal viral labeling method.

SANTIAGO RAMÓN y CAJAL (1852-1934) I. EARLY ACCOMPLISHMENTS IN NEUROANATOMY AND SCIENTIFIC ILLUSTRATION. R.A. Johnson[1] and L.H. Marshall[2]. Department of Psychology[1] and Neuroscience History Program[2], UCLA, Los Angeles, CA 90024.

Cajal was born in a humble room in a stone house in the village of Petilla, in the mountainous Aragon region of Northern Spain. Medical school was attended at the insistance of his father; later, Cajal began study and research in histology at the University of Zaragova while convalascing after military service in Cuba. An appointment to the chair of anatomy at Valencia at age 32 was followed three years later by a move to the chair of histology at Barcelona. The next year, 1888, saw the beginning of his experimentation with the reduced silver method for staining the nervous system, introduced by Golgi. Cajal's facility with this and subsequent techniques employed from 1890 at the University of Madrid contributed to the revelation and faithful documentation of the histological organization of the central nervous system. The published documentation of this work reflects both technical and artistic accomplishment. Indeed, Cajal's early devotion to drawing and painting appear to have become sublimated in his later career, in the preparation of scientific illustrations. The quantity and quality of Cajal's hand-prepared drawings will be considered, with a comparison to the talents and achievements of his contemporaries. They will also be placed in perspective to the origins and continuing development of techniques for the transcription, enlargement, and reproduction of hard copy histology.

SANTIAGO RAMÓN y CAJAL (1852-1934) II. THE SPANISH TRADITION IN NEUROSCIENCE. L.H. Marshall[1] and R.A. Johnson[2]. Neuroscience History Program[1] and Department of Psychology[2], UCLA, Los Angeles, CA 90024.

Cajal and Golgi shared the Nobel Prize in Physiology or Medicine in 1906 in recognition of their work on the structure of the nervous system. Cajal's drawings of nerve cells, stained by his own and by Golgi's techniques, are marvels of precision and art. The Spanish government belatedly facilitated the achievements of the largely self-taught professor of anatomy at the University of Madrid by providing a new building in 1932. The top floor was for the master's microscopic work and the remainder accommodated programs in subspecialties beyond neurocytology, resembling the institutes established much earlier in Vienna, Leipzig, and Zurich. With the new facilities, Cajal continued to expand a school of followers, including Lorente de Nó and Rio-Ortega. His clear proof of collateral sprouting after neuronal trauma formed the basis of discoveries of reorganization of pathways in cerebral and cerebellar cortex. Cajal's emphasis on the synapse, fundamental to his demonstration of the correctness of the neuron doctrine, furthered interpretations of old work and opened the central nervous system to new understanding. A beautiful modern institute now carries forward the elegant Spanish tradition of nervous system research.

604.1

THE GENERATION OF A MOUSE MUTANT FOR THE ALPHA SUBUNIT OF THE CA/CALMODULIN KINASE II THROUGH GENE TARGETTING IN EMBRYONIC STEM CELLS.

Alcino J. Silva*, Jeanne M. Wehner#, and Susumu Tonegawa*. * Cancer Center, Massachusetts Institute of Technology, Cambrige, MA 02139, USA. # Institute of Genetics, University of Colorado, 80309 USA.

The brain-specific Ca/Calmodulin Kinase II (CAMKII) is thought to have a role in a myriad of phenomena ranging from synaptic transmission to neural development. In the hippocampus and forebrain, two regions of the CNS often implicated in memory, this enzyme is mostly composed of alpha subunits. Using homologous recombination, we disrupted the alpha-subunit gene of CAMKII in embryonic stem cells, and these cells were used to derive a mouse mutant for this gene. We will provide a preliminary report on our attempts to test these mice for abnormalities in development and long term potentiation, for anatomical defects in structures such as the barrel fields of the somatosensory cortex, and for spatial memory deficits in a modified Morris water maze.

604.2

CHARACTERIZATION OF FOS*LACZ* TRANSGENE EXPRESSION IN THE CNS. R.J. Smeyne, K. Schilling, L. Robertson, D. Luk*, J.G. Corbin*, J. Oberdick*, T. Curran* and J.I. Morgan. Roche Institute of Molecular Biology, Roche Research Center. Nutley, NJ 07110

Cellular immediate early genes (cIEG) are thought to orchestrate the link between transient external stimuli and long-term changes in cellular phenotype. One of these cIEGs, c- fos, is induced in specific neural regions in response to various stimuli, including seizure and light stimulation. We have constructed a transgenic mouse containing a lacZ reporter gene, fused in-frame, into the entire fos gene (FosβGal). Initiation of seizure using either kainic acid (KA) or pentylenetetrazole (PTZ) reproducibly induces expression of FosβGal in brain. The patterns of expression seen in the transgenic CNS following PTZ stimulation is identical to that previously reported using antibodies to Fos. Furthermore, subtle differences are apparent in PTZ-seizured brain compared to KA. In addition, we have found that FosβGal is expressed in the SCN following brief periods of light, delivered at night, as has also been reported using antibodies to Fos. During early postnatal CNS development, we have observed regional differences in the patterns of basal FosβGal expression; dependent on the age of the animal. Primary sites of basal expression include, but are not limited to, the olfactory bulb, hippocampus, and cerebral cortex. The versatility of this transgenic mouse has also been demonstrated through the use of characterized primary neuronal and glial cultures. Defined cells within these cultures respond to various neurotransmitters and growth factors with an induction of lacZ. In addition, we have constructed transgenic mice with specific mutations in the 5' control elements of the c-fos-lacZ promoter. Analysis of these animals will provide a picture of the in vivo utilization of these specific regulatory sequences. Supported by NRSA NS 08680-02 (to RJS) and DFG Schi 271/2-2 (to KS).

604.3

SYNAPSIN I 5' FLANKING SEQUENCES DIRECT NEURONAL LACZ REPORTER GENE EXPRESSION IN TRANSGENIC MICE.
L. J. DeGennaro[2], R. Franco[2]*, H. Dressler[1]*, L. M. Hemmendinger[2] & K. Herrup[1]. [1]E.K. Shriver Center, Waltham, MA and [2]UMass Med Ctr., Worcester, MA.

The synapsin I gene encodes a neuron-specific protein found in virtually all nerve cells. In order to define DNA sequences necessary for tissue-specific expression of this X-linked gene, we joined a 2.5 kb fragment of the synapsin I promoter to sequences encoding E. coli β-galactosidase. A line of transgenic mice was produced in which 10 to 20 copies of this transgene have integrated onto an autosome. Analysis of heterozygotes reveals a high degree of fidelity in the expression of the transgene. Transgene mRNA is found exclusively in the brain and testis. X-gal histochemistry stains most neurons, and the relative intensity of staining varies among neuronal cell types in a pattern similar to that observed for synapsin I immunostaining in their terminal fields. X-gal staining is high in cerebellum, olfactory bulb, dentate gyrus, hypothalamus and layers II, V and VIb of cortex, and low in hippocampal pyramidal cells. An unexplained observation is the near absence of staining in striatum. Furthermore, the amount of transgene mRNA in the brain is much lower than that of endogenous synapsin I mRNA. Our results suggest that DNA sequences required for the neuron-specific expression of the synapsin I gene are present in our construct. Nonetheless, the relatively low levels of transgene mRNA and protein suggest that additional regulatory sequences may be missing, that positional effects of the site of integration may affect expression, or that transgene mRNA stability may be different than that of the endogenous synapsin I mRNA. Supported by NS20591, NS18381 to KH, NS25050 to LD and NS27833 to LH and LD.

604.4

EXPRESSION OF A RHOMBOTIN TRANSGENE IN PHENOTYPICALLY DEFINED SUBSETS OF HIPPOCAMPAL NEURONS: ADVANTAGES OF IMMUNOHISTOCHEMICAL OVER HISTOCHEMICAL DETECTION OF ß-GALACTOSIDASE IN TRANSGENIC MICE.

K. Staley*, T. Boehm*, J. Greenberg*, T. Rabbitts* and M.V. Sofroniew. Department of Anatomy, University of Cambridge and MRC Laboratory of Molecular Biology, Cambridge, U.K.

Patterns of gene expression associated with specific cell phenotypes in the CNS are not well documented. Here we report the expression in transgenic mice of a rhombotin promoter 1-lac Z fusion construct in previously described subsets of hippocampal (Hp) neurons. The rhombotin gene was identified adjacent to a T-cell tumour-associated chromosomal translocation and is believed to be involved in tumorigenesis. Histochemical staining for ß-galactosidase (ß-Gal) in these transgenic mice has previously revealed expression during development in several CNS sites including the Hp (Nature 344:158). We have now found that immunohistochemical detection of ß-Gal is both more sensitive and more precise in visualizing cell morphology than histochemical staining. The latter can give both false positive (i.e., misinterpretation of labelled terminals as cells) and false negative results. As detected immunohistochemically, ß-Gal expression was found throughout adult life in Hp pyramidal neurons of CA1 and CA2 but not of CA3 or CA4 or in dentate gyrus granule cells. Expression also occured in dentate gyrus basket cells and certain glial cells. While the cellular functions controlled by this gene are not known, rhombotin gene expression via promoter 1 occurs in certain previously defined classes of Hp neurons.

604.5

CHARACTERIZATION OF NF-H GENE EXPRESSION IN TRANSGENIC MICE.
F.Cote*(1), A.C.Peterson(2) G.A.Rouleau(1) and J.-P.Julien*(1). (1) The Montreal General Hospital Research Institute, Canada. H3G 1A4. (2) Ludwig Institute for Cancer Research. Montreal, H3A 1A1.

Neurofilaments (NFs) are the most abundant cytoskeletal elements of neurons. They are formed by the copolymerization of 3 proteins, NF-L, NF-M and NF-H. NF-H is believed to form the side arm projections seen in NFs. Various observations suggest a central role, for NFs, in the maintenance of axonal calibre. To further study the role of NF-H, we have generated transgenic mice expressing the human NF-H gene (hNF-F). A complete genomic clone for the human NF-H gene has been obtained by screening a cosmid library enriched in chromosome 22. The cosmid was linearized using the Not 1 restriction enzyme and microinjected into mouse eggs. Two founder mice with a high copy number of the hNF-H gene have been obtained. Northern blot analysis of total RNA from various tissues indicates that the human gene is specifically expressed in the mouse nervous system. Work is in progress to determine the effect of high expression of the hNF-H protein on the axonal NF architecture.

604.6

A PREPROENKEPHALIN PROMOTER SEGMENT CONFERS TRANSSYNAPTIC REGULATION AND ELEVATED TESTES EXPRESSION IN TRANSGENIC MICE.
D.M. Donovan, B.F. O'Hara, M. Takemura*, R.J. Marley#, C.W. Schindler#, M.T. Brannock*, and G.R. Uhl,. L. Mol. Neurobiol. & #Beh. Pharm. Gen, NIDA/ARC, & Depts. of Neurol. & Nsci, JHUSM, Box 5180, Baltimore, MD 21224.

Transgenic mice containing a 193 bp segment of the preproenkephalin A promoter fused to a CAT reporter (pENKAT-12) or to a preproenkephalin cDNA show expression in brain and testes. CAT (chloramphenicol acetyl transferase) activity measurements from brain regions following treatments that upregulate the wild type gene show that this short promoter fragment is sufficient for correct trans-synaptic regulation in vivo during haloperidol treatment and primary afferent stimulation. However, there was no increase in hippocampal CAT activity 2 hours following seizures. These findings support differential utilization of transcriptional regulatory elements in different trans-synaptic regulatory settings.

Modest levels of brain overexpression of the preproenkephalin cDNA were insufficient to produce significant differences in baseline or opiate-altered nociception, locomotion, or respiration. However, large increases in testes enkephalin mRNA produced significant alterations in transgenic male fertility with normal reproductive behavior.

CHARACTERIZATION OF PROENKEPHALIN HETERONUCLEAR RNA IN INDIVIDUAL NUCLEI IN THE RAT BRAIN. Martin K.-H. Schäfer*[1], Yu-Fung Lin*[2] and S.J. Watson[1], [1]Mental Health Research Institute and [2]Dep. Physiology, University of Michigan, Ann Arbor, MI 48109 USA

While in vitro transcription assays have proven to be a powerful method to assess the transcriptional activity of specific genes, their application to brain tissue has been limited. An alternative approach involves analyzing changes of steady state levels of primary RNA transcripts of specific genes, which are rapidly processed in the cell nucleus by intron splicing into mature mRNA. Using probes specific for the short-lived intervening sequences, primary RNA transcripts and processing intermediates can both be localized in tissue sections and biochemically characterized in RNase protection assays. The goal of this study has been 1) to generate the specific tools for proenkephalin (PENK) RNA transcripts 2) to examine the cellular distribution of PENK hnRNA in rat brain and 3) to establish the fundamental methodology to record rapid transcriptional changes of the PENK gene. A PENK genomic clone was isolated from a rat genomic library and DNA fragments containing either intron A or intron B sequences were subcloned into pGEM4 vectors to generate intron specific cRNA probes. Use of these intron specific ^{35}S-NTP labeled cRNA probes in an in-situ hybridization assay of frozen brain sections revealed many positively labeled neurons in various brain areas after exposure time longer than four weeks. The strongest signal occurred in striatum, in which silver grains were specifically localized over counterstained cell nuclei. These nuclei were located within PENK synthesizing neurons, as identified by labeling of adjacent sections with a PENK RNA probe specific for exon 3 of PENK mRNA. This probe yielded an identical labeling pattern, but with cytoplasmic localization of the grains. PENK hnRNA levels in brain regions of known lower abundance of PENK mRNA were below our detection limit. The existence of nuclear RNA intermediates and the splicing order of PENK hnRNA is currently being assessed in RNase protection assays. Supported by NIDA #DA02265.

REGULATION OF MOUSE GLUTAMIC ACID DECARBOXYLASE GENE(Gad-1(2))EXPRESSION IN ADULT BRAIN AND IN DEVELOPING EMBRYO. G.Szabo^, Z. Katarova*, Zs. Urban*, J. Mann#, E. Mugniani" and R.Greenspan. ^*Dept.of Biochem., BRC,Szeged P.O.Box.521, H-6701, Hungary; #Div. of Biol. Beckman Research Inst. City of Hope Med.Cent. Duatre CA 91010; " Lab. of Neuromorphology, Univ. of Connecticut, Storrs, CT 06269-4154; Dept of Neurosciences, Roche Inst. of Mol.Biol.,Nutley.,NJ 07110.

In mouse Gad-1(2) gene codes for at least two mRNA-s different in size. A 3.4 kb message is predominant in adult and codes for the 66.5kD GAD isoform. Two distinct 2.2 kb transcripts are detectable as early as embryonic day 10.5. These messages have been found to be functionally bicistronic . The late and early transcripts utilize different promoters and have multiple start sites. The adult prompter is highly rich in GC and lacks TATA and CAATboxes .The embryonic transcriptional start site is 180 bp upstream from the adult ones and its 5'-flanking region contains a TATA motif. The embryonic transcripts contain additional 80 bp and 86 bp exons as a result of alternative splicing and use a different poly-A addition signal very close to the translational stop site. In an attemt to functionally disect the regulatory region of Gad-1(2) gene we studied the beta-galactosidase expression in several transgenic lines containing different parts of the regulatory region. Detailed analysis of the expression pattern will be presented.

DIFFERENTIAL EXPRESSION OF CEREBELLIN-RELATED TRANSCRIPTS IN THE ADULT AND DEVELOPING RODENT NERVOUS SYSTEM. B. Kavety*, Y. Urade*, J. Oberdick*, R. Molinar-Rode* and J.I.Morgan. Department of Neuroscience, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

To investigate the molecular genetic basis of cell-specific gene expression in the developing nervous system a series of genes have been cloned that show differential expression in cerebellum. Previous studies have established that a hexadecapeptide, termed cerebellin, is highly enriched in cerebellum. Furthermore, a number of cerebellar mutant mice have reduced levels of cerebellin. To pursue the question of the regulation of this neuropeptide we have cloned a cDNA and the cognate gene that encode the cerebellin sequence. In Northern blot, the cDNA detects multiple, cerebellum-specific, transcripts that increase during postnatal development. Southern blot, suggested the presence of other genes related to precerebellin. A cDNA encoding a related gene, here termed pseudocerebellin, has been cloned using a PCR strategy from whole brain mRNA. The protein encoded by this sequence contains the cerebellin motif with one amino acid change. This transcript appears to be more ubiquitously expressed in the CNS than precerebellin. We are examining the 5' regulatory sequences of the two genes to determine the basis of their differential expression using transgenic mouse technology.

ISOLATION AND EXPRESSION OF *TRK* PROTO-ONCOGENE FAMILY MEMBERS. D.S. Battleman*, C. Lai, D.A. Fischman, M.V. Chao* and G. Lemke. The Department of Cell Biology and Anatomy, Cornell University Medical College, New York, New York 10021 and The Salk Institute, P.O. Box 85800, San Diego, CA 92186.

The product of the *trk* proto-oncogene is a low affinity receptor for nerve growth factor (NGF) that participates in the formation of the high affinity NGF receptor complex (Hempstead et al., Nature **350**, 678, 1991). *Trk* encodes a receptor tyrosine kinase which, together with p75 NGF receptor, is responsible for signal transduction by NGF. A direct prediction from these results is that the specificity of action of other neurotrophic factors is mediated by the expression of other *trk*-related receptor tyrosine kinases. We have utilized a PCR-generated fragment, tyro-10 (Lai and Lemke, Neuron, in press) as a probe for *trk*-related tyrosine kinases. A 1.75 kb cDNA clone was isolated from a two week rat brain cDNA library. Northern blot analysis with this isolate revealed an expression pattern distinctly different from both *trk* and *trk B*. PC12 cells displayed as many as four distinct mRNAs, ranging in size from 3.5 kb to 7.7 kb. In developing rat brain only two transcripts of 4.2 kb and 7.7 kb size could be detected, with the 4.2 kb mRNA being the most prominent. Expression of this 4.2 kb transcript appeared to increase during embryonic and early post-natal period and declined after postnatal day fourteen.

604.11

DEVELOPMENTAL REGULATION OF NCAM, N-CADHERIN AND ACETYLCHOLINE RECEPTOR mRNA LEVELS IN CHICK SKELETAL MUSCLE. J. Capasso, C.G. Hahn, M. Sasner, S. Tilney and J. Covault, Department of Physiology & Neurobiology, Univ. of CT, Storrs, CT 06269

Synaptic regulation of gene expression is thought to be an important process involved in neural development and in learning and memory. Neural regulation of muscle gene expression provides a simple system in which to study such trans-synaptic interactions. The cell adhesion molecules NCAM and N-cadherin are both down-regulated by innervation of skeletal muscle fibers during development as is the acetylcholine receptor in extrasynaptic regions of muscle. All three proteins are reexpressed at high levels in extrasynaptic regions following denervation of adult muscle. In order to identify mechanisms linking neural activation of muscle fibers with changes in the level of these proteins we have compared the time course during development of the down regulation of mRNA levels for NCAM, N-cadherin and the acetylcholine receptor alpha and delta subunits. We find that, in spite of exposure to the same neural stimulation, the timing of the decrease in mRNA levels for these four genes differs markedly . N-cadherin mRNA levels decline first, around 2-3 days following muscle fiber innervation. Levels of NCAM and acetylcholine receptor alpha subunit decline following an additional 4-5 days of development while decline in the acetylcholine receptor delta subunit is delayed until near hatching. Our results suggest that the neural regulation of these four genes either involves different second messenger pathways or different levels of a common second messenger signal. DIFFERENTIAL EXPRESSION OF THE ANDROGEN-BINDING PROTEIN GENE IN THE RAT BRAIN. Y-M. Wang, P.M. Sullivan*, and D.R. Joseph. Curriculum in Neurobiology, Departments of Pediatrics and Biology, The Laboratories for Reproductive Biology, University of North Carolina, Chapel Hill, NC 27599.

The observation that the androgen-binding protein (ABP) gene is expressed and processed differently in the rat brain (Endocrinol. 127:3124, 1990) led us to further examine its gene structure. A 20-kb fragment upstream from the testis specific exons was cloned and characterized. Three brain specific coding regions were localized on this fragment by restriction mapping and sequencing. They are approximately 15, 6.3 and 4.8-kb upstream of testicular exon 1. One kb upstream of the 5'-most exon was sequenced to locate possible promotor and regulatory regions. Analysis of the sequence shows that it is extremely G-C rich with seven GC box-like elememts. Sequences homologous with two AP2 binding sites, a GRE core sequence and an SRE were also found. Further study is underway to confirm the functional relevence of the above entities and to dissect the heterogeniety of ABP transcripts in the brain. (supported by NIH grants HD-21744 and HD-18968).

TISSUE-SPECIFIC TRANSCRIPTION OF THE RAT TYROSINE HYDROXYLASE GENE REQUIRES A SYNERGY BETWEEN AN E-BOX CONTAINING DYAD AND AN OVERLAPPING AP1 MOTIF WHICH RESPONDS TO ELEVATED LEVEL OF cAMP. Sung Ok Yoon and Dona M. Chikaraishi, Neurosci. Program, Tufts Univ. Sch. Med., Boston, MA, 02111 USA.

Tyrosine hydroxylase (TH) is the rate-limiting enzyme in catecholamine biosynthesis and is regulated in a tissue-specific manner at the transcriptional level. Using site-directed mutagenesis, we have determined that the DNA segment between -205 and -182 bp from the transcriptional start site constitutes the minimal enhancer for the tissue-specific expression of the rat TH gene in cultured pheochromocytoma cells. This segment is composed of an AP1 motif and an overlapping 20 bp dyad whose core resembles an E box consensus site (TGATTCAGAGGCAGGTGCCTGTGA). Despite the overlap, both the AP1 and the dyad elements bind proteins independently in vitro. Interaction between the two elements, however, is necessary for in vivo expression. Therefore, we conclude that the synergism between the AP1 and dyad elements is responsible for the tissue-specificity of TH. This is the first identification of a tissue-specific element in a mammalian neuronal gene, and the first known case where tissue-specificity is elicited by an obligate synergy with an AP1 motif.

Despite the 1 nucleotide difference from the consensus, the AP1 motif in TH functions as a ubiquitous activator, and mediates cAMP response upon induction with forskolin and 8-bromo cAMP. The response to elevated level of cAMP by the AP1 motif is weaker than that via the cAMP response element (CRE) located downstream at -45. Unlike other neuroendocrine genes, the CRE in TH is not essential for basal or cAMP-induced expression. The CRE in TH, however, augments the basal level of TH transcription directed by the AP1 and E-box/dyad motif.

cDNA CLONING AND mRNA DISTRIBUTION OF A NOVEL MOUSE PITUITARY HOMEOBOX-LIKE (mPHB1) PROTEIN HOMOLOGOUS TO mec-3 HOMEOBOX GENE OF C. ELEGANS.

M. Marcinkiewicz*, R. Day, M. Chrétien and N.G. Seidah*.
Clinical Research Institute of Montreal, 110 Pine Avenue Ouest, Montréal, Québec, H2W 1R7, Canada.

During our ongoing studies on the endocrine proteins expression in the pituitary, we isolated a clone containing a cDNA coding for a novel protein designated mPHB1. 1.6 kb insert was obtained from total mouse pituitary cDNA library established in pCDM8 vector. The open reading frame of the cDNA sequence codes for the last 188 amino acids, with a predicted C-terminal Cys, and the relatively long untranslated region with an AATAAA polyadenylation signal, suggesting that mPHB1 is translated into a functional protein. The alignment of the first 19 amino acids revealed that mPHB1 is highly homologous (84%) to the essential segment of the homeobox protein mec-3 found in C. elegans and also to the mouse homeobox proteins Hox 2.5; 2.9; 2.6 and 2.3.

A northern blot analysis of the total mouse RNA extracts carried out using [^{32}P]cRNA probes allowed the detection of a major 2 kb transcript in different tissues such as pituitary anterior and neurointermediate lobes. Lower levels of mRNA transcripts were found in the CNS, especially in the hypothalamus and cerebellum. Furthermore, in situ hybridization studies completed in neonatal and adult mice using [^{35}S] cRNA probes (antisense and sense) demonstrated the presence of mPHB1 transcripts within the majority of the adenohypophyseal cells and in virtually all melanotrophs of the intermediate lobe.

Based on the sequence similarity to the homeobox gene products, mPHB1 is expected to exhibit homeobox-like properties and therefore may represent a novel factor implicated in the development of particular cells within nervous and endocrine systems.

EXPRESSION OF HELIX-LOOP-HELIX TRANSCRIPTIONAL FACTOR E12/E47 HOMOLOGUES IN CHICK DEVELOPING NERVOUS SYSTEM. E.Knapik, H.O.Nornes, T.Neuman. Dept. of Anatomy & Neurobiology, Colorado State University, Fort Collins, CO 80523.

The helix-loop-helix (HLH) transcriptional factors play important roles in specifying different cell types in Drosophila neurogenesis and also in muscle differentiation of vertebrates. Using PCR and low stringency screening of cDNA libraries from chick embryonic neural tube from different stages of development, several cDNAs were isolated that have homology to the HLH region of the mouse and human E12/E47 transcriptional factor. Northern blot analyses with cloned cDNAs show expression of multiple mRNAs in the developing nervous system. Sequencing data from these clones indicate that differential splicing is involved in the generation of these transcripts. The highest level of expression was detected in early stages of development of nervous system, and the expression was weak or missing in many nonneuronal tissues at different stages. This indicates that the expression of the cloned gene is developmentally regulated. These observations further indicate that E12/E47 like transcriptional factors have a role in neuronal differentiation of vertebrates. (Funded by BRSG# 2S07RR05458-29)

THREE DIFFERENT TYPES OF NEURONS IN THE RAT MEDIAL SEPTUM (MS) NUCLEUS. M.Tsurusaki* and J.P.Gallagher. Department of Pharmacology & Toxicology, Univ. of Texas Medical Branch, Galveston, TX 77550.

The role of the MS as part of a larger nuclear complex, the medial septum/diagonal band of Broca (MS/DBB) is considered essential for the generation and/or modulation of a characteristic electrical activity recorded from the brain and termed rhythmical slow wave activity (theta rhythm). The MS is thought to receive its primary afferent input from the dorsolateral septal nucleus, and serve as the major septal efferent pathway to the hippocampus. While hippocampal neurons may be the most investigated of all mammalian CNS neurons, relatively little is known of the cellular physiology and pharmacology of MS neurons in rat. Here we report on the membrane properties of rat medial septum neurons recorded in vitro. Resting membrane potentials were -60.3 ± 4.8 mV; n = 26), while individual neuronal input resistances ranged from 36 to 216 MΩ (134 MΩ ± 45 MΩ; n = 26). Within this sample of neurons three distinct populations emerged based upon: action potential firing pattern, action potential shape and amplitude, the presence of different ionic conductances,and different synaptic responses. Following a 500 msec cathodal stimulus, one population of neurons (15%) fired action potentials separated by a rapid afterhyperpolarization and exhibited no accommodation between spikes. A second group, (55%) displayed a small slow afterhyperpolarization between spikes and an early decline in firing rate. The last group (30%) of neurons exhibited strong accommodation. Synaptic responses depended on the site of stimulation and could also be divided into three types: an IPSP; a fast EPSP followed by an IPSP; or simply an EPSP. Our data suggest that the MS contains a heterogeneous population of neurons with a complex input-output relationship. (Supported by NSF Grant #BNS 89-19549)

EFFECTS OF SEROTONIN (5-HT) ON DIAGONAL BAND NEURONS OF THE RAT *IN VITRO*. Wai Ling Lee and J.P. Gallagher, Dept. of Pharmacology & Toxicology, Univ. of Texas Medical Branch, Galveston, TX 77550

The effects of 5-HT on neurons of the vertical and horizontal limb of the diagonal band of Broca (vnDBB, hnDBB) were examined using intracellular recording from rat brain slices. Bath application of 5-HT (10-30μM) produced either a membrane hyperpolarization or depolarization. In the hnDBB, a membrane hyperpolarization, 6 ± 1.4 mV (S.E.M., n = 19) was accompanied by a reduction of input resistance, 18.8 ± 4.55% (S.E.M, n = 18). This hyperpolarization was mimicked by the 5-HT$_{1A}$ receptor agonist 8-OH-DPAT (10-30μM) or by 5-CT (1μM), and was antagonized by the 5-HT$_{1A}$ antagonist, NAN-190. 5-HT depolarized only 2 out of 25 neurons. Six neurons were studied from the vnDBB: 5 were depolarized by 5-HT; one did not respond; while no hyperpolarization was observed. Although the nDBB of the guinea pig is known to contain at least three different types of neurons (W.H. Griffith, J. Neurophysiol., 59:1590-1612, 1988), we observed no correlation between cell types and response to 5-HT in the rat.

5-HT or 8-OH-DPAT also reduced or blocked a late afterhyperpolarization which follows a train of cathodally induced spikes. Both agonists also reduced the width of an individual spike and the amplitude of its subsequent medium or slow afterhyperpolarizations; half width decreased by 7.3% and afterhyperpolarization amplitudes by 37%. Our data suggest that 5-HT has both inhibitory and excitatory effects on electrical activity within the diagonal band. (Supported by NSF #BNS 89-19549)

EFFECT OF NH_4CL ON EXCITATORY TRANSMISSION IN CA1 PYRAMIDAL NEURONS RECORDED INTRACELLULARLY. P.Fan* and J.C.Szerb, Dept.Physiol.& Biophys. Dalhousie U.Halifax,N.S. Canada B3H 4H7

We have shown that NH_4^+ blocks synaptic transmission from Schaffer collaterals to CA1 neurons without inhibiting the evoked release of glutamate, suggesting a postsynaptic block. However, NH_4^+ was only a weak inhibitor of firing induced by electrophoretic glutamate. To clear up this discrepancy, we applied 10-20 μM quisqualate (QUIS) or NMDA to slices, while the membrane current was recorded with single-electrode voltage clamp. 2-4 mM NH_4Cl induced an inward current and had opposite effects on QUIS and NMDA-induced currents: it abolished the QUIS current and greatly potentiated that of NMDA. Since transmission involves mostly QUIS receptors, block of the QUIS current explains the inhibitory effect of NH_4^+ on transmission. The action of NH_4^+ is probably due to depolarization of inadequately clamped distal dendrites, because the potentiation of the NMDA effect is not seen without Mg^{2+}. (Supported by MRC, P.F. is an MRC Fellow).

ELECTROTONIC LENGTH ESTIMATES IN NEURONS WITH SOMA SHUNT
W.R. Holmes and W. Rall, Neurobiology Program, Department of Zoological & Biomedical Sciences, Ohio University, Athens, OH 45701 and Math. Research Branch, NIDDK, NIH, Bethesda, MD 20892.

Previously (Soc. Neurosci. Abstr. 13:1517, 1987) we discussed the discrepancies to be expected when equivalent cylinder formulae are applied to neurons with soma shunting having L=1.0. Here we compare L estimates in hypothetical and real neurons with soma shunting having different L values.

Hypothetical cells were modeled as a cylinder with a soma when the L of the cylinder was 0.5, 1.0, or 1.5. Time constants were estimated from computed transients with the program DISCRETE. When L was 0.5 and soma shunting was large, the formula L_{τ_0/τ_1} overestimated L by 2-3-fold, but when L was 1.5, the overestimate was only 10-15% regardless of the size of the shunt.

L can be estimated graphically if τ_0 and R_N are known with and without soma shunting. If shunted and non-shunted values of τ_0 and R_N in a neuron with an extensive dendritic tree differ by a factor of four, and the only factor causing this difference is soma shunting, then L is approximately 0.5.

L_{τ_0/τ_1} estimates were computed for models of a motoneuron having different dendritic R_m and degrees of shunting. Estimates of τ_1 in these motoneuron models were complicated by the fact that no time constant after τ_0 had a coefficient larger than 2% of the signal. Overestimates of L by L_{τ_0/τ_1} were larger when dendritic R_m was large than when dendritic R_m was small, but the magnitude of the overestimates depended on the size of the shunt and on whether 2, 3, or 4 time constants could be resolved from the data.

In conclusion, L_{τ_0/τ_1} estimates computed for cells with soma shunting have overestimated L by a factor of 2 in electrotonically short cells but by only 0-20% in electrotonically long cells.

COMPUTER MODELS OF DENDRITIC EXCITABILITY. I. Segev* and W. Rall. Dept. Neurobiol. Hebrew Univ. Jerusalem, and Math. Res. Br., Bethesda, MD 20892.

Computer models with excitable membrane at different dendritic locations were used to gain insights into the possible functional roles of dendritic excitability. Simulations were on theoretical trees and on a reconstructed Purkinje cell from guinea-pig cerebellum. A previous report (Segev and Rall, Neurosci. Abstr. 12:726) focused on the "chain reaction" of action potential firing between clusters of excitable spines at distal dendritic branches. Here we modeled trees with many "hot spots" (on dendritic shafts and on spines). The main findings are: a) The chain reaction tends to spread distally; it fails toward the soma. b) The propagation delay of the chain reaction may be significant (tens of msecs), depending on the passive membrane time constant and on the kinetics of the excitable channels. c) Timing between different excitatory inputs distributed along the tree is critical for the degree of firing within the tree; when inputs to proximal regions are delayed (to allow for depolarization from distal inputs to reach the proximal sites), a larger part of the tree is more likely to fire than when all inputs are simultaneous. d) Inhibition is very effective in restricting the chain reaction to only parts of the tree. Strong somatic inhibition tends to block the spread of the chain reactions anywhere in the tree. The possible functional role for cellular plasticity will be discussed.

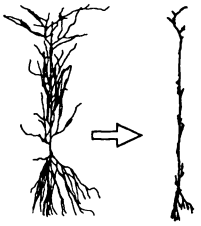
Electrotonic Transforms of Hippocampal Neurons. A.M. Zador, B. J. Claiborne,† and T.H. Brown, Dept. of Psychology, Yale University, New Haven, CT 06520 and †Div. of Life Sciences, Univ. of Texas, San Antonio, 78285.

The electrotonic structure of dendrites is of central importance to their potential for information processing. This structure has traditionally been analyzed using concepts like electrotonic distance and length, which have only limited applicability to cells with complex morphology. We present a new graphical method that provides direct insight into key aspects of a neuron's electrotonic structure. The method is based on the attenuation $A_{ij} = V_i/V_j$ of voltage from location i to j following current injection at i. Specifically, the length of each segment in an anatomically reconstructed neuron is replaced by the log-attenuation $L_{ij} = \log(A_{ij})$ across the segment, as calculated using a compartmental simulator. The log-attenuation is a generalization of the concept of electrotonic distance X to morphologically complex structures, and is identical to X in the case of an infinite or semi-infinite cylinder. Because the log-attenuation depends on the frequency and site of the input, many complementary views of a neuron emerge. We have extended this method to the attenuation of current and to temporal consequences of electrotonic structure.



The method is illustrated at the right. The neuron on the left is a 2734-compartment 3-dimensional reconstruction of a region CA1 pyramidal neuron. On its right is a representation of voltage attenuation from the soma with respect to a 100 Hz sinusoidal current. (Supported by ONR and DARPA.)

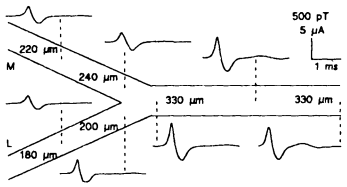
MAGNETIC CHARACTERIZATION OF ACTION CURRENTS AT THE PRIMARY BRANCH OF THE SQUID GIANT AXON. R.N. Friedman*, J.M. van Egeraat* and J.P. Wikswo, Jr. Department of Physics and Astronomy, Vanderbilt University, Nashville, TN 37235.

Magnetic field recording provides a more direct means of measuring the action currents (ACs) in active, squid (Loligo pealei) giant axons. A room-temperature biomagnetic current probe system enables study of the spatial variations of ACs by scanning a toroidal probe along the axon. This affords acquisition of nearly continuous AC profiles. We used this system to examine the currents as the action signals approach and cross the primary branch of the stellar nerve. The figure shows the result of stimulating a 2 cm axon (1 cm shown) 3 mm distal to the ligated and cut proximal end. The axon diameters are indicated. The vertical scale represents a magnetic field strength of 500 picoTesla, corresponding to a current of 5 μA. Medial (M) and lateral (L) branches were dissected to lengths of 8 and 7 mm, respectively, and ligated and cut. Branch ACs were measured 3 mm past the bifurcation. AC amplitude increased (24%) as the depolarization wave front approached the branch and decreased 48% and 57% in the M and L branches, respectively. The conduction velocity decreased at the bifurcation from 17 m/s to 12 m/s (L) and 15 m/s (M). The late, positive deflections of the ACs in the two most proximal traces are artifacts of fin nerve depolarization. We also examined the currents resulting from antidromic stimulation.



This work was supported by a Grass Foundation fellowship to JMvE and NIH grant NS-19794.

605.8

EFFECT OF QX314 ON SOMATIC AND DENDRITIC ACTION POTENTIALS IN HIPPOCAMPAL CA1 CELLS.
S.B.COLLING*, E.W.STOCKLEY* and H.V.WHEAL.
Department of Physiology and Pharmacology, Southampton University, Southampton, SO9 3TU, UK.

Hippocampal CA1 pyramidal cells *in vitro* can be excited via stimulation of afferent fibres to the proximal and distal apical dendrites (Andersen, Storm & Wheal, 1987, J.Physiol. **383** pp.509-526). The local anaesthetic QX314 (35 mM) was injected intracellularly, and it's effects on the proximally and distally evoked synaptic responses were monitored over time. The proximally evoked action potential (AP) was totally blocked after 57±10 minutes (n=5), whereas the distally evoked AP was present up to 88±14 minutes (n=5). The excitatory postsynaptic potentials were still present after this time. In control recordings there appears to be a pre-AP component which contributes to the threshold event. This component also appears to be sensitive to QX314.

The data suggests that there is more than one triggering site for AP's in pyramidal cells and that these sites are spatially separate. The shapes of the synaptic potentials as well as their generation from these sites can be explained by the electrical properties of these cells. A compartmental cable model was used to confirm the idea that the proximally evoked AP may be triggered at either the soma or the initial segment, whereas the distally evoked somatic AP may be triggered by a dendritic spike which appears as a prepotential at the soma.

Supported by MRC and Wellcome Trust grants. The QX314 was donated by Astra Pain Control, Södertälje, Sweden.

DEPOLARIZATION-DEPENDENT STIMULATION OF POLYRIBOSOME LOADING IN SYNAPTONEUROSOMES. J.J. Weiler, W. I. Davenport, W. T. Greenough, Depts. Psychol. and Cell & Struct. Biol, Neurosci. Prog, and Beckman Inst., Univ. Illinois, Urbana-Champaign, IL 61801.

The polyribosomal aggregates observed within or at the bases of dendritic spines have suggested that some proteins, produced quickly under localized control, might contribute to synaptic plasticity. Protein synthesis has been demonstrated in synaptosome preparations by several groups. We added a depolarizing dose (40 mM) of K+ to synaptoneurosome preparations, on ice in the presence of cycloheximide. By measuring the fraction of total RNA trapped in polyribosomes at intervals (1',2',5',10',20') we were able to observe that ribosomes and some pre-formed protein rapidly associate with mRNA; this was verified by centrifugation on a continuous sucrose density gradient. Ribosomal loading peaks at 2-5 minutes and then declines. Incorporation of labelled methionine into TCA-precipitable polypeptides is transiently accelerated.

Calcium chelators reduce the steady-state size of polyribosomal complexes, but do not eliminate the response to depolarization, suggesting that there is mobilization of intracellular Ca++ stores. We suggest that depolarization-related changes may affect binding and release of translation initiation complexes with messenger RNA found near synaptic junctions. Such rapid, local protein synthesis may have implications for synaptic efficacy change.

EFFECTS OF SOMATOSTATIN ON POTASSIUM CURRENTS IN BULLFROG SYMPATHETIC GANGLION NEURONS. D.E.Kurenny*, H.Chen* and P.A.Smith. Dept. of Pharmacology, Univ. of Alberta, Edmonton, Canada.

Somatostatin (SS) increases M-current (I_M; Moore *et al.*, Science **239**, 278, 1988) in hippocampus whereas in submucous plexus, it activates an inwardly-rectifying K^+-current (I_{AIR}; Tatsumi *et al.*, J. Neurosci. **10**, 1675, 1990). Since both types of current are well characterized in amphibian sympathetic ganglia (Selyanko *et al.*, J. Physiol., **425**, 471, 1990), we used the whole-cell patch-clamp technique to examine the effects of cyclic SS (cSS) and whole SS (wSS) on isolated bullfrog paravertebral ganglia neurons. In small cells, where muscarine activated I_{AIR}, wSS (1-2 μM, 2/7 cells) sometimes activated I_{AIR} whereas cSS (1-5 μM, 8/8 cells) was ineffective. cSS was effective in modulation of I_M in the large cells in which muscarine inhibited I_M. An initial suppression of I_M by 24% was followed by a 13% potentiation (12/23 cells). Both effects were associated with shifts of the I_M activation curve. Occasionally, monophasic responses were seen: I_M suppression (6/23 and 4/23 cells for wSS and cSS, respectively) or I_M potentiation (1/23 and 2/23 cells). This implies that receptor subtypes are involved in the multiple actions of SS in this tissue (Wang *et al.*, Proc. Natl. Acad. Sci. **86**, 9616, 1989). Supported by the Canadian MRC.

THERMAL DEPENDENCE OF ACTION POTENTIALS AND AFTERHYPERPOLARIZATIONS IN RAT HIPPOCAMPAL CA1 PYRAMIDAL CELLS AT 20°C TO 25°C. M.P. Thomas* and J.M. Horowitz, Animal Physiol., Univ. Calif. Davis, CA 95616.

Previous studies over the range of 37°C to 27°C suggested that different channels have different temperature sensitivities (e.g., Thompson et al., J. Neurosci. 5:817, 1985). The intent of this study was to extend consideration of thermal effects to a lower range of temperature. Conventional intracellular recording and current injection techniques were used to elicit spike trains in CA1 pyramidal cells at 20°C to 25°C. We measured the amplitude and duration of the following slow afterhyperpolarization (sAHP). The normalized duration of the sAHP (measured at 50% of peak height) was 750 ± 301 msec/mV. The duration of single spikes (measured at 50% of peak height) was 2.3 ± 0.2 msec, and the interspike interval (measured between the first and second spikes) was 13.5 ± 1.5 msec. The duration of the sAHP is greatly extended at 25°C compared with durations measured at 37°C, an increase of approximately 750%. In contrast, the width of single action potentials did not increase as markedly as the sAHP. Data indicate that different ionic currents can have markedly different thermal sensitivities and that the sensitivity of the Ca^{2+}-activated potassium current responsible for the sAHP may reflect greatly altered calcium metabolism at low temperatures. Supported by NSF Grant BNS-88-19973.

ETHOSUXIMIDE BLOCKS CHOLINERGIC RHYTHMICAL SLOW ACTIVITY (THETA) IN CA1 REGION OF HIPPOCAMPAL SLICE. D.D. Fraser and B.A. MacVicar Neuroscience Research Group, Department of Medical Physiology, University of Calgary, Alberta, Canada T2N 4N1.

Neuronal activity resembling rhythmical slow activity (theta) can be generated by perfusion of carbachol (CCH), a non-hydrolyzable cholinergic agonist, on isolated hippocampal slices. Each burst of theta consists of 4-10 Hz oscillatory depolarizations with a rise time much slower than conventional EPSPs (MacVicar and Tse, J. Physiol. 417:197, 1989). The presence of low-threshold Ca^{2+} spikes imparts the possibility of rhythmic burst discharge patterns in neurons at a theta frequency. In the CA1 region, CCH enhances a low-threshold Ca^{2+} current in isolated lacunosum-moleculare interneurons (Fraser and MacVicar, J. Neurosci., in press, 1991). We hypothesize that CCH enhancement of a low-threshold Ca^{2+} current could underlie theta generation. Ethosuximide, an anticonvulsant used in the treatment of petit mal epilepsy, has been shown to attenuate low threshold Ca^{2+} currents at clinically relevant concentrations (Coulter et al., Ann. Neurol. 25:582, 1989). Therefore, we have examined the action of ethosuximide on CCH-induced theta in the CA1 region of rat hippocampus.

Intracellular recordings were obtained from the CA1 neurons in hippocampal slices to determine the sensitivity of CCH-induced theta to ethosuximide (700 μM). Perfusion of 50 μM CCH produced 4-10 Hz oscillatory depolarizations with amplitudes of 12-16 mV. Theta oscillations occurred repetitively for periods of several seconds separated by 20-40 seconds of quiescence. This pattern was stable in some cells for greater than one hour in the continued presence of CCH. Co-perfusion of ethosuximide reversibly blocked CCH-induced theta without altering resting potential or input resistance. The results from this study support our hypothesis that a low-threshold Ca^{2+} current underlies the generation of theta in the hippocampus. (Supported by the MRC of Canada)

CALCIUM CHANNELS: PHYSIOLOGY AND PHARMACOLOGY IV

606.1

CALCIUM INDUCED CALCIUM RELEASE CONTRIBUTES TO THE STIMULATED RISE OF INTRACELLULAR CALCIUM IN SYMPATHETIC NEURONS. D.A. Przywara, S.V. Bhave, A.S. Bhave*, T.D. Wakade* & A.R. Wakade. Dept. of Pharmacology, Wayne State Univ. School of Medicine, Detroit, MI 48201.

We have shown that Ca^{2+} influx into sympathetic neurons causes a greater increase in free Ca^{2+} concentration ($[Ca^{2+}]_i$) in the nucleus than in the cytosol (Przywara et al., FASEB J. 5:217, 1991). In the present work we examined the mechanism underlying this pattern of Ca^{2+} distribution. Ca^{2+} imaging revealed a similar Ca^{2+} distribution regardless of the stimulus used to elevate $[Ca^{2+}]_i$. The differential increase in nuclear $[Ca^{2+}]_i$ was apparent when Ca^{2+} entered neurons during depolarization by excess K^+ or electrical stimulation, during receptor activation by acetylcholine or by application of ionophore. The same pattern of Ca^{2+} distribution resulted from caffeine-induced Ca^{2+} release from internal stores. It is well known that Ba^{2+} passes through Ca^{2+} channels and may "substitute" for Ca^{2+} in stimulating transmitter release. When neurons were stimulated in Ca^{2+}-free medium containing 2.5 mM Ba^{2+} a significant increase in $[Ca^{2+}]_i$ occurred. The greatest $[Ca^{2+}]_i$ was in the nucleus. These results indicate that Ba^{2+} is able to induce Ca^{2+} release from internal sites. We conclude that the similar pattern of Ca^{2+} distribution produced by the various stimuli is due to Ca^{2+} induced Ca^{2+} release following the initial rise in $[Ca^{2+}]_i$.

PEROXIDE INDUCED DECREASE OF I_{Ca} IN LOBSTER NEURONS; REGULATION BY $[Ca]_i$? R.S. Hernandez, R.J. Lowy, D.A. Miller, D.R. Livengood. Physiology Department, AFRRI, Bethesda, MD 20889-5145.

Previously we reported that H_2O_2 blocked calcium currents (I_{Ca}) in neurons of the lobster cardiac ganglion. We proposed that an increase in $[Ca]_i$ could be responsible (Biop. J. 53: 555a, 1988). To test this hypothesis, FURA-2 (free acid pentapotassium salt) was pressure injected into Neurons #1 or #2 of the ganglion, which were ligated and bathed in control lobster saline at 18°C. Fluorescence changes were quantified using a low-light-level video microscope and image processing system. Perfusion with 3.5 mM H_2O_2 saline for 30 min. failed to alter the $[Ca]_i$ signal from control values in either soma or dendritic components of the neuron. The dye responded to 100 mM KCl saline exposure, with a large reversible increase in the $[Ca]_i$ signal. In vitro exposure of Fura-2 acid to hydroxyl free radical generating conditions failed to alter the amount or Kd of the dye. To determine if FURA-2 was chelating internal Ca and thereby preventing the Ca-dependent I_{Ca} block, FURA-2 was pressure injected into neurons and electrophysiological measurements taken using a 2-electrode voltage clamp. FURA-loaded cells were found to respond similarly to non-loaded cells except, the Ca-mediated outward K currents displayed a small time-dependent decrease in amplitude. This may have indicated the chelating of internal Ca by FURA-2. Thus the H_2O_2 induced block appeared to be independent of $[Ca]_i$. However, when cells were depolarized by clamping them to -20 mV for 20 min., the inward I_{Ca}, was also blocked. This electrical depolarization block mimicked the block caused by H_2O_2. Therefore one of two possibilities exists: 1) The H_2O_2-induced block is not calcium mediated and what we have described is an epi-phenomenon; both H_2O_2 and depolarization independently produce the same results. 2) or: calcium mediated calcium block occurs, but the change in $[Ca]_i$ that produced the block is so small and/or localized that it is not measured with FURA-2.

THAPSIGARGIN STIMULATES CALCIUM INFLUX IN NEURONS.
W.C. Moore*, H.M. Hargrove* and J. Patel. Department of Pharmacology, ICI Americas, Inc., Wilmington, DE 19897.

Using the neuronal tumor cell line SK-N-SH, we demonstrate that receptor-mediated activation of phosphoinositide hydrolysis not only causes the release of Ca^{++} from intracellular stores but also causes a concomitant influx of Ca^{++} from the extracellular space. Treatment of fura-2 loaded cells with 1μM thapsigargin (TG) in the presence of extracellular Ca^{++} causes a depletion of the inositol 1,4,5-trisphosphate-sensitive intracellular Ca^{++} stores and a sustained elevation of intracellular Ca^{++} concentration ($[Ca^{++}]_i$). In the absence of extracellular Ca^{++}, TG produces only a transient increase in $[Ca^{++}]_i$. These data suggest that TG activates both the release of intracellular Ca^{++} and the influx of extracellular Ca^{++}. This supports the proposal that the depletion of the inositol 1,4,5-trisphosphate-sensitive intracellular Ca^{++} pool initiates extracellular Ca^{++} influx.

606.4

ACTIVATION OF RYANODINE-SENSITIVE CALCIUM RELEASE BY THE IP_3-FORMING AGONIST HISTAMINE IN BOVINE ADRENAL CHROMAFFIN CELLS.
K. A. Stauderman and M. M. Murawsky. Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

Histamine stimulation of bovine adrenal chromaffin cells leads to the release of Ca^{2+} from internal stores. Since histamine also stimulates the formation of inositol 1,4,5-trisphosphate (IP_3), Ca^{2+} release is believed to result from activation of IP_3 receptors located on IP_3-sensitive organelles. The possible involvement of additional Ca^{2+} releasing mechanisms on other organelles was suggested by the recent observation that caffeine-sensitive, IP_3-insensitive, Ca^{2+} pools are also discharged during histamine treatment. To see if histamine might be activating a caffeine-sensitive Ca^{2+}-induced Ca^{2+}-release (CICR) mechanism, we tested the effects of ryanodine, an inhibitor of CICR in muscle, on repetitive histamine- or caffeine-induced Ca^{2+} spikes in single cells loaded with fura-2. The presence of a ryanodine-sensitive mechanism was demonstrated by both use-dependent inhibition of repetitive 10 mM caffeine-induced Ca^{2+} spikes by 10 μM ryanodine, and high-affinity binding of [^{3}H]ryanodine to cell membranes (Kd 3.3 nM). Most importantly, repetitive 10 μM histamine-induced Ca^{2+} spikes were also inhibited by ryanodine in a use-dependent manner, implicating the involvement of CICR. These data are consistent with the suggestion that Ca^{2+} released from IP_3-sensitive stores serves to activate CICR from caffeine-sensitive stores via the ryanodine-receptor.

606.5

PHARMACOLOGY OF INOSITOL 1,4,5-TRISPHOSPHATE (IP_3) SENSITIVE CALCIUM INFLUX (ISCI) IN *XENOPUS* OOCYTES.
H. J. Taub*, S. C. Sealfon, S. Mundamattom*, B. Gillo. Fishberg Center in Neurobiology, Mount Sinai School of Medicine, New York, NY 10029.

Xenopus oocytes injected with IP_3 develop an increase in the plasmalemma permeability to calcium ions. Increases in $[Ca]_i$ were assayed via activation of the oocyte's native Ca-sensitive Cl channel. When oocytes were loaded with > 5pmol IP_3 and kept in Ca-free solution, the increase in Ca membrane permeability lasted for more than 1h. We studied the pharmacology of this response in order to explore the mechanism involved in ISCI. The ISCI was not sensitive to organic voltage-sensitive calcium channels (VSCC) modulators (Bay K, nifedipine, verapamil, MK 801) and exhibited low sensitivity to inorganic VSCC blockers (Cd, Ni, La,). ISCI was not affected by agents that modulate Na/Ca cotransport (amiloride, Na/Li substitution, Na/NMG substitution). Lowering the extracellular pH to 6.5 or applying the protonphore (FCCP) completely blocked the ISCI. Application of the Ca-ATPase blocker vanadate did not affect this current. However, addition of the H-ATPase blocker (NBD-Cl) potentiated this current and at high concentrations enhanced Ca entry by itself. The pharmacology may suggest that H/Ca exchange (possibly as part of the H-ATPase complex) contributes to ISCI.

606.6

EVALUATION OF VOLTAGE- AND Ca^{++}-DEPENDENT MECHANISMS IN THE INACTIVATION OF THE Ca^{++} CURRENT IN HELIX NEURONES.
I.M.Stanford* and J.E.Chad, Dept. of Physiology and Pharmacology, Univ.of Southampton, SO9 3TU, UK.

The inactivation kinetics of the whole cell Ca^{++} current measured in isolated Helix neurones has been widely interpreted as due to separate Ca^{++}- and voltage-dependent processes, however the relative contributions of these processes are less widely agreed. We have attempted to separate the two processes by manipulation of the intracellular buffering agents (10mM) and extracellular divalents (50mM). Experiments were conducted on isolated dialysed, whole cell patch clamped neurones, using conditions designed to isolate the divalent current through Ca^{++} channels. Inactivation produced by a 50ms prepulse 100ms before a test pulse generating maximum inward current, and inactivation within single 200ms pulses to different membrane potentials were measured. In the prepulse experiments, maximal inactivation was obtained with Ca^{++} as charge carrier and no added buffering (values given as mean ±SD, n>=5; 0.23 ±0.06), reduced inactivation was obtained with Ba^{++} and EGTA (0.1 ±0.03), and Ba^{++}/BAPTA further reducted inactivation. Even under these conditions, the inactivation was not monotonic with regard to prepulse voltage. The inactivations of currents during single 200ms test pulses were tested with a series of BAPTA analogues, showing a dependence related to the Ca^{++} K_D of the buffer. Dimethyl-BAPTA (K_D 40nM) permitted less inactivation (ICa^{++} 0.32 ±0.03; IBa^{++} 0.18 ±0.04) than was observed with 4,4' difluoro-BAPTA (K_D 2450nM; ICa^{++} 0.57 ±0.09; IBa^{++} 0.30 ±0.07), for both Ca^{++} and Ba^{++}. Thus either Ba^{++} can produce some divalent dependent inactivation itself, or acts via an elevation in intracellular Ca^{++}, due to contamination or displacement from buffers. Cautioning against the assumption that inactivation kinetics with Ba^{++} and less stringent buffering conditions reflect voltage-dependent inactivation alone.

GADOLINIUM SELECTIVELY BLOCKS Ca++ INFLUX THROUGH VOLTAGE-OPERATED CALCIUM CHANNELS IN CENTRAL NERVE ENDINGS.
L.M.T.Canzoniero, A.M.Rossi*, A.Fatatis, G.F.Di Renzo* and L.Annunziato# Sect. of Pharmacology Dept of Human Communcation Sciences 2nd Sch.Med. Univ. Naples "Federico II", Naples and Chieti#, ITALY

The pharmacological modulation of Ca++ entrance in cerebral nerve endings is still a matter of debate and there is a lack of suitable agents which potently and selectively block Voltage-Operated Ca++ Channels. Ca++ influx in Percoll-purified rat brain synaptosomes was investigated either through the measurement of cytosolic Ca++ levels, monitored by Fura-2 or by the evaluation of the "fast phase" of 55mM K+-elicited 45Ca++ influx. The trivalent rare earth lanthanide, Gadolinium (Gd+++) (1-1000uM) dose-dependently counteracted the increase of[Ca++]i induced by 35mM K+ . Gd+++ (1-30 uM) also inhibited the "fast phase" of 45Ca++ influx induced by 55mM K+ . Among the organic Ca++ entry blockers, dihydropiridines were completely ineffective, whereas the phenilalkylamine Verapamil (100 and 300uM) and the aminoglycoside Neomycin (300 and 1000uM) prevented [Ca++]i elevation and 45Ca++ "fast phase " influx only at elevated concentrations. These results suggest that Gd+++ is a suitable tool to selectively block Ca++ influx in cerebral nerve endings.(Supported by C.N.R. and M.U.R.S.T. 883416 Grants to L.A.)

ZINC (Zn^{2+}) BLOCKS VOLTAGE GATED CALCIUM CHANNELS IN CULTURED RAT DORSAL ROOT GANGLION CELLS.
D. Büsselberg, M.L. Evans, D.O. Carpenter, and H.L. Haas. Institute für Physiologie der Heinrich-Heine Universität Düsseldorf, D-4000 Düsseldorf, FRG, SmithKline Beecham, Harlow, Essex CM19 5AD, UK, and NYS Dept. of Health and School of Public Health, Albany, NY 12201-0509, USA.

Dorsal root ganglion cells (DRGs) exhibit three types of voltage-dependent calcium channels. We have cultured DRGs from 2 to 4 day old rat pups and obtained whole cell patch clamp recordings of calcium channel currents after 1 to 5 days in culture. These currents, carried by barium cations, were recorded in the following external solution: TEA Cl 135 mM, HEPES 10 mM, glucose 10 mM, $BaCl_2$ 10 mM, $MgCl_2$ 1 mM, TTX 0.002 mM. A cesium based internal solution containing 2 mM ATP was used in the recording pipette. The divalent cation zinc (Zn^{2+}) blocked sustained and transient voltage sensitive calcium channel currents of cultured rat dorsal root ganglion cells. The IC_{50} for inhibition of the total peak current evoked by a step depolarization from -80 mV to 0 mV for 100 ms was 35 μM. The current evoked by a voltage step from -80 mV to -30 mV (T-type current) was more sensitive (>80% block with 20 μM Zn^{2+}). During wash the effect was only partly reversible. Thus Zn^{2+} is a potent blocker of all three types of voltage dependent calcium currents in mammalian neurons, but shows some specificity for the T channel.

DIVALENT IONS FROM STAINLESS STEEL HYPODERMIC NEEDLES REDUCE NEURONAL CALCIUM CURRENTS.

S.C. Nam and P. E. Hockberger. Dept. of Physiology, Northwestern Univ. Medical School, Chicago, IL 60611.

Stainless steel hypodermic needles are widely used in both biomedical research and in patient care because they are purportedly non-toxic and corrosion-resistant. The most common type of stainless steel (#304) is formed primarily with Fe, Ni and Cr, although other elements may be present depending upon the manufacturer's raw materials and processing steps. We have compared nickel- and chrome-plated stainless steel needles from several manufacturers on their ability to affect voltage-dependent Ca currents in isolated chick (E13-E16) DRG neurons and rat (P7-P13) cerebellar Purkinje cells. Our protocol involved allowing external saline (in mM: choline-Cl, 120; $CaCl_2$, 5; $MgCl_2$, 2; HEPES, 10; pH 7.3) to sit in needles for various durations of time (20s-1hr), and then analyzing Ca currents during local application of the test salines. Salines exposed to needles with brass hubs, but not those with plastic hubs, for 20s reduced currents by 30±10%. Longer exposures resulted in proportionately greater reductions. These reductions were recorded immediately upon saline application and were completely reversible. Elemental analysis of the test salines using ICP-AE spectroscopy revealed that Cu and Zn (but not Cd, Cr, Co, Fe, Pb, Mn or Ni) were released from brazed needles. The amount of Cu+Zn released in 20s was estimated to be 10-30μM, depending upon the specific needle examined. Longer exposures produced higher concentrations. Application of 100μM $CuSO_4$ in external saline reduced Ca currents in both cell types by 65±15% (n=6), whereas 100μM $ZnSO_4$ reduced currents by 20±5% (n=6). These results indicate that Cu (and possibly Zn) ions released from stainless steel needles with brass hubs can reduce neuronal Ca currents.

This research was supported by NIH grants #NS-26915 and NS-17489. ICP-AE spectroscopy was perfomed by Saman Shafaie, Chemistry Dept., Northwestern University, Evanston, IL.

PURKINJE CELL CALCIUM CURRENTS: ARE THEY UNIQUE?

P.E. Hockberger and S.C. Nam. Dept. of Physiology, Northwestern Univ. Medical School, Chicago, IL 60611.

Voltage-dependent calcium currents are distinguished by differences in biophysical and pharmacological properties. At last year's meeting we reported that calcium currents in isolated rat (P7-P13) cerebellar Purkinje cells (PCs) were sensitive to dihydropyridines and Ω-conotoxin, as is the case for many other nerve cell types. Those results were obtained using salines exposed to stainless steel needles possessing brass hubs, and were consequently confounded by the presence of interfering divalent ions (cf. Nam and Hockberger, these abstracts). We have therefore reinvestigated the actions of dihydropyridines and Ω-conotoxin on these cells, as well as on isolated chick (E13-E16) DRG neurons. Using local application of drugs via micropipet, we have found that high-threshold currents in both cell types were insensitive to 10μM nifedipine (dissolved in ethanol or acetone), 10μM nimodipine (in ethanol or polyethyleneglycol), and 10μM BayK8644 (in ethanol). This was the case regardless of the holding potential (between -100 and -40mV), although current inactivation increased progressively at holding potentials positive to -80mV in both cell types. In contrast to the effects of dihydropyridines, 10μM Ω-conotoxin irreversibly reduced DRG calcium currents by 90±5% within seconds. PC currents, on the other hand, were reduced 20±5%, and this effect was reversible. The sensitivities to divalent ions and diacylglycerol analogs (e.g., OAG) also differed between cell types. PC currents were uniformly more sensitive to Ni, Cu, and Zn than DRG cells (cf. Nam and Hockberger, these abstracts). However, DRG currents were more sensitive to OAG being reduced 50±5% by 25μM while PC currents were unaffected by this concentration of drug. Thus, upon reevaluation, we have found several differences in the pharmacological properties of calcium currents in rat PCs and chick DRG cells. These results support the notion that calcium currents in PCs, as well as chick DRG cells, are different from dihydropyridine-sensitive cell types.

LEAD IONS (Pb^{2+}) PERMEATE THROUGH CALCIUM CHANNELS.

J.L.Tomsig and J.B.Suszkiw. Dept. of Physiol. and Biophys. Univ. of Cincinnati Sch. of Med. Cincinnati, OH 45267

Neurotoxic properties of lead are associated with the entry and intracellular interaction of Pb^{2+} ions with Ca^{2+}-mediated cell functions. In this study we have employed Fura-2 to monitor Pb^{2+}entry into isolated, bovine chromaffin cells exposed to low (micromolar) concentrations of PB^{2+} in basal or depolarizing, high-K^+ media. In basal media, the accumulation of Pb^{2+} in chromaffin cells was a linear function of $[Pb^{2+}]_{out}$, indicating passive leakage. Exposure of cells to high K^+ stimulated the entry of Pb^{2+} from 2-8-fold as a function of $[K^+]_{out}$. The depolarization-stimulated Pb^{2+} entry was further enhanced by calcium channel agonist Bay K 8644 and blocked by channel antagonist nifedipine, suggesting the involvement of L-type channels. In contrast to fura-2-monitored $[Ca^{2+}]_{in}$ transients in K^+-stimulated cells, the increase in $[Pb^{2+}]_{in}$ was sustained over a period of minutes, suggesting lesser rate of channel inactivation and/or saturaton of lead-buffering capacity of the cell cytosol.

PATTERNS OF SECRETION ELICITED BY CA^{2+} vs. BA^{2+} IN ISOLATED RAT NERVE TERMINALS.

Elizabeth P. Seward and Martha C. Nowycky. Med. Coll. Penn., Philadelphia, PA 19129

Peptide secretion from neurohypophysial terminals isolated from the rat neurohypophysis (NHP) is triggered by Ca^{2+}-entry through voltage-dependent Ca^{2+}-channels. Exocytosis may be measured with whole terminal patch clamp techniques as changes in membrane capacitance (C), presumably resulting from fusion of secretory vesicles with the plasma membrane. It has been shown previously that the magnitude of the C jumps associated with Ca^{2+}-entry are influenced by the pattern of stimulation used, with repetitive depolarization producing 'facilitation' (Lim *et al.* 1990, Nature **344**, 449).

In isolated NHP terminals, 5 step depolarizations (46ms duration, 280ms interval; 10mM $[Ca^{2+}]_o$) elicited large C jumps. Despite Ca^{2+} -channel inactivation, in 60% of these terminals (n=15) the amplitude of the C jumps initially increased for successive pulses, usually peaking at the third pulse (Fig. a). With 10mM $[Ba^{2+}]_o$, the inward Ca^{2+}-channel current was increased. A striking difference between Ca^{2+}-triggered and Ba^{2+} -triggered exocytosis was that much larger depolarizations were necessary for the latter and the C jumps were small, of fairly uniform amplitude, and did not show 'facilitation' (Fig. b). This data suggests that Ba^{2+} may support peptide secretion, although with lower affinity than Ca^{2+} , and does not induce 'facilitation'.

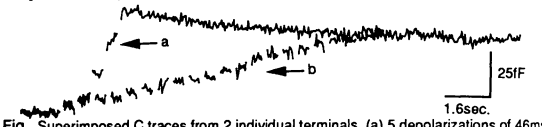

Fig. Superimposed C traces from 2 individual terminals, (a) 5 depolarizations of 46ms duration in 10mM $[Ca^{2+}]_o$, (b) 20 depolarizations of 72ms duration in 10mM $[Ba^{2+}]_o$.

606.13

CALCIUM MOBILIZATION AND TRANSMITTER RELEASE IN SYMPATHETIC NEURONAL GROWTH CONES.

P.S. Chowdhury, A.S. Bhave*, T.D. Wakade*, S.V. Bhave, D.A. Przywara, R. Skoff & A.R. Wakade. Dept. of Pharmacology, Wayne State Univ. School of Medicine, Detroit, MI 48201.

An equal number of stimulus pulses applied at increasing frequency is known to increase release of norepinephrine (NE) in neuroeffector organs. Kirpekar et al. (Naunyn-Schmiedeberg's Arch. Pharmac. 287:205, 1975) proposed that greater influx of Ca^{2+} may occur at high frequency. This idea was tested by measuring cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) in growth cones in cultured sympathetic neurons (SN). Release of [^{3}H]NE increased from $0.49x10^{-2}$ to $3.35x10^{-2}$ when 150 pulses were delivered at 1 and 10 Hz, respectively. The net increase (stimulated - basal) in $[Ca^{2+}]_i$ at 1 Hz was 230 nM and at 10 Hz 310 nM. The rate of rise in $[Ca^{2+}]_i$ at 10 Hz was much faster than at 1 Hz. Continuous stimulation of SN at 1 Hz for 3 min resulted in a sustained increase in $[Ca^{2+}]_i$ and [^{3}H]NE release. At 10 Hz there was a faster and greater sustained rise in $[Ca^{2+}]_i$ and [^{3}H]NE release. 55 mM K^+ caused a sharp rise in $[Ca^{2+}]_i$ and [^{3}H]NE release but both parameters rapidly declined during 3 min exposure to excess K^+. We conclude that net increase and rate of increase of $[Ca^{2+}]_i$ determine [^{3}H]NE release at different frequencies. We also show that sustained depolarization (excess K^+) inactivates Ca^{2+} entry and [^{3}H]NE release while high frequency stimulation maintains the release.

EFFECTS OF TEMPERATURE ON CALCIUM CURRENT OF BULLFROG SYMPATHETIC NEURONS.

E. van Lunteren, K.S. Elmslie and S.W. Jones. Departments of Medicine, Physiology and Biophysics, and Neurosciences, Case Western Reserve University, Cleveland, OH 44106.

The present study assessed the effects of temperature on the magnitude and kinetics of voltage-activated calcium current in dissociated frog sympathetic neurons. Calcium current increased with increasing temperature, peak current being ~1.5 to 2 fold greater at 30°C compared to 20°C. Estimates of the magnitude of the effects of temperature on peak current amplitude were complicated by the considerably faster run-down of current at high compared to low temperatures. Activation and deactivation kinetics became slightly faster over time during current run-down, but were substantially faster at high compared to low temperatures. The time constant of activation (over a range of -30 to 20 mV) was 4 to 7 times larger at 20°C compared to 30°C (eg. 4.18 ± 0.75 vs. 0.61 ± 0.10 msec at -10mV; mean ± SD; n=6), whereas the time constant of deactivation (over a range of -70 to -20 mV) was 1.5 to 4 times larger at 20°C compared to 30°C (eg. 1.42 ± 0.14 vs. 0.56 ± 0.07 msec at -40mV; n=5). Current inactivation was tested during a short depolarization to -10 mV following either a longer (0.2 to 2 second) prepulse of -10 mV or no prepulse. The reduction of current following the -10 mV prepulse compared to no prepulse was 1.8 to 2.3 fold greater at 30°C than at 20°C (eg. 47.3 ± 4.5 vs. 25.0 ± 8.4% reduction following a 2 second prepulse; n=6). Furthermore, the rate of inactivation became faster over time and with current run-down. These findings confirm the importance of temperature as a major determinant of the magnitude and kinetics of calcium currents.

CALCIUM TRANSIENTS IN INDIVIDUAL SCHWANN CELLS UPON NERVE STIMULATION V. Lev-Ram and M. H. Ellisman. San Diego Microscopy and Imaging Resource, Department of Neurosciences, University of California, San Diego, La Jolla, Calif.92093-0608.

Our working hypothesis for nodal function incorporates the idea that the axon/glial cell ensemble plays an active role in the physiology of impulse conduction. This study was designed to expand on previous observations indicating active participation of the Schwann cell in the functioning of the node of Ranvier. In order to evaluate the potential role of Ca in nodal activation we developed a system for *in vitro* studies that combines simultaneous optical and electrophysiological recording of single fibers.

Frog sciatic nerve was dissected and loaded with the membrane permeable Ca indicator fluo3-AM. Action potentials of single fibers were recorded with a fine suction microelectrode. These active fibers were followed to observe healthy looking active nodes of Ranvier after they entered a bundle of surrounding fibers. The Ca transients in the ensheathing Schwann cell were then recorded using a laser-scanning confocal microscope system. The fluo3 staining was observed only in the Schwann cells and did not stain the axoplasm. This is probably due to physical barriers associated with the structure of the node of Ranvier in the PNS. Upon stimulation, an increase in intracellular [Ca]i concentration was observed in the paranodal region and other cytoplasmic pockets of the ensheathing Schwann cells. Calcium transients were observed in the single fibers monitored with the microelectrode as well as in Schwann cells of surrounding fibers. These other fibers were presumably also ensheathing electrically activated nerve fibers.

Fibers were also observed after the stimulation was halted. The [Ca]i continued to increase briefly after the cessation of long and rapid stimulation. After a recovery to near prestimulation levels, repeated stimulation of shorter duration produced a fast increase in [Ca]i, which decreased more rapidly after cessation stimulation. This observation is interpreted to indicate that the Schwann cells response was not damaged by the initial long periods of stimulation. The physiological basis for these Ca transients will be investigated further.

606.16

INVESTIGATION OF FAST EXTRACELLULAR CA^{2+} TRANSIENTS IN GUINEA-PIG HIPPOCAMPAL SLICES USING LOW IMPEDANCE ION SENSITIVE ELECTRODES. J.C. Behrends*, E. Ujec*‡ and G. ten Bruggencate. Dept. Physiol., Univ. of Munich, Germany and ‡ Dept. Physiol., Čechoslovak Acad. Sci., Prague, ČSFR. Spon: EBBS.

The measurement of changes in extracellular free $[Ca^{2+}]$ ($[Ca]_e$) using ion-sensitive microelectrodes (ISMs) has been useful in studying activity-related movements of Ca^{2+}-ions implicated in synaptic plasticity, epileptogenesis and excitotoxicity. Recordings with conventional ISMs, however, show very limited time resolution and signal to noise ratio due to high electrode resistance (1-50 GΩ). Using low impedance (100-500 MΩ) ISMs with a concentric, double barrelled ion-sensitive channel and an effective exchanger column length of 20-50 μm, we were able to record fast decreases in $[Ca]_e$ during single epileptiform interictal burst discharges ($\Delta[Ca]_e$=50-100 μM, time to peak=200-300 ms) in the guinea-pig hippocampus in vitro.

Further, these fast-responding ISMs enable repetitive (1/30 s) and stable recordings of $[Ca]_e$-decreases in response to short (0.5 s) ionophoretic application of glutamatergic agonists ($\Delta[Ca]_e$=100-400 μM), greatly facilitating pharmacological studies. N-methyl-D-aspartate- (NMDA-) receptor antagonists reduced glutamate-induced $[Ca]_e$-decreases in stratum radiatum of the CA1 subfield without affecting the associated field potentials, whereas perfusion with Mg^{2+}-free solution potentiated the $[Ca]_e$-signal. Ionophoresis of the non-NMDA-receptor agonist quisqualate produced smaller decreases in $[Ca]_e$ which on recovery showed a characteristic overshoot.

In summary, this is the first report of the use of fast-responding ISMs in brain slices. Using this technique, it is possible to pharmacologically determine the contribution of different glutamate receptor mechanisms and/or voltage-dependent Ca^{2+}-channels to Ca^{2+}-fluxes during neuronal activity.

EFFECTS OF ISOFLURANE ON CALCIUM CURRENTS RECORDED BY THE WHOLE-CELL PATCH CLAMP TECHNIQUE IN NEOCORTICAL SLICES. B. Hutcheon, E. Puil and P.B. Reiner. Dept. of Pharmacology and Therapeutics, Dept. of Anaesthesia, and Dept. of Psychiatry. Univ. of British Columbia. Vancouver, Canada. V6T 1Z3.

Rat sensory-motor cortical neurons were voltage-clamped using whole-cell patch clamp techniques in an *in vitro* slice preparation. Calcium currents were isolated by the extracellular application of 4-aminopyridine, tetraethylammonium, cesium, and tetrodotoxin. Patch pipettes contained 2 mM ATP; $[Ca^{++}]$ in the pipette was buffered to 10 nM. High-threshold (-30 to -10 mV) inward currents were evoked by depolarizing pulses from holding potentials near -80 and -40 mV. The evoked Ca^{++} currents were completely blocked by 3% isoflurane applied in the bathing solution. Lower concentrations of isoflurane reduced the peak amplitude, slowed the onset, and raised the threshold of activation of the Ca^{++} currents. The depressant effects were seen within 1-2 minutes after beginning isoflurane application (flow rate >2 ml/min), and recovered within 1-2 minutes. The present studies reveal that isoflurane may depress neuronal excitability by blocking a high-voltage activated Ca^{++} current.

CHRONIC DEPOLARIZATION ELEVATES INTRACELLULAR CALCIUM LEVELS IN CULTURED RAT MYENTERIC NEURONS. D.J. Fickbohm[1] and A.L. Willard[1,2]. Curric. in Neurobiology[1] and Dept. of Physiology[2], Univ. of North Carolina, Chapel Hill, NC 27599-7545.

We have been studying the effects of chronic depolarization on survival and development of rat myenteric neurons in cell culture. Previously, we found that growth in medium containing elevated potassium (25 mM), which depolarizes these neurons to a mean resting membrane potential of -40 mV, alters their development in several ways: it enhances survival, it increases neuronal size, and it suppresses voltage-dependent Ca currents. Here, we report that chronic depolarization causes persistent elevation of intracellular Ca ($[Ca]_i$) and that dihydropyridine (DHP) antagonists prevent this increase.

Myenteric neurons dissociated from intestines of 2-3 d old rat pups were grown in cell culture for 3-6 d in medium containing control (5 mM) or elevated (25 mM) KCl. $[Ca]_i$ was estimated by Indo-1 and fura-2. Although the 2 dyes gave different estimates of $[Ca]_i$, both methods revealed significantly higher $[Ca]_i$ in depolarized neurons. The DHPs nitrendipine and nifedipine (5 μM) prevented or reduced the effects of elevated potassium. The estimated values of $[Ca]_i$ depended critically on the method of calibration. "In situ" calibration (using ionophores) yielded values roughly half those estimated with "in vitro" calibrations, possibly due to vigorous intracellular Ca buffering mechanisms reducing the apparent R_{MAX}. With in vitro calibration, estimated $[Ca]_i$ was 337 ± 9 nM (Indo) or 187 ± 12 nM (fura) for depolarized neurons and 196 ± 5 nM (Indo) or 126 ± 9 nM (fura) for control neurons (all n's ≈ 100).

These results support the hypothesis that persistent elevation of $[Ca]_i$ is a mechanism by which chronic depolarization alters the development of myenteric neurons in culture.

CHARACTERIZATION OF A PANCREATIC BETA CELL LINE FROM TRANSGENIC MICE. R.E. Hice, C. Katnik*, L. Philipson*, D.F. Steiner*, and D.J. Nelson*. Depts. of Medicine & Neurology, and the Howard Hughes Institute, University of Chicago. Chicago, IL 60637.

We have examined insulin secretion, voltage-gated ionic conductances, and cellular Ca^{2+} levels in βTC3 cells. βTC3 cells are a nonclonal cell line derived from insulinomas of mice carrying hybrid genes of an insulin promotor and SV 40 (T) antigen, described by Efrat, *et al.* (*PNAS* 85:9037,1988). Perifusion experiments have established that our cultures retain the ability to secrete insulin in response to 5 mM glucose (16-18 hr preincubation in 1 mM glucose). Under normal ionic conditions, voltage-dependent ionic conductances are predominated by outward K^+ currents (typically > 1 nA during depolarizations to 60 mV). A transient Na^+ current was also present, but was largely masked by the outward currents. Outward currents were substantially reduced, but not fully blocked when external Na^+ was replaced by TEA^+ (140 mM). Net inward Ca^{2+} currents were not observed at room temperature (ca. 22°C) with 140 TEA in the external solution but were observed in some cells under identical ionic conditions when the temperature was elevated to 30°C. However, the cells fire action potentials in response to glucose (10 mM) at room temperature. FURA-2 fluorescence (340:380 ratio) was used to monitor changes in cell Ca^{2+} levels in response to glucose. Glucose (20 mM) induced a biphasic change in cellular Ca^{2+} levels. Glucose rapidly (52 ± 10 sec, n=5 @ 27°C) caused a transient lowering (ca. 10% ratio decrease) of $[Ca^{2+}]_i$. The initial decrease in $[Ca^{2+}]_i$ was followed (253 ± 170 sec, n=5 @ 27°C) by a sustained increase comparable in magnitude to the increase in $[Ca^{2+}]_i$ elicited by 25 mM K^+ (ca. 2-fold increase in ratio 340:380). Both responses were also present at 22°C.

Supported by NIH DK20595-13 (DJN).

PHARMACOLOGICAL CHARACTERIZATION OF K^+-INDUCED Ca^{2+} FLUX INTO RAT NEOCORTICAL PRISMS. J.J. Geer and D.J. Dooley. Parke-Davis Research Division, Warner-Lambert Company, Ann Arbor, MI 48105.

$^{45}Ca^{2+}$ flux into 100μm x 100μm prisms of adult rat neocortex was measured at 25°C in HEPES/Tris buffered HBSS (137mM Na^+, 3mM K^+, 1.25mM $Ca2^{2+}$) and also under conditions where K^+ was substituted for Na^+ up to 100mM K^+. After 30s incubation, elevated K^+ induced a 3-fold increase in Ca^{2+} flux over basal conditions which was half maximal at 25mM, and reached a plateau at 50mM K^+. The time course for 30mM K^+-stimulated flux showed a rapid rise in Ca^{2+} from 1-30s followed by a plateau between 30-100s. A 60s pre-depolarization in 30mM K^+ buffer containing zero Ca^{2+} did not affect the time course for Ca^{2+} flux, suggesting that the relevant Ca^{2+} channels are of the non-inactivating type.

K^+(30mM)-induced Ca^{2+} flux was unaffected by TTX(1μM), the NMDA antagonists CPP(100μM) and MK-801(10μM), and the non-NMDA antagonist NBQX(100μM). Divalent cations inhibited Ca^{2+} flux with a rank potency order of Cd^{2+} > Ni^{2+} > Co^{2+}. The following rank potency order, with IC_{50}s ranging from 20-500μM, was seen with various classes of Ca^{2+} channel antagonists: verapamil > nimodipine > nifedipine > dextromethorphan > diltiazem > neomycin. ω-Conotoxin GVIA(1μM) was inactive. These relatively high IC_{50} values and the inactivity of ω-conotoxin GVIA do not correlate well with classic Ca^{2+} channel pharmacology, suggesting the possibility of a novel Ca^{2+} channel subtype.

INTRACELLULAR CHANNELS: THE VOLTAGE-DEPENDENT ANION CHANNEL (VDAC) OF RAT BRAIN MITOCHONDRIA: CHARACTERIZATION AND IMMUNOHISTOCHEMICAL LOCALIZATION. M.W. McEnery, T.M. Dawson, A. Verma, and S.H. Snyder, Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205

The voltage-dependent anion channel (VDAC) is a 32 kDa protein that has been localized to the outer membrane of mitochondria. VDAC has been shown by other investigators to function as: 1) an anion channel, 2) a non-specific pore through which many solutes may pass to gain assess to the mitochondrial inner membrane, and 3) an intracellular receptor for cytoplasmic kinases, such as hexokinase. Rat brain VDAC has been purified by conventional procedures and this protein cross-reacts with an anti-kidney VDAC antiserum. Immunohistochemically, VDAC is shown to be very heterogeneous. While the localization is primarily to glia, specific neurons were positively identified with the anti-VDAC antiserum. The glomerular layer of olfactory bulb, thalmus, caudate putamen, supraoptic nuclei, pontine nuclei, CA4 region of the hippocampus (glia and pyramidal cells), deep cerebellar nuclei, cell bodies and dendrites of Purkinje cells were the regions most intensely stained. These regions were also the most intensely stained with histochemical stains for mitochondrial enzymes: cytochrome oxidase, monoamine oxidase, and succinate dehydrogenase. VDAC localization is thus coincident with the regions of greatest mitochondrial density in rat brain. These results demonstrate heterogeneous mitochondrial populations in glia and neurons.

Secretory Vesicle-Specific Channels from the Neurohypophysis. K.E. Krebs, S.H. Goldberg*, and G. Ehrenstein*. Lab. of Biophysics, NINDS, National Institutes of Health, Bethesda, MD 20892.

Two distinct populations of secretory vesicle are present in nerve terminals in the bovine neurohypophysis: 100-300 nm diameter neurosecretory granules (NSG) that contain peptide neurohormones, and 40-60 nm microvesicles (MV) of unknown function that are biochemically related to small synaptic vesicles of presynaptic nerve terminals. We now report that these two classes of neurohypophysis vesicle contain distinct ion permeable channels. NSG and MV from bovine neurohypophysis were prepared by differential centrifugation, followed by separation on a 3000 Å controlled pore glass bead column, to yield highly purified vesicles on the basis of size. Purified NSG or MV were added to the *cis* side of painted lipid bilayers (80% PE/20% PC). Fusion of NSG with the bilayer resulted in the incorporation of a calcium-dependent (peak open probability of 80% at 300 nM Ca^{2+}), imperfectly selective chloride-permeable channel (>150 pS) that was blocked with 400 μM DIDS. In contrast, the fusion of MV with the bilayer resulted in the incorporation of a potassium-permeable channel (>100 pS) that appeared to be similar to channels identified in small synaptic vesicles purified from presynaptic nerve terminals of bovine brain.

MEMBRANE CAPACITANCE CHANGES ARE CORRELATED WITH $[CAMP]_I$ AND ACTIVATION OF CL^- CONDUCTANCE. **Sarah S. Garber, Cystic Fibrosis Res. Ctr., Neurobiology Res. Ctr., and Dept. Physiol. & Biophys., Univ. Alabama, Birmingham, Birmingham, AL 35294.**

I have used the whole-cell (w/c) patch clamp technique to simultaneously monitor changes membrane capacitance (C_m) and activation of Cl^- conductance (g_{Cl}) in the colonic cell line, T84. An EPC-9 amplifier was used to assess a possible relationship between vesicle fusion events stimulated by $[cAMP]_i$ and Cl^- conductance. C_m and R_{series} were determined by analyzing the RC decay of the membrane current in response to a series of voltage pulses. When recording in (mM) NaCl 155, $MgCl_2$ 2, $CaCl_2$ 1, Hepes 10 (bath) and Cs glutamate 130, $MgCl_2$ 2, Hepes 10, ATP 2, GTP 0.2 with $[Ca^{++}]_i$ buffered to $\leq 10^{-8}$ M with EGTA (pipet), 0/12 cells showed an increase in C_m, while g_{Cl} was activated in 9/12 cells. In contrast, when 100 μM $[cAMP]_i$ was included in the pipet solution, C_m increased in 5/8 cells and g_{Cl} was activated in 7/8 cells. Increases in C_m ranged from 0.5-4.0 pF, or ~10-20% of cell membrane area. No cells (n=6; 100 μM $[cAMP]_i$) showed a change in C_m when 50-100 μM DIDS was added to the bath to block Cl^- conductance. Recordings made in Na glutamate (bath) and K^+ or Cs glutamate 100 μM $[cAMP]_i$ (internal) also prevented increases in C_m (12/13 cells). These observations suggest that activation of g_{Cl} alone is insufficient to stimulate an increase in C_m, but is required for cAMP-dependent fusion of vesicles to the plasma membrane.

EFFECTS OF RECOMBINANT HUMAN TUMOR NECROSIS FACTORα ON CHLORIDE CHANNELS IN HUMAN NEUTROPHILS. M. A. Schumann and T. A. Raffin*. Division of Pulmonary and Critical Care Medicine, Stanford University School of Medicine, Stanford, CA 94305.

Tumor necrosis factor α is a cytokine with stimulatory effects on neutrophil functions such as phagocytosis, degranulation, and respiratory burst activity. To date, little is known about the intracellular pathways of cytokine signal transduction in neutrophils. By means of whole-cell, voltage-clamp recording we studied the effects of the recombinant human tumor necrosis factor α (rhTNFα) on macroscopic chloride currents in human neutrophils freshly isolated utilizing Ficoll-Hypaque density gradient centrifugation. To separate chloride currents, *N*-methyl-D-glucamine and choline were used as major cations and glutamate and chloride as major anions in pipette and bath solutions. Internal calcium ions were buffered at 10 nM. Bath application of the rhTNFα (0.01 μM), induced an increase (172.2±s.e.m 6.8%, n=9) in the amplitude of the outward chloride currents within 1 minute of exposure. Due to an ensuing desensitization, there was a time-dependent recovery toward the control level of current amplitude. Some cells did not respond (n=3) or responded with a minor increase in current amplitude (n=4), while others (n=2) exhibited a slight reduction in current amplitude. Phorbol 12-myristate 13-acetate (PMA; 0.1 μM) augmented the outward chloride currents within 1 minute (n=6). There was also an observed variability in response among cells. In the presence of PMA (0.1 μM), bath application of the rhTNFα (0.01 μM) did not result in an additive or a synergistic response of current enhancement. There was an insignificant increase (compared to control) in the amplitude of the current in the presence of both rhTNFα and PMA (n=14). This observation might be explained by a resultant cross desensitization between the two agents. These data suggest that protein kinase C activation may play a role in TNFα signal transduction in some human neutrophils.

Effects of monosialoganglioside GM1 on rat hippocampal CA1 pyramidal cells. P. Miu and K. Krnjević. Anaesthesia Research Dept., McGill University, Montréal, Québec, Canada, H3G 1Y6.

When recorded with CsCl-filled electrodes, and superfused with ACSF (at 33°) containing TTX (1 μM), TEA (10 mM), Cs (4 mM), and 4-AP (100 μM), pyramidal cells consistently responded to exogenous monosialoganglioside GM1 with an increase in the leak conductance (G_L) and an inward shift in the holding current (I_H) *(Agopyan et al, 1990, Soc. Neurosci. Abstr., 16:623)*.

Under identical condition (V_H = -40 mV) but recording with Cs acetate-filled electrodes, 4 out of 6 CA1 pyramidal cells responded to 1 μM GM1 application with a reduction in G_L by 7.9 ± 2.1 % (n = 5; $p < 0.025$, 1 tail t-test), and a slight outward shift in I_H (0.007 ± 0.007 nA; n = 7; N.S., 2 tail t-test). As observed previously, 1 μM GM1 reduced the high threshold calcium currents by 39.3 ± 6.5 % (n = 5; $p < 0.005$, 1 tail t-test). However, the GM1-induced reduction in the high threshold calcium currents could be reversed by 1 mM kynurenic acid.

In conclusion, the present findings suggest that a) GM1 may activate chloride conductance, and b) GM1 facilitates TTX-insensitive glutamate release as shown by the enhanced excitatory postsynaptic currents *(Miu and Krnjević, 1990, CJPP, 21:261)*. The potentiated glutamate release would increase the intraneuronal Ca^{2+} concentration, and thereby trigger Ca^{2+}-dependent Ca^{2+} inactivation *(Eckert and Chad, 1984, Prog. Biophys. Molec. Biol., 44:215)*, thus explaining the reduction in high threshold calcium currents.

Ca SUPPRESSED NONGATED CATION CONDUCTANCE IN NEURONS. F.N. Quandt. Dept. of Physiology and Multiple Sclerosis Research Center. Rush University, Chicago, IL 60612

The properties of the resting conductance were studied using patch clamp techniques applied to N1E-115 neuroblastoma cells. Current across a patch of membrane was recorded in response to depolarization from a holding potential of -50 with successive 10 mV voltage steps through +50 mV. The current-voltage relationship exhibited outward rectification when measured without contributions from channels which generate current jumps due to opening and closing. In an excised membrane with NaCl, 3 mM Ca external solution, and Kglutamate EGTA internal solution, the slope conductance was 10 pS for a 10 mV step from -50 to -40 mV, 100 pS for a step between -10 to 0 mV, and 600 pS for a voltage step from +40 to +50 mV. The nonlinear current was not associated with the seal between the pipette glass and the membrane since outward rectification could be recorded from an attached patch when depolarized in the whole cell mode using an independent electrode. The Q10 for the slope conductance between 0 and +50 mV was found to be 6.0. The conductance pathway was permeable to K, Na and Cs, but not N-methyl-D-glucamine (NMG). The conductance was controlled by external Ca through a voltage dependent block, since the current amplitude was increased and the current-voltage relationship became linear as Ca was reduced below 3 mM. The reversal potential with internal K and external Na was not a function of external Ca. However, the reversal potential for inward rectification recorded in internal NMG and external Na became more positive potential when external Ca was reduced. Depolarization of the membrane in low Ca could be eliminated by substituting external Na with NMG. Internal Ba blocked the conductance and also caused a voltage and time dependent membrane depolarization. Supported by the National Multiple Sclerosis Society.

TETRAETHYLAMMONIUM (TEA) AND RELATED QUATERNARY AMMONIUM IONS BLOCK CHLORIDE CHANNELS IN CEREBRAL CORTICAL NEURONS. D.Y. Sanchez and A.L. Blatz, Physiology Department, UT Southwestern Medical Ctr., Dallas, TX 75235-9040

TEA and other symmetric quaternary ammonium ions (QAs) are commonly used to block potassium channels. We have found that QAs also block current through fast chloride channels in rat cerebral cortex. Symmetric QAs with alkyl chain lengths of 1 - 6 carbons were studied using excised, inside-out membrane patches with either external or internal blocker. Unlike TEA, which reduced single channel conductance, longer chain QAs reduced mean open duration with no effect on conductance. QAs blocked current through these channels in a voltage-dependent manner when applied externally. Internal block was less dependent on voltage. The Figure shows mean open duration with 0.5 mM external blocker (currents filtered at 3kHz, -3dB) and demonstrates that, similar to internal QA block of K channels, the larger blocking ions have higher affinity for the channel (lower K_D). Increased concentration of blocker decreases open duration suggesting that the blocker binds the channel's open state. Supported by NIH grants HL07360 & GM39731.

Expression of glycine receptor subunits in higher brain regions. J. Kuhse*, A. Kuryatov*, Y. Maulet*, M.L. Malosio*, H.Betz Max-Planck-Institut für Hirnforschung, Deutschordenstaße 46, D-6000 Frankfurt 1, Germany

The postsynaptic glycine receptor (GlyR) is a ligand-gated chloride channel protein which mediates inhibition of neuronal activity in the vertebrate central nervous system. Two different subunits of 48 kD (α) and 58 kD (ß) were identified that form a pentameric receptor. Immunological and molecular cloning data have disclosed heterogeneity of GlyR α subunits during development. In the CNS of rat, α1, α2, α2* and α3 subunit genes are expressed.

We have used molecular cloning of cDNA and genomic sequences to demonstrate the expression of alternative splicing products of the α2 transcript (α2 A and α2B). Furthermore, we have compared the expression of these mRNAs with that of other GlyR mRNAs in various regions of the rat CNS using *in situ* hybridisation techniques. The α2A, α2B and α2 * mRNAs are expressed in spinal cord and various brain regions and are down-regulated during development. In contrast, ß subunit mRNA is expressed throughout the CNS at very high levels, suggesting the existence of additional α subunit genes.

INCREASED CYTOPLASMIC CHLORIDE CAUSES GLYCINE-ACTIVATED CHLORIDE CHANNELS TO SHIFT TO LOWER PERMEABILITY OPEN STATES. A. I. McNiven* and A. R. Martin. Dept. of Physiology, Univ. of Colorado Sch. of Med., Denver, CO 80262.

Outside-out membrane patches were pulled from mouse spinal cord cells maintained in culture for 2 - 4 weeks. Single channel activity was produced by application of glycine to the outer surface of the patch at a concentration of 10 uM. The extracellular (bath) chloride concentration, $[Cl]_o$, was maintained at 157 mM. With a cytoplasmic (electrode) concentration, $[Cl]_i$, of 7 mM, channels activated by glycine had chord conductances at zero membrane potential of 26 pS, 19 pS and 13 pS. A few openings at 33 and 47 pS were also observed. The equivalent permeabilities and relative number of occurrences of the major open states were 14 (41%), 10 (23%) and 7 (20%) x 10^{-14} cm^3/sec, respectively. With increased chloride in the electrode ($[Cl]_i$ = 20 mM), similar permeability states were observed, but with different distributions: 14 (13%), 10 (54%) and 7 (23%) x 10^{-14} cm^3/sec. The remaining openings were to a still smaller permeability of 4 x 10^{-14} cm^3/sec (10%). Thus it appears that one effect of increased $[Cl]_i$ is to shift the preferred channel openings to lower permeability states. (Supported by N.I.H. Grant #NS09660.)

TETRAHYDROCANNABINOL RAISES BASAL AND GABA-MEDIATED SYNAPTONEUROSOME 36-CHLORIDE ION INFLUX. D.T.Shirac and B.E. Morton, Dept. Biochem-Biophys, Univ. Hawaii Sch. of Med., Honolulu, HI 96822.

(-)-Delta-9-tetrahydrocannabinol (THC) is the major psychoactive compound present in marijuana (Cannabis savita). In humans THC alters nausea, pain, anxiety, muscle tension, and memory. Many of these effects are similar to those produced by benzodiazepines, barbiturates, and alcohol which act on the chloride channel regulated by the gamma aminobutyric acid (GABA) type A receptor. Here, we examined the effect of THC on the GABA chloride channel complex.

Synaptoneurosomes were prepared from rat whole brain and 36-chloride ion (36-Cl) influx was assayed, using a slightly modified version of a standard procedure (Harris, R.A. and Allan, A.M., Science 228, 1108, 1985). Basal 36-Cl influx was enhanced 8-45% (average, 22%) when 0.1-1.0 mM THC was present in a colloidal suspension with 3%, w/v, polyvinyl-pyrrolidone-40.

When the effects of GABA on basal 36-Cl influx were examined, half maximal stimulation was found at 15 uM GABA with a maximum being reached by 100 uM at which point influx was at least doubled. In the presence of 1 mM THC, there was a leftward shift of GABA stimulation so that it was enhanced by at least 20% for both 3 and 10 uM GABA, falling off at 30 uM GABA, so that by the 100 uM maxima, no increase was produced. Generally similar results were observed with muscimol. These effects suggest THC released endogenous GABA.

600 uM Picrotoxin, or 100 uM of the GABA-A antagonist, bicuculline, reduced both GABA-muscimol and THC induced chloride increases to basal levels. 100 uM Baclofen or 100 uM 2-hydroxysaclofen, GABA-B ligands, were ineffective, as was 10 mM caffeine.

THC appears not to compete directly with the chloride channel complex receptors. It is proposed that THC binds the newly identified cannabinoid receptor, whose distribution parallels that of the GABA-A receptor, to somehow mobilize endogenous GABA. This opens the chloride channel to produce THC behavior.

607.11

DUAL EFFECT OF GABA ON NEUROSECRETORY CELLS OF CRAYFISH. García, U., *Onetti, C., Valdiosera, R., and Aréchiga H. Depto. de Fisiología, Biofísica y Neurociencias, CINVESTAV 07000 México, DF *CUIB Univ.de Colima, 2800 Colima,México.

GABA has been known for long as an inhibitory neurotrans mitter. There are evidences of its role as a transmitter in medulla terminalis X-organ cells or crustaceans. (Aréchi ga, H., García, U. and Martínez Millán, L. in Frontiers in Crustacean Neurobiology K. Wiese et al Eds. Birkhauser, 1990 pp 373).

In isolated eyestalks of adult crayfishes, the effect of GABA was tested while recording from X-organ cells either with microelectrodes or with whole-cell voltage clamp. Spontaneous activity of single X-organ cells varies from a silent mode with a -65 mV M.P. to a tonic or bursting activity at -45 -50 mV. Pulses of GABA resulted in depolarization and firing of spikes in hyperpolarized cells, and in a slow hyperpolarization and arrest of spontaneous firing in depolarized cells. These responses were blocked by picrotoxin (50 uM). In whole-cell voltage clamp, GABA responses were dependent on the chloride gradient. These results suggest that chloride equilibrium potential in X-organ neurons determines wheather GABA acts as excitatory or inhibitory transmitter.

SINGLE CHANNEL CURRENTS INDUCED BY PALYTOXIN IN NEUROBLASTOMA CELLS. S.Y. Kim*, C.H. Wu and L Beress*. Dept. of Pharmacology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Palytoxin is a potent marine toxin isolated from corals of the genus Palythoa. We have shown previously that palytoxin forms ouabain sensitive ion channels in frog red blood cells (Rana pipiens) and neuroblastoma cells (N1E-115). Palytoxin-induced channels had a single channel conductance of 10 pS, were permeable to small cations, did not inactivate, and were inhibited by ouabain. Antagonism by ouabain suggested that palytoxin acted through the Na,K-ATPase to form ion channels. At present, we are examining a substate of the palytoxin-induced channel in the neuroblastoma cell. Palytoxin-induced currents, from cell-attached patches, frequently stepped down to an amplitude about 30% of the full amplitude. In most cases, the channels initially opened to the full amplitude, then converted to the smaller amplitude for a short duration, then returned to the fully open state. Less commonly, channels opened directly to the substate from the closed state. The conductance of the substate at the resting potential was similar to that of the fully open state. The reversal potential of the substate was significantly more negative than that of the fully open state, indicating a different ion selectivity. These characteristics of the substate suggest the presence of complex dynamics within the palytoxin-induced channel.

PALYTOXIN ACTIONS ON LONGITUDINAL SMOOTH MUSCLE FROM GUINEA PIG ILEUM. R. E. Sheridan and S. S. Deshpande*. Neurotoxicology Branch, U. S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD 21010.

Palytoxin (PTX) is a potent vasoconstrictor and cytotoxin isolated from marine coelenterates of the genus *Palythoa*. The precise mechanism of the toxin action is not clear but has been attributed to increased cation conductance in the plasma membrane of affected cells. We have investigated the actions of PTX on intact and dissociated longitudinal smooth muscle from guinea pig ileum.

PTX at 1 to 10 nM produced a rapid contraction in strips of longitudinal muscle. These contractions were, at most, about 50% of the maximal contracture produced by 45 mM K^+ in the same tissue. This initial peak contraction was followed over a period of minutes by a gradual relaxation of the tissue. Subsequent applications of similar toxin concentrations after this relaxation failed to elicit a further response, suggesting a form of desensitization. The contractions induced by PTX were dependent on external calcium and could be reversed by 1μM verapamil, a Ca^{++} channel antagonist.

In isolated muscles under whole cell patch clamp, PTX in the range of 1 to 10 nM induced a substantial (3 to 5 fold) increase in the resting conductance of the muscle fibers. The conductance increase was associated with a positive shift in the reversal potential and could be blocked by complete replacement of extracellular Na^+ with TEA^+, suggesting an increase in sodium and possibly potassium permeability. Like the contractile effects in muscle strips, this PTX-induced conductance was not relieved by extensive washing with toxin-free solutions. Further, even after washes with toxin-free TEA^+ solution that blocked the PTX effects, return to control saline revealed the PTX-induced conductance. At high doses, the conductance increase produced by PTX declined to a plateau, similar to the desensitization-like decrease in tension seen in muscle strips.

ION CHANNELS: MODULATION AND REGULATION IV

608.1

CO-FACTOR(S) FROM RAT BRAIN MODULATES THE GATING MODES OF SKELETAL MUSCLE (μ1) AND BRAIN (RIIa) VOLTAGE-SENSITIVE Na CHANNELS

J.F. Potts, J. Zhou, M. Hollmann*, J.S. Trimmer#, S.A. Tomiko, S. Heinemann*, F.J. Sigworth & W.S. Agnew Dept. of Cellular & Molecular Physiology and Program in Neuroscience, Yale School of Medicine, New Haven, CT 06510, *Molecular Neurobiology Laboratory, The Salk Institute, La Jolla, Calif. 92037, #Dept. of Cellular Biology & Biochemistry, SUNY at Stony Brook, Stony Brook, NY 11794.

Recent studies (Zhou, J. *et al.*, Biophys. J. (1990) and manuscript submitted) demonstrate that Na channels expressed in *Xenopus* oocytes from skeletal muscle μ1 cRNA exhibit fast and slow inactivating current components; single channel analysis reveals that individual channels may interconvert between any of several gating modes with distinct activation, inactivation and slow-inactivation properties. Co-expression of μ1 α-subunits with mRNA from rat brain or skeletal muscle, but not liver, results in a single, rapidly inactivating current component, but single channel studies reveal individual channels displaying the same gating modes present with μ1 α-subunit alone. The factor evidently modulates the time spent in each mode. cRNA transcribed from a subfraction of a rat brain expression library (RTB1; Hollmann *et al.*, Nature, 1989), by itself, fails to elicit Na currents. Co-expression with μ1 cRNA, however, results in a shift to rapidly inactivating gating modes. Precisely similar modulation is observed with Na channels expressed from rat brain RIIa α-subunit cDNA, demonstrating the co-factor(s) to be capable of modulating various Na channel isoforms.

608.2

PANCURONIUM AFFECTS Na^+ CURRENT IN CHICK EMBRYO SENSORY NEURONS. V.Magnelli*, M.Nobile*, E.Maestrone*, and C.Usai. Ist. di Cibernetica e Biofisica CNR, Genova, Italy and Ospedale Civile di Sondrio, Italy.

The interaction of pancuronium with Na^+ currents was investigated, by using whole cell patch-clamp technique, in dorsal root ganglion sensory neurons of chick embryo. The above agent is a largely employed neuromuscular blocking drug. After Ca^{++} and K^+ currents suppression, external bath application of pancuronium 10^{-4} M to 10^{-3} M caused a reversible reduction of Na^+ current amplitude. At $5*10^{-3}$ M, steady-state inhibition was reached in 5 seconds and complete recovery occurred within 20 seconds after washing. The amplitude reduction appeared to be voltage and concentration dependent, whereas the time course of the activation and inactivation of the Na^+ current was unalterated by the drug. These data suggest that the well known mechanism of action of pancuronium (competitive inhibition of NachR), may be potentiated by the additional block of Na^+ conductance.

608.3

THE TIME COURSE OF THE LOSS OF A SODIUM CURRENT IN ASCIDIAN EGGS IS ASSOCIATED WITH CELL CYCLE EVENTS. J.L.Coombs* and W.J.Moody. University of Washington, Seattle, WA 98195.

The densities of many ion currents in eggs are strictly regulated over time in conjunction with specific developmental events. The eggs of the ascidian, Boltenia villosa, have a voltage-dependent, TTX-insensitive sodium current that is known to disappear after fertilization, becoming barely detectable by the two cell stage. The sodium current is responsible for the fast, rising phase of the long lasting action potential which these eggs can produce. There are other currents in these eggs whose densities in the membrane do not change, and a chloride current that appears at each meiotic and mitotic cell division once the egg has been fertilized. We studied the loss of the sodium current in these eggs over time and found that this current is largest in the immature oocyte (the growing oocyte that is arrested in the first meiotic metaphase) and begins its decline around the time of egg maturation (when the nuclear envelope breaks down and the egg is ready to be fertilized). This loss continues after maturation and during the two hours between fertilization and the first mitotic cleavage. However, the decline is arrested transiently during times when the chloride current appears.

TEMPERATURE DEPENDENCE OF LIMITATION OF SRF BY MK-801. A.W. Wamil and M.J. McLean. Dept. of Neurology, Vanderbilt Univ. Med. Ctr., Nashville, TN 37212

Anticonvulsant compounds, including MK-801, which protect against maximal electroshock seizures in animals limited sustained repetitive firing (SRF) of intracellularly recorded sodium-dependent action potentials cultured mammalian neurons. We studied the effect of temperature on the limitation by MK-801 of SRF of mouse spinal cord neurons in cell culture. Limitation occurred between 10^{-9} and 10^{-6} M (EC_{50} $1.5x10^{-7}$ M) at 37°C; between 10^{-8} and 10^{-3} M at 32°C (bimodal distribution); and, between $5x10^{-7}$ and 10^{-2} M at 23°C (EC_{50} about 10^{-6} M). Thus, temperature changes altered concentration-dependence of limitation of SRF and could explain the high concentrations of MK-801 needed to see effects on I_{Na} in patch clamp experiments.

TEMPERATURE DEPENDENCE OF MAGNETIC FIELD EFFECTS ON SUBTYPES OF SENSORY NEURONS IN VITRO. R.R. Holcomb, A.W. Wamil, J.D. Pickett* and M.J. McLean. Dept. of Neurology, Vanderbilt Univ. Med. Ctr., Nashville, TN 37212

Dorsal root ganglion neurons (DRGn) in cell culture were classified by waveform of intracellularly recorded action potentials (APs; SD: duration <2 msec; LD: duration >2 msec). Current pulses (1 msec; 1 Hz) elicited firing in neurons with SD or LD AP waveform repeatedly with rare failures. During exposure at 37°C to a static magnetic field produced by an array of four permanent magnets of alternating polarity, the number of stimuli failing to elicit APs increased significantly and APs of both types were completely blocked in many neurons. At 32°C, SD APs failed, but less frequently than at 37°C; LD APs were not affected. No effect of the field was seen on SD APs at 23°C. Modulation of magnetic field effects on functional subtypes of DRGn with temperature may have implications in the treatment of neuropathic pain.

ATP-DEPENDENT RUN-DOWN OF $GABA_A$ RECEPTOR FUNCTION DURING WHOLE-CELL RECORDING IS STIMULATED BY PENTOBARBITAL. M. Gyenes*, T.T. Gibbs and D.H. Farb. Department of Pharmacology and Experimental Therapeutics, Boston University School of Medicine, Boston, MA 02118.

We have recently shown, using whole cell recording from chick spinal cord neurons in primary monolayer cell culture, that the currents evoked by 30 μM GABA progressively run down by about 60% within 30 min. This is accompanied by an acceleration of desensitization. Surprisingly, the response to 3 μM GABA remains stable, even after run-down of the response to 30 μM GABA. Inclusion of ATP or ATPγS in the recording pipet reduces the extent of GABA-induced run-down.

In the presence of 100 μM pentobarbital, the response to GABA is potentiated such that the peak current evoked by 3 μM GABA is comparable to that elicited by 30 μM GABA in the absence of pentobarbital (2.5 nA). The pentobarbital-potentiated GABA response exhibits rapid run-down and acceleration of desensitization, as is seen with 30 μM, but not 3 μM, GABA in the absence of pentobarbital. In this case as well, ATPγS effectively prevents both the run-down and the acceleration of desensitization.

Run-down of the 30 μM GABA response and inhibition of run-down by ATPγS occur also in isolated outside-out patches demonstrating that these phenomena are not contingent upon the organization of the intact nerve cell. As in whole cell recordings, the 3 μM GABA responses remain stable.

INHIBITION OF HYPERPOLARIZATION-ACTIVATED CURRENT I_h IN SUBSTANTIA NIGRA COMPACTA NEURONS BY GABA, TAURINE AND GLYCINE. M.G.Lacey, M.A.Häusser* and W.H.Yung*. Dept. of Pharmacology, University of Birmingham, B15 2TT, UK, and *Laboratory of Physiology, University of Oxford, OX1 3PT, UK.

The time-dependent hyperpolarization-activated inward current I_h (or I_f, I_Q, I_{AR}) has been observed in a variety of cell types including neurones. Several recent reports have described effects on cell excitability through modulation of I_h by intracellular messengers, and also by activation of muscarinic and aminergic receptors.

Intracellular recordings were made from presumed dopaminergic substantia nigra compacta neurons in rat brain slices. I_h was studied using single electrode voltage clamp. The inhibitory amino acids GABA (0.3 mM), taurine (3 mM) and glycine (0.3 mM) all increased membrane Cl^- conductance and also markedly reduced the amplitude of I_h. These effects were mimicked by the $GABA_A$ receptor agonist muscimol, but not by $GABA_B$ agonist baclofen. The modulation of I_h by activation of neurotransmitter receptors thought to be ligand-gated Cl^- channels represents a novel mechanism for control of cell excitability.

Experiments investigating the mechanism of this effect will be described.

ZINC REDUCES THE TRANSIENT OUTWARD CURRENT IN IMMATURE RAT HIPPOCAMPAL NEURONS.
I. Spigelman & P. L. Carlen. Playfair Neuroscience Unit, Toronto Western hospital, Toronto, Canada.

Previous studies have shown that exogenous zinc application has predominantly excitatory effects on mammalian central neurons. The giant GABA-mediated depolarizing potentials in immature hippocampal CA3 neurons (Ben-Ari et al. J. Physiol. 416:303-325, 1989) were recently proposed to result from an inhibitory action of Zn^{2+} on the pre- and postsynaptic $GABA_B$-mediated receptors (Xie & Smart, Nature 349:521-524, 1991). We studied the effects of Zn^{2+} and the $GABA_B$ receptor agonist baclofen on the transient outward current (I_A) in immature rat hippocampal neurons. Whole-cell patch recordings from dentate granule or CA1 neurons in hippocampal slices from immature (7-13 day old) Wistar rats revealed that bath application of Zn^{2+} (200 μM) reversibly decreased the amplitude of I_A (32%, n=7) and its rate of decay (54%), while the latency to peak I_A activation was increased. Application of baclofen (200 μM) increased the I_A amplitude (n=3). Concomitant baclofen and Zn^{2+} applications that followed application of Zn^{2+} alone partly offset the Zn^{2+}-induced decreases in I_A amplitude (n=3). These results suggest that one possible consequence of endogenous Zn^{2+} release in the immature hippocampus is an increase in both pre- and postsynaptic excitability via actions on the I_A.

EFFECT OF TEMPERATURE AND TIME ON THE AFFINITY OF AN ENDOGENOUS SUBSTANCE OF CENTRAL BENZODIAZEPINE RECEPTOR. H.L. Komiskey, J. Harper * , S.E. Demick * and A. Rahman *. College of Pharmacy, Xavier University of Louisiana, New Orleans, LA 70125.

An endogenous compound with high affinity for central benzodiazepine receptor has been extracted from rat brain tissue (Pharmacologist 30: 25, 1988). The endogenous compound was stored at 25°C, 0-4°C and -80°C for 48 hours in 70% methanol. The central benzodiazepine binding sites in homogenate of rat cerebral cortex were labeled with ^{3}H-flumazenil. Incubations were conducted at 0-4°C. Specific binding was measured as the difference between the ^{3}H-flumazenil bound in the absence and presence of 1uM clonazepam.

The affinity of the endogenous compound for the central benzodiazepine binding site, as well as its ultraviolet light absorbance decreased over time at each temperature. Storage of the compound at colder temperatures did not slow the apparent breakdown of the compound. In contrast, the benzodiazepines, diazepam and desmethyldiazepam were found to be more stable relative to the endogenous compound in 70% methanol. (Supported by NIH grant NS27265).

CHLORIDE CHANNEL REGULATION IN SKELETAL MUSCLE OF AGED RAT
D.Conte Camerino*, A.De Luca*, D.Tricarico* and S.H.Bryant Dept. Pharmacobiology,Faculty of Pharmacy,University of Bari,Bari,Italy* and Dept.Pharmacology and Cell Biophysics, University of Cincinnati,Cincinnati,OH 45267.

Skeletal muscle fibers of aged rats have a reduced resting chloride conductance(GCl)(De Luca et al.,Pflügers Arch,415,642,1990). Our recent data evidenced that protein kinase C(PKC) exterts an inhibitory control on chloride channel of adult rat and goat skeletal muscle fibers(Bryant and Conte Camerino,Pflügers Arch,417,605,1991; Tricarico et al.,Pflügers Arch, in press). The present study was aimed at clarifying if perturbation of PKC system can explain the GCl defect of aged rats. Measurements of GCl were made on extensor digitorum longus muscle fibers from 3-4 and 29 months old rats, "in vitro" at 30°C with standard two microelectrodes metodology. The PKC activator 4-B-phorbol-12,13-dibutyrate was more potent in blocking GCl in old (IC50=5nM) than in adult rats(IC50=50nM). PKC inhibitor staurosporine(1uM) did not restore the low GCl of aged rats but prevented the block of GCl by the phorbol ester.The present data suggest that an overactivity of PKC may play a role in the reduced GCl of aged rat skeletal muscle.

BETA-ENDORPHIN MODULATES A MECHANO-SENSORY CALCIUM CHANNEL IN *STENTOR*. M. J. Marino and D. C. Wood. *Dept.of Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15260*

Mechanical stimulation opens a population of mechano-sensory calcium channels in the ciliate protozoan *Stentor*. The resulting depolarizing receptor potential can trigger an action potential and lead to a contraction of the organism. We have found that the peptide beta-endorphin (BEND) markedly reduces the probability that *Stentor* will contract to mechanical stimuli. This action of BEND is naloxone sensitive, and dose dependant (100 nM - 10 uM). The drug is most effective immediately after application, with the contraction probability returning to control values after two hours of continued exposure. The reduction in response probability is specific to mechanically induced contractions, with no change in probability of contraction produced by electric or photic stimulation. Electrophysiological studies have shown that BEND produces a reduction in mechano-sensory receptor potential amplitude without altering other passive or active membrane properties. On going voltage clamp studies are aimed at elucidating the nature of this channel modulation.

BINDING CHARACTERISTICS OF [^{3}H]RYANODINE TO RAT BRAIN CORTICAL MICROSOMES. I. Zimanyi and I.N. Pessah* Department of Veterinary Pharmacology and Toxicology, University of California, Davis, CA 95616.

Specific binding of [^{3}H]ryanodine to sucrose gradient purified rat brain cortical microsomes recently has been characterized pharmacologically (Zimanyi and Pessah, Brain Res. 1991). The association of 0.5 nM [^{3}H]ryanodine is complete within 80 min and remains stable for up to 5 hr. Dissociation of the [^{3}H]ryanodine-receptor equilibrium complex has been examined in two ways. Addition of 1000-fold unlabeled ryanodine results in biphasic dissociation curves best fit by a double exponential decay which yield two dissociation rate constants. The dissociation rate constants and the pseudo first order rate constant of the association yield two dissociation constants of 0.1 and 1.7 nM for the high- and low-affinity binding of ryanodine. Dissociation of [^{3}H]ryanodine by 100-fold dilution of the assay medium results in monophasic dissociation with halftime of 63 min and yields a calculated K_d of 0.5 nM. Pretreatment of the microsomes with 1 μM unlabeled ryanodine which was subsequently removed by sufficient washing and centrifugation steps reduced the available specific binding sites for [^{3}H]ryanodine by 50%. These results indicate an irreversible action of ryanodine on multiple binding sites in the brain. In general [^{3}H]ryanodine receptors found in brain have higher affinities than in those found in skeletal muscle SR. Supported by NIH grant ES05002 and BRSG 90-19 to INP.

ALTERATIONS IN CALCIUM AND POTASSIUM CHANNEL ANTAGONIST BINDING IN CARDIOMYOPATHIC HAMSTER TISSUE. J.A. MILLER, P.A. Chmielewski* and D. Rampe*, Marion Merrell Dow Research Institute, Cincinnati, OH, 45215.

The Syrian cardiomyopathic hamster (CMH) (BIO 14.6) develops cardiac hypertrophy and congestive heart failure, possibly due to cellular calcium overload. To characterize the pathophysiology involved in this animal model we have examined the density of L-type calcium and ATP-sensitive potassium channels in 30 and 180 day old hamster heart and brain using membrane receptor binding and quantitative autoradiography (QAR). In the heart, [^{3}H]PN200-110 binding to calcium channels was elevated 84% above controls in 30 day old CMH and 31% above controls in 180 day old CMH. In contrast, [^{3}H]glibenclamide ([^{3}H]GLI) binding to cardiac potassium channels was unaltered in 30 day old animals but was decreased to 64% of control levels in 180 day old CMH. In brain membranes there was no significant difference in the binding density of either ligand between groups or between ages. However, QAR revealed a 41% increase in [^{3}H]GLI binding in frontal cortex of 30 day old CMH versus the same age control. There was no difference in [^{3}H]GLI binding in frontoparietal or striate cortex or in cerebellum or brainstem. Further QAR analyses will include other brain and heart regions with both [^{3}H]PN and [^{3}H]GLI binding. These findings suggest distinct differences in regional levels of potassium and calcium channels in CMH that may be related to the progression of the disease.

BLOCKADE OF K^+ CHANNELS IN PC12 CELLS BY PROPOFOL. M.Nobile*, V.Magnelli*, E.Maestrone*, L.Spadavecchia*. Ist. Cibernetica e Biofisica CNR, Genova, Italy and Osp. Civ. Sondrio, Italy. (SPON: Europ. Neurosci. Ass.)

The general anaesthetic Propofol (PR) reduced reversibly K^+ currents in voltage clamped PC12 cells. In control conditions, current activation time course was fitted by 2 exponential terms, with n=2 and n=1 kinetics, whereas, when PR was applied extracellularly, the n=2 component only gave the best fit. PR $5*10^{-5}$ to 10^{-3}M decreased currents amplitude in a concentration dependent way, but independently of holding potential (V_H). K^+ currents block was neither frequency nor use dependent. A complex voltage-dependent block pattern was observed, when the above concentrations were employed. Single channel outside-out experiments (V_H= -50 mV) revealed 2 different K^+ channels, with unitary conductances of 10 and 22 pS. PR $5*10^{-5}$ M decreased the open probability of the bigger channel, but did not affect the smaller one. At higher concentrations channels were fully blocked. These results might suggest either different sensitivities or different blocking mechanisms for the two channels.

INTERACTIONS OF POLYAMINES WITH THE NICOTINIC ACETYLCHOLINE RECEPTOR IN RAT BRAIN. R.D. Kusztos, C.R. Mantione and E.D. London. Neuropharmacology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224

A previous report indicated the presence of specific recognition sites for polyamines on the nicotinic acetylcholine receptor (nACh-R) of *Torpedo* electic organ (Anis, N. et al., *J. Pharmacol. Exp. Ther.*, **254**:764, 1990). We, therefore, were interested in whether polyamines, which modulate activity of the N-methyl-D-aspartate receptor, also influence nACh-R in brain. In this regard, we tested the effects of various endogenous and synthetic polyamines on the binding of [^{3}H]methylcarbamylcholine and [^{3}H]mecamylamine ([^{3}H]MEC), which label the acetylcholine recognition site and the open cationic channel of the nACh-R (London, E.D. et al., *Soc. Neurosci. Abstr.*, **15**:64, 1989, Banerjee, S. et al., *Biochem. Pharmacol.*, **40**:2105, 1990), respectively. Although the polyamines had no effect on the binding of [^{3}H]methylcarbamylcholine, they inhibited the binding of [^{3}H]MEC at μmolar concentrations. The rank order of potencies of the compounds tested was as follows: spermine > spermidine > 1,10-diaminodecane > putrescine > diethylenetriamine. The sequence is similar to the rank order of these substances in inhibiting the binding of [^{3}H]spermidine, a radioligand for polyamine binding sites in brain (Mantione, C.R. et al., *Eur. J. Pharmacol.*, **180**:393, 1990). The present findings support the view that polyamines in brain may modulate the activity of nACh-R through recognition sites on the receptor.

608.16

QUINIDINE SULFATE ACTION ON GUINEA PIG SMOOTH MUSCLE. X. García, L. Herrera*, and E. Gijón. Dept. of Physiol. Sch. of Med. Universidad Nacional Autónoma de México. Ap. P. 70-250, México, D.F. 04510. MEXICO.

Previous studies in our laboratory have shown an anticholinergic effect of quinidine sulfate, an antiarrythmic compound, carachterized by producing a slight increase in tone, at low doses, and a decrease in tone and rhythm when applied at high doses on the isolated intestine of guinea pigs. Segments of intestine from 300 g male guinea pig were prepared for isometric recording. Quinidine inhibited the contraction elicited by acetylcholine. This effect can also be observed with histamine and barium chloride. These effects are calcium non-dependent as they can be observed in low calcium solutions. Our results support an anticholinergic, an antihistaminic, and an antibarium effect of quinidine, calcium non-dependent.

EVALUATION OF A MEMBRANE CONDUCTANCE FROM SPIKE TRAINS. Jon Berner and C.D. Woody. MRRC, UCLA Medical Center, Los Angeles CA 90024.

A method for detecting changes in one membrane conductance, the slow gK+(Ca), which does not require intracellular penetrations, could speed the study of associative learning (Alkon, 1979; Coulter et. al., 1989).

A single compartment, Hodgkin-Huxley model of a cortical pyramidal cell (containing features of gK+(A), gNa+, gNa+(P), gK+(DR), fgK+(Ca), and the slow gK+(Ca)) generated a spike train in response to random perturbation of membrane potential (c.f. Abeles, 1982) which was represented by a two dimensional plot of the interspike interval between successive spikes. A distinctive effect of a reduction in the maximal conductance of the slow gK+(Ca) on the geometry of the underlying spike train was revealed by subtractive techniques. This effect, a symmetric reduction in short-medium/medium-short intervals, was observed to be robust to changes in the variance and the mean of the stimulus and the maximal conductance of gK+(A).

Although comparison of these plots with other data from in-vivo preparations suggests that the baseline spike train geometry might need to be uniquely specified for a cell type of interest, these techniques might also be used to identify changes in other voltage-gated conductances.

ACETYLCHOLINE: SYNTHESIS AND DEGRADATION

609.1

REGULATION OF HIGH-AFFINITY CHOLINE TRANSPORT IN THE NEUROBLASTOMA CELL LINE LA-N-2. A. Lambros*, S. Goddard* and R.J. Rylett. Department of Pharmacology and Toxicology, University of Western Ontario, London, Ontario, Canada, N6A 5C1.

The sodium-dependent, high-affinity choline transport protein has not been purified or characterized biochemically and very little is known about its long-term regulation. We have observed that transfer of cholinergic neuroblastoma LA-N-2 cells into serum-free N2 (SF-N2) media results in enhanced high-affinity choline uptake (HACU) activity accompanied by proportional increases in acetylcholine (Ach) synthesis, but not choline acetyltransferase (ChAT) activity. Maximal increases in HACU (approximately 7-fold) were achieved after four days in SF-N2 media. Enhanced HACU was characterized by an increase in the maximum velocity of transport (Vmax) for the high-affinity carrier with no significant change in the affinity (Km) of the carrier for substrate. In the presence of cycloheximide or α-amanitin,increases in HACU activity were substantially reduced. This suggests that transfer of LA-N2 cells into SF-N2 media results in increased synthesis of mRNA transcript for the high-affinity carrier which is effectively translated into new transport protein. Our findings indicate that LA-N-2 may serve as an effective model for studying regulation of HACU in culture. (Supported by MRC Canada and The Upjohn Company).

ANALYSIS OF REGULATORY ELEMENTS IN THE 5' FLANKING REGION OF THE *DROSOPHILA* CHOLINE ACETYLTRANSFERASE GENE. K. Ikeda, T. Kitamoto* and P. M. Salvaterra. Division of Neurosciences, Beckman Research Institute of the City of Hope,1450 East Duarte Road, Duarte, CA 91010.

We have analyzed the 5' flanking region of the *Drosophila* choline acetyltransferase gene (ChAT, E.C.2.3.1.6) for the presence of cis-regulatory elements. DNA fragments containing various lengths of flanking DNA were fused to the *E. coli* lacZ gene used to transform *Drosophila*. The histochemical localization of β-galactosidase expression was used to evaluate the ability of different fragments to direct lacZ expression. A 7.4 kb flanking sequence was found to direct β-gal expression in specific somal and synaptic layers of the optic lobe and other cephalic structures. The pattern of β-gal staining corresponded closely to the distribution of endogenous ChAT protein. In contrast, a construct containing only the proximal 3.3 kb of 5' flanking DNA resulted in a qualitatively and quantitatively different expression pattern. In general, a more restricted pattern of expression was observed which appeared to be a subset of the structures seen with the 7.4 kb construct. Further deletion to the proximal 1.2 kb of flanking DNA led to an even more restricted pattern. Our results indicate that both qualitative and quantitative regulatory elements are present in the 5' flanking DNA and these elements distinguish subsets of cholinergic neurons. We have also fused the 5' flanking DNA to wild type ChAT cDNA, and used these constructs to transform *Drosophila* stocks carrying a temperature sensitive ChAT allele. The 7.4 kb-cDNA transformants had higher levels of wild type ChAT activity than either the 3.3 or 1.2 kb constructs. All three constructs were able to rescue mutant flies from paralytic and lethal phenotypes.

ALTERNATIVE SPLICING OF CHOLINE ACETYLTRANSFERASE TRANSCRIPTS IN THE NEMATODE *C. elegans*. J. B. Rand, A. Alfonso*, K. Grundahl*, J. R. McManus*, and J. M. Asbury*, Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104.

We have previously cloned and analyzed the *cha-1* locus from the soil nematode *Caenorhabditis elegans* (Alfonso et al., Soc.Neurosci.Abstr. **16**:199). *cha-1* is the structural gene for choline acetyltransferase (ChAT). Genetic evidence indicates that *cha-1* interacts with the closely linked *unc-17* locus (Rand and Russell, Genetics **106**:227; Rand, Genetics **122**:73). *unc-17* mutants have normal ChAT activity, but are resistant to AChE inhibitors. This suggests a probable cholinergic function for the *unc-17* gene product.

We have identified and characterized two classes of cDNA which appear to arise through alternative splicing and which correspond to *cha-1* and *unc-17* transcripts, respectively. The coding sequence of the *cha-1* transcript is disrupted by mutations in the *cha-1* gene. Sequence comparison with ChAT from other species confirms that *cha-1* encodes ChAT. Transcription of both transcripts is from right to left on the genetic map, and both share a common 5' untranslated exon at the right end of the region. The *cha-1* transcript then has a very long (~5kb) intron. The *unc-17* transcript has a much shorter intron, and the entire *unc-17* coding sequence lies within the long *cha-1* intron. The two cDNAs have no coding sequence in common.

The open reading frame of the *unc-17* cDNA gives a deduced 58 kd protein with no significant homology to any known protein. The precise nature and function of the *unc-17*-encoded protein are unclear.

Supported by grants from NIGMS and NSF.

THE EFFECT OF CHLORIDE IONS ON CHOLINERGIC FUNCTION IN RAT HIPPOCAMPAL SYNAPTOSOMES. B.M. Schmidt and R.J. Rylett. Dept. Physiology, University of Western Ontario, London, Canada. N6A 5C1.

Choline acetyltransferase [ChAT; EC 2.3.1.6] catalyses the biosynthesis of acetylcholine (ACh) in cholinergic nerve terminals. Little is known about possible short-term regulation of this enzyme which exists in both cytosolic (cChAT) and membrane-associated (mChAT) pools. Previously, it was shown that rat brain ChAT is regulated *in vitro* by anion concentration, with chloride ions being the most effective (Rossier, J.Neurochem, 29:1007, 1977). These studies were done with the enzyme following extraction from tissue, and it is not yet known whether the two distinct fractions of ChAT in intact tissue are regulated similarly. Using rat hippocampal synaptosomes as a model, we observed that partial replacement of extracellular chloride ions (131 mM reduced to 48 mM) with the largely impermeant anion isethionate selectively reduced the activity of mChAT (61.7±1.9% control, n=7) following 30 min incubation. There was no change in cChAT activity. Further reduction of extracellular chloride to 6mM decreased mChAT to a similar extent (47.4±11.4% control, n=7). High affinity choline uptake (HACU) and concomitant ACh synthesis were also depressed in 6 mM chloride (50.7±7.2 and 43.0±2.7% control, respectively, n=7). To determine whether chloride ions were specifically required for maintaining normal cholinergic function, equimolar concentrations of bromide or iodide ions were also substituted for chloride in the incubation medium. Bromide ions substituted well for chloride in maintaining mChAT activity, HACU, and ACh synthesis (143.8±17.1, 113.1±12.0, and 103.1±16.9% control, respectively, n=6). Results obtained with iodide ions paralled those of isethionate. It appears that of the two distinct ChAT pools in rat hippocampal synaptosomes, only mChAT activity was sensitive to extracellular anion substitution. (Supported by M.R.C. of Canada).

MICRODIALYSIS REVEALS REGIONAL DIFFERENCES IN RESPONSE TO CHOLINESTERASE INHIBITION BY HEPTYL-PHYSOSTIGMINE.

E. Messamore, U. Warpman*, N. Ogane, and E. Giacobini, Dept. Pharmacol., SIU Sch. Med., Springfield, IL 62794.

Heptyl-physostigmine (HEP) is a long-acting physostigmine (PHY) derivative which inhibits acetylcholinesterase (AChE) and elevates acetylcholine (ACh) concentration in homogenates of the cerebral cortex and striatum (De Sarno et al, 1989). This study examined the effect of systemically administered HEP on extracellular ACh using a microdialysis technique which did not incorporate additional AChE inhibitors in the probe perfusate. Basal ACh concentration in the cortical dialysate of conscious rats was 5.7 ± 0.3 nM which increased by 200% after 1 mg/kg (i.p.) and by 1200% after 5 mg/kg (i.p.) HEP. The observed HEP effects were not altered by the presence of atropine (0.1 μM) in the dialysis probe perfusate. In contrast to the increases noted in cerebral cortex, microdialysis in the striatum did not reveal increased extracellular ACh in response to either dose of HEP. When the dialysis probe contained PHY (10μM), the 5 mg/kg HEP injection decreased extracellular ACh by 20%, despite an overall 60% increase in ACh content of the striatal homogenate. These results do not support a necessary correlation between the ACh content in brain homogenate and the extracellular space. They further suggest marked regional variation in the response to cholinesterase inhibition.

DO CHOLINESTERASE INHIBITORS PREFERENTIALLY INHIBIT CERTAIN BRAIN MOLECULAR FORMS? N. Ogane, E. Messamore and E. Giacobini, Dept. Pharmacol., Southern IL Univ. Sch. Med., Springfield, IL

Aqueous-soluble and detergent-soluble acetylcholinesterase (AChE) molecular forms were separated from rat brain by sucrose density sedimentation. The bulk AChE corresponds to globular tetrameric (G_4) and monomeric (G_1) forms. The effect of eight AChE inhibitors (AChEIs) was studied on separated AChE molecular forms. Five drugs, physostigmine (PHY), echothiophate (ECH), BW284C51 (BW), tetrahydroaminoacridine (THA), and metrifonate (MTF), inhibited both forms of aqueous- and detergent-soluble AChE with similar potency. However, heptyl-physostigmine (HEP) and di-isopropylfluorophosphate (DFP) were more selective for the G_1 forms than G_4 forms in aqueous-soluble extract. Neostigmine (NEO) showed slightly but significantly higher inhibition of G_1 form in both aqueous- and detergent-soluble extracts. These results suggest allosteric effects of AChEIs on globular forms which involve structure-dependent affinities. (Supported by Snow Brand Milk Products Co., Ltd. Japan)

SARIN-INDUCED NEUROPATHOLOGY IN RATS - A COMPARATIVE STUDY WITH OTHER CHOLINESTERASE INHIBITORS. T. Kadar*, G. Cohen*, R. Sahar*, D. Alkalai*, L. Raveh* and S. Shapira. Dept Pharmacol, IIBR, Ness-Ziona IL 70450, ISRAEL.

Sarin, a highly toxic organophosphate administered at near 1LD50 dose causes persistent brain lesions, the mechanism of which is not fully understood. The present study was designed to evaluate the immediate and long-term neuropathology of a single 1LD50 dose of sarin, and to elucidate the role of excessive acetylcholine in creating these neuronal lesions, by comparing them to other cholinesterase (ChE) inhibitors. Rats surviving 1LD50 dose of sarin, soman or DFP were sacrificed at 1, 7, 30 and 90 days after administration, and their brains were histologically evaluated. While brains of all soman-injected rats were severely damaged, only 70% of the sarin and none of the DFP injected rats were affected. Although the general location of brain neuropathology following sarin resemble that of soman, sarin induced lesions were variable and uniquely affected nerve fibers whereas soman initially damaged only cell-bodies. The different patterns of brain lesions of soman, sarin and DFP indicated a distinctive mode of action for each of them, not mediated solely by ChE inhibition.

IN VIVO AND IN VITRO INTERACTION OF CARBAMATES WITH QUATERNARY OXIMES G. Cohen*, E. Cohen*# and G. Amitai, IIBR, Ness Ziona 70450, and #Agricul. Faculty The Hebrew Univ., Rehovot 76100, Israel.

The antidotal treatment employed in the case of poisoning by AChE inhibitors usually consists of a combination of atropine and a quaternary oxime (e.g. toxogonin or 2-PAM). However, in the case of carbaryl poisoning toxogonin increases its toxicity by 3.5 fold. AB-8 and AB-13 are quaternary oximes previously shown to be potent antidotes against poisoning by various AChE inhibitors. In the case of carbaryl poisoning in mice, no survival was obtained with either AB-13 (50 mg/kg, i.v.) or toxogonin (12.6 mg/kg, i.v.) in combination with atropine (0.2 mg/kg, i.m.). However, AB-8 (50 mg/kg) protected 80% and 60% of the animals against 3 and 4xLD50 of carbaryl, respectively. In vitro reactivation studies with purified eel AChE showed that toxogonin and AB-13 are 1500 and 500 fold more active than AB-8, respectively. It is, therefore, suggested that oximes which are potent AChE reactivators should be excluded from the antidotal treatment of carba-ryl poisoning. In addition, the mechanism of action of AB-8 may not be solely related to either AChE reactivation or anticholinergic activity.

BOTULINUM NEUROTOXIN TYPE A BREAKS DOWN AT pH 5.0 AT THE TWO ASP-PRO BONDS OF THE HEAVY CHAIN. B. R. DasGupta and W. Tepp*. Food Research Institute, University of Wisconsin, Madison, WI 53706.

The neurotoxin (NT) is made of L-chain (residue 1-447) and H-chain (residue 448-1295) linked by an interchain disulfide (J.Biol. Chem. 265, 9153). The NT binds to the cholinergic presynaptic membrane and is internalized by endocytosis. A segment of the N-terminal half of the H chain is thought to form channels in the vesicular membrane after the vesicles become acidic. L-chain or L-chain and a part of H-chain is presumed to escape from the endosome through these channels into the cytosol where the L-chain inhibits neurotransmitter release [J.Physiol. (Paris) 84, 180, 220, 237]. We had reported that the NT breaks down at pH 5, 25°C in 5 min at the Asp 906-Pro 907 bond. We have now exposed the isolated H-chain to pH 5.0 at 25° for 5 min. The 40 and 20 kDa fragments, also found earlier from the NT, gave the N-terminal sequences (Edman degradation): Pro.Ile.Asp.Lys.Asn.Gln.Ile.Gln.Leu.Phe- and Pro.Asn.Lys.Tyr.Val.Asp.Val.Asn.Asn.Val-, respectively. The only two Asp-Pro bonds in the H-chain, residue #906-907 and 1117-1118, are therefore acid labile. Cleavages of the H chain at these two sites may allow segments of the NT containing the L-chain (residue 1-906 or 1-1117) to escape the endosome leaving the rest of the molecule presumed to have the receptor binding site anchored to the receptor. Funded by NIH; NS17742.

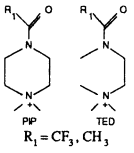
EFFECTS OF SOLUTION STRUCTURE AND DYNAMICS ON THE FUNCTION OF A SERIES OF NICOTINIC CHOLINERGIC AGONISTS. K.A. McGroddy, A.A. Carter, M.M. Tubbert & R.E. Oswald*. Dept. Pharmacology, Cornell Univ., Ithaca, NY 14853.

The binding of a ligand to its receptor, which leads to receptor activation, is dependent upon the structure and dynamics of the agonist both in solution and in the binding site. We have synthesized two classes of chemically similar cholinergic ligands based on the parent compounds shown below in order to determine the contributions of solution structure and dynamics to the ability of these compounds to bind to and activate nicotinic acetylcholine recptors (nAChRs).



The structural and dynamic variations of these compounds have been compared experimentally and theoretically. 1D and 2D ^1H and ^{19}F NMR studies have shown that the TED compounds exist in two stable solution structures of different energy, with a high barrier to interconversion. Only the higher energy conformer appears to achieve the correct conformation for binding to the receptor. The more stable TED structure differs significantly from the rigid PIP structure and this can account for a large portion of the difference in binding affinities between the two compounds. Molecular dynamics simulations have been been carried out using the CHARMm program. The systems have consisted of one ligand in a box of TIP3P water with periodic boundary conditions. Trajectories of each of these compounds have been simulated and analyzed in order to study the effect of solvation on the structures and dynamics of these molecules and to determine the relative contributions of enthalpy and entropy to the interaction of these drugs with nAChRs. These studies indicate that the solution structure and dynamics of a compound can make an important contribution to the binding affinity of a ligand to its receptor.

DO NONCOMPETITIVE INHIBITORS BIND TO SUBSITES WITHIN NICOTINIC ACETYLCHOLINE RECEPTOR CHANNELS? J.M. Herz and E. Schmid*. Institute for Neuroscience and Cell Research Inst., Univ. of Texas at Austin, Austin, TX 78713.

We have examined the interactions of noncompetitive inhibitor ligands (NCIs) with the allosterically-coupled NCI site on the AChR. To determine whether NCIs bind to a single site or spatially distinct subsites within the channel, effects of a series of NCIs on ethidium binding were analyzed. In the presence of 100 μM carbamylcholine, all of the following NCIs completely displaced ethidium with the indicated K_ds: chlorpromazine (0.15μM), proadifen (0.14μM), meproadifen (0.24μM), PCP(0.52μM), TPMP(0.95μM), QX-314 (20.1μM) and QX-222(494μM). Indirect Hill coefficients for all NCIs were 1.0. Analysis of ethidium's excited state lifetime in the presence of competing NCIs showed that >90% of the total amplitude of the double-exponential decay process was characterized by a short lifetime component of 1.6 ns. This lifetime is attributed to ethidium in buffer indicating that ternary complexes, in which ethidium and another NCI are simultaneously bound, do not form (Herz, et. al., JBC 262, 7238, 1987). Dissociation rates induced by addition of PCP, TPMP and meproadifen were similar, but distinct from chlorpromazine and QX-222. Ethidium association rates in the presence of competing NCIs have been measured. These data will be discussed in terms of competitive mechanisms and subsite models. BENZOQUINONIUM(BZQ) INTERACTIONS WITH PERIPHERAL NICOTINIC ACETYLCHOLINE RECEPTORS (AChR): ELECTROPHYSIOLOGICAL AND BIOCHEMICAL STUDIES. T. Tano[1,2], A. Maelicke[3]*, R.S. Aronstam[4] and E.X. Albuquerque[1,2]. [1]Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201; [2]Lab. Mol. Pharmacol.II, IBCCF, 21944; [3]Inst. Physiol. Chem., Johannes-Gutenberg Univ. of Med. Sch., Duesbergweg, D-6500 Mainz, FRG; [4]Dept. Pharmacol. Toxicol., Med. Coll. Georgia, Augusta, GA 30912.

BZQ, a synthetic neuromuscular blocking agent (*J. Am. Chem. Soc.*, 72: 2661, 1950), has been proposed to block the physostigmine (PHY) agonistic action on the AChR complex from *Torpedo* (Okonjo et al.; *in press*). In this work, further characterization of the BZQ effects at the AChR was done by electrophysiological studies in *Rana pipiens* muscles and ligand-binding assays in *Torpedo* membranes. Voltage-clamp was performed on sartorius muscle-sciatic nerve preparation, and ACh-activated single channel currents were recorded from interosseal fibers using cell-attached modality. At the neuromuscular junction, BZQ (10 and 30 μM) depressed endplate currents (EPC) peak amplitude and shortened the τ_{EPC} in a voltage- and concentration-dependent manner. In addition, analysis of ACh-activated single channel currents showed that BZQ (3 and 10 μM) decreased the mean open (τ_o) and burst (τ_b) times. At -140 mV, 3 and 10 μM BZQ decreased both τ_o and τ_b by 44% and 80% of control values, respectively. In agreement with the EPC data, these effects were also enhanced at hyperpolarized potentials. At 1 μM BZQ, [^{3}H]histrionicotoxin binding was enhanced by 30% in the absence of agonist, however it was reduced at higher concentrations. ^{125}I-α-bungarotoxin binding was also reduced at higher concentrations of BZQ. These results suggest that BZQ has complex effects at the AChR: binding studies suggest that BZQ at concentrations < 1 μM might activate channel openings; however, binding and electrophysiological data show that higher concentrations of BZQ block the nicotinic channel in the open conformation. 610.4

EXPRESSION OF ALPHA-BUNGAROTOXIN-INSENSITIVE FUNCTIONAL NICOTINIC ACH RECEPTORS IN *XENOPUS* OOCYTES. V. M. Gehle and K. Sumikawa. Dept. of Psychobiology, Univ. Calif., Irvine, CA 92717.

A conserved feature of many ligand-gated ion channels, including the muscle and neuronal ACh receptors, GABA receptor, and glycine receptor, is a pair of cysteine residues separated by 13 amino acids in the extracellular portion of the protein. In the *Torpedo* AChR α subunit, this pair has been demonstrated to form a disulfide bond. This disulfide bond may be important for receptor function because removal of the two cysteines from the AChR α subunit was demonstrated to affect the ligand binding and ACh response of the AChR (Mishina et al., 1985, Nature 313: 364-369). That report indicated the cysteines are critical for AChR function, but did not precisely define the role they perform. We created the same mutant α subunits, having one or the other of the cysteines replaced by serine, for additional detailed studies. Both of the mutant α subunits assembled with β and γ subunits when expressed in *Xenopus* oocytes. The mutant α subunits also assembled with δ subunits, but with greatly decreased efficiencies. Additionally, electrophysiological studies of these oocytes using voltage-clamp techniques documented small responses to ACh. These responses could not be blocked by application of α-BuTX. Thus, formation of a disulfide bond between Cys128 and Cys142 of the *Torpedo* AChR α subunit is necessary for α-BuTX binding, but not ACh binding and ion channel function.

610.5

EFFECT OF SUBSTITUTION OF *TORPEDO* ACETYLCHOLINE RECEPTOR (AChR) α-SUBUNIT RESIDUES WITH SNAKE RESIDUES ON BINDING OF α-BUNGAROTOXIN (α-Btx). D. L. Donnelly-Roberts*, V. Chaturvedi*, and T. L. Lentz. Department of Cell Biology, Yale University School of Medicine, New Haven, CT 06510.

A fusion protein consisting of the Trp E protein fused to residues 166-211 of the AChR α-subunit was produced in *E. coli*. A cDNA clone encoding *Torpedo* AChR α-subunit (gift of Toni Claudio) was digested with restriction enzymes to yield a 137 base pair fragment encoding residues 166-211. This fragment was fused to the 3' terminus of the *E. coli* TrpE gene using a pATH10 expression vector. Whereas *Torpedo* AChR binds α-Btx with high affinity, AChR from snakes are toxin-resistant (Burden *et al.*, PNAS 72, 3245, 1975). Three residues in the *Torpedo* sequence were mutated to residues present in snakes (Neumann *et al.*, PNAS 86:7255, 1989) in order to assess the role of these residues in binding. The 137 base pair *Torpedo* fragment was subcloned in an M13 vector and mutagenesis performed by means of oligonucleotide-directed mutagenesis. The following mutations were produced in the *Torpedo* sequence: W184F, K185W, and W187S. The affinities of the fusion proteins for ^{125}I-α-Btx were compared. Competition with unlabeled α-Btx yielded IC_{50} values of 5.5×10^{-8}M and 1.6×10^{-5}M for the *Torpedo* and mutated proteins respectively. Equilibrium saturation binding experiments yielded K_Ds of 6.0×10^{-8}M for the *Torpedo* sequence and 1.7×10^{-5}M for the mutated sequence. Conversion of three *Torpedo* residues to snake residues causes a 500-fold decrease in affinity of the peptides for α-Btx. Therefore, these results suggest that one or more of the residues at positions 184, 185, and 187 of the AChR α-subunit plays an important role in the binding of α-Btx. Supported by NIH grant NS 21896.

A MUTANT GAMMA SUBUNIT OF *TORPEDO* ACHR CAUSES DEGRADATION OF CO-EXPRESSED NORMAL SUBUNITS. K. Sumikawa and V. M. Gehle. Dept. of Psychobiology, Univ. Calif., Irvine, CA 92717.

Using site-directed mutagenesis, we changed the asparagine residue at the conserved N-glycosylation site (position 141) on the γ subunit of the *Torpedo* acetylcholine receptor (AChR) to aspartic acid. When these mutant subunits were expressed in *Xenopus* oocytes along with non-mutant α, β, and δ subunits (mγ-AChR), very little ^{125}I-α-bungarotoxin (α-BuTX) binding activity was seen, but, interestingly, α-BuTX binding was easily detected in *Xenopus* oocytes expressing only α, β, and δ subunits. When ^{35}S-methionine labeled mutant and normal subunits were precipitated with AChR antibodies and analyzed on SDS gels, we could detect neither the mutant γ subunit nor most of the co-expressed other normal subunits. Since the incomplete receptor consisting of only the α, β, and δ subunits could be precipitated easily from other oocytes, the mutant γ subunit was likely to be responsible for the apparent absence of the co-expressed non-mutant subunits. Oocytes expressing the α, β, and δ subunits produced larger membrane currents in response to ACh than those elicited in oocytes expressing the mγ-AChR. This apparent mγ-AChR response may have been due to a low-level expression of AChRs consisting of only the α, β, and δ subunits and not AChRs containing the mutant γ subunit. These results suggest that the mutant γ subunit assembled with the other normal subunits, leading to the subsequent degradation of all the subunits.

610.7

MODULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR ION CHANNEL FUNCTION BY THE M4 TRANSMEMBRANE DOMAINS. L. Li*, Y-H. Lee*, and M. G. McNamee. Dept. of Biochem. & Biophys., Univ. of California, Davis, CA 95616.

The role of M4 transmembrane helices in nicotinic acetylcholine receptor (AChR) channel function was investigated by studying the functional consequences of the site-specific mutations of cysteine residues in the M4 helices of *Torpedo californica* AChR α and γ subunits using *Xenopus laevis* oocytes injected with *in vitro* synthesized AChR RNA transcripts. The mutation of αCys418 to Trp increased the AChR *normalized* channel activity (measured as the ACh-induced conductance per femtomole of surface α-bungarotoxin (α-BGT) binding sites) by more than 40 fold. In contrast, the mutation of γCys451 to either Ser or Trp decreased the normalized channel activity by about 50%. The surface ^{125}I-α-BGT binding assay and the Western blot analysis of the oocyte membrane preparation revealed that these mutants had the same expression level as the wild type receptor. These mutant AChRs displayed a linear current-voltage relationship with a reversal potential of around 0 mV similar to that of the wild type receptor, suggesting that these mutations did not alter the selective permeability of the AChR channel for cations. Moreover, these mutations did not change other AChR functional properties such as agonist binding ability, the slow phase of desensitization, and boockade by competitive and noncompetitive antagonists. These results suggest that M4 transmembrane domains can modulate AChR ion channel function, possibly by altering channel gating. (Supported by USPHS Grant NS 22941).

LOCALIZATION OF ACETYLCHOLINE RECEPTORS SUBUNITS MRNA IN CULTURED MYOTUBES. X.SU*,S.Berman,and S.Bursztajn. Mailman Research Center, Harvard Medical School, Boston, MA 02178

One of the hallmarks of neuromuscular synapse formation is the accumulation of the acetylcholine receptors (AChRs). The AChRs are composed of five different subunits, two of which are identical. Our previous studies have shown that the levels of AChRs α mRNA vary greatly from one nucleus to another in cultured non-innervated myotubes. In the present study we have addressed the question whether the other subunits also exhibit a heterogenous distribution of mRNA. For this purpose we have prepared intron/exon, or intron probes. Since the γ and δ subunits have a high degree of homology to one another, we have used computer analysis to obtain least homologous DNA sequences. We isolated specific DNA regions by the polymerase chain reaction (PCR) and ligated the synthesized DNA into Bluescript plasmid (SKII+). The ligated DNA was amplified by PCR in the presence of 5′ primer and the universal primer to produce extended DNA sequences containing a multicloning site and universal primer region at a defined end for use in further labelling and cloning procedures. We made 35S labeled probes via a modified previously described primer extension method, checked probe specificity by dot blot assay, and hybridized the myotubes with 35S labeled AChR α, γ, and δ subunits. Using nuclear track emulsion autoradiography and combined dark field/fluorescent microscopy we observed a heterogenous distribution of silver grains over nuclei of the same myotube for the AChR α and δ subunits. The γ subunit is being analyzed. Our results show differential activation of myotube nuclei for the AChR subunits. (Supported by NIH and MDA grants).

MUSCLE ACTIVITY SUPPRESSES EXPRESSION OF EMBRYONIC-TYPE NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) GENES VIA A CYCLIC AMP SECOND MESSENGER SYSTEM. K. G. Chahine*, J. Staple, L. Vanover, W. Walke* and D. Goldman. Mental Health Research Institute and the Department of Biological Chemistry, University of Michigan, Ann Arbor, MI 48109.

During development of the neuromuscular junction there is a switch in expression of nAChR genes from an embryonic- ($\alpha_2\beta\gamma\delta$) to an adult-type ($\alpha_2\beta\varepsilon\delta$). Embryonic-type genes are expressed throughout the muscle fiber prior to innervation. However, after innervation, extrajunctional expression of these genes is suppressed by nerve induced muscle activity. We investigated the mechanism by which this repression occurs by using a rat primary muscle culture system that responded to muscle activity (induced by stimulation with extracellular electrodes) in a similar manner as observed in vivo. We found that increasing intracellular cAMP reversed the effects of muscle activity on embryonic-type nAChR gene expression. Genes not regulated by muscle activity, such as those encoding the nAChR ε-subunit and creatine kinase, were not induced by increasing cAMP. Consistent with these results was the finding that muscle inactivity, induced in vitro by tetrodotoxin or in vivo by muscle denervation, caused an increase in cAMP and protein kinase A activity prior to inducing nAChR gene expression. In order to define the cis-acting DNA sequences conferring electrical sensitivity to the embryonic-type nAChR genes we have cloned the rat δ-subunit gene promoter and have used it to drive expression of the luciferase structural gene in transfected cultured muscle cells. These experiments have identified a 950 bp fragment that confers electrical regulation on expression of the luciferase reporter gene. Deletion analysis, band shift assays, and DNA footprinting are being used to characterize the cis-acting element(s) conferring electrical sensitivity to this promoter.

610.10

STABILIZATION OF ACETYLCHOLINE RECEPTORS IN ANEURAL RAT MUSCLE CULTURES BY CYCLIC AMP ANALOGUES J.P.O'Malley*, M.L. Shelanski & L.L.Rubin, Department of Pathology, Columbia Univ., New York, NY 10032.

The stabilization of AChRs at the neuromuscular junction (nmj) occurs at birth when the receptor's half life increases from the fetal value of approximately 1 day to the mature value of 7-10 days. Denervation has been shown to partially reverse AChR stabilization and results in the expression of two populations of AChR, one with a rapid turnover of 1 day (R_F AChRs) and another with a slower turnover of approximately 4 days (R_S AChRs). Recently it has been shown that agents which elevate cAMP can stabilize the R_S AChRs at the nmj of denervated muscle to a level similar to that of adult-type AChRs found in normal muscle ($t_{1/2}$~7 days). We wanted to determine if these agents were also able to stabilize AChRs in aneural muscle cell cultures, which normally only express fetal-type AChRs with a half-life of 1 day.

We report that cells treated for 4 days with 250 μM 8-(4-chlorophenylthio)-cAMP, 1 mM Dibutyryl-cAMP or 10 μM forskolin express two populations of AChR, one with a half-life of 1 day and another with a half life of approximately 12 days and which constitute approximately 75 % and 25 % of the total receptor population respectively. However if the period of treatment was shortened to less than 4 days the stable AChR population was not seen.

It would be interesting to know if the receptors which have a half-life of 12 days share other properties, such as channel kinetics, with adult-type AChRs in normal muscle and if they are thus physiologically equivalent to the stable AChRs of adult muscle.

610.11

TRANSCRIPTIONALLY-MEDIATED REGULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR EXPRESSION IN HUMAN CLONAL CELLS. Ronald J. Lukas and Linda Lucero. Division of Neurobiology, Barrow Neurol. Institute, Phoenix, AZ 85013.

Chronic treatment of TE671/RD human cells with phorbol 12-myristate-13-acetate (PMA) or with nicotinic agonists induces upregulation of muscle-type nicotinic acetylcholine receptors (nAChR). Only the PMA effect is blocked by cycloheximide or the topoisomerase II inhibitor, novobiocin, suggesting a requirement for protein and RNA synthesis. Northern blot analysis of mRNA in PMA-treated cells (but not in control cells or in cells treated with nicotinic ligands or dibutyryl cyclic AMP) indicates that there are coordinate and sustained (for at least 5 days) increases in levels of transcripts corresponding to human muscle-type nAChR alphal, betal, gamma and delta subunit genes within 6 hours of drug application. Treatment with sodium butyrate, which induces nAChR downregulation alone or in the presence of PMA, induces a transient (at 6 and 24 hours) decrease in nAChR gene transcript levels that is followed by a return to control levels at 3 days of drug exposure. Other studies done using cells of the SH-SY5Y human neuroblastoma clonal line indicate that chronic PMA treatment (but not treatment with nicotinic ligands, nerve growth factor, or dibutyryl cyclic AMP) also induces increases in neuronal nAChR alpha3, beta2 and beta4 subunit mRNA levels. Thus, chronic PMA treatment can activate transcription of muscle-type and neuronal nAChR genes.

610.12

UP REGULATION OF ACETYLCHOLINE RECEPTORS IN THERMAL INJURY J.M.Ward and J.A.J.Martyn*. Dept. Anaesthesia, Harvard Medical School and Anesthesia Services of Massachusetts General Hospital and Shriners Burns Institute, 51, Blossom Street, Boston MA 02114.

Severe burn injury results in dramatic changes in human pathophysiology which can result in many pharmacotherapeutic difficulties. Important sequelae in muscle include weakness and respiratory muscle failure and an altered response of peripheral nicotinic acetylcholine receptors (nAChR) to neuromuscular relaxant type drugs used clinically.

In thermally injured rats using a single, saturating concentration of [125I] alpha-bungarotoxin (a-BGT), we have demonstrated an increase of a-BGT binding to nAChR extracted from gastrocnemius muscle with respect to control (P=0.05 ANOVA oneway). This result has been confirmed by Scatchard analysis which also revealed that the Kd in the thermally injured animals was lowered.

We propose that the altered responses to neuromuscular relaxant type drugs are due, in part, to a decrease in affinity which promotes up-regulation of the nAChR.

610.13

INNERVATION OF MYOTUBES REGULATES TYROSINE PHOSPHORYLATION OF THE NICOTINIC ACETYLCHOLINE RECEPTOR. Z. Qu and R.L. Huganir, Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

The nicotinic acetylcholine receptor (nAChR) is highly phosphorylated on tyrosine residues in vivo. Previous studies have shown that denervation of muscle decreases tyrosine phosphorylation of the AchR suggesting that innervation of muscle regulates phosphorylation of the AChR. To examine more directly the role of innervation in the stimulation of tyrosine phosphorylation of the AChR, we have used neuron-muscle cell cultures. Immunocytochemical staining with anti-phosphotyrosine antibodies show that AChR clusters at synapses between nerve and muscle contain high levels of phosphotyrosine. In addition, neuronal innervation of muscle cell cultures increased tyrosine phosphorylation of the AChR as analyzed by immunoblot techniques with anti-phosphotyrosine antibodies or by directly examining the ^{32}P-incorporation into the AchR. Recent results have suggested that the neuronal extracellular matrix protein, agrin, which is thought to be released from the neuron and induce clustering of the AChR, may be the factor from the nerve that regulates tyrosine phosphorylation. These results suggest that tyrosine phosphorylation may mediate nerve induced clustering of the AChR at the neuromuscular junction.

610.14

EXPRESSION OF THE NEURONAL AND A NOVEL FORM OF FYN PROTEIN TYROSINE KINASE IN TORPEDO CALIFORNICA ELECTRIC ORGAN S.L. Swope, K.R. Wagner, E. Moritz*, and R.L. Huganir, Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, Md. 21205

Phosphorylation of the nicotinic acetylcholine receptor (AchR), by protein kinase A, protein kinase C, and an unidentified protein tyrosine kinase(s) appears to regulate the rate of desensitization as well as clustering of the AchR at the neuromuscular junction. The intent of the present study is to identify, by molecular cloning, tyrosine kinase(s) involved in the phosphorylation and modulation of the AchR. Oligonucleotides based on conserved subdomains of the tyrosine kinase src were used in the polymerase chain reaction (PCR) with cDNA prepared from Torpedo californica electric organ, a tissue highly enriched in AchR. PCR products which encoded tyrosine kinase fragments were generated. The cloned fragments were used to screen a λgt10 library prepared from electric organ. Two distinct clones, Torpedo Tyrosine Kinase (TTK) I and II, were identified and shown by Northern analysis to be highly expressed in electric organ. The nucleotide sequence of TTKI encoded a 61.2KD protein which was most homologous to the neuronal form of FYN tyrosine kinase whereas TTKII encoded a 60.8KD novel form of FYN. The role of TTKI and/or TTKII in modulating the AchR is under investigation.

610.15

DEPHOSPHORYLATION OF NICOTINIC ACETYLCHOLINE RECEPTOR: PURIFICATION AND CHARACTERIZATION OF THE PROTEIN TYROSINE PHOSPHATASE. L. Mei and R.L. Huganir. Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Tyrosine phosphorylation has been shown to regulate the functional properties of the nicotinic acetylcholine receptor (nAChR). The level of tyrosine phosphorylation of nAChR is regulated through a balance between tyrosine phosphorylation by protein kinases and phosphotyrosyl dephosphorylation by protein phosphatases. We have purified and characterized a protein tyrosine phosphatase that dephosphorylates tyrosine-phosphorylated nAChR from Torpedo electroplax. The [^{32}P]-labeled tyrosine phosphorylated nAChR was used as a substrate to monitor the enzyme activity during purification. The protein tyrosine phosphatase activity was purified using three consecutive cation-exchanger columns (phosphocellulose, S Sepharose Fast Flow, BioRex 70), followed by two affinity matrices (p-aminobenzylphosphonic acid-agarose and thiophosphotyrosyl nAChR-Sepharose 4B). The enzyme activity was purified to homogeneity, with an overall purification of 25,000-fold and a yield of 20 %. The purified enzyme had an apparent molecular weight of 43 kDa on SDS polyacrylamid gels and migrated as a monomer during Superose 12 chromatography. It had a neutral pH optimum and a specific activity of 18 μmol/mg protein/min., with a Km of 4.7 μM for tyrosine phosphorylated nAChR. The phosphatase was specific for tyrosine phosphorylated nAChR; it showed no activity towards the nAChR phosphorylated on serine residues by cAMP-dependent protein kinase. The tyrosine phosphatase had unique sensitivities to inhibitors and metal ions, suggesting that it may be a novel protein tyrosine phosphatase that dephosphorylates the nAChR and other neurotransmitter receptors. We have recently obtained protein sequence of tryptic peptides of the purified phosphatase and are currently attempting to isolate cDNA clones of the protein tyrosine phosphatase.

610.16

STAUROSPORINE INHIBITION OF RECOVERY FROM DESENSITIZATION IS REVERSED BY CALCIUM AT SNAKE TWITCH FIBER ENDPLATES. J.C. Hardwick and R.L. Parsons. Dept. of Anat. & Neuro., Univ. of Vermont, Burlington, VT 05405. We showed previously, at snake nicotinic acetylcholine receptors, that the recovery of receptor sensitivity to agonist following desensitization was inhibited by pretreatment with the protein kinase inhibitor, staurosporine (Hardwick & Parsons (1990) Neurosci Abstr 16:205). These findings suggested that recovery of the desensitized receptor involved protein phosphorylation. We demonstrate here that elevation of the external calcium concentration during agonist application, which results in an increase in calcium influx through agonist-activated endplate channels, reversed the inhibition of the extent of recovery produced by staurosporine. Garter snake *(Thamnophis)* twitch fibers were maintained in an isotonic potassium propionate solution and individual endplates voltage clamped to +30 mV. Desensitization was produced by microperfusion with 540 μM carbachol containing either 1 mM or 10 mM Ca^{++} for 2-3 minutes. Recovery was determined by measuring the reappearance of spontaneous miniature endplate currents (MEPCs) during the wash period. Elevation of the external calcium concentration during the carbachol application completely antagonized the inhibition of recovery produced by pretreatment with 0.5 μM staurosporine. Elevation of external calcium in the absence of agonist increased the frequency of MEPCs but did not alter their amplitude or decay time course in either control or staurosporine treated fibers. Elevation of external calcium also increased the rate of desensitization onset of the initial carbachol-induced current in both control and staurosporine-treated fibers. However, the subsequent acceleration of desensitization seen with a second application of carbachol was less in staurosporine-treated fibers as compared to controls. (Supported by NS 08580 (JCH), NS 25973 (RLP) and an MDA grant (RLP)).

ACETYLCHOLINE RECEPTORS: MUSCARINIC IV

611.1

ISOLATION AND CHARACTERISATION OF GENOMIC ELEMENTS REGULATING THE EXPRESSION OF THE CHOLINERGIC MUSCARINIC m4 GENE. I.C.Wood*, C.E.Stansfeld and N.Buckley*. Dept Pharmacology, University College London, London WC1E 6BT.

There are five genes (m1-m5) encoding cholinergic muscarinic receptors. Each of the receptors has a characteristic pharmacological profile and the mRNA coding for each receptor has a unique distribution within the mammalian brain. To investigate genomic cis elements responsible for this transcriptional control, genomic clones, which contain the coding region for the m4 gene, have been isolated from a rat cosmid library. As transcriptional regulatory elements are usually located 5' to the transcription initiation site, work has concentrated on one particular clone which contains approximately 25kb of upstream sequence from the coding region.

Since a full length cDNA clone for the m4 gene is unavailable to aid in the location of the transcription initiation site within the genomic clone, primer extension and PCR techniques have been used in an attempt to identify this sequence in the clone. Complementary to this, DNA fragments upstream from the coding region have been subcloned into a CAT reporter plasmid, ptkAGPT, for transfection into cell lines. These lines include those that express endogenous m4 receptors, *e.g.* NG108-15, PC12 and those that do not express m4 receptors *e.g.* CHO. The use of these cell lines should identify those promoter elements which are m4 specific.

611.2

REGULATION OF CARDIAC mAChR EXPRESSION AND FUNCTION BY INSULIN. M.E. Morton and N.M. Nathanson. Department of Pharmacology, University of Washington School of Medicine, Seattle, WA 98195.

Muscarinic acetylcholine receptors (mAChRs) coupled to guanine nucleotide regulatory-binding proteins (G-proteins) are part of an important signal transduction pathway in cardiac tissue. Alterations in the number and/or function of cardiac mAChR have been observed in various animal models of diabetes, suggesting that insulin may regulate mAChR in the heart. Here we demonstrate that insulin regulates muscarinic acetylcholine receptor (mAChR) number, function, and mRNA levels in embryonic chick heart cells cultured in serum-free, defined medium. In embryonic chick heart cultures, insulin regulates expression of mAChR protein and mRNA in a concentration dependent manner. Increasing concentrations of insulin [0.01 nM-2000 nM] caused a 60% decrease in the number of mAChR binding sites. Similar changes in mRNA levels of both cm2 and cm4 were also measured by solution hybridization analysis, although cm2 was more strongly regulated. Insulin-like growth factor type I mimics the effects of insulin on mAChR protein expression in these cultures. Carbachol-mediated inhibition of forskolin-stimulated cAMP accumulation in these cultures was measured in order to determine if the change in mAChR binding sites was accompanied by a change in functional responsiveness. Chick cardiomyocytes cultured in the presence of higher concentrations of insulin (therefore expressing lower numbers of mAChR), are less responsive to carbachol than cells cultured in low concentrations of insulin. These data demonstrate that insulin directly influences cardiac mAChR function, protein and mRNA expression and suggests that regulation of mAChR expression and function may contribute to the cardiomyopathies associated with diabetes.

611.3

DEVELOPMENT OF THE MUSCARINIC ACETYLCHOLINE RECEPTOR IN THE CHICK RETINA. M.P. Lambert, S. Aguilar, M-F. Aguilar, J. Sullivan*, J. Bergin*, and W. L. Klein. Northwestern University, Institute for Neuroscience, Evanston, IL 60025.

In an effort to understand the developmental control of cell specific surface proteins in the CNS, our laboratory has utilized the muscarinic acetylcholine receptor (mAChR) as a model system. Previous work has shown that there are two molecular weight forms of the mAChR in the chick retina, the ratio of which changes as a function of embryonic development (Large, et al.,1985, PNAS, 82:8785). To determine the source of these two forms, we began to probe the chick CNS with a 516 bp fragment of the rat m1 mAChR gene (generously provided by T. Bonner). The fragment recognizes muscarinic sequences in the chick as indicated by hybridization with several bands of an Eco I and Bam HI digest of chick genomic DNA. Screening of an E13 chick brain cDNA library (expressed in lambda gt11) with the m1 probe yielded several clones. We selected one to sequence, based on its hybridization at high stringency and size of 2.3 kb. This 2.3 kb fragment was subcloned into pGEM 7Z and partially sequenced using the method of nested deletions supplemented with synthetic oligonucleotide primers. It was found to be 98% identical in the open reading frame to the sequence of the muscarinic gene found in chick heart (cm4, Tietje, et al., 1990, J.Biol. Chem. 265:2828). The sequence of the 3' untranslated end is presently being evaluated. The 2.3 kb fragment was used to probe the developmental appearance and control of the mAChR message in retina. Preliminary data indicate that the one species of mRNA which hybridized with the probe at high stringency varies with developmental age, attaining a peak near E15, the time of maximum synaptogenesis. Furthermore, in cultured cells, a 4 hour exposure to muscarinic agonist results in an increase of the mAChR message, indicating a coupling between receptor activity and gene regulation.

611.4

Development of muscarinic receptor proteins in the forebrain of the Balb/CByJ mouse. E. Potter, A. Levey, C.A. Kitt, D. Price, J.T. Coyle and C.F. Hohmann. Depts. of Psychiatry, Neuropathology and Neuroscience, The Johns Hopkins University, Baltimore, Maryland.

Five different muscarinic cholinergic receptor genes are expressed in the CNS and at least 3 of these can be immunocytochemically detected in the forebrain of the adult rat. Here we show the ontogenetic time course and distribution pattern of these three subtypes m1, m2 and m4 in the mouse.

Antisera were raised against fusion proteins specific for each receptor subtype and purified by affinity chromatography. Immunohistochemistry was performed in brains aged postnatal day [PND] 5, 7/8, 14, 21, 30 and adult (2-4month). Immunoreactivity for m1,m2 and m4 was diffusely distributed in the neuropil at PND5 and 7 and only thereafter became associated with neuronal somata in some areas. The neuropil distribution pattern of all three antibodies changed with maturation, particularly in neocortex, hippocampus, striatum and thalamus. In addition, localization of m1 and m4 to fiber tracts, such as the corpus callosum, fimbria fornix and descending cortico-bulbar systems abated following the first postnatal week. Patterns of m1 and m4 immunoreactivity were similar but not identical. At all ages m2 displayed a distribution pattern virtually complimentary to both m1 and m4. Immunostaining intensity for all antisera appeared to increase postnatally until the end of the first month and thereafter declined.

Ontogenetic pattern changes, for all muscarinic receptor subtypes, appeared closely linked to the maturational schedule of each brain area. Thus the present results are compatible with a role of cholinergic receptors in the regulation of forebrain development.

611.5

ONTOGENIC PROFILE OF ACETYLCHOLINE MUSCARINIC RECEPTORS QUANTIFIED BY PCR ANALYSIS. U di Porzio, F Morelli*, N J Buckley*$ and M C Steel*$. International Institute of Genetics and Biophysics C.N.R. Naples, Italy and $National Institute for Medical Research Mill Hill, London, U.K.

Recent molecular cloning studies have demonstrated the existence of five acetylcholine muscarinic receptor genes, differentially distributed and pharmacologically distinct. We examined the ontogenic expression of m_1-m_5 receptor gene by the Polymerase Chain Reaction (PCR) method. RNA from foetal and newborn rat brains, from selected brain regions, or from primary cultures generated from the various CNS areas was amplified by the PCR using specific sets of primers designated to recognize each individual receptor subtype. Cycle conditions were optimized to permit coamplification of receptor reverse transcribed RNA and that of hypoxanthine phosphoribosyltransferase which was included as a constitutively expressed internal standard. The signals were quntifyed by densitometric analysis using a^{32}p-dATP. This technique revealed that each receptor subtype displays a unique pattern of expression during ontogeny: m_1, m_3 and m_5 are apparently expessed aroud the time of birth. m_2 and m_4 can be detected as early as E13. In vitro they also show caracteristic expression profiles, which might be modulated by different culture conditions. This suggests a controlled regulation of muscarinic receptor gene expression. There may be common regulatory mechanisms for the members within the two groups, the nature of which requires to be examined further.

611.6

POSTNATAL EXPRESSION OF MUSCARINIC RECEPTORS IN RAT SEPTUM AND HIPPOCAMPUS. J.B.Suszkiw and J.L.Tomsig
Dept. Physiol. and Biophys. Univ. of Cincinnati Sch. of Med. Cincinnati, OH 45267.

Since it has been reported that the septo-hippocampal projection neurons are sensitive to atropine, the objective of this study was to determine whether or not the expression of muscarinic receptors correlates with functional maturation of the septo-hippocampal pathway i.e., the development of hippocampal theta activity. In rat, the hippocampal theta activity appears at postnatal day 10 and attains adult characteristics within two weeks thereafter.

[^{3}H]QNB binding was measured in homogenates of rat septa and hippocampi isolated from postnatal day 1 through 31 (PN1-PN31) and adult (3 months) animals. In adult animals, the concentrations of high affinity (K_D @ 50 nM) QNB binding sites were similar in septal (551±99 fmol/mg P) and hippocampal (487±34 fmol/mg P) homogenates. The QNB binding capacity of PN1 septum was @ 20% of adult and reached maximal levels between PN14 and PN21. QNB binding in PN1 hippocampus was < 10% of adult, increased to 75-85% between PN14-PN21, and attained adult levels by PN31.

These results suggest that postnatal expression of muscarinic receptors in both septum and hippocampus may be an important parameter in the development of atropine-sensitive, hippocampal theta activity. Supported by BRSG S07RR05408-29 and University Research Council.

DIFFERENTIAL REGULATION OF m1-m5 MUSCARINE ACETYLCHOLINE RECEPTOR GENE EXPRESSION IN THE RAT CNS DURING ONTOGENY. S. Vincent, L. Tsiokas and M. Watson. Department of Pharmacology, UMDNJ-NJ Med. Sch., Newark, NJ 07103-2714.

Data from expression cloning studies reveal five muscarinic receptor (mAChR) subtypes. We studied postnatal ontogeny in brain sections from rats at postnatal days 1,7,14,21,28,35 and adult (3mo) to map development using adjacent 10um sections for quantitative ligand autoradiography and in situ hybridization histochemistry (ISHH). LiCl was used in cerebral cortical slices (350x350um) to study inositol phospholipid (IP) hydrolysis by prelabeling with myo[-2-3H]inositol (0.5uM) in Krebs PO4 buffer (95%O_2,5%CO_2). [3H](-)quinuclidinylbenzilate, a very specific nonsubtype selective antagonist, [3H]cismethyl-dioxolane, a label for the super high affinity agonist state, [3H]pirenzepine, an M1 antagonist, [3H]AF-DX 384, an M2 antagonist and [3H]hemicholinium-3, a Na-dependent high affinity choline uptake inhibitor, were each used as has been previously described to obtain quantitative autoradiograms. Quantitative ISHH data was obtained via 3'-end labeled oligonucleotide probes (^{35}S-dATP;>1,000 Ci/mmol) complementary to 4-48 or 4-51 base sequences of m1-m5 mAChR after verifying specificity by Northern blot analysis. Slices were incubated (25°C,24hr), washed (Tm= 55°C;0.5xSSC), dried, apposed (~4wk;0-4°C) to Hyperfilm-ßmax and quantified via DUMAS densitometer. Differential progressive increases occur during ontogeny. (MH-43024).

ALTERATIONS IN CORTICAL MUSCARINIC RECEPTOR SUBTYPE mRNAs FOLLOWING KAINIC ACID LESION OF RAT NUCLEUS BASALIS MAGNOCELLULARIS. Z. Zang and Ian Creese. Center for Molecular & Behavioral Neuroscience, Rugters, The State University of New Jersey, Newark, NJ 07102.

The cholinergic deficit seen in Alzheimer's disease (AD) is associated with cells loss in the nucleus basalis magnocellularis (nBM). Previous studies have shown that a major portion of the cholinergic projection to the cerebral cortex is derived from the nBM. This cholinergic input can be destroyed in rat by kainic acid microinjection into the nBM. The present studies examined the expression of muscarinic receptor subtype (m1, m2, m3, m4 and m5) mRNAs by solution hybridization/RNase protection analysis in rat frontal cortex following unilateral kainic acid lesion of the nBM. The absolute quantification of muscarinic receptor mRNAs in frontal cortex of rats indicated high levels of m1 mRNA (3.31 ± 0.28 pg/per µg total RNA), while the levels of m3 or m4 mRNAs were relatively lower (m3: 0.93 ± 0.13 pg/per µg total RNA; m4: 1.09 ± 0.10 pg/per µg total RNA). Almost no m2 or m5 mRNA was detected. 1 week or 3 weeks following unilateral injection (1.5 µl) of kainic acid (3 µg), we found that the m1 receptor mRNA on the nBM-lesioned side, in comparison to the unlesioned side, was significantly decreased (1 week -24.4%, 3 weeks -26.3%). The level of m4 receptor mRNA was decreased by 28.2% at 1 week, and by 18.2% at 3 weeks post lesion. However, the m3 receptor mRNA was not significantly affected by lesion. Elevation of m1 receptor mRNA has been reported in Alzheimer's brain. These results suggest that other pathogenic mechanisms are involved in AD, in addition to the cholinergic denervation, that regulate muscarinic receptor gene expression.

CHRONIC SCOPOLAMINE ADMINISTRATION DIFFERENTIALLY ALTERS REGULATION OF m1-m5 CNS MUSCARINE ACETYLCHOLINE RECEPTOR GENE EXPRESSION IN AGED BUT NOT YOUNG RATS. M. Watson, S. Vincent, E.A. Tolomeo and L. Tsiokas. Dept. of Pharmacol. UMDNJ- N.J. Medical School, Newark, NJ 07103-2714.

Prolonged drug treatment (Rx) may up- or down-regulate CNS muscarine acetylcholine receptor (mAChR) subtype densities. Using previously described methods, quantitative autoradiograms were obtained for the nonsubtype selective antagonist [^{3}H](-)quinuclidinylbenzilate, an agonist to bind the super high affinity state, [^{3}H](+)cismethyldioxolane, an M1 antagonist [^{3}H]pirenzepine, an M2 antagonist, [^{3}H]AF-DX 116, and an inhibitor of Na+-dependent high affinity choline uptake, [^{3}H]hemicholinium-3, with adjacent 10uM CNS sections. Quantitative in situ hybridization histochemistry (ISSH) was done via oligonucleotide probes complementary to 4-48/4-51 base sequences of m1-m5 mRNA by ^{35}S-dATP 3'-end labeling (s.a.>2.4x10^{9}dpm/ug) via terminal deoxynucleotidyltransferase. Slices were hybridized (36h;25°C), washed (Tm=55°C;0.5xSSC), dried and Hyperfilm-ßmax-apposed. 14d scopolamine Rx (10mg/kg/d;ip) induced no affinity changes but raised mAChR subtype densities. Levels of m1-m5 mRNA expression were similar. Up-regulation may not be regulated at the gene transcription level. Yet aged (30mo) Rx rats had high (p<.05) m1 mRNA & low mAChRs in some areas. One may speculate this reflects failed efforts to up-regulate mAChRs to necessary levels, and may be linked to lower cognition with aging. MH-43024

611.10

REGULATION OF m1-m5 MUSCARINE ACETYLCHOLINE RECEPTOR GENE EXPRESSION IN ALZHEIMER'S DISEASED BRAINS AND AGE-MATCHED POST-MORTEM CONTROLS. X. Ming, L. Tsiokas, S. Vincent, E.A. Tolomeo, Z. Jelisijevic, Y. Robitaille#, R. Quirion# and M. Watson. Dept. of Pharmacol., UMDNJ-N.J. Med. Sch., Newark, NJ 07103-2714 & #Dept. of Psychiat., McGill U. & Douglas Hos. Res. Ctr., Verdun, Quebec, Canada.

Binding, biochemical and autoradiographic data from post-mortem brain tissue of Alzheimer's Diseased (AD) and control (C) patients suggest changes occur in muscarinic acetylcholine receptor (mAChR) subtypes seen on both pre- and post-synaptic neurons. [3H](-)quinuclidinylbenzilate, [3H](+)cismethyldioxolane, [3H]pirenzepine, [3H]AF-DX 116 and [3H]hemicholinium-3 autoradiograms and in situ hybridization histochemistry (ISHH) data was quantified as described previously. No Kd changes are seen. [3H]HC-3 density in AD hippocampal formation is ~53% of C, consistent w/ low CAT activity. Other ligands show changes. ISHH via 5 human 3'-end labeled (^{35}S-dATP;SA~0.8mCi/ug) oligodeoxyribonucleotide probes complementary to 3 regions of 4-48/4-49 base sequences of m1-m5 mAChR is done after verifying specificity by Northern blots. Slices are incubated (36h;25°C), washed (Tm=46-53°C;.5xSSC) dried & apposed to Hyperfilm-ßmax (1w;3°C). Low levels of hippocampal m3 expression (p<0.05) and higher m5 mRNA transcript levels in the temporal cortex (p<0.05) are seen in AD. No other alterations are significant. Lost or altered abilities to modulate mAChR gene expression may occur in AD.(MH-43024)

611.11

MEASUREMENTS OF BRAIN MUSCARINIC RECEPTOR mRNA LEVELS IN ALZHEIMER'S DISEASE BY DNA-EXCESS SOLUTION HYBRIDIZATION. S.-Z. Wang*, S. Zhu*, D.C. Mash and E.E. El-Fakahany. Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201 and Department of Neurology, University of Miami School of Medicine, Miami, FL 33136.

The levels of mRNA encoding various subtypes of muscarinic cholinergic receptors (m1-m4) were measured using the quantitative and sensitive technique of DNA-excess solution hybridization. Single stranded hybridization probes corresponded to segments of the third cytoplasmic loop of the muscarinic receptor sequence which is unique to each receptor subtype. The probes were also chosen to exhibit a minimal degree of self complementarity. Measurements were performed in brain regions obtained postmortem from Alzheimer's disease patients and age-matched controls as follows: frontal cortex (m1, m3 and m4); temporal cortex (m1 and m4); occipital cortex (m1, m3 and m4); hippocampus (m1); nucleus basalis (m2) and brainstem (m2). Data were expressed as amol mRNA/100 µg of total RNA. Our results indicate that there was generally no significant change in the level of the message encoding the various muscarinic receptor subtypes in the different brain regions in Alzheimer's disease, although some trends for a decrease were noted in certain cases. The only exception was a statistically significant decrease in the concentration of mRNA coding for m1 receptors in the occipital cortex. These data suggest that the spared neurons in Alzheimer's disease mostly contain a normal level of muscarinic receptor messages.

611.12

CHOLINERGIC RECEPTOR CHANGES IN AN ANIMAL MODEL OF ALZHEIMER'S DISEASE. B. Thorne and P.E. Potter, Dept. Anesthesiology, Albert Einstein College of Medicine, Montefiore Medical Center, Bronx NY 10467.

The effects of cholinergic agonists on the evoked release of ^{3}H-acetylcholine (ACh) were studied in male Sprague-Dawley rats in which hippocampal cholinergic terminals were lesioned with the neurotoxin AF64A (ethylcholine mustard aziridium, 2 nmoles/ventricle). AF64A treatment causes reductions in cholinergic markers similar to those in Alzheimer's disease. Two weeks after AF64A infusion, choline acetyltransferase activity was decreased by more than 40%. ACh release was evoked from superfused hippocampal slices by electrical stimulation (1 or 2 Hz, 2 min). In control tissues, ACh release was enhanced by nicotine (EC_{50} 40 μM). In slices from AF64A treated rats, the dose response curve for nicotine was shifted to the left (EC_{50} 3.5 μM). The effects of nicotine were blocked by the antagonist dihydro-ß-erythroidine (10μM). In contrast, the dose response curve for inhibition of ACh release by the muscarinic agonist oxotremorine, was shifted significantly to the right in slices from AF64A-treated rats compared to controls. These results suggest that functional changes have occurred in hippocampal ACh receptors as a result of lesioning cholinergic inputs, with an increase in nicotinic receptor number or sensitivity, and a decrease in muscarinic receptor number or responsiveness.

611.13

QUANTITATIVE DISTRIBUTIONS OF MUSCARINIC RECEPTOR SUBTYPE m1-m5 mRNAS IN LONG SLEEP AND SHORT SLEEP MURINE BRAINS. L. Tsiokas, S. Vincent, J.J. McArdle and M. Watson. Dept. of Pharmacology, UMDNJ-N.J. Med. Sch., Newark, NJ 07103.

Molecular cloning of five distinct genes encoding each muscarine acetylcholine receptor (mAChR) subtype from rat tissue implies the rat synthetic oligodeoxyribonucleotide probes may specifically identify mouse mRNA analogs by in situ hybridization histochemistry (ISHH) and/or Northern blot (NB) analysis in long- and short-sleep (LS,SS) mice that are differentially sensitive to the hypnotic effects of ethanol. Our murine data show m1 mRNA predominates in cerebral cortical structures and is found in hippocampal, striatal and other regions of LS and SS mice. Murine m2 mRNA is found in extremely low levels in the murine CNS. The m3, m4 and m5 mRNAs were localized to hippocampus, cerebellum and brainstem in high abundance and m4 mRNA is also seen in significant levels in the caudate-putamen. Quantitative autoradiograms obtained via ISHH revealed no significant differences in relative CNS levels of m1, m4 and m5 mRNAs in LS vs SS. Unlike the strong signals seen in areas probed for m5 mRNA via ISHH, poly(A+)RNA NB of identical tissues show little, if any, detectable signal, even after unduly long exposures. Yet, ISHH shows m3 mRNA levels are lower (p<0.05) in hippocampal areas of SS. NB also show higher mRNA levels which imply higher levels of expression of a murine m3 mAChR gene in the hippocampus, as compared to other CNS or cardiac regions. (MH-43024).

BINDING CHARACTERISTICS OF PONTINE AND CORTICAL MUSCARINIC CHOLINERGIC RECEPTORS. H.A. Baghdoyan. Department of Anesthesia, Penn State Univ., College of Medicine, Hershey, PA 17033.

Microinjection studies using intact animals have demonstrated that muscarinic cholinergic receptors (MCR) in the medial pontine reticular formation are important for generating rapid eye movement (REM) sleep, and our recent studies have shown that cholinoceptive forebrain regions can influence pontine REM sleep generating mechanisms (Soc. Neurosci. Abs., 16:1056,1990). In order to pharmacologically characterize MCR in regions of cat brain important for controlling sleep and wakefulness, we have adapted a MCR binding assay for cat tissue (Sleep Res., 20:54, 1991). To date, non-linear least squares analyses of [^{3}H]QNB equilibrium binding to tissue homogenates from 3 cats revealed dissociation constants for pons and cortex of 96.2 pM and 52.9 pM, respectively, and number of binding sites (in fmol/mg protein) for pons and cortex of 506 and 1551, respectively. Thus, in comparison to cortex, MCR in the pons have a lower affinity for [^{3}H]QNB, and the pons contains fewer [^{3}H]QNB binding sites than the cortex. Competition binding assays will be used to identify and characterize subtypes of MCR in regions of cat brain known to be important in generating specific sleep states. *Supported by The Department of Anesthesia and MH45361.*

DEVELOPMENT OF SUBTYPE-SELECTIVE ANTISERA FOR THE m1-m5 MUSCARINIC CHOLINERGIC RECEPTORS. M. Li*, S.J. Wall, R.P. Yasuda, W. Ciesla*, and B.B. Wolfe. Dept. of Pharmacology, U. Pennsylvania, Philadelphia, PA and Georgetown U., Washington, D.C.

The third intracellular (i3) loop of each of the subtypes of muscarinic receptor is unique and was chosen to be used as an antigen to raise antisera selective for each of the subtypes. The cDNAs encoding most of the i3 loops of the m1, m2, m4, and m5 receptors were subcloned into expression vectors (either pRIT or pET). The areas close to the putative membrane-spanning regions 5 and 6 were avoided as these areas do not have the uniqueness found in the remainder of the i3 loop. The plasmids were sequenced to verify orientation and protein was produced by transforming *E. Coli.* Proteins were purified by a variety of methods (affinity chromatography, isoelectric focusing, size exclusion chromatography) to obtain full-length or nearly full-length proteins representing the i3 loop of a given subtype of muscarinic receptor. These proteins were injected into rabbits and sera were tested by immunoprecipitating solubilized receptors from cells transfected with the cDNA encoding a single muscarinic receptor subtype. Following 2 to 5 boosts with antigen, the antisera were able to quantitatively immunoprecipitate the expected subtype with no precipitation of any of the other subtypes. Additionally, for the m3 receptor, a short (18 amino acid) synthetic peptide corresponding to the sequence of the C-terminus was coupled to large carrier proteins and utilized as an antigen. Antisera obtained quantitatively precipitated m3 receptors with no precipitation of any other subtype of muscarinic receptor. Supported by GM31155 and NS26934, PDF and ADRDA.

EXAMINATION OF SUBTYPES OF MUSCARINIC CHOLINERGIC RECEPTORS USING SUBTYPE-SELECTIVE ANTISERA. R.P. Yasuda, S.J. Wall, M. Li*, C. Adams, S.J. Boyson, and B.B. Wolfe. Dept. of Pharmacology, Georgetown U., Washington, D.C., Dept. Pharmacology, U. Pennsylvania, Philadelphia, PA, Dept. Neurology, U. Colorado, Denver, CO.

Using a set of subtype-selective antisera we have generated against each of the five cloned muscarinic receptor subtypes (Li *et al. accompanying abstract*), the density and distribution of each of the subtypes has been determined in a number of tissues and following a number of experimental paradigms. Thus, the densities of each of the receptors in 7 areas (cortex, hippocampus, striatum, olfactory tubercule, thalamus/hypothalamus, pons/medulla, and cerebellum) of rat brain and 18 areas of human brain have been determined. Likewise, the densities of the subtypes were determined in several peripheral tissues of the rat (lung, ileum, bladder, parotid) as well as in several widely used clonal cell lines (SK-N-SH, 132-1N1). Additionally, the effects on receptor densities of chronic administration of the nonselective muscarinic receptor antagonist, atropine, were determined in rat cerebral cortex/dorsal hippocampus. Also, the ontogenetic profiles of each subtype were determined in rat forebrain. Furthermore, the effects of aging on the density of muscarinic receptor subtypes in the rat hippocampus were studied. It will be useful to compare these results to those obtained previously using ligand binding techniques. Supported by GM31155 and NS26934, PDF, and ADRDA.

ALTERATIONS IN CHOLINERGIC RECEPTORS FOLLOWING DEAFFERENTATION OF THE HIPPOCAMPUS AND CINGULATE CORTEX. L.F. Kromer, L.A. Pabreza*, S.J. Wall, K.J. Kellar and B.B. Wolfe. Dept. of Anat. & Cell Biol. and Dept. of Pharmacol., Georgetown Univ., Washington, DC 20007

In the present experiments, afferent input to the hippocampus (HPC) and cingulate cortex (CC) of adult female rats was removed unilaterally by an aspiration lesion of the rostral supracallosal stria/cingulum bundle and fimbria/fornix. Ten days after the lesion cholinergic receptors were examined in the HPC and CC. Nicotinic receptors were measured using ^{3}H-cytisine binding at near saturating concentrations (3.7nM). No significant difference in nicotinic binding between control and lesioned sides was found in the HPC, suggesting that few, if any, of these receptors are localized on cholinergic terminals. In contrast, nicotinic sites in the CC were significantly decreased (28%; $p<.001$) on the lesioned side. This decrease could reflect a loss of receptors on cholinergic or non-cholinergic afferents, such as dopaminergic axons. Total muscarinic receptors in the HPC (measured using 1nM ^{3}H-QNB) were increased slightly (19%; $p<.05$) on the lesioned side. More interestingly, measurements of each receptor subtype (m_1-m_5) using selective antisera revealed marked increases in m_3 (81%; $p<.01$) and m_4 (31%; $p<.05$) receptors and a decrease (27%; $p<.01$) in m_2 receptors. The direction of these changes may indicate the pre- or post-synaptic localization of these receptor subtypes.

611.18

INTERACTIONS OF HALOPERIDOL WITH MUSCARINIC RECEPTORS. RJ Smyth†, GR Luthin‡, TJ Shickley†. †Department of Pharmacology, Philadelphia College of Pharmacy & Science, Phila. PA 19104. ‡Department of Physiology & Biophysics, Hahnemann University, Phila. PA 19102.

Chronic administration of the antipsychotic drug haloperidol is often accompanied by extrapyramidal motor disturbances and dyskinesias. Other researchers have demonstrated that chronic haloperidol treatment causes an up-regulation of muscarinic cholinergic receptors. Comparison of primary amino acid sequences reveals a high degree of homology between anti-haloperidol monoclonal antibodies, and putative transmembrane domains of dopaminergic and muscarinic receptors. Our studies of secondary structure of these membrane bound proteins also predict structural similarity between dopaminergic and muscarinic receptors.

We therefore hypothesized the presence of a specific haloperidol binding site on muscarinic receptors, capable of interfering with agonist and antagonist binding, which may contribute to the muscarinic effects observed following haloperidol treatment.

Radioligand binding to muscarinic receptors was examined using [^{3}H]-oxotremorine-M for high affinity agonist binding and [^{3}H]-N-methyl-scopolamine for antagonist binding. Haloperidol inhibited both agonist and antagonist binding in rat cerebral cortex, and heart membranes with IC_{50} values in the μM range. Binding was unaffected by addition of GTP. Inhibition occurred over approximately a ten-fold concentration gradient, indicating possible positive cooperativity. A concentration-dependent effect of haloperidol on association kinetics was also observed. Together these data suggest that haloperidol inhibition of muscarinic ligand binding may not be explained by simple competitive interactions. Supported by USPHS Grant NS-26040 to TJS and by NS-23006 and a Scottish Rite Schizophrenia Grant to GRL.

MORPHOLOGY AND MUSCARINIC RECEPTOR DENSITY IN THE RAT BRAIN FOLLOWING EXPOSURE TO HYPOBARIC HYPOXIA

B. Shukitt-Hale, T. Kadar, A. Levy, M.J. Stillman*, J.A. Devine*, and H.R. Lieberman, Military Performance and Neuroscience, U.S. Army Research Institute of Environmental Medicine, Natick, MA 01760.

The histological and histochemical consequences of hypobaric hypoxia were studied in five rats exposed for 16 hours to an altitude of 5500 m (18,000 ft) and in four sea level control animals. When hematoxylin and eosin stained sections from altitude-exposed rats were compared to sections obtained from control animals, no morphological differences were observed. Even the CA1 layer of the hippocampus and the pyriform cortex, which are known to be especially vulnerable to hypoxia, appeared normal. Using in vitro receptor autoradiography, changes in cholinergic muscarinic receptor density were examined. Frozen sections from five additional rats were cut at the level of the hippocampus after exposure to hypoxia or control conditions. These sections were incubated in [^{3}H]pirenzipine to label M_1 receptors or [^{3}H]AF-DX 116 to label M_2 receptors, and receptor densities were measured using a computerized image analysis system. Both M_1 and M_2 receptor densities were somewhat greater in the altitude-exposed animals in most brain areas assessed, especially in the deeper layers of the frontoparietal cortex. It appears that exposure to an altitude of 5500 m (18,000 ft) for 16 hours is not sufficient to produce significant structural damage or significant changes in muscarinic receptor density in the rat brain. Of course, other histological methods may revel changes in brain structure not readily apparent with the methods we employed.

612.1

HIGH pH INCREASES THE POTENCY OF PHOSPHONATE SUBSTITUTED COMPETITIVE ANTAGONISTS AT NMDA RECEPTORS

M. Benveniste and M. L. Mayer. Section of Neurophysiology and Biophysics, LDN, NICHD, NIH, Bethesda, MD 20892.

Structure-activity relationships have shown that ω-phosphono-amino acids are more potent competitive antagonists at the NMDA receptor than ω-substituted analogs with carboxylate or tetrazole groups. The phosphonate group can have a maximum of two negative charges while carboxylate and tetrazole analogs have only one negative charge, suggesting that the higher potency of ω-phosphonate compounds could result from increased electrostatic interaction between these ligands and the NMDA receptor. Because the pK_a of one phosphonate oxygen in these compounds is ≈ 7.8 (Chenard et al. 1990 J. Med. Chem. 33:1077), the proportion of ionic species is strongly influenced by slight changes in pH in the physiological range.

Dose-inhibition analysis of NMDA activated currents for two ω-phosphonate antagonists, D-AP7 and its piperidine analog, LY 257883, indicated a > 3-fold increase in equilibrium potency between experiments on voltage clamped mouse hippocampal neurons conducted at pH 7.3 and pH 8.2. For the same pH range, the potency of the ω-carboxylate analog of LY 257883 increased only 1.4-fold. Analysis of the kinetics of block of NMDA activated currents in response to rapid concentration jumps of LY 257883, revealed a 79% increase in its association rate at the higher pH but also a 14% decrease in its dissociation rate. No such changes in rate constants were observed for the ω-carboxylate analog, LY 221501. The increase in the potency and concentration dependent association rate of LY 257883 is also consistent with an increase in concentration of the doubly charged antagonist species at higher pH.

Compound	pH	k_{on} ($\mu M^{-1}s^{-1}$)	k_{off} (s^{-1})	K_i (μM)
LY 257883	7.3	3.36 ± 0.99	0.83 ± 0.24	0.45 ± 0.05
LY 257883	8.2	5.99 ± 2.64	0.71 ± 0.20	0.14 ± 0.01
LY 221501	7.3	7.30 ± 2.58	3.45 ± 0.26	1.34 ± 0.15
LY 221501	8.2	7.06 ± 1.94	3.45 ± 0.27	0.92 ± 0.10

612.2

MECHANISM OF pH ANTAGONISM ON NMDA-INDUCED MEMBRANE CURRENTS IN ISOLATED CATFISH CONE HORIZONTAL CELLS.

X.G.Wu and B.N.Christensen. Dept. of Physiology and Biophysics, University of Texas Medical Branch, Galveston, TX 77550.

We have observed that the NMDA-induced membrane currents vary as a function of extracellular pH over the range of 5.5 to 9.5 with lower pH (pH < 7.4) decreasing current (Society for Neuroscience, 1990). The inhibitory effect of lower pH could be attributed to the effects of H^+ on various factors underlying the NMDA response. H^+ could affect the binding of NMDA with its receptor, block the NMDA-gated channel in a voltage dependent manner or alter an aspect of channel function such as channel kinetics, gating or conductance.

Concentration-response curves measured at pH 6.5 and 7.4 revealed a non-competitive type of inhibition indicating that H^+ does not interfere with agonist binding. Current-voltage curves measured at these pH's showed a uniform inhibition over the voltage range indicating that H^+ probably does not penetrate sufficiently far into the channel to feel the membrane field. To discriminate between an effect of H^+ on channel gating vs channel kinetics or conductance we are using fluctuation analysis to measure channel open time and single channel conductance. Supported by Grant NEI EY-01897.

612.3

EFFECTS OF EXOGENOUS GLUTAMINE (GLN) ON CA1 FIELD POTENTIALS AND SPONTANEOUS ACTIVITY IN RAT HIPPOCAMPUS IN VITRO.

W.D. YONEKAWA, I.M. KAPETANOVIC, AND H.J. KUPFERBERG*. Epilepsy Branch, NINDS, NIH, Bethesda, MD 20892.

GLN, normally present in brain extracellular fluid and CSF in the range of 0.2 to 0.5 mM, plays an important role in energy and neurotransmitter metabolism, but is not included in ACSF used for in vitro slice studies. This study examined the effects of GLN on the latency to onset (LAT) and amplitude (AMP) of extracellular CA1 population spikes (PS) and on spontaneous activity both in normal and in 9.4 mM K^+ ACSF. Rat slices were equilibrated for 60' in a submerged slice chamber either with or without 0.5 mM GLN in the ACSF. The slices were monitored for 15' and then the media switched to normal or 9.4 mM K^+ ACSF with or without 0.5 mM GLN. When 0 mM GLN + 9.4 mM K^+ was added to slices equilibrated in normal ACSF, an immediate increase in AMP and a decrease in LAT was seen in 4 of 5 slices. Full rhythmic bursting developed in 3 of the 5 slices while small infrequent bursts occurred in 1 other slice. When 0.5 mM GLN was added along with 9.4 mM K^+, 5 of 5 slices gave an increase in LAT while 2 of 5 had an increase in AMP. All 5 of these slices developed bursting, but in 4 of the 5 slices the bursts were small and short-acting. We found that GLN alone had no effect on the PS or on spontaneous activity. Adding 9.4 mM K^+ when 0.5 mM GLN was present throughout the entire run, led to an increase in AMP in 5 of 6 slices with no change in LAT in 4 of the 6 slices. Only 1 of the 6 showed full bursting, 2 of 6 had small and infrequent bursts, and 3 of 6 had no bursts at all. These data indicate that while 0.5 mM GLN appeared to decreased the onset and severity of K^+-induced spontaneous bursting activity, the effect on the evoked population spike was slight and limited to a small attenuating effect on LAT.

612.4

ISOPROTERENOL INHIBITS NMDA-INDUCED CURRENTS IN XENOPUS OOCYTES.

A. Omerovic* and S.R. Kelso. Dept. of Biological Sciences, Univ. of Illinois at Chicago, Chicago, IL 60680, USA.

The modulatory action of beta-1 adrenergic agonist on NMDA receptors was studied in Xenopus Leavis oocytes injected with total rat brain mRNA.Using two electrode voltage-clamp techniques, changes in NMDA currents were measured during bath application of different concentrations of isoproterenol. After incubation in isoproterenol (100 to 1000uM) for 1-30 minutes, the NMDA current was not significantly changed. However, in the presence of isoproterenol (200 uM) the NMDA current was significantly and reversibly reduced to 54.3±3.8 % of control (n=11).The minimal inhibition (10%) was obtained with 1uM; the maximal (96%) with 2mM (IC_{50} = 200 uM). The Beta-1 adrenergic antagonist, acebutolol (100-200uM) did not block the isoproterenol effect. A dose-response curve for NMDA in the presence of 200 uM of isoproterenol showed a noncompetitive antagonism, in which maximal response was decreased without change of EC_{50} for NMDA. The modulatory action of isoproterenol was selective for NMDA subtype of glutamate receptors. Kainate, AMPA and t-ACPD responses were not changed significantly in 5 cells tested. Isoproterenol inhibition of NMDA current was not voltage dependent; NMDA conductance was reduced and reversal potential was not changed by isoproterenol (5 cells). A similar reduction (to 71.4±2.7 % of control) was seen in 6 cells perfused with saline in which Ca^{2+} was replaced by Ba^{2+} in order to eliminate the contribution of Ca^{2+} dependent Cl channel to NMDA current. The inhibitory effect of isoproterenol on NMDA current was mimicked by norepinephrine; bath application of 100uM and 1mM of NE reversibly reduced the NMDA current to 44.1±2.9% and 13.6±0.9% of control, respectively.This inhibition was not blocked by acebutolol. The results suggest direct inhibitory effect of isoproterenol on NMDA receptors in total rat brain injected oocytes. Supported by NIH grant NS24591 and Klingenstein Fund.

612.5

EFFECTS OF GLYCINE AND STRYCHNINE ON RESPONSES OF RAT SPINAL NEURONS TO NMDA.

D. Budai, G. L. Wilcox and A. A. Larson. Departments of Pharmacology and Veterinary Biology, University of Minnesota, Minneapolis, MN 55455, U.S.A.

The strychnine-insensitive increase in NMDA-activated channel opening by glycine (Gly) is distinct from its classical inhibition of synaptic transmission. It has been postulated that extracellular Gly saturates its binding sites on the NMDA receptors but we and others have found effects of exogenously administered Gly *in vivo*. We examined the effects of NMDA, Gly and strychnine on nociceptive dorsal horn neurons of the rat spinal cord to test the hypothesis that neurons responsive to NMDA are facilitated by Gly acting at a strychnine-insensitive Gly receptor. Compound recording and iontophoresis electrodes were used to record single unit extracellular activity from the lumbar spinal cord of anesthetized rats and to apply drugs iontophoretically. Computerized instument control and data acquisition were performed using an NB-MIO-16 multifunction board programmed in LabVIEW 2. Application of NMDA by iontophoresis produced excitation in all 26 neurons tested. Gly significantly inhibited the NMDA-evoked increase in the neuronal firing rate (71±3%). Strychnine potentiated the NMDA-induced excitation (140±3%), perhaps because of the presence of endogenous glycine. When Gly was co-ejected with strychnine, the number of action potentials evoked by NMDA was further elevated (170±9%). These data provide evidence *in vivo* for the unsaturated nature of the Gly binding site of the NMDA receptor complex. *(Supported by USPHS grants DA04090 and DA04274).*

612.6

SINGLE CHANNEL PROPERTIES OF THE NMDA ION CHANNEL WITH DIFFERENT AGONISTS.

J. G. McLarnon and D. Sawyer*. Dept. Pharmacology & Therapeutics, The University of British Columbia, Vancouver, B. C., V6T 1Z3, Canada.

The glutamate receptor subtype, N-methyl-D-aspartate (NMDA), is activated by a variety of ligands. We have used the cell-attached patch-clamp technique, with agonist included in the patch pipette, to study the single channel properties of the NMDA channel, with different ligands. The compounds used included the D and L forms of N-methyl-aspartate (NMA) and the D and L forms of homocysteic acid. All of the ligands activated the high conductance (45 pS) state of the NMDA ion channel. In nominally free Mg^{2+} solution, the mean open times of the NMDA channel were decreased with patch hyperpolarization. At the cell resting potential, the mean open times were longer for NMDA compared with NMLA and were longer for L-homocysteic acid compared with D-homocysteic acid. The frequency of channel openings, but not the mean open times, were dependent on the concentration of ligand. When the pipette concentration of L-homocysteic acid was increased from 25 μM to 50 μM, the frequency of channel events was increased two-fold. Measurements of the single channel properties of the NMDA channel should be useful in the pharmacological characterization of agonist actions at the NMDA receptor.

612.7

DITHIOTHREITOL POTENTIATES N-METHYL-D-ASPARTATE STIMULATED NEUROTRANSMITTER RELEASE FROM RAT BRAIN SLICES

J. J. Woodward and D. Compton. Department of Pharmacology and Toxicology, Box 524, Medical College of Virginia, Richmond, VA, USA 23298

Rat brain slices released tritiated or endogenous neurotransmitters during a two minute stimulation with N-methyl-D-aspartate (NMDA). The dose response curve for NMDA was dramatically shifted to the left and upwards after treatment of slices with dithiothreitol (DTT; 0.1-5 mM), a sulfhydral reducing agent. Following DTT treatment, cortical slices released approximately the same amount of ^{3}H-NE with 10 uM NMDA (about 5%) as control slices did with 500 uM NMDA. In addition, DTT treatment more than doubled the NMDA stimulated release of ^{3}H-NE from cortical and hippocampal slices and increased endogenous dopamine release from striatal slices by 7-10 fold. This effect was not due to an increase in basal non-stimulated release or to a non-specific effect on depolarization as DTT did not enhance KCl induced release. The effects of DTT were fully reversed by treating the slices with the sulfhydral oxidizing agent di-thio-bis-nitrobenzoic acid (0.5 mM) prior to NMDA stimulation. DTT did not significantly alter the ability of magnesium (1.3 mM) or the polyamine antagonist arcaine to inhibit NMDA stimulated release. In contrast, DTT treatment significantly attenuated the antagonist effects of the competitive glycine antagonist, 7-chloro-kynurenic acid, and the competitive NMDA antagonist, amino-phosphono-valeric acid (AP-5). These results suggest that oxidation and reduction of disulfide bonds located within the NMDA receptor complex might regulate the activation of the NMDA receptor *in vivo*. Supported by NIAAA AA08089 and a grant from the Alcoholic Beverage Medical Research Foundation.

DEVELOPMENTAL CHANGES IN THE EFFECT OF MAGNESIUM ON [^{3}H]TCP BINDING TO RAT HIPPOCAMPAL MEMBRANES.

M.A. Bowe and J.V. Nadler, Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Mg^{2+} less potently blocks the NMDA-evoked depolarization of CA1 hippocampal pyramidal cells in 10-15 day old rats compared with adults. To investigate the cellular and molecular basis for this developmental change, we studied the effects of Mg^{2+} on the binding of [^{3}H]TCP to hippocampal membranes. The initial rate of binding reflects access of the radioligand to its binding site within the NMDA receptor channel. The rate is influenced by the state of the receptor and its membrane environment, but not by membrane potential, intracellular constituents or the presence of spare receptors. The initial rate of [^{3}H]TCP binding in the presence of saturating NMDA and glycine was greater in membranes from 10-15 day old rats. Mg^{2+} increased this rate at both ages, but to a lesser degree at 10-15 d. NMDA enhanced the initial rate of [^{3}H]TCP binding with similar potency at both ages. Low concentrations of Mg^{2+} increased the maximal effect of NMDA but to a lesser degree at 10-15 d. No age-related changes were observed in the equilibrium binding of [^{3}H]TCP, the effects of Mg^{2+} alone on equilibrium binding or the biphasic concentration-response curve for the effect of Mg^{2+} on the initial rate of [^{3}H]TCP binding. The weaker effects of Mg^{2+} on some aspects of [^{3}H]TCP binding during development may be related to its lower potency as an NMDA receptor antagonist in physiological studies. (Supported by NIH grant NS 16064.)

612.9

The distribution of spinal cord N-methyl-D-aspartate receptors is developmentally regulated.

Robert G. Kalb and Susan Hockfield, Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, Ct 06510

We have studied the molecular development of spinal motor neurons by examining the regulation of the cell surface proteoglycan recognized by monoclonal antibody Cat-301 (*J. Neurosci.***8**:2350). Cat-301 expression depends upon the coordinated activity of spinal segmental and descending afferents during a critical period in early postnatal life. This activity-dependent development is mediated through activation of the N-methyl-D-aspartate (NMDA) receptor: blockade of the NMDA receptor in early life inhibits the expression of the Cat-301 proteoglycan on motor neurons in a stereospecific and dose-dependent manner (*Science* **250**:294). The site of action of NMDA receptor antagonists at the spinal segmental level is not clear because the distribution of spinal NMDA receptors during postnatal development is not known.

We have examined the distribution of spinal cord NMDA receptors during development by employing quantitative receptor autoradiography. We studied NMDA-displacable 3H-Glutamate binding. All studies were carried out in the presence of CNQX and Kainate to block binding to non-NMDA glutamate receptors. In the adult spinal cord, NMDA receptors are concentrated in the substantia gelatinosa (SG) with very little binding elsewhere in spinal grey matter. In marked contrast, in P7 rat spinal cord, NMDA receptors are evenly distributed through out the grey matter. The neonatal ventral horn 3H-Glutamate binding to the NMDA receptor has approximately the same affinity and density as in the adult spinal cord. Between P7 and P28 the distribution of NMDA receptors gradually adopts the adult pattern. These changes cannot be accounted for by changes in spinal cord myelination over this period. These results demonstrate that the NMDA receptor-mediated development of motor neurons could occur through activation NMDA receptors in the ventral horn of the spinal cord.

612.10

DEVELOPMENTAL CHANGES IN THE NMDA RECEPTOR POPULATIONS OF THE RAT HIPPOCAMPAL SLICE.

R.J.Brady, M.T.M.Monroe* and J.W.Swann, Wadsworth Ctr. for Labs. & Res., New York State Dept. of Health, Albany, NY 12201-0509.

Information continues to accumulate indicating the existence of heterogeneity in the NMDA preferring excitatory amino acid population. We have previously reported observations of developmental changes in the characteristics of the NMDA receptor-channel complex in the CA3 infrapyramidal zone (CA3/IPZ) of *stratum oriens* in the hippocampal slice. In recent studies NMDA evoked responses have been recorded in both the CA1 and CA3 regions of the rat hippocampal slice. Agonist was iontophoretically applied in the IPZ region in CA3 and 100-150 μm away from the center of the cell body layer in *stratum radiatum* of CA1 (CA1/SR). The response to agonist application was recorded using whole-cell patch and field techniques. Recordings were obtained in mature (PND>35) and immature (PND 10-15) hippocampal slices treated with bath application of tetrodotoxin. The apparent potency of the competitive NMDA antagonist D(-)2-amino-5-phosphonovaleric acid (D(-)AP5) was measured in both regions during the different developmental periods. The effect of a series of increasing, bath applied, antagonist concentrations was assessed using the local negative extracellular field potentials produced by iontophoretic agonist application. Inhibition curves were then produced for the two regions during each age window. These relationships were then used to estimate the concentrations of D(-)AP5 needed to produce a 50% inhibition in each case. The antagonist was more potent in both regions of the immature hippocampal slice than in the older tissue. Within each age group the potency did not seem to differ significantly between regions. The 50% inhibition concentration in immature hippocampal CA1/SR and CA3/IPZ was approximately 4μM while the mature regions required approximately 11μM D(-)AP5. These differences in antagonist potency are further indications of developmental changes in the hippocampal NMDA receptor population. Supported by grants NS23071 to RJB and NS18309 to JWS from NIDS-NIH.

612.11

MODULATION OF THE DEVELOPING NMDA RECEPTOR-CHANNEL COMPLEX BY PHENCYCLIDINE IN RAT BRAIN.

R. Sircar, S.R. Zukin and D.L. Dow-Edwards[§] Departments of Psychiatry, Albert Einstein College of Medicine, Bronx, New York and [§]Department of Pharmacology, State University of NY Health Science Center, Brooklyn, New York.

The NMDA receptor-channel complex has been shown to be involved in the activity-dependent synaptic plasticity in developing animal. The present study was directed at determining the effects of chronic postnatal phencyclidine (PCP) exposure on [^{3}H]MK-801 binding properties. We have earlier shown that [^{3}H]MK-801 binding can be used as a marker for NMDA channel activity. Rat pups were daily injected (i.p.) with PCP (5 mg/kg) or saline beginning on postnatal day 5 till day 15. Animals were sacrificed on postnatal day 21, six days after the last injection. [^{3}H]MK-801 binding was measured in well-washed experimental and control rat forebrain CSMs, both in the virtual absence of any excitatory amino acids and under various degrees of channel activation i.e. in the presence of L-glutamate and/or glycine. In the absence of any exogenous L-glutamate and/or glycine, data from equilibrium saturation experiments indicate that PCP treatment produced a decrease in the density of high-affinity [^{3}H]MK-801 binding sites. When binding was carried out in the presence of L-glutamate alone or in the added presence of glycine there was no difference in [^{3}H]MK-801 binding between PCP- and saline-treated brains. The affinities of [^{3}H]MK-801 binding did not differ under any condition. These data suggest that chronic PCP exposure during development can alter NMDA receptor regulation.

612.12

REGIONALLY DISTINCT NMDA RECEPTOR SUBTYPES DISTINGUISHED BY [^{3}H]MK-801 BINDING.

S.Y. Sakurai, J.B. Penney and A. B. Young. Neuroscience Program and Dept. of Neurology, U. of MI., Ann Arbor, MI 48109.

The existence of NMDA receptor subtypes has been proposed, but has yet to be verified with detailed pharmacological analysis. We performed *in vitro* quantitative [^{3}H]MK-801 autoradiography in rat brain, under baseline and maximally stimulated conditions, to assess potential NMDA receptor subtypes. Displacements of [^{3}H]MK-801 binding were examined with the NMDA antagonist, 3-(2-carboxypiperazin-4-yl)propyl-1-phosphonic acid (CPP) and the strychnine-insensitive glycine binding site antagonist, 7-chlorokynurenic acid (7-ClKyn).

Under control conditions, several brain areas were differentially sensitive to CPP displacement of [^{3}H]MK-801 binding. CPP inhibited [^{3}H]MK-801 binding in outer cortex (OC) and inner cortex (IC) with Ki values of 0.32-0.48 μM, while in medial striatum (MS), lateral striatum (LS), CA1 and dentate gyrus (DG) of hippocampus Ki values were 1.1-1.5 μM. In medial thalamus (MT) and lateral thalamus (LT) the Ki was 0.78 μM (the groups differed significantly, $P < 0.0001$, Fisher PLSD). In the presence of glutamate (3 μM), the Ki values between regions maintained a similar relationship with the exception of the Ki for OC which increased 2.5 times more than other areas.

7-ClKyn inhibition of [^{3}H]MK-801 binding also distinguished regionally distinct subtypes which differed from CPP displacements. Under control conditions, 7-ClKyn inhibited [^{3}H]MK-801 binding in OC, IC, MS and LS with Ki values of 6.3-8.6 μM, while in CA1, DG, LT and MT, Ki values were 11.4-13.6 μM (the groups differed significantly, $P < 0.0001$, Fisher PLSD). In the presence of glycine (1 μM), the Ki values shifted similarly, with the exception of OC which increased 1.5 times more than other areas.

These data support the existence of NMDA receptor subtypes that can be distinguished pharmacologically using [^{3}H]MK-801 binding. By analogy to the $GABA_A$ receptor, one would predict the existence of regional differences in subunit composition of the NMDA receptor. Supported by USPHS NS19613, AG08671.

AGE-DEPENDENT INHIBITION BY LEAD OF NMDA-INDUCED CURRENT IN CULTURED HIPPOCAMPAL NEURONS. H. Ujihara and E.X. Albuquerque. Dept. Pharmacol. & Exp. Ther., Univ. of Maryland, Sch. of Med., Baltimore, MD 21201.

The N-methyl-D-aspartate(NMDA)-evoked current recorded at early stages of development from hippocampal neurons kept in culture was very sensitive to Pb^{2+}, but after the second week of culture the sensitivity to this cation decreased significantly. The whole-cell current was recorded according to the standard patch-clamp technique. NMDA (5-100 μM) and glycine (0.5-10 μM) were delivered to the neuron under whole-cell clamp condition via a U-tube located 50-100 μm away. $PbCl_2$ at concentrations varying from 1 to 100 μM was applied in the extracellular perfusion medium. The perfusion medium contained (mM), NaCl 165, KCl 5, $CaCl_2$ 2, HEPES 5, D-glucose 10 and TTX 0.0003 (pH 7.3, 340 mOsm), and the micropipette solution contained (mM), CsCl 80, CsF 80, CsEGTA 10 and HEPES 10 (pH 7.3, 330 mOsm). The patch micropipette resistance was 2-4 MΩ. The hippocampal culture was obtained from 16-18 day fetal rats and the cells were used 3 to 28 days after plating. Pb^{2+}-induced inhibition of NMDA-current was concentration-dependent at the range over 1-10 μM, although this effect was reduced at higher doses. The inhibition was most prominent during the first week of cell culture, and reduced along with maturation. The current-voltage relationship disclosed a voltage-independent inhibition of NMDA current by Pb^{2+}. Analysis of the relationship between NMDA concentration and Pb^{2+}-induced inhibition demonstrated that Pb^{2+} was a non-competitive antagonist of the NMDA-site of the receptor-channel complex. The same analysis for the glycine-site showed a non-linear relationship between glycine concentration and Pb^{2+}-induced inhibition, and suggested heterogeneity of glycine-sites. The present results show 1) the NMDA receptor may undergo some molecular conformational adjustment during maturation, and as a result, Pb^{2+} sensitivity is markedly decreased, 2) the Pb^{2+}-site is located outside of the electrical field of the channel, and 3) there may be at least two types of glycine-site which differ from each other in their sensitivity to Pb^{2+}. (Supported by U.S. Army Med. Res. & Devel. Comm. Contr. DAMD-17-88C-8119)

612.14

Inhibition of the NMDA-Activated Ion Current by Ethanol in Rat Hippocampal Neurons Does Not Involve the Glycine or Proton Modulatory Sites. Robert W. Peoples and Forrest F. Weight. Section of Electrophysiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

Previous studies in this and other laboratories have shown that physiologically relevant concentrations of ethanol inhibit responses mediated by N-methyl-D-aspartate (NMDA) receptors in mammalian neurons. We have investigated whether ethanol interacts with the glycine or proton modulatory sites of the NMDA receptor/ion channel complex in voltage-clamped rat hippocampal neurons in culture. As shown previously, the NMDA-activated current in these cells was increased by glycine and inhibited by ethanol. Concentration-response data for glycine (0.1-100 μM) enhancement of NMDA-activated current indicated that ethanol, 50 mM, decreased the maximal response to glycine without significantly altering its EC_{50}. In addition, the percent inhibition by ethanol did not vary significantly with glycine concentration. Similarly, elevating extracellular pH enhanced NMDA-activated current in these cells, but did not alter the percent inhibition by ethanol. Thus, ethanol appears to inhibit NMDA-activated current in hippocampal neurons at a locus different from the glycine or proton modulatory sites. (This work was supported in part by a National Research Council-NIH Research Associateship to R.W.P.).

612.15

ETHANOL INHIBITION OF THE NMDA-STIMULATED INCREASE IN INTRACELLULAR CALCIUM IN HIPPOCAMPAL MICROSACS: EFFECT OF TEMPERATURE, MG, GLYCINE AND MK-801. Laura C. Daniell. Dept. of Pharmacol. & Toxicol., Medical College of GA., Augusta, GA. 30912-2300.

The effect of N-methyl-D-aspartate (NMDA) on the intracellular free calcium concentration (Ca_i) was determined in microsacs (a cell-free membrane vesicle preparation) isolated from mouse hippocampus loaded with the fluorescent indicator, Indo 1. NMDA increased Ca_i in hippocampal microsacs with an EC_{50} of 30 μM. Ethanol inhibited NMDA-stimulated Ca_i increases in a noncompetitive manner with an IC_{50} of 67 mM. NMDA responses were markedly temperature-sensitive, but lowered temperature (from 32 to 22°C) did not alter the relative degree of ethanol inhibition. Preincubation with ethanol also did not alter the degree of ethanol inhibition. However, ethanol inhibition was reduced, in a concentration dependent manner, by glycine, Mg and MK-801. These data show that a variety of allosteric modulators of the NMDA receptor can reverse ethanol inhibition of NMDA-mediated calcium flux. This work was supported by the Alcoholic Beverage Medical Research Foundation and NIAAA (AA01866).

NMDA RECEPTOR-MEDIATED CONTRIBUTION TO HIPPOCAMPAL DENTATE GRANULE CELL POPULATION EPSPs *in vivo*: INTERACTION BETWEEN STIMULUS INTENSITY AND GABAergic INHIBITION. Thomas A. Blanpied and Theodore W. Berger. *Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh., PA 15260*

We have measured an NMDA receptor-mediated component of the hippocampal dentate granule cell population synaptic response *in vivo* to low frequency (<0.2 Hz) stimulation of the perforant path, and investigated the extent to which that component is dependent upon the stimulus intensity and the activation of local $GABA_A$ receptors. Extracellular recordings were obtained from the dentate molecular layer in anesthetized rabbits, and the perforant path was stimulated electrically using two intensities: below the threshold required to elicit a population spike ("low"), or 2-3 times the population spike threshold intensity ("high"). CNQX (50μM), APV (100μM), bicuculline (100μM), or saline were applied by pressure microinfusion from a multibarrelled pipette located 200-400μm from the recording site.

APV applied in the presence of saline alone did not reliably reduce the area of the EPSP evoked by either low or high intensity stimulation. However, the evoked EPSP contained an NMDA receptor-mediated component which was revealed in the presence of CNQX (50 μM; N=7): APV reduced the area of the CNQX-resistant EPSP on average by an amount corresponding to 12% of the pre-drug baseline in response to low intensity stimulation, and 27% of baseline in response to high intensity stimulation. In other preparations (N=6), bicuculline was infused in a concentration sufficient to eliminate paired impulse inhibition of the granule cell population spike. In 4 of these cases, a larger NMDA-mediated component of the EPSP was observed: APV reduced the area of the EPSP evoked using low intensity stimulation by 22%, and using high intensity stimulation by 40% of the respective pre-drug baselines. These data indicate that local inhibitory mechanisms *in vivo* interact with convergent excitatory afferents to determine the nonlinear intensity-response properties of the NMDA receptor channel. A MATHEMATICAL MODEL FOR THE DYNAMICS OF THE NMDA RECEPTOR-CHANNEL. Gilbert A. Chauvet, Nathaniel N. Urban*, and Theodore W. Berger. *Depts. of Behavioral Neuroscience and Psychiatry*, University of Pittsburgh, Pgh, PA 15260.

The kinetics of the NMDA receptor channel complex have yet to be fully characterized. While the kinetics of many non-zero conductance states can be directly observed, experimental determination of the kinetics of electrophysiologically invisible zero conductance states is much more difficult. Kinetic parameters of zero conductance states may be fixed through the use of computer simulations.

A kinetic model of the NMDA receptor channel complex is proposed which describes the actions of glutamate, glycine and magnesium at independent sites. The model assumes the existence of three distinct channel states: ground, open and desensitized. Extensions of the model to include additional ligands and channel states are also described. The case in which multiple glutamate and glycine sites are assumed is compared to the single site model. Experiments involving glycine-indenpendent desensitization, paired impulse activation and fast concentration stepping are simulated. Kinetic parameters including binding constants and state transition rates were modified to achieve the best fit to the experimental data. Thus, kinetic parameters which are presently experimentally inaccessible were constrained. Simulation results support the hypothesis that glycine-independent desensitization is mediated by the affect of glutamate binding on the duration of a desensitized state.

The formalism and notation used in this model is generalized and proposed as a general mathematical formalism for the description of receptor channel kinetics. The sensitivity of the system to changes in kinetic parameters is described. The mathematical analysis of the system, including the determination of steady states and stability are shown to be generally applicable to all kinetic models to which this formalism can be applied.

CONTRIBUTIONS OF NMDA AND NON-NMDA RECEPTORS TO VISUALLY EVOKED POTENTIALS IN ALBINO RATS. D.F. Sisson, J. Siegel, B. Cox and S.J. Grant. School of Life and Health Sciences and Department of Psychology, University of Delaware, Newark, DE 19716.

Excitatory amino acids (EAA) are the putative transmitter of neurons that project from LGN to visual cortex (OC1). Because early components of visually evoked potentials (VEPs) are indicative of geniculo-cortical activity, the effects of 2-amino-5-phosphonopentanoic acid (AP5), an NMDA receptor antagonist, and 6-cyano-7-nitroquinoloxaline-2,3-dione (CNQX), a non-NMDA receptor antagonist, on flash VEPs from albino rats anesthetized with chloral hydrate were evaluated.

Drugs were superfused over left OC1 using a cortical cup. VEPs were recorded from this cortical surface and from the unoperated, right, cortex simultaneously.

CNQX decreased amplitudes of VEP components N_1 and N_2 in a dose-dependent manner; neither P_1 nor P_2 were affected. This effect was reversed after 30 min of CSF wash. AP5 at concentrations up to 200 μM had no effect on VEP amplitude.

CNQX has an effect similar to kynurenic acid, a non-specific, EAA antagonist. These results suggest that non-NMDA receptors generate epsp's in response to visually driven input into primary visual cortex, and that these epsp's are reflected in N_1. P_1 is either presynaptic or reflects a fast, non-EAA, visual pathway.

EFFECTS OF DEXTROMETHORPHAN AND CARBETAPENTANE ON THE NMDA RECEPTOR-CHANNEL IN SINGLE CHANNEL RECORDINGS. J.M. Wright and L.M. Nowak, Dept. of Pharmacology, Cornell Univ., Ithaca, NY 14853.

Dextromethorphan (DM) and carbetapentane (CBP) have anticonvulsant actions (Tortella & Musacchio, *Brain Res.* 383:314-318, 1986) DM, but not CBP, protects against NMDA induced mortality in mice (Leander, *Epilepsy. Res.* 4:28-33, 1989). We examined the actions of these drugs on single NMDA channels in preliminary experiments (DM: N=7, CBP: N=3) with excised outside-out patches from mouse cortical neurons in culture. In 10 μM NMDA, 1 μM DM reduced the average current through the patch 86% at -60 mV but only 45% at +40 mV. In 1 μM DM with 2 μM NMDA at -60 mV, current was reduced 56%. Responses stabilized within 3 min of DM application; full recovery was seen after removing the drug. A new closed time (1.1 mS) was introduced at -60 mV and burst length was reduced 15%. The reduction in total current by DM was due primarily to a decrease in open time per burst; a reduction in the number of bursts also occurred. In contrast to the inhibition seen with DM, 10 μM CBP applied at -60 mV in 2 μM NMDA introduced a new closed time of 3 mS but did not reduce total current through the patch. ETHANOL INHIBITION OF N-METHYL-D-ASPARTATE (NMDA) RECEPTOR FUNCTION: SELECTIVE INTERACTIONS WITH THE GLYCINE RECOGNITION SITE. G. C. Yeh, D. W. Bonhaus, J.O. McNamara. Duke & V.A. Medical Center. Durham. N.C.

Ethanol inhibits N-methyl-D-aspartate (NMDA) receptor-mediated neurotransmission. To elucidate the mechanism of this inhibition, we examined effects of ethanol on the binding of ligands to the NMDA and glycine recognition sites of the NMDA receptor ([^{3}H]L-glutamate and [^{3}H]glycine respectively) and on the agonist-dependent binding of an NMDA channel blocker ([^{3}H]TCP). Ethanol decreased [^{3}H]glycine binding to a strychnine-insensitive glycine recognition site and inhibited the glycine-dependent binding of [^{3}H]TCP. By contrast ethanol had no effect on NMDA-sensitive [^{3}H]L-glutamate binding or on the potency of glutamate's stimulation of [^{3}H]TCP binding. Ethanol reduced [^{3}H]glycine binding by decreasing the maximum number of detectable sites (without altering binding affinity) and similarly reduced glycine-stimulated [^{3}H]TCP binding by reducing the maximum rate of glycine-stimulated binding (without modifying glycine's EC_{50} or steady state levels). Ethanol inhibited [^{3}H]TCP association and [^{3}H]glycine binding with similar potency (479 and 581 mM respectively). These data suggest that ethanol inhibits NMDA receptor function by modifying the glycine binding site so as to prevent ligand binding. This action of ethanol is similar to that of zinc. Thus regulation of the glycine binding site is a mechanism common to structurally diverse allosteric regulators of the NMDA receptor.

613.2

EFFECTS OF ETHANOL ON GLUTAMATE/GLYCINE ACTIVATION OF [^{3}H] TCP BINDING: A MODEL FOR THE NMDA RECEPTOR-ION CHANNEL. M.L. Michaelis, D. Joseph and E.K. Michaelis. Department of Pharmacology and Toxicology. University of Kansas, Lawrence, KS 66045.

Work from our laboratories back to 1978, has implicated brain glutamate receptors in the CNS actions of ethanol (ETOH) (e.g., Biochem. Pharm. 1978, 27:1685). Recent observations in several laboratories that the NMDA subtype of glutamate receptors is unusually sensitive to ETOH at physiologically relevant concentrations led us to use a model of NMDA channel activation, i.e., glutamate/glycine activation of [^{3}H] TCP binding, in studies designed to explore the site on the channel complex with which ETOH interacts in brain membranes. When both glutamate and glycine were present at 100nm, ETOH inhibited [^{3}H] TCP binding marginally (~12%) at concentrations up to 200 mM. When the effects of 100mM ETOH were examined with varying concentrations of each agonist alone, ETOH had little or no effect on glutamate stimulation of the [^{3}H] TCP binding but did inhibit activation by glycine. Dose response curves for ETOH measured at 120nM glycine alone revealed an IC_{50} of ~5mM ETOH and 90% inhibition of the glycine stimulated response by 10mM ETOH. Experiments to determine whether glycine could overcome the effects of ETOH indicated that, when ETOH was present at 2.5mM, its inhibitory effects could be overcome by glycine concentrations greater than 10uM. In agreement with studies involving ^{45}Ca influx, it appears that the site through which glycine activates TCP binding is likely to be the major site with which ETOH interacts. Studies are underway with the purified NMDA receptor complex reconstituted in liposomes (Ly and Michaelis, Biochemistry, in press) to determine the effects of ETOH on the isolated protein complex which does exhibit pronounced glutamate/glycine activation of TCP binding. GLYCINERGIC MODULATION OF [^{3}H]MK-801 BINDING TO THE NMDA RECEPTOR: EFFECT OF TEMPERATURE. J.C. Marvizon, P. Skolnick and I.A. Paul. Lab. Neuroscience, NIDDK/NIH, Bethesda, MD. 20892.

[^{3}H]MK-801 binding to an extensively washed rat forebrain P_2 fraction was measured at 4, 25 and 37 °C. At 25 °C, glycine (G) produced a monophasic enhancement of binding with an EC_{50} of 65 nM. D-serine (DS) and the putative partial agonists 1-aminocyclopropanecarboxylic acid (ACPC) and D-cycloserine (DCS) produced an enhancement (EC_{50}s 101, 88, 3000 nM) followed by an inhibition (IC_{50}s > 1 mM). This biphasic pattern was observed for all four compounds when the incubation temperature was reduced to 4 °C. At 37 °C G, ACPC, and DS elicited a biphasic enhancement of [^{3}H]MK-801 binding with EC_{50} values of 65, 31 and, 209 nM and > 1 mM. In contrast, DCS produced a monophasic inhibition of binding (IC_{50} > 1 mM). These data demonstrate that modulation of the NMDA receptor via the glycine binding site is temperature-dependent. Further, this evidence suggests that variations in incubation temperature may be employed to differentiate ligand subclasses at the strychnine-insensitive glycine receptor.

THE AMPA/QUISQUALATE RECEPTOR IS A SUBSTRATE FOR CALPAIN. P. Vanderklish*, M. Kessler, R. Hall*, B.A. Bahr, K. Sumikawa[1], and G. Lynch, Center for the Neurobiology of Learning and Memory and [1]Dept. of Psychobiology, University of California, Irvine, CA 92717.

The subclass of glutamate receptors selective for AMPA (α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid) generates the largest component of postsynaptic responses evoked at glutamatergic synapses and recent data by Staubli *et al.* (*Psychobio.* 18:377, 1990) have identified the conductance of AMPA receptors as the variable of expression in LTP, a lasting enhancement of synaptic strength triggered by postsynaptic Ca^{2+}-influx. It is of interest, then, to elucidate the mechanisms regulating these receptors, especially those which are activated by Ca^{2+}. We have found the AMPA receptor to be a good substrate for the micromolar-requiring form of the Ca^{2+}-activated neutral proteases (calpains). *In vitro* digestion of synaptic plasma membrane proteins (prepared from telencephalon) with 1μg calpain I per mg membrane protein (in 20 mM HEPES/Tris, 35°C, 0.5 mM $CaCl_2$, pH 7.4) resulted in the cleavage of the AMPA receptor and a concomitant loss in specific [^{3}H]AMPA binding. As evidenced by the use of a polyclonal antibody specific for Glu-R1 (one of the subtypes of the AMPA receptor, cloned by Hollmann *et al.*, *Nature* 342:643, 1989), this cleavage is characterized by the generation of a 95 kDa intermediate from the parent 102 kDa band within 30 seconds, followed by a gradual and almost complete loss of immunoreactivity on immunoblots. A similar cleavage profile was observed when hippocampal slices were depolarized in the presence of NMDA. The specificity of the anti-Glu-R1 antibody was confirmed by *i*) the comigration of the antigen with a protein which had been photo-affinity labeled with [^{3}H]CNQX (an AMPA receptor antagonist), *ii*) a loss of labeling at 102 kDa on immunoblots when the antibody was preabsorbed with the immunogen, and *iii*) comparable increases in specific [^{3}H]AMPA binding and immunolabeling following successive chromatographic steps. Determining whether this cleavage represents a way to change receptor properties or merely a mechanism of turnover will require functional studies of partially cleaved AMPA receptors. (Supported by AFOSR #89-0383.)

SUBSTANCE P AND POLYAMINES MODULATE THE NMDA RECEPTOR OPERATED ION CHANNEL BY SIMILAR MECHANISMS.

P.J. O'Malley*, D.O. Calligaro, and J.A. Monn. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Substance P (SP) has been shown to enhance NMDA receptor elicited responses in spinal neuron preparations. We hypothesized that SP and the polyamines spermine and spermidine, potentiate glutamate by similar mechanisms. SP 1-11, 1-7 and C-terminal SP fragments 7-11, 8-11 and 9-11 were tested for possible interaction with the NMDA receptor operated ion channel. SP 8-11 was the most efficacious fragments (EC_{50} 60-200 μM), increasing [^{3}H]MK801 binding 900% in well washed membranes and 20% in the presence of maximal glutamate and glycine concentrations, 100 and 10 μM respectively. SP fragments did not have affinity for or affect the kinetics of either [^{3}H]glycine or [^{3}H]CGS19755 binding. The enhancement of [^{3}H]MK801 binding was eliminated by glutamate or glycine receptor antagonists as well as putative polyamine antagonists putrescine, cadaverine and arcaine. SP 8-11 increased the association rate of [^{3}H]MK801 without affecting dissociation or number of binding sites. This is consistent with enhanced channel accessibility to [^{3}H]MK801. These results suggest that SP fragments modulate the NMDA operated channel by a mechanism similar to polyamines.

EFFECTS OF STRESS AND CORTICOSTERONE ON THE BINDING PROPERTIES OF GLUTAMATE RECEPTORS.

G. Tocco, T.J. Shors, S. Standley*, M. Baudry, R.F. Thompson, Program in Neurosciences, U. South. Calif. Los Angeles CA. 90089

The hippocampus is particularly vulnerable to the deleterious consequences of both acute and chronic stress. Since glutamate is the main excitatory neurotransmitter in the hippocampus, we investigated whether either the NMDA or AMPA subtypes of glutamate hippocampal receptors were modified in response to stress and corticosteroid administration by quantitative ligand binding autoradiography using ^{3}H-TCP and ^{3}H- AMPA as ligands for the NMDA and AMPA receptors, respectively.

Male Long -Evans rats were exposed for 1 hour to restraint plus 60, 1 mA, 1 sec tailshocks. Naive controls received no handling at all and another group was injected with corticosterone (1mg s.c.). While no change was observed in the binding properties of the ^{3}H-TCP under any condition, ^{3}H-AMPA binding was significantly decreased in several areas of the hippocampus of corticosterone-injected rats relative to naive controls. Restraint plus tailshock, however increased AMPA binding, even though corticosteroid levels were high. These results indicate that glucocoticoids may down regulate the AMPA receptor , but that some forms of stress trigger additional mechanisms that override the effects of glucocorticoids.

CHRONIC NEONATAL MK-801 TREATMENT RESULTS IN LONG-LASTING CHANGES IN NMDA RECEPTOR SENSITIVITY AND INCREASED SEIZURE SUSCEPTIBILITY

J.A. Gorter, M. Veerman*, M. Titulaer*, N.P.A. Bos*, M. Mirmiran. Netherlands Institute for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam, The Netherlands.

Persistent effects of neonatal interference with NMDA receptors were investigated by measuring 1) NMDA receptor sensitivity to its agonist and antagonists and 2) susceptibility to "kindling" evoked seizures. Rats were neonatally treated with MK-801 (two s.c. injections per day, 0.25mg/kg, on postnatal days (PND) 8-19) and micro-iontophoretically tested for NMDA receptor sensitivity in the hippocampal CA1 pyramidal cells at PND 70-100. In a dose-dependent fashion NMDA evoked responses were more severely suppressed by APV, but not by MK-801 in the MK-801 treated group. Furthermore, hippocampal kindling in adulthood showed an increase in the electrical seizure duration during the first kindling stage in the MK-801 group. These results suggest that neonatal interference with MK-801 leads to a long-lasting change in NMDA receptor sensitivity to APV, which in turn could accompany the observed increase in seizure susceptibility.

CHOLERA AND PERTUSSIS TOXIN SENSITIVE G-PROTEIN ON NMDA/PCP RECEPTOR ION CHANNEL COMPLEX. T.Hori[1*], T.Yamamoto[1], H.Yamamoto[1], K. Hatta[1], T. Moroji[1] and K. Yoshikawa[2]. Dept. of Psychopharmacology[1] and Molecular biology[2], Psychiatric Research Institute of Tokyo, Tokyo 156, JAPAN.

We previously reported that there may exist two Mg^{2+} sites on the N-methyl-D-aspartate (NMDA)/phencyclidine (PCP) receptor ion channel complex; the high affinity Mg^{2+} (≤300 uM), which stimulates and low affinity Mg^{2+} (≥1 mM) site, which inhibits [^{3}H]TCP binding. We also showed that GppNHp decreased the affinity of Mg^{2+}-stimulated [^{3}H]TCP binding. In the present study, we investigated a possible interaction of the GTP binding site and high affinity Mg^{2+} site or glycine site.

The binding of [^{3}H]TCP to rat cerebral cortices was determined as described before (Neurosci Lett 119; 9-11, 1990). GDPβS, GTP, GTPγS, GppNHp and GDP potently inhibited Mg^{2+}-stimulated [^{3}H]TCP binding (by more than 50 %), whereas ATP, CTP, GMP, cGMP, ITP and guanosine exhibited no significant inhibition. GppNHp reduced Mg^{2+}-stimulated binding by only 16 % in cholera toxin (CTX)-, but not pertussis toxin (PTX)-, treated membranes. On the other hand, GppNHp inhibited the glycine-stimulated [^{3}H]TCP binding to CTX- and PTX-pretreated membranes by 31 % and 20 %, respectively. The present findings indicate that the high affinity Mg^{2+} site may be coupled to CTX sensitive G-protein (Gs) and glycine site may be coupled to both CTX and PTX sensitive G-protein (Gs and Gi/o).

613.9

DIFFERENTIAL EFFECT OF SUBCHRONIC COMPETITIVE AND NON COMPETITIVE NMDA RECEPTOR ANTAGONISTS ON HABITUATION IN RATS. M.P.Pellicano*, A.Cerbone and A.G.Sadile. (SPON: European Brain and Behaviour Society). Dip. Fisiologia Umana e Funzioni Biologiche Integrate "F.Bottazzi", Univ. Napoli, I.

Non contingent multiple injections of N-methyl-D-aspartate (NMDA) receptor antagonists were used to test the behavioral response on habituation to novelty. Adult male Sprague-Dawley rats were given non competitive (Ketamine: 6 mg/Kg; MK-801: 0.1mg/Kg) or competitive (CPP: 0.1mg/Kg) NMDA receptor antagonists, or drug vehicle intraperitoneally twice a day for 7 days. They were all tested in a Làt-maze 12 hr after the last injection. Additional injections were given 12, 24 and 36 hr after testing. Retention was run 48 hr later. Habituation of activity and defecation score was measured by the between-test decrement in corner-crossings and rearings (with prevailing cognitive and noncognitive meaning, respectively) and of fecal boli (non cognitive). Subchronic blockade of NMDA receptors by low doses of competitive antagonists had no effect on habituation of horizontal and vertical activity. In contrast, non competitive antagonists impaired habituation of horizontal and vertical activity during the entire test, but only MK-801 did it significantly ($p < 0.025$). Thus, allosteric and isosteric blockade of high-affinity NMDA receptors differentially affect the processing of cognitive and noncognitive behavioral components, as suggested earlier (Behav.Brain Res., 39:187, 1990). **(Supported by CNR/MURST 40% grants).**

CHLORIDE TRANSPORT BLOCKERS PREVENT NMDA RECEPTOR-CHANNEL COMPLEX ACTIVATION

J. Lerma* and R. Martín del Río+, *Instituto Cajal, C.S.I.C., Av. Doctor Arce 37, and +Hosp. Ramón y Cajal. 28002-Madrid, Spain.

Activation of the N-methyl-D-aspartate (NMDA) receptor-channel complex has been implicated in a number of physiological and pathological phenomena. In particular, it mostly mediates the neurotoxic effect of the neurotransmitter glutamate. The NMDA complex contains several distinct binding sites targets for regulation by endogenous as well as exogenous compounds. In cultured spinal cord neurons we found that blockers of chloride transport (furosemide, a widely used loop diuretic, and the related compounds piretanide and bumetanide; niflumic and flufenamic acids, used as antiinflamatory agents) prevented NMDA receptor activation. The inhibitory effect was dose-dependent and specific for this class of glutamate receptor, as kainate- and AMPA-activated currents were only slightly altered. Antagonism of NMDA mediated currents by chloride transport blockers was voltage-independent and showed fast on-off kinetics. The action was non-competitive with NMDA and did not arise from interaction with the Zn^{2+} inhibitory site since blockade of NMDA induced responses by furosemide and Zn^{2+} was additive. The inhibition was greater in low concentration of glycine but it could not be overcome by increasing glycine concentration (up to 100 μM). In contrast the inhibition was attenuated by the polyamine spermine. Since the presence of spermine was not required for inhibiton to develop, we conclude that chloride transport blockers are non-competitive antagonists of the NMDA receptor acting as inverse agonists of the polyamine receptor and/or as agonists of the postulated inhibitory polyamine site. This action may explain the protective effect that has been shown for some of these drugs in neuronal degeneration.

613.11

N-METHYL-D-ASPARTATE RECEPTORS (NMDA) ARE ACTIVATED BY 4-METHYLPYRAZOLE, AN ALCOHOL DEHYDROGENASE INHIBITOR. W.M. Cintra, M. Marchioro*, Y. Aracava and E.X. Albuquerque. Lab. Mol. Pharmacol. II, IBCCF, UFRJ, RJ, Brazil, 21941; Dept. Pharmacol. Expt. Ther., Univ. Maryland Sch. of Med., Baltimore, MD, 21201.

It has been previously shown that pyrazole, an alcohol dehydrogenase inhibitor, is able to interact with NMDA receptors on hippocampal neurons (*Neurosci. Abst.*, 16:86, 1990). In this work, using the single channel patch-clamp technique we evaluated the effects of 4-methylpyrazole on outside-out patches excised from cultured fetal rat hippocampal neurons. After the outside-out configuration was achieved, the patch was placed inside a glass mini-pipe conected to a perfusion system that was used to deliver the drugs. Nominally Mg^{2+}-free solutions were used for the records. 4-methylpyrazole (1-10 μM) induced channel openings that resembled those activated by NMDA and by low concentrations of pyrazole. The voltage-current relationship showed that these channels had a predominant conductance value of 50 pS. Openings interrupted by numerous brief closures were seen and the burst pattern was more pronounced at hyperpolarized potentials. As the membrane was hyperpolarized, the number of events per burst increased and the duration of intraburst openings decreased. This channel activity was blocked by APV (100 μM), a competitive antagonist of NMDA receptors. In contrast to pyrazole, which activated and blocked the NMDA receptors at similar concentrations, the methylated derivative did not block the NMDA channels at the concentrations tested. These findings coupled to a very simple and rather rigid structures of pyrazoles make this series of compounds promising probes for structure-activity relationship analysis regarding activation and blockade of the NMDA receptors. 613.12

NMDA STIMULATES DOPAMINE RELEASE IN THE STRIATUM OF AWAKED RATS: A MICRODIALYSIS STUDY. D. Martínez-Fong, M. Rosales*, J.L. Góngora*, S. Hernández* and J. Aceves. Dept. of Physiology, CINVESTAV-IPN, Ap. Postal 14-740, 07000 México, D. F. México.

In vitro studies have demonstrated that glutamate may modulate dopamine (DA) release in striatum (Krebs et al. J. Neurochem. 56:81, 1991). We have explored in vivo the participation of NMDA receptors in this modulation. A guide cannula was stereotaxically implanted into the right striatum of anaesthetized male wistar rats (300 g). Five days after surgery DA was recollected by 3 mm microdialysis probes and measured by HPLC.

NMDA (90-800 µM) perfused through the probe caused a dose-dependent DA release. This effect was reversible and blocked by 2-amino-5-phosphonovalerate. Also, the NMDA evoked DA release was blocked by increasing Mg^{2+} concentration to 2.5 mM in the perfusion ringer. No turning behavior was seen in spite of the finding that NMDA induced an increase in striatal DA up to 1,700% of basal value. The accurate position of the cannula was verified histologically.

These results suggest that glutamate from the cortico-striatal pathway may stimulate in vivo the DA release of nigro-striatal terminals via NMDA receptor.

Supported by CONACYT No. P228CCOX891561.

N-METHYL-D-ASPARTATE UNILATERALLY INJECTED INTO THE STRIATUM OF RATS PRODUCES CONTRALATERAL CIRCLING:ANTAGONISM BY 2-AMINO-7-PHOSPHOHEPTANOIC ACID AND CIS-FLUPENTHIXOL. P.K.Thanos, K.Jhamandas and R.J.Beninger. Department of Psychology, Queen's University, Kingston K7K 3N6, Canada.

To evaluate the contribution of striatal glutamate receptors to motor control, circling responses were observed in rats following unilateral intrastriatal microinjections of the agonist, N-methyl-D-aspartate (NMDA) or the antagonist, 2-amino-7-phosphoheptanoic acid (APH). The role of dopamine (DA) in NMDA-produced circling also was evaluated. In experiment 1, an NMDA dose of 5.0 µg (in 0.5 µl), but not 0.5 or 0.05 µg produced significant contraversive circling. In experiment 2, an APH dose 10.0 µg but not 1.0 or 0.1 µg produced significant ipsiversive circling. In experiment 3, microinjection of the ineffective 0.1 µg dose of APH or a dose (20 µg) of the DA antagonist, cis-flupenthixol, that did not produce circling when administered alone, significantly reduced the circling response produced by the 5.0 µg dose of NMDA. As NMDA produced circling in the same direction as that seen following similar unilateral injections of locomotion-stimulating DA agonists, the present results suggest that glutamate, acting via NMDA receptors in the striatum, may exert an excitatorry influence on motor systems. The observation that a DA receptor blocker antagonized the NMDA response further suggests that the observed motor excitatory effect of glutamate at NMDA receptors requires concurrent stimulation of DA receptors in the same region of the striatum.

613.14

AMINO ACID NEUROTRANSMITTER RELEASE FROM KAINATE-TREATED CEREBELLAR CULTURES. K.L. Rogers[1], M.L. Simmons[2], G.R. Dutton[2]. Departments of Psychiatry[1] and Pharmacology[2], University of Iowa.College of Medicine, Iowa City, IA 52242.

Post-natal rat cerebellar cultures were treated with 50µM kainate from day five to day nine *in vitro*. Release of endogenous amino acids in response to kainate stimulation was quantified by reverse-phase HPLC at day nine and at day 11 (following 48 hours of recovery). Release of glutamate and GABA was suppressed at both time points in the cultures exposed to kainate as compared to untreated cultures. We have previously reported that in kainate-treated cultures depolarized with 50 mM potassium, the measured glutamate efflux recovers following the removal of kainate (day 11), whereas GABA release remains suppressed due to loss of inhibitory interneurons. This would indicate that the granule cell kainate receptors may be persistently down-regulated following chronic kainate exposure since the non-specific potassium stimulation of glutamate efflux recovers. Kainate-induced neurotransmitter efflux is calcium-dependent at the doses applied, and is receptor-mediated based on inhibition of amino acid release with co-administration of CNQX but not CPP or MK-801. Supported by NS20632.

613.15

POSSIBLE INTERACTION BETWEEN NMDA AND DOPAMINE RECEPTORS. O.GANDOLFI and R.DALL'OLIO*, Dept. of Pharmacology University of Bologna, ITALY, 40126.

The administration of the NMDA non competitive antagonist MK-801 (0.25 mg/kg i.p.) produced a long lasting increase in rat locomotor activity which is blocked by D--cycloserine (3 mg/kg i.p.) or spermidine (250 µg/rat). Although these results strongly suggest that this effect is specific for NMDA receptor blockade, direct or indirect DA-ergic mechanisms could be involved. In well washed membranes the (3H)-MK-801 specific binding was decreased by the "in vitro" addition of either SKF 38393 or LY 171555 (100 µM). The stimulatory effect of (3H)-MK-801 binding by glutamic acid was inhibited by dopaminergic agents in an apparently non competitive manner. Acute treatments neither with indirect DA-ergic agents neither with specific D1 or DE DA-ergic drugs failed to change (3H)-MK-801 specific binding. Repeated administrations with MK-801 (0.25 mg/kg i.p. daily for 21 days) failed to change (3H)-MK-801 specific binding, in contrast (3H)-spiroperidol binding was decreased. Consistently LY 171555 induced hyperactivity was reduced while neither (3H)-SCH 23390 binding nor SKF 38393 induced grooming behavior were affectd.

PHARMACOLOGICAL EVIDENCE SUGGESTING MULTIPLICITY OF KAINATE RECEPTORS IN THE RAT CENTRAL NERVOUS SYSTEM. Aizawa H.*[1], Kwak S.[1], Ishida M.[2] and Shinozaki H.[2]. [1]National Institute of Neuroscience, Tokyo 187, [2]The Tokyo Metropolitan Institute of Medical Science, Tokyo 113, Japan.

Effects of various kainate analogues, including acromelic acid (ACRO) and newly synthesized kainate derivatives 4-(2-hydroxyphenyl)-2-carboxy-3-pyrroridineacetic acid (HFPA) and 4-(2-methoxyphenyl)-2-carboxy-3-pyrroridineacetic acid (MFPA), on [^{3}H]kainate and [^{3}H]AMPA binding to rat spinal cord synaptic membranes were investigated. Scatchard analysis of the saturation binding experiments revealed a single population of [^{3}H]kainate and [^{3}H]AMPA binding sites with Kd of 6.2 ± 0.35 and 7.6 ± 1.5 nM , each exhibiting similar value to Kd of the high affinity [^{3}H]kainate and [^{3}H]AMPA binding sites in the brain, respectively. The rank order of the potency to inhibit the binding of [^{3}H]kainate was domoate ≥ HFPA ≥ kainate ≥ MFPA > quisqualate ≥ ACRO B ≥ L-glutamate ≥ ACRO A >> AMPA and that of [^{3}H]AMPA was quisqualate > AMPA > MFPA ≥ ACRO A ≥ L-glutamate ≥ HFPA > domoate > kainate. ACRO, MFPA and HFPA depolarize newborn rat spinal motoneurons and dorsal root C-fibers more potently than kainate. Therefore, ACRO may exert the potent depolarization not through activating either kainate or AMPA receptors but through other receptors. Present results lend support to the presence of plural kinds of kainate receptor subtypes which we have presumed from the complicated systemic neurotoxic effects of ACRO and kainate in the rat.

SELECTIVE KAPPA ACTIVITY OF DYNORPHIN Ia (DYN Ia) IN MICE. V.K. Shukla*, M. Bansinath* and S. Lemaire. Department of Pharmacology, University of Ottawa, Ottawa, Ontario, Canada and Department of Anesthesiology, NYU Medical Center, New York, USA.

Effect of Dyn Ia (i.c.v.) was studied on the visceral pain (acetic acid-induced writhing), gastrointestinal transit and body temperature in mice. In control groups, Dyn-Ia dose dependently protected against acetic acid-induced writhing with an ED_{50} of 1.78 nmol/mouse (95% confidence limits (CL) 0.72-0.84 nmol/mouse). Nor-binaltorphimine pretreatment (10 nmol/mouse 15 min before) increased the ED_{50} of Dyn Ia to 4.61 nmol/mouse (95% CL, 3.67-5.81 nmol/mouse). The potency ratio between control and nor-binaltorphimine pretreated groups was 0.39 (95% CL, 0.27-0.55, ($P<0.05$). The ED_{50} of Dyn Ia was 2.45 nmol/mouse (95% CL 1.82-3.31 nmol/mouse) in metaphit pretreated (10 umol/mouse 24 hr before) group. The potency ratio between control and metaphit pretreated group was not significant. Dyn Ia (i.c.v., 1-10 nmol) did not have any effect on gastrointestinal transit and body temperature. These results indicate that the potent antinociceptive effect of supraspinal Dyn Ia in the writhing test is mediated by the stimulation of the κ opioid receptor and is not accompanied by any change in gut motility and body temperature. Supported by the MRCC.

PHARMACOLOGICAL CHARACTERIZATION OF NALBUPHINE, A MIXED KAPPA$_1$ AND KAPPA$_3$ OPIOID ANALGESIC. C.G. Pick, D. Paul, and G.W. Pasternak. The Cotzias Lab. of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Depts. of Neuroscience and Pharmacology, Cornell U. Medical College, New York, NY 10021.

Nalbuphine is potent mixed agonist/antagonist analgesic with little respiratory depression, presumably due to low efficacy at μ receptors. We now present evidence suggesting that nalbuphine analgesia is mediated through a combination of κ_1 and κ_3 receptors. In CD-1 mice, nalbuphine produced a dose-response analgesia in the tailflick assay (ED_{50} 41.8 mg/kg). This analgesia was reversed by the κ_1-selective antagonist nor-BNI but not by the μ antagonist β-FNA or the δ antagonist naltrindole, implying a possible κ_1 mechanism. Nalbuphine demonstrated cross-tolerance with the κ_1 agonist U50,488H and with the κ_3 agonist NalBzoH, but not with morphine. These results suggest the importance of κ_3 receptors as well as κ_1. Both spinal and supraspinal mechanisms of action were important for nalbuphine analgesia. Nalbuphine was equipotent when injected i.c.v. or i.t. However, following systemic administration, the supraspinal mechanism predominates since Win44,441 antagonized nalbuphine analgesia over 100-fold more potently when the antagonist was administered i.c.v. than i.t. Nor-BNI effectively antagonized systemic nalbuphine analgesia when given i.t. but not i.c.v. Together, these results imply that nalbuphine analgesia involves both a supraspinal κ_3 and a spinal κ_1 opioid receptor mechanisms, with the supraspinal component playing the major role following systemic administration.

AMNIOTIC-FLUID INGESTION INHIBITS CONTRALATERAL CIRCLING AFTER UNILATERAL MORPHINE INJECTION INTO THE VENTRAL TEGMENTAL AREA. A.C. Thompson, J.M. Di Pirro, C.D. Dickerson* and M.B. Kristal. Dept. of Psychology, SUNY at Buffalo, Buffalo, NY 14260.

Ingestion of amniotic fluid (AF) or placenta has been shown in rats to enhance opioid-mediated analgesia, but not to affect opioid-mediated hyperthermia. The present study assessed the effect of ingestion of AF on another opioid-mediated behavior: contralateral circling induced by ventral tegmental (VTA) microinjection of morphine. We decided to test this opioid-induced behavior because its neural mechanism has been dissociated from that producing analgesia.

Rats were given unilateral morphine injections (0.0, 0.1, 0.3, or 1.0 μg) into the VTA, followed by orogastric infusion of 0.25 ml AF or control fluid (beef bouillon, BB). Circling was monitored for 1 hr following injection. The dependent measure was *net number of contralateral circles per hour* (NCC/hr). Pain threshold was assessed (using tail-flick latency) at 1 hr post-treatment to confirm that morphine-induced analgesia had not been produced. Each rat was tested at all doses of morphine in a balanced design.

As expected, NCC/hr among BB-infused rats (n = 4) was significantly elevated at all doses of morphine (NCC/hr = 35 - 60 after morphine injections; NCC/hr = 0 after vehicle injection). In contrast, NCC/hr among AF-infused rats (n = 4) was not elevated after any dose of morphine ($p < 0.01$) (NCC/hr ≈ 0 after all morphine injections and after the vehicle injection). Pain threshold was unaffected by any treatment (no analgesia was produced).

These results demonstrate that the effect of AF ingestion on opioid-mediated behavior is not limited to analgesia and is not mediated through a single neuroanatomic site.

VENTRAL TEGMENTAL AREA (VTA) AND NUCLEUS ACCUMBENS (NAS) *k*- OPIOID AGONIST, U50488H, INHIBITS MALE SEXUAL BEHAVIOR. M. Leyton and J. Stewart. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montréal, Québec, Canada H3G 1M8.

We previously reported that systemic injections of the *k*- agonist U50488H (U50) naloxone reversibly decrease both appetitive and consummatory aspects of male sexual behavior (Leyton & Stewart, 1991a,b). Moreover, selective aspects of these U50-induced deficits could be differentially reversed by infusions of the *k*- antagonist nor-binaltorphimine into the VTA, NAS and medial preoptic area (mPOA). In the present study, male rats with bilateral VTA, NAS or mPOA cannulae were centrally administered U50 (.0005-5.0 nmol/.5µl/side). Infusions of U50 into the VTA decreased the proportion of males to ejaculate, and increased the latencies to mount, intromit and ejaculate at the lowest dose. Intra-NAS U50 decreased the proportion of males to intromit and ejaculate, and, the mean number of ejaculations as well as increasing the latencies to mount, intromit and ejaculate except at the highest dose. Intra-mPOA U50 did not significantly alter any measures. Comparing these findings to our previous reports suggests that mPOA *k*- receptor activation only weakly inhibits sexual behavior in otherwise unhampered males, but, synergistically potentiates the inhibition of appetitive aspects of sexual behavior induced by VTA or NAS *k*- receptor stimulation. Conversely, *k*- receptor stimulation in either the VTA or NAS is sufficient to delay the initiation of male sexual behavior.

NEURAL SUBSTRATES UNDERLYING AMYGDALOID CONTROL OF DEFENSIVE RAGE ELICITED FROM THE PERIAQUEDUCTAL GRAY IN THE CAT. M.B. Shaikh and A. Siegel. Department of Neurosciences, N.J. Medical School, Newark, NJ 07103.

Recently, we have shown that opioid peptides powerfully suppress feline defensive rage (DR) from the midbrain periaqueductal gray (PAG) and that a primary source of such input is the central amygdaloid nucleus (CE). This study provides anatomical/immunocytochemical evidence in support of this hypothesis. Cannula electrodes were implanted into the PAG for elicitation of DR as well as for infusion of non-selective and selective opioid antagonists and the retrograde tracer, Fluoro-Gold (FG)[4-8%]. Monopolar electrodes were implanted into amygdaloid sites from which suppression of DR was obtained. Brain tissue was processed for identification of met-enkephalinergic (met-enk) cell bodies within the amygdala. CE suppression of DR was blocked by infusion of naloxone or B-FNA into the PAG. Met-enk cells were located within the CE and retrogradely labelled cells within the ventral CE and adjoining regions of the lateral and basal nuclei. Neurons double labelled with FG and met-enk were identified within the rostral half of CE and adjoining portions of the lateral nucleus. Sites from which suppression of DR was obtained corresponded to the same general regions where single or double labelled neurons were identified. The results provide evidence that met- enk neurons from the CE can directly inhibit DR at the level of the PAG.

ENHANCEMENT OF MET-ENKEPHALIN STAINING IN THE RAT BRAINSTEM AS A RESULT OF SOCIAL STRESS. C.A.Cohen, R.M. Kream*, J.E. Marchand, and K.A. Miczek. Department of Psychology, Tufts University, Research Building, 490 Boston Ave., Medford, MA 02155 and the Department of Anesthesiology, Tufts University School of Medicine, 136 Harrison Ave., Boston MA 02111.

Immunohistochemistry was used to assess the effects of social stress on the endogenous opioid system. Similar studies have already indicated that socially stressed animals show marked potentiation of the analgesic effect of morphine, as demonstrated by a shift in the dose response curve to the left, during the social stress experience. Within 24 hours after social confrontation, there is also evidence for mild tolerance to opiate analgesia, and tolerance continues to develop as a function of time. In the current experiment an intruder male rat was placed into the home cage of a resident and subsequently exposed to attack and threat. Once the animal showed unambiguous signs of submission (i.e. through ultrasounds and supine postures), the intruder was placed into a protective cage for one hour while being exposed to the threat of an attack. No physical harm could come to the intruder at this time. The intruders were perfused with saline followed by 4% paraformaldehyde, at various time intervals after the social stress experience. The brains were removed and placed in fixative for two hours followed by a solution of 20% sucrose and 0.1M phosphate buffer where they remained until sectioning. The control animals were housed in the same room and were located in proximity to the defeated animals. They were perfused and their brains handled in the same manner as mentioned above. All brains were sectioned (32 µm) and prepared for immunohistochemistry using antibodies for met-enkephalin. Preliminary observations suggest that at the mesencephalic and pontine levels there was an increase in met-enkephalin immunoreactive elements in the central gray surrounding the aqueduct in the socially stressed animals three hours after the encounter, in comparison to controls. These changes are being monitored via radioimmunoassay and molecular biological techniques.

DIFFERENTIAL EFFECTS ON MOUSE LOCOMOTOR ACTIVITY OF MU-SELECTIVE VS DELTA-SELECTIVE OPIOIDS. M. E. Nevins and S. A. Nash* Dept. of CNS Diseases Research, Searle, Skokie, IL 60077.

It has been suggested that mu-selective and delta-selective opioids produce different profiles of locomotor activation after i.c.v. administration to mice. Michael-Titus, et al. [Neuropeptides (1989) 13,235-242] and Mickley, et al. [Psychopharmacology (1990) 101,332-337] showed that while mu-selective opioids such as morphine and [D-Ala^2 Me Phe^4 Glyol] enkephalin (DAMGO) produce large increases in horizontal movements and decreases in vertical movements, the delta-selective opiate [D-Pen^{2,5}] enkephalin (DPDPE) increases horizontal movements to a lesser extent and either increases (Michael-Titus, et al.) or does not affect (Mickley, et al.) vertical movement. The current study was conducted to determine whether the profile of locomotor activation reported for DPDPE would extend to other delta-selective peptides. The locomotor activity of male CD-1 mice was monitored by use of infrared photocell-based activity monitors (Omnitech Electronics). Mice were habituated to the monitors for 20 min. prior to i.c.v. drug administration. The results show that [D-Ala^2] Deltorphin I produced a locomotor profile similar to that of DPDPE, while [D-Ser^2-Leu] enkephalin (DSLET), [D-Thr^2-Leu] enkephalin (DTLET), and [D-Ala^2-D-Leu^5] enkephalin (DADLE) produced profiles similar to the mu-selective agents. The results are discussed in terms of delta-receptor selectivity.

MECAMYLAMINE ALTERS DIFFERENTLY THE MORPHINE- AND METHADONE-INDUCED CATALEPSY AS WELL AS CHANGES IN STRIATAL DOPAMINE METABOLISM. L. Ahtee, M. Attila and P. Lehtonen*. Div. of Pharmacology and Toxicology, Dept. of Pharmacy, Univ. of Helsinki, SF-00170 Helsinki, Finland.

Morphine and methadone induce catalepsy in rats and elevate the acidic dopamine metabolites. The nicotinic antagonist, mecamylamine, reduces methadone catalepsy (Ahtee, Eur.J.Pharmac. 1976:**39**:203) but prolongs morphine catalepsy (Ahtee & Kaakkola, Br.J.Pharmac. 1978:**62**: 213). In the present experiments mecamylamine (4 mg/kg i.p.) given 20 min before the opioids potentiated and prolonged the cataleptic effect of morphine (10 mg/kg s.c.) but reduced that of methadone (6 mg/kg s.c.). Both morphine (20 mg/kg) and methadone (10 mg/kg) elevated the striatal DOPAC and HVA concentrations. Mecamylamine pretreatment antagonized these effects of morphine (by 70-80%) more than those of methadone (by 30-35%). However, mecamylamine antagonized the methadone-induced decrease of striatal 3-MT concentration but tended to potentiate the morphine-induced decrease of 3-MT. Thus the mecamylamine-induced alterations in morphine and methadone catalepsy could be related to changes in striatal dopamine metabolism.

MU OPIOID ACTIVITY IN MEDIAL THALAMUS: EFFECTS ON BEHAVIOR AND DOPAMINE UTILIZATION. K.D. Carr, S. Uysal, J.W. Schweitzer* and A.J. Friedhoff. Millhauser Labs, NYU Medical Center, NY, NY 10016.

Subcataleptic doses of the mu-selective opioid agonist DAMGO, infused into the lateral segment of the thalamic dorsomedial nucleus, elevate stimulus thresholds for pain vocalization and brain stimulation reward (Carr and Bak, 1988). Higher doses produce naloxone-reversible catalepsy. In the present study, bilateral medial thalamic (MT) infusions of DAMGO (1.0 ug) increased latencies to shuttle-escape from gridshock, while the kappa-selective agonist, U50,488 (25.0 ug) and the delta-selective agonist, DPDPE (10.0 ug) had no effect. Pre-infusion of the mu-selective antagonist, CTP (5.0 ug), blocked the DAMGO-induced increase in escape latency while pre-infusion of the delta-selective antagonist, ICI 174,864 (5.0 ug), did not. Lower doses of DAMGO (0.1 to 0.25 ug) sometimes reduced conditioned avoidance without affecting escape from gridshock. Many of the above mentioned behavioral effects of MT DAMGO are also produced by systemically administered neuroleptics. Moreover, MT has strong anatomical and functional connections with several forebrain dopamine (DA) terminal regions. To investigate whether modulation of dopaminergic activity may account for the behavioral effects of MT DAMGO infusion, we used HPLC to measure DA and DA metabolite levels in striatum, nucleus accumbens, and medial prefrontal cortex (mpfc) of rats sacrificed 20 minutes after MT DAMGO (1.0 ug) infusion. MT DAMGO elevated DOPAC levels in mpfc (saline = 0.39 $\pm$ 0.015 ng/mg protein vs DAMGO = 0.54 $\pm$ 0.03 ng/mg protein; $t(6) = 4.37$, $p<.005$) and tended to elevate DOPAC levels in striatum and accumbens as well. Systemically administered neuroleptics also increase DA utilization and elevate DA metabolite levels but do so as a compensatory response to postsynaptic receptor blockade. Whether MT DAMGO alters postsynaptic sensitivity to DA release remains to be determined.

EVIDENCE FOR THE CONTRIBUTION OF NON-OPIOID MECHANISMS IN THE ANTINOCICEPTION PRODUCED BY THE CENTRAL ANALGESIC TRAMADOL. W.S. Reimann, N. Selve, and J.L. Vaught, Grunenthal Gmbh, Dept. Pharmacology, W-5100 Aachen, FRG, and The R.W. Johnson Pharmaceutical Research Institute, Welsh & McKean Roads, Spring House, PA 19477-0776.

Tramadol is a centrally acting analgesic with low affinity for opioid receptors and the ability to inhibit norepinephrine (NE) and serotonin (5-HT) uptake as well as facilitate 5-HT release. The antinociceptive effects of tramadol are only partially reversed by naloxone (Nlx) in some tests. Thus, the contribution of potential non-opioid mechanisms was the focus of the present research. In the Randall-Selitto test, tramadol produced a dose-related antinociception with an ED50 value of 4.6 mg/kg i.v. Nlx (1 mg/kg i.v.) only partially reversed tramadol-induced antinociception suggesting a non-opioid component. In the rat tail flick test, i.t. tramadol and morphine prolonged tail flick latencies. Nlx blocked morphine but not tramadol-induced antinociception. In contrast, the serotonin antagonist ritanserin (1 mg/kg i.p.) antagonized the effects of tramadol but not those of morphine. This antagonism was very similar to that previously reported for the alpha$_2$-adrenergic antagonist yohimbine. These results demonstrate the probable contribution of a serotonergic component to tramadol antinociception at spinal sites. In concomitant experiments we tested a small and ineffective dose of i.t. serotonin. When added to a subthreshold dose of the combination of morphine and desipramine, pronounced antinociception was observed demonstrating the potentiation of noradrenergic and opioid effects by a weak serotonergic stimulus.

CATECHOLAMINES: LOCUS COERULEUS

615.1

AFFERENTS TO THE RAT LOCUS COERULEUS (LC) USING CHOLERATOXIN B SUBUNIT (CTb) AS A RETROGRADE TRACER P.H Luppi,[1] G. Aston-Jones, H. Akaoka, P. Charléty[1], C. Kovelowski, M. T. Shipley[2], Y. Zhu, M. Ennis[2], P. Fort[1], G. Chouvet[1] and M. Jouvet[1]. Dept Mental Health Sci, Hahnemann Univ, Philadelphia, 19102; [1]CNRS UA 1195, INSERM U52 & 171, Lyon, France;[2]Univ. Cincinnati, Dept Anat Cell Biol, OH.

CTb when iontophoretically applied and visualized with streptavidin-HRP immunohistochemistry has been reported to be a highly sensitive retrograde and anterograde tracer (Luppi et al., 1990). Using CTb, we have reexamined the afferents to the LC. Physiologic recordings were made through glass micropipettes containing CTb (4µm tip, 1% CTb in PB 0.1M, pH 6) and the LC identified by its characteristic discharge properties. Iontophoretic application (0.5µA, 5min, n=20) of CTb produced injection sites that appeared to be restricted to the LC. The present results confirm major inputs from the nuclei paragigantocellularis and prepositus hypoglossi, and minor projections from the hypothalamic paraventricular nucleus (Aston-Jones et al., 1986). After some injections, that previous study noted occasional retrogradely labeled neurons in the rostral and posterior hypothalamic areas, median (MnR) and dorsal raphe (DR) nuclei, and periaqueductal gray (PAG). In contrast, after all CTb injections in the LC, we found numerous retrogradely labeled neurons in the lateral preoptic area (LPO), the posterior, dorsal and lateral areas of the caudal hypothalamus, the area ventrolateral to the MnR (B9 area), the area of the Kölliker-Fuse nucleus (KF), and the ventrolateral part of the PAG. Small numbers of cells were also observed in other nuclei including rostral DR, the area of the A5 noradrenergic cell group and nucleus parabrachialis lateralis. Control CTb injections in peri-LC areas (Barrington nuc., n=1, and mesencephalic trigeminal nuc., n=2) yielded a pattern of labeled cells different in some areas from that after LC injections indicating specificity of LC innervation. Anterograde tracing using CTb (n=3) and PHAL (n=3) from the LPO and the KF yielded numerous labeled fibers in the LC while injections in the ventrolateral PAG, the posterior hypothalamic areas and the B9 area gave rise to a moderate amount of fibers in LC. For PAG and hypothalamic labeling in particular, this labeling was more prominent in peri-LC areas and dendritic fields than within LC itself, possibly accounting for some retrograde labeling following LC injections. The demonstration of these additional afferents may be explained by higher sensitivity of CTb compared to the previously used WGA-HRP. Supported by grant NS 24698.

615.2

AUDITORY-EVOKED RESPONSES OF LOCUS COERULEUS (LC) NEURONS ARE ATTENUATED BY EXCITATORY AMINO ACID (EAA) RECEPTOR ANTAGONISTS IN THE AWAKE RAT. C. Chiang, A.L. Curtis, G. Drolet, R.J. Valentino, and G. Aston-Jones. Division of Behavioral Neurobiology, Dept. Mental Health Sciences, Hahnemann University, Philadelphia, PA 19102

LC neurons of behaving rats respond to multimodal non-noxious stimuli (Aston-Jones and Bloom, 1981). This study was designed to elucidate the transmitter mechanisms through which auditory stimuli exert their effects on LC. Experiments were performed in unanesthetized rats 5-7 days after implantation surgery. Extracellular single- and multi-unit activity were differentially recorded through stainless steel wires in the LC, and drug solutions (5 µl) were injected into the lateral ventricle. Activation of LC neurons by auditory stimuli (2-3 KHz, 50 or 100 ms duration, 90 dB) was significantly attenuated by the broad spectrum EAA antagonist kynurenate (KYN: 175 nmoles, 20.1 $\pm$ 4.9% of control, $n = 5$, $p < 0.05$). Similarly, the selective NMDA antagonist, 2-amino-5-phosphonopentanoic acid (AP5: 70 nmoles), also attenuated this activation (28.2 $\pm$ 7.2% of control, $n = 3$). The preferential non-NMDA antagonist, 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX: 18 nmoles) caused a smaller reduction in the auditory-evoked response (65.6 $\pm$ 16.3% of control, $n = 4$), which was significantly different from the attenuations produced by KYN and AP5 ($F_{2,9} = 5.6$, $p < 0.05$). Recovery of the response was seen 30 to 60 min post-KYN and at 15 min post-CNQX; the response post-AP5 did not recover within 30 min. Vehicle injections of artificial CSF were largely ineffective. These preliminary results suggest that LC discharge evoked by phasically presented auditory stimuli requires EAA neurotransmission that may act primarily at NMDA receptors. Additional work is underway to localize the site(s) of EAA neurotransmission mediating these responses. Supported by PHS grants NS24698, DA06214, MH 40008, MH00840, MH42796, NARSAD (A.L.C.) and FRSQ (G.D.).

615.3

PUTATIVE GLUTAMATERGIC AFFERENTS TO THE NUCLEUS LOCUS COERULEUS FROM THE NUCLEUS PARAGIGANTOCELLULARIS: IMMUNOHISTOCHEMISTRY AND TRACT-TRACING.

G. Drolet and G. Aston-Jones, Division of Behavioral Neurobiology, Dept. Mental Health Sciences, Hahnemann University, Philadelphia, PA 19102

Recent investigations have found that the nucleus paragigantocellularis (PGi) in the ventrolateral medulla provides a major excitatory input to the nucleus locus coeruleus (LC). Morever, pharmacological studies revealed that this excitatory pathway, which mediates somatic- and visceral-evoked activation of the LC, uses an excitatory amino acid (EAA) neurotransmitter. The endogenous EAA used in this pathway is not known, but glutamate is a good candidate. In the present study, we combined retrograde transport and immunohistochemical techniques to identify the source of possible glutamatergic inputs to the LC. The retrograde tracer, a wheat germ agglutinin conjugate coupled to colloidal gold particles (WGA-apoHRP-Au), was injected into the electrophysiologically identified LC nucleus of two rats. After survival for 5-7 days, the rats received colchicine (100 µg, icv) and were perfused 24 hours later. A mouse monoclonal IgM antibody against phosphate-activated glutaminase (PAG, kindly provided by Dr. T. Kanebo, Kyoto University, Japan) which is a major synthetic enzyme of glutamate, was used to tentatively identify glutamatergic neurons. Numerous PAG-immunoreactive (ir) cell bodies were observed in the PGi. Preliminary double labeling studies indicated that PAG-ir neurons represent a substantial proportion of the LC-projecting neurons in the PGi. These results provide anatomical support for the existence of an excitatory amino acid pathway, putatively, glutamatergic, from PGi to LC. Supported by PHS grants NS 24698, DA 06214 and Le Fonds de la Recherche en Santé du Québec.

615.4

ELECTROPHYSIOLOGICAL CHARACTERISTICS OF LOCUS CERULEUS NEURONS IN MAUDSLEY REACTIVE AND NON-REACTIVE RAT STRAINS. J. S. Verbanac[2], R.L. Commissaris[2,3] H.J. Altman[3], G.M. Harrington[1] and D.K. Pitts[2]. [1]Univ. N. Iowa, Cedar Falls, IA, [2]Dept. of Pharm. Sci., Coll. Pharmacy & A.H.P., [3]Dept. of Psychiatry, Sch. Med., Wayne State Univ., Detroit, MI 48202.

The Maudsley Reactive (MR) and Non-Reactive (MNRA) inbred rat strains, have been shown to perform differently in various animal models for anxiety. Changes in noradrenergic function have been implicated in anxiety states. In the present study extracellular single-unit recording techniques were used to examine the physiology and pharmacology of noradrenergic locus ceruleus (LC) neurons in urethane anesthetized rats. The basal discharge rate of LC neurons in MR ("anxious"), MNRA ("non-anxious") and Sprague-Dawley (SD; outbred control) rats was 2.6 + 0.8 (n=7), 4.6 + 0.8 (n=6) and 3.0 + 0.8 (n=5) respectively. The sensitivity of somatodendritic alpha-2-adrenergic receptors to i.v. clonidine was also examined. An analysis of covariance (basal discharge rate=covariate) indicated that the dose-response (DR) curves for both Maudsley strains were significantly ($P< 0.01$) shifted to the right relative to SD rats and that MR and MNRA DR curves were not significantly different from each other ($P=0.23$). Although these studies are preliminary, a clear difference in clonidine sensitivity was observed between Maudsley and SD rats. A more complete analysis of the physiological and pharmacological characteristics is currently underway. (Supported by MH47181).

615.5

DECREASED TONIC DISCHARGE AND INDUCTION OF PERIODIC BURSTING OF LOCUS COERULEUS (LC) NEURONS AFTER ACUTE MORPHINE IN WAKING MONKEYS J.Rajkowski, H. Akaoka, C.J. Kovelowski, II and G. Aston-Jones Div. Behav. Neurobiol., Dept. Mental Health Sci., Hahnemann Univ. Philadelphia, PA 19102.

Substantial evidence indicates that the LC may be an important site of action for exogenous opiates. However, the effects of opiates on the electrical activity of LC neurons in conscious animals remain controversial, and never have been reported in primates. Here, the discharge activity of 11 neurons located in the LC region and tentatively identified as noradrenergic cells (>2 ms spike, low frequency, burst-pause response to salient stimuli) was recorded before, and up to 4 hours after i.m. injections of morphine sulphate in a chair restrained Cynomolgus monkey (3 cells each with 0.3 mg/kg, 1 mg/kg or 3 mg/kg, and 2 cells with 10 mg/kg). After injection, the animal sat quietly appearing sedated with his eyes open. One-half to 1 hour following morphine administration, the animal's eyes exhibited episodic slow drifts, the pupil diameter oscillated widely, and there were occasional short periods of drowsiness.

LC activity prior to drug administration was characteristically tonic and regular; closer analysis revealed that there were small oscillations in discharge rate occuring at a frequency of about 0.04 Hz. At 3 to 7 min after morphine injection, LC neurons showed pronounced periodic bursting activity which continued for the duration of the recording session. Such bursting also occurred with a frequency of 0.04 -0.05 Hz, as detected by autocorrelation of unit discharge, and was most pronounced about 20 min after injection. Interspike intervals increased with time after injection, resulting in an overall decrease of impulse activity. By 2 hrs following a high dose of morphine, LC neurons were nearly silent, even though the animal's eyes were fully open. Although most pronounced for higher doses of morphine, the above effects were observed for all cells tested. Supported by AFOSR grant 90-0147 and PHS grant DA 06214.

PHASIC LOCUS COERULEUS STIMULATION: EFFECTS IN THE RAT LATERAL GENICULATE NUCLEUS. R.N. Holdefer and B.L. Jacobs. Psychology Dept., Princeton Univ., Princeton, NJ 08544

Neuronal discharge in the locus coeruleus (LC) conveys to the CNS both a tonic information code related to behavioral state, and a phasic code elicited by sensory stimuli. Phasic activation of LC (0.26-0.62 mA at 30 Hz over 200 ms) in urethane-anesthetized rats increased spontaneous activity in the LGN by 9.4±6.0 spikes/s (mean±s.d.) in 13 out of 15 cells (onset latency: 299±70 ms, duration < 3.3 s). In some LGN neurons this increased discharge was preceded by a change from burst firing mode to a predominantly single spike mode. LGN activation was much weaker in animals with stimulating electrodes medial to the LC (2.5±2.2 spikes/s, $t=2.41$, $p<.05$). Microiontophoretic phentolamine (α-receptor antagonist, 5-10 nA) in the LGN partially reversed the increased firing after LC stimulation, but also decreased spike amplitude, making interpretation difficult. Increased LGN neuronal activity after LC stimulation was significantly reduced (2.9±4.4 spikes/s, $F=4.47$, $p<.05$) in animals pretreated (3-11 h) with a dose of AMPT (175-200 mg/kg, i.p.), known to deplete NE in the brain. We conclude that phasic LC activation can phasically activate LGN neurons in urethane-anesthetized animals. Supported by NSF BNS8921348.

MODULATION OF FOREBRAIN EEG BY THE LOCUS COERULEUS-NORADRENERGIC (LC/NE) SYSTEM. C.W. Berridge, *M. Page, *R.J. Valentino, S.L. Foote. UC San Diego; *Hahnemann Univ.

We previously reported that peri-LC infusions of the cholinergic agonist, carbachol (CARB) enhance LC neuronal activity and elicit forebrain EEG activation in halothane-anesthetized rats. These effects were observed only when the infusion needle is placed within 500 µm of the LC. To determine whether β-receptors are involved in these effects, we examined the effects of the β-receptor antagonist, DL-propranolol (PRO, 200 µg; ICV). Animals received a peri-LC CARB infusion (100 nl; 1ng/nl) 15 min after an ICV injection of PRO (3 µl). Whereas PRO did not affect the CARB-induced activation of LC, PRO blocked or severely attenuated the LC-stimulated activation of neocortical and hippocampal EEG. Preliminary data suggest an involvement of β_2-receptors in mediating the LC-induced activation of forebrain EEG. The effects of inhibition of LC neuronal activity by peri-LC infusions of the α_2-agonist, clonidine (125 nl; 1 ng/nl) were also examined. These infusions completely inhibited LC neuronal discharge activity for a 40-60 min period. Unilateral infusions typically had no obvious effects on cortical EEG activity. Bilateral inhibition of LC activity significantly increased the incidence and amplitude of slow-wave activity. Recovery of EEG activity was closely correlated with recovery of LC activity. These results suggest the LC/NE system is a potent modulator of forebrain EEG activity.

615.8

PACEMAKER ACTIVITY OF LOCUS COERULEUS (LC) NEURONS: DEPENDENCE ON cAMP AND PROTEIN KINASE AS SHOWN BY WHOLE-CELL RECORDINGS IN BRAIN SLICES.

M.Alreja and G.K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Noradrenergic neurons of the rat LC are endogenous pacemakers that exhibit slow, tonic firing even in the complete absence of synaptic inputs. Conventional extracellular and intracellular recordings in LC neurons show persistent basal firing rates of ~1-2 Hz both in *in vivo* and *in vitro* preparations. In contrast, we now report a time-dependent decline in LC spontaneous firing rates during whole-cell recording with low-resistance patch electrodes. A majority of the neurons tested gradually stopped firing after establishing whole-cell configuration, presumably due to wash-out of an intracellular molecule. Inclusion of PKI_{5-24} (a specific inhibitor of cAMP-dependent protein kinase) in the patch pipette accentuated the washout phenomenon: in all the cells tested there was a rapid cessation of firing accompanied by a 2-7 mV hyperpolarization, suggesting the involvement of endogenous cAMP and protein kinase in pacemaker activity. The inclusion of cAMP, 8-Br-cAMP or the catalytic subunit of cAMP-dependent protein kinase (PKA_{cat}) in the patch-pipette prevented the loss of firing and dose-dependently increased LC firing rates; PKI_{5-24} blocked both 8-Br-cAMP and PKA_{cat}-induced firing in LC neurons.

We conclude that endogenous cAMP drives tonic pacemaker activity in LC neurons via cAMP-dependent protein kinase and its phosphorylation pathway.

Both Transient and Tonic Activation Elevates C-Fos Levels in the Locus Coeruleus. K. Bittman*, S. Grant, D.A. Highfield, M. Iadarola, B. Benno Dept. Psychology and Prog. in Neuroscience, Univ. Delaware, Newark, DE 19716; NIDR; and Wilm. Patterson College.

Increased neuronal activity induces the early intermediate gene product c-fos. The nuc. locus coeruleus (LC) is ideal for studying mechanisms coupling neuronal activity to c-fos induction. The LC has a homogenous (noradrenergic) composition, clear nuclear boundaries and well established pharmacological and physiological response patterns. Since past studies used treatments that elicit tonic elevations in firing rates, we immuhistochemically compared c-fos levels in LC neurons after transient sensory evoked and tonic pharmacological increases in neuronal activity.

Halothane anesthetized rats received either Yohimbine (5mg/kg) to tonically elevate LC firing, 30 min of brief intermittent contralateral footshocks (0.5 Hz, 1 msec, 1-9 mAmp) to evoke transient LC activation or no stimuli (controls). Rats were sacrificed 3 hours later. C-fos like immunoreactivity was stained using the ABC-peroxidase method and a polyclonal antibody that detects both c-fos and fos -related proteins.

C-fos like staining was present in the nuclei of cells in the LC (and surrounding areas) in response to both classes of stimuli, but not controls. Not all neurons in the LC exhibited c-fos like staining, even though presumably all LC neurons respond neurophysiologically to these treatments.

It is concluded that transient neuronal activation elevates c-fos levels, and that c-fos induction does not require high tonic firing rates. Furthermore, since LC neurons are spontaenously active and virtually no c-fos like staining was seen in controls, neuronal activity alone is insufficient for c-fos induction. Many cellular substrates of LC neuronal activation are known; this should facillitate determination of the critical events that link neuronal activation to c-fos expression in LC neurons.

8-OH-DPAT PERFUSION INTO THE DORSAL RAPHE NUCLEUS OF THE FREELY MOVING RAT DECREASES TERMINAL BUT NOT SOMATODENDRITIC 5-HT RELEASE. *A. Adell and S. Hjorth. Dept. of Pharmacology, University of Göteborg, Box 33031, S-400 33 Göteborg, Sweden.*

Previous research has described the occurrence of extracellular serotonin (5-HT) in the vicinity of midbrain raphe nuclei of freely moving rats (Adell & Artigas, NSAP **343**: 237, 1991). The present work was undertaken to investigate whether the 5-HT release in the dorsal raphe nucleus (DRN) is regulated by cell body 5-HT_{1A} autoreceptors. For this purpose a microdialysis probe (1 mm membrane length) was stereotaxically implanted in the DRN. Approximately 24 h later probes were perfused with artificial CSF. Cumulative doses of 8-OH-DPAT (10 nM-1 μM) were then perfused. For every dose, the effect of a single 20-min pulse of K^+ (100mM) was tested. Dialysate 5-HT and 5-hydroxyindoleacetic acid (5-HIAA) were analyzed by HPLC(EC). The basal extracellular levels of 5-HT and 5-HIAA were 1.62 ± 0.3 nM and 6.8 ± 0.5 μM, respectively, corrected for *in vitro* probe recovery (5%). K^+-stimulation increased dialysate 5-HT to 438% and decreased 5-HIAA to 56% of respective basal values. 8-OH-DPAT did not affect the spontaneous release of 5-HT in the DRN, but at concentrations ≥ 1 μM clearly enhanced the K^+-evoked 5-HT release (to 1670%). As this drug is known to inhibit the firing of 5-HT neurons in DRN, our results suggest that the spontaneous 5-HT output in this nucleus is not dependent on the firing of 5-HT neurons. In a second experiment rats were implanted with two dialysis probes, one in the DRN and the other in ventral hippocampus. Perfusion of 8-OH-DPAT (1 mM) through the probe located in the DRN decreased 5-HT and 5-HIAA output in the ventral hippocampus. The findings confirm that terminal, but not cell body, 5-HT release is regulated by somatodendritic 5-HT_{1A} autoreceptors.

616.2

ANTIDEPRESSANT-LIKE ACTIVITY OF COMPOUNDS WITH EFFICACY FOR THE 5-HT_{1A} RECEPTOR. A. Singh, J.N. Wolfe* and I. Lucki. Departments of Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

The present study examined the ability of three novel compounds with high affinity but with varying efficacies for the 5-HT_{1A} receptor to produce antidepressant-like behavioral effects in the forced swim test in rats. The compounds used were: WY 48,723, WY 50,324 and WY 47,846, respectively an agonist, a partial agonist and a putative antagonist at the 5-HT_{1A} receptor. WY 50,324 is also a 5-HT_2 receptor antagonist. The rats received three subcutaneous injections of WY 48,723 (0.06-0.5 mg/kg), WY 50,324 (0.125-20 mg/kg) or WY 47,846 (10-20 mg/kg) after the 15-min pretest swim session. Behavioral immobility was measured during a 5-min test session, which occured one hour after the last injection. The 5-HT_{1A} agonist 8-OH-DPAT (0.5 mg/kg) and the tricyclic antidepressant desipramine (10 mg/kg) served as positive controls.

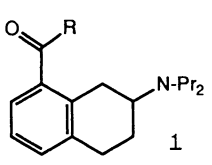
WY 48,723 and WY 50,324 significantly reduced behavioral immobility as compared to saline-treated controls. These results were similar to those obtained with desipramine and 8-OH-DPAT. In contrast, WY 47,846 failed to alter behavioral immobility when tested alone, and antagonized the reduction in behavioral immobility produced by the 5-HT_{1A} agonist. These results support our previous findings that compounds with agonist or partial agonist activity at the 5-HT_{1A} receptor may possess antidepressant-like activity. Further studies are currently underway to ensure that the activity of these compounds in the forced swim test was not due to their effects on locomotor activity.

616.3

8-ACYL-2-DIPROPYLAMINOTETRALINS: A NEW SERIES OF POTENT 5-HT_{1A} AGONISTS J. M. Schaus, D. L. Huser*, R. D. Titus*, C. S. Hoechstetter*, D. T. Wong, R. D. Marsh*, R. W. Fuller, and H. D. Snoddy*
Lilly Research Laboratories, Eli Lilly and Co. Indianapolis, IN 46285

8-Hydroxy-2-dipropylaminotetralin (8-OH-DPAT) is a potent and selective 5-HT_{1a} agonist which has limited oral activity. In an effort to obtain orally active 5-HT_{1a} agonists, we prepared a series of 8-substituted-2-dipropylaminotetralins. We report here the synthesis and phamacologic activity of a series of 8-acyl-2-dipropylaminotetralins (1, R = alkyl).

The 8-acyl-2-dipropylaminotetralins (1, R = Me, Et, i-Pr, t-Bu, and Ph) were found to have high affinity *in vitro* for the 5-HT_{1a} receptor (IC_{50}'s varied from 0.4 - 9 · M). The compounds were tested for 5-HT_{1a} agonist activity *in vivo* by their ability to lower brain 5-HIAA levels and increase serum corticosterone levels in rats. All of these compounds (except 1, R = Ph) were found to exert one or both of these effects at doses between 0.1 and 1.0 mg/kg, sc. The most potent compounds were found to lower brain 5-HIAA levels following oral dosing with the i-Pr and t-Bu ketones having the longest duration of action.



1

Molecular modelling studies of this series of ketones show that conformations in which the carbonyl system is coplanar with the aromatic ring are not accessible for 1, R = i-Pr and 1, R = t-Bu. Hence it is likely that the hydrogen bonding interaction between the carbonyl group of compounds 1 and the 5-HT1a receptor are out of the plane of the tetralin ring system.

616.4

COMPARATIVE EFFECTS OF 5-HT_{1a} AGONISTS ON SEXUAL BEHAVIOR OF MALE RATS. M. M. FOREMAN, K. RASMUSSEN, J. M. SCHAUS* AND M. E. FLAUGH*, The Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN, 46285.

Sexual behavior in the male rat is suppressed by most pharmacologic agents that amplify 5-HT receptor activity. The only known serotonergic agonists that stimulate this behavior are the 5-HT_{1a} agonists. These agonists have been proposed to be autoreceptor agonists which act on the 5-HT soma to suppress the activity of these neurons. The present studies have compared effects of different types of 5-HT_{1a} agonists including pyrimidinylpiperazines (PP), aminotetralins (AT) and "ABC" partial ergolines (PE). These agonists amplified sexual behavior, but at higher, postsynaptic doses sexual behavior was suppressed coincidental with the amplification of the 5-HT behavioral syndrome responses. The PP agonists were less potent, efficacious and shorter acting than either AT or PE agonists. The efficacy and duration of action of the AT and PE agonists varied with the aromatic substitution patterns.

616.5

5-HYDROXYTRYPTAMINE HYPERPOLARIZATION IN CA3 HIPPOCAMPAL PYRAMIDAL CELLS MAY NOT BE 5-HT_{1A} RECEPTOR MEDIATED K. Choi*, H. Read and S.G. Beck, Department of Pharmacology, Loyola University Chicago Stritch School of Medicine, Maywood, Il 60153.

Intracellular recording techniques were used to characterize 5HT actions in area CA3 of the hippocampal slice. 5HT and the 5HT analog 5-carboxyamidotryptamine elicited a hyperpolarization: Emax 15±5 mV, EC_{50} 10±5 µM and slope 1.9±0.7 and Emax 13.7±3.4 mV, EC_{50} 0.050±2 µM, slope 1.8±0.7 respectively. The K_d of the $5HT_{1A}$ antagonist spiperone from a Schild plot analysis was 72 nM. The K_d of the 5-HT_{1A} partial agonist BMY 7378 was 87 nM, but BMY also decreased the Emax, an effect that was reversible. The hyperpolarization was obtained with 2M KCl or 2M K Methyl Sulphate electrodes and in the presence of 1 µM TTX. The reversal potential was -105 mV in 3 mM extracellular KCl buffer and -85 mV in 5 mM KCl. We conclude that the 5HT hyperpolarization is mediated by an increase in potassium conductance. The identity of the 5HT receptor mediating the hyperpolarization has not been conclusively identified; however, evidence against the 5-HT_{1A} receptor includes: 1) The difference in the affinity of 5HT and 5CT is 200 fold, 2) the K_d of spiperone is low for a 5-HT_{1A} receptor, 3) the rank order of BMY and Spiperone is reversed and 3) BMY acts as a non-competitive antagonist. Other agonists and antagonists are being tested to obtain rank order potencies of agonists and K_d's of antagonists. USPHS grants MH41917, NS28512, KO2-MH00880 to SGB.

616.6

THE 5-HT_{1A} AGONISTS IPSAPIRONE AND 8-OH-DPAT DIFFERENTIALLY INFLUENCE THE 5-HT_2 AGONIST DOI-INDUCED INCREASE IN PLASMA ACTH, CORTICOSTERONE AND RENIN. Q. Li, P.A. Rittenhouse, A.D. Levy & L.D. Van de Kar. Dept. Pharmacology, Loyola Univ. Stritch Sch. Med. Maywood IL 60153

Evidence suggests that activation of 5-HT_{1A} receptors leads to inhibition of 5-HT_2 mediated behaviors. The purpose of this study was to investigate the interaction between 5-HT_{1A} and 5-HT_2 receptors. 5-HT_2, but not 5-HT_{1A} receptors are involved in the regulation of renin secretion. On the other hand, stimulation of 5-HT_{1A} and 5-$HT_{1C/2}$ receptors increases ACTH and corticosterone secretion. In the present experiment, rats were pretreated with the 5-HT_{1A} agonists ipsapirone (0, 1.0, 2.5 mg/kg ip) or 8-OH-DPAT (0, 50, 200 µg/kg sc) 45 min. before decapitation. The 5-$HT_{1C/2}$ agonist DOI was administered 15 min. following injection of the 5-HT_{1A} agonists, in a dose response manner (1-10 mg/kg ip). Plasma renin activity (PRA), plasma renin concentration (PRC), plasma corticosterone and plasma ACTH were measured by radioimminoassay.

Neither ipsapirone nor 8-OH-DPAT influenced the basal level of PRA/PRC or ACTH, but 8-OH-DPAT increased basal level of plasma corticosterone. Ipsapirone, but not 8-OH-DPAT, potentiated the effect of DOI on renin secretion. In contrast, 8-OH-DPAT, but not ipsapirone, potentiated the DOI-induced increase of plasma ACTH. In conclusion, the results suggest that activation of 5-HT_{1A} receptors does not inhibit the effect of a 5-HT_2 agonist on hormone secretion. Furthermore, the data suggest that ipsapirone and 8-OH-DPAT have distinct pharmacological profiles. (Supported by NIDA DA04865, NIMH MH 45812 and American Heart Association of metropoloton Chicago).

EVIDENCE THAT SOMATODENDRITIC 5-HT_{1A} AUTORECEPTORS IN THE DORSAL/MEDIAL RAPHE ARE FUNCTIONAL IN PREWEANLING RAT PUPS. G. A. Goodwin, C. J. Heyser, and L. P. Spear. Center for Developmental Psychobiology, SUNY Binghamton, Binghamton, NY 13902-6000.

Brainstem raphe nuclei such as the dorsal/medial raphe, appear to be regulated in adulthood by somatodendritic autoreceptors of the 5-HT_{1A} subtype. (Hjorth and Magnusson, 1988). Previous work from our laboratory examining the ontogeny of low dose effects of the 5-HT_{1A} agonist 8-OH-DPAT has led to the suggestion that 5-HT_{1A} autoreceptors are functional in preweanling but not infant rat pups (Frambes, Spear, & Goodwin, submitted). To further assess this possibility, the present study examined the neurochemical and behavioral effects of microinjections of 8-OH-DPAT into the dorsal/medial raphe of postnatal day 17 (P17) rat pups. Local microinjection of 1.0 and 5.0 µg of 8-OH-DPAT was observed to decrease 5-HIAA/5-HT ratios, with the higher dose inducing clear behavioral alterations, including the induction of flat body posture and an increase in sniffing. These data provide evidence that 5-HT_{1A} somatodendritic autoreceptors in the dorsal raphe are functional during the late preweanling period (i.e. by 17 days of age). Future studies will explore the consequences of local microinjection of 8-OH-DPAT in younger rat pups in order to determine when these autoreceptors first become functional.

616.8

THE EFFECT OF 8-HYDROXY-2-(DI-N-PROPYLAMINO) TETRALIN ON CHEMICALLY INDUCED DEFENSIVE BEHAVIOUR. S. R. C. Beckett*, A. J. Lawrence*, C. A. Marsden* and P. W. Marshall*, Dept. of Physiology and Pharmacology, Queen's Medical Centre, Nottingham, NG7 2UH. U. K. and ICI Pharmaceuticals, Bioscience II, Mereside, Alderley Park, Macclesfield, Cheshire, U. K. (SPON: Brain Research Association).

The ability of the 5HT1A receptor agonist 8-hydroxy-2-(di-n-propylamino) tetralin (8-OH-DPAT) to modulate a chemically induced defence response has been studied in Lister hooded rats. Microinjections of the excitatory amino acid D, L-Homocysteic acid (DLH: 5nmol in 250nl) in both the rostral and caudal dorsal periaqueductal gray matter (DPAG) caused explosive motor behaviour characteristic of defence. Pretreatment with 8-OH-DPAT (10nmol in 250nl) resulted in a significant attenuation, and in some cases a complete abolition, of the DLH evoked response. Thus the results suggest that in vivo activation of 5HT1A receptors mediates an antiaversive response with respect to defensive behaviour elicited by specific chemical stimulation of the DPAG.

616.9

REDUCTIONS OF STRIATAL SEROTONIN RELEASE BY ACTIVATION OF 5-HT_{1A} RECEPTORS. D.S. Kreiss & I.Lucki. Institute of Neurological Sciences, Depts of Pharmacology & Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

The regulation of serotonin (5-HT) release in the striatum by somatodendritic 5-HT_{1A} autoreceptors was investigated using in vivo microdialysis. 5-HT release was measured in the ventral caudate nucleus of rats maintained under chloral hydrate anesthesia. Dialysate samples, collected at 20 min. intervals, were analyzed by an HPLC equipped with a microbore column. The sensitivity of detection was approximately 0.5 fmoles 5-HT/5 ul (2 X background noise), enabling reductions of 5-HT release to be measured without a 5-HT uptake inhibitor in the perfusion medium.

The major portion of dialysate 5-HT content was neuronal in origin, as determined by sensitivity to blockade of sodium ion channels with 1.0 uM TTX (mean ± s.e.m.: -69.2% ± 7.5) and to removal of calcium from the perfusion medium (-52.0% ± 11.2).

Systemic administration of the selective 5-HT_{1A} receptor agonist 8-OH-DPAT reduced striatal dialysate 5-HT content dose-dependently. 8-OH-DPAT was infused directly into the dorsal raphe nucleus, the origin of most of the serotonergic innervation of the striatum, reduced striatal dialysate 5-HT content to a similar magnitude. In contrast, infusion of 1.0 uM 8-OH-DPAT into the striatum via the probe perfusion medium, did not alter striatal dialysate 5-HT content. These observations suggest reductions in striatal 5-HT release are mediated by activation of somatodendritic 5-HT_{1A} autoreceptors in the dorsal raphe nucleus. Further experiments are being conducted to evaluate the pharmacological and anatomical specificity of this effect. This work was supported by MH36262 & MH48125.

616.10

ELECTROPHYSIOLOGICAL RESPONSES OF HIPPOCAMPAL, SEPTAL AND RAPHE NEURONS TO MDL 73,005EF, A POTENT AND SELECTIVE 5-HT_{1A} RECEPTOR LIGAND. J. Sprouse, D. McCarty, P. van den Hooff and M. Galvan, Marion Merrell Dow Research Institute, Cincinnati, OH and Strasbourg, France.

MDL 73,005EF exhibits anxiolytic-like effects in behavioral paradigms, but like other 5-HT_{1A} ligands, its mode of action is uncertain. A preferential agonist effect on 5-HT_{1A} receptors located on raphe cell bodies over those located postsynaptically in raphe projection areas has been proposed. The purpose of the present study was to examine this possibility by comparing the actions of MDL 73,005EF on single neurons in the dorsal raphe (DR), hippocampus (HC) and lateral septum (LS).

In DR slices, MDL 73,005EF produced a concentration-dependent inhibition of cell firing. Based upon IC_{50} values, MDL 73,005EF was equipotent with buspirone (129 ± 34 vs 97 ± 8 nM; means ± S.E.M.). Pretreatment with (-)-propranolol (1 µM), a mixed 5-$HT_{1A/B}$ antagonist, blocked MDL 73,005EF-induced inhibition. In contrast, in HC and LS slices, MDL 73,005EF (1 - 30 µM) did not change membrane potential but did antagonize hyperpolarizations induced by 5-HT. Buspirone induced a slowly developing hyperpolarization which was small in HC cells (30 µM: 1.4 ± 0.3 mv) but significantly larger in LS neurons (10 µM: 7.0 ± 0.7 mv).

These data indicate that MDL 73,005EF is an agonist at 5-HT_{1A} autoreceptors on DR cell bodies. Little or no agonist activity was detected on HC or LS neurons and instead MDL 73,005EF acted as an effective antagonist of 5-HT-induced hyperpolarization. Buspirone also inhibited DR cell firing; however, the small but significant activations of HC and LS postsynaptic 5-HT_{1A} receptors by buspirone signify potential differences between its mode of action and that of MDL 73,005EF.

616.11

ANTIDEPRESSANT ACTIVITY OF FLESINOXAN IN ANIMAL MODELS. J. Schipper, M.Th.M. Tulp*, H.S. Berkelmans*, F.N.C. Krijzer*, J.A.M. van der Heyden and B. Olivier. Dept. Pharmacology, Duphar B.V., P.O. Box 900, 1380 DA Weesp, The Netherlands.

The antidepressant properties of flesinoxan, a selective 5-HT_{1A} agonist, have been investigated in a number behavioural and neurochemical models. Flesinoxan, like clinical active antidepressants, prolongs the period of active resistance of rats in the forced swimming test (0.2 to 1.8 mg/kg). The effects of flesinoxan occur at much lower doses and the active period of resistance lasts longer compared with the classical antidepressants. Similar effects have been found with other 5-HT_{1A} agonists such as 8-OH-DPAT and ipsapirone. Longterm treatment with flesinoxan (1 mg/kg/day p.o. during 7 days) does not show tolerance on immobility in the forced swimming test.

Two weeks treatment with flesinoxan (6 mg/kg/day i.p.) shows no significant changes in the β-receptor number (B_{max}) nor affinity (K_d). Also autoradiographic studies reveal no significant change in the β-receptor binding in any of the brain regions studied. However, noradrenaline stimulated c-AMP production in brain slices is reduced, whereas isoprenaline stimulated c-AMP production is not changed after chronic flesinoxan. After chronic desmethylimipramine, both noradrenaline and isoprenaline stimulated c-AMP production is reduced. These data indicate that flesinoxan induces adaptive changes in β-adrenoceptor mediated c-AMP response, but in a different way compared with the tricyclic antidepressants.

In the rat, the EEG profile of flesinoxan shows characteristics of that of both antidepressants and anxiolytics, with a slightly greater similarity to that of anxiolytics. Similar EEG profiles are seen with 8-OH-DPAT and ipsapirone.

In conclusion, the animal pharmacology data on flesinoxan strongly suggest that this potent and selective 5-HT_{1A} agonist will have potential antidepressant activity in man.

616.12

Effects of 5-HT_{1A} agonists in the conflict test. A. Meneses and E. Hong. (Spon: J.E. Villarreal). Terapéutica Experimental, Depto. de Farmacología y Toxicología, CINVESTAV-IPN, Mexico City, México 14370.

Contradictory evidence exists concerning the anxiolytic effects of 5-HT_{1A} agonists in the conflict test. In the present work a modification of the Vogel conflict model was used to assess different doses of diazepam (0.1-10.0 mg), ipsapirone (0.56-17.8 mg), buspirone (1.0-17.8 mg) and indorenate (0.56-17.8 mg) in rats receiving two different electric shock intensities (0.16 and 0.32 mA). The results show that the three 5-HT_{1A} agonists had a smaller anticonflict effect than diazepam. The anticonflict effect with each compound was of a greater magnitude at 0.16 mA intensity than at 0.32 mA. This study shows that using different electric shock intensities, compounds produce a differential effect: the anticonflict effects were more pronounced with the lower electric shock intensity than with the higher intensity. The present results suggest that the use of different shock intensities, can play distint roles over the drug's effect in the conflict test.

616.13

VARIATION IN CEREBRAL METABOLISM OF EXOGENOUS L-TRYPTOPHAN IN BALB/C AND C57/BL MICE. D. Ghosh and B.O. Anyanwu*, Department of Biology, Texas Southern University, Houston, Texas 77004

L-Tryptophan, an essential amino acid, is metabolized in two major (i) kynurenine and (ii) serotonin (5-HT) pathways in mammalian cells. In the brain, the tryptophan →5-HT→5-hydroxyindole-3-acetic acid (5-HIAA) pathway is predominant, and 5-HT so synthesized serves as a crucial neurotransmitter in some discrete areas of the brain. Experiments were conducted to explore the existence of any difference in the cerebral metabolism of exogenous L-tryptophan (0.375 mg/g body weight/intraperitoneal/2 hrs) in two inbred [BALB/C (albino) and C57/BL6(dark-coat color)] lines of male mice which were 12 weeks of age. Each single whole mouse brain was extracted in 0.05 M perchloric acid (16.7% homogenate). HPLC/electrochemical detection was performed on supernatants obtained from crude homogenates centrifuged at 15,000 g for 15 minutes. Our results indicate that C57/BL6 mice produced significantly higher levels of 5-HT and 5-HIAA than BALB/C mice. [5-HT : C57/BL6 = 394 ± 12.5 ng/g (=100%) & BALB/C = 336 ± 6.9 ng/g (=85%); N = 7; P<.05/5-HIAA: C57/BL6 = 742 ± 1.1 ng/g (=100%) & BALB/C = 476 ± 8.8 ng/g (=64%); N = 7; P <.01.] Central 5-HT and its turnover regulate a number of physiological states in mammals, and this biogenic amine assumes added importance if the underlying cause of its tissue level is genetic. (Supported by NIH grant RR03045).

CENTRAL EFFECT OF METHYSERGIDE ON SUCKLING. J. Zhang and C. P. Cramer. Department of Psychology, Dartmouth College, Hanover, NH 03755

5-HT antagonists, such as methysergide, administrated systematically to 20-day-old rats facilitate nipple attachment behavior. Conversely, 5-HT agonists inhibit attachment at this age. We have recently demonstrated that the agonist-induced inhibition is peripheral. Here we examine the effect of methysergide, injected ICV, on nipple attachment of 20-day-old rats.

20-day-old rats were anesthetized by metophane, and injections of drug or vehicle were made directly into the left lateral ventricle. In the first experiment, 4 pups were taken from each of 8 litters. 1 male and 1 female served as controls and received only isotonic saline (0.03 ml). The other two (M, F) received methysergide (0.010 mg/ml) in isotonic saline (0.03 ml). 10 min after injection, the pups were placed for 31 min with their anesthetized mother (Nembutal sodium, 1 ml/kg, IP). In the second experiment, dye (Evans Blue, 0.010 mg/ml) was added to each injection to confirm injection location. The same testing procedure as in the first experiment was used and immediately followed by a histological examination.

Result of the first experiment showed a significant facilitating effect of methysergide in terms of percentage of attachment, latency and duration (all p<.01). In the second experiment, only those subjects whose injections were accurately placed were included. (67.5% of these injected, confirming the first experiment). In this case, methysergide produced a weak facilitating effect.

The results suggest that the facilitating effects of methysergide are mediated centrally and that the dye may reduce the effect perhaps by binding the drug. Further experiments with other 5-HT drugs are underway.

ZATOSETRON, A SELECTIVE 5-HT_3 ANTAGONIST, DECREASES THE NUMBER OF SPONTANEOUSLY ACTIVE A10 DOPAMINE NEURONS. *M. E. Stockton* and K. Rasmussen*. *Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN 46285.*

5-HT_3 receptor antagonists have been shown to have a modulatory effect on the mesolimbic dopaminergic system, leading to the hypothesis that 5-HT_3 antagonists could have antipsychotic actions in schizophrenic patients. Previous studies have shown that chronic treatment with antipsychotics (e.g., haloperidol) decreases the number of spontaneously active A9 and A10 dopamine (DA) cells. However, chronic treatment with atypical antipsychotics (e.g., clozapine), which lack extrapyramidal motor side-effects, only decreases the number of spontaneously active A10 DA neurons. Apomorphine, a DA agonist, reverses these inhibitory effects of antipsychotics. Previous studies of the effects of 5-HT_3 antagonists on the number of spontaneously active DA cells have produced divergent results. This study evaluated the effects of zatosetron, a 5-HT_3 antagonist belonging to a different structural class than previously tested 5-HT_3 antagonists, on A9 and A10 single unit activity. Extracellular, single-unit recordings were made in chloral hydrate anesthetized rats and the number of spontaneously active A9 and A10 DA cells was counted. Both chronic (21 days) and acute administration of zatosetron resulted in a dose-related suppression of the number of spontaneously active A10 neurons , with no change in A9. Apomorphine did not reverse the effects of zatosetron, indicating that the response may not be mediated via depolarization inactivation. These data indicate that zatosetron's effects on spontaneously active DA neurons: (1) differs from other 5-HT_3 antagonists; (2) may not be mediated by depolarization inactivation; and, (3) may be predictive of an atypical antipsychotic action without delayed onset.

LACTATION-INDUCED ENHANCEMENT OF GASTRIC CONTRACTILITY TO SEROTONIN IN VITRO

S.B. DESHPANDE AND K.S. RAO* Department of Physiology, Institute of Medical Sciences, Banaras Hindu University, Varanasi 221 005 (India)

Studies have shown that lactating rats exhibit enhanced absorptive and motor activity of the gastrointestinal tract. In order to explore the possible changes associated with lactation, the contractility of gastric fundus to serotonin (5-HT) was studied. The serotonin-evoked isometric contractions of rat fundal strip preparations obtained from four groups viz., lactating rats (LR), non-lactating non-pregnant rats (NLR), pregnant non-lactating rats (PR) and adult male rats (MR), were measured and compared. An analysis of variance revealed that the fundal tissues from LR are more sensitive to 5-HT than those of NLR ($F = 18.3$; $P < 0.001$), while those from PR are less sensitive ($F = 8.04$; $P < 0.001$). Furthermore, the preparations from MR were more sensitive to 5-HT than those of NLR ($F = 6.5$; $P < 0.001$). While preliminary, these data suggest enhanced sensitivity of fundal strips to 5-HT in lactating rats. (Supported by ICMR Grant No. 5/3-5(17)/89-BMS-II).

GASTRIC EMPTYING IN THE RAT: EFFECTS OF CENTRAL AND PERIPHERAL TREATMENT WITH AGENTS ACTIVE AT SEROTONIN-3 AND/OR 4 RECEPTORS. B. J. Chase, D. J. Rossi, Jr. and G. E. Martin, Rhône-Poulenc Rorer Central Research, King of Prussia, PA 19406

The effects on gastric emptying (GE) of intracerebroventricularly (ICV) and IP administered agents acting at 5-HT-3 or 4 receptors was compared. In male rats, GE of a semi-solid meal was compared between treated and control animals 60 min post meal administration (p.o.). ICV -15 min and IP injections -30 min were given prior to the meal.

	5-HT	Agonist/	Maximal Effect on Emptying	
Agent	Receptor(s)	Antagonist	ICV	IP
RG 12915	3	Ant	+	++
2-methyl-serotonin	3	AG	++	NT
Phenylbiguanide	3	AG	-	--
Zacopride	3,4	Ant/AG	+	+++
Renzapride	3,4	Ant/AG	NE	+++
ICS 205,930	3,4	Ant/Ant	+	++
Reglan	3,4	Ant/AG	-	++
Serotonin	ALL	AG	--	NT

-,+>25%,--,++>50%,---,+++>75%,NE=No effect,NT=Not Tested

5-HT-3 antagonists increased gastric emptying in this model whether given ICV or IP, but compounds with 5-HT-4 properties were more potent. Both central and peripheral receptors play a role in modulating GE in the rat.

ADENOSINE

617.1

IDENTIFICATION AND CHARACTERIZATION OF ADENOSINE A2 AND A1 RECEPTORS cDNAs. LOCALISATION OF THE A2 RECEPTOR IN THE HUMAN STRIATUM AND SELECTIVE EXPRESSION BY THE RAT ENKEPHALINERGIC STRIATAL SUBPOPULATION. SN Schiffmann1*, F Libert2*, C Maenhaut2*, JE Dumont2*, G Vassart2* and J-J Vanderhaeghen1 [1]Lab. Neuropeptide Res. and [2]IRIBHN, Brussels Univ., 1070 Brussels, Belgium.

We have recently cloned RDC8 and RDC7, two orphans G protein-coupled receptors (Libert et al., *Science* (1989) 244:568-572). RDC8 has been identified as an adenosine A_2 receptor (A_2r) (Maenhaut et al., *Biochem. Biophys. Res. Comm.* (1990) 173:1169-1178) and we have now identified RDC7 as an A_1 receptor (A_1r). RDC8 and RDC7 were expressed in several mammalian cells. This confer to these cells the capacity to bind specifically either an A_2 ([^{3}H]CGS 21680) or an A_1 agonist ([^{3}H]CHA); and to stimulate or inhibit adenylyl cyclase in response to A_2 or A_1 agonists, respectively.

Using *in situ* hybridization (ISH), the mRNA encoding for this A_2r is exclusively detected in the medium-sized neurons of the rat and dog striatum (Schiffmann et al., *Brain Res.* (1990) 519:333-337). The human A_2r mRNA is also exclusively expressed by the medium-sized striatal neurons. A_2r is homogeneously distributed in the adult striatum, whilst it exhibits a striosomial pattern during the early postnatal development. Morover, a ISH colocalization study revealed that in the rat caudate-putamen A_2r is mainly expressed by the GABAergic-enkephalinergic subpopulation as compared to the substance P or the cholinergic neurons. The dopamine D_2 receptor is also selectively expressed by these neurons and, conversely to the A_2r, inhibits cAMP formation.

617.2

MOLECULAR CLONING AND CHARACTERIZATION OF A RAT A1 ADENOSINE RECEPTOR THAT IS WIDELY EXPRESSED IN BRAIN AND SPINAL CORD. D.R. Weaver, S.A. Rivkees, J.H. Stehle*, and S.M. Reppert. Laboratory of Developmental Chronobiology, Children's Service, Massachusetts General Hospital, Boston, MA, 02114.

Libert et al. (Science 244: 569, 1989) reported the cloning of four unidentified receptors belonging to the superfamily of G protein-coupled receptors. Two of these receptors, RDC7 and RDC8, appear to comprise a receptor subfamily. With the identification of RDC8 as an A_2-adenosine receptor (BBRC 173:1169, 1990; see also abstract by J.S. Fink et al.), it seemed likely that RDC7 encodes an adenosine receptor subtype. We used the polymerase chain reaction to clone a fragment of the rat homolog of RDC7, leading to isolation of a full-length clone from rat brain. The rat cDNA encodes a protein of 327 amino acids which shares several structural features with the A_2-adenosine receptor. Expression studies in COS-6M cells demonstrated that the cloned cDNA encodes a protein with high affinity for the A_1-adenosine specific ligand ^{3}H-CCPA (K_d = 882 ± 139 pM; n = 3) and appropriate pharmacological specificity (rank order for inhibiting ^{3}H-CCPA binding: CPA > R-PIA > NECA > S-PIA). In situ hybridization studies revealed a widespread distribution of the receptor mRNA, with high levels in cerebral cortex, hippocampus, cerebellum, thalamus, brainstem and spinal cord. The distribution of the receptor mRNA is generally in good agreement with the distribution of A_1-adenosine receptors as revealed by autoradiography, but several receptor/mRNA mismatches exist. The cloning and identification of A_1- and A_2-adenosine receptor cDNA's represents an important advance toward defining the role of adenosine receptor subtypes in CNS function.

617.3

MOLECULAR CLONING OF AN A_1 ADENOSINE RECEPTOR. E.M. Smyk-Randall*, L.D. McVittie*, H. Nakata*, F.J. Monsma, Jr, C.R. Gerfen, D.R. Sibley & L.C. Mahan*. ETB, NINDS and LCB & LCS, NIMH, NIH, Bethesda, MD 20892.

We have utilized the polymerase chain reaction technique to selectively amplify G protein-coupled receptor cDNA sequences from rat striatal mRNA. A novel cDNA fragment was identified which exhibits considerable homology to various members of the G protein-coupled receptor family. This fragment was used to isolate a full-length cDNA from a rat striatal library. A 2.2 kb clone was obtained encoding a protein of 326 amino acids with seven transmembrane domains as predicted by hydropathy analysis. Stably transfected mouse A9-L cells and chinese hamster ovary cells that express mRNA for this clone were screened with putative receptor ligands. Saturable and specific binding sites for the A_1 adenosine antagonist, [^{3}H]DPCPX, were identified on membranes from transfected cells. The rank order of potency and affinities of various adenosine agonist and antagonist ligands confirmed the identity of this cDNA clone as an A_1 adenosine receptor. The high affinity binding of A_1 adenosine agonists was shown to be sensitive to the non-hydrolyzable GTP analogue, Gpp(NH)p. In adenylyl cyclase assays, adenosine agonists inhibited forskolin-stimulated cAMP production by greater than 50% in a pharmacologically specific fashion. Northern blot and *in situ* hybridization analyses of receptor mRNA in brain tissues revealed two transcripts of 5.6 kb and 3.1 kb, both of which were abundant in cortex, cerebellum, hippocampus, and thalamus with lower levels in olfactory bulb, striatum, mesencephalon and retina. These regional distribution data are in good agreement with previous receptor autoradiographic studies involving the A_1 adenosine receptor. We conclude that we have cloned a cDNA encoding an A_1 adenosine receptor linked to the inhibition of adenylyl cyclase activity.

617.4

THE RAT A2 ADENOSINE RECEPTOR: MOLECULAR CLONING, EXPRESSION AND LOCALIZATION IN BASAL GANGLIA. J.S. Fink, D.R. Weaver, S. A. Rivkees, R. Peterfreund*, E. M. Adler* and S. M. Reppert, *Molecular Neurobiology and Developmental Chronobiology Labs, Massachusetts General Hospital, Boston, MA 02114.*

Selective ligand binding and receptor autoradiography have demonstrated that the A2 subtype of adenosine receptor is expressed exclusively in striatum, nuc. accumbens and olfactory tubercle in rat (Eur J Pharm 1989; 168:243). Using the technique of PCR cloning with homologous sequences we have isolated the cDNA encoding the rat A2 adenosine receptor. With degenerate oligonucleotide primers corresponding to conserved transmembrane domains of G protein-linked receptors and first strand cDNA from rat brain as template, 230 bp fragments of G protein-linked receptor cDNAs were amplified using PCR. One of these receptor fragments hybridized to mRNA in rat striatum. Using this receptor fragment as probe, a full-length cDNA was isolated from a gt10 rat striatal library. This rat receptor was highly similar to the canine G protein-linked receptor RDC8 (Science 1989; 244:569) which has recently been shown to be a canine A2 adenosine receptor (BBRC 1990; 173:1169). Identification of the rat cDNA as an A2 receptor was achieved by expression in COS cells. In situ hybridization demonstrated abundant and exclusive expression of the rat A2 receptor mRNA in striatum, nuc. accumbens and olfactory tubercle. The abundant expression of the rat A2 receptor mRNA in basal ganglia may underlie the known interaction between dopaminergic and adenosinergic systems on behavior.

617.5

CONTRIBUTION OF THE SECOND ADENOSINE GROUP TO THE TOTAL BINDING OF BIS(N^6-ADENOSYL)ALKANES TO THE ADENOSINE A$_1$ RECEPTOR. J. B. Wollack and R. M. Collins, Jr.* Dept. of Pediatrics, School of Medicine, Univ. of Maryland at Baltimore, Baltimore, MD 21201

Bis(N^6-adenosyl)alkanes are "bivalent" analogs of adenosine, in which the two adenosyl groups are separated by a spacer of methylene groups. We have previously reported a series of these compounds whose affinities for the A1 adenosine receptor range from approximately 3 to 300 nanomolar. In order to assess the contribution that the presence of the second adenosyl group makes to this binding, we have compared one of the best bivalent compounds, bis(N^6-adenosyl)decane, with its monovalent counterpart, N^6-decyladenosine. Since N^6-decyladenosine contains not only one of the adenosyl groups, but also the bridging structure from bis(N^6-adenosyl)-decane, any differences in binding affinity should be attributable to the second adenosine group.

N^6-decyladenosine and bis(N^6-adenosyl)decane were synthesized by the reaction of 6-chloropurine riboside with either decylamine or diaminodecane. Binding to the A$_1$ adenosine receptor in rat brains was assessed using ^{3}H-cyclohexyladenosine as the radioligand. The binding of the monovalent N^6-decyladenosine was 30 nanomolar, 12 - fold less than the bivalent bis(N^6-adenosyl)decane. These results suggest that the presence of the second adenosyl group contributes significantly to the overall binding of the bivalent analog. Supported by grants from the NIH (1-KO8-NS01514) and the American Paralysis Association.

[^{3}H]CV 1808 LABELS A NOVEL NON-ADENOSINE A$_2$ BINDING SITE IN RAT BRAIN. L. J. Cornfield, P.S. Loo, S. D. Hurt and M. A. Sills. CIBA-GEIGY Corp., Research Dept., 556 Morris Ave., Summit, NJ 07901, and NEN-DuPont, 549 Albany St., Boston, MA 02118.

The vasoactive agent CV 1808 (2-phenylaminoadenosine) has previously been shown to possess 10-fold selectivity for the adenosine A$_2$ receptor (Jarvis et al., J. Pharmacol. Exp. Ther., 251:888, 1989). CV 1808 was subsequently radiolabeled and binding was evaluated in membranes prepared from Sprague-Dawley rat striatum, cortex and hippocampus. Specific binding accounted for 65-70% of total binding. Using 5 nM [^{3}H]CV 1808 in a series of competition studies, CV 1808 produced shallow inhibition curves in all three tissues. Computer analysis of the data indicated that CV 1808 inhibited 61-75% of the binding in the three brain areas with IC$_{50}$ values of 16-24 nM, and 25-37 % of the binding with IC$_{50}$ values of 590-1130 nM. The adenosine A$_1$ selective compounds, CPA and CHA, inhibited only ~35% of total specific binding with IC$_{50}$ values of 270-1750 nM and 960 - 2560 nM, respectively. Interestingly, the adenosine A$_2$ selective agonist CGS 21680 and the non-selective agonists NECA and MECA inhibited < 20 % of total specific binding at a concentration of 10 µM. In contrast, CGS 15943, an adenosine antagonist, inhibited 56-68 % of total binding, with an IC$_{50}$ value of 128-310 nM. In addition, several novel adenosine analogs, such as CGS 22988, inhibited 100% of specific binding with IC$_{50}$ values of 370 - 430 nM in the three brain areas. The adenosine uptake inhibitor, dipyridamole, and the guanine nucleotide analog, GTPγS, were unable to inhibit the binding of [^{3}H]CV 1808. These results suggest that [^{3}H]CV 1808 labels two binding sites in rat brain, neither of which appear to be the adenosine A$_2$ receptor. One site appears to be an adenosine A$_1$-like component, whereas the second site appears to be a novel adenosine binding site. Further studies to identify a functional correlate for this novel binding site are presently in progress.

617.7

TRANSPORT KINETICS AND METABOLISM OF ACCUMULATED [^{3}H]D-ADENOSINE AND [^{3}H]L-ADENOSINE IN RAT CEREBRAL CORTICAL SYNAPTONEUROSOMES. **J.G. Gu., A.N. Sawka* and J.D. Geiger. Dept of Pharmacology and Therapeutics, Faculty of Med., Univ. of Manitoba, Winnipeg, Manitoba, Canada, R3E 0W3.**

[^{3}H]L-Adenosine was previously found to be more metabolically stable than [^{3}H]D-adenosine and to be a substrate for CNS adenosine transporters [Gu et al., J. Neurochem. 56 (1991) 548-552]. Here we examined the degree to which accumulated [^{3}H]D- and [^{3}H]L-adenosine were metabolized and the effects that this metabolism had on transport characteristics. For [^{3}H]D-adenosine, there was an inverse relationship between transport reaction times and Km values; for 5, 15 and 600 sec there were 24, 32, and 76% conversions to nucleotides; the Km values (uM) were 9.4±4.2, 8.4±2.3, and 4.5±0.6, respectively. Ten minute preincubations of tissue with 10 uM EHNA, an adenosine deaminase inhibitor, and 5'-iodotubercidin, an adenosine kinase inhibitor, resulted in significantly higher Km values of 36±1 for 5 sec and 44±13 for 15 sec incubations; metabolism of accumulated [^{3}H]D-adenosine to nucleotides was decreased to 6.4% at 5 sec and 9.0% at 15 sec. In the presence of these inhibitors, 32% of accumulated [^{3}H]D-adenosine was metabolized to nucleotides for 600 sec incubations and Km value of 15.8±4.7 were not significantly different from control value of 4.5±0.6. For [^{3}H]L-adenosine, Km value for 20 sec incubations were 38.7±6.8. Metabolism of accumulated [^{3}H]L-adenosine to nucleotides was 2.5, 4.8, and 30.9% for 5, 15 and 600 sec incubations, respectively. Metabolism of accumulated adenosine affects measured kinetic parameters for adenosine transport and the Km value for adenosine transport in rat cerebral cortical synaptoneurosomes is approximately 40 uM.

617.8

THE ADENOSINE REUPTAKE ANTAGONIST SOLUFLAZINE REDUCES AND DELAYS POPULATION ANOXIC DEPOLARIZATION IN RAT HIPPOCAMPAL NEURONS IN VITRO. C.G. Boissard and V.K. Gribkoff. Neuropharmacology, Bristol-Myers Squibb Pharmaceutical Research Institute, 5 Research Parkway, Wallingford, CT 06492.

Endogenous adenosine, released by hippocampal neurons during hypoxia, mediates hypoxic depression of synaptic transmission, a response which may be neuroprotective (Gribkoff et al., Brain Res. 512: 353, 1990). Application of metabolically stable adenosine analogs prior to an ischemic event results in a reduction in ischemic neuronal death (Evans et al., Neurosci. Lett. 83:287, 1987), while application of an adenosine antagonist exacerbates ischemia-related hippocampal injury (Rudolphi et al., J. Cereb. Blood Flow Metab. 7 :74, 1987). In the present experiments we have begun to examine the ability of an adenosine reuptake antagonist, soluflazine, to potentiate the potentially protective effects of endogenous adenosine release; this compound has been previously shown to increase the inhibitory effects of exogenously applied adenosine in hippocampal slices (Ashton et al., Eur. J. Pharm. 142:403, 1987).

Population anoxic depolarizations, recorded from stratum radiatum in area CA$_1$ of rat hippocampal slices in response to exposure to N$_2$ gas, were reduced in amplitude in slices incubated in 10 µM soluflazine (to 39.8% of control); this effect was less pronounced at 20 and 50 µM soluflazine, although the higher concentrations of this reuptake antagonist produced a clearly concentration-dependent increase in synaptic inhibition. In similar fashion, the latency to the onset of anoxic depolarization was significantly increased by the lowest concentration of soluflazine (to 227.4% of control). These data suggest that increasing extracellular adenosine levels by blocking reuptake of the nucleoside can ameliorate a potentially cytotoxic neuronal response to hypoxia.

AUTORADIOGRAPHIC VISUALIZATION OF ADENOSINE A1 RECEPTORS IN HUMAN HIPPOCAMPUS. J.Deckert, W.Berger*, K.Kleopa*, S.Heckers*, G.Ransmayr*, H.Heinsen*, A.Wree*, H.Beckmann* and P.Riederer*. Dep. of Psychiatry, University of Würzburg, FRG.

20 micron-sections from autoptic samples of the hippocampus and parahippocampal gyrus were cut and thaw-mounted on gelatine-coated slides.

After preincubation (30 minutes, 20 °C) in 150 mM Tris-HCl buffer pH 7.4 with 1.5 IU/l ADA the sections were incubated (2 hours, 20° C) with (^{3}H)DPCPX (0.2 to 20 nM) followed by 2 rinses with buffer (4° C, 120 sec). Non-specific binding in the presence of 20 uM R-PIA was 15%.

Kinetic parameters as determined by wiping the incubated sections off the slide and liquid scintillation spectophotometry were Kd=1.6 nM and Bmax=169.9 fmol/section.

Saturation analysis using quantitative autoradiography and determination of cell density in adjacent Gallocyanin-stained sections provided receptor density corrected for cell density in subregions and individual layers of hippocampus.

617.10

RADIOLIGAND BINDING STUDIES OF CGS 21680 TO ADENOSINE RECEPTORS IN SPINAL CORD AND STRIATAL MEMBRANES. V. Pirec, H. K. Proudfit, J. I. Choca. Dept. of Pharmacology, Univ. of Illinois College of Medicine at Chicago, Chicago, IL 60612

To better characterize adenosine A$_2$ receptors in the spinal cord we performed parallel studies in membranes of spinal cord and striatum. In both preparations CGS 21680 displaced [^{3}H]NECA from two sites with similar K$_i$ values (K$_{i1}$ = 37.4 and 22.0nM; K$_{i2}$ = 6.4 and 4.0 µM for cord and striatum, respectively). In the spinal cord 20% of these [^{3}H]NECA sites have characteristics of A$_2$ receptors. Additional displacement studies with R-PIA, CPA, CHA, CADO, DMPA, DMPX, confirmed that 12 to 30% of the [^{3}H]NECA binding sites show characteristics of an adenosine A$_2$ receptor.

However we have been unable to detect direct binding of [^{3}H]CGS 21680 to spinal cord membranes using concentrations in the range of its K$_d$ (4 to 80 nM). At higher concentrations (30 to 400 nM) [^{3}H]CGS 21680 binds to a site which has a K$_d$ of 125 nM. Various displacement studies (CGS 21680, DMPA, CPA, CPX), suggest that 90 to 99.9% of this binding is to a site which has characteristics of adenosine A$_1$ receptors. The remaining 0.1 to 9% of the displacable binding appears to be an A$_2$-like receptor.

These conflicting results suggest that A$_2$ receptors in the spinal cord differ from those in striatum. Perhaps the binding kinetics of [^{3}H]CGS 21680 are much faster in the spinal cord than in the striatum. Faster kinetics could explain our inability to observe direct binding. (Supported by USPHS Grant DA03980.)

617.11

EFFECT OF NEONATAL CAFFEINE ON ADENOSINE A1 RECEPTOR ONTOGENY USING AUTORADIOGRAPHY. Barbara A. Etzel and Ronnie Guillet. Department of Psychology, University of Rochester, Rochester, NY 14627.

Caffeine (C), an adenosine antagonist, is commonly administered as treatment for apnea of prematurity in human infants. To investigate the long term effects of this treatment, an animal model was developed. Homogenate assay of 14-90 day old rat brain has shown that neonatal C exposure significantly increased specific adenosine A1 receptor (A1R) binding in cerebellum (CBL) and hippocampus (H), two areas in which A1R binding increases with age. To further specify the subregional effects of neonatal C treatment on ontogeny, autoradiography was performed. The brains of unhandled (NH) or neonatally C-exposed (C-ex) 14 and 30-31 day old rats were removed, quick frozen, sectioned and treated with adenosine deaminase. Sections were then incubated with 1 nM 3H-cyclohexyladenosine (3H-CHA). Nonspecific binding was determined in adjacent sections with L-phenylisopropyladenosine. The sections were apposed to LKB Ultrofilm for 4 weeks. Quantification was performed using Analytical Imaging Concepts software.

3H-CHA binding was greatest in the H. Within H, binding was more pronounced in CA1 and CA3 than in dentate gyrus. In all H subregions there was an age by treatment interaction ($p<0.01$). Binding was less in 14d C-ex rats than in controls. However, by 30d, binding in C-ex rats equalled or exceeded that in controls. In CBL more labelling was apparent in the molecular layer (M) than in the granular layer (G), especially in the older rats. The layers could not be distinguished in the 14d C-ex CBL in which there was minimal binding. In M and G, 3H-CHA binding increased with age in the NH groups ($p<.01$). Binding was greater in C-ex than in NH rats at 30d (M, $p=0.05$; G, $p<0.01$). These studies corroborate and enlarge upon the homogenate binding studies by demonstrating differences in subregional A1 adenosine binding as a function of age and early developmental caffeine exposure. Grant No. HD22782

PENETRATION OF ADENOSINE ANTAGONISTS INTO MOUSE BRAIN AS DETERMINED BY EX VIVO BINDING. K. A. Jacobson,+ O. Nikodijevic,+ and J. Baumgold,* +NIDDK, NIH, Bethesda, MD, *Dept. of Radiology, George Washington Univ., Washington, DC.

The penetration of peripherally-administered adenosine antagonists into mouse brain was determined using ex vivo binding and locomotor studies. CPT (8-cyclopentyltheophylline), CPX (8-cyclopentyl-1,3-dipropylxanthine), 8-PST (8-p-sulfophenyltheophylline), and XAC (xanthine amine congener) were examined. At 10 min post-injection (IP), CPT and CPX (25 mg/kg and 0.25 mg/kg, respectively) both had penetrated into brain substantially: 49 and 17 % of theoretical levels (assuming free penetration throughout the body), respectively. Brain levels of CPT decreased rapidly, declining to undetectable levels by 30 min post-injection, whereas levels of CPX increased to 51% penetration at 20 min, then declined slowly. As expected, no detectable brain levels of 8-PST were found following intraperitoneal injection of 50 mg/kg. XAC (20 mg/kg) penetrated into brain poorly: 1.6% of theoretical after 10 min and 3.2% 20 min post injection. As a control for vascular content of brain tissue, ^{14}C-bovine serum albumin was administered iv., and the level of radioactivity found in the brain was 1% of that found per equal volume of plasma (corresponds to 1.1% penetration). The ability of CPT to stimulate locomotor suppression paralleled the brain levels, ie. it was similar to theophylline at short times, and the effect rapidly diminished. These studies demonstrate the usefulness of ex vivo binding in determining CNS penetration of adenosine receptor ligands.

617.13

PHORBOL ESTERS DIFFERENTIALLY MODULATE PRESYNAPTIC AND POSTSYNAPTIC ACTIONS OF ADENOSINE A1 RECEPTORS. L. Arlinghaus*, N.F. Kassell and K.S. Lee. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Phorbol esters and adenosine are potent modulators of neuronal activity in the central nervous system. In the CA1 region of hippocampus, activation of protein kinase C (PKC) by phorbol esters results in an increase in neuronal activity, whereas activation of adenosine A1 receptors inhibits neuronal activity. Previous studies indicate that these systems can interact; phorbol esters attenuate the inhibitory action of adenosine on population spike responses in the hippocampus (Worley et al., PNAS 84, 1987). The studies presented here examined the influence of phorbol esters on two physiological actions of adenosine mediated by A1-type receptors.

In vitro hippocampal slices from adult gerbils were utilized to record: 1) orthodromically-evoked, synaptic responses in the stratum radiatum of CA1 (fEPSPs) and, 2) antidromically-evoked afterdischarges in the stratum pyramidale of CA1 (recorded in the presence of low calcium medium). The inhibitory effect of adenosine on fEPSPs was diminished by phorbol 12,13 diacetate (PDAc) and phorbol 12,13 dibutyrate (PDBu), but not by the relatively inactive phorbol 12,13 didecanoate (PDD). In contrast, the inhibitory action of adenosine on repetitive neuronal discharges elicited in low calcium was enhanced by PDAc and PDBu while PDD was ineffective. Thus, phorbol esters can differentially modulate presynaptic and postsynaptic actions of adenosine A1 receptors. These observations may reflect fundamental differences in the manner in which the PKC second messenger system interacts with the adenosine modulatory system at presynaptic and postsynaptic sites. SELECTIVE CHANGES OF ADENOSINE RECEPTORS IN RAT BRAIN SLICES FOLLOWING IN VITRO EXPOSURE TO RECEPTOR AGONISTS. M.P. Abbracchio, A.M. Paoletti*, B. Paternieri* and F. Cattabeni. Institute of Pharmacological Sciences, University of Milan, Via Balzaretti 9, 20133 Milan, Italy

Adenosine is known to physiologically inhibit excitatory neurotransmission in the CNS by activation of specific receptor subtypes. This is believed to be at the bases of neuroprotection by adenosine analogues against ischemia- and excitatory amino-acid-induced cerebral damages. However, there are indications that adenosine neuroprotection might be reduced when brain adenosine concentrations are markedly and pathologically increased (e.g., prolonged ischemia and aging). To verify whether such possible losses of adenosine neuroprotective activity might be due to agonist-induced desensitization of cerebral receptors in consequence to the prolonged exposure to adenosine, we have studied the regulation of adenosine receptors in rat brain slices exposed for different time-periods to selective adenosine receptor analogues, such as cyclo-pentyl-adenosine (CPA) and N-ethyl-carboxamido-adenosine (NECA). After exposure of slices to 0.1-10 μM CPA for up to 1 h, the ability of adenosine analogues to inhibit membrane adenylate cyclase activity and cAMP production was dose- and time-dependently reduced, suggesting a loss of A1 receptor function. Desensitization of A1 receptors with NECA was slower in onset and less pronounced, according to the lower A1 receptor selectivity of this adenosine analogue with respect to CPA. Moreover, A2 receptors seemed to be less affected by both agonists in the experimental conditions used, resulting in an umbalance between A1 and A2 receptor function, which might be of functional relevance to ischemic conditions.

ADENOSINE RELEASE EVOKED BY ISCHEMIC-LIKE CONDITIONS AND ELECTROPHYSIOLOGICAL ACTIVITY IN HIPPOCAMPAL SLICES. F. Pedata*, A.M. Pugliese*, M. Pazzagli* and G. Pepeu. Pharmacol. Dept., Univ. Florence, Italy.

The release of endogenous adenosine (ADO) and inosine (INO) from rat hippocampal slices was investigated by HPLC. Recovery of stable evoked population spikes, recorded from the CA1 region, occurred within 150 min from cut when ADO and INO release were stable and reached 14.3±1.5 and 16.0±2.0 ng/g/min respectively. Ischemia was then produced by superfusing the slices with glucose free Krebs saturated with 95% N2/5% CO2 for 5 min. The ischemia-evoked release of ADO and INO was respectively 132±37 and 106±20 ng/g/min. Electrophysiological responses disappeared within 3 min of ischemia; complete recovery occurred in 4 min after returning to normal oxygenated Krebs solution. Release of ADO and INO evoked by 5 min ischemia was reduced by 62% and 39% respectively in the presence of TTX (0.5 uM) and by 25% and 20% in the presence of the NMDA receptor antagonist D-AP7 (100 uM). The results indicate that ischemia-evoked release of ADO and INO is greatly dependent on influx of Na+ through voltage dependent Na+ channels activity and partly mediated by activation of NMDA receptors. (C.N.R. and University Grants).

FORSKOLIN-STIMULATED CYCLIC AMP ACCUMULATION IN RAT CORTEX SLICES IS MARKEDLY ENHANCED BY ENDOGENOUS ADENOSINE. N. W. DeLapp and K. Eckols*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

This study investigated a role for endogenous adenosine in forskolin (F)-stimulated cyclic AMP (cAMP) accumulation in brain slices. cAMP accumulation was measured in adult rat cortex slices prelabeled with [3H] adenine. Adenylate cyclase was assayed in membrane preparations by conversion of [3H] ATP to [3H] cAMP.

Adenosine deaminase (ADA)-treatment of slices caused marked reductions in F-stimulated cAMP accumulation of 50% at 100 uM F up to 96% at 1 uM F. ADA inhibition was completely reversed by 5 uM 2-chloroadenosine (2CA). In ADA-treated slices stimulated with 1-100 uM 2CA, 1 uM F shifted the dose-response curve to the left and increased maximal stimulation 6-fold. Caffeine (200 uM) and 8-phenyl theophylline (10 uM) significantly inhibited 1 uM F stimulation in control slices and 1 uM F + 5 uM 2CA stimulation in ADA-treated slices. 1 uM vasoactive intestinal polypeptide stimulation of cAMP accumulation in slices was unaffected by 200 uM caffeine or ADA. 1 uM F-stimulated adenylate cyclase in cortex membranes was unaffected by ADA, 200 uM caffeine, or 100 uM 2CA. These data demonstrate that stimulation of cAMP accumulation in cortex slices by 1 uM F is primarily due to synergism with endogenous adenosine and that its inhibition by caffeine is largely due to blockade of adenosine receptors.

ADENOSINE A1-RECEPTOR ACTIVATION DECREASES NEURONAL EXCITABILITY IN RAT BRAINSTEM NEURONS: IN-VITRO INTRACELLULAR STUDIES. J.D. Marks and G.G. Haddad. Dept. of Pediatrics, Section of Respiratory Medicine, Yale Univ. Sch. of Medicine, New Haven, CT 06510.

Adenosine analogue administration into the brainstem decreases blood pressure and breathing in in-vivo preparations. To understand the cellular basis of these adenosine-mediated effects, we recorded intracellularly from vagal motoneurons using superfused rat brainstem slices. Input resistance (R_N), membrane potential (Vm), firing rate, and action potential waveform were recorded from 25 neurons before and after superfusion with a potent and specific A1 receptor agonist (S-ENBA or CPA) at 3 doses (1-100 uM). With A1 agonist superfusion, spontaneous firing ceased, without statistically significant changes in Vm. Both R_N and spike after-hyperpolarization amplitude (AHP) increased in a dose-dependent fashion (ANOVA, $p<.05$). Prior superfusion with a potent and specific A1 receptor antagonist (8-CPT, 800 uM) prevented these effects. Since the increase in AHP suggests an alteration in a Ca-dependent conductance, additional slices were superfused with Ca-free solution containing $CoCl_2$. This treatment blocked the adenosine-induced increases in R_N and AHP. We conclude that A1 receptor activation 1) reduces vagal motoneuron excitability by increasing $gK_{(Ca)}$; 2) most likely decreases other conductances to explain the increase in R_N.

FUNCTIONAL ADENOSINE A_2 RECEPTORS MAY BE PRESENT ON ENTERIC NERVE ENDINGS. R.M.Broad, T.J.MacDonald* and M.A.Cook. Departments of Pharmacology & Toxicology, and Medicine, University of Western Ontario, London, CANADA, N6G 2J7

Adenosine is a neuromodulator which may play a physiological role in the enteric nervous system to modify gastrointestinal motor function. We have demonstrated the inhibition, by adenosine analogs, of the evoked release of Substance P (SP) and Neurokinin A (NKA) from nerves in the myenteric plexus of the guinea pig ileum as well as inhibition of field-stimulated contraction of guinea pig longitudinal muscle-myenteric plexus (LMMP) preparations. Identification of the subtype of adenosine receptor mediating this response was sought. Inhibition of contraction of field stimulated LMMP was observed for all adenosine analogs; the A_1-selective agonist N^6-cyclopentyl adenosine (CPA) being more potent than the A_2-selective agonists which included CGS-21680. Antagonism of the responses with the A_1-selective antagonist 1,3-dipropyl-8-cyclopentylxanthine (DPCPX) and subsequent Schild analysis revealed, for CPA, a slope of 0.971 and a pA_2 of $1.1x10^{-8}$M. The same analysis for the A_2-selective agonists yielded slopes that were not significantly different from zero. Direct measurement of the inhibition of release of SP and NKA from perifused enteric ganglia yielded similar results. These data provide evidence for the presence of A_1 receptors functionally coupled to the release of excitatory mediators. The consistent micromolar EC_{50}'s obtained for the A_2 agonists suggest either a high threshold activity at A_1 receptors or action at putative distinct A_2 receptors. The lack of antagonism of A_2 agonists by the A_1 antagonist DPCPX suggests that the former possibility may not involve simple competitive interaction. Supported by MRC of Canada.

N^6-CYCLOPENTYLADENOSINE, A STABLE ADENOSINE ANALOG, EXERTS CONCENTRATION DEPENDENT EFFECTS ON EVOKED DENTATE GRANULE CELL ACTIVITY. T.H. Swanson and L.M.Masukawa. Dept. of Neurology, Graduate Hospital and Institute of Neuroscience, Univ. of Pennsylvania School of Med., Philadelphia, PA 19106.

Adenosine is involved in intercellular signalling in the hippocampus, although in what capacity is not entirely clear. Inhibitory actions of adenosine have been identified in regions CA3 and CA1 , but relatively little is known about its role in the dentate gyrus. Since the dentate is an important "gateway" to the hippocampus, we chose to characterize the role of adenosine in this region. Standard microelectrode field recordings were performed on dentate granule cells during perforant path stimulation in rat hippocampal slices. The amplitudes of the population post synaptic potential (PSP) and population spike (PS) were measured before and after application of N6-cyclopentyladenosine (CPA), a stable, A-1 receptor specific adenosine analog, at several concentrations. CPA at concentrations at and above 10 nanomolar (nM) reversibly inhibited the PSP and PS amplitude shortly after application. Application of 1 nM CPA resulted in little alteration of the PSP, but a marked enhancement of the PS amplitude which was slow to reach its maximal effect, but reversible. These preliminary data indicate that A-1 adenosine receptor activation results in both excitatory and inhibitory effects at different concentrations. The inhibitory effect may be due to a decrease of excitatory transmitter release while the excitatory effect may be a direct effect on the post-synaptic membrane, or a decrease of inhibitory transmitter release. Supported by a grant from the Epilepsy Foundation of America to THS, and NIH #NS23077 to LMM.

UNITARY EPSPs MEASURED BY WHOLE-CELL RECORDING ARE REDUCED BY ADENOSINE IN RAT HIPPOCAMPAL CA1 PYRAMIDAL NEURONS *IN VITRO*. T.V. Dunwiddie, C.R. Lupica, and W.R. Proctor, Veterans Administration Medical Research Service and University of Colorado Health Sciences Center, Denver, CO 80262.

Adenosine is an inhibitory neuromodulator of synaptic transmission in the central nervous system. Although indirect evidence indicates that adenosine acts at least in part by reducing transmitter release, direct evidence regarding the actual pre- and postsynaptic actions are lacking. In the present experiments, we have characterized the effects of adenosine at excitatory Schaffer collateral and commissural synapses onto hippocampal CA1 pyramidal neurons. Unitary EPSPs generated by low intensity stimulation ("minimal stimulation") showed a high degree of variability, which is most likely the result of quantal release of the excitatory transmitter. The stimulus voltage was set so that in 10 - 30% of the trials there was no apparent response ("failures"), i.e., the response (if any) was smaller than the baseline noise (std. dev. of noise estimates was 50 μV). Superfusion of adenosine (20 μM) resulted in a profound reduction in the mean EPSP amplitude and an increase in the number of failures. The ratio of variance/mean EPSP amplitude for these responses was virtually unchanged by adenosine, and was the same for both the 1st EPSP and the 2nd potentiated EPSP elicited with paired-pulses (50 msec interval). These results are consistent with the hypothesis that the major effect of adenosine in this preparation is to decrease the amount of transmitter released from excitatory presynaptic nerve terminals.

SYNAPTIC INHIBITION BY ADENOSINE IS NOT ABOLISHED BY BARIUM S. Birnstiel, U. Gerber, and R.W. Greene.
Harvard Medical School/VAMC, Brockton, MA 02401

Adenosine-induced inhibition of evoked postsynaptic potentials (PSPs) and epileptiform burst firing was studied with intracellular recordings in the CA1 subfield of rat hippocampal slices. Adenosine (50 μM) hyperpolarized the membrane by 3.7±1.4 mV (n=19) in association with a decrease of the evoked PSP of 75±22% for control PSPs of 10-15 mV amplitude (n=9). During superfusion with 2 mM Ba^{2+}, the hyperpolarization evoked by 50 μM adenosine was abolished. The adenosine-induced inhibition of the PSPs was still evident, although the magnitude of this effect was significantly reduced ($p<.05$, Wilcoxon matched-pairs signed-ranks test). Analysis of the input-output curves showed little dependence of the percent PSP inhibition on the amplitude of the pre-adenosine PSP.

Adenosine also reduced Ba^{2+}-induced burst firing by 32±16% (n=16). Epileptiform activity evoked by 5 mM TEA was more potently inhibited by adenosine (by 88±11%, n=3). The results suggest that adenosine inhibits synaptic transmission and epileptiform activity by at least 2 mechanisms: an postsynaptic increase in g_K and a presynaptic effect independent of the adenosine-evoked outward potassium conductance.

ADENOSINE MODULATES PURINERGIC MOTOR TRANSMISSION IN RAT URINARY BLADDER. J. Pablo Huidobro-Toro*, C. Gloria Acevedo*, E. Contreras and G. Bustos. Neurohumoral Regulation Unit, Dept. Physiology, Faculty of Biological Sciences, P. Catholic Univ. Chile and Dept. Pharmacology, Faculty of Biological Sciences, Univ. Concepción, CHILE.

To examine whether adenosine (A) modifies the purinergic motor tone of the bladder,experiments were conducted in isolated bladders superfused with buffer containing atropine plus guanethidine; tissues were electrically stimulated. A and related structural analogs blocked the electrically induced twitches (0.1-5 Hz) in a concentration-dependent fashion. The rank order of potency was R-PIA > CHA > NECA > A > S-PIA. A also reduced the ATP-induced contraction (NECA > CADO > R-PIA > A > CHA). The application of 8 phenyl theophylline (8PT) increased the magnitude of the twitch response without modifying the basal activity; 8PT antagonized the A-induced inhibitory effect. The ATP-induced contractions were mimicked by mATP, ADP but not by AMP or A. Preincubation with 5-30 μM 8PT potentiated the ATP but not the mATP-induced contractions. Results support the hypothesis of a physiological regulatory A tone in the rat bladder mediated via A1 and A2 receptors acting at pre and postjunctional sites respectively. FONDECYT Grants #699-90 and 767-90.

REDUCTION OF EPILEPTIFORM ACTIVITY BY THE ADENOSINE BINDING ENHANCER PD 81,723. C.A. Janusz[1] & R.F. Berman[2]. Dept. [1]Physiol. & [2]Psych., Wayne State Univ., Det. MI.

The potency of exogenous adenosine in reducing orthodromically evoked population spike potentials elicited in area CA1 of rat hippocampal slices was greatly enhanced by the addition of the adenosine binding enhancer, PD 81,723, to the bathing medium. PD 81,723 alone had no effect on hippocampal cell excitability, but required the presence of adenosine. In addition, PD 81,723 significantly enhanced the adenosine-mediated facilitation observed in paired pulse trials. Since the CA2/CA3 pyramidal cells are believed to be primary generators of epileptiform activity in the hippocampus, we studied the actions of PD 81,723 on synaptic bursting in this area. Superfusion of slices with low Mg^{2+} medium while antidromically stimulating the Schaffer collaterals in stratum radiatum of CA3 resulted in the development of spontaneous as well as stimulus-triggered bursts of multiple population spikes. Addition of PD 81,723 to the low Mg^{2+} medium resulted in a dose-dependent reduction in the number and duration of the evoked and spontaneous multiple population spikes. These results suggest that bursting activity seen in the hippocampal slice can be suppressed by the adenosine binding enhancer, PD 81,723, perhaps through an enhancement of the actions of endogenous adenosine, released during synaptic bursting. (Supported by NIH Grant No. RR-08167).

NEUROTRANSMITTER TRANSPORT AND RELEASE

CHARACTERIZATION OF [^{3}H]DIPYRIDAMOLE BINDING TO RABBIT AND GUINEA PIG CNS NUCLEOSIDE TRANSPORTERS. K.W. Jones*, M.A. Cook, and J.R. Hammond*. Department of Pharmacology and Toxicology, University of Western Ontario, London, Canada, N6A 5B8.

In some species, [^{3}H]dipyridamole ([^{3}H]DYP) may label a subset of nucleoside transporters that the more established probe [^{3}H]nitrobenzylthioinosine ([^{3}H]NBMPR) cannot. This transporter heterogeneity was investigated in both rabbit and guinea pig CNS by comparing the binding of [^{3}H]DYP and [^{3}H]NBMPR to cortical synaptosomes. In initial studies, two "specific" (inhibitor displaceable) binding components were observed for [^{3}H]DYP: the first (50%) being to the cortical membranes, the second being to the glass fibre filters. [^{3}H]DYP binding to the filters was inhibited by 1μM DYP and dilazep (DIL) but not by nitrobenzylthioguanosine (NBTGR), and could be prevented completely by including 0.01% CHAPS in the assay medium. This concentration of CHAPS did not affect [^{3}H]DYP binding to the cortical tissue. In rabbit, using 10 μM DIL to define non-specific tissue binding and 0.01% CHAPS to prevent "specific" filter binding, [^{3}H]DYP bound to a single class of high affinity sites (K_D=1.4nM, B_{max}=153 fmole/mg, n_H=0.99) and was inhibited in a monophasic manner by the recognized transport inhibitors NBTGR (K_i=0.78nM), DIL (K_i=0.082nM), and R75 231 (K_i=0.65nM). Almost identical results (B_{max} and K_i) were found using [^{3}H]NBMPR as the probe. [^{3}H]NBMPR and [^{3}H]DYP (+0.01% CHAPS) were also found to label a similar number of binding sites (B_{max} ≈ 175 fmole/mg) in guinea pig cortical synaptosomes. After correcting for the displaceable binding of [^{3}H]DYP to glass fibre filters, no evidence was found for specific NBMPR-resistant [^{3}H]DYP binding sites, nor DYP-resistant [^{3}H]NBMPR binding sites. These results suggest that [^{3}H]DYP and [^{3}H]NBMPR bind to the same subset of nucleoside transport proteins in rabbit, and possibly guinea pig, cortical membranes. Supported by the MRC of Canada.

EVIDENCE FOR AN ESSENTIAL HISTIDINE IN CYTOCHROME b561 FROM SECRETORY VESICLES. P.M. Kelley and D. Njus*, Dept. Biol. Sci., Wayne State Univ., Detroit MI 48202

The biosynthesis of catecholamines, such as epinephrine and norepinephrine, as well as peptide hormones, such as vasopressin and oxytocin, within secretory vesicles requires reducing equivalents from ascorbic acid. To maintain the levels of ascorbic acid within these vesicles, reducing equivalents are shuttled in to the ascorbate via a trans-membrane protein, cytochrome b561. We have recently analyzed the kinetics of the individual reactions between ascorbate and the cytochrome both on the internal and external surfaces of the vesicle membrane and hypothesized that the reaction between cytochrome b561 and ascorbate involves the concerted transfer of both a proton and an electron (J. Biol. Chem. 266, 6878 (1991)). Since histidine has a pK near neutrality and might participate in proton transfer, we tested compounds which react with histidine for effects on the electron transfer properties of the cytochrome. We now report that diethylpyrocarbonate, a chemical modifier of histidine residues, dramatically slows the rate of electron transfer from ascorbate to oxidized cytochrome b561. The inhibition is greater at higher pH, and the electron transfer is completely blocked at pH 8.5. This argues that at least one of the seven histidines in cytochrome b561 participates in the electron transfer process and supports the hypothesis of concerted electron/proton transfer. Supported by NIH grant GM 33849 and the American Heart Association.

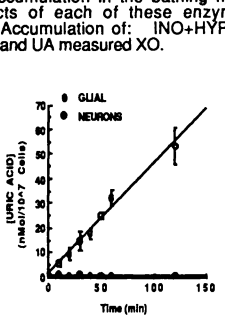
DIFFERENTIAL DISTRIBUTION OF PURINE DEGRADATIVE PATHWAYS BETWEEN GLIAL (G) AND NEURONAL (N) CELLS IN CULTURE. G. CEBALLOS*, R. RUBIO*, and J.TUTTLE. Univ. of Virginia, Charlottesville, VA., 22908.

Degradation of adenosine (ADO) in nervous tissues appears to occur in G but not in N. To demonstrate that is the case we performed studies in cultured embryonic chick G and N cells from ciliary ganglia. Cells were incubated in Krebs-Henseleit solution containing saturating concentrations (10^{-4} M) of the exogenous substrate for each degradative enzyme activity: ADO for adenosine deaminase (ADA), inosine (INO) for nucleoside phosphorylase (NP) and hypoxanthine (HYP) for xanthine oxidase (XO). Accumulation in the bathing media (nMoles/10^7 cells) of the products of each of these enzymatic reactions were evaluated by HPLC. Accumulation of: INO+HYP+UA measured ADA, HYP+UA measured NP and UA measured XO. As far as XO, the accumulation of UA rises with time and is greater in G than in N (fig). These results show that XO is preferentially found in G cells and is almost absent in N. The same patterns was found for ADA and for NP.



These results demonstrate that there is a preferential distribution of purine degradative pathways in G. In addition our results also demonstrate, for the first time, the presence of XO in G. RELEASE OF AN ENDOGENOUS LIGAND FOR THE CANNABINOID RECEPTOR FROM RAT BRAIN SLICES. D.M. Evans, M.R. Johnson* and A.C. Howlett. Dept. Pharmacological and Physiological Science, Saint Louis University, 1402 S. Grand Blvd., St. Louis, MO 63104

Although marijuana and cannabinoid drugs have been used for medicinal purposes for centuries, only recently has the cellular mechanism of action - namely inhibition of adenylate cyclase via a Gi-coupled receptor - been elucidated. Binding of the synthetic ligand [^{3}H]CP55940 allowed the characterization of the cannabinoid receptor. This receptor has been shown to exist in brains of many animal species and has recently been cloned. However, to date, an endogenous ligand for this receptor has not been identified. The localization of receptors on neurons may suggest a role in modulation of responses and hence would indicate a possible neurotransmitter-like molecule as the endogenous ligand. In order to investigate whether an endogenous ligand is present in rat brain and can behave in a similar fashion to "classical" neurotransmitters we examined the ability of the calcium ionophore A23187 to release a compound which could subsequently interact with the cannabinoid receptor on rat brain membranes. We report that release of inhibitory activity was dependent on both concentration of A23187 and time of exposure to the ionophore. Because many classical transmitters as well as eicosanoid metabolites are released in response to such treatment, a large number of these compounds were analyzed for their abilities to inhibit [^{3}H]CP55940 binding. Results from these studies are reported.

METHIONINE INCORPORATION AND TAURINE CONTENT DURING DEVELOPMENT. P.-L. Lleu* and R.J. Huxtable. Department of Pharmacology, University of Arizona Health Sciences Center, Tucson, Arizona 85724.

Huxtable *et al.* (*Neurochem. Int.*, 15:233; 1989) found an inverse correlation between the increase of the phosphatidylethanolamine/phosphatidylcholine ratio and the decrease of the taurine concentration in rat brain P_2B fraction during development. However, Schaffer *et al.* (*FASEB Abs.*, A591; 1991) found that, in the heart taurine inhibits phospholipid methyltransferase, the enzyme converting phosphatidylethanolamine to phosphatidylcholine. These observations led us to study the incorporation of [^{3}H-methyl]methionine in rat hemisphere P_2B fraction during development to determine if a relationship exists between taurine concentration and the incorporation of [^{3}H-methyl]methionine into phospholipid. Seven, 14, 21 and 28 days-old rat were injected i.p. with 300 μCi/Kg [^{3}H-methyl]methionine. At 9 h, the amount of radioactivity was determined in the P_2B fraction (protein, supernatant and phospholipid). Compared to younger rats, 28 days-old rats have significantly increased incorporation of [^{3}H-methyl]methionine into phospholipid, with no change in incorporation into protein. In general, incorporation is inversely correlated with taurine concentration. These results suggest that taurine alters the phospholipid membrane composition which in turn may affect taurine modulation of Ca^{2+} binding to membranes.

RELEASE OF CHOLECYSTOKININ AND GASTRIN-RELEASING PEPTIDE, AND THEIR PRECURSORS FROM THE HUMAN NEUROEPITHELIOMA CELL LINE SK-N-MCIXC P.N.M. Konings, M.C.Beinfeld, T.W. Moody and T.P. Davis. Dept. of Pharmacol, Univ. of Arizona, Tucson, 85724, Univ. Med. Center, St. Louis, Dept. of Biochem., The George Washington Univ. Med. Center, Washington D.C..

A variety of neuropeptides are involved in the central control of gastrointestinal (GI) functions. Amongst these peptides are cholecystokinin (CCK) and gastrin-releasing peptide (GRP). A large number of studies indicate that these two peptides function as neurotransmitters or neuromodulators in the brain. Several of the CCK and GRP central effects relate directly to GI tract functions and control, such as effects on gastric acid secretion, satiety and feeding behavior. The role which these peptides play is linked to the mechanisms which regulate their biosynthesis and metabolism. The cholinergic human neuroeptihelioma cell line SK-N-MCIXC expresses high levels of mRNA for CCK and GRP (Verbeeck M.A.E. and Burbach, J.P.H.;FEBS 268:88-90 (1990). This cell line provides a useful model to study regulation of gene expression and metabolism of CCK and GRP. The secretion of CCK and GRP was studied to further characterize the cell line. Spontaneous release (s) versus 75 mM KCl stimulated release (KCl) experiments were performed. CCK/GRP were detected by region specific RIA following chromatography. The cell line mainly releases nonamidated CCK-precursor fragments (all data in pg/million cells/10 min: CCK-58-like, 270(s) /330(KCl); CCK-39/33, 280(s)/518(KCl); Gly extended CCK, 314(s)/536(KCl)), and a relatively small portion of amidated CCK, 24(s)/ 40(KCl)/amidated GRP, 369(s). Therefore, spontaneous release versus KCl depolarization release of CCK/GRP demonstrate regulated secretion in this cell line. (Supported by NIH grants DK-36289 and NS-18667).

BIOGENIC AMINES: UPTAKE AND RELEASE

ANALYSIS OF SINGLE ADRENAL MEDULLARY CELLS BY REVERSED PHASE MICROCOLUMN LIQUID CHROMATOGRAPHY. B.R. Cooper, J.A. Jankowski, D.J. Leszczyszyn, R.M. Wightman, J.W. Jorgenson*. Dept. of Chemistry, Univ. of North Carolina, Chapel Hill, NC 27599-3290.

The increasing need to analyze small sample volumes has prompted the development of miniaturized liquid chromatography designs. Micropacked liquid chromatography columns not only are capable of handling low nL injection volumes, but they offer higher separation efficiencies than conventional sized columns. A micropacked liquid chromatography column with electrochemical detection has been used to quantitatively determine the total amount of epinephrine (EPI) and norepinephrine (NE) in single cultured adrenomedullary cells. The percent release of EPI and NE by a single cell due to a chemical stimulation has also been determined. A single cell was exposed to acetylcholine or carbachol, and an aliquot of the cellular bathing solution was removed and analyzed. Then the stimulated cell was lysed, and the remaining solution was analyzed.

619.2

INTRICACIES OF HANDLING [^{3}H]RESERPINE AND DETERMINING RESERPINE BINDING PARAMETERS. J.D. Deupree and R. Zielinski*, Dept. of Pharmacology, Univ. Nebraska Medical Center, 600 S. 42nd Street, Omaha, NE 68198-6260.

Reserpine has been used extensively for both therapeutic purposes and as a research tool for depleting catecholamine stores and to identify the catecholamine transporter in the membranes of storage vesicles found in adrenergic nerve endings and in the chromaffin cells of the adrenal gland. One of the difficulties of working with reserpine is that it sticks extensively to both glass and plastic surfaces. In the presence of less than 20 μg of protein, over 70% of the [^{3}H]reserpine in a binding assay bound to glass test tubes in a time dependent fashion with steady state conditions being reached in one hour. Stock solutions of [^{3}H]reserpine, prepared in either 1 mM HCl or 10 mM acetic acid, also bound to glass test tubes to the extent of 25 and 45% respectively. Much of the variation in apparent Kd values reported for [^{3}H]reserpine binding to the catecholamine transporter appears to be due to depletion of free [^{3}H]reserpine due to binding to both the test tube and the vesicle membranes. Both of these problems can be overcome by using assay volumes in the 4 to 6 ml range with protein concentrations of less than 10 μg/assay tube. Using these improved assay conditions the concentration of [^{3}H]reserpine required to occupy 50% of the catecholamine displacable binding sites on storage granule membranes (the apparent Kd) dropped from 1 nM to 0.03 nM. These results point out that quite often reserpine concentrations are up to 90% less than expected and large assay volumes with small protein concentrations are essential for obtaining reasonable estimates of the apparent Kd. (Support by NIH grant #NS 15187)

ION DEPENDENCES OF SEROTONIN TRANSPORT IN A TRANSFECTED CELL MODEL. Albert S. Chang* and Dominic Man-Kit Lam. Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX 77381.

A clonal, transfectant cell line, L-S1, which stably manifests high-affinity serotonin transport properties, was produced by transfection of human genomic DNA into mouse L-M fibroblasts. Using this cell line, we analyzed imipramine-sensitive, 5-[^{3}H]HT binding to the transport system. This binding activity was not attributable to the presence of 5-HT receptor subtypes in L-S1 cells, and was Na^+ independent but Cl^- dependent. In contrast, 5-[^{3}H]HT transport was both Na^+ and Cl^- dependent for these cells. The apparent K_m, but not the apparent V_{max}, varied with extracellular concentrations of either ion.The coupling ratio for 5-HT, Na^+ and Cl^- was deduced to be 1:1:1 per transport cycle.

By postulating that both Na^+ and Cl^- ions facilitate 5-HT transport by directly interacting with, or binding to, the transport system along with 5-HT , we used kinetic modelling to account for the involvement of each ion in this transport process. Both binding and transport results supported an ordered sequence of Cl^- and 5-HT binding to the transporter (Cl^- first, and may facilitate 5-HT binding); Na+ binding is not ordered relative to 5-HT binding, but is necessary for membrane translocation of 5-HT.

KINETIC AND ALLOSTERIC MODEL FOR THE ACETYLCHOLINE TRANSPORTER-VESAMICOL RECEPTOR. E.D. Clarkson, B.A. Bahr, G.A. Rogers and S.M. Parsons. Neuroscience Research Institute, Univ. of California, Santa Barbara , California 93106

The ligand binding relationship between the acetylcholine transporter (AcChT) and the vesamicol receptor (VR) in synaptic vesicles purified from the Torpedo electric organ was studied using analogs of AcCh and vesamicol. AcCh inhibits binding of [^{3}H]vesamicol with an affinity much lower (200-fold ratio) than its affinity for active transport (K_m= 0.3 mM). Three analogs of AcCh that are up to 57% larger in volume than AcCh also exhibit large ratios for the macroscopic competitive dissociation constants measured by inhibition of vesamicol binding and active transport of AcCh. AcCh analog 15 (N,N-dimethyl-3-pyrrolidinium benzoate iodide), that exhibits a ratio of 20, was synthesized in tritiated form and shown to be actively transported with the same V_{max} as AcCh itself. Trans-6-methoxyvesamicol was shown to be a noncompetitive inhibitor of AcCh and analog 15 active transport. The data demonstrate that vesamicol binds to an allosteric site in the AcChT. A specific model is proposed, and values for some of the microscopic constants in the model are estimated. The model posits very loose binding of AcCh to the AcChT (K_{AO}= 50 mM) that is followed by rapid transport. Little selectivity for the structure of the transported ion is exhibited.

EFFECTS OF LOCAL ANESTHETICS/COCAINE ON CHOLINE UPTAKE. Merouane Bencherif and Ronald J. Lukas. Division of Neurobiology, Barrow Neurol. Institute, Phoenix, AZ 85013.

Cells of the TE671/RD human clone and the PC12 rat pheochromocytoma exhibit a number of neuron-like features including the expression of high affinity choline uptake (HACU). IC_{50} values for blockade of HACU in the presence of 10nM ^{3}H-choline at 20°C are 1uM for native choline and 2uM for hemicholinium-3. By contrast, IC_{50} values are 100 and 1000uM, for nicotine and carbamylcholine, respectively. HACU is also sensitive to blockade by local anesthetics dimethisoquin (5uM), tetracaine (50uM) and procaine (500uM) at concentrations comparable to those that inhibit ion flux through nicotinic receptors expressed by TE671/RD or PC12 cells (IC_{50} values of about 3, 3, and 40 uM, respectively). These observations suggest that local anesthetics at therapeutic doses may not only affect ligand-gated and voltage-gated ion channel function, but may also affect HACU, which is the principal regulatory factor in acetylcholine synthesis. Furthermore, the local anesthetic cocaine inhibits HACU by TE671/RD and PC12 cells with IC_{50} values of about 500uM, suggesting that anomalous parasympathetic effects of cocaine and the observation that behaviorally-relevant and lethal doses of cocaine exceed those known to inhibit high affinity catecholamine uptake may both be explained by heretofore unrecognized effects of cocaine on acetylcholine metabolism and HACU.

Endogenous Sodium-dependent High Affinity Choline Uptake in *Xenopus Laevis* Oocytes. R.S. Fiore, S. Shimada, G. Uhl and J.T. Coyle. Depts. of Neurosci., Psych., and Neurol., Johns Hopkins Sch. of Med., Balto., MD 21205 and Lab. Mol. Neurobiol., ARC/NIDA, Balto., MD 21224.

Sodium-dependent high affinity choline uptake (SDHACU) is believed to be the rate-limiting mechanism in the production of acetylcholine by cholinergic neurons. We have discovered that *Xenopus laevis* oocytes possess endogenous high affinity choline uptake which is pharmacologically and kinetically similar to the SDHACU of cholinergic synaptosomal preparations.

Defolliculated *Xenopus laevis* oocytes were incubated with 100nM[^{3}H]choline chloride and examined for choline uptake under varying conditions. Competition against [^{3}H]choline uptake by unlabeled choline resulted in a complex displacement curve. Computer analysis indicated two components of uptake with high(Kt=3.7μM) and low affinities(Kt=148μM). Hemicholinium-3(HCh-3), a competitive inhibitor of SDHACU, selectively inhibited high affinity [^{3}H]choline uptake with an apparent Ki of 278nM. At much higher concentrations, HCh-3 also inhibited low affinity uptake with an apparent Ki of 36μM. Similar to the SDHACU of cholinergic preparations, the uptake of 100nM choline chloride by *Xenopus* oocytes was both sodium-, time- and temperature-dependent.

619.7

INHIBITION OF THE REUPTAKE OF NOREPINEPHRINE AND SEROTONIN. CONFORMATIONALLY CONSTRAINED ANALOGUES OF ANTIDEPRESSANT DRUGS AS SELECTIVE MONOAMINE REUPTAKE INHIBITORS. Gary L. Grunewald, David B. Lewis*, and Sheila M. Zipfel*. Department of Medicinal Chemistry, University of Kansas, Lawrence, KS 66045.

While some antidepressant drugs show selectivity in the inhibition of reuptake of either serotonin (5-HT) or norepinephrine (NE), no clear relationship between the chemical structure of the antidepressant drug and the neurotransmitter selectivity has been shown. Previous molecular mechanics calculations in our laboratory (*J. Med. Chem.* **1988**, *31*, 913-919) have suggested a correlation between the neurotransmitter selectivity and the conformation of key portions of flexible amine reuptake inhibitors. To probe this point, we have synthesized several conformationally constrained monoamine reuptake inhibitors which have been designed to mimic calculated low energy conformations of known antidepressant drugs selective for either NE or 5-HT reuptake.

The new conformationally constrained analogues have been evaluated for selectivity for the inhibition of [^{3}*H*]NE *vs.* [^{3}*H*]5-HT into chopped rat cortex. The selectivity ratio (ratio of IC_{50} values for inhibition of the uptake of NE compared to 5-HT) was determined for each compound and compared to the conformationally flexible parent drug. We will discuss our preliminary results, which show that the synthesis of conformationally constrained analogues may be of value to probe the effects of conformation on the selectivity of neurotransmitter reuptake by antidepressant drugs. Supported by NIH training grant GM 07775 and by NSF REU grant CHE 9100476.

INTERACTION BETWEEN OUABAIN AND THE DOPAMINE TRANSPORT RECEPTORS IN THE HUMAN FRONTAL CORTEX. J. Clardy*, A. Hitri, R.J. Wyatt and J.E.Kleinman. NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

Dopamine uptake (DAU) and the binding of DAU blockers to the transport receptors is a Na^+ and K^+ dependent process that may be linked to the Na^+,K^+-ATPase. Ouabain as an inhibitor of the Na^+,K^+-ATPase causes accumulation of Na^+ ions inside of the cell and competitively inhibits DAU in the striatal synaptosomes (Holz and Coyle 1974). We hypothesize that the effect of ouabain on DAU results from its direct inhibition of DA binding to the transporter receptor. To test this hypothesis, we labeled the DA transport receptors with [^{3}H]GBR 12935 and studied the binding inhibition by inhibitors of Na^+,K^+-ATPase in human brain. Aliquots of membrane preparations were incubated with 10 nM [^{3}H]GBR 12935 in the presence of increasing concentrations of ouabain analogue strophanthidine. The results indicate a 40% reduction in [^{3}H]GBR 12935 binding, which is concentration independent as the 40% reduction remained constant throughout nano and micromolar concentrations. In contrast the DAU blocker GBR 12909 inhibited [^{3}H]ouabain binding in a concentration dependent fashion with a shallow inhibition cur(IC_{50} of $1x10^{-5}$M). The decrease in saturable [^{3}H]GBR 12935 binding by a ouabain analogue is suggestive of receptor deactivation, and contrasts the nondestructive nature of inhibition of [^{3}H]ouabain binding by GBR 12909.

DORSOVENTRAL STRIATAL DIFFERENCES IN STIMULATED DOPAMINE (DA) OVERFLOW: RELATIONSHIP TO NOMIFENSINE EFFECTS. D. Ruskin and J.F. Marshall, Dept. of Psychobiology, University of California, Irvine, DA 92717

Relative to the caudate-putamen (CPu), the nucleus accumbens septi (NAS) has a paucity of high-affinity DA uptake sites, as evidenced by a lower *Vmax* for [^{3}H]DA uptake and a lower *Bmax* for [^{3}H]mazindol binding to the associated recognition sites. We investigated possible effects of these differences on stimulated DA overflow with a brain slice superfusion paradigm. [^{3}H]DA - labelled 350 μm coronal rat CPu and NAS slices (bathed in 10 μM pargyline) were electrically stimulated at 10 Hz to promote ^{3}H release. Calcium-dependent overflow of ^{3}H was demonstrated to be >85% [^{3}H]DA. Stimulated overflow (expressed as % of total radioactivity of the tissue at the start of stimulation) from NAS was 53% greater than that from CPu. This result is apparently due to regional differences in uptake site density, since stimulated overflow was equivalent in both areas in the presence of 10 μM nomifensine. Nomifensine potentiated overflow in both NAS and CPu; however, potentiation of CPu overflow was 1.9 times that of NAS. The results suggest that a given amount of terminal depolarization will cause greater overflow in ventral striatum than in dorsal due to differential transmitter reuptake, while the dorsal striatum may be preferentially affected by DA-reuptake blockers.

IMMUNOHISTOCHEMICAL EVIDENCE OF AMPHETAMINE INDUCED EXTRACELLULAR DOPAMINE DIFFUSION IN THE RAT NEOSTRIATUM RELEVANCE OF VOLUME TRANSMISSION

B. Bjelke; C. Andersson*; §H.W.M. Steinbusch; K. Fuxe
Dept. of Histology & Neurobiology, Karolinska Institutet, Stockholm, Sweden. §Dept. of Pharmacology. Free University, Amsterdam, The Netherlands

Dopamine (DA) may diffuse from DA nerve terminals to reach, via extracellular fluid pathways, D2-receptors on prolactin producing cells transplanted into neostriatum, and modify their activity (Bjelke et al. 91). In order to further analyze DA diffusion we induced DA release by amphetamine administration. Rats (Sprague-Dawley 200g b.w.) were given a high dose of d-amphetamine (10mg/kg i.p.) one hour prior to sacrifice. Perfusion with 5% glutaraldehyde was performed followed by vibratom sectioning. Antisera against DA and DARPP-32 were applied to the sections using a double immunofluorescence protocol. Following d-amphetamine administration increased DA immunoreactivity (IR) was seen in the striatal patches. DA IR was even visualized within the cytoplasm of the DARPP-32 nerve cellbodies especially within the striatal patches. Thus, after amphetamine induced DA release, DA appears to diffuse extra cellularly and to be taken up by DARPP-32 IR cells. On the basis of these findings Volume Transmission appears to be an important mode of communication for amphetamine induced increases of DA neurotransmission.

AMMONIUM RELEASES DOPAMINE IN THE NUCLEUS ACCUMBENS: MICRODIALYSIS EVIDENCE FOR A WEAK BASE MODEL OF PSYCHOSTIMULANT ACTION. H. M. Sung*[1], E. Pothos[1], D. Sulzer[2], G.P. Mark[1], S. Rayport[2] and B. G. Hoebel[1]. [1]Dept. of Psychology, Princeton Univ., Princeton, NJ 08544 and [2]Dept. of Psychiatry/NYS Psychiatric Inst., Columbia Univ., New York, NY 10032.

D-amphetamine (AMPH) and phencyclidine (PCP) are membrane-permeable weak bases. Local infusion of AMPH or PCP significantly elevates synaptic dopamine (DA) levels in the rat nucleus accumbens (NAC) by more than 20-fold (Br. Res. Bull. 19: 623, 1987; Life Sci.42: 1713, 1988) and rapidly reduces pH gradients in cultured midbrain DA neurons (Neuron 5: 797, 1990). It has been suggested that reduction of synaptic vesicle pH gradient contributes to elevated DA levels for some psychostimulants. In the present study, the classic weak base ammonium chloride (NH_4Cl) or ammonium sulfate ($(NH_4)_2SO_4$) was dissolved in Ringer's solution and infused in the NAC of freely moving rats through reverse dialysis (30 uL of a 100 mM solution was infused for 30 minutes; an estimated 10%, i.e. 10 mM, diffused into the brain). Both compounds increased extracellular dopamine more than 20-fold ($n=10, p<.05$). DOPAC and HVA also increased ($p<.01$). The same effects were observed when the pH of the infused ammonium solution was adjusted to the original pH of the perfusate (pH=6.2). Other weak base compounds gave similar results. The findings indicate that ammonium, a weak base that changes vesicular proton gradients, releases DA and therefore mimics the effects of AMPH and PCP if applied to the accumbens terminals in vivo. Consequently, the mechanism of action of some psychostimulants may be related to the reduction of intracellular proton gradients.

REVERSE ACTION OF THE PLASMA MEMBRANE TRANSPORTER MEDIATES WEAK BASE-INDUCED DOPAMINE RELEASE: IMPLICATIONS FOR AMPHETAMINE ACTION. D. Sulzer[1], N.T. Maidment[2], and S. Rayport.[1] [1]Dept. Psychiatry, Ctr. Neurobiol. & Behav., Columbia Univ.; Dept. Neuropathol., NYS Psychiatric Inst., NY 10032; [2]Dept. Psychiatry, UCLA, Los Angeles 90024

As a lipophilic weak base, amphetamine (AMPH) reduces vesicular pH gradients; this inhibits uptake and increases release of monoamines from storage vesicles (Sulzer & Rayport, 1990). We examined whether the resulting increased cytosolic transmitter reaches the synapse via reverse action of the uptake transporter. Ventral midbrain from P7 rats was dissociated, plated at a density of about 1,000 DA neurons/well, and maintained for >2 weeks. In control incubations, we measured about 100 fmoles of extracellular DA (release *minus* reuptake). Extracellular DA increased over 5-fold with 200 μM AMPH. The plasma membrane DA uptake blocker benztropine (BENZ; 10 μM) significantly increased extracellular DA (release alone). When normalized for the effect of BENZ on reuptake, BENZ attenuated the AMPH-induced increase in DA. BENZ might act by inhibiting uptake of AMPH through the DA transporter, blocking reverse transport of DA, or both. To circumvent effects due to specific AMPH uptake, we mimicked the weak base action of AMPH with ammonia (added as NH_4Cl), which is membrane permeable and partitions according to the pH gradient, and the proton/cation ionophore monensin. NH_4Cl (5 mM) increased extracellular DA 2-fold; BENZ inhibited this increase by 50%. Monensin (50 nM) increased extracellular DA 3-fold, but this was not affected by BENZ, perhaps due to an attenuation of the Na^+ gradient by monensin. These findings support a model whereby AMPH and other weak bases, once accumulated in the cell, increase cytosolic DA through inhibition of vesicular proton gradients; elevated cytosolic DA is then discharged, at least in part, by reverse action of the uptake transporter.

619.13

THE AROMATIC AMINO ACID DECARBOXYLASE INHIBITOR, NSD-1015, INCREASES DOPAMINE RELEASE IN VITRO FROM SUPERFUSED CORPUS STRIATAL TISSUE FRAGMENTS OF MALE RATS. D. E. Dluzen and J. L. McDermott. Departments of Anatomy and Geriatric Medicine, N.E.O.U.C.O.M., Rootstown, OH 44272, and University Hospitals, Cleveland, Ohio.

Addition of NSD-1015 (10μM) to Krebs-Ringer Phosphate (KRP) superfusion medium significantly increased potassium stimulated (K^+ - 30mM) dopamine (DA) release in vitro from superfused corpus striatal tissue fragments (areas under K^+ - stimulated curves: KRP = 134 ± 23, N=6 vs. KRP + NSD-1015 = 203 ± 22, N=10, pg/70 min). This increased K^+ - stimulated release appears attributable to an increase in the spontaneous output of DA since basal (pre - K^+) DA release of superfusions with KRP + NSD-1015 (17 ± 6 pg/mg/min) were significantly greater than those with KRP alone (6 ± 3 pg/mg/min). To test the effect of NSD-1015 upon spontaneous DA release, superfusions with KRP medium were either continued with KRP or changed to KRP + NSD-1015. The change to KRP + NSD-1015 produced a significant increase in DA release (areas under DA release curves: KRP = 19 ± 8, N=4 vs. KRP + NSD-1015 = 107 ± 37, N=4, pg/70 min). Moreover, spontaneous DA release showed a dose dependent response as a function of NSD-1015 concentration (areas under DA curves: 0.1μM = 20 ± 3, N=4; 1.0μM = 103 ± 23, N=4; 10μM = 104 ± 21, N=6; 100μM = 181 ± 17, N=3; 1000μM = 419 ± 27, N=4, pg/70 min). Supported by grants from the Parkinson's Disease Foundation and United Way of Stark County.

ONTOGENETIC STUDIES ON BINDING SITES FOR DOPAMINE UPTAKE BLOCKERS IN NIGRO-STRIATAL DOPAMINERGIC NEURONS. M. Valchar*, A. G. Wright, Jr.* and I. Hanbauer. Lab. of Chemical Pharmacology, National Heart, Lung, and Blood Institute, Bethesda, MD 20892.

The expression of dopamine uptake sites that are sensitive to dopamine uptake blockers is developmentally linked to neuritic outgrowth. Our results show that in embryos and in newborn rats the binding sites for dopamine uptake blockers appear not to be colocalized with the dopamine transporter in plasma membranes. In 19-day-old embryos and in newly born rats specific binding sites for ^{3}H-GBR-12935 can be measured in intact striatal synaptosomes, but are not detectable in washed synaptosomal membrane preparations. Permeabilization of striatal synaptosomes prepared from these age groups with streptolysin-O (0.2 units/ml) causes leakage of cytosolic proteins into the incubation medium and reduces ^{3}H-GBR-12935 binding by 70%. In contrast, six days after birth 100% of the specific binding sites for ^{3}H-GBR-12935 and ^{3}H-WIN-35428 are expressed in neuronal membranes; no loss of binding sites for these radioligands occurs in lysed and washed synaptosomes. This is similar to the distribution of binding sites found in striatal synaptosomes of adult rats. The cytosolic binding protein for ^{3}H-WIN-35428 that leaks out of streptolysin-O-treated synaptosomes is presently being purified. (M. Valchar is supported by a grant from ICI Pharmaceuticals, Wilmington, DE, and the Scottish Rite, N.M.J., Lexington, MA.)

AGONISTIC AND ANTAGONISTIC INTERACTIONS OF DOPAMINE UPTAKE BLOCKERS IN THE HUMAN FRONTAL CORTEX. Ana Hitri Ph.D., Manuel E. Casanova M.D., Joel E. Kleinman M.D. Ph.D. and Richard Jed Wyatt M.D. NIMH, Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

The pharmacology of the high affinity site of [^{3}H]GBR 12935 binding in the human frontal cortex is consistent with that of the dopamine transporter in the striatum. Of the structurally unrelated dopamine uptake blockers the most potent inhibitor of [^{3}H]GBR 12935 binding in the frontal cortex is benztropine (BZT) whereas amfonelic acid is the weakest (Hitri et al 1991). BZT inhibition of [^{3}H]GBR 12935 binding in the human frontal cortex involves multiple binding sites. To determine the pharmacological profile of the BZT inhibited binding sites we studied the effects of the known dopamine (DA) blockers on BZT inhibition. Aliquots of human frontal cortex homogenate were incubated with [^{3}H]GBR 12935 and increasing concentrations of BZT in the presence and absence of DA uptake blockers at their uptake IC50 concentrations. GBR 12909 potentiated nanomolar BZT inhibition from 20 to 80%. In contrast amfonelic acid prevented the inhibition of BZT in the nano and micromolar range. Nomifensine, cocaine, and DA moderatly potentiated BZT inhibition without altering the shape of the curve. The data indicate that GBR 12909 exerts a synergistic agonistic effect, whereas amfonelic acid exerts an antagonistic effect on BZT sensitive [^{3}H]GBR 12935 binding sites in the human frontal cortex.

619.16

^{125}I-PIA (*p*-IODOAMPHETAMINE) MAY LABEL MONOAMINE OXIDASE A (MAO_A) IN CRUDE RAT FRONTAL CORTEX HOMOGENATE. Xuemei Huang*, Michael P. Jonhson, David E. Nichols and Chester A. Mathis. Depts. of Pharmacology and Toxicology, and Medicinal Chemistry and Pharmacognosy, Purdue Univ., W. Lafayette, IN 47907. Donner Laboratory, Lawrence Berkeley Laboratory, Univ. of California, Berkeley, CA 94720.

In attempts to develop a novel label for the serotonin uptake carrier, ^{125}I-*p*-iodoamphetamine (^{125}I-PIA) was synthesized. A specific binding site for ^{125}I-PIA was subsequently identified in rat frontal cortex homogenate. Scatchard analysis yielded a K_D of 421 ± 16 nM, a Hill coefficient of 0.991 ± 0.003, and B_{max} of 32.1 ± 1.9 pmol/mg protein. Certain amphetamine derivatives were tested but did not displace ^{125}I-PIA with very high affinity. The K_I values of *p*-chloroamphetamine (PCA), d-amphetamine (*d*-AMP), and *S*-3,4-methylenedioxymethamphetamine (*S*-MDMA) were 603 ± 53 nM, 2045 ± 238 nM, and 4758 ± 603 nM repectively. Surprisingly, the K_I value for displacement of ^{125}I-PIA by the 5-HT uptake inhibitor paroxetine was 6654 ± 965 nM. The NE and DA uptake inhibitors desipramine and GBR-12909 did not displace ^{125}I-PIA ($K_I > 10$ μM). Serotonin and dopamine also had K_Is > 10 μM. One week after treating rats with a neurotoxic regimen of PCA (10 mg/kg i.p. twice), neither the K_D nor B_{max} of ^{125}I-PIA binding were significantly different from saline treated animals. However, the B_{max} of [^{3}H]-paroxetine binding was decreased almost 80%. This suggested that the ^{125}I-PIA binding site was not the serotonin uptake carrier and was also not located on the 5-HT axon terminal. It seemed possible that membrane-bound monoamine oxidase might therefore be the site labeled by ^{125}I-PIA. The MAO_B inhibitor deprenyl did not displace ^{125}I-PIA ($K_I > 10$ μM). However the MAO_A inhibitor clorgyline displaced ^{125}I-PIA binding with a K_I of 95 ± 14 nM. The results suggest that ^{125}I-PIA may bind to membrane bound MAO_A. The possible use of tritiated clorgyline to label membrane bound MAO_A is suggested.

BW 1370U87 - A SELECTIVE, COMPETITIVE INHIBITOR OF MONOAMINE OXIDASE-A H.L. White and P.W. Scates*. Division of Pharmacology, Wellcome Research Laboratories, Research Triangle Park, NC 27709.

BW 1370U87, a potent, selective inhibitor of rat and human brain monoamine oxidase-A (MAO-A) is being developed as a potential antidepressant/antiphobic/antipanic agent. Kinetic experiments demonstrate a competitive mechanism of action for this compound, with $K_i = 0.01$ µM using either serotonin or tyramine as substrate. After preincubation of BW 1370U87 with mitochondrial MAO, full activity was restored by dialysis, indicating complete reversibility of the inhibition. Following oral administration to rats, BW 1370U87 inhibited brain MAO-A in a dose-dependent manner, with an ED_{50} = 8 mg/kg p o and a duration greater than 7 hr, but less than 24 hr. No significant inhibition of MAO-B by BW 1370U87 was observed either in vitro or ex vivo. Ex vivo inhibition was also reversed by extensive dialysis of brain homogenates from pretreated rats. The selectivity, reversibility, and competitive kinetics of the inhibition by BW 1370U87 may contribute to an improved safety profile with this novel MAO-A inhibitor.

619.18

EFFECT OF 1370U87, BROFAROMINE, AND MOCLOBEMIDE ON RAT BRAIN BIOGENIC AMINES AND THEIR ACID METABOLITES. R. Norton*, S. Jones-Humble*, G. Pollard, H.L. White, B. Cooper. Division of Pharmacology, Wellcome Research Labs., Research Triangle Pk., NC 27709.

Monoamine oxidase (MAO) inhibitors have been shown to increase brain concentrations of biogenic amines while decreasing concentrations of their acid metabolites. It has been suggested that the magnitude of this effect is an indicator of MAO inhibition. Oral doses of 1370U87, a novel and reversible selective MAO-A inhibitor, moclobemide and brofaromine were given to rats at doses shown to inhibit brain MAO-A by 80%. The effects on brain biogenic amines and their metabolites were quantified 2 and 4 hours after injection. Moclobemide (10mg/kg) and 1370U87 (20mg/kg) induced larger increases in 5HT, NE, and DA and larger decreases in DOPAC, 5HIAA, and HVA than did brofaromine (3mg/kg). The effect of 1370U87 (20mg/kg po) on biogenic amines lasted 6 hours significantly ($p <= 0.05$) increasing NE, 5HT, and DA while decreasing DOPAC, HVA, and 5HIAA. Similar results were found in a dose response study when 1370U87 was given orally at 10, 20, or 40mg/kg.

619.19

BLOOD PRESSURE EFFECTS OF MONOAMINE OXIDASE INHIBITORS IN RESPONSE TO ORALLY ADMINISTERED TYRAMINE IN THE RAT. M. S. Carroll*, O. G. Beek*, and B. R. Cooper. Division of Pharmacology, Burroughs Wellcome Co., Research Triangle Park, NC 27709.

The reversible monoamine oxidase A inhibitors 1370U87, 616U76, brofaromine, and moclobemide, and the irreversible nonselective monoamine oxidase inhibitor phenelzine were compared for potentiation of the pressor response to oral tyramine. Conscious rats were pretreated with doses of the monoamine oxidase inhibitors sufficient to produce 80% inhibition of brain monoamine oxidase, and then were challenged with orally-administered tyramine. Blood pressure was monitored prior to and after tyramine, and peak pressor responses were compared. At a dose of 15 mg/kg tyramine, the pressor response of 1370U87 was statistically similar to the vehicle control response. 616U76, brofaromine, and moclobemide elicited mild tyramine pressor effects, whereas phenelzine resulted in a marked elevation of blood pressure. Higher doses of tyramine elicited blood pressure elevations from all of the monoamine oxidase inhibitors.

619.20

CNS PHARMACOLOGY OF 1370U87: A NOVEL REVERSIBLE SELECTIVE MAO-A INHIBITOR. B. Cooper, H.L. White, G. Rigdon, O. Beek*, R. Norton*, G. Kraemer*, R. Ferris. Division of Pharmacology, Wellcome Research Labs., Research Triangle Pk., NC 27709.

1370U87 is a potent reversible selective inhibitor of rat and human brain MAO-A having a competitive mechanism of action and an oral ED_{50} (ex vivo) of 8 mg/kg. The duration of action exceeds eight hours. The ED_{80} dose for inhibition of MAO-A (20 mg/kg) elevates NE, DA, and 5HT levels in brain without significantly potentiating the blood pressure effects of orally administered tyramine. No inhibition of MAO-B with 1370U87 has been observed. 1370U87 is effective in the 5-HTP potentiation test and Porsolt test. The compound also has effects on abnormal behavior produced by early mother/infant separation in monkeys. Autonomic testing with 1370U87 revealed that there are no adverse cardiovascular symptoms in dogs or rats. No pharmacologically significant effects were observed on various isolated tissues, receptors or uptake systems. 1370U87 is representative of a new class of safer reversible MAO-A inhibitors which are expected to create a new generation of agents to use for depression, anxiety conditions, phobias, obsessive compulsive behaviors and borderline personality disorders.

619.21

AUTORADIOGRAPHIC LOCALIZATION OF NOREPINEPHRINE UPTAKE SITES IN RAT BRAIN USING [^{125}I]-IODOTOMOXETINE. S.L. Gackenheimer, E.S. Littlefield*, D. E. Mais*, D.W. Robertson and D.R. Gehlert. CNS and Cardiovascular Pharmacology, Lilly Research Labs., Indianapolis, IN 46285.

The norepinephrine (NE) uptake transporter is a primary mechanism involved in the termination of the effects of NE. These sites were originally studied using radioligands which lacked specificity for this site or had high levels of nonspecific binding. Therefore, localization using autoradiography has been difficult. We have developed a method for localization of NE uptake sites using a novel radioiodinated analog of the potent and specific NE uptake inhibitor, tomoxetine.

A series of biochemical studies were conducted to determine the appropriate conditions for labeling slide mounted sections of rat forebrain. Once optimal conditions were determined, labeled sections were exposed against a sheet of Hyperfilm-B max for 24-48 hours. Quantitation of the binding was accomplished using [^{125}I]-Microscales standards (Amersham) which were placed against the film along with the labeled sections. Following film development, the images were analyzed by desitometry using a MCID (Canada) image analysis system.

[^{125}I]-iodotomoxetine (N-methyl-3-[2-[^{125}I]-iodophenoxy] benzene propanamine, 2200 Ci/mmol) bound to tissue sections with an apparent K_d value of 50 pM and a B_{max} of 26 fmol/mg tissue. Specific [^{125}I]-iodotomoxetine binding was inhibited by low nanomolar concentrations of desipramine or tomoxetine while higher concentrations of paroxetine (5HT uptake inhibitor) or GBR 12909 (DA uptake inhibitor) were required to displace binding. The distribution of binding sites correlated well with the known location of NE containing cell bodies and terminals. High densities of binding were found in the locus coeruleus, zona incerta, nucleus of the solitary tract, dorsal raphe nucleus, anterior thalamic nuclei, hypoglossal nucleus and ventral tegmental area. Moderate levels of binding were seen in the paraventricular nucleus of the hypothalamus. Low densities were found in the caudate-putamen, globus pallidus and cerebral cortex. There appeared to be no laminar distinction within the cerebral cortex.

These results indicate that [^{125}I]-iodotomoxetine exhibits high affinity and specificity for NE uptake sites and provides a useful tool for autoradiographic studies by providing rapid exposure of autoradiograms.

PHORBOL ESTERS CAUSE PREFERENTIAL SECRETION OF NOREPINEPHRINE FROM BOVINE CHROMAFFIN CELLS. A.L. Cahill and R.L. Perlman, Depts. of Pediatrics and Pharmacol. and Physiol. Sciences, The University of Chicago, Chicago, IL 60637

Phorbol esters stimulate the secretion of [^{3}H]norepinephrine from intact bovine chromaffin cells and potentiate Ca^{2+}-induced secretion from permeabilized chromaffin cells (Pocotte et al., PNAS 82, 930-934, 1985).To examine the effects of phorbol esters on the secretion of the individual catecholamines, we have assayed catecholamine secretion by HPLC with electrochemical detection. We find that phorbol dibutyrate (PDBu) causes a much greater release of norepinephrine (NE) than of epinephrine (E):

Secretagogue	% NE Secreted	% E Secreted	%NE/%E
None	0.29 ± 0.03	0.27 ± 0.03	1.07
55 mM K^+	22.21 ± 0.67	13.77 ± 0.61	1.61
1 µM PDBu	11.26 ± 0.53	2.44 ± 0.23	4.61

In efforts to understand this differential effect of phorbol esters, we have measured secretion in primary cultures of bovine chromaffin cells which are highly enriched in either epinephrine- or norepinephrine-containing cells (Moro et al., Anal. Biochem. 185, 243-248, 1990). Phorbol dibutyrate was a much more effective secretagogue in norepinephrine- as opposed to epinephrine-containing cells. These studies reveal an unsuspected difference in the regulation of epinephrine and norepinephrine secretion. (Supported by research grants from NIH and NSF)

REAL-TIME IDENTIFICATION OF EPINEPHRINE AND NOREPINEPHRINE COSECRETION FROM INDIVIDUAL BOVINE ADRENAL MEDULLARY CELLS. E.L. Ciolkowski, B.R. Cooper, J.W. Jorgenson*, and R.M. Wightman, Dept. of Chemistry, University of North Carolina, Chapel Hill, N.C. 27599-3290.

Carbon-fiber microelectrodes placed adjacent to individual bovine adrenal medullary cells have been used to monitor the nicotine-evoked release of catecholamine and to distinguish between epinephrine (E) and norepinephrine (NE). The identity of released catecholamine was determined using cyclic voltammetry at electrodes coated with a thick (>350 nm) Nafion film. The identification is based on the difference in the rates of the intra-cyclization reaction of the oxidized forms of the catecholamines (1). Three types of cells were identified: those which secreted primarily E; those which secreted primarily NE; and those which secreted mixtures of E and NE. Liquid chromatographic analysis of single cells shows that the relative proportions of E and NE in the individual cells is the same as the proportions observed during secretion of those same cells. These findings show that although individual adrenal cells in culture primarily contain either E or NE, they are capable of storing and secreting both catecholamines simultaneously.

NEUROTRANSMITTER AND HORMONE RECEPTORS

620.1

STEROIDAL REGULATION OF TYPE II CORTICOSTERIOD RECEPTORS IN PRIMARY CULTURES OF DISPERSED HIPPOCAMPAL NEURONS. D. O'Donnell and M.J. Meaney. McGill University, Dept. of Neurology & Neurosurgery, Douglas Hosp. Res. Ctr., Montreal, Que. H4H 1R3, Canada.

The existence of two corticosteroid receptor systems in the rat brain is well established, however regulation of their expression by corticosteroids remains controversial. The present study examined the effects of RU 28362, corticosterone (CORT) and aldosterone (ALDO) on type II (^{3}H-dexamethasone ± RU 28362) corticosteroid receptor binding in dispersed hippocampal cell cultures derived from animals sacrificed at E19-20 days of gestation. Four days of exposure to 10 nM RU 28362 resulted in a robust down-regulation of type II receptors (~70%) whereas similar exposure with 10 nM of either CORT or ALDO produced a more moderate (40-45%) decrease in type II receptor binding capacity. Scatchard analysis revealed that diminished type II receptor level was due to a decrease in total number of binding sites (Bmax) with no differences in Kd (~0.8nM). Given that both CORT and ALDO decrease type II binding to the same extent, it is possible that this effect is mediated via type I corticosteroid receptors. Furthermore, the calculated EC_{50} for ALDO in the hippocampal cell cultures is low (EC_{50} = 7-8 nM) and thus strongly suggests the involvement of type I receptors. In order to address this question, we treated cultured hippocampal cells with 10 nM ALDO ± 20 nM of either type I receptor antagonist (RU 26752) or type II recepotor antagonsist (RU 38486). Neither antagonist was successful in blocking the type II corticosteroid receptor down-regulation by ALDO. Surprisingly, incubation with either RU 26752 or RU 38486 on their own produced a decrease in type II binding. Studies are currently underway to further characterize these agonist-like effects on type II receptors via type I and/or type II receptors.

DIURNAL RHYTHMS OF GLUCOCORTICOID AND MINERALOCORTICOID mRNA EXPRESSION IN THE HIPPOCAMPAL FORMATION: REGIONAL SPECIFICITY AND STEROID DEPENDENCE. J.P. Herman, B.S. McEwen, H.M. Chao, H Coirini, and S.J. Watson, Mental Health Research Institute, U. of Michigan, Ann Arbor, MI 48109, and the Rockefeller University, New York, NY 10021.

Brain mineralocorticoid (MR) and glucocorticoid (GR) receptor subtypes are exposed to a wide range of diurnal glucocorticoid (GC) concentrations. The availability of MR and GR proteins is clearly essential to integration of GC signals across the circadian cycle. To assess this availability, we have employed semi-quantitative in situ hybridization histochemical analysis of MR and GR mRNA expression across the circadian cycle (4 h intervals) in intact rats and rats deficient of endogenous GCs (adrenalectomized (ADX) rats). MR mRNA showed a significant, bimodal diurnal rhythm in all hippocampal subfields. ADX resulted in a small (25%) but significant overall increase in MR mRNA in all subfields. GR mRNA, on the other hand, showed a monotonic diurnal rhythm restricted to CA1 and dentate gyrus (DG). Effects of ADX were subfield dependent: pronounced round-the-clock increases were observed in CA1 and CA3 following ADX, whereas in the DG ADX served to eliminate the circadian trough in GR mRNA expression. No circadian or ADX-induced changes in GR or MR mRNA were observed in the frontoparietal cortex or in the posterior thalamic nuclei. These data indicate that MR and GR mRNA exhibit hippocampus-specific diurnal rhythms of expression which interact with, but cannot be totally explained by, circulating GCs. We hypothesize that hippocampal steroid receptor gene expression is synchronized by both steroid and neuronal input across the daily light-dark cycle.

620.3

HOMOLOGOUS REGULATION OF GnRH RECEPTOR mRNA IN A GONADOTROPE CELL LINE. Tsutsumi, M., S.C. Laws*#, P. L. Mellon##, J. L. Roberts, and S. C. Sealfon. Fishberg Center in Neurobiology, Mount Sinai School of Medicine, New York, NY 10029, US EPA, Research Triangle Park, NC 27711#, and The Salk Institute, La Jolla, CA 92037##.

Using the *Xenopus* oocyte system as a bioassay for GnRH receptor (GnRH-R) mRNA level, we have previously demonstrated that regulation of the GnRH-R in ovine pituitary cultures by gonadal hormones is associated with concomitant changes in receptor mRNA levels (Mol. Endo. 4:119,1990). The transgenic mouse-derived cell line, αT3-1 cells, express a GnRH-R similar to those found in rat and mouse pituitary (Mol. Endo.5:347, 91), making this cell line an excellent model system for the study of the regulatory mechanisms of the GnRH-R by GnRH.

Exposure of αT3-1 cells to GnRH induces alterations of GnRH-R mRNA levels, as assayed in oocytes. The effect of GnRH is bimodal and both time and concentration dependent. Exposure to physiological concentrations of GnRH for 20 minutes causes a significant increase in GnRH-R mRNA at 24 h, but after a continous 24 h exposure, the mRNA level is unchanged. In contrast, a 20 minute exposure to 1μM GnRH does not alter GnRH-R mRNA at 24 h, whereas 24 h exposure leads to a marked decrease. Preliminary binding data suggest that up- and down-regulation of the GnRH-R mRNA is accompanied by similar changes in receptor number. In rat pituitary, similar effects on GnRH-R biosynthetic rate have been reported (Endo. 126:2577,90). Thus, both homologous and heterologous regulation of the GnRH-R involve modulation of biosynthetic rate. (NIH Grant K11 DK01854)

620.4

REGULATION OF SUBSTANCE P RECEPTOR SYSTEMS BY NALTREXONE. O.J. Igwe. Division of Pharmacology, Schools of Pharmacy/Medicine, UMKC, Kansas City, MO 64108.

Opiate antagonist, naltrexone (NALT), increases opioid peptides in the brain and up-regulates brain opioid receptors resulting in functional supersensitivity, i.e., an enhanced morphine-induced analgesia. SP causes the release of met-enkephalin. Recent evidence strongly suggests that SP system is regulated by endogenous opioid peptides. Here, NALT was used to explore the functional link between SP and endogenous opioid receptor systems. Male Sprague-Dawley rats under ether anesthesia were implanted subcutaneously with Alzet® miniosmotic pumps, filled with either NALT HCl (100mg/ml) or vehicle (control), for 7 days. Animals were decapitated on day 8, whole brains rapidly removed and homogenized in ice-cold buffer for use in in vitro binding assays in order to explore the regulation of SP and intracellular inositol 1,4,5-trisphosphate (IP_3) receptors. Using tritiated SP and IP_3 as ligands, the affinities (K_D) for SP and IP_3 receptors were unaffected by chronic NALT treatment. However, the densities (B_{max}) for both SP and IP_3 were significantly increased by 35% and 52%, respectively. NALT appears to up-regulate SP receptor. It also appears that IP_3 receptor, a calcium mobilizing receptor, is positively modulated by stimulation of other classes of cell-surface receptors.

620.5

UP-REGULATION OF δ OPIOID RECEPTORS IN NEUROHYBRID CELLS IS ACCOMPANIED BY LOSSES IN LYSOSOMAL ENZYME ACTIVITIES M. M. Belcheva#*, J. Barg#*, R. J. McHale#*, X-M. Gao†*, D-M. Chuang† and C. J. Coscia# # Dept. of Biochem. and Mol. Biol., St. Louis Univ. Sch. Med. St.Louis, MO 63104, and the †Biological Psychiatry Branch, NIMH, Bethesda, MD 20892

Opioid receptor binding affinities and densities in subcellular fractions from neurohybrid cells were assessed using 2 models of up-regulation. Na-butyrate was added to NCB-20 cell cultures to achieve heterologous up-regulation, whereas δ sites in NG108-15 cells were up-regulated by chronic treatment with the opioid antagonist naltrexone (homologous). In both paradigms, sites in light (LM) and heavy membranes (HM) (resolved by density centrifugation of Con A pretreated cells) displayed increases in ^{3}H-DADLE and ^{3}H-diprenorphine B_{max} values without changes in affinity. In contrast to 48 h antagonist treatment, 5 min exposure to naltrexone down-regulated HM δ sites. β-Glucuronidase and β-hexoseaminidase activities were reduced in naltrexone-treated cells in a time and dose-dependent manner suggesting opioid-induced alteration in lysosomal enzyme trafficking. Comparable down- and up-regulation and attenuation of lysosomal enzyme activity was observed following treatment with the δ-selective opioid peptide antagonist ICI174864. These results suggest that homologous up-regulation entails down-regulation followed by an inhibition of receptor degradation.

620.6

IMIPRAMINE REDUCED BINDING NUMBER OF SIGMA SITES IN RAT STRIATUM AND HIPPOCAMPUS. Y.Shirayama*, T.Nishikawa*, M.Watanabe and K.Takahashi Natl. Inst. Neurosci., NCNP, Tokyo and Natl. Defence Med. College, Saitama, Japan

Repeated treatment for 14days with imipramine (IMI; 10mg/kg, i.p., once a day) induced a decrease in the Bmax, without affecting the Kd, of [3H]DTG (1,3-di-o-tolylguanidine) binding to the haloperidol-sensitive sigma sites in the striatum and hippocampus of the rat. This reduction dose not seem to be due to the residual IMI in the brain tissues, since luM of IMI in the assay medium of cortical [3H]DTG binding augmented the Kd value, in the absence of change in the Bmax value, of the binding. Finally, repeated treatment with IMI in combination with p-chlorophenylalanine (a serotonin synthesis inhibitor) no longer altered the striatal and hippocampal [3H]DTG binding. These results indicate that depletion of the brain serotonin may antagonize the ability of subchronic administration of IMI to reduce [3H]DTG binding sites in the striatum and hippocampus, suggesting that serotonergic system could be involved in the regulation of sigma binding sites in these brain areas.

620.7

CO-ADMINISTRATION OF THE PERIPHERAL BENZODIAZEPINE ANTAGONIST PK11195 ATTENUATES LORAZEPAM-INDUCED TOLERANCE AND RECEPTOR DOWNREGULATION. W.R. Galpern, L.G. Miller, D.J. Greenblatt* and R.I. Shader*. Div. of Clinical Pharmacology, Depts. of Pharmacology and Psychiatry, Tufts Univ. School of Medicine, Boston, MA 02111

Some evidence indicates that ligands at the peripheral benzodiazepine site can influence effects at the central $GABA_A$ receptor site. The peripheral antagonist PK11195 (PK) was co-administered with the benzodiazepine agonist lorazepam (LRZ) to evaluate interactions during chronic administration in a mouse model. PK alone (5 mg/kg/d) did not alter motor activity, benzodiazepine binding, or GABA-dependent chloride uptake over 14 days. LRZ alone (2 mg/kg/d) produced tolerance at 7 days, with accompanying benzodiazepine receptor downregulation in cortex (CX) and hippocampus (HI) and decreased GABA-dependent chloride uptake in CX. Animals receiving PK/LRZ in combination had a reduction in the development of tolerance. Benzodiazepine binding in vivo was reduced in cortex but not hippocampus at days 7 and 14. GABA-dependent chloride uptake was decreased, but not significantly ($p<0.15$), in cortex at 7 days. Thus, PK appears to attenuate effects of chronic LRZ on behavior and $GABA_A$ receptor binding and function. This might be due to interactions at peripheral benzodiazepine sites on neurons or to indirect effects of compounds such as neurosteroids.

CHOLINERGIC INVOLVEMENT IN RENAL PERIPHERAL BENZODIAZEPINE RECEPTOR RESPONSE TO STRESS. P.V. Holmes & R.C. Drugan. Schrier Research Lab., Dept. of Psychology, Brown University, Providence, R.I. 02912

Rats exposed to inescapable shock stress exhibit a rapid reduction in the density (B_{max}) of renal peripheral benzodiazepine receptors (PBR). Prior investigations have revealed that neither adrenalectomy, hypophysectomy, nor 6-hydroxydopamine lesions reverse the stress-induced alteration in renal PBR suggesting that the effect is independent of pituitary and adrenal hormones or catecholaminergic activity. We presently report a dose-dependent attenuation of the stress-induced reduction in renal PBR with methyl-scopolamine pretreatment. Though the previous studies discount a role of noradrenergic mechanisms in the PBR response to stress, peripheral cholinergic receptors appear to be involved. We tested the hypothesis that direct cholinergic innervation of the kidney mediates the stress-induced reduction in PBR by surgically denervating the kidney. PBR in denervated kidneys continued to exhibit a reduction in [^{3}H]-Ro5-4864 binding similar to that seen in sham control kidneys in stressed rats. Denervation had no effect in non-stressed rats. Cholinergic effects on renal PBR appear not to be mediated by direct cholinergic renal innervation. We are currently investigating the role of cholinergic cardiovascular systems in the etiology of the stress-induced alterations in renal PBR. MITOGENICALLY-INDUCED ALTERATION OF PERIPHERAL-TYPE BENZODIAZEPINE (τ) RECEPTOR DENSITY ON THE NB2-11C CELL CLONE. J.M. Evans-Shields* and H.E. Laird II. College of Pharmacy, Dept. of Pharmacology & Toxicology, Univ. of Arizona 85721.

The affinity and density of the peripheral-type benzodiazepine (τ) receptors expressed in Nb2-11c clonal cells were compared under different stages of mitogenesis. Previous work from this laboratory (Laird et al. **Eur. J. Pharmacol.** 171:25, 1989.) has shown that Nb 2 cells possess a τ receptor and that ligands acting on this site modulate prolactin-stimulated mitogenesis. Therefore, this receptor has a functional role in Nb 2 cellular physiology. The Nb2 node lymphoma cells are undifferentiated T cells and are dependent on prolactin for mitogenesis. For this work we chose the Nb2-11c, the cloned cell line due to its genetic homogeneity. When prolactin is removed from the culture medium the cells enter the quiescent or stationary state. Both stationary and log growing cells were collected and processed for binding. Saturation experiments using PK11195, a ligand specific for the τ receptor yielded a Kd value of 1.93 ± .003 nM and a Bmax of 2.19 ± .001 pM for the stationary cells. Log cells yielded a Kd value of 1.54 ± .03 nM which is similar to that of the stationary cells. However, the Bmax was 3 fold lower than the value obtained for the stationary cells (Bmax=879 ± .12 *f*M). These data suggest that the τ receptor may play a significant role in the ability of the cells to undergo mitogenesis. Further studies are underway to kinetically and pharmacologically characterize these changes in the receptor. (Supported by Ariz. Dis. Con. Res. Comm. #82-1685, HEL)

Hippocampal sympathetic ingrowth alters the kinetics of Phorbol Ester receptor binding. V. Ayyagari and L.E. Harrell. Departments of Neurology and Psychology, VA Medical Center and University of Alabama, Birmingham, AL 35294.

Fibers from the superior cervical ganglion (SCG) replace the cholinergic input to the hippocampus following medial septum (MS) lesions. Hippocampal sympathetic ingrowth (HSI) has been shown to induce an upregulation of the carbachol-stimulated PI hydrolysis. We now report ^{3}H-Phorbol-12,13-dibutyrate (PDBu) binding kinetics in the dorsal and ventral hippocampus. Adult male Sprague-Dawley rats were divided into 3 surgical groups: sham surgery; MS lesions; or MS lesions + SCGx. Receptor binding studies were performed 4 to 6 weeks post-surgery, using cold PDBu to measure non-specific binding. Preliminary results indicate that MS lesions increase the B_{max}, while HSI appears to normalize K_d. Both the K_d and B_{max} of ^{3}H PDBu were consistently higher in the dorsal compared with the ventral part of the hippocampus. These results indicate that HSI, which causes an upregulation of the products of PI hydrolysis, may also activate protein kinase C (PKC), which in turn phosphorylates the cellular proteins involved in learning/memory processes.

621.1

EFFECT OF SOCIAL STRESS AND HOUSING CONDITIONS ON NEUROENDOCRINE MEASURES. R.R. Sakai, S.M. Weiss*, C.D. Blanchard, R.J. Blanchard, R.L. Spencer and B.S. McEwen. The Rockefeller University, 1230 York Ave., NY., NY 10021 and The University of Hawaii, Manoa, 2430 Campus Rd., Honolulu, HI 96822.

Analysis of social and agonistic interactions in rat groups in semi-natural burrowing situations have revealed complex patterns of behavioral changes for subordinate males. These behaviors include reduced social, sexual and aggressive activity, changes in sleep cycles, weight loss associated with lower food intake and other behaviors consonant with the symptoms of clinical depression.

In the current study we examined 8 groups, each with 4-5 males and 2 females in visible burrow systems. Dominant hierarchies were monitored and documented during the 2 week colony period, after which a basal blood sample was collected for determination of plasma corticosterone (CORT) levels and the males were adrenalectomized. Brains (hippocampus and cortex), pituitary, spleen, thymus and adrenal glands were removed on the following day. Plasma CORT levels of dominant male rats were lower than those of male subordinates (6.37μg% vs 16.15μg%) but higher than singly-housed control males (1.4 μg%). Adrenal and spleen weights were increased in both subordinates and dominants compared to controls. In contrast, there was no difference between the three groups in Type I or Type II glucocorticoid binding in the brain areas examined.

These data suggest that both subordinate and dominant male rats in a burrow system habitat may provide useful models for analysis of the behavioral and neuroendocrine effects of prolonged social stess. [Supported by AA06220(RJB), MH42803(DCB) and MH41256(BSM)].

EFFECT OF SWIM STRESS ON THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS: A TIME COURSE STUDY. J. F. López, D. M. Vázquez, H. Akil and Stanley J. Watson . Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

The anterior pituitary corticotroph uses different biochemichal strategies to cope with acute vs chronic stimulation. It has been shown that chronic foot shock stress causes a significant increase in both Proopiomelanocortin (POMC) peptide content and POMC mRNA in the anterior lobe, when compared to acute stress (Endocrinology 119:1793). In contrast, chronic swim stress does not cause a significant increase of POMC peptide content in the anterior lobe (Neuroendocrinology 52:405). To further characterize the effect of swim on the hypothalamic-pituitary-adrenal axis, we performed a time course study in which rats underwent daily swim stress sessions for 1, 3, 7, 10, 14, 17 and 21 days. Rats were sacrificed 24 hours after the last swim session. One group sacrificed immediately after one swim session (acute swim) and one control group were also included. Corticosterone levels were significantly elevated after an acute swim session (ANOVA $p < 0.05$) but returned to baseline after 24 hours. Corticosterone was again slightly elevated after 3 days of swim and slowly decreased after 7 and 10 days of swim. From days 14 to 21, corticosterone levels began to rise again. Plasma ACTH levels closely resembled corticosterone levels. No statistically significant changes in POMC peptide content or POMC mRNA levels were detected in the anterior lobe at any of the time points studied. The relationship of this findings to changes observed in the intermediate lobe of the pituitary will be presented. Supported by The Robert Wood Johnson Minority Medical Faculty Development Program (J.F.L.) and by MH422251 (H.A., S.J.W.)

HPA RESPONSES TO ACUTE RESTRAINT STRESS FOLLOWING CHRONIC EXPOSURE TO COLD IN HANDLED AND NONHANDLED RATS. S. Bhatnagar, V. Viau, and M.J. Meaney. Douglas Hospital Res. Ctr. Depts. of Psychiatry, and Neurology and Neurosurgery, McGill Univ., Montréal, Canada H4H 1R3

Neonatal handling results in altered HPA responses to stress. As adults, handled (H) animals show reduced plasma ACTH and corticosterone (B) levels both during and following the termination of stress. These effects appear to be, in part, related to differences in the negative-feedback sensitivity to elevated glucocorticoid levels. In the present study we examined differences in response to acute exposure to a 20-min restraint stress in H and NH animals following exposure to 3-weeks to cold stress. Chronic stress has previously been shown to enhance HPA responses to novel stressors. In the present study we found an overall effect of handling, such that H animals, regardless of pretreatment, showed lower plasma B levels than NH animals during and following stress. Chronic stress had little or no effect on the plasma B response to restraint in H animals. In contrast, chronically-stressed, NH animals exhibited significantly elevated plasma B levels following the termination of stress, compared with NH controls. Thus, the effect of previous exposure to chronic stress on HPA responses to a novel stressor were significantly greater in the NH animals. These findings extend previous data on differences in delayed negative-feedback between H and NH animals. Such differences appear to be selective to the delayed forms of negative-feedback. In a second study we examined plasma ACTH responses to restraint in H and NH rats treated 5-min prior to stress with 30 µg B or saline. Plasma ACTH responses to stress were greater in NH animals, but the response to pretreatment with B was similar in both groups of animals.

621.4

ENDOCRINE RESPONSE OF INFANT RATS TO HANDLING. C. Kuhn, J. Eck* and R. Francis*. Dep't of Pharmacology, Duke Medical Center, Durham, NC 27710.

"Handling"(removal from the nest) of infant rats influences adult responsivity to stress, an effect that may be mediated by the altered ontogeny of glucocorticoid receptors that results. The neural/hormonal mediators of this response are not clear. In the present study, we evaluated the effect of a single handling episode on several potential endocrine mediators of handling effects. Corticosterone (CS), growth hormone (GH), T_3 and T_4 secretion were measured throughout the developmental period that handling maximally influences glucocorticoid receptors and behavior.

Five, 10 and 15 day old rats were placed in a room-temperature container for 15 min. Animals were decapitated, and serum collected for hormone assay at the end of this time, or were returned to the dam, and killed 15, 45 min or 2 hrs later. Controls remained with the dam until decapitation. All hormones were measured by radioimmunoassay. CS was elevated significantly at the end of treatment at every age, but the response was larger and more prolonged in 15 d.o. pups than in younger pups. GH rose transiently on day 10 and 15 but not on day 5. Neither T_3 nor T_4 changed at any age. These results best support a role for CS as a mediator of biochemical and behavioral changes, as handling produces robust changes only in CS throughout the critical period. Supported by NIH DK 41777

621.5

ANDROGEN INHIBITS THE NEUROENDOCRINE AND NEUROCHEMICAL RESPONSE TO NOVELTY STRESS. R.J.Handa, S.A.Lorens, K.R.Nunley, M.George and G.Hejna. Depts. of Cell Biology, Neurobiology and Anatomy and Pharmacology. Loyola University, Chicago. Maywood, IL 60153

To determine the effects of androgen in modifying the neuroendocrine and neurochemical response to novelty stress, we gonadectomized (gx'd) male rats and implanted a subcutaneous Silastic capsule containing either dihydrotestosterone (DHT; 2cm length), or estradiol (E; 0.5 cm length). Control groups were either left intact or gx'd and given a blank capsule. After 28 days of treatment, animals were placed into an open field (OF) and sacrificed after 20 min. Control animals within each treatment group were killed upon removal from their home cage (HC). Increases in plasma corticosterone (CORT) were seen following OF in all treatment groups ($p<0.01$ vs. respective HC controls). OF CORT levels in gx'd males were greater than levels in intact rats ($p<0.01$). DHT treatment of gx'd rats **decreased** OF CORT levels to the level of the intact animal whereas treatment with E **increased** OF CORT levels ($p<0.02$) above that of gx'd males. Dopamine (DA) turnover in the medial frontal cortex was elevated in response to OF in gx'd, intact and E treated groups but **not** in DHT treated animals (OF DOPAC/DA ratio = 2.0$\pm$ 0.1 GX'D; 1.8$\pm$ 0.1 intact; 0.7$\pm$0.1 DHT; 2.4$\pm$0.2 E; $p<0.01$). DHT treatment also decreased activity in the OF during the first 5 minutes ($p<0.02$) but not during later periods. These data demonstrate that androgen treated rats respond differently to stress. Such differences may underlie androgen dependent non-reproductive behavioral changes.

621.6

INTERACTIONS OF NOVELTY STRESS AND TREATMENT WITH GONADAL STEROIDS ON CIRCULATING CORTISOL. J. A. Czaja, Department of Psychology, Miami University, Oxford, OH 45056

Individual and combined effects of novelty stress and gonadal steroids on circulating cortisol levels were studied in guinea pigs. Forty eight gonadectomized adults (24 females and 24 males) were injected for 7 days with either sesame oil (0.2 cc per day), testosterone propionate (TP, 1 mg/kg BW), or estradiol benzoate (EB, 10 µg/kg BW). On the last day of injections, subjects assigned to the Novelty Groups were individually moved from their home cage into a novel environment (open-topped glass container). After 30 minutes, they were placed into a similar sized methoxyflurane-filled container with a cover. Two minutes later they were sacrificed by decapitation and trunk blood collected. Subjects in the Control Groups were moved from their home cages immediately into the methoxyflurane-filled container and sacrificed 2 minutes later in the same manner. Plasma cortisol was estimated by radioimmunoassay. The gonadal hormone treatments had an effect ($F[2,36] = 3.85$, $p < .04$). Estradiol elevated cortisol levels relative to treatments with oil ($t[14] = 2.667$, $p < .02$) or TP ($t[14] = 4.471$, $p < .001$). Exposure to the novel environment also had a significant impact on cortisol levels ($F[1,36] = 30.691$, $p < .0001$). There were no significant overall gender differences in these cortisol responses ($F[1,36] = .158$, $p > .10$). The novel experience elevated cortisol levels in the oil and TP treated subjects ($t[14] = 4.508$, $p < .0001$ and $t[14] = 6.488$, $p < .0001$). In EB treated subjects, this increase was not significant compared to the already elevated levels produced by this hormone treatment ($t[14]=0.863$, $p > .10$).

MALE AND FEMALE DIFFERENCES IN RESPONSE TO RESTRAINT STRESS IN RATS. W.T.Gallucci*, L. Schneiderman,* M.A. Smith, H. J. Whitfield and P.W. Gold*. Clinical Neuroendocrinology Branch, NIMH, Bethesda MD 20892

Clinical data suggest that stress may precipitate the onset of major psychiatric illness such as depression and eating disorders. Manifestations of these illnesses may be attributed to perturbations in stress-responsive neurohormonal systems such as the hypothalamic-pituitary-adrenal axis (HPA). Epidemiological studies have shown that these illnesses are much more common in women than in men. Previous studies in animals have shown that female rats are more responsive than male rats to restraint stress as indicated by elevated levels of ACTH, corticosterone and AVP in peripheral blood during a single 2 hour restraint period. In this study, we investigated the secretion of these stress responsive hormones into the blood after 0, 15, 45, or 180 minutes of restraint stress. After the restraint period, the animals were sacrificed and trunk blood collected. The results indicate that female rats had significantly higher ($p<.001$), corticosterone levels than male rats over the total restraint period. In addition, female rats had higher peak ($p<.002$) and basal corticosterone levels ($p<.001$) than males. The AVP response showed marked differences between the sexes ($p<.0001$). Female AVP levels were elevated after the 15, 45, and 180 minute periods of restraint and showed a 44% increase over males at 45 and 180 minutes. On the other hand, males were not significantly different from baseline at 15, 45 and 180 minutes of restraint. The ACTH response also showed a significant sex difference ($p<.0005$). This response is in contrast to the males whose response is not significantly different from baseline at the 180 minute time period. These findings suggest that female rats produced more ACTH, AVP and corticosterone in response to similar stress conditions. Central factors involving corticotropin-releasing activity may differ between male and female rats which may account for the increased hormonal responsiveness in females. Whether these results are related to behavioral vulnerabilities between the sexes and whether they reflect excessive stress system responsiveness of the female sex to stress, remains to be studied.

EVIDENCE FOR ENHANCED TRANSLOCATION OF LYMPHOID GLUCOCORTICOID RECEPTORS IN PTSD. R. Yehuda, E.L. Giller, D. Boisoneau, S.M. Southwick, M.T. Lowy and John W. Mason. Psychiatry Department, University of Connecticut Health Center, Farmington, CT 06032.

Our previous finding of a significantly lower mean 24-hr urinary cortisol excretion and a greater number of lymphocyte glucocorticoid receptors (GR) in combat veterans with posttraumatic stress disorder (PTSD) has suggested an enhanced negative feedback sensitivity of the hypothalamic-pituitary-adrenal axis in this disorder. To further explore this possibility we examined 8:00 a.m. cortisol levels and lymphocyte GR number in 10 PTSD and 10 normal controls at baseline and following the 11:00 p.m. administration of 0.5 and 0.25 mg doses of dexamethasone (DEX). Consistent with our earlier report, the PTSD group had a significantly larger number of 8:00 a.m. GR at baseline compared to normal controls (mean GR/cell = 8716 ± 1212 and 5128 ± 1284 for PTSD and normals, respectively). Nine hours following DEX, the PTSD group showed a significantly greater decline in cortisol (i.e., a 90% vs. 76% suppression to 0.5 mg DEX, and 58% vs. 30% suppression to 0.25 mg DEX), and a decrease in the number of cytosolic GR (i.e., 40% vs. 14% fewer receptors following 0.5 mg and 19% vs. 3% following .25 mg DEX in PTSD and normals, respectively). Percent cortisol suppression at 8:00 a.m. postDEX was significantly correlated with decreases in GR in both groups at the 0.50 mg dose. The greater decline in cytosolic GR following DEX in the PTSD likely represents an enhanced translocation of the steroid-GR complex into the cell nucleus, and provides further support for HPA dysfunction in this disorder.

GENETIC DETERMINANTS OF HYPOTHALAMUS-PITUITARY-ADRENAL AXIS RESPONSIVENESS IN HUMANS. C. Kirschbaum*, S. Wüst*, H.-G. Faig*, J. Buchtal*, C. Strasburger*, H. Lehnert and D. Hellhammer. University of Trier, Trier, F.R.G.

Hypothalamus-pituitary-adrenal (HPA) axis responses are characterized by large interindividual differences. The present study was designed to clarify if a specific individual sensitivity of the HPA-axis exists and to which extent it is genetically determined.

Twenty-five monozygotic and dizygotic twin pairs (15-33 yrs) performed physical exercise (ergometry until exhaustion) and were exposed to psychological stress (public speaking and mental arithmetics in front of an audience and a video camera). Additionally, 20 of these twin pairs received an injection of 100 μg h-CRH i.v. HPA activity was indexed by salivary cortisol measures with saliva samples being obtained in 10-min intervals. On each occasion twins were studied together with their siblings and tests were performed between 5 p.m. and 6 p.m. Moreover, each twin pair spent one day together in their natural environment and saliva samples were collected for analysis of circadian cortisol rhythm at 20-min intervals from 8 a.m. to 10 p.m.

Under all experimental conditions, significant increases in salivary cortisol levels were observed. Since analysis of zygosity has not been completed results on intra-pair correlations with respect to HPA axis responses in twins will be presented on the meeting.

621.10

DIFFERENTIAL DEVELOPMENT OF THE STRESS RESPONSE IN CONGENITAL LEARNED HELPLESSNESS. J.A. King, D. Campbell, F.A. Henn and E. Edwards.
Dept. of Psychology, Emory University, Atlanta GA 30022.
Dept. of Psychiatry, SUNY, Stonybrook, NY 11794-8101.

Early in the development of the hypothalamic-pituitary-adrenal (HPA) axis the rat undergoes a stress hyporesponsive period of blunted responses to several stressors including cold exposure (CE) and maternal deprivation (MD). We examined the development of the axis by monitoring adrenocorticotropic hormone (ACTH) plasma levels in an animal model of depression and/or anxiety characterized by learned helpless (LH) behavior and a dysfunctional HPA axis in adult life (Biol. Psychiatry 26:530, 1989). On postnatal day 7 there was no significant difference between basal plasma ACTH levels among LH rats and controls, but LH animals showed a blunted response to CE ($p<0.05$). By postnatal day 15 there was a 98% increase in ACTH response to CE. On postnatal day 21 baseline ACTH and response to CE were significantly suppressed in LH rats. Stress response to MD was present in all groups but was insignificantly different for all ages of development between groups. These findings suggest that rats with congenital learned helplessness undergo a differential response in the development of the HPA axis in that the axis was hypersensitive at postnatal day 15 and hyporesponsive by day 21 and this may in part account for the dysfunctional stress response observed during adulthood.

621.11

CORTICOSTERONE RESPONSE TO RESTRAINT STRESS IN RATS BRED FOR LEARNED HELPLESSNESS. F.A.Henn, E. Edwards, R.L. Spencer, Y. Watanabe and B.S. McEwen. SUNY at Stony Brook & Rockefeller University.

We have measured the corticosterone (CORT) response to a 1hr restraint stress of rats bred for learned helplessness (LH).

Basal CORT levels in the morning (AM) were lower in LH strain rats compared to rats bred for non-learned helplessness (NLH), and basal cort levels of LH rats in the evening (PM) were lower than those of outbred Sprague Dawley controls.

Outbred Sprague Dawley rats, NLH and LH strain rats could be differentiated by their overall CORT response to the restraint stress paradigm. Plasma CORT of LH rats immediately after restraint stress was significantly reduced as compared to NLH and outbred controls (μg/100ml: 10.4 ± 1.5, LH vs 32.8 ± 1.7, NLH & 32.1 ± 4.0, outbred controls; n=8/group). Plasma Cort levels of LH strain rats after a 1hr recovery from restraint stress were lower than NLH in the AM (but not PM) and lower than outbred controls in the PM. There was no significant differences in Type I nor Type II steroid receptors in the hippocampus & the hypothalamus of LH strain rats as compared to outbred control and NLH strain rats. CRF and ACTH mechanisms of LH strain rats are under investigation.

621.12

PHYSIOLOGIC, BIOCHEMICAL AND BEHAVIORAL RESPONSES TO UNCONTROLLABLE STRESS IN HUMAN SUBJECTS J. Fertig, R. Peters*, J. Leu, G. Mueller, T. Bottegal.* Walter Reed Army Institute of Research, Washington, D.C. 20307.

In an attempt to characterize the physiologic, biochemical and cognitive responses to uncontrollable stress, 40 healthy male subjects were exposed to bursts of 95 dB noise while attempting to solve a visual-spatial task under either controllable stress (CS) or uncontrollable stress conditions (UCS). CS subjects could terminate both stressors while their yoked UCS partners could not. Measures of physiologic reactivity, biochemical response, cognitive function, and mood were made before and after stress induction. Both CS and UCS stress produced a rise in diastolic and systolic blood pressure during the stress induction period. However, these rises were significantly attenuated in the UCS condition. Several biochemical markers of stress accompanied these physiologic changes and differentiated the UCS from the CS subjects. Cortisol and immunoreactive beta endorphin were significantly elevated by UCS. Subjects in the UCS condition also reported higher ratings of helplessness, lack of control, confusion and total mood disturbance. Cognitive performance on a delayed memory task was impaired by both stress manipulations. Results suggest that lack of control over psychological stressors can produce alterations in mood as well as physiologic and neuroendocrine changes in healthy subjects.

621.13

DIFFERENTIAL ENDOCRINE AND AUTONOMIC REGULATION OF RESTRAINT-INDUCED HSP70 EXPRESSION IN THE ADRENAL GLAND AND VASCULATURE. M.J. Blake, R. Udelsman*, and N.J. Holbrook*. Lab. Mol. Genet., NIA, Gerontol. Res. Cntr., Baltimore, MD 21224.

Restraint is known to illicit a physiologic stress response characterized by sympathetic nervous system stimulation and activation of the hypothalamic-pituitary-adrenal (HPA) axis. We have shown that restraint induces the selective expression of HSP70 mRNA in the adrenal cortex and blood vessels of the rat and have proposed that their induction in mammalian tissues plays an important role in physiologic stress response mechanisms. In this report we have used perturbations of the HPA axis and sympathetic adrenergic receptor blockade to assess the respective contribution of neuroendocrine and sympathetic activity to restraint-induced HSP70 expression *in vivo*. The influence of the HPA axis was investigated by restraining hypophysectomized and control rats for 60 min then determining HSP70 expression in adrenals and aorta by northern blot analysis and *in situ* hybridization. Hypophysectomy resulted in a 5-fold decline in HSP70 expression in the adrenals but did not significantly alter expression in the aorta. Treatment of normal rats with chronic release pellets containing the glucocorticoid receptor antagonist RU486 (5 mg) for two weeks prior to restraint also significantly reduced HSP70 expression in the adrenal but had less effect in the aorta. To determine if the reduced responsiveness of the aorta to HPA manipulation was due to alternative regulation in this tissue by sympathetic nervous system activity, rats were pretreated with either propranolol (30 mg/kg i.p.) or prazosin (1 mg/kg i.p.) prior to restraint. Prazosin virtually eliminated aortic HSP70 induction but did not significantly alter its induction in the adrenal. Propranolol was less effective than prazosin in reducing restraint-induced expression in the aorta (3-fold decline) and also did not affect induction in the adrenal. Thus, restraint-induced HSP70 mRNA expression in the adrenals is modulated by the HPA axis whereas expression in the aorta is controlled by adrenergic sympathetic activity, each involving distinct receptor mediated events.

PAIN MODULATION: CNS

Afferent projections from the anterior pretectal nucleus to the ventral medulla oblongata: anterograde tract tracing with Phaseolus vulgaris leuco-agglutinin in rats. M.G.Terenzi*, A.Zagon[1], M.H.T.Roberts*, Department of Physiology, UWCC, Cardiff and [1]University Department of Pharmacology, Oxford U.K.

Recent electrophysiological data have shown that the anterior part of the anterior pretectal nucleus (APTA) plays a role in processing noxious stimuli while other nuclei of the pretectal complex are engaged in control of visual system reflexes. The ventral medulla oblongata is known to be involved in central cardiovascular and nociceptive regulation and medullo-spinal pathways can transmit descending impulses from several higher centres. In the present study the possibility of a direct projection from the APTA into the ventral medulla was investigated. Ionophoretic injections of the anterograde tract tracer Phaseolus vulgaris leuco-agglutinin were placed into the APTA and control injections into the surrounding posterior thalamic cell groups.

Fibres descending from the APTA innervated almost exclusively the ipsilateral side of the medulla oblongata. A high density of varicose labelled fibres was observed in the rostral part of the ventral gigantocellular reticular nucleus, in the gigantocellular reticular nucleus pars alpha. Labelled terminals were present in the rostral part of the raphe obscurus and within the raphe magnus. Labelled fibres in the inferior olivary complex were most numerous in the ventral aspects of the dorsal olive. From control injections the majority of labelling in the ventral medulla appeared as non-varicose fibres in the region of the pyramidal tract and the dorsal inferior olive.

A direct APTA-medullary connection might be involved in descending control of nociception.

622.2

RESPONSES OF RAPHESPINAL NEURONS TO VAGAL AFFERENT NERVE STIMULATION. **A.R. Evans and R.W. Blair. Dept. Physiol. & Biophysics, Univ. Okla. Health Sci. Ctr., Oklahoma City, OK, 73190.**

Stimulation of vagal afferent nerve fibers has been shown to modulate nociceptive transmission in the spinal cord. It has been proposed that vagal afferent fibers engage medullary raphespinal (RAS) neurons to modulate nociception. The goal of this study was to determine response characteristics of medullary raphespinal (RAS) neurons to electrical and chemical stimulation of vagal afferent fibers. Six cats were anesthetized with sodium pentobarbital (35 mg/kg). Extracellular potentials were recorded from 10 RAS neurons whose axons were antidromically activated from the T_2-T_3 segments of the spinal cord. Seven cells were inhibited and 3 cells were excited by electrical stimulation of vagal afferent fibers. The inhibitory response to electrical stimulation was intensity and frequency dependent. Left atrial injections of veratridine and phenylbiguanide were used to chemically stimulate vagal afferent fibers. Four of 7 cells inhibited by electrical stimulation were also inhibited by chemical stimulation. Two of 3 cells excited by electrical stimulation were inhibited by chemical stimulation. No cells were excited by chemical stimulation. We conclude that vagal afferent fibers can modulate the activity of RAS neurons and, therefore, can affect RAS influences in the spinal cord. (Supported by NIH grant HL29618 and OCAST grant HR9-089).

622.3

C-FOS GENE EXPRESSION IN PONS AND MEDULLA DURING PERIPHERAL INFLAMMATION. G. Draisci, D.G. Quarta*, M.E. Dell'Anna*, D. Camaioni*, M.J. Iadarola & M. Molinari. Istituto di Anestesiologia e Rianimazione e Istituto di Neurologia, U.C.S.C., 00168 Roma, Italy

In the CNS, c-fos is an useful marker of neuronal activity that can be used to map functionally related neural pathways. Our previous studies showed an increase of c-fos gene expression in the spinal cord and in the PAG during experimentally induced peripheral inflammation in rats. In the present study we analyze immunocytochemically c-fos gene expression in pons and medulla.

Carrageenan was injected in the left foot of 4 male Sprague Dawley rats, 3 non-injected rats were used as controls. 24 hrs after injection, the rats were perfused transcardially with 10% formalin. Serial 40 µm criostate coronal sections were obtained from pons and medulla and processed for ABC immunocytochemistry and for cresyl violet staining. Fos-immunoreactive cells were identified with an affinty purified antiserum to a conserved sequence in the c-fos DNA binding region.

Quantitative analysis evidences a clear increse of the number of c-fos IR cells in the treated animals with respect to the controls in the pontine and medullary reticular formation and in the raphe magnus.

These results in line with our previous findings, indicate that c-fos expression is enhanced after inflammation in pontine and bulbar structures that have been related to nociception.

THE RELATIONSHIP OF SUBSTANCE P VARICOSITIES TO PERIAQUEDUCTAL GRAY-RAPHE MAGNUS PROJECTION NEURONS: ANALYSIS USING INTRACELLULAR INJECTION AND LASER CONFOCAL MICROSCOPY D. R. Onstott and A. J. Beitz, Department of Veterinary Biology, Univ. of Minnesota, St. Paul, MN 55108.

The descending projection from the periaqueductal gray (PAG) to the raphe magnus (NRM) has been identified as an important component in the pain modulation system. Substance P (SP) has been shown to produce analgesia when injected into the PAG, and SP-immunoreactive (SP-IR) terminals make synaptic contacts within the PAG. The present study was undertaken to develop a method of quantifying possible sites of interaction between SP-IR axonal varicosities and PAG-NRM projection neurons, including sites on distal dendrites not normally filled by retrograde tracers. After injection of Fluoro-Gold into the NRM of rats, retrogradely labeled cells in the PAG were visualized in 150 µm vibratome sections with epifluorescence illumination and injected iontophoretically with Lucifer yellow (LY). SP-like immunoreactivity was detected in the same sections using Fluoroprobe 670-labeled secondary antiserum (Jackson ImmunoResearch). Confocal scanning laser microscopy (BioRad MRC-600 Imaging System) was used to produce two separate series of 1 µm "optical sections" of injected cells and of SP-IR varicosities. Individual images from the same plane in each series were merged to reveal varicosities apposed to neuronal elements of LY-filled cells. Complete LY filling of the soma and dendritic tree was accomplished in several cells of varying morphology in each section. Occasionally dye-coupling between PAG neurons was noted, suggesting the presence of gap junctions. Preliminary examination has indicated that a small number of SP-IR varicosities come into close contact with the somas and the proximal and distal dendrites of PAG-NRM projection neurons. This study suggests that retrograde labeling coupled with LY intracellular injection and confocal microscopy may be a useful procedure for elucidating the interactions of peptide-containing varicosities with identified projection neurons. DOMINANCE OF 5HT-1A OR 5HT-2 AND CHOLINERGIC RESPONSE IN RAPHE MAGNUS CELLS VARIES WITH INHIBITORY, EXCITATORY OR MIXED EFFECT OF NOXIOUS STIMULI. K. Taguchi, M. Andresen*, T. Shibuya, and I. D. Hentall. Univ. of Ill. Coll. of Med., Rockford, IL 61107.

Neurons of the nucleus raphe magnus (NRM) are known to be responsive to serotonin (5HT), possibly via autoreceptors, recurrent axonal branching, or remote inputs. In pentobarbital-anesthetized rats, we examined responses to 5HT, to 5HT-1A agonist buspirone, to 5HT-1A antagonists propranolol and methiothepin, to 5HT-2 antagonist ketanserin, to mixed antagonist methysergide, and to acetylcholine (ACh). Neuronal responses to skin pinching were also tested. As well as the previously known on-cells and off-cells, we found at ventral sites neurons with biphasic responses to prolonged (10s) pinching; the excitatory and inhibitory responses became prominent, respectively, at low and high spontaneous activity.

Iontophoresis of 5HT (5-60 nA for 10s) caused excitation (*E*), inhibition (*I*), inhibition followed by excitation (*IE*), or no effect (n=76). In off-cells most responses were *I*; in biphasic-cells they were about equally *I* and *IE*; in on-cells they were about equally *I*, *IE*, and *E* (chi-square: P=0.026, 4x3 table). A similar distribution of responses was obtained with ACh (n=36). Iontophoresis of ketanserin prevented *E* from 5HT or unmasked *I*; methysergide prevented *I*. Alone, buspirone or ketanserin caused *I*, methysergide either *I* or *E*, and methiothepin *E*. Propranolol caused *I* (probably a ß- adrenergic effect).

In conclusion, NRM cells which tend to have inhibitory nociceptive responses are more likely to be inhibited by 5HT-1A action and by ACh. (Supported by NINDS grant NS 26116.)

622.6

LAMINA II CELLS PROJECT STRONGLY TO THE VENTROLATERAL RETICULAR FORMATION OF THE MEDULLA OBLONGATA IN THE RAT D. Lima* and A. Coimbra* (Spon: European Neuroscience Association) Institute of Histology and Embryology of the Faculty of Medicine of Oporto, 4200 Porto, Portugal

The substantia gelatinosa Rolandi (lamina II) is considered a pain modulatory system acting locally upon the transmission of nociceptive input through dorsal horn neurons. Several retrograde tracing studies accordingly showed no significant numbers of lamina II cells projecting supraspinally. Stereotaxic injections of 1.5% cholera toxin subunit B (CTb) in the ventrolateral reticular formation intermediate between the lateral reticular nucleus and the spinal trigeminal nucleus, pars caudalis, of adult, chloralose anaesthetized rats, resulted in retrograde labelling of spinal neurons in laminae I-III and the lateral spinal nucleus. Labelled lamina II cells were on average 430 in the cervical and 210 in the lumbar enlargement, representing, respectively, 28% and 21% of the labelled spinal cells. Most cells had dendritic arbors spread in the parasagittal plane making up a circular dendritic field across lamina II. The ventrolateral reticular formation thus appears to be a specific target of lamina II cells. It is suggested that these neurons exert a modulatory action upon the descending, probably noradrenergic antinociceptive input generated in that medullary region. (Supported by JNICT, project nº PMCT/C/SAU/31/90)

622.7

HYBRIDIZATION HISTOCHEMICAL ANALYSIS OF GLUTAMATE RECEPTOR mRNAs IN THE VENTRAL MEDULLA IN A RAT MODEL OF PERIPHERAL NEUROPATHY. E.M. Jansen[1], F.G. Williams[2] and A.J. Beitz[1,2,1]Grad. Prog. in Neurosci., Univ. of Minnesota, Minneapolis, MN 55455, [2]Dept. of Vet. Biology, Univ. of Minnesota, St. Paul, MN 55108.

Nuclei in the ventral caudal medulla (VCM) are involved in the modulation of nociception. However, the distribution of neurons that express the mRNAs for glutamate receptors within the VCM nuclei is not known. The purpose of this study was to compare the number and distribution of neurons expressing GluR-A flip and flop mRNAs in VCM nuclei from control animals and from animals with a unilateral peripheral neuropathy (according to the model of Bennett and Xie, Pain, 33:87, 1988). cDNA oligonucleotide probes for the GluR-A flip and flop receptors were synthesized according to the sequences published by Sommer, et al. (Science, 249:1580, 1990). Hybridization histochemistry was performed using biotinylated oligonucleotides followed by FITC-avidin detection. The resulting labeling was quantified using image analysis of digitized video micrographs. Neurons containing GluR-A flip mRNA were observed in the following VCM nuclei: raphe magnus, gigantocellular reticular, lateral paragigantocellular and gigantocellular pars alpha. There was considerably less hybridization signal in the VCM following application of the GluR-A flop probe. The raphe magnus in lesioned animals contained significantly higher levels of GluR-A flip mRNA compared to unlesioned controls (p<.01, ANOVA and Fisher PLSD). The frequencies of raphe magnus neurons expressing this mRNA were increased, but did not achieve statistical significance. These changes were less pronounced in other nuclei in the VCM. These data suggest that peripheral neuropathy activates glutamate receptor biosynthesis in nuclei in the VCM and imply that peripheral neuropathy affects excitatory amino acid transmission in medullary nuclei involved in antinociception. Supported by NIH grants NS28016, DA06687, DE06682 and NS19208.

622.8

NOCICEPTIVE MODULATORY NEURONS IN THE ROSTRAL VENTROMEDIAL MEDULLA ARE FOUND IN BOTH HALOTHANE- AND BARBITURATE-ANESTHETIZED RATS. M.M. Morgan, M.M. Heinricher and H. L. Fields. Depts. of Neurology and Physiology, Univ. of California, San Francisco, CA 94143.

The physiological and pharmacological properties of two classes of putative nociceptive modulatory neurons in the rostral ventromedial medulla (RVM) have been extensively characterized in rats lightly anesthetized with barbiturates. "On-cells" show a burst of activity, and "off-cells" a sudden pause immediately preceding nocifensive reflexes. We have recently shown that the reflex-related pause of off-cells is mediated by GABA, and since barbiturates are known to potentiate GABAergic influences, it is important to demonstrate that these neurons can be characterized in non-barbiturate preparations.

Activity of RVM neurons was recorded in rats maintained under halothane anesthesia (0.6-1.0% in oxygen, 0.3 l/min). RVM cells that showed an increase in activity (on-cells) or a decrease in activity (off-cells) that immediately preceded the occurrence of the tail flick were found in this preparation. On-cells were found more frequently, but this seemed to result at least in part from using somatic stimulation as a search stimulus for cells of this class. When noxious inputs were limited by testing only one cell per animal, similar numbers of on- and off-cells were found.

Thus, both on- and off-cells can be identified in rats anesthetized with halothane, indicating that neurons with these properties are not an epiphenomenon of barbiturate anesthesia. Moreover, the reported inability to demonstrate off-cells in the awake rat (Oliveras et al., 1989; 1990) may be due to the lack of an appropriate search stimulus for cells of this class.

622.9

ACTIVATION OF THE RAPHE-SPINAL PAIN INHIBITORY SYSTEM BY MEDIAL PREOPTIC NUCLEUS(MPO). M. Jiang*, M.M. Behbehani, S.D. Chandler, T. Rizvi and M.T. Shipley. Depts. of Physiology and Anatomy. U. of Cincinnati. Cincinnati, OH 45267-0576.

Anatomical studies (See Rizivi et al.) have shown a strong projection from the MPO to the nucleus raphe magnus(NRM). In this study we examined the functional interaction between these sites. In rats, recordings were made from NRM neurons that were identified by their response to peripheral stimulation and designated as "E" and "I" if they were excited or inhibited by pinch. In addition cells were identified by the ability to be antidromically activated by DLF stimulation at the lumbar level. A total of 100 neurons were recorded. Stimulation of MPO at a frequency of 100 Hz excited 17/43 and inhibited 12/43 of the E cells. The majority (20/30) of the I cells were inhibited by train stimulation of MPO and only 5/30 I cells were excited. Injection of 5 mM homosysteic acid (HA) into the MPO excited 10/31 E and inhibited 8/13 I cells. The response to HA lasted for an average of 106± 143 seconds. Electrical stimulation of MPO at 1 Hz excited 23%, inhibited 5% and had no effect on 70% of NRM cells. The mean latency to peak excitation was 9.6 ± 6.6 msec. Antidromic activation of MPO neurons by NRM stimulation showed an average latency of 6.3 ± 3.4 msec. Iontophoresis or micropressure injection of proglumide, naloxone and kynurenic acid next to the recording electrode suggested that a glutaminergic pathway may play a role in this system but the involvement of either a cholecystokinin or an enkephalinergic pathway in the NRM-MPO interaction is unlikely. It is concluded that 1) MPO inhibits the I cells and excites the majority of E cells, 2) simultaneous activity of many synapses is required for activation of MPO-NRM pathway and 3) MPO-NRM interaction is mediated by fibers with a conduction velocity of less than 1m/sec. Supported by PHS grant NS20643.

622.10

A CONFOCAL MICROSCOPIC STUDY OF ENKEPHALIN IMMUNOREACTIVE APPOSITIONS ONTO PHYSIOLOGICALLY IDENTIFIED NEURONS IN THE ROSTRAL VENTROMEDIAL MEDULLA (RVM) OF THE RAT. P. Mason, S.A. Back and H.L. Fields. Department of Neurology, UCSF, San Francisco, CA 94143-0114.

The RVM contains neurons that are inhibited (on-cells), excited (off-cells) or unaffected (neutral cells) by systemic morphine. Iontophoretic application of morphine, in contrast, while inhibiting on-cells, does not alter the spontaneous or evoked activity of off- or neutral cells (Heinricher et al., Soc. Neurosci. Abstract 1991), indicating that opioid receptors may be differentially distributed upon RVM neurons of different physiological classes. The present study, therefore, investigates the distribution of enkephalin-immunoreactive appositions onto physiologically identified RVM cells.

RVM neurons were characterized by their response during a nociceptive withdrawal reflex in lightly anesthetized rats. Cells were then injected intracellularly with Neurobiotin and subsequently visualized with a Texas Red fluorophore. Sections that contained labeled neurons were processed for enkephalin immunoreactivity using a FITC fluorophore. These sections were optically sectioned at 1 m intervals using a dual channel confocal laser scanning microscope (MRC-600). Appositions between enkephalin immunoreactive varicosities and intracellularly labeled neurons were mapped onto reconstructions of labeled on-, off- and neutral cells.

Enkephalin appositions were found on the somata and dendrites of all on-cells. Although enkephalin varicosities were also apposed to some off-cells, their density was significantly less than onto on-cells. These results support the idea that on-cells are directly inhibited by opioid peptides and that the opioid excitation of off-cells is produced indirectly, possibly by opioid blockade of an on-cell mediated inhibition.

Comparing the effects of barbiturate and Ketamine anesthesia on the neuronal output in the rostral ventromedial medulla of the rat.
S. McGaraughty*, S. Reinis, & J. Tsoukatos. Div. of Biopsychology, U. of Waterloo, Waterloo, Ont., Canada N2L 3G1.

Using a novel technique developed in our laboratory we simultaneously record the activity of both a single neuron and the cells immediately surrounding it. Then, correlograms illustrating the commonality of interspike intervals are calculated giving information about the neuronal output at the single cell, multi-unit, and interactional levels. While recording in the rostral ventromedial medulla (RVM) we have previously shown that a majority of neurons in Ketamine-Rompun anesthetized rats have about a 30 ms delay in their output which is independent of nociceptive input. These findings were replicated with Ketamine (80 mg/kg, IP) and Rompun (8 mg/kg, IM). Similar findings have been seen with Pentobarbitol (40 mg/kg, IP). The rats were in a deep state of anesthesia throughout recording under both anesthetics. The barbiturate anesthetized rat had a greater quantity of cells exhibiting output delay, the delay in most cases was longer than 30 ms. In the multi-unit records of Pentobarbitol rats there was almost a complete absence of any other activity other than the delay which is in strong contrast to the Ketamine rats. This suggests that under anesthesia the RVM is producing lower output probably due to the direct actions of the anesthetics. Pentobarbitol decreases the RVM output more than Ketamine.

The Location of Noradrenergic Neurons that Innervate the Ventromedial Medulla and Modulate Nociception: Anatomical Studies Using Retrograde Tracers and Immunocytochemistry.
J. I. Choca, M. Monsen*, and H. K. Proudfit. Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

Noradrenergic neurons modify the activity of neurons in the ventromedial medulla (VMM) that modulate nociception. We determined the location of noradrenergic neurons that project to the VMM using retrograde tracers combined with tyrosine hydroxylase immunocytochemistry. Each of three retrograde tracers were injected into the VMM: horseradish peroxidase, Fluoro-Gold or rhodamine labeled latex microspheres. The A5 cell group contained about 80% of the total number of tyrosine hydroxylase-immunoreactive (TH-ir) neurons in the brainstem that were retrogradely labeled by rhodamine microspheres. In contrast, the other two retrograde tracers labeled only a few TH-ir neurons. These results demonstrate that noradrenergic neurons in the A5 cell group are the principal source of noradrenergic neurons that innervate the VMM. In addition, the retrograde tracers horseradish peroxidase and Fluoro-Gold do not appear to be transported by the axons of noradrenergic A5 neurons. Supported by USPHS Grant DA03980.

AN ANIMAL MODEL FOR INVESTIGATION OF THE NEUROPHYSIOLOGIC MECHANISMS OF TOURNIQUET PAIN
James C. Crews, Michael M. Behbehani, Constance S. Sehlhorst*; Department of Anesthesiology, University of Cincinnati College of Medicine; Cincinnati, Ohio.

Tourniquet pain is a clinical problem resulting from the maintenance of inflation of a pneumatic tourniquet on an extremity to provide a bloodless operating field during orthopedic surgical procedures. This severe, dull, aching, pain sensation complicates regional or general anesthetic procedures despite otherwise adequate anesthesia for the surgical procedure. Treatment of tourniquet pain is nonspecific and involves increasing anesthetic depth to maintain patient comfort and hemodynamic stability. Investigation into the etiology of this pain has been limited due to the lack of an animal model for study. This study utilized an anesthetized rodent model for detection and monitoring of nociceptive activity in medullary nuclei in response to tourniquet inflation. Male rats were prepared for single unit recording of cell firing rate (CFR) of medullary neurons in nucleus raphe magnus (NRM). Anesthesia was maintained by IV infusion of pentobarbital at 20mg/kg/hr. BP was monitored continuously. A 1x9mm tourniquet was inflated on the (R) lower extremity. Changes in BP and CFR were analyzed by "t" test, with $p<0.05$ as the minimum level of statistical significance. The animals demonstrated an increase in BP and a nociceptive response to maintenance of tourniquet inflation manifested as a decrease in CFR of medullary OFF cells. After a 60 min inflation period the tourniquet was deflated; BP and CFR returned to preinflation baseline values following a brief period of hyperexcitability. These results indicate that this rodent model demonstrates a reproducible nociceptive response to maintenance of tourniquet inflation and is suitable for use in the investigation of the neurophysiologic and neuropharmacologic mechanisms of tourniquet pain.

STUDY OF NOCICEPTIVE AND OTHER NEURONAL SYSTEMS IN THE VENTROPOSTERIOR THALAMIC COMPLEX OF ANAESTHETIZED RATS.
J. Tsoukatos, S. Reinis, and S. McGaraughty*. Department of Psychology, University of Waterloo, Waterloo Ont., Canada.

We have used auto-, cross-, and mass-correlograms to identify the types of cell response in the ventroposterior thalamic complex. We have recognized three different types of cell activity, under spontaneous conditions and during noxious tail heating. The first type is characterized by constant levels of activity both in the spontaneous and the stimulated condition. In the second type, the spontaneous activity of the leading cell decreases in the stimulated condition. In the third type, leading cell activity increases in the stimulated condition. The mass-correlograms of the background activity for the second and third types showed that the background cells interact forming regular sinusoids, at a frequency of approximately 70/sec. Other cells and systems showed a self-inhibitory period of about 40 ms, a replication of similar findings in the ventromedial medulla. We hypothesize that the cells of the first type may represent networks unrelated to analgesia (e.g. proprioception). The cells of the second type might be related to the transmission of the stimulation in the areas of the ventroposterior thalamus. The cells of the third type might be implicated in the production of analgesia, at the level of the thalamus.

BURSTING ACTIVITY OF THALAMIC NEURONS RECORDED FROM CHRONIC PAIN PATIENTS IS MODIFIED BY ELECTRICAL STIMULATION IN PVG.
P.C. Rinaldi, R.F. Young and V.M., Tronnier*. Div. of Neurological Surgery, University of California, Irvine, CA 92717.

In chronic pain patients electrical stimulation of the PAG or PVG (periaqueductal or periventricular gray) and somatosensory relay nuclei Vc (Ventralis caudalis of Hassler or VPL & VPM, ventralis posterolateral & posteromedial) via permanently implanted electrodes has been employed over the past 15 years to treat intractable pain. The mechanisms for PVG/PAG pain relief are thought to involve descending systems associated with opioid, noradrenergic and serotonergic mediation. However, little is known about the role of PVG/PAG modulation of somatosensory thalamic activity.

The present work is part of an ongoing study to assess the effect of PVG stimulation on neurons in Vc in patients suffering from intractable pain. Electrical activity of single cells in Vc was recorded while the patient was undergoing stereotactic surgery under local anesthetics for implantation of chronic stimulating electrodes in PVG and Vc. The chronic electrode in PVG, implanted first, provided electrical stimulation (single pulses & trains) controlled with a Grass stimulator and isolation unit. A custom designed microelectrode introduced for localization of the appropriate target for the Vc chronic electrode served for recording single cells in that region and also allowed for microstimulation to determine fields for a specific cell. Activity of single neurons was recorded and taped for later analysis.

Computer analysis consisted of determination of interval histograms and detailed intraburst analysis for pre- versus post-stimulus time periods. Stimulation of PVG produced pronounced inhibition of activity of neurons recorded from Vc, the length of the inhibition varying with the amount of stimulation. Intraburst intervals as well as rhythmicity of Vc cells were also altered following return of activity after PVG stimulation. This modification of somatosensory activity may play a role in pain relief elicited by PVG stimulation.

THE FORMALIN TEST FOR TONIC PAIN AFFECTS LIMBIC, BASAL GANGLIA AND THALAMIC REGIONS IN RAT BRAIN.
H. Siegel and L.L. Brown Albert Einstein College of Medicine, Bronx NY 10461.

The [^{14}C]-2-deoxyglucose method was used to identify regions in the rat central nervous system activated during the rat paw formalin test, a continuous, inflammatory pain stimulus. Animals were awake but partially restrained. [^{14}C] -2-deoxyglucose was injected 20 minutes after the formalin (5%, 0.05 ml s.c.) or saline (0.05 ml s.c.) injection. Bilateral increases in local cerebral glucose utilization in the formalin-treated group as compared with the saline-treated control group included the hippocampus (granular layer, +34%), lateral and medial habenula (+51, +73%, respectively), anterior accumbens (+30%), subthalamic nucleus (+41%), entopeduncular nucleus (+70%) and ventromedial thalamic nuclei. Unilateral changes were found in areas of the hippocampus, amygdala, and in medullary reticular nuclei implicated in pain and analgesia. The results demonstrate the involvement of many structures in the rat CNS which represent associated functions activated during a painful stimulus. Of special interest is the specific limbic structures involved.

NEURONAL RESPONSES IN CINGULATE CORTEX TO NOXIOUS STIMULATION MAY ORIGINATE IN MEDIAL THALAMUS
R.W. Sikes and B.A. Vogt Dept. Physical Therapy, Northeastern Univ., Boston, MA 02115 and Dept. Physiology and Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1083.

Anterior cingulate cortex has been implicated in affective responses to noxious stimuli. This study investigates the neuronal basis for such responses. Single-unit recordings were made in area 24 of Dutch-belted rabbits anesthetized with halothane. Stimuli included transcutaneous electrical, mechanical and thermal stimulation. About 25% of cingulate neurons responded to noxious levels of these stimuli and did not respond to innocuous levels. Nearly 84% of the units that responded to noxious stimulation were located in layers II and III. Excitatory units were located mainly in layer III while most inhibitory units were in layer II. Only about 16% of layer V units responded to these stimuli.

To identify the source of this input, cortical lesions were made separating area 24 from adjacent cortical areas. In other animals, lidocaine injections were made to reversibly block neuronal activity in the medial thalamus. Responses to noxious stimuli occurred after complete cortical lesions while lidocaine injections reversibly blocked the responses of all units tested.

In conclusion, neurons in cingulate cortex respond to noxious stimulation and this signal may originate in the medial thalamus.

622.18

NEURONAL RESPONSES TO STIMULATION OF REPRODUCTIVE AND OTHER PELVIC ORGANS IN THE THALAMUS OF FEMALE RATS.
G. Guilbaud, K.J. Berkley, J.M. Benoist* and M. Gautron*. INSERM, U. 161, 2 rue d'Alésia 75014 PARIS, France.

Recent studies indicate the existence of CNS input from the uterus and other pelvic organs which gives rise to conscious sensations, including pain, suggesting that neurons in somatosensory relay nuclei receive such input (1). The present study examined responses of 61 neurons in and near the thalamic ventrobasal nucleus (VB) of 14 estrous female rats anesthetized with nitrous oxide/halothane to mechanical stimulation of uterus, cervix, vagina, colon and somatic structures (skin, joints). Neurons responsive to uterus (26%) or uterus and vaginocervix stimuli (28%) were located throughout VB, preferentially dorsally and rostrally (as were neurons responsive to colon stimuli ; 18%). Of 42 viscera-responsive neurons, half also had somatic receptive fields, most on the hindlimb (86%), but also on forelimb or face (14%). Many (62%) required noxious levels of somatic stimulation. While these neurons (38% of sample) were located equally within VB and its dorsal or ventral borders, neurons responsive only to somatic stimulation (30% of sample) were located primarily within VB and those responsive only to visceral stimulation (28%) were all located at VB's dorsal (88%) or ventral (12%) borders. These results reveal a surprisingly large, well-organized representation of internal female reproductive organs in and near VPL.

PAIN MODULATION: MONOAMINES

623.1

RECEPTOR MEDIATION OF 5-HT-INDUCED INFLAMMATORY NOCICEPTION IN RATS.
K. J. Sufka, F. Schomburg* and J. Giordano. Neuropharmacology Lab., COPHS, Drake Univ., Des Moines, IA 50311.

The present study examined the effects of intraplantar (ipl) injection of 5-HT and the ability of selective 5-HT receptor antagonists to differentially attenuate 5-HT-induced edema and nociception. Ipl 5-HT (0.05-1 µmol) produced dose-dependent hindpaw edema and nociceptive responses (lifts/licks of affected limb). The 5-HT_1 antagonist, methysergide (MS: 1-10 nmol; ipl), 5-HT_2 antagonist, ketanserin (KT:30-300 nmol; ipl) and 5-HT_3 antagonist, odansetron (OD:100 nmol - 1 µmole; ipl) differentially affected the nociceptive and edematous response produced by a fixed algesic dose of 5-HT (0.25 µmol; ipl). Ranked by magnitude of inhibition of 5-HT-induced nociception, MS > KT > OD. These results demonstrate the differential involvement of heterogeneous 5-HT receptors in 5-HT-induced inflammatory nociception.

623.2

PATTERNS OF ANALGESIA PRODUCED BY S AND R ISOMERS OF THE NOVEL 5-HT3 RECEPTOR ANTAGONISTS ADR-851 AND ADR-882 IN RATS.
I. Giordano and K. J. Sufka, Neuropharmacology Lab., COPHS, Drake Univ., Des Moines, IA 50311

The present study examined the antalgic efficacy of S and R isomers (0.1-10 mg/kg; sc) of the novel 5-HT_3 receptor antagonists, ADR-851 and ADR-882 against acute thermal, mechanical and formalin-induced inflammatory pain in male rats. No motoric, overt behavioral or physiologic effects were produced by any dose of S and R isomers of ADR-851 and ADR-882. Neither isomer of ADR-851 or ADR-882 was analgesic in the thermal or mechanical pain test. In the formalin test, ADR-851R produced significant antalgic effects at 3 mg/kg and 10 mg/kg doses. ADR-851S produced analgesia only at 1 mg/kg. Neither isomer of ADR-882 was effective in this assay. These results suggest that by antagonizing peripheral 5-HT_3 receptors, ADR-851 may be useful in the therapy of inflammatory pain.

623.3

EFFECTS OF THREE ALPHA-2 ADRENERGIC AGONISTS GIVEN INTRATHECALLY IN RATS.
D.K. Douglass, E. Carstens and P.J. Pascoe*. Depts. of Animal Physiology and Veterinary Surgery, University of California, Davis, CA 95616.

Systemically given alpha-2 adrenergic agonists can produce analgesia, marked sedation and significant cardiovascular changes. Intrathecal (IT) administration produced more intense analgesia with fewer systemic effects. This study examined the analgesic and sedative properties of 3 alpha-2 agonists given IT.

Forty male Sprague Dawley rats had IT catheters placed via the cisterna magna with the tip lying at the thoracolumbar junction. At least 2 weeks after surgery rats were randomly assigned to one of 4 groups to receive 10 ul IT injections of saline, xylazine (30,60,120 ug), detomidine (DET; 20,40,100 ug) or dexmedetomidine (DEX; 2.5,5,10 ug). Drug dose order was randomized. Tail flick latency and motor function were assessed 5,15,30,45,60,90 and 120 min following IT drug injection.

IT DEX and DET produced significant, dose-dependent analgesia. Sedation accompanied analgesia at higher doses but was usually of shorter duration. Analgesia and sedation were prevented by pre-administration, and reversed by post-administration, of the alpha-2 antagonist atipamezole (1 mg/kg). Xylazine produced analgesia and sedation at higher doses with antagonism by atipamezole.

Thus, appropriate doses of DEX or DET may afford analgesia with less accompanying sedation.

623.4

DIFFERENTIAL EFFECTS OF MONOAMINE UPTAKE BLOCKADE ON MU, KAPPA$_1$ AND KAPPA$_3$ ANALGESIA.
D. Paul. Department of Pharmacology, Louisiana State University Medical Center, New Orleans, LA 70112.

Selective stimulation of mu, kappa$_1$ or kappa$_3$ opioid receptors produces analgesia through neuroanatomically and neuropharmacologically distinct mechanisms. Blockade of monoamine uptake potentiates morphine analgesia. To determine whether monoamine uptake blockade will potentiate kappa$_1$ and kappa$_3$ analgesia, as well as mu analgesia, we assesed the analgesic effects of U50,488H, NalBzoH and morphine in mice treated with clomipramine or saline using the tail-flick assay. We first determined that 1 mg/kg of clomipramine, given 2 hr before testing, produced a 10-fold shift to the left of the analgesic dose-response curve for intrathecal NE without affecting intrathecal 5-HT analgesia. This dose by itself did not produce analgesia. The clomipramine treatment potentiated the analgesic effects of morphine (2 mg/kg, s.c.) and NalBzoH (10 mg/kg, s.c.), but had no significant effect on U50,488H analgesia (2 mg/kg, s.c.). These results indicate that a monoamine may modulate kappa$_3$ analgesia as well as mu analgesia.

623.5

ENKEPHALINERGIC ANTINOCICEPTION INDUCED BY ELECTRICAL STIMULATION AND SUBSTANCE P MICROINJECTION INTO THE A7 NORADRENERGIC CELL GROUP D. C. Yeomans and H. K. Proudfit
Dept. of Pharmacology, Univ. of Ill. at Chicago, Chicago, Ill. 60612.

We have recently demonstrated that the A7 catecholamine cell group in Sprague-Dawley rats (Sasco, Inc.) provides a dense noradrenergic innervation of the dorsal horn of the spinal cord. We have also demonstrated that activation of A7 cells by either electrical stimulation or microinjection of substance P induces antinociception which can be attenuated by intrathecal injections of noradrenergic antagonists. In addition, we have used neuroanatomical tract-tracers combined with immunocytochemistry, to show that some met-enkephalin immunoreactive cells in the A7 area project to and terminate in the dorsal horn. To investigate the possibility that these cells might be involved in the antinociception induced by stimulation of the A7 area, we determined whether such antinociception could be blocked by intrathecal injection of an opioid antagonist using lightly anaesthetized (urethane 1.0 g/kg) rats. The latency to foot withdrawal in response to a strong thermal stimulus was used as a measure of nociception. Electrical stimulation of the A7 area induced antinciception that was reduced by intrathecal injection of the opioid antagonist naltrexone (30 μg in 15 μl saline). Similarly, microinjection of 3.7 pmoles of substance P into the A7 area produced antinociception which was also partially antagonized by intrathecal administration the same dose of naltrexone. These results support the proposal that spinally-projectiong enkephalin-containing neurons near the A7 cell group can modulate nociception. Supported by USPHS Grants DA03980 to HKP and DA05406 to DCY.

623.6

EVIDENCE THAT THE ANTINOCICEPTION PRODUCED BY STIMULATION OF NEURONS IN THE DORSOLATERAL PONTINE TEGMENTUM IS MEDIATED BY RAPHE-SPINAL SEROTONIN NEURONS. J.A. Paice and H.K. Proudfit. Department of Pharmacology, University of Illinois at Chicago, Chicago, IL 60680.

Anatomic evidence indicates that neurons originating in the dorsolateral pontine tegmentum (DLPT) project to the nucleus raphe magnus (RMg). These neurons may contribute to the modulation of nociception by activating the spinally projecting serotonergic neurons in the NRM. To test this hypothesis, the DLPT, specifically the region near the A7 noradrenergic cell group was stimulated in partially anesthetized female Sprague Dawley rats. The latency to elicit a reflex paw-withdrawal to noxious heat was determined before, during and after electrical stimulation. Stimulation of the A7 region resulted in antinociception as measured by increased paw-withdrawal latencies. This effect was blocked by the intrathecal administration of the serotonergic antagonists methysergide and propranolol, but not by saline. These findings provide evidence for the existence of projections from the DLPT to the RMg, which are involved in modulating nociception. (Supported by USPHS grant DA03980.)

623.7

ANTINOCICEPTION INDUCED BY ELECTRICAL STIMULATION OF NORADRENERGIC NEURONS IN THE A7 CATECHOLAMINE CELL GROUP OF THE RAT. F.M. Clark, D.C. Yeomans, J.A. Paice and H.K. Proudfit, Pharmacology Dept., Univ. of Illinois at Chicago, Chicago, Illinois 60612.

We have shown that noradrenergic neurons in the A7 catecholamine cell group innervate the spinal cord dorsal horn in rats. This observation suggests that these neurons modulate nociception by inhibiting nociceptive transmission in the spinal cord. This hypothesis was tested by determining whether electrical stimulation at various sites in the dorsolateral pontine tegmentum in lightly anesthetized rats could modify nociception. The results indicated that stimulation at sites near the A7 cell group produced antinociception that was reduced by intrathecal injection of the α-noradrenergic antagonists phentolamine and yohimbine. The results of these experiments provide evidence that pontospinal noradrenergic neurons located in the A7 cell group are important components of the descending neuronal system that inhibits nociception. Supported by USPHS Grant DA03980.

623.8

CHARACTERIZATION OF α-ADRENERGIC RECEPTORS IN RAT BRAINSTEM. G.C. Newsom, J.I. Choca, and H.K. Proudfit. Pharmacology Dept., Univ. of Illinois, Chicago 60612.

Previous studies provide evidence for the existence of α_1 and α_2 noradrenergic receptors in the ventromedial medulla that are involved in the modulation of nociception. The present studies characterized the adrenoceptor subtypes in this area using radioligand binding assays. α_1 receptors were characterized using [^{3}H]prazosin. Ligand analysis yielded a K_d of 89 pM and a B_{max} of 48 fmoles/mg protein. Displacement studies were performed using WB4101 and phentolamine. Ligand analysis of these data best fit a one site model. Treatment with chloroethyl clonidine, which selectively alkylates α_{1b} receptors, reduced specific binding by 70 to 80%. These data suggest that [^{3}H]prazosin binds to a single site with characteristics of the α_{1b} receptor. α_2 receptors were studied using [^{3}H]rauwolscine. Ligand analysis yielded a K_d of 16 nM and a B_{max} of 58 fmoles/mg protein. Displacement studies were done using prazosin, yohimbine, and idazoxan; these data were best fit by a one site model. The K_i values were 1.5 nM, 200 nM, and 140 nM, respectively. The high affinity of prazosin and the low affinities for yohimbine and idazoxan suggest that the majority of the rauwolscine binding sites appear to correspond to the α_{2b} subtype. Supported by USPHS Grant DA03980.

623.9

RELATIVE INTRINSIC ACTIVITY OF INTRATHECALLY ADMINISTERED ALPHA 2 AGONISTS, DEXMEDETOMIDINE AND CLONIDINE, AS DETERMINED BY THE USE OF EEDQ, AN IRREVERSIBLE ANTAGONIST Y. TAKANO,* M. GRAFE, T. L. YAKSH Department of Anesthesiology, University of California, San Diego, La Jolla, CA 92093

Intrathecal dexmedetomidine and clonidine produce a dose dependent antinociception, which, based on the similar relative antagonist potency of intrathecal α_2 adrenergic antagonists (atipamezole = idazoxan > yohimbine >> prazosin) suggests an action on an α_2 adrenergic receptor site. To estimate the relative intrinsic activity of these spinally administered α_2 adrenergic agonists in vivo, dose response curves for dexmedetomidine and clonidine were carried out on the 52.5°C hot plate test with Sprague-Dawley rats using chronically implanted intrathecal catheter. EEDQ (N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline), an irreversible α_2 adrenergic antagonist was administered in dose of 8.1, 81 or 810 nmol, 24 hours before the spinal administration of one of the two agonists. Each animal was used once with a single dose of a single agonist. EEDQ alone resulted in an acute mild hyperalgesic effect. Intrathecally injected dexmedetomidine and clonidine resulted in a dose dependent increase in the hot plate response latency: ED50 of the percent of maximal possible effect (%MPE) = 10 (7.3-15) nmol and 118 (86-164) nmol, respectively. Pretreatment with intrathecal EEDQ caused a rightward shift of dose-response curve and reduction of the maximal effect of both dexmedetomidine and clonidine. Analysis of double reciprocal plot indicated that the fractional receptor occupancy required to produce the ED50 was 10 % and 36 % for dexmedetomidine and clonidine, respectively. These results suggest that dexmedetomidine has a higher intrinsic activity than clonidine to produce an antinociceptive effect when injected intrathecally. These experiments were supported partly by Dokkyo University, School of Medicine(YT) and DA02110(TLY).

623.10

AN IN VIVO MICRODIALYSIS STUDY OF THE EFFECTS OF KAPPA AGONISTS ON THE RELEASE OF SEROTONIN IN THE SPINAL CORD DORSAL HORN. J.L. Brown*, F.F. Matos[1], A.I. Basbaum, Division of Neurosciences and Depts. Anatomy and Physiology, University of California San Francisco, CA 94143 and [1]CNS Pharmacology, Bristol-Myers Squibb Company, Wallingford, CT 06492.

Several studies indicate that kappa opioid agonists exert an analgesic effect by activating inhibitory serotonergic mechanisms that operate at the spinal level. Ho and Takemori (1990) reported that kappa agonists evoke the release of newly incorporated ^{3}5-HT from spinal cord slices. To develop an in vivo model of kappa agonist effects on spinal cord 5-HT, we have begun in vivo microdialysis recordings in the awake rat. A loop-shaped dialysis probe was placed transversely across the dorsal horn of the spinal cord according to Skilling et al (1988). Two selective kappa agonists, U50488H (10mM) and CI-977 (1.0mM), were perfused through the dialysis probe for 15 minutes while extracellular release of 5-HT and its major metabolite, 5-HIAA, were monitored by HPLC and electrochemical detection. Infusion of either agonist produced at least a twofold increase of serotonin above basal levels, while 5-HIAA levels decreased. These kappa mediated effects were delayed, occurring one hour after the onset of agonist infusion, and were reversible; both 5-HT and 5-HIAA returned to basal levels within 2 hours. At this time a second injection of the kappa agonist again increased 5-HT release. The high concentration of kappa agonist required and the delayed time course suggest that there is either poor transfer of the compounds across the membrane or that the agonists do not act locally to produce this effect. We are presently examining the effects of intrathecal or supraspinal administration of U50488H and CI-977 on spinal cord 5-HT levels and evaluating the effects of selective opioid antagonists. Regardless of the site of action of these compounds, these results provide the first *in vivo* evidence demonstrating that activation of kappa receptors evokes 5-HT release in the dorsal horn. 623.11

THE SIMULTANEOUS MEASUREMENT OF EXTRACELLULAR MORPHINE AND SEROTONIN (5-HT) IN BRAIN TISSUE AND CSF BY MICRODIALYSIS IN AWAKE RATS. F.F. Matos, J. Brown, H. Rollema,* Y. Taiwo, J.D. Levine and A.I. Basbaum. Depts. Anatomy, Physiology, Medicine and Dentistry, UCSF, 94143 and *Univ. Center for Pharmacy, Groningen, The Netherlands.

A systemic injection of morphine produces its analgesic effect through interactions with opioid receptors at diverse supraspinal and spinal targets. Since simultaneous action of opiates at different sites exerts synergistic analgesic effects (Yeung and Rudy, 1980), it is of interest to simultaneously monitor behavior and the levels of morphine in different brain sites and in CSF. Furthermore, since morphine is proposed to exert its analgesic effect in part through release of 5-HT in the spinal or trigeminal dorsal horns (Yaksh and Tyce, 1979; Rivot et al, 1988), concurrent measurement of indolamines would also be valuable. To this end, we have combined *in vivo* microdialysis and HPLC with electrochemical detection to measure the extracellular levels of morphine, 5-HT and 5-HIAA in brain and CSF of the awake rat, while evaluating analgesia with the tail flick and paw withdrawal methods. Rats were implanted with dialysis probes (U- or loop-shaped) in the periaqueductal gray, lateral hypothalamus, cerebellum, spinal cord and cisterna magna.

Extracellular morphine could be detected in brain with doses as low as 1.0mg/kg, ip. After 10mg/kg, morphine was detected within 15min; peak levels were reached 45-65min after injection. Maximal levels varied with the probe used and with the area sampled. The most efficient recovery was in the cisternal CSF, presumably because of minimal tissue interference with the probe membrane. Although there was a high correlation between the time course of morphine recovery in the dialysate and behavioral analgesia and although morphine markedly increased cisternal CSF levels of 5-HIAA, we found no significant effect of morphine on extracellular levels of 5-HT or 5-HIAA in the spinal cord or in any of the brain areas sampled. These studies emphasize the utility of measuring levels of morphine and neurotransmitters in brain while simultaneously monitoring behavior and suggest that spinal cord release of 5-HT is not necessary for morphine to exert its analgesic action.

AFFERENT PROJECTIONS FROM THE NUCLEUS RAPHE MAGNUS TO THE LATERAL RETICULAR NUCLEUS AND THEIR ROLE IN THE DESCENDING ANALGESIA SYSTEM. A.Z. Murphy, M.M. Behbehani, and F.P. Zemlan. Dept. of Physiology, Univ. of Cincinnati College of Medicine, Cinti., OH 45267-0559.

Recent anatomical data have shown that the nucleus raphe magnus (NRM) sends direct projections to the lateral reticular nucleus (LRN). We have recorded from 98 cells in the LRN of the rat, determining: (1) response to electrical and chemical stimulation of the NRM, (2) response to noxious and innocuous peripheral stimulation, and (3) the role of glutamic acid and norepinephrine in the NRM-LRN interaction. Of the LRN cells tested, 41/49 (86%) were responsive to both train stimulation of the NRM (100 Hz, 50-200 uA, 200 usec pulses) and microinjection of HA (5 mM). Of these cells, 69% responded in the same direction to both chemical and electrical NRM stimulation, with 41% inhibited and 41% excited. Kynurenic acid was effective in blocking the excitatory effects of HA-induced excitation, suggesting the involvement of glutamate in this pathway. The majority of these cells were classified as either nocispecific or wide-dynamic range. Of the cells that were inhibited by peripheral stimulation, 56% were also inhibited by NRM stimulation. Response to 1 Hz single pulse stimulation showed that 24/50 cells were responsive: 75% were excited and 25% were inhibited. A post-excitation inhibitory response indicative of a collateral inhibition circuitry was noted in 33% of the cells. Phentolamine was effective in blocking this response suggesting the involvement of norepinephrine in this system. Supported by PHS grant NS20643.

623.13

THE EFFECT OF 5-HT_{1A} AGONISTS, SEROTONIN AND RAPHE STIMULATION ON SPINAL DORSAL HORN NOCICEPTIVE NEURONS IN THE RAT. R. Maureen Murphy, M.M. Behbehani, A.Z. Murphy, and F.P. Zemlan. Depts. of Psychiatry and Physiology, Univ. of Cincinnati College of Medicine, Cinti., OH 45267-0559.

The effect of iontophoretic application of serotonin (5-HT), 5-HT_{1A} selective agonists and electical stimulation of 5-HT cells of origin in nucleus raphe magnus (NRM) on lumbar spinal cord dorsal horn nociceptive neurons was determined in the rat. NRM stimulation significantly inhibited 48% of the 78 units tested while 13% were excited. Iontophoretic 5-HT administration inhibited 10 of 15 cells also inhibited by NRM stimulation while iontophoretic administration of the 5-HT_{1A} agonists, 8-OH-DPAT and buspirone, inhibited the response of 19 of 34 cells also inhibited by NRM stimulation. Comparison of the effect of 5-HT versus 5-HT_{1A} agonist iontophoresis on the same dorsal horn cells revealed that 5-HT_{1A} agonist administration inhibited 31 of 46 cells also inhibited by 5-HT iontophoresis. The inhibitory effect of 5-HT_{1A} agonists on unit activity elicited by noxious stimulation, glutamic acid or baseline firing rate could be blocked by the 5-HT_{1A} receptor blocker spiperone. Iontophoretic administration of 5-HT_{1A} agonists increased the firing rate of 7 of 20 cells also facilitated by 5-HT iontophoresis. These data suggest that 5-HT_{1A} receptors mediate a major portion of the inhibitory effect of NRM-induced release of serotonin on dorsal horn nociceptive neurons. The present study, in conjunction with parallel analgesiometric studies, suggests that 5-HT_{1A} receptors differentially affect two anatomically distinct groups of dorsal horn nociceptive neurons. Supported by PHS grant NS20643.

THE ANTINOCICEPTIVE EFFECTS OF I.V. CLONIDINE ARE ENHANCED IN ARTHRITIC COMPARED TO NORMAL RATS V. Kayser*, G. Guilbaud and J.M Besson U 161 INSERM, 2, rue d'Alésia, 75014 Paris, France.

The antinociceptive effects produced by an acute i.v. injection of the prototypic alpha-2 (α2)-adrenergic agonist clonidine (0.03-0.1 mg/kg) were investigated in normal and in Freund's adjuvant-induced arthritic rats used as a model of clinical pain. As a nociceptive test, we used the measure of the vocalization threshold (VT) elicited by foot pressure. Antagonism of clonidine's effects by the α-2 adrenoceptor antagonists yohimbine and idazoxan (0.25-1 mg/kg i.v., administered 30 min before clonidine) was also tested.

In normal rats, clonidine produced significant and dose dependent effects (mean VT increased by 24, 32 and 35 % of the control at 10 min after the injection, respectively for 0.03, 0.05 and 0.1 mg/kg i.v. clonidine), an effect roughly comparable to that of the μ-opioid agonist morphine (0.1, 0.3 and 1 mg/kg i.v.) in these animals.

In arthritic rats, clonidine displayed a more potent and prolonged analgesic effect than in normal rats (mean VT increased by 60, 63 and 86 % of the control, respectively for 0.03, 0.05 and 0.1 mg/kg i.v. clonidine). For the highest dose used (0.1 mg/kg), the antinociceptive effect of clonidine lasted for up to 110 min. in these animals.

In both groups of rats, yohimbine or idazoxan (0.25 to 1 mg/kg i.v.) significantly antagonized clonidine-induced antinociception in a dose-dependent manner.

These results suggest that α-2 adrenoceptors are involved in clonidine-induced antinociception in both normal rats and this model of inflammatory pain.

THE ROLE OF NOREPINEPHRINE IN DAMPGO-INDUCED ANTINOCICEPTION. U.D. Sivaskandan*, J.L. Stafinsky* and T. Crisp. Dept. of Pharmacology, N.E. Ohio Univs. Coll. of Med., Rootstown, OH 44272.

The present study was designed to determine if spinal norepinephrine (NE) contributes to supraspinal and/or spinal DAMPGO-induced antinociception. Male Sprague-Dawley rats were cannulated with intracerebroventricular (i.c.v.) and intrathecal (i.t.) catheters, and injected with different i.c.v. or i.t. doses of DAMPGO. Opiate-induced effects were measured on the spinally-mediated tail-flick test. The results demonstrated that DAMPGO (0.3 nmol) significantly elevated tail-flick latency (TFL) when administered i.c.v. or i.t. To determine the contribution of NE to DAMPGO-induced antinociception, a separate group of rats received i.t. pretreatments with prazosin (an α_1-adrenoceptor antagonist) or idazoxan (an α_2-adrenoceptor blocker) prior to DAMPGO. The supraspinal effects of DAMPGO were reversed by i.t. idazoxan, but not by prazosin. Apparently, i.c.v. DAMPGO activates a descending noradrenergic pain-inhibitory pathway to produce elevations in TFL. The NE released at the spinal level then interacts with α_2-adrenoceptors to mediate DAMPGO-induced antinociception. Neither prazosin nor idazoxan inhibited the spinal effects of DAMPGO, suggesting that μ agonists produce spinal antinociception in the absence of a noradrenergic component.

Monaminergic changes induced by morphine in hypoalgesic and hyperalgesic domestic fowl.
R. A. Hughes, Department of Psychology, Iowa State Univ., Ames, IA 50011-3180, K. J. Sufka, J. Giordano, and D. A. Hoganson*, Drake Univ., Des Moines, IA 50311-4505.
In replication of previous research morphine (0.0, 5.0, 10.0 mg/kg i.m.) induced dose and strain dependent hypoalgesia in Rhode Island Red (RIR) and hyperalgesia in White Leghorn (WL) cockerels on the formalin test. Assay (HPLC) of monoamines (NE, D, and 5HT) and metabolites (DOPAC and 5HIAA) in brain, brainstem, and spinal cord 30 min. after morphine (0.0, 5.0, and 10.0 mg/kg i.m.) increased 5HT ($p<.05$; this and subsequent p values refer to 0.0 vs. 10.0 mg/kg) in sp. cord and br. stem for both strains and no consistently reliable change in NE, D, 5HIAA or DOPAC, in these regions for either strain. Thus, monoaminergic correlates of morphine in brainstem and spinal cord monoamines did not differentiate the hypoalgesic from the hyperalgesic strain. On the other hand, morphine decreased brain **NE** ($p<.01$) and 5HIAA ($p<.02$) in the hypoalgesic RIR strain and increased brain 5HT ($p<.001$) and DOPAC ($p<.05$) in the hyperalgesic WL strain. Thus, morphine-induced changes in brain monoamines discriminated between the analgesic and the hyperalgesic strain.

624.1

IMMUNOLOCALIZATION AND CHARACTERIZATION OF SPECTRIN (240/235) AND (240/235E) IN THE MOUSE VISUAL SYSTEM. T. Isayama, S.R. Goodman†, and I.S. Zagon, Penn. State Univ., Hershey PA and †Univ. S. Alabama Coll. Med., Mobile AL.

Spectrin is a major structural component of the mammalian central nervous system, with cellular/dendritic (brain spectrin 240/235E) and cellular/axonal (brain spectrin 240/235) isoforms. We have characterized spectrin isoforms in the mouse visual system using Western blots, and localized spectrins with immunocytochemistry, using polyclonal antibodies directed against two brain spectrin isoforms. Immunoblot analysis of proteins isolated from mouse retinas revealed the presence of two spectrin isoforms; these two isoforms corresponded to brain spectrins (240/235E) and (240/235) on similar preparations of mouse brain. Spectrin (240/235E) was localized in cell bodies found in the inner nuclear, outer nuclear, and ganglion cell layers, and in processes of the inner and outer plexiform layers. Spectrin (240/235) was more diffusely distributed throughout the retina, with light immunostaining of neurons in the ganglion cell, inner nuclear, and outer nuclear layers. Spectrin (240/235E) was apparent in the nerve fiber layer and in the optic nerve; antibodies to spectrin (240/235) detected only diffuse immunoreactivity in the nerve fiber layer and optic nerve. These results indicate that the neuronal cytoskeletal proteins, brain spectrin (240/235) and (240/235E), are present in the visual system. Although the disposition of spectrin isoforms in the central nervous system and visual system have similarities, some important differences were detected.

THE ISOLATION OF DIRADYL CHOLINE PHOSPHOGLYCERIDES, INCLUDING THE PRECURSOR OF PLATELET-ACTIVATING FACTOR, FROM RETINA. **J.S. Hurst,* H.E.P. Bazan, and N.G. Bazan. LSU Eye Center and Neuroscience Center, New Orleans, LA 70112.**

Choline phosphoglycerides (PC) constitute an important source of both arachidonic acid (the precursor of eicosanoids), and bioactive glycerolipids, such as platelet-activating factor (PAF), which are significant inflammatory mediators in many tissues. It would be important, therefore, to establish which PC component in the retina is the most prominent contributor of arachidonic acid. Lipids were extracted from retinal homogenates and the PC fraction was purified by thin-layer chromatography (TLC). Diradyl derivatives, i.e. the alkylacetyl, alkenylacetyl, and diacylacetyl, were prepared from the PC isolate by phospholipase C treatment, followed by acetylation. The derivatives, separated by TLC and high-performance liquid chromatography, were subjected to alkaline methanolysis. The fatty acid methyl esters, generated from the diradyl acyl constituents, were extracted and analyzed by capillary gas-liquid chromatography and quantified, using C21:0 as the internal standard. The diacyl molecular species comprised more than 95%, the alkyl less than 5%, and the alkenyl less than 1% of the PC pool. Arachidonic acid and docosahexaenoic acid were the only significant polyunsaturated fatty acids represented in all three diradyl PC components. However, on a mole basis, the alkenyl fraction was the most enriched in arachidonic acid, with 30% of the total fatty acids as arachidonic acid. The PAF precursor, on the other hand, was the most enriched in docosahexaenoic acid. Supported by NEI EY05121.

DISTRIBUTION OF G-PROTEIN β SUBUNITS IN THE PRIMATE RETINA. Y.-W. Peng*[1,2], C. Emala*[3], J.D. Robishaw*[4], M.A. Levine*[3] and K.-W. Yau[1,2]. Howard Hughes Medical Institute[1]; Departments of Neuroscience[2] and Medicine[3], Johns Hopkins University School of Medicine, Baltimore, MD 21205; Geisinger Clinic[4], Danville, PA 17822.

The guanine nucleotide-binding proteins (G proteins) involved in various signal transduction processes in cells are heterotrimeric proteins composed of α, β and γ subunits. Each G protein possesses a distinctive α subunit, which is thought to confer functional specificity. In contrast, β subunits appear to be highly conserved, and are thought to couple promiscuously with various α subunits. To further examine this question, we have used anti-peptide antibodies against three β subunits that have been molecularly cloned to locate these proteins in the retina with immunocytochemistry. β_1 immunoreactivity is observed in rod photoreceptors as well as some amacrine cells and ganglion cells. β_2 immunoreactivity is predominently present in discrete sublaminae of the inner plexiform layer and some amacrine cell bodies. Most interestingly, β_3 immunoreactivity is present in all cone photoreceptors, as well as selective bipolar cells. The segregation of β_1 and β_3 in rod and cone photoreceptors, which contain related but distinct G-protein (transducin) α subunits, suggests that β subunits may be involved in defining the functional specificities of G proteins.

STAINING OF THE HUMAN RETINA WITH MONOCLONAL ANTIBODIES TO PROTEIN KINASE C ISOZYMES. Helga Kolb, Li Zhang* & Nicolas Cuenca*. Physiology Dept., University of Utah, Salt Lake City, U.S.A. and Histology Dept., University of Alicante, Spain.

Monoclonal antibodies made to the three isozymes of protein kinase C (Type 1, Type II and Type III, Seikagaku America Inc.) were applied to post-mortem human retina. Immunostaining was done on wholemount, cryostat or Vibratome sectioned retina and visualized after ABC/DAB procedures.

The three isozymes of PKC gave completely different staining patterns. The Type I antibody failed to stain any cells at all. The Type III antibody stained rod bipolar cells in mid-peripheral and peripheral retina. The smallest-field cells with tiny axon terminals in s5 of the IPL appeared first at 1mm from the foveal pit. Peripheral retina appeared covered with an even distribution of beaded, narrow-field rod bipolar axon terminals in s5 of the IPL. Wide-field bipolar axon terminals (over 100 µm spread) stratifying in s5 were also stained.

The Type II isozyme stained cone bipolar cells, amacrine cells and ganglion cells. Cone bipolar staining occurred all the way into the fovea and clearly both midget and diffuse varieties of cone bipolar were included. The IPL was so heavily stained due to amacrine and ganglion cell immunoreactivity that banding contributed by bipolar endings was difficult to discern. However, s2 and s4 appeared to stand out somewhat more heavily than others. Ganglion cells of all soma sizes, their axons and to some degree their dendrites were also immunostained. PKC appears to be a second messenger used in neurotransmission by both rod and cone systems in the human retina.

Retinal Protein Substrates For Tyrosine-specific Kinases. D.J. Bare, J.S. Biscardi* and P.F. Maness. Dept. of Biochemistry and Biophysics, Univ. of North Carolina School of Medicine, Chapel Hill, NC 27599.

Tyrosine-specific protein kinases are abundant in the adult vertebrate retina. Recently, it was shown that protein substrates in the synapse-rich plexiform layers of the retina are phosphorylated to a high degree. Subcellular fractionation of retina homogenate analyzed by immunoblotting with Phosphotyrosine (PTyr) antibodies revealed that several PTyr-modified proteins were enriched 5-20 fold in synaptosomes and that some were preferentially localized in a synaptic vesicle fraction. Immunocytochemical labeling with PTyr antibodies has revealed that PTyr proteins are prominent in the cytoplasm of horizontal cells and their processes. The most abundant substrates for Tyr phosphorylation are 106, 100, 78, 60 and 38 kD proteins. Our approach to revealing the function of Tyr kinases is directed towards the identification of substrates from bovine retina. A synaptosomal fraction was obtained from retina homogenates by differential centrifugation. The synaptosomes were lysed and a pellet that contained synaptic plasma membranes was obtained. Detergent solubilized PTyr-modified proteins were fractionated by affinity chromatography using PY20 monoclonal antibody. Through this procedure 10-15 µg of PTyr protein were purified from 25 bovine retinas.

COMPARATIVE LOCALIZATION OF C-FOS AND C-JUN-LIKE IMMUNOREACTIVITY IN THE TURTLE RETINA. W.D. Eldred and A. Yaqub*. Department of Biology, Boston University, Boston, MA 02215.

C-jun and c-fos are proteins encoded by the c-fos and c-jun proto-oncogenes, which have been reported to be neuronal activity markers. As a preliminary step in the analysis of the role of these proteins in retinal function, we have localized these antigens in the turtle retina using immunocytochemistry. C-fos-like immunoreactivity was widely distributed in the retina. The labeling was primarily somatic and many cells in the inner nuclear and ganglion cell layers were immunoreactive. In isolated cases, there were cells with higher levels of immunoreactivity throughout their cytoplasm, which filled their processes in the inner plexiform layer (IPL). In contrast, the c-jun-like immunoreactivity was much more selectively localized. Only small numbers of amacrine cells and some ganglion cells were immunoreactive. The immunoreactivity in the amacrine cells was found throughout the cell bodies and in the dendritic arborizations. The majority of amacrine cells were monostratified with extensive dendritic arborizations in strata 2 of the IPL. These amacrine cells had elongated, vertically oriented cell bodies located near the middle of the inner nuclear layer. The immunoreactivity in the ganglion cells was primarily confined to the cell bodies, although some immunoreactivity was apparent in the ganglion cell axon layer. It appeared that most ganglion cells with c-jun-like immunoreactivity had small cell bodies. Our results show that c-jun is more specifically localized in the turtle retina than c-fos immunoreactivity, which suggests that c-jun may provide more selective indications of neuronal activation. This research supported by EY04785 to W.D.E.

DOUBLE-LABELING STUDIES OF THE DISTRIBUTION OF ALPHA-BUNGAROTOXIN BINDING PROTEINS AND NICOTINIC RECEPTORS IN THE CHICK RETINA. D.E. Hamassaki-Britto, L.R.G. Britto, K.T. Keyser, H.J. Karten and J.M. Lindstrom*. Dept.Neurosci., Univ.California, San Diego, La Jolla, CA 92093, and *Inst.Neurol.Sci., Univ. Pennsylvania, Philadelphia, PA 19104.

The present study was undertaken to compare the distribution of α1 and α2 subunits of the α-bungarotoxin binding proteins (BP)-like immunoreactivities (BP-LI) to that of nicotinic receptor-like immunoreactivity (nAChR-LI) in the chick retina. Double-labeling experiments were conducted to test the possibility that the same cell could contain both BP-LI and nAChR-LI. In the inner nuclear layer, displaced ganglion cells contained only nAChR-LI. Bipolar cells stained for α2BP-LI, and their processes could be observed in the outer plexiform layer. Amacrine cells, and cells in the ganglion cell layer, exhibited α1BP-LI, α2BP-LI and nAChR-LI. However, there were differences in the distribution of these immunoreactivities: (1) the α1BP-LI cells tended to be larger than the α2BP-LI and nAChR-LI cells; (2) the density of α2BP-LI cells was higher than the densities of α1BP-LI and nAChR-LI cells; (3) in the ganglion cell layer, the larger cells containing α2BP-LI also contained α1BP-LI; (4) many cells in the ganglion cell layer exhibiting α2BP-LI showed nAChR-LI, whereas no α1BP-LI cell appear to contain nAChR-LI. Although both BPs were distributed in all laminae of the inner plexiform layer, the outer laminae (mainly lamina 2) exhibited a heavier staining for α2BP-LI, and the inner laminae (mainly lamina 4) for α1BP-LI. In turn, nAChR-LI was observed in laminae 1, 2, and 4 of the inner plexiform layer. Our results show that α1BP-LI, α2BP-LI and nAChR-LI are differentially distributed in the chick retina, although co-localization could be observed in some cases.

EXPRESSION OF GLUTAMATE DECARBOXYLASE (GAD) mRNAs IN THE ADULT AND DEVELOPING RAT RETINA. Mable Lai*, Martin Humphrey, Catia Sternini and Nicholas Brecha. Depts. of Medicine and Anatomy & Cell Biology and CURE, UCLA School of Medicine and VAMC-West Los Angeles, Los Angeles, CA., Dept. of Psychology, University of Western Australia.

GABA is a prominent inhibitory neurotransmitter, which is synthesized by two structurally different GAD molecules with predicted molecular weights of about 65 and 67 Kd (GAD_{65} and GAD_{67}, respectively). The cellular expression of GAD mRNAs was examined in the adult and developing rat retina using *in situ* hybridization histochemistry with ^{35}S-labeled rat GAD_{65} or GAD_{67} RNA probes. Cryostat sections were incubated with sense or antisense RNAs, washed at high stringency and processed for autoradiography. Specific labeling is not observed in sections incubated in sense RNA probes. In adult retina, GAD_{65} and GAD_{67} mRNAs are expressed in numerous cells distributed to the proximal inner nuclear layer (INL) and to the ganglion cell layer (GCL), and in some cells located in the inner plexiform layer. At early postnatal ages, cells containing both GAD mRNAs are sparse and localized to the proximal INL and GCL. By day 10, the distribution of GAD mRNAs is comparable to that observed in the adult retina. These results demonstrate that both GAD mRNAs are present in the retina and are predominantly expressed in amacrine and displaced amacrine cells.

We thank Dr. A. Tobin for providing the GAD_{65} and GAD_{67} cDNAs.
Supported by NIH grants EY 04067 and VAMC Research Funds.

624.9

EXPRESSION OF GABA NEURONAL TRANSPORTER mRNA IN THE RAT RETINA. Christine Weigmann* and Nicholas Brecha. Depts. of Anatomy & Cell Biology and Medicine, Jules Stein Eye Institute and CURE, UCLA School of Medicine and VAMC-Wadsworth, Los Angeles, CA.

GABA transporters play an important role in synaptic activity in the nervous system. Recently, a cDNA (named GAT-1) encoding a GABA transporter that is pharmacologically similar to neuronal GABA transporters has been cloned. The present study evaluates the cellular localization of this GABA transporter mRNA in the rat retina using *in situ* hybridization histochemistry with a ^{35}S-GAT-1 RNA probe. Retinas were fixed in 4% paraformaldehyde and sectioned perpendicularly to the vitreal surface with a cryostat. Retinal sections were incubated in antisense or sense RNA at 53°C, washed at high stringency, processed for autoradiography and exposed for 11 to 45 days. Only background labeling was seen in sections incubated with the sense RNA probe. In all retinal regions, GAT-1 mRNA is localized to numerous cells distributed to the proximal inner nuclear layer (INL). There is little labeling over the distal INL. In the inner plexiform layer, some discretely labeled cells are present. In the ganglion cell layer, many cells containing GAT-1 mRNA are seen. Labeling is not observed in the outer nuclear layer. The distribution of GAT-1 mRNA closely matches the reported neuronal uptake pattern of GABA. Overall, this labeling pattern suggests that amacrine and displaced amacrine cells are the main cell types expressing this transporter.

We thank Dr. J. Guastella for providing the GAT-1 cDNA.

$GABA_A$ RECEPTOR FUNCTION IN RETINAL NEURONS: MODULATION BY CYCLIC AMP. M.L. Veruki and H.H. Yeh, Neuroscience Program, University of Rochester Medical Center, Rochester, NY 14642.

We are investigating the intracellular mechanisms underlying our previously reported phenomenon that vasoactive intestinal polypeptide (VIP) can potentiate $GABA_A$ receptor-mediated whole-cell current responses in bipolar and ganglion cells of the rat retina. Since VIP is a potent elevator of intracellular cyclic AMP, the peptide may work through a cyclic AMP-dependent intracellular cascade to modify $GABA_A$ receptor function. However, a prerequisite for formulating this hypothesis is the demonstration that elevating intracellular cyclic AMP levels mimics the potentiating effect of VIP on GABA.

Freshly isolated bipolar cells and ganglion cells were obtained from the rat retina following treatment with protease. Agonists, dissolved in bath solution, were applied via a micropressure ejection system and the resultant current responses were monitored under voltage clamp using conventional whole-cell patch clamp recording procedures.

Exposure of bipolar cells and ganglion cells to forskolin ($\leq$200 uM), an activator of adenylate cyclase, but not its biologically inactive analog, 1,9-dideoxyforskolin ($\leq$100uM), resulted in a robust and reversible potentiation of the GABA-activated current (I_{GABA}) recorded in both cell types. Extracellular application of 8-Bromo-cyclic AMP ($\leq$500uM), the membrane permeable analog of cyclic AMP, also potentiated the I_{GABA}. However, control tests of specificity indicated that extracellular application of cyclic AMP ($\leq$1mM) also had a similar potentiating effect. We thus are cautioned to interpret our data with care, especially with regard to the potential non-specific effects of membrane-permeable analogs of cyclic AMP. Overall, our results to date are consistent with the notion that increasing intracellular levels of cyclic AMP in bipolar and ganglion cells may ultimately lead to a facilitation in $GABA_A$ receptor efficacy.

EFFECTS OF DOPAMINE D_1 AND D_2 RECEPTOR AGONISTS ON ELECTRICAL COUPLING BETWEEN FISH HORIZONTAL CELLS. Krisztina Harsanyi* and Stuart C. Mangel. Dept. of Ophthalmology, Univ. of Alabama School of Medicine, Birmingham, AL 35294.

In order to characterize the action of dopamine on horizontal cell coupling, SKF38393, a D_1 receptor agonist, LY171555, a D_2 receptor agonist, or dopamine, itself, were superfused onto the isolated intact goldfish retina, while the light responses of L-type (H1) cone horizontal cells were monitored. Either dopamine (2-50 uM) or SKF38393 (2.5-20 uM) uncoupled horizontal cells. That is, responses to small (500 um) centered spot stimuli were increased and annulus and full field responses were decreased. However, LY171555 (0.5-10 uM) increased the coupling of horizontal cells; spot responses decreased and annulus and full field responses increased during application of this drug. Interestingly, at low dopamine concentrations (0.2 uM), horizontal cells were sometimes observed to first uncouple slightly and then to recouple beyond their initial state.

To test whether fish horizontal cells, themselves, possess D_2 receptors that might directly increase horizontal cell coupling at low dopamine concentrations, LY171555 (10 uM) was bath-applied following horizontal cell uncoupling by SKF38393 (2.5-10 uM). However, LY171555 had no effect under these conditions. These results suggest that LY171555 couples horizontal cells by activating D_2 autoreceptors on dopaminergic interplexiform cells, thus decreasing dopamine release onto horizontal cells.

HIGH EXTRACELLULAR LEVELS OF DOPAMINE IN XENOPUS RETINA DETECTED BY HIGH-SPEED CYCLIC VOLTAMMETRY. P. Witkovsky, M.E. Rice and C. Nicholson. Depts. of Ophthalmol. and Physiol. & Biophys., New York University Medical Center, New York, NY 10016.

We measured extracellular dopamine concentration in superfused eyecups using Nafion-coated carbon fiber electrodes and high-speed cyclic voltammetry (Rice and Nicholson, *Analyt. Chem.*, 61:1805, 1989). The dopamine concentration in or adjacent to the subretinal space was 734 ± 154 nM (mean ±sem, n=13, 4 eyecups). Peak oxidation/reduction potentials of dopamine and DOPAC were identical. However, the electrode selectivity for dopamine/DOPAC was 15:1 and a dopamine/DOPAC ration of 3:1 in the vitreous was determined by HPLC-ED (K. Bohmaker and M. Meller, personal communication). Thus, DOPAC contributed ≤3% to the voltammetric signal. Preliminary measures indicated that dopamine levels increase in steady light and diminish following light extinction, on a time scale of minutes. Our data show that retinal dopamine levels are much higher and DOPAC levels are much lower, compared to their respective concentrations in brain. These differences were interpreted in terms of the distinct geometries of dopaminergic terminals in retina and brain. Supported by grants EY03570 (PW), NS28480 (MER) and NS28642 (CN).

TYROSINE DEPENDENCE OF DOPAMINE RELEASE IN STIMULATED RETINA. C.J. Gibson. Dept of Pathology, University of Western Ontario, London, CANADA N6A 5C1.

Retinae were removed from male Sprague-Dawley rats and placed in individual perfusion chambers for the measurement of endogenous dopamine (DA) release (Gibson, J.Neurosci.Methods,32:75-79,1990). DA release was stimulated 5 to 7-fold over basal release following a 10 minute pulse of 40 mM potassium (K). In this system, perfusion with a second pulse of 40 mM K resulted in a roughly similar increase in releasable DA. Expressed as a ratio of the fractional release, K2/K1 = 0.96 $\pm$ .07. When 100 μM tyrosine was added throughout the perfusion this ratio increased to 1.42 $\pm$ .20 ($p \leq .05$). Addition of α-methyl-p-tyrosine (50 to 200 μM) progressively decreased the amount of DA released. At 200 μM, DA release during the second K pulse was totally abolished. In this system, in which DA release is dependent on newly synthesized transmitter, the addition of the precursor tyrosine maintains and even increases the amount of DA released.
(Supported by the Canadian MRC).

624.14

MELATONIN RECEPTOR-MEDIATED INHIBITION OF CYCLIC AMP ACCUMULATION IN CHICK RETINAL CELL CULTURES. P.M. Iuvone and J.Gan*. Dept. of Pharmacology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

In addition to its role as a pineal hormone, melatonin is synthesized in vertebrate retina, where it acts locally as a neuromodulator. Melatonin in retina has been implicated in the circadian regulation of photoreceptor outer segment disk shedding and dark-adaptation, and in the regulation of dopamine release from retinal amacrine cells. The cellular transduction mechanism(s) responsible for melatonin's actions in retina are not known. We have examined the effect of melatonin and related indoles on cyclic AMP accumulation in glia-free monolayer cultures of photoreceptors and neurons prepared from embryonic chick retinas. Melatonin had no significant effect on basal cyclic AMP accumulation, but significantly inhibited forskolin-stimulated cyclic AMP formation. Melatonin inhibited cyclic AMP formation in both photoreceptor-enriched and neuron-rich cultures, suggesting that both photoreceptors and multipolar neurons may contain melatonin receptors. Melatonin receptor agonists and related indoles inhibited cyclic AMP accumulation with an order of potency indicative of action at a melatonin receptor: 2-iodomelatonin $\geq$ melatonin $\geq$ 6-chloromelatonin > 6-hydroxymelatonin > 5-methoxytryptamine $\geq$ N-acetylserotonin > serotonin. Melatonin was potent, acting in the picomolar - nanomolar range, and produced a maximal inhibition of approximately 60% of the cyclic AMP accumulation evoked by 1 μM forskolin. The effect of melatonin on cyclic AMP formation was inhibited by the putative melatonin receptor antagonists luzindole (N-0774) and N-acetyltryptamine. Inhibition of cyclic AMP formation by melatonin was blocked by pretreating the cells with pertussis toxin. The results suggest that some of melatonin's actions in the retina may involve receptor-mediated inhibition of cyclic AMP formation.

TISSUE-TYPIC CELL PRODUCTION IN RETINAL SLICE CULTURE
Andreas F. Mack*, Thomas L. Kasten* and Russell D. Fernald, Institute of Neuroscience, University of Oregon, Eugene OR, 97403 and Department of Psychology, Stanford University, Stanford, CA 94305.

Two features distinguish retinas of teleost fish from those of warm blooded vertebrates: 1. Teleost retinas can regenerate after lesioning and 2. they continue to grow after embryongenesis, generating new retinal tissue in the retinal periphery, and new rod photoreceptors throughout the retina. We have developed a retinal slice culture system to study these processes in the African cichlid fish Haplochromis burtoni. We used ^{3}H-thymidine to label newly divided cells and immunocytochemistry with rod and cone specific antibodies to demonstrate differentiation of proliferating cells in culture.

After 2-3 days in culture, double labelled cells were distributed in a tissue-typic pattern. Newly generated cells were found at the margin and in the outer nuclear layer (ONL). Those in the ONL were labelled with a rod specific antibody whereas those near the margin were principally labelled with a cone specific antibody. This demonstrates that tissue-typic division and differentiation continue in the slice preparation. However, some presumptive rod progenitor cells central from the proliferating edge of the retina also stained positively with the cone antibody. This suggests that rod progenitors are possibly multipotent and may be able to differentiate into phenotypes other than rods. For example, rod progenitor cells might get important cues for differentiation from their cellular environment and its alteration could play a role in changing their fate during retinal regeneration. We are now analyzing candidate factors which play a role in proliferation and differentiation of the retinal slice.

CHEMICAL AND ELECTRICAL SYNAPSES FORMED BY CHICK RETINAL NEURONS MAINTAINED IN DISSOCIATED CELL CULTURE. E. Gleason and M. Wilson. Department of Zoology, University of California, Davis CA 95695.

Sparsely cultured retinal neurons derived from 8 day chick embryos form synapses that may be identified ultrastructurally and whose physiology we have begun to investigate. Communication between 103 pairs of large (cell bodies 12-20 μm diameter) multipolar cells has been examined using the perforated patch technique to voltage clamp both neurons. Electrical coupling was present in 61% of the cell pairs and was always ohmic, time-independent and ranged in magnitude from 100 pS to several nS.

Overall, chemical synaptic communication was seen in 55% of cell pairs with 49% of these pairs showing reciprocal connections. The frequency with which chemical synapses were observed increased over time in culture. On day 5 in culture 44% of pairs showed chemical synapses whereas on day 9, 73% of cell pairs showed chemical communication. Presynaptic depolarization positive to -30 mV elicited postsynaptic currents that were always noisy and could often be resolved into discrete events with conductance values as large as 1 nS. Spontaneous discrete events of similar amplitudes could also be seen in 28% of cell pairs. Discrete events peaked within 13 msec, decayed with time constants of about 18 msec, and were reversibly abolished by 3 mM Co^{++}. All postsynaptic currents were outward positive to -60 mV and in all cell pairs examined (n=7), 3-10 μM bicuculline reversibly inhibited the current, suggesting that GABA was the transmitter at these synapses.

ORGANOTYPIC SLICE CULTURE OF THE MAMMALIAN RETINA.
H. Wässle and A. Feigenspan*. Max-Planck-Institut für Hirnforschung, Frankfurt, Germany.

Vertical slices of 6 day postnatal rat retina were cut at a thickness of 100 μm and cultured using the roller culture technique of Gähwiler (J. Neurosci. Meth. 4, 329-342). After 14-21 days in vitro, the slices showed the typical pattern of layering of mature retina. The following immunocytochemical markers were used to characterize the different cell types: antibodies against protein kinase C (PKC), calcium binding protein (CabP 28 kD), parvalbumin (PV), neurofilaments (NF), gliaspecific antibodies (GFAP, vimentin) and transmitterspecific antibodies (GABA, TH). These markers labelled populations of cells comparable to those in the mature mammalian retina. In particular, antibodies against PKC in the mature retina stain rod bipolar cells (Greferath et al. J. Comp. Neurol. 301, 433-442). In the 6 day postnatal retina no staining was observed. However, after 14-21 days in the slice culture many presumptive rod bipolar cells were labelled.

The experiments show that a mammalian slice culture can be used to study differentiation of retinal cell types.

VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) IN NORMAL AND DIABETIC HUMAN RETINA.
E.D. McGookin[1*], E.G. Stopa[1], R. Chorsky[1*], G.H. Collins[1], A. Baird[#*], A.M. Gonzalez[#*] and A Hanneken[#*] Depts. of Pathology[1] and Ophthalmology SUNY-HSC Syracuse, New York 13210; The Whittier Institute for Diabetes and Endocrinology[#], LaJolla, California 92037.

The recent identification of vascular endothelial growth factor (VEGF) has indicated that this growth factor is a mitogen for vascular endothelial cells. Studies, using immunocytochemistry, compared the distribution of VEGF-like and basic fibroblast growth factor-like (bFGF) immunoreactivity in human eyes, snap frozen post-mortem from control and diabetic subjects. Ten micron sections were cut and stained with specific polyclonal antibodies directed against the amino terminus of VEGF (Ab#61) and bFGF (Ab#773) respectively. The results indicate that bFGF-like immunoreactivity was present in the ganglion, inner nuclear and outer nuclear cell layers of the retina. VEGF-like immunoreactivity was most noted in the ganglion cell layer and in contrast to bFGF, VEGF was more diffusely distributed within the inner nuclear and outer nuclear layers. In addition to their presence in neurons, both bFGF and VEGF were also seen associated with the neovascularization of diabetic retinopathy. Although VEGF is thought to have a role in angiogenesis, our data provide evidence that VEGF may also be an important growth factor in the retina and central nervous system.

SITES OF BRAIN INVOLVEMENT IN A MURINE MODEL OF HERPETIC RETINITIS. J.C. Hedreen, J.S. Pepose* and J.A. Whittum-Hudson*. Depts. of Pathol. and Ophthalmol., The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205 and the Department of Ophthalmology, Washington University School of Medicine, St. Louis, MO 63110.

When Herpes simplex virus type 1, KOS strain, is inoculated into the anterior chamber of one eye in BALB/c mice, a severe infection develops in the anterior segment, but the retina remains almost normal. In contrast, the opposite uninjected eye develops a delayed necrotizing viral retinitis. To investigate possible paths of interocular transfer, we examined the localization of virus in the brain by immunocytochemistry at 1-14 days postinoculation. At day three, antigen-positive neurons were observed in the ipsilateral Edinger-Westphal nucleus and vicinity and the ipsilateral oculomotor nerve root exit zone. At day four, neurons in the contralateral medial pretectal area, the ipsilateral suprachiasmatic nucleus, and the ipsilateral intergeniculate leaflet of the lateral geniculate body became positive. Necrotizing contralateral retinitis occurred by day ten. The probable route by which virus reaches the opposite eye is: retrograde axonal transport from the ciliary ganglion to the ipsilateral midbrain; from the midbrain to the ipsilateral suprachiasmatic nucleus; and from the suprachiasmatic nucleus to the contralateral retina.

PATTERN ELECTRORETINOGRAM & VISUAL EVOKED POTENTIAL (VEP) IN RETINITIS PIGMENTOSA (RP).

J. Mishra and S. Rana*, University of Texas Health Sciences Center & Houston Eye Associates, Houston, TX 77030.

RP is a hereditary disease of photoreceptors, progressive in nature and primarily affects the peripheral retina. Since pattern electroretinogram (PERG) is believed to reflect the activity of the ganglion cells and is mostly evoked from the the foveal retina like VEP, we analyzed PERG and VEP in patients with RP who retained only the central vision.

Ten patients (18 eyes) with RP were evaluated using VEP, PERG, FERG (Flash-ERG) and Goldmann visual fields. For VEP and PERG, the visual stimuli were 0.5^0 black and white checks with 98% contrast reversing at 2 and 8 Hz. The central retina (16^0 x 19^0) was stimulated. FERG was performed using a Ganzfeld stimulator. In 14 eyes $5\text{-}10^0$ of the central retina was spared on the visual field. In these eyes the photopic response was abnormal and PERG was extinguished. In 4 eyes, 30^0 of the central retina was spared. The photopic response was normal and PERG was present in these eyes. The scotopic ERG was abnormal in all the eyes. On the other hand, VEP was abnormal in only 5 eyes. VEP gave normal results in 13 eyes, although 9 of the same eyes tested abnormal using the PERG method. From these findings, it appears that: 1) normal PERG response is dependent not only on the foveal but also the parafoveal retina, 2) PERG is more sensitive than VEP in detecting wide-spread disease of the retina. (Partially supported by NIH EY 07024).

GLIAL RESPONSE TO HETEROLOGOUS INTRAVITREAL RETINAL PIGMENT EPITHELIAL (RPE) CELLS. S.A. Vinores, H.A. Sen*, E.E. Van Niel*, and P.A. Campochiaro*. Dept. Ophthalmol., Univ. of Virginia, Charlottesville, VA 22908.

The pathogenesis of epiretinal membranes (ERMs), which can lead to traction retinal detachments (TRDs) is not clearly understood. To induce ERM formation, human RPE cells were injected into rabbit vitreous and the eyes were examined grossly, ultrastructurally, and immunocytochemically at 7,14,16,21, and 28 days. Early TRDs were seen at 7 days and progressed thereafter. Donor RPE cells stopped expressing keratin(K) intravitreally as in vitreous cultures. By 21 days, some K+ cells were evident and some RPE cells appeared to begin re-acquiring pigment.

At the site of ERM formation, some Müller cells appear to lose GFAP, retract their processes, and develop abundant rough endoplasmic reticulum (RER). These cells, round GFAP+ cells, which also express glutamine synthetase (GS), and unretracted Müller cell processes, break through the inner limiting membrane. The Müller cells with abundant RER (GS+) remain on the inner retinal surface. The round cells appear to flatten out and cover heterologous cells on the inner retinal surface or migrate into the ERM. These results show that Müller cells react to cells in the vitreous, migrate from the retina and contribute to ERM formation.

AN ISCHEMIA-REPERFUSION INJURY BY HIGH INTRA-OCULAR PRESSURE IN THE RAT RETINA. Z. H. Liu*, Y. P. Chu*, X. G. Luo. Dept. of Neurobiology, Hunan Med. Univ. P. R. C.

The effect of the high intraocular pressure on artificial glaucoma was investigated in 20 albino rats. Isotonic saline was perfused into the anterior chamber of the right eye, as ischemia/reperfusion (I/R) eye, with intraocular arterial perfusion pressure (PP) for 1 hr (ischemia), then decreased the intraocular pressure to be normal for another hr. The left eye, as simple ischemia (SI) eye, was just perfused only with the PP for 1 hr (reperfusion). As comparing these two groups, the malondialdehyde in I/R retina was higher than that in SI retina ($p<o.oo1$). When both of the I/R and SI retinas were incubated in 1% lanthanum nitrate solution, a lot of lanthanum grains were seen inside along the cytoplasmic membrane of the retinal ganglion cells (RGCs) in I/R group, but the grains were accumulated outside the RGCs in SI group. Morphologically, the clumped nuclear chromatin, vacuolization of the cytoplasm in the RGCs could be observed under light microscope. By electron microscope, the thrombosis in the capillaries and the swollen endothelial cells were demonstrated obviously. The changes of the RGCs included increase in electron density, the disruption of cytoplasmic membrane and/or nuclear membrane, the swelling and vacuolation of mitochondria (Mi). In constrat, only a little changes such as the mild dilatation and the cristae disappearance of the Mi were recognized in the RGCs of the SI retina. These results suggest that the virtual injury occurred mostly during the postischemia rather than the ischemia period. It is reasonable to assume that the oxygen free radical plays vital role in the development of some glaucoma. (supported by NSFC 3870621).

ARTERIOLES AND VENULES OF NEONATE RETINA DILATE IN RESPONSE TO INTRAVITREAL 2-CHLOROADENOSINE.
J.M. Gidday, T.M. Lanius*, A.R. Shah*, E.R. Gonzales*, and T.S. Park. Department of Neurological Surgery, Washington University, St. Louis, MO 63110.

Studies designed to identify metabolic regulators of retinal blood flow (RBF) in the neonate eye are scant. We are investigating the hypothesis that adenosine regulates neonate RBF. The present study was undertaken to determine if retinal vessels of the newborn pig eye respond to an intravitreal injection of 2-chloro-adenosine (2-CADO), an adenosine agonist. Isoflurane-anesthetized, ventilated, pancuronium-paralyzed piglets (<5 days old) were used (n=5). The iris was dilated with 1% tropicamide, and the cornea and lens were removed and replaced with a glass coverslip to permit visualization of the fundus via videomicroscopy and xenon epi-illumination. Under 310x magnification, the diameters of a single arteriole (71±8 μm) and venule (154±29 μm) were measured by videocalipers before, and at 5 min intervals following, an adjacent intravitreal injection (20 μl) of 100 μM 2-CADO. Arterioles and venules maximally dilated to 168±15% and 121±9% of their respective control diameters 15 min after 2-CADO administration. These dilations were sustained for at least an additional 20 min. The significant increases in arteriolar size induced by 2-CADO lend support to the hypothesis that adenosine may regulate neonate RBF.

COMPUTER SYSTEM FOR MAPPING PHOSPHENES PRODUCED BY INTRACORTICAL MICROSTIMULATION OF VISUAL CORTEX. E.M. Schmidt and S.R. Charagundla*. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Intracortical microstimulation of the visual cortex in human subjects elicits the sensation of small points of light called phosphenes. Implantation of arrays of intracortical electrodes may provide a means of producing a visual prosthesis for patients with certain types of blindness.

A DEC PDP 11/23 computer has been programmed to provide control of photically isolated stimulators that are connected to an array of intracortical electrodes. Once threshold stimulation currents are established for the electrodes then the position in visual space must be established to provide meaningful information to the subject. The fact that phosphenes move with eye position complicates most methods of mapping the absolute position of phosphenes. Thus a pair-wise mapping procedure was implemented. Stimulation is applied first to a reference electrode and then to the electrode to be mapped. The subject inputs the direction of the vector from the reference electrode to the map electrode by positioning a joystick in one of 16 possible directions. A binary search, regulated by the directional input of the subject, through the phosphenes already mapped determines the neighbors of the phosphene to be mapped. The final position of the phosphene is determined through the use of a weighted average of two directional pairs. As each phosphene is mapped it is displayed on a video monitor so that the investigator can observe the developing map.

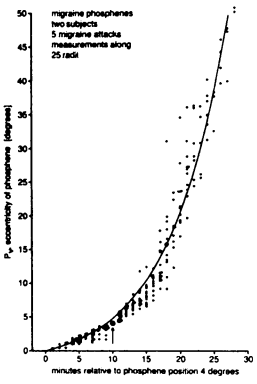
QUANTITATIVE STUDIES IN MIGRAINE PHOSPHENES. O.-J. Grüsser, U. Grüsser-Cornehls* (Spon: European Neuroscience Association) Dept. Physiology, Freie Univ. Berlin, Germany

Scintillating phosphenes are typical aura phenomena of "classical" migraine. We analysed the size ß of the "fortification" particles and the position P_V of the migraine phosphenes within the visual field as a function of time t past since the fortification pattern first appeared in the fovea. The distance P_V could be uniformly described, whereby normalization was attained for 4 degrees distance from the fovea center (fig.):



$$P_V = k\,(e^{bt} - 1)\ [deg] \quad (1)$$

Eq (1) is the solution of :

$$dP_V/dt = a + b\,P_V \quad (2)$$

describing the dynamics of spread of migraine phosphenes. Particle size ß of the pattern was a linear function of P_V:

$$ß = k^{*}\,P_V + c\ [deg] \quad (3)$$

TEMPORAL ORGANIZATION OF THE VISUAL SYSTEM IN THE AWAKE MACAQUE. C.E. Schroeder & S.J. Givre, Departments of Neuroscience & Neurology, Albert Einstein College of Medicine, Bronx, NY.

We investigated the organization of the primate visual system by comparing the timing of responses to standardized luminance and pattern (in fixating animals) stimuli across LGN, V1, V2, V3a, V4 and inferotemporal (IT) cortex. Timing was measured using laminar profiles of current source density and concomitant multiunit activity, recorded with multicontact electrodes in 9 awake, macaques. Luminance response latencies (range/mean/n of animals sampled) are:

a) LGN, 14-24ms/ 17.5ms/(n=5) b) V1, 20.5-30.5/ 27.6ms/(n=5)
c) V2, 26-32ms/ 28.3ms/(n=2) d) V4, 23-33ms/28.6ms/(n=3)
e) V3a, 42-65ms/ 53.6ms/(n=1) f) IT, 42-60ms/ 52.3ms/(n=3)

Latencies to pattern reversal are 3-16 ms longer than collocated luminance evoked latencies. In cortical areas, responses in superficial laminae lag the initial response by 4-10ms. The direct, luminance response has a minimum duration of about 35 ms in LGN, and 40 ms in V1. We conclude that: 1) The latency differences between LGN and V1, between V1 and V3a and between V4 and IT are consistent with sequential organization of processing; 2) The small latency differences between areas V1, V2 and V4 are inconsistent with purely sequential/hierarchical organization of processing in this portion of the system; 3) Despite the latency offset between early responses in LGN and V1, and later responses in IT, due to the long duration of activity at each point, processing throughout the system is broadly concurrent. Thus, feedback from extrastriate cortices can influence visual processing in V1 and even in LGN, during the time frame of the response to a single stimulus. TIMING AND LAMINAR DISTRIBUTION OF ACTIVITY EVOKED BY WHITE LIGHT VERSUS COLOR IN V1 AND V4 OF THE AWAKE MACAQUE. S.J. Givre[1], C.E. Schroeder[1], R.A. Bazarian*[,3] & J.C. Arezzo[1,2]. Depts. Neurosci.[1], Neurol.[2] & Ophthal.[3], Albert Einstein Coll. Med., Bronx, NY 10461.

Intracortical profiles of visual evoked potentials (VEP), concomitant multiunit activity (MUA) and current source density (CSD) were obtained from V1 (N=1) and V4 (N=2) of awake monkeys. 16-channel electrodes, capable of spanning the cortical laminae, were used for recording. Stimuli were full-field, stroboscopic flashes of white, red, blue and green light. In V1, white flash stimulation predominantly activates Lamina 4, as indexed by current sinks and increased MUA in this layer. Successive decrements in flash intensity reduce the amplitude of the VEP and associated current sinks, and increase the onset latency of the response. Colored stimuli increase the amplitude and peak (not onset) latency of the current sink in Lamina 4cß, but not 4cα, and in addition, produce a pattern of large current sinks of sequential onset in upper Lamina 4 and Lamina 3. Red produces the largest effect, approximately doubling the amplitude of the initial VEP component (N40-50).

In V4, the initial response to white light is a brief, small current sink. As in V1, decreasing the intensity of the flash reduces the amplitude and increases the onset latency of the response. Colored stimuli can prolong the initial sink without increasing its onset latency. In addition, they can prolong MUA or produce MUA bursts which were not resolvable during white light stimulation.

These data illustrate a surprising degree of differential processing of color versus white light full-field flashes both within the laminae of V1 and between V1 and V4. (Supported by MH06723 and T32GM7288-NIGMS).

SPATIAL DISCRIMINATION OF MULTIPLE NEUROMAGNETIC SOURCES EVOKED BY SEPARATE AND SIMULTANEOUS PRESENTATION OF VISUAL STIMULI. S. Supek, C.J. Aine, and P.A. Medvick*, Los Alamos National Laboratory, MS M715, Los Alamos, NM, 87545.

The objective of this study was to characterize the superposition of human neuromagnetic responses and the resolution of sources when responses evoked by single visual stimuli are compared with responses evoked by the simultaneous presentation of paired stimuli.

Two-dimensional difference of gaussians (DOG) stimuli were presented to three different field positions located 2.5° to the right of the vertical meridian and either 2.5°, 8.5° or 12° below the horizontal meridian. The size of the stimuli was adjusted according to the cortical magnification factor and stimuli were presented either separately or in simultaneous pairs. Neuromagnetic measurements (56-112 sensor locations) were recorded from four right-handed human subjects. Sources were localized by fitting instantaneous neuromagnetic field maps with a multiple-dipole, spherical model. The reduced chi-square statistic was used to determine model order and best-fitting dipole parameter values.

A preliminary analysis of the data suggests that only initial responses (<160 ms) reflect superposition. For separate presentations, two dominant sources were identified from the major waveform deflection at 150ms: (1) a source in the left extrastriate occipital region that varied in location and orientation as a function of stimulus position in the visual field; and (2) a source in left inferior occipito-temporal cortex that was invariant across stimulus position. For simultaneous presentations, a source in left occipito-temporal cortex was observed that was indistinguishable from that seen for separate presentations. In the left extrastriate region two sources predictable from the separate conditions were observed but some of their parameters differed from those in the separate conditions presumably due to their close spatial proximity.

A 8-12 Hz ("ALPHA") RHYTHM IN CAT VISUAL CORTEX
M. Chatila, C. Milleret, J.J. Bouyer, A. Rougeul, P. Buser. Institut des Neurosciences, Dépt de Neurophysiologie comparée, CNRS-UPMC, 9 quai St Bernard, F-75005 Paris.

In behaving cats, exploration of the visual and adjacent areas reveals several sets of electrocortical rhythms. One of those displays the following characteristics : 1) its frequency lies in the "alpha" 8-12 Hz band. 2) it is interrupted by *visual stimulation*. 3) it is *localized* in area 18, or at the limit between areas 17 and 18, in the projection zone of the central vertical meridian. No such rhythm could be found in the most posterior part of the visual cortex nor in the posterior parietal cortex. 5) it optimally develops while the animal is *waiting* for a significant target to appear; roughly similar conditions were previously shown to favour another set of rhythms, those in the somatic cortex ("mu rhythms"); coherence computation has however indicated that the two rhythms develop independently. 6) concerning its putative *thalamic command zone*, alpha recording electrodes were localized in the medial part of the lateral geniculate body, very close to nucleus lateralis posterior and pulvinar. We thus confirm that an alpha-like rhythm exists in carnivora, but with a restricted cortical localization, and that it is definitely independent of the anterior mu activity whose command zone is situated in n. ventralis posterior of the thalamus. Supported by DRET (Contract 89/069) and Fondation pour la Recherche Médicale.

625.7

INFLUENCE OF PUPIL DIAMETER ON PATTERN-ELICITED VISUAL EVOKED POTENTIALS IN PIGMENTED RATS. W.K. Boyes, D.W. Herr and H.K. Hudnell. US EPA, RTP, NC 27711.

Visual evoked potentials (VEPs) are a useful methodology for studying the neurotoxic and neuroactive properties of chemical compounds. Many compounds, in addition to having CNS actions, may alter pupil diameter and thus effect both the refraction and luminance of the stimulus image on the retina. It is important to differentiate peripheral from CNS changes when using VEPs to study the potential hazards of chemical compounds. Pigmented male rats (Long-Evans) with previously implanted electrodes overlying the left and right sides of visual cortex were given drops of vehicle (n=10), the mydriatic tropicamide (n=7), or the miotic neostigmine (n=4) into either one or both eyes. Stimuli were vertical sinusoidal gratings at 5 spatial frequencies (0.05, 0.1, 0.2, 0.4 or 0.8 cpd), 40% contrast, modulated in an on/off fashion with a 5 Hz temporal sinusoid. VEP waveforms were averaged over 100 trials, spectral analyzed, and spectral amplitudes at 5 (F1) and 10 (F2) Hz were measured. Preliminary data analysis suggested that neostigmine reduced F2 amplitude, and that tropicamide had little effect. A trend across drugs suggested that F1 amplitude was directly related to pupil diameter at certain spatial frequencies. Further studies should increase the available sample sizes and examine the influences of contrast and luminance.

BACKGROUND WHITE NOISE ALTERS FLASH EVOKED POTENTIALS (FEPs) IN RATS. D.W. Herr[1,2], D. King*[3], W.P. Watkinson[1], W.K. Boyes[1], and R.S. Dyer[1]. [1]US EPA, RTP, NC 27711 and [3]METI, RTP, NC, 27709.

We are examining how test procedures alter FEPs, and have found changes with daily testing, stimulus intensity, and within a test session (Dyer, R.S., Physiol. Behav., 45:355-362, 1989; Herr et. al., Physiol. Behav., 49:355-365, 1991; Herr et al., Soc. Neurosci. Abst., 16:570, 1990). We now report the impact of a non-visual stimulus on FEPs. Long-Evans rats were implanted with epidural electrodes over the visual cortex and subcutaneous ECG electrodes over the dorsal chest areas. Motor activity levels were recorded from the rectified and integrated signal on an exposed headset lead. Sequential 50 trial averages and test days were within-subject factors. On each of 9 days, 350 flashes/day (0.3 Hz) were presented. White noise (80 dB(A)) was presented either over trials 201-350 on day 9, over trials 1-350 on day 9, or over trials 1-350 on days 1-9. The presence of noise increased peak P_{21} and N_{70} amplitudes. When presented over trials 1-350, peak P_{63} and P_{90} amplitudes decreased. Peak N_{160} amplitude decreased initially, then increased, when noise was presented to naive subjects on day 9. Noise presentation over trials 201-350 decreased peak P_{63} latency. Motor activity was briefly increased and heart rate was not altered by noise. The data provide further evidence that non-visual variables play a role in modulating FEPs. Most of these effects appear unrelated to noise-induced effects on motor activity. **[2]DWH was supported by a NRC Research Associateship.**

CORRELATIONS of EEG and VEP SCOPOLAMINE EFFECTS in HUMANS. W.G.SANNITA.Center for neuroactive drugs, Institute of Neurophysiopathology, University; Center for cerebral neurophysiology, CNR, Genova,16132 Italy.

Acute 0.25-0.75 mg im scopolamine reduced the amplitude of flash-evoked cortical potentials (VEP) (P2-N2 waves) and quantitative background electroencephalogram (EEG) in healthy humans. These effects were parallel in the 0-120 min postdrug time on-going and both related to dose; VEP/EEG correlation was across doses, within-dose correlation was restricted to 0.75 mg administration. Pattern-VEP were unaffected. To remove the EEG effect on flash/pattern-VEP amplitude nonlinear regression vs the EEG total power was computed and VEP residuals from the regression function were re-tested.Flash-VEP residuals replicated the original data as to post-drug timing and relation to dose while pattern-VEP were unchanged by this data processing.The results suggest the indipendence of scopolamine induced flash-VEP changes from those on background EEG signal.The effects of stimulus physical characteristics are to be considered to generalize the results in human neuropharmacology.Quantitative EEG monitoring in VEP drug studies allows inference with respect to the CNS activation levels and assessment of CNS drug effects on VEP and EEG variables unrelated to each other is praticable whenever interferences are excluded.

625.10

BARBITURATE SENSITIVE COMPONENTS OF VISUAL ERPs IN A REPTILE J. C. Prechtl and T.H. Bullock. Dept. of Neurosciences & Neurobiology Unit, Scripps Institution of Oceanography, UCSD, La Jolla, CA 92093-0201.

Barbiturate sensitivity was used to compare different components of visual evoked (VEPs) and omitted stimulus potentials (OSPs) recorded with electrode arrays in the optic tectum (OT), dorsal cortex (DC) and dorsal ventricular ridge (DVR) of pond turtles (*Pseudemys scripta*).

For every 60 s of the baseline and treatment (Na^+ methohexital, 13 mg/kg i-p) periods, 2 s segments of EEG were sampled (pass band 0.1-75 Hz) as well as: the rested VEP to a single flash, the 5 Hz frequency following response (FFR), and the OSP that follows the first missing flash after 10 s conditioning with 10 Hz flashing. The minute-by-minute sampling continued until recovery of the OSP. The diffused flashes were delivered through closed eyelids and under a constant background illumination of ca. 2 lux. Epochs containing movement artifacts were rejected and consecutive 7 min averages were examined for short-lived effects. Longer averages based on 20 epochs were used for comparing baseline and treatment periods.

The OSP (OT, DVR and DC) is particularly sensitive to barbiturate and is reversibly abolished while the first wave of the VEPs in the DC or DVR (110-120 ms) were reduced by only 34 ± 9%. At the same time (OSP abolished) the earliest wave of the tectal VEP (55-65 ms) was increased by 79 ± 21% and its larger wave at 110-120 ms was unchanged or slightly reduced (-15 ± 6%). The abolition of the OSP correlates with the loss of late VEP components in both the forebrain (200-500 ms) and tectum (140-350 ms), and with a decline or loss of the 5 Hz FFR. Notable is the quicker loss and slower recovery of the tectal than the cerebral OSP.

The barbiturate sensitivity of the late VEP components is similar to that reported in the mammalian literature and the sensitivity of the OSP underscores its endogenous nature and its independence in the tectum and the cerebrum.

INTRACEREBRAL LHRH RELIEVES MATING BEHAVIOR DEFICITS CAUSED BY VOMERONASAL LESIONS: LHRH ANALOGS MAY EXERT AN EXTRA-PITUITARY EFFECT ON MATING BEHAVIOR IN MALE HAMSTERS. G.Fernandez*, G. Howard* and M. Meredith. Program in Psychobiology & Neuroscience., Dept. Biol. Sci., Florida State Univ., Tallahassee, FL.

Vomeronasal organ (VNO) sensory input is followed by the release of LHRH, which facilitates mating behavior in rodents of both sexes. Previous results (Meredith et al, Chem Sens 15:619) suggest that exogenous intracerebral LHRH might "substitute" for VNO input in sexually inexperienced male hamsters with mating behavior deficits following VNO removal (VNX). In the present experiments we used prepubertal VNO removal (17 days) and explored other routes of peptide delivery. Behavioral restoration by intracerebral LHRH was confirmed in VNX animals. LHRH, saline or an LHRH analog (NAL- GLU or Ac-LHRH 5-10) was injected (2ul) intracerebrally into the lateral ventricles of VNX or intact (CON) animals. Mating behavior was tested 30 min after injection and investigation time, mounts, thrusts and intromissions were recorded. VNX animals, compared to controls significantly increased mating behavior ($p<0.05$) after LHRH (50ng). Subcutaneous (500ng) or intranasal (10ug) injection had no significant effect. NAL- GLU, a potent antagonist of pituitary LH release and Ac-LHRH 5-10, a fragment of LHRH that has no effect on pituitary LH release, both appeared to significantly facilitate mating behavior in both VNX and CON animals ($p<0.02$) suggesting that analogs effective in facilitating mating behavior may act via receptors other than the pituitary type.

626.2

SPATIO-TEMPORAL CHARACTERIZATION OF FACILITATED OPTICAL RESPONSES DURING PAIRED ORTHODROMIC STIMULI IN THE SALAMANDER OLFACTORY BULB. A.R. Cinelli and J.S. Kauer, Neuroscience Program, Tufts/NEMC, Boston, MA 02111.

Response suppression and facilitation have been reported in orthodromic optical responses using paired stimuli. The presence of suppression or facilitation depends in the stimulus intensity as well as in the condition/test (c/t) intervals. In the present study, the spatio/temporal properties of the signals were studied by video imaging voltage-sensitive dye responses, after orthodromic electric stimulation of the olfactory nerve or of peripherial nerve fascicles. Low intensity stimulation which submaximally activates the olfactory bulb was necessary for the response facilitation. In addition, low temperature could enhance the size, duration and spatial distribution of these facilitated test responses. Depending on the intensity and c/t interval, different sectors in the same layer were selectively facilitated. Sectors which exhibited short latency responses were facilitated at short c/t intervals and sectors which exhibited longer latencies at longer c/t intervals. Stimulation of particular regions of the mucosa evoked facilitated responses in different sectors of the olfactory bulb, depending on the c/t interval. The selective enhancement of activity in a particular sector reduced the activity in other adyacent locations. These data suggest a widespread, non-homogeneous, pattern of activation of the olfactory bulb with a modular-like organization. Futhermore, the spatial distribution of activity in the bulb is influenced by spatial as well as temporal patterns of activity in the olfactory epithelium.

ROLE OF STIMULATION FREQUENCY IN THE INDUCTION OF SELECTIVE LONG-TERM POTENTIATION IN THE PIRIFORM CORTEX. M. P. Galupo and J. S. Stripling. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Repeated high-frequency stimulation of the granule cell layer of the olfactory bulb (OB) induces a long-term potentiation (LTP) in the piriform cortex (PC) that is selective to late components of the evoked potential (Stripling, Patneau, and Gramlich, Brain Res. 542: 107-122, 1991). In previous research we have typically induced selective LTP by stimulating the OB with trains of 10 pulses delivered at a frequency of 100 Hz. In the present experiment we examined the ability of 10-pulse trains varying in frequency from 5 to 400 Hz to induce selective LTP in the PC. Male Long-Evans rats with chronically implanted electrodes received one LTP treatment per day for 4 consecutive days. Each LTP treatment consisted of thirty 10-pulse trains applied to the granule cell layer of the OB at 5 sec intervals. Eight groups of animals received stimulation that differed only in the frequency of pulses within each train, which varied from 5 to 400 Hz. Animals receiving stimulation frequencies of 5 or 10 Hz failed to potentiate. In contrast, selective LTP was produced in animals receiving stimulation at frequencies of 25 to 400 Hz, with no significant differences within this frequency range. Examination of potentials evoked by the potentiating stimulation indicates that LTP is induced only by frequencies at which there is temporal overlap of the potentials evoked by each stimulus pulse. Previous research has demonstrated that afferent stimulation evokes an NMDA-mediated potential in hippocampal slices only at stimulation frequencies comparable to those that produced LTP in the present study (Collingridge, Herron, and Lester, J. Physiol. 399: 301-312, 1988). These observations are consistent with the involvement of NMDA receptors in selective LTP in the PC. Supported by NSF grant BNS 85-19700 and the Marie Wilson Howells Fund.

626.4

ALTERED RESPONSE TO PAIRED-PULSE STIMULATION FOLLOWING INDUCTION OF SELECTIVE LONG-TERM POTENTIATION IN THE PIRIFORM CORTEX. J. S. Stripling, D. K. Patneau, and M. P. Galupo. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Stimulation of the olfactory bulb (OB) or lateral olfactory tract (LOT) evokes a potential in the piriform cortex (PC) whose initial component (A_1) represents monosynaptic activation of PC pyramidal cells by the LOT. In a naive animal, paired-pulse stimulation produces potentiation of A_1 due to Ca^{++} accumulation in presynaptic terminals. Repeated high-frequency stimulation of the granule cell layer of the OB induces a long-term potentiation (LTP) selective to late components of the evoked potential (Stripling, Patneau, and Gramlich, Brain Res. 542: 107-122, 1991). Although selective LTP leaves the expression of A_1 unaltered following single-pulse stimulation, paired-pulse stimulation causes a depression rather than a potentiation of A_1 (Stripling, Patneau, and Gramlich, Brain Res. 441: 281-291, 1988). This effect was investigated in male Long-Evans rats with chronically implanted electrodes by testing with paired-pulse stimulation before and after the induction of selective LTP. High frequency stimulation of the OB produced selective LTP and paired-pulse depression of A_1, while high-frequency stimulation of the LOT produced neither effect. Paired-pulse stimulation that caused depression of A_1 also depressed the pre-synaptic volley in the LOT. Even non-potentiated animals showed paired-pulse depression rather than potentiation of A_1 if very short inter-pulse intervals were used. Taken together, these results suggest that paired-pulse depression of A_1 following selective LTP is due to an enhancement of evoked inhibitory responses in the OB, resulting in activation of fewer mitral cells by the second pulse. This interpretation is consistent with previous evidence that selective LTP produces an enhancement of functional inhibition within the OB and PC. Supported by NSF grant BNS 85-19700 and the Marie Wilson Howells Fund.

CORTICOFUGAL INFLUENCE ON TASTE RESPONSES IN THE NUCLEUS OF THE SOLITARY TRACT OF THE RAT. S. Monroe and P.M. Di Lorenzo Dept. of Psychology,SUNY at Binghamton,Binghamton, NY 13902.

To investigate the influence of the forebrain on the neural code for gustation in the brainstem, the effects of reversible lesions of the gustatory neocortex (GN) on taste responses in the nucleus of the solitary tract (NTS) were studied in rats. Initially, taste-responsive NTS neurons were classified as "relay" or "non-relay" units based on the evoked response to electrical stimulation of the taste-responsive portion of the parabrachial pons. Electrophysiological responses to taste stimuli bathed over the tongue were then recorded before, after and following recovery from an infusion of procaine (10% in saline, 1 µl over 2 min) into the ipsilateral GN. Presentation of taste stimuli was then repeated in the same unit before, after and following recovery from a contralateral GN procaine infusion. Test stimuli consisted of sapid solutions of NaCl (.1 M), HCl (.01 M), quinine-HCl (.01 M), sucrose (.5 M) and Na-saccharin, (.004 M). Of 43 taste-responsive NTS units that were recorded in this paradigm, 12 units were identified as relay units and 13 were identified as non-relay units. Taste responses in 32 (74%) NTS units were different following procaine infusions into at least one side of the GN. These changes most often took the form of stimulus-specific enhancement or attenuation of the response to one or more taste stimuli within a given unit. The across unit pattern of response for NaCl in relay units, and for sucrose in non-relay units was altered following ipsilateral, but not contalateral, GN procaine infusions. These results point to the possibility that information about taste that enters the NTS may be affected by the GN differently according to where it will be relayed. This distinction may have important functional correlates.

TASTE NEURONS OF THE HAMSTER SOLITARY NUCLEUS: VARIATION IN IMPULSE RATE AND AMPLITUDE. T.P. Hettinger*, L.D. Savoy* and M.E. Frank. Dept. of BioStructure & Function, Univ. of CT Health Center, Farmington, CT 06030.

In extracellular recordings of taste-responsive neurons of the solitary nucleus (SN) of the golden hamster (Mesocricetus auratus), neurons differ in their stimulus profiles, latencies and interspike interval patterns. We have found that some SN neurons also show variation in impulse rate and amplitude. We recorded single-unit activity of SN neurons responding to anterior tongue stimulation, using micropipettes with 1-2 µm tips filled with 4% HRP and 0.5 M KCl in tris buffer, pH 7.6. Recording sites identified by HRP injections were located within the central and lateral subdivisions of the rostral SN, regions containing elongate, stellate and tufted cells and the preponderance of chorda tympani (CT) afferent endings. Neurons responding maximally to 0.1 M sucrose typically displayed bursting patterns of impulses, with as many as 20 impulses per burst. Bursting responses to sucrose have been found also in CT neurons. At high instantaneous rates (greater than 100 Hz), sucrose-responsive SN neurons often showed serial attenuation of amplitude within each burst, in some cases near to the point of extinction. Impulse attenuation has not been observed in CT fiber recordings. SN neurons responding maximally to 0.03 M NaCl or 0.1 M KCl did not generally show bursting or spike attenuation. The unique pattern of impulse rate and amplitude variation seen in sucrose-sensitive SN taste neurons probably reflects the incoming afferent signals and the integrative properties of the impulse generating sites, and may be important for the coding of sweet taste. NIH grant DC00853.

626.7

INTERSPIKE INTERVAL PATTERNS OF TASTE-RESPONSIVE NEURONS OF THE NUCLEUS OF THE SOLITARY TRACT: SIMULATIONS AND SPECIFIC AFFERENT INFLUENCES. S.C. Nuding and M.E. Frank. Center for Neurological Sciences and Dept. of BioStructure and Function, UCONN Health Center, Farmington, CT 06030.

Taste-responsive neurons in the nucleus of the solitary tract (SN) of the golden hamster (*Mesocricetus auratus*) generate two distinct interspike interval (ISI) patterns: simple unimodal ISI patterns and complex multimodal ISI patterns. We attempted to simulate simple and complex ISI patterns with computer-generated spike trains, using a random number generating function to place spikes in 1-ms bins. First approximations of simple ISI patterns were obtained with samples at one (eg. 2.5 hz) response rate, but complex ISI patterns required samples of at least two independent rates (eg. 2.5 hz, 50 hz). More exact simulation of neural responses may require consideration of refractory periods. We also attempted to restrict the afferent input to SN neurons with the sodium-channel blocker, amiloride. Amiloride can completely inhibit the NaCl responses of one class of afferents in hamsters (Hettinger and Frank, 1990). Response rates of some SN neurons to lingual application of 0.03 M NaCl are also much reduced by 0.01 mM amiloride and the two peaks in complex ISI patterns may be affected differently. As amiloride affects the perceptual quality of salts, ISI patterns could contribute to the code for taste quality. Supported by NIH grant DC00853.

EFFECTS OF DEPHASING OLFACTORY INPUT FROM RESPIRATORY CYCLE ON FIRING PROPERTIES OF OLFACTORY BULB NEURONS. E. Sobel and D.W. Tank. Biophysics Research Dept., AT&T Bell Laboratories, Murray Hill, NJ 07974

Single unit studies have demonstrated that mitral cells in the mammalian olfactory bulb can change the temporal structure of action potential firing in response to olfactory input without changing mean firing rate. Under natural breathing, the action potentials "bunch", becoming more frequent during the inspiratory phase and less frequent during the expiratory phase. There is uncertainty over the relative contributions to this phenomenon from, 1) the phasic nature of the olfactory stimulation and, 2) centrifugal control, synchronized to the respiratory rhythm.

To examine this issue, we have developed an experimental preparation that provides cyclical olfactory stimulation synchronized in frequency to the natural respiratory rhythm, but shifted in phase. We have examined the respiratory patterning of olfactory bulb unit activity while altering the relative phase of odor stimulation and the natural breathing cycle in anaesthetized rats.

Preliminary results suggest that the relative phase of on-going tracheal breathing does not affect the single unit activity evoked by phasic stimulation of the olfactory epithelium. Consequently, action potential "bunching" appears to be produced by the phasic nature of the stimulation and the inherent dynamics of the circuitry of the olfactory bulb.

CHANGES IN INFORMATION FLOW IN DISSOCIATED MOUSE OLFACTORY BULB CELL CULTURES J. Weil and S.P.Fracek Jr. Department of Biological Sciences and Center for Network Neuroscience, University of North Texas, Denton, TX 76203.

Bursting dominates the spontaneous electrophysiological activity of neural networks formed from cultured, dissociated mouse olfactory bulb cells. Measurements of various burst characteristics (e.g. duration, interval, period) are assumed to be a finite first order Markov chain (considering the relation of a burst X_n to the following burst X_{n+1}). A transition matrix is collected and the average stored information (ASI) is calculated using methods outlined by Shaw (The Dripping Faucet as a Model Chaotic System, Santa Cruz, CA: Aeriel Press, 1986). ASI is a map from a data set to a real number representing the complexity of the network activity. When used in conjunction with power spectra and phase space reconstructions, this measure helps to present a more complete quantification of the states occupied by the neural network. Spontaneous bursting activity is typically ergodic and thus creates information. This information can be stored for at least 5-10 measurements into the future. Some aspects of bursting activity can be viewed as the function of a dynamical system. GABAergic circuits may function as a control parameter, which can be modulated by bicuculline. As the concentration of bicuculline is increased, the ASI decreases, implying that the bursting activity is storing less and less information. This stored information is propagated less than three measurements into the future at high concentrations of bicuculline. These bicuculline effects are reversible. ASI compares favorably to the Lyapunov characteristic exponent in the case of the logistic equation. Generalization to higher dimensions (multiple burst characteristics) and consideration of higher order Markov processes are planned. Potentially ASI may be used to identify functional subpopulations of cells, which may correspond to the various cell types found in the bulb.

LIMITS AND INFORMATION PROCESSING REQUIREMENTS IN OLFACTORY DISCRIMINATION. W. T. Nickell. Dept. of Anat. and Cell Biol., U. of Cincinnati Coll. of Med., Cincinnati, OH 45267.

In analogy with color vision and taste, it is a plausible hypothesis that the sensory quality of an odor is composed of a number of "primary odors." In the olfactory system the "primary odors" might be defined by the response properties of each of an unknown number of different classes of receptor neuron. If the response of each of the receptor classes to a particular odor can be described by a single numerical parameter, then the list of these numbers identifies the odor. It is therefore of interest to explore the limits and information processing requirements inherent in discrimination among odors specified in this way. We have approached this question by analysis of a simple model system. In this model an "odor" is simulated by a sequence of randomly generated numbers representing the responses of the receptor classes to the odor. A large number of these "odors" is then generated and stored as a table. The behavioral task of odor recognition is simulated by determining whether a matching procedure (linear correlation) can select the correct match between an arbitrarily selected test odor and the corresponding entry in the table. Numerical simulation and analysis demonstrate that, when the number of stored odors is plausibly large, reliable detection of a match requires many classes of receptor neurons. *Supported by NIDCD DC00347 and DAMD 86-C-6005.*

RAT PUPS CAN ACQUIRE NEUROBEHAVIORAL RESPONSES TO MORE THAN ONE ODOR. O. Carmi and M. Leon. Department of Psychobiology, University of California, Irvine, CA 92717.

Exposure of rat pups to an odor during postnatal days (PND) 1-18 with concurrent tactile stimulation results in an olfactory preference. This odor preference appears to correspond with physiological, anatomical and neurochemical changes in the olfactory bulb. Since previous studies of this phenomenon used only one odor, we considered the possibility that the neurobehavioral consequences of preference training was limited to a single olfactory cue. Therefore, we determined whether rat pups would develop neural and behavioral changes after training with two odors. During PND 1-18, all animals were exposed for 10 min/day to an odor while receiving perineal stimulation to peppermint odor only, orange odor only, or peppermint and orange odors on alternate days. On PND 19, the pups were tested for a behavioral preference between either: (1) orange and air, (2) peppermint and air, or (3) peppermint and orange. Neural activity in response to either odor was examined in other pups by assessing 14C-2-deoxyglucose (2-DG) uptake in the olfactory bulb.

Pups trained with only one odor had an olfactory preference only to that odor relative to either air or novel odor. However, pups trained with both odors developed preferences to both odors relative to air and showed an equal preference for the two odors when allowed to chose between them. The preferred odors also elicited changes in the uptake of 2-DG in the olfactory bulb glomerular foci. The data suggest that early experience with more than one odor can successfully induce behavioral preferences and neural changes in the olfactory bulb.

MODULATION OF OLFACTORY HABITUATION IN INFANT RATS BY A DEPRIVATION SENSITIVE NORADRENERGIC MECHANISM. C.M. Anderson, C.D. Kilts, G.L. Miller and W.G. Hall. Depts of Psychology, Pharmacology and Psychiatry, Duke University, Durham, NC 27706.

Deprivation of nutrients and maternal care affects activity and reactivity of infant rats (pups) and may decrease habituation to novel odors. Related to this deprivation effect is the finding of increases in noradrenaline (NA) turnover in the olfactory bulbs (OB's) of adult rats which is implicated in decreasing habituation to meaningful odors (Dluzen & Ramirez, 1989). To quantify deprivation-mediated influences on odor habituation, we compared the ability of 12-day old rat pups to habituate to 15 presentations of a novel odor after 8-hr nutrient deprivation (**FOSTER**), 8-hr deprivation of nutrients and maternal care (**TOTAL**), or no deprivation (**CONTROL**). In addition, NA turnover was estimated by assaying OB's of pups from the same conditions for [MHPG], the primary metabolite in rodent brain of NA. **TOTAL** pups exhibited more orienting in the first 3 blocks (3 trials/block) than **FOSTER** pups and more orienting than **CONTROL** pups in the 2nd and 3rd blocks. Overall, **TOTAL** pups oriented more than **FOSTER** pups in 4 out of 5 blocks and more than **CONTROL** pups in 3 out of 5 blocks. Matching the deprivation-induced changes seen in olfactory orienting were changes in [MHPG] in the OB's of individual pups from the same conditions; i.e., [MHPG] was only elevated in the OB's of **TOTAL** pups. **FOSTER** pups were not different from **CONTROL**s. In summary, the **TOTAL** pups were slower to habituate to a novel odor than **FOSTER** or **CONTROL** pups. MHPG is increased in **TOTAL** pups, but not in the other groups, suggesting that increased NA turnover may play a role in modulation of odor habituation at the level of the OB. *Supported by NICHD (HD17458).*

MICROSTRUCTURAL ANALYSIS OF INCENTIVE CONTRAST. P.S. Grigson, A.C. Spector[1], and R. Norgren. Dept. of Behavioral Science, College of Medicine, Pennsylvania State University, Hershey, PA 17033 and Dept. of Psychology[1], Univ. of Florida, Gainesville, FA 32611

Free-feeding and deprived rats were given 5 min access either to 0.1M sucrose for 14 days or to 1.0M sucrose for 10 days and then switched to 0.1M sucrose for 4 additional days. Subsequently, the deprivation conditions were reversed and the experiment was repeated. Free-feeding rats consumed less than deprived rats, but both groups licked more for 1.0M than for 0.1M sucrose. In addition, following reward downshift, both groups demonstrated an equivalent contrast effect, i.e. they licked significantly less 0.1M sucrose than did the unshifted controls. The microstructural analysis, however, revealed that the deprived and free-feeding rats achieved these similar shifts in overall lick frequency by altering different parameters of the behavior. For deprived subjects, both the concentration effect and the contrast effect were manifested by changes in the number of licks per burst, the burst duration, and the interburst interval. For free-feeding animals, both effects were accounted for solely by a change in interburst interval. The neural basis for these effects of reward shift are unknown, but a preliminary investigation suggests that the pontine parabrachial nucleus may play a role. OPTICAL IMAGING OF CEREBELLAR AFFERENTS IN THE ISOLATED TURTLE CEREBELLUM. S.A. ELIAS, T.J. EBNER, C. NICHOLSON. DEPTS. NEUROSURGERY & PHYSIOLOGY, UNIV. MINNESOTA, MINNEAPOLIS, MN 55455 AND DEPT. PHYSIOLOGY & BIOPHYSICS, NYU MEDICAL CTR., NEW YORK, NY 10016.

The flat, non-foliated cerebellum of the turtle is superior to its highly convoluted mammalian counterpart for mapping afferent pathway distribution. Using optical recordings with a voltage-sensitive dye we observed the spatial patterns evoked by peduncular stimulation. Turtles were quickly decapitated and the entire cerebellum and peduncles removed. The tissue was stained with RH 795 for 30 minutes then placed, ventral side up, in a recording chamber below an epifluorescent microscope and imaged with a Photometrics CCD (14 bit A/D, 576X384 pixels). Stimulation of a peduncle with a tungsten microelectrode evoked a depolarizing optical signal that formed a narrow bundle, < 400 μm in width, which extended sagittally 4-5 mm from the electrode. Simultaneously recorded electrical field potentials were consistent with the image. The optical signal was recorded at various depths by changing the focus of the microscope. Signals were small (~ 0.02% change in fluorescence with a 2.5X, 0.08 n.a. objective) but reproducible and consistent. Supported by NIH Grants NS-27210 (TJE) and NS-13742 (CN).

DEBLURRING OF SERIALLY SECTIONED IMAGES OF THE OPTICALLY RECORDED PARALLEL FIBER BEAM IN THE RAT CEREBELLAR CORTEX *IN VIVO*. H. YAE*, S.A. ELIAS, T.J. EBNER. Depts. of Neurosurgery and Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

Serially sectioned images of neuronal activity detected with voltage sensitive dyes contain significant amounts of out-of-focus information. We have used a deblurring algorithm to improve the spatial patterns of neuronal activity in the X-Y plane. Rats were anesthetized with ketamine/xylazine, the cerebellar cortex exposed, placed beneath an epifluorescent microscope (6.3 X 0.20 n.a.) and stained with the dye RH 795. A parallel fiber beam was evoked with a tungsten microelectrode. A series of images were taken with a Photometrics CCD camera, at 25μm increments of focus from the cortical surface to 350μm. Prior to deblurring, the depolarizing optical signal for the beam was observed throughout the entire depth series. However, depth profiles of evoked field potentials confined the Purkinje cell EPSP to a narrower range of depths, 50-75μm in extent. Application of the deblurring algorithm to this series of images restricted the appearance of the optical signal to the levels where the EPSP was recorded. Outside this range, the deblurred optical signals from the beam were absent. The net affect of the deblurring is to reduce the effective depth of field of the objective lens and reduce artifacts due to light scatter within the tissue. This method of restoration is a necessary prerequisite for three-dimensional analysis and rendering. Supported by NIH Grant #RO1-NS-27210.

DEVELOPMENT, PHARMACOLOGY, DISTRIBUTION, AND CELLULAR LOCALIZATION OF $GABA_B$ BINDING IN RAT CEREBELLUM. SM Turgeon, RL Albin, and S Gilman. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, Michigan 48109.

Receptor autoradiography using [3H] GABA under selective conditions was used to characterize the development, pharmacology, distribution, and cellular localization of $GABA_B$ binding sites in the rat cerebellum. Binding is greater in the molecular layer (ML) than in the granular cell layer at all ages and reached adult levels by postnatal day (PND) 14. A pattern of parasagittal zonation was observed in the ML of lobules IV-IX in adult rats. Transient expression of high levels of $GABA_B$ binding was observed in the deep cerebellar nuclei, peaking at PND 7 and decreasing to adult levels by PND 28. Drugs active at the $GABA_B$ binding site displaced [3H]GABA with the following order of potency: 3-APA >S-AVA = saclofen = 2-hydroxysaclofen > phaclofen. GTP-γ-S and GDP-β-S inhibited [3H]GABA binding in a dose dependent manner. The cellular localization of $GABA_B$ binding was investigated using lesion techniques. Neither MAM nor 3-AP lesions resulted in a decrease in [3H]GABA binding. Homozygote stumbler mutants, deficient in Purkinje cell dendrites, had a significant decrease in [3H]GABA binding in the ML. These results suggest that the majority of $GABA_B$ binding sites in the ML are located on Purkinje cell dendrites. Supported by NS 19613, NS 01300, MH 14279.

EXCITATORY AND INHIBITORY AMINO ACID BINDING SITES IN HUMAN DENTATE NUCLEUS. R.L. Albin, R.H. Price*, S.Y. Sakurai, J.B. Penney, and A.B. Young. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI 48104-1687.

We used receptor autoradiography to study the distribution of excitatory and inhibitory amino acid binding sites in human dentate nuclei. There was no binding to N-methyl-D-aspartate (NMDA) or $GABA_B$ binding sites, and there was a low level of kainate binding sites. α-Amino-3-hydroxy-5-methylisoxazole-4-propionic acid, metabotropic-quisqualate, benzodiazepine, and $GABA_A$ binding sites were present in moderate abundance. Our NMDA results are different than those found previously in rodents. $GABA_A$ receptors are probably the primary mediators of inhibitory neurotransmission within the deep cerebellar nuclei while α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid and metabotropic-quisqualate receptors are probably the primary mediators of excitatory neurotransmission within the human deep cerebellar nuclei. *Supported by USPHS grants NS01300, NS15655, NS19613, and AG 08671.*

627.5

CHANGES IN GAD IMMUNOREACTIVITY IN THE DEEP CEREBELLAR NUCLEI OF GENETICALLY DYSTONIC (*dt*) RATS AND RATS WITH 3-ACETYLPYRIDINE LESIONS. J. Lutes*, J.F. Lorden*, and B. Davis**. Dept. Psych.* and Dept. Cell Biol.**, UAB, Birmingham, AL 35294.

Both *dt* rats and rats with 3-acetylpyridine (3AP) lesions of the inferior olive display an increase in deep cerebellar nuclei (DCN) glutamate decarboxylase (GAD) activity. GAD, the synthetic enzyme for GABA, is located primarily in Purkinje cell terminals. In 3AP rats, increased DCN GAD activity coincides with increased Purkinje cell activity, following destruction of the climbing fibers. The *dt* rats, however, show lower than normal Purkinje cell activity. Immunocytochemistry was used to determine whether *dt* and 3AP rats showed different patterns of GAD distribution in the DCN. The size and density of GAD+ puncta were examined in three groups of 20-day-old rats: *dt*, normal saline-treated, and normal rats given 3AP (65 mg/kg) at 18 days of age. Separate groups of 3AP and saline controls were also examined at 14 days postinjection. An increase in the size of DCN GAD+ puncta in comparison with normal rats was seen only in the 3AP group at 2 days postinjection when GABA levels, as measured by HPLC, were also increased in the 3AP group only. Increases in puncta size were no longer present at 14 days postlesion, when GAD activity is still elevated but Purkinje cell activity has declined. Puncta density was reduced in the *dt* rats only. Other studies show that GAD activity remains elevated in 3AP rats after Purkinje cell activity declines. The *dt* rats resemble 3AP rats following extended survival. In both cases, increased GAD activity may represent a persistent change initiated by elevated Purkinje cell activity and may be related to a shift in the form and function of GAD that predominates in Purkinje cells at different times. RELATIVELY SMALL NUMBERS OF PONTOCEREBELLAR AXONS PROVIDE COLLATERALS TO THE CEREBELLAR NUCLEI. G. A. Mihailoff, Dept. of Anatomy, University of Mississippi Medical Center, Jackson, MS 39216.

An issue that continues to be relevant to motor control studies is the question of whether information being transferred from sensorimotor cerebral cortex to the cerebellar cortex via the basilar pontine nuclei (BPN) is also distributed to the cerebellar nuclei (CN) through pontocerebellar axon collaterals. There is little data in the literature to support such a connection, yet schematic diagrams depicting cerebrocerebellar communication often include such circuitry. As an extension of ongoing research in our laboratory focused on the structure and function of the BPN, we have undertaken a study of this question using the orthograde axonal transport of the lectin *Phaseolus vulgaris* leucoagglutinin (PHAL). Long-Evans rats received electrophoretic or pressure injections of 2.5% PHAL into the BPN or nucleus reticularis tegmenti pontis (NRTP). After a survival period ranging from 5-19 days, rats were sacrificed and sections of the cerebellum reacted for the presence of PHAL using a biotin-avidin immunocytochemical procedure. Our observations indicate that only a small number of pontocerebellar axons give rise to collaterals that terminate in the CN, and of those that do so, the majority arise from NRTP and not the BPN. Accumulations of labeled fibers and terminals are found in the ventral and lateral portions of the lateral cerebellar nucleus, the posterior interpositus nucleus, and portions of the medial cerebellar nucleus. These findings suggest that sensorimotor cortical information does not have a relatively direct route to the CN but rather is transmitted to the CN after passage through the cerebellar cortex. Although other precerebellar nuclei such as the lateral reticular nucleus receive sensorimotor cortical projections, such projections are far less substantial than that received by the BPN and it is unlikely that these nuclei represent a major link between the cerebral cortex and CN. *Supported by USPHS grant NS12644.*

627.7

CORTICONUCLEAR AND -VESTIBULAR PROJECTION ZONES CORRESPOND TO ZEBRIN-POSITIVE AND -NEGATIVE ZONES IN ANTERIOR VERMIS OF RAT CEREBELLUM. J.Voogd (1),L.M.Eisenman (2), T.J.H. Ruigrok (1)*. Depts. of Anatomy Erasmus University Rotterdam 3000 DR The Netherlands (1) and Jefferson Med. Coll. Jefferson University Philadelphia PA 19107 (2).

Purkinje (P) cells with projections to vestibular nuclei are located in lateral A (A2) and B zones of anterior vermis (Voogd et al.,Arch.Ital.Biol.129:3'91). A2 borders on B in lobules I-III, but in IV-VI they are separated by the X zone which projects to the junction of the fastigial (F) and posterior interposed (IP) nuclei (Voogd, Exp.Brain Res.Ser 17:3'89). This zonal arrangement was compared to the compartmentalization for zebrin (Hawkes and Leclerc,J.Comp.Neurol.256:29'86) in the cerebellar cortex of the rat. Pcells were retrogradely labeled with WGA-HRP from injections in Deiters' and the F and IP nuclei. Cobalt-stabilized HRP reaction product and immunoreactivity for zebrin I were visualized in the same sections. Vestibular Pcells in the anterior vermis are exclusively zebrin-negative. HRP-labelled cells of the B zone correspond to the zebrin-negative N2 zone of Hawkes and Leclerc, A2 cells occupy the lateral part of N1. A2 is separated from the rest of N1 by a strip zebrin-positive Pcells in IV-VI. Pcells of the zebrin-positive P2 zone correspond to the X zone and can be labelled from F/IP. In lobule VIII the labelling is shifted laterally with respect to Hawkes and Leclerc's nomenclature with vestibular Pcells in N2 and N3 and F/IPcells in P3.

BRANCHING IN THE ROSTROCAUDAL AXIS WITHIN THE PROJECTION FROM THE INFERIOR OLIVE TO THE C_1 ZONE OF THE CAT CEREBELLUM. R. Apps* and J. R. Trott*. (SPON: Brain Research Association) Dept. of Physiology, School of Medical Sciences, University Walk, University of Bristol, Bristol, UK, BS8 1TD.

We have used a combined physiological and retrograde fluorescent technique to investigate the extent to which olive cells branch in the rostrocaudal axis to innervate the c_1 zone in the anterior (lobule V) and posterior (paramedian lobule, PML) lobes of the cat paravermal cerebellum.

Under full pentobarbitone anaesthesia (n=4 cats) the c_1 zone was identified physiologically at the two rostrocaudal levels. At each site injections of either rhodamine- or coumarin- tagged latex microspheres (Lumafluor) were made (total volume at each site 250-600 nl). After 4-5 days survival the cerebellum and brainstem were removed, cut at 50 and 30 µm respectively, and the distribution of retrogradely labelled cells within the contralateral inferior olive was plotted. Cells double-labelled (DL) ie. that have axons which branch to terminate within the c_1 zone in both lobule V and PML, were consistently located in a caudomedial to rostrolateral column within the Dorsal Accessory Olive (AP levels 12.00 to 10.25).

On average, DL cells represented 14% and 24% respectively of the total number of cells labelled from lobule V or PML injections. This contrasts to a previous study of branching in the mediolateral plane between the x and lateral c_1 zones (Apps, Trott and Dietrichs 1991, Exp. Brain Res., in press), in which olive cells that innervated both zones represented only 5-7% of either single-labelled population.

These results suggest that branching in the olivocerebellar projection is, on occasion, more extensive in the rostrocaudal than in the mediolateral axis.

THREE-DIMENSIONAL VISUALIZATION OF THE INTERNAL MEMBRANE SYSTEM OF AVIAN PURKINJE CELL DENDRITES M. E. Martone, Y. Zhang*, V. M. Simpliciano*, B. O. Carragher* and M. H. Ellisman. San Diego Microscopy and Imaging Resource, Department of Neurosciences, University of California, San Diego, La Jolla, Calif. 92093-0608.

In a previous study from this laboratory, two proteins involved in intracellular calcium regulation, the IP3 receptor and the ryanodine receptor, were found to have distinct but partially overlapping distributions within cerebellar Purkinje cells. While the IP3 receptor was localized to the smooth endoplasmic reticulum (SER) in the cell body, dendritic shaft and dendritic spines, the ryanodine receptor was restricted to the SER in the cell body and dendritic shaft. Here, we employ 3-D computer reconstruction and high voltage electron microscopic (HVEM) techniques to determine whether the differential distribution of these proteins is due to the presence of physically separate SER networks within the dendrites of Purkinje cells.

Three-dimensional reconstructions were obtained from serial sections of chick cerebellum. Contours representing the SER and plasma membrane were traced and digitized for each individual section following which a tiling algorithm was used to fit a surface to these structures. The reconstructed region could then be inspected using a viewing program which allows for interactive modification of transformation parameters and image attributes. A second approach involves a volumetric analysis of selectively stained membrane systems viewed in thick sections with HVEM. A study is now underway to obtain volumetric reconstructions from both serial sections and tomographic reconstructions of single axis tilt series.

Preliminary results show that the SER forms a complex network of cisterns and tubules throughout the Purkinje cell dendrite. As noted previously (Harris et al., J. Neurosci., 8:4455, 1988), the SER of the spine shaft was found to be in continuity with the SER of the main dendrite. In most cases, the SER of the spine appeared to emanate from the hypolemmal cisternal system which, in turn, was continuous with the SER in the interior of the dendrite. These observations suggest that the IP3 receptor and the ryanodine receptor are present on a continuous SER network.

CEREBELLAR PROJECTIONS TO SPINAL MOTONEURONS. J.J. Smith*, A.R. Gibson, K.M. Horn and P.L.E. van Kan. Barrow Neurological Institute, Phoenix, AZ 85013

Intermediate cerebellum projects to the spinal cord via connections to magnocellular red nucleus. Rubrospinal terminals lie largely in lamina VII, but some lie among C8-T1 motoneurons serving distal limb musculature. Do other motoneuronal pools have specific relations with cerebellar output?

We first investigated spinal projections of the lateral vestibular nucleus, which receives afferents from the B zone of cerebellar cortex and medial nucleus. WGA-HRP injections in lvn produced heavy label among motoneurons supplying the neck and intraspinal muscles. Some lateral pools such as those innervating trapezius were conspicuously devoid of label. Therefore, the B zone and parts of the medial nucleus selectively target neck and intraspinal motoneurons via lvn.

Determining cerebellar relations with motoneurons serving proximal limb musculature has been more difficult. A large injection into the medullary reticular formation that produced heavy retrograde label throughout the cerebellar medial nucleus did not label terminals among proximal limb motoneuronal pools. A small injection placed in the biceps motoneuron pool at C6 failed to identify any brainstem area as a major source of input. However, the reticular injection resulted in heavy anterograde label in C3-C4 propriospinal neurons, which were also retrogradely labeled by the C6 injection. We are now investigating the possibility that medial nucleus targets proximal limb musculature via connections through brainstem reticular and C3-C4 propriospinal neurons.

SPATIAL ORGANIZATION OF SPINOCEREBELLAR INPUT TO THE UNFOLDED CEREBELLAR ANTERIOR LOBE. D.L. Tolbert, K. Yates-Siilata and B.R. Clark. Departments of Anatomy and Neurobiology and Surgery (Neurosurgery), St. Louis Univ. Sch. of Med. and Program in Physical Therapy, Washington Univ. Sch. of Med., St. Louis, MO

Lower thoracic-upper lumbar (LTUL) projections to the cerebellar anterior lobe were studied in adult rats using WGA-HRP orthograde labeling techniques and image analysis software (Bioquant) that graphically unfolds the cortex while maintaining spatial relationships between identified spinocerebellar (SpCb) mossy fiber terminals and the overlying surface. Small injections restricted to approximately one LTUL segment labeled SpCb terminals located mainly near the junctions of lobules I-II, II-III, and III-IV. Computer reconstruction showed that these terminals formed medial-lateral oriented bands that extended from midline though intermediate regions but not into lateral areas of these lobules. Fewer terminals were distributed in other areas of these lobules and in lobule V. WGA-HRP injections into two adjoining LTUL segments labeled greater numbers of terminals in the medial-lateral oriented bands at the junction of lobules I through IV and more terminals in superficial parts of the lobules. Computer reconstructions suggest two levels of organization of adjoining segmental input to the anterior lobe. First, in each lobule SpCb terminals form two to three medial-lateral oriented bands separated by well circumscribed similarly oriented terminal free areas. Along the medial-lateral bands the number of terminals was not uniform, rather alternating high and lower densities of terminals existed. These high and lower terminal densities were respectively aligned anterior-posteriorly forming a secondary pattern of organization of sagittally oriented stripes. Supported by NIH grant NS20227.

PRELIMINARY CHARACTERIZATION OF A MODEL OF HEREDITARY PURKINJE CELL-INFERIOR OLIVARY DEGENERATION IN RATS. K. Yates-Siilata, M.G. La Regina, L. Woods, T. Pittman, and D.L. Tolbert. Depts. Anatomy and Neurobiology, Comparative Medicine, and Surgery (Neurosurgery). St. Louis Univ. Sch. of Med., St. Louis, MO

The cerebellum and brainstem of adolescent and young adult Sprague-Dawley rats from a colony which spontaneously displays abnormal motor signs characterized by ataxia, wide-based hindlimb posture, and dorsal arching of the tail (shaker rats) were studied by light microscopy. The histological organization of the cerebellar anterior lobe cortex was dramatically altered in shaker rats, due to the complete absence of Purkinje cells (PCs) and shrinkage of the molecular layer. These changes were not as dramatic in the posterior lobe. Along the PC monolayer some cells have degenerated but immediately adjacent PCs persisted. The overall number of surviving PCs increased from anterior (VI) to posterior (IX). The cerebella from shaker rats were analyzed morphometrically and the findings compared with data from similar measurements in age and weight matched controls. The total area of the midline cerebellum from shaker rats was 39% smaller than in controls. When analyzed separately the shaker anterior lobes were 50% smaller than controls. The largest percentage decrease in area occurred in the molecular layer and the white matter.

Brainstem pontine, lateral reticular and inferior olivary precerebellar nuclei were examined in the shaker rats. The only apparent neurohistological alterations were localized to the inferior olivary nuclei where almost all neurons had degenerated. This animal model of hereditary PC-inferior olivary degeneration warrants futher study because of similarities with human cerebellar disease states. Supported by NIH grant NS20227.

CALCITONIN GENE-RELATED PEPTIDE IN THE CAT'S CEREBELLUM. GEORGIA A. BISHOP Dept. of Cell Biology, Neurobiology and Anatomy and Neuroscience Program, The Ohio State University, Columbus, OH 43210

In the present study the distribution, origin and physiological effects of calcitonin gene related peptide (CGRP) were analyzed in the cat's cerebellum. The PAP technique revealed that CGRP-immunoreactivity (IR) is present in profiles that have morphological characteristics of mossy fibers. These CGRP-IR mossy fibers have a heterogeneous distribution. In the vermis, the densest distribution is in lobules VII, VIII and the dorsal folia of IX. In anterior vermal lobules only scattered fibers, located primarily at the apex of the folia, are present. Laterally, CGRP-IR mossy fibers are located in the paramedian lobule, paraflocculus and crus II. No CGRP-IR mossy fibers are present in lobule X or the flocculus. Our distribution data are in partial agreement with the findings of Sugimoto et al (Brain Res. 439:147, 1988) who described CGRP-IR mossy fibers and granule cells. Whereas CGRP positive mossy fibers were identified in the present study, no CGRP-IR granule cells or parallel fibers were evident. A double label technique revealed that CGRP-IR mossy fibers arise from neurons located in the lateral reticular nucleus, external cuneate nucleus, inferior vestibular nucleus and basilar pons. Physiologically, CGRP has a weak suppressive effect on spontaneous activity in most Purkinje cells. In addition, this peptide decreases the level of the cell's excitatory response to simultaneous application of glutamate or aspartate. Occasionally, CGRP increased neuronal excitability. Taken together, these data indicate that there is a chemically and physiologically distinct population of mossy fibers that arises from specific precerebellar nuclei. Functionally, CGRP likely modulates Purkinje cell activity in restricted regions of the cerebellar cortex by altering the responsiveness of these cells to the excitatory amino acids glutamate and aspartate. (Supported by NS18028).

5-HT IN THE CAT'S CEREBELLAR CORTEX: ULTRASTRUCTURAL ANALYSIS AND IDENTIFICATION OF RECEPTORS. C.W. Kerr, Y.F. Chen, J.S. King and G.A. Bishop Dept. of Cell Biology, Neurobiology and Anatomy and Neuroscience Program, The Ohio State University, Columbus, OH 43210

Serotoninergic neurons in the caudal reticular formation project to the cat's cerebellar cortex and terminate as a beaded fiber plexus in the granule and Purkinje cell layers (JCN, 304:502, 1991). Ultrastructural analysis revealed serotonin-immunoreactive (5-HT-IR) profiles approximating the dendrites and somata of granule cells as well as the somata of a few Purkinje cells. In addition, 5-HT-IR fibers contributed to the formation of the mossy fiber glomerulus. To date however, no conclusive synaptic specializations have been observed. Functionally, 5-HT potently reduces the firing rate of spontaneously active Purkinje cells as well as activity induced by the application of glutamate or aspartate, the putative neurotransmitters of mossy and climbing fibers, respectively. 5-HT also potentiates the inhibitory effects of GABA. In addition to decreasing Purkinje cell firing rate, 5-HT increases the interval between firing bursts in approximately 45% of the tested cells. Iontophoretic application of the 5-HT_{1A} agonist, 8-OH-DPAT, mimicks the suppressive action of 5-HT in a dose-dependent manner. This response, as well as the 5-HT mediated suppression are blocked by application of spiperone a 5-HT_{1A} antagonist. Compounds selective for the 5-$HT_{1C,2}$ and $_3$ receptors are physiologically ineffective. Preliminary experiments have demonstrated that the 5-HT_{1B} selective agent, TFMPP, may act as a partial agonist when compared with the actions of 5-HT. The present data are in agreement with previous studies in the rat cerebellar cortex which reported that selective activation of the 5-HT_{1A} receptor replicates the 5-HT-mediated suppression of Purkinje cell activity (Neurosci. Abst., 15:406, 1990). However, our study did not find evidence for the functional presence of the 5-HT_2 receptor, a putative heteroreceptor on glutaminergic neurons in the rodent cerebellar cortex (Br.J.Pharm., 82:271, 1984). In summary, 5-HT may mediate its suppressive effects on Purkinje cell firing through non-junctional transmission and subsequent activation of 5-HT_{1A} receptors in the cat's cerebellar cortex. (Supported by NS 18028).

627.15

DO TRANSIENT CLIMBING FIBERS PROVIDE A TEMPLATE FOR THE SAGITTAL ORGANIZATION OF MOSSY FIBERS? J.S. King and G.A. Bishop Dept. of Cell Biology, Neurobiology and Anatomy and Neuroscience Program, The Ohio State University, Columbus, OH 43210.

The PAP method was used to detect cholecystokinin (CCK) in the developing cerebellum of the opossum. In the adult, CCK immunoreactivity is present almost exclusively in mossy fibers (King & Bishop,'90,JCN 298:373). During development, CCK-positive fibers are present in the cerebellar peduncle by postnatal day (PD) 1, where they wait and then penetrate the cerebellar anlage on PD 7. The early arriving fibers remain in the medullary core of the cerebellum until PD 26. At that time, in the anterior lobe vermis, some CCK-positive puncta organize in four sagittal bands which overlie populations of Purkinje (PK) cells; at this stage of development PK cells are in a layer 4-5 cells deep. Most of these immunoreactive elements are transient as they do not persist beyond PD 68. A population of inferior olivary neurons also transiently expresses CCK during this time interval. Prior to the disappearance of these transient elements and subsequent to granule cell migration sagittal bands of CCK puncta develop in the internal granule cell layer immediately below the transient sagittal bands in the PK cell layer. In contrast, in other areas of the vermis and hemispheres CCK positive fibers do not penetrate the PK cell layer. Rather, they remain in the medullary core of the cerebellum until the internal granule cell layer (IGL) can be differentiated histologically (PD 33); coincident with this developmental event CCK axons grow into the IGL. Arsenio-Nunes et al. ('88,JCN 273:120)) have suggested a primary role for the Purkinje cell in organizing spinocerebellar afferents, as spinal axons (mossy fibers) are arrayed in sagittal bands in the vermis even in the absence of their target cell (the granule cell). Our findings provide additional morphological evidence to support an organizational role for populations of Purkinje cells in the anterior lobe and their associated climbing fibers in the subsequent development of sagittal bands of mossy fibers; they are likely derived from the external cuneate or lateral reticular nuclei (King and Bishop, 90). However, in other areas of the vermis and hemispheres additional cues important for target recognition and afferent organization must be present. (Supported by NS 08798).

627.16

ACTIVITY-DEPENDENT EXPRESSION OF CRF IN THE OLIVO-CEREBELLAR AXIS. S.L. Cummings, G.P. Chrousos, and W. S. Young, III. U. C. Davis, CA, DEB/NICHD and LCB/NIMH, Bethesda, MD

Corticotropin releasing factor (CRF) is widely distributed within brainstem-cerebellar climbing and mossy fiber afferents, and has been demonstrated to modulate the physiological effects of aspartate, glutamate, and GABA in the cat cerebellum. CRF potentiates the excitatory effects of aspartate and glutamate on Purkinje cell firing, and does so in a dose-dependent manner. In addition, CRF overcomes the supressive effects of GABA on aspartate and glutamate induced-activity in the cerebellar cortex (Cummings, Bishop and King, Anat. Rec. (1990) 226:294A; Bishop, Neurosci. (1990) 39:251). Results of studies utilizing in situ hybridization histochemistry and radioimmunoassay now indicate that CRF expression within the olivocerebellar axis is altered by electrophysiologically- and pharmacologically- induced activity, in paradigms known to synchronously activate the GABA-containing Purkinje cells and deep cerebellar nuclei. CRF mRNA and CRF are increased in the inferior olivary complex (IOC), and CRF is depleted from the cerebellar cortex of the cat in response to 6 hr of electrophysiological stimulation of the IOC (0.1mA, 0.1ms at 1 Hz), stimulation of the dorsal column afferent projection to the IOC with equivalent parameters, or 6 hr after administration of the tremor-inducing ß-carboline harmaline (10mg/kg, i.p.). Following harmaline treatment, increased CRF hybridization signal is evident in the dorsal and medial accessory olives and in areas of the IOC thought previously to be unresponsive to harmaline. No difference existed between CRF levels in the vermis as compared to the hemispheres in normal or experimental animals. Results of these studies support suggestions that CRF-coded circuits function in motor responses generated via the olivocerebellar axis.

CHOLINERGIC AND CRF-CONTAINING NEURONS IN VESTIBULAR NUCLEI AND RELATED CELL GROUPS PROVIDE CEREBELLAR MOSSY FIBER PROJECTIONS.

M. Ikeda, T. Houtani*, T. Ueyama and T. Sugimoto.
Dept. of Anatomy, Kansai Medical Univ., Osaka 570, Japan.

By avidin-biotin peroxidase immunohistochemistry, choline acetyltransferase (ChAT) and corticotropin-releasing factor (CRF) were examined in cat vestibular nuclei and related cell groups. Surgery was conducted on adult cats under general anesthesia with intraperitoneal pentobarbital (40 mg/kg). Alternate sections from colchicine-treated cats stained for ChAT or CRF revealed a similar but different localization of ChAT neurons and CRF neurons in the medial and descending vestibular nuclei, prepositus hypoglossi, intercalatus and solitary nuclei, nucleus of Roller and cell groups f, x and z. ChAT neurons predominated in the caudal half of the medial and descending vestibular nuclei while CRF neurons concentrated in their rostral half; ChAT and CRF did not show colocalization in these neurons. In the cerebellum ChAT- and CRF-positive mossy fibers and rosettes were observed in many cortical areas which receive vestibular projections. Following unilateral destruction of vestibular nuclei, these mossy fiber elements were largely decreased ipsilaterally while CRF-positive climbing fibers remained unchanged. Following WGA-HRP injections in the vermal lobules I, II, IX and X, most of the ChAT and CRF neurons in the vestibular area were retrogradely labeled by the tracer. The results suggest that the vestibular area contains two independent populations of vestibulocerebellar projection neurons chemically coded by ChAT and CRF.

628.1

GLUTAMIC ACID DECARBOXYLASE (GAD) ACTIVITY AND mRNA LEVELS IN CEREBELLAR PURKINJE CELLS AFTER CHANGES IN CELL FIRING. J. Litwak*, Z. Yin*, M. Beales* and G. A. Oltmans. Dept. of Pharm. and Mol. Biol., Chicago Med. Sch., N. Chicago, IL 60064

The neurotoxin 3-acetylpyridine (3-AP) destroys the climbing fiber input to the cerebellar cortex, abolishing Purkinje cell (PC) complex spike (CS) activity and increasing simple spike (SS) activity (+100%). The SS activity returns to pre-lesion levels over a 30 day period, while GAD activity in PC terminals gradually increases, remaining elevated up to 45 days post-lesion. GAD is the synthetic enzyme for GABA, the PC neurotransmitter, and the increase in GAD activity presumably reflects increased GABA utilization as a consequence of increased SS activity. In contrast, the drug harmaline activates climbing fibers, increasing the low frequency CS activity (+10-fold) and strongly inhibiting SS activity. This produces a decline in overall PC activity, and should reduce GABA demand and, subsequently, GAD activity. In the current study, the effects of prolonged climbing fiber stimulation on PC GAD activity were measured. In addition, in situ hybridization was used to establish the time course for GAD mRNA induction after lesion-induced increases in PC firing.

Rats were administered a single injection of 3-AP (70 mg/kg) or six injections of harmaline (20 mg/kg/4h) or saline. Animals administered 3-AP were euthanized 1, 3, 7 and 30 days post-lesion, and those given harmaline after 24 h. GAD mRNA and GAD activity were measured in PC bodies, or terminal areas in the deep cerebellar nuclei (DCN), respectively. In climbing fiber-lesioned animals GAD mRNA levels in PC bodies were significantly increased at 1 (+38%), 3 (+42%), 7 (+42%), and 30 (+22%) days post-lesion. In harmaline-treated subjects GAD activity was significantly decreased in the medial (-29%), and interpositus (-20%) subdivisions of the DCN. These results suggest that decreases in overall cell firing (harmaline treatment) reduce GAD activity in PC terminals, while increases in firing (3-AP treatment) increase both GAD mRNA levels and GAD activity in these cells. The effects of harmaline on PC GAD mRNA levels are currently being studied. (Supported in part by the Dystonia Medical Research Foundation)

QUIPAZINE HAS DIFFERENTIAL ELECTROPHYSIOLOGICAL EFFECTS IN THE DEEP CEREBELLAR NUCLEI OF DEVELOPING NORMAL AND GENETICALLY DYSTONIC RATS. V.L. Michela and J.F. Lorden. Dept. Psych., Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Systemic administration of the serotonin (5-HT) agonist quipazine produces an 18 Hz forepaw tremor in newborn rats. The effect declines to negligible levels by postnatal day 16 in normal rats but persists indefinitely in the genetically dystonic rat (dt), a mutant that shows a movement disorder appearing around postnatal days 9-10. Since quipazine acts on the olivo-cerebellar pathway, extracellular recordings were made of the Purkinje cells in the cerebellar vermis of rats aged 16-25 days, both before and after treatment with quipazine. Significant increases in complex spikes and decreases in simple spikes were observed only in the mutant rats. Although the enhanced sensitivity of Purkinje cells in dt rats paralleled the behavioral sensitivity of the mutants, the magnitude of the change appeared insufficient to explain the observed tremor. When the experiment was repeated in the deep cerebellar nuclei (DCN), quipazine induced significant increases in firing rate and rhythmicity of cells in normal rats, suggesting that quipazine can act directly on serotonin receptors in the DCN. In dt rats, the spontaneous firing rate and rhythmicity of DCN cells were significantly greater than in normal rats. Quipazine increased firing rate in dt rats, however, unlike cells in normal rats, cells in dt rats either showed no change in rhythmicity or showed increases that greatly exceeded those seen in controls. The tremor may result from activity in a subset of DCN neurons in the mutant rats. (Supported by a grant from the Dystonia Medical Research Foundation and grant BNS 90-10187 from NSF.)

ACUTE UNILATERAL SENSORIMOTOR CORTEX INJURY IN RATS BLOCKS d-AMPHETAMINE INDUCED NOREPINEPHRINE RELEASE IN CEREBELLUM. L.B. Goldstein* and V. MacMillan. V.A & Duke Medical Centers, Durham, NC 27705

Pharmacologic studies have implicated norepinephrine (NE) in amphetamine-facilitated motor recovery following sensorimotor cortex (SMC) injury in rats. We studied the acute effects of unilateral SMC ablation on the release of NE in cerebellum with in vivo microdialysis. Diasylate samples were collected in 10 min. fractions and NE assayed by HPLC-ECD. All studies were carried out in anesthetized rats.

Baseline levels of NE were undetectable in the cerebellar diasylate. The administration of a single dose of d-amphetamine (2.6 mg/kg base weight, i.p.) resulted in a significant increase in dialyzable NE reaching its peak 30 min. later (~15 pg/µl, not corrected for recovery). However, the administration of the same dose of d-amphetamine to naive rats 60 min. following a suction-ablation lesion of the right SMC did not result in NE release into the cerebellar diasylate.

This data provides evidence for an acute remote effect of SMC injury on amphetamine-induced NE release in the cerebellum (diaschisis). Experiments are in progress to establish the duration of this effect.

TRIPHASIC GABA RESPONSES RECORDED FROM PURKINJE CELL DENDRITES IN THE RABBIT CEREBELLAR SLICE. B. G. Schreurs, J. V. Sanchez-Andres, and D. L. Alkon. Neural Systems Section, NINDS, NIH, Bethesda, MD 20892.

Gamma-aminobutyric acid (GABA) has been shown to elicit triphasic neuronal responses in a number of mammalian CNS locations including the somatosensory cortex and the primary visual cortex. We report a triphasic GABA response recorded intradendritically from Purkinje cells (n=50) in vermal slices of the rabbit cerebellar cortex.

Focal pressure applications of GABA (2 mM, 50-500 ms) to the Purkinje cell layer of a rabbit cerebellar slice produced a three-phase response consisting of (1) rapid hyperpolarization ($GABA_{hf}$); (2) slower depolarization ($GABA_d$); and (3) later long-lasting hyperpolarization ($GABA_{hl}$). The three phases were associated with varying increases in membrane conductance. Elicitation of the triphasic response in the presence of TTX confirmed that it was intrinsic to the recorded cell.

Bath application of $GABA_A$ antagonists (bicuculline or picrotoxin) eliminated $GABA_d$ and $GABA_{hl}$ while leaving $GABA_{hf}$ intact, suggesting that $GABA_{hf}$ was mediated by bicuculline-insensitive or possibly $GABA_B$ receptors whereas the $GABA_d$ and $GABA_{hl}$ response were mediated by $GABA_A$ receptors. Previous immunohistochemical evidence for the predominance of $GABA_A$ receptors in the Purkinje-cell dendrites and $GABA_B$ receptors at the cell body suggests that the present triphasic response arose from distinct compartments of the Purkinje cell. This hypothesis was supported by our observation that somatic spikes failed to occur despite the fact that membrane potentials during $GABA_d$ exceeded the threshold for passive propagation of somatic spikes to the recording site.

IMAGING OF REGIONAL VARIATIONS OF ELECTRICALLY EVOKED SODIUM INFLUX IN CEREBELLAR PURKINJE CELLS. N. Lasser-Ross and W.N. Ross, Dept. of Physiology, New York Medical College, Valhalla, NY 10595.

We used the fluorescent sodium indicator SBFI to monitor changes in $[Na]_i$ associated with intrasomatically and synaptically stimulated events. Neurons in sagittal slices from the guinea pig cerebellum were injected with the impermeant form of the dye with an electrode also used for stimulating and recording. Changes in fluorescence, excited at 380 nm, were recorded with a high speed CCD camera.

Intrasomatically evoked bursts of fast action potentials caused an increase in $[Na]_i$ limited to the soma and axon. The optical signal was proportional to the number of fast action potentials. The change in $[Na]_i$ (measured by $\Delta F/F$) was much larger, and the recovery time much faster ($\tau_{\frac{1}{2}} < 1$ sec), in the axon than in the soma. The larger surface to volume ratio in the axon is probably one factor determining these differences. There was no detectable change in $[Na]_i$ in the dendrites corresponding to either Na or Ca dependent action potentials. The lack of signal also shows that SBFI was not responding to changes in $[K]_i$.

Climbing Fiber activation caused a small change in $[Na]_i$ in the lower part of the dendritic tree. The signals showed paired pulse depression consistent with whole cell voltage clamp recordings (Konnerth et al., PNAS 87, p.2662-2665 (1990)). Therefore, these synaptic signals probably reflect Na entry through ligand gated channels.

INTRINSIC DETERMINANTS OF DENDRITIC CALCIUM INFLUX IN TURTLE PURKINJE CELLS IN VITRO. J. Midtgaard, N. Lasser-Ross & W.N. Ross. Institute of Neurophysiology, Univ. of Copenhagen, DK-2200 Copenhagen N, Denmark and Dept. of Physiology, New York Medical College, Valhalla, NY 10595.

In order to determine the significance of active membrane properties in synaptic integration simultaneous electrical and optical recordings were made from Fura-2 injected Purkinje cells in slices from the turtle (Pseudemys scripta elegans) cerebellum. Fluorescence changes were imaged with a high speed CCD camera. Voltage dependent Ca influx in the soma was mostly correlated with fast, TTX-sensitive spikes. Ca transients in the spiny dendrites were correlated with calcium spikes and had much faster rise and fall times. In some cases the locations of Ca influx varied from spike to spike implying localized and varied spiking in the dendrites. In these aspects turtle Purkinje cells resemble guinea-pig Purkinje cells. When an external electric field was applied across the cerebellum Ca spikes were evoked with Ca influx confined to the tips of the spiny dendrites demonstrating that very localized firing can take place in the spiny dendrites. Both PF and CF stimulation evoked voltage dependent Ca influx. The distribution and amplitude of synaptically evoked Ca influx was dramatically affected by a 4-AP sensitive A-like potassium conductance (Chan, Hounsgaard & Midtgaard, J.Physiol. 409, 143-156, 1989).

ELECTROPHYSIOLOGICAL PROPERTIES OF IDENTIFIED GRANULE CELLS. C. Huang, C.-F. Hsiao and R. Huang*. School of Basic Life Sciences, Univ. Missouri-Kansas City, Kansas City, MO 64110

The cerebellar granule cells provide important sources of excitation for all cell types in the cerebellar cortex. Yet the electrophysiological properties of granule cells remained poorly known. Indeed, it was unclear whether the somata of mature granule cells possess the necessary combination of ion channels to generate conventional action potentials. We have recorded single granule cells intracellularly followed by horseradish peroxidase (HRP) injection in cats under chloralose anesthesia (70mg/Kg). The site of recording and injection was confirmed to be at the soma of the injected granule cell. The resting membrane potential was -43.5±6.7mV (n=31). The action potentials were 7.7±2.6mV extracellularly and 53.4±15.8mV intracellularly (n=22). Among the 31 granule cells, 26 responded to sound (60dB above threshold) with average latencies at 24.9±8.2ms while 17 responded to light with longer average latencies at 53.0±11.0ms. Five granule cells, however, did not respond to either sound or light. The mean inter-spike interval of granule cells was 152.7±68.8ms (n=21). (Supported by PHS grant AA07643).

CONTROL OF POSTURE AND MOVEMENT V

629.1

A NEURAL NETWORK FOR LEARNING MUSCLE COORDINATION J.B.J. Smeets*, and J.J. Denier van der Gon*, Utrechts Biofysica Instituut, University of Utrecht, Princetonplein 5, Utrecht, The Netherlands. (SPON: European Neuroscience Association).

In the human arm, there are more muscle pairs than degrees of freedom. To make a specific movement, the nervous system has ample choice from combinations of muscle activations. We present a neural network model which learns, unsupervised, from afferent signals to coordinate muscles in a realistic way.

The model consists of a planar arm with two joints, controlled by four mono-articular and two bi-articular muscles. As a substitute for a homogeneously innervated motoneuron pool we used one motoneuron. A pooled Ia-afferent signals muscle stretch. An array of central neurons innervates the motoneurons. Movements are generated by the activation of abutting central neurons. All central neurons and all afferents are connected to all motoneurons. The weights of these connections are adapted during centrally induced movements of the arm, using only information present at the location of that neuron. Simulations start with poor coordination: each central neuron has only one non-zero connection with a motoneuron.

The resulting coordination of the muscles conforms to experimental data on muscle activation. Furthermore, the model predicts homonymous and heteronymous monosynaptic reflexes in a realistic way, for instance a heteronymous reflex in the mono-articular elbow flexor when shoulder-flexors are stretched.

629.2

THE RELATIONSHIP BETWEEN LATERAL DOMINANCE AND TURNING PREFERENCE ON THE STEPPING TEST. Fred H. Previc and Joanna Saucedo*. Armstrong Laboratory, Brooks AFB, Tx 78235-5000.

Previous research has shown a relationship between handedness and the direction of turning during Fukuda's stepping test. This study attempted to correlate directional preference on the stepping test with several measures of lateral dominance, including handedness. A total of 111 students from a local high school participated as subjects. The vast majority of subjects (89%) were right-handed, while a smaller percentage (59%) were right-footed and right-eyed. Subjects performed the stepping test with their vision occluded and their arms folded in front of them, and their angular rotation during a 1-min interval was measured. Although only a slight majority of subjects turned rightward, the direction and magnitude of turning correlated significantly with footedness and eyedness (but not handedness). For example, 60% of right-footed and right-eyed subjects turned rightward, whereas less than 40% of subjects with left and mixed preferences did so. The results indicate that axial turning preferences and various lateral dominance tendencies may at least partially share a common mechanism, possibly involving the vestibular system.

629.3

EFFECTS OF DORSAL ROOT CUT ON FORCES EVOKED BY SPINAL STIMULATION IN SPINALIZED FROGS. E.P. Loeb, S.F. Giszter, E. Bizzi, and F.A. Mussa-Ivaldi* Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Recent experiments in spinal frogs have shown that focal microstimulation of a single site in the lumbar grey, in conjunction with positioning the leg in different workspace locations, results in the generation of a force field with a single equilibrium point. The equilibrium point is that spatial location at which the leg would be at steady state were it free to move. The force fields are produced by spinal circuits and modulated by afferent feedback. The purpose of this work was to investigate the contribution of afferent feedback to the force fields. We measured the force fields before and after cutting the dorsal roots without moving the stimulating electrode. After cutting the dorsal roots we found that the current threshold required to induce a force field was temporarily elevated, and when induced the dynamics of the rise and fall of the force traces was altered. This suggests a role for afferent activity in the maintenance of spinal circuit excitability, and shaping of the force fields. We will present a quantitative analysis of the effects of the dorsal root cuts on the shape of the force traces.

DISCRIMINATING AMONG RHYTHMICAL BEHAVIORS IN THE CHICK. R. M. Johnston, S.M. Woolley, M.B. Smith and A. Bekoff. Dept. of E.P.O. Biology, University of Colorado, Boulder, CO 80309-0334.

Our intent in this study was to quantify the degree of relatedness among different rhythmical hindlimb behaviors using discriminant function analysis. We chose to compare the kinematic profiles of five behaviors: walking, swimming, airstepping, foot shaking and head scratching. The following results do not yet include head scratching.

Small dots of black ink placed on the skin overlying the lateral surface of the right hindlimb were used to define the hindlimb and the hip, knee and ankle joints. Video recordings were made as chicks produced one of the five behaviors being examined. The hindlimb movements were digitized and we quantified several features of intra- and interjoint coordination patterns. Discriminate function analyses were performed on groups of non-complementary variables using a cross validation approach for behavioral classifications.

Our results show that functions based on the actual time (ms) of kinematic features discriminate unilateral foot shaking from the three bilateral behaviors. We conclude that this separation corresponds to a cycle duration constraint between unilateral (max $\leq$ 150 ms) and bilateral behaviors (min $\geq$ 150 ms). When variables were expressed as a proportion of their cycle durations, converting real time to relative time, functions discriminate walking, which involves weight support, from the other three behaviors which lack weight support. When walking is removed from these analyses relative latencies and not relative durations discriminate among the remaining three closely related behaviors. These results suggest that the behavioral implications of weight support are dramatic and that discrimination among the more closely related behaviors may reflect different interjoint coordination patterns in each behavior. By establishing the relatedness among diverse behaviors we provide the foundation for interpreting the differences in the motor patterns underlying these behaviors. Supported by NIH grant NS20310.

WAVEFORMS AS A MEASURE OF CHANGES IN EMG ACTIVITY. J.A. Hodgson*, R.R. Roy, C.P. de Guzman*, R. de Leon*, R.J. Prober*, A.J. Garfinkel and V.R. Edgerton, Dept. of Kinesiology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1527.

Fluctuations in the amplitude of the EMG envelope throughout a step cycle have been reported for some muscles and it appears that the rectified and smoothed EMGs reflect the frequency of discharge of motor units in a muscle (Hoffer et al., J. Neurophysiol. 57:530, 1987). Thus EMG waveforms can be interpreted to be indicative of the patterns of activation experienced by motoneuron populations. We have computed averaged EMG waveforms for several muscles in normal and spinal cats and normal rats walking on a treadmill over several speeds. It was found that the speed of locomotion, level of loading and selected neuropharmacological agonists and antagonists had unique and repeatable effects on the waveforms of some muscles. These changes in waveform were restricted to only one part of a burst in some muscles (soleus, medial gastrocnemius, tibialis anterior). In muscles exhibiting two bursts per step cycle (vastus lateralis, rectus femoris), these interventions often affected only one burst. These waveform modifications may reflect changes in timing (soleus) or amplitude (tibialis anterior) or both (medial gastrocnemius, vastus lateralis, rectus femoris). These results indicate that the timing and amplitude of EMGs may be controlled separately and that the mechanisms contributing to the timing or amplitude of a burst pattern may change throughout the duration of the burst. The extent to which the unique waveforms which characterize each motor pool output during locomotion reflect central pattern generation versus supraspinal and/or sensory feedback can be defined. For example, the EMG waveforms executed during carefully controlled locomotor tasks can be compared with the efferent output of the surgically isolated spinal cord during fictive locomotion. *Supported by NIH Grant NS16333.*

EFFECTS OF LOW THORACIC SPINALIZATION ON EMG OF ADULT CATS. D.J. Pierotti, R.R. Roy, J.A. Hodgson*, R. Prober*, C.P. de Guzman*, R. de Leon* and V.R. Edgerton. Brain Research Institute and Kinesiology Department, UCLA, L.A., CA 90024-1527.

The hindlimbs of adult spinal cats (T12-T13) can be induced to step on a treadmill and daily training can improve this locomotor capability (Lovely et al., Exp. Neurol. 92:421, 1986; Barbeau and Rossignol, Brain Res. 412:84, 1987). Although the general pattern of EMG bursts of selected extensors and flexors appear to be similar in spinal and intact cats, some effects of spinalization are evident. In the present study, the EMG patterns were studied in the same cat during quadrupedal and bipedal stepping and during bipedal stepping at 1 and 2 months postspinalization. EMG recording electrodes were implanted in the soleus (Sol), medial gastrocnemius (MG), tibialis anterior (TA), vastus lateralis (VL), semitendinosus (St), gluteus medius (GM) and iliopsoas (IP) as described by Pierotti et al. (Brain Res. 481:57, 1989). Treadmill training was initiated within 1 week postspinalization in contrast to our previous studies where training was initiated after 1 month. Some differences in the EMG waveforms during quadrupedal and bipedal walking were evident. The general features of the EMG waveforms recorded postspinalization were remarkably similar to those recorded bipedally before spinalization. In contrast to previous studies, clonus was absent in the cats in which training was initiated 1 week after spinalization. The major effect on burst patterns was an increased amplitude of the EMG in primary flexors (TA, IP, St), but not primary extensors (Sol, MG, VL, GM). After spinalization, a double burst occurred in the St, with the initial burst doubling in amplitude compared to prespinalization. In addition, the GM, IP and MG had less distinct bursts 1 month after, than before spinalization. Normal waveforms were reestablished by 2 months postspinalization. These data indicate that, with the exception of the St, the EMG patterns of activation of each of the hip, knee and ankle muscles studied in normal cats can be reestablished following spinalization by appropriate locomotor training techniques.

PHARMACOLOGICAL EFFECTS ON EMG ACTIVITY OF HINDLIMB FLEXORS AND EXTENSORS IN ADULT SPINAL CATS. C.P. de Guzman*, J.A. Hodgson*, R.R. Roy, R. de Leon*, R.J. Prober*, S.C. Bodine-Fowler and V.R. Edgerton, Dept. of Kinesiology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1527.

Two adult cats underwent different training regimens following spinalization (T12-T13). One was trained to walk on a treadmill at varying speeds (0.2-1.0 m/s) and the other was trained to stand for 30 min/day, 5 days/week. Once the locomotor performance had reached a plateau, the effects of i.p. administration of several pharmacological agonists and antagonists of neurotransmitters and modulators were tested during treadmill locomotion. The EMG activity of hindlimb flexors and extensors, i.e. semitendinosus (St), vastus lateralis, gluteus medius, iliopsoas, soleus (Sol), medial gastrocnemius (MG) and tibialis anterior during stable treadmill stepping over a range of speeds before and after administration of each drug was studied. The cat trained to stand was unable to step when first tested. One of the most dramatic pharmacological effects was the initiation of full-weight supporting stepping after the administration of 0.02 mg/kg of strychnine (specific binding to glycine receptors). On two subsequent occasions, the administration of strychnine (0.02-0.06 mg/kg) also improved locomotion dramatically. Similar doses of strychnine had minimal effects on the locomotor behavior of the cat that was already trained to walk. A dosage of 150 or 300 *ug*/kg of clonidine had no noticeable effect on locomotion prespinalization. In the cat trained to walk, clonidine (60 *ug*/kg) increased the EMG burst amplitude and duration of the St during stepping and restored the waveform to its appearance before transection. Clonidine also increased the amplitude of the Sol, but not the MG. These data show that the effects of selected neuromodulators and neurotransmitters can be very specific to selected motor pools and even to selected segments of the burst pattern of a single muscle during stepping. *Supported by NIH Grant NS16333.*

PERCEPTUAL AND NYSTAGMIC RESPONSES TO BODY TURNING: SOMATOSENSORY AND MOTOR INFLUENCES. P. DiZio, J. R. Lackner, J. Segal*. Ashton Graybiel Spatial Orientation Laboratory, Brandeis University, Waltham, MA 02254.

Somatosensory and motor inputs from active stepping in a circle elicit compensatory nystagmus with a gradual rise in slow phase velocity (SPV) in normal individuals. We simultaneously assessed in seated subjects how nystagmus and perceived self-motion (PSM) are influenced by pedalling or dragging movements of the feet.

Subjects (N=10) sat in a rotating chair in darkness and were turned for 60 s at 90 deg/s. They either sat passively, dragged their feet, or pedalled in time with the chair's motion the whole time, or began dragging or pedalling after 45 s when vestibular nystagmus and PSM had decayed. Eye position and PSM were continuously measured during and after rotation.

Relative to the passive conditions, SPV and PSM decayed more slowly (sometimes not at all for PSM) in the dragging and pedalling conditions. When dragging or pedalling commenced after vestibular nystagmus and PSM had decayed, PSM returned immediately but SPV showed no significant increment. Neither the initial SPV of post-rotary nystagmus nor its decay rate depended on the prior conditions, but PSM either decayed quicker or failed to reverse following active pedalling as compared to passive turning.

THE BACKDRIVING ALGORITHM FOR THE CONTROL OF REDUNDANT MOTOR SYSTEMS: ANALYSIS AND PREDICTIONS. J. McIntyre, F.A. Mussa-Ivaldi* and E. Bizzi,
Department of Brain and Cognitive Sciences,
Massachusetts Institute of Technology, Cambridge, MA 02139

Biological motor system are redundant with respect to many of the tasks required of them. This redundancy exists in terms of both the positions assumed by a limb and the forces which are produced by the motor system on its environment. For instance, there are typically more degrees of freedom in the joints of an arm than are required to achieve a given hand position and similarly there are more muscles acting around the joints than are necessary to produce a desired torque or force. The CNS must resolve, and perhaps exploit, this redundancy to produce the muscle activations necessary to achieve a given task.

In this study we analyzed and tested the *backdriving* algorithm, which has been proposed as a model for the control of vertebrate motor systems [Mussa-Ivaldi et al. 1989]. According to this algorithm, active coordination is obtained by reproducing the patterns of passive forces and motions which are induced by the environment at the point of contact with the motor system.

First, it was shown that the backdriving algorithm can deal with a variety of problems faced by the CNS, including redundancy, non-linear geometries, kinematic singularities and muscle saturation. Second, the backdriving algorithm was used to predict the behavior of the human motor system. Using anatomical data acquired from the literature [An et al. 1981], we simulated the backdriving algorithm on a computer to predict the muscle activations utilized by the CNS to produce a desired output in an isometric force task. These predictions were compared with published experimental data for the same tasks [Buchanan et al. 1986]. The backdriving algorithm successfully predicts a number of the features of the observed muscle behavior, including the direction of maximal activation for a given muscle and the agonist/antagonist pattern of activation for a group of muscles.

ELBOW FLEXION MOVEMENTS IN C5/C6 QUADRIPLEGICS WITH NO (WEAK) TRICEPS AND WITH ARTIFICIAL TRICEPS SUPPORT. M. M. Wierzbicka and A.W. Wiegner West Roxbury VA Medical Center & Harvard Medical School, Boston MA 02132.

We have previously shown using a mathematical model and with electrical stimulation (Wierzbicka at al. Exp Brain Res 63: 331, 1986), that in fast one-joint movements the antagonist muscle provides an effective means to reduce movement time. To further study the role of the antagonist we have now analyzed movements performed by patients with C5/C6 spinal cord injury who had relatively normal biceps and little or no voluntary control of triceps. We also explored the effect of an "artificial triceps", provided to the elbow joint by an external torque motor, on movement characteristics. Four quadriplegic patients and 6 control subjects performed elbow flexion movements "as fast and accurately as possible" to targets of 10°, 20°, 30°. Despite the lack of antagonist, patients used the same "pulse height" control strategy as normal subjects to scale their responses with movement amplitude. However, patients' movement time was on average twice that of normal subjects, and durations of both accelerative and decelerative phases of movement were increased. Movement speed and accelerations were significantly reduced (2-5 times) in comparison to the corresponding values of normal subjects. Patients overshot all targets to a larger extent than normal subjects, particularly 10° targets, with nearly twice the error. When a constant 2.5 or 5 Nm extensor torque was provided by a motor, patients were able to move faster than without triceps assistance and movement accuracy was within the normal range. These results provide direct evidence that the antagonist has an important effect on time and accuracy of fast goal-directed movements. (Supported by NIDRR and VA)

SUPERIOR COLLICULUS LESIONS IMPAIR OBSERVATIONALLY-RATED ORIENTING RESPONSES, BUT NOT LICK SUPPRESSION OR HEART RATE CHANGES, TO ACOUSTIC STIMULI IN RATS. B.J. Young and R.N.Leaton. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Despite more than two decades of research, there continues to be debate concerning the nature of the orienting deficit produced by superior colliculus (SC) lesions. We examined the nature and extent of the impairment in orienting to auditory stimuli in rats with SC lesions. Three measures of orienting response were used: heart-rate changes, lick suppression, and a measure of behavioral orienting scored from video records. Bilateral electrolytic SC lesions were made in 7 rats, and another 7 rats served as sham-operated controls. All animals were water deprived for 23.5 hours per day and trained to lick at a drinking tube. Pulsed white noise stimuli (65-dB SPL, 0.5-s duration, 1-Hz) were presented through small peripherally located speakers. Each animal received four presentations of the stimulus, two on each side, on each of three test days. The SC-lesioned animals were significantly impaired on the video-scored behavioral orienting measure, but they did not differ from controls on the lick-suppression and heart-rate measures. That the lesions impaired orienting on only one of the three response measures suggests a response-based rather than a sensory-based deficit. The failure of the lick suppression measure to differentiate between the groups emphasizes the importance of selecting an appropriate response measure, and may account for some previous negative results with auditory stimuli. Our previous work showed that SC-lesioned rats were significantly impaired in their orienting responses to visual stimuli on both the video rating and lick-suppression measures.

Speed-accuracy tradeoff must take into account the biomechanics of the movement. C.C.Bassile, T.Kaminski, Teachers College, Columbia University, New York, NY 10027.

Previous speed-accuracy investigations have identified relationships between movement time (MT) or peak velocity (PV) and extrinsic variables (i.e. displacement, accuracy requirements, contextual demands). This investigation demonstrated that biomechanical variables also affect MT and PV. Four subjects performed two types of pointing movements, reaches (shoulder and elbow moving in opposite directions) vs. whips, (shoulder and elbow moving in same directions) under two conditions, fast vs. fast/accurate. These multijoint arm movements were compared across three amplitudes of displacement (10.16cm, 20.32cm, 30.48cm) in the horizontal plane. As expected, we found: (1) MT and PV were linearly related to displacement, and (2) accuracy demands increased MT and decreased PV. However, MT was briefer and PV was higher for whips under both fast and fast/accurate movements of comparable displacements. These MT/PV differences between whips and reaches are not accounted for by Fitts' Law (Fitts, P.M.,*JEP* 47: 381,1954) or subsequent modifications (Schmidt,R.A. et.al., *Psychol Rev* 86:415, 1979; Meyer D.E. et.al., Attention and Performance XIII,173,1990). Therefore, the speed at which a movement proceeds is based not only on the accuracy and distance requirements of the task but also on biomechanical factors, such as, the summation of interactional forces.

DIRECTED MOVEMENT IN THE FROG: EXPLORATIONS USING BACK PROPAGATION NETWORKS J. N. Carr*, D. Louca*, and P. Grobstein, Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

Prey orienting behavior in the frog depends on successive map-like and parcellated representations of target location in space. Both forms of spatial representation underlie a variety of behaviors in a diversity of organisms, suggesting that they exist for reasons unrelated to the idiosyncrasies of particular organisms or tasks. To explore this, we are studying the behavior of back propagation networks presented with frog-like sensorimotor problems, to see whether such networks create solutions with either map-like or parcellated spatial representations and, if so, under what circumstances.

Networks given simple sensorimotor problems (direction of target location to direction of movement; 1-D) frequently created solutions involving distributed rather than map-like spatial representations. Maps are thus not an inevitable consequence of the need to associate each of a set of input locations with the appropriate output directions. We were able to bias the networks towards the generation of map-like solutions by manipulation of either the range of initial synaptic weights, or the parameters governing subsequent synaptic modification. Hence, neither kind of representation is an inevitable consequence of simple sensorimotor tasks; the starting conditions and methods by which a solution is found influence its form.

Given analogues of slightly more complex problems (direction and distance of target location to direction and distance of movement; 2-D), networks again frequently created distributed spatial representations, in which two spatial dimensions are coded together, rather than parcellated representations, in which the two dimensions are coded independently. Hence, parcellated representations are also not inevitable consequences of simple sensorimotor tasks. Networks modified to include simulated inhibitory interneurons did tend to form parcellated representations. This suggests that a distinction between excitation and inhibition is among the starting conditions which can influence the form of a solution. The nature of the problem presented also appears to bias the networks towards solutions involving parcellated spatial representations, and this is currently being further explored.

DIRECTED MOVEMENT IN THE FROG: ELECTROPHYSIOLOGICAL STUDIES OF A TECTO-TEGMENTAL PATHWAY. C. Smeraski and P. Grobstein, Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

Tectofugal signals representing the horizontal eccentricity of the targets of prey orienting movements apparently descend on axons originating from a large cell column (LCC) in the ventral midbrain tegmentum. The anatomically defined LCC is also identifiable physiologically, as a region which exhibits distinctive spontaneous activity. The present studies were undertaken to determine whether neurons in this region could be activated by local stimulation of the tectum, and to begin a characterization of the physiological organization of such a tecto-tegmental projection.

Tungsten microelectrodes were used to record in the LCC while stimulating at various locations in one tectal lobe. A second recording electrode, in the opposite tectal lobe, monitored activation of the topographically organized tecto-isthmo-tectal pathway, so as to verify that the stimulus strengths employed activated only local tectal regions. Such stimuli did produce unit activity in the LCC, at variable latencies as would be expected of post-synaptic responses. Theshhold responses in the LCC occurred when the stimulating electrode was in tectal laminae deeper than those at which threshhold responses in the opposite tectal lobe were observed, suggesting that tecto-isthmal and tecto-LCC projections arise from different tectal laminae.

Responses at a given location in the LCC could be produced by local activation of either tectal lobe, and from a wide array of locations within one tectal lobe. The findings are consistent with prior work suggesting that 1) activity in the LCC on one side of the brain represents the horizontal eccentricity of targets to one side of the body irrespective of the tectal lobe activated by such targets, 2) projections from tectum to LCC lack a clear topographic organization, and 3) it is activity over a wide area of the LCC rather than the particular region of LCC activated which codes the relevant information. Further studies of LCC responses to local tectal stimulation may provide new information about the nature of the LCC population code and how a transformation from topographic coding to activity coding is achieved.

THE EFFECTS OF CLONIDINE ON METHYLPHENIDATE-INDUCED MOTOR BEHAVIORS IN RATS. Lester, C.C.* and Moss, D.E. Dept. of Psychology, Univ. of Texas at El Paso, El Paso, TX 79968.

The success of clonidine, an alpha-2 adrenergic agonist, in some Tourette's syndrome patients implicates noradrenergic involvement in this hyperkinetic motor disorder which has traditionally been viewed to be the result of dopaminergic dysfunction. In order to examine the role of noradrenergic control of dopamine-dependent behaviors, the effect of clonidine on methylphenidate-induced motor behaviors was examined. Female rats were assigned to one of three groups receiving methylphenidate HCl (MP, 30 mg/kg) i.p. alone, clonidine HCl (CL, 150 ug/kg) i.p. alone, or CL (150 ug/kg) i.p. followed 40 minutes later by MP (30 mg/kg) i.p. All three groups were rated for stereotypy and locomotor movements were counted. The group receiving CL followed by MP had significantly decreased stereotypy and, paradoxically, increased locomotor activity. These data suggest an important interaction between the noradrenergic and dopaminergic systems in extrapyramidal motor functioning. (Supported by MH47167.)

EFFECT OF FOCAL TRANSCRANIAL MAGNETIC STIMULATION ON SIMPLE REACTION TIME. A. Pascual-Leone, J. Valls-Solé*, E.M. Wassermann, J. Brasil Neto*, L.G. Cohen, and M. Hallett. NINDS-NIH, Bethesda, MD 20892.

We studied the effect of transcranial magnetic stimulation (TMS) on simple reaction time (RT) to auditory, visual, and somatosensory stimuli. The subjects were requested to flex the right arm rapidly in response to the go-signal. RT was measured from go-signal to onset of biceps EMG activity. TMS was delivered at different intensities, over different scalp positions, and at variable delays before or after the go-signal. We also studied motor cortex excitability during RT by determining the probability of inducing motor evoked potentials (MEP) with a subthreshold transcranial stimulus (S) delivered at variable times before movement onset. We compared trials using a visual go-signal (control) with trials using a visual stimulus coupled with a subthreshold TMS stimulus (test).

TMS shortened RT to the different go-signals by approximately 30 ms when delivered over the left motor cortex at intensities below motor threshold. This effect was present at TMS delays of -30 to +30 ms, and was maximal at approximately +10 ms delay. TMS over other left-sided scalp areas did not affect RT. S did not evoke MEPs until the time to EMG onset was ≤ 80 ms. Thereafter, probability and amplitude of MEPs increased with decreasing interval. We found no differences between control and test trials.

In the RT paradigm used, the subjects were able to plan the response completely during the foreperiod. The motor program had to be held in memory, and upon arrival of the go-signal, be executed. TMS shortens RT by speeding up initiation of the execution, without affecting execution itself.

AN ANIMAL MODEL OF OPTIC FLOW UTILIZATION IN THE CONTROL OF LOCOMOTION. H. Sun*, D. P. Carey and M. A. Goodale. Univ. Western Ontario, London, Ontario, Canada.

In spite of numerous claims of flow-field processing in visual neurons of the CNS (Steinmetz, et al., 1987, *J. Neurosci.*), few investigators have manipulated optic flow to examine its effects on behaviour. Although there have been some laboratory studies of the use of optic flow by humans and some demonstrations of its use in free-living birds, there have been no laboratory studies of the use of this important visual cue in non-human mammals. In the present study, eight male Mongolian gerbils were trained to run random distances (varying from 95 to 165 cm) to a target presented on a computer screen at the end of an elongated runway. The target consisted of a solid white circle on a black background. During training days and many of the trials on test days, the size of the circle remained constant during an individual trial but was varied across trials from 1.5 to 6 cm. On probe trials, however, the size of the circle suddenly expanded (from 3 cm to 6 cm) or contracted (from 3 cm to 1.5 cm) over a period of 450 ms after the animal crossed an infra-red photobeam 70 cm away from the target. Analysis of digitized video recordings of the runs suggested that when the target size was increased the gerbils tended to decelerate earlier and/or more rapidly than on control runs to a constant-size target (3 cm) at the same distances. Contracting the target during the run had the opposite effect. These results provide strong support for the use of the relative rate of retinal expansion as an important variable in locomotor control. Moreover, this paradigm may provide a useful means of studying the neural mechanisms that are critical for the extraction of optic flow by moving animals. CHANGES IN FORCE RESULT IN INCREASED AMPLITUDE OF SCALP-RECORDED MOVEMENT-RELATED POTENTIALS. **D.H. York, D. Fousek*, Dept. of Physiology, School of Medicine, University of Missouri, Columbia, MO. 65212.**

The question of whether alterations in force opposing movement could be detected in ballistic movements of the thumb was evaluated with scalp recordings in human subjects. Bipolar recordings were made overlying the precentral gyrus and referenced either anterior or posterior to a site lying 6 cm lateral to the vertex. Subjects performed either a flexion and hold movement or a flexion-extension movement against a spring load at constant displacement and movement time. Increases in initial resting spring tension from 200 - 500 gm did not result in significant changes in cortical potentials. However, increases in spring constant resulted in significant increases in amplitude of an N1-P1 component defined in anterior referenced recordings but not in posterior referenced recordings. Posterior recordings did show a profile of the acceleration changes occurring during movement. Increases in velocity of movement were associated with increases in N1-P1 amplitude and decreases in latency of a post movement, P2 component.

LATERALIZATION IN HAPTIC PROCESSING: SEX AND HAND DIFFERENCES IN EXPLORATORY STRATEGIES. J. Fagot, J. Vauclair and J. Requin. C.N.R.S., L.N.F, Unit of Cognitive Neurosciences, 31 ch. Joseph Aiguier, 13402 Marseille, France.

Right-handed adults (12 males and 12 females) had to touch unseen non-sense stimuli for a maximum of 10 sec., and then to recognize their outline drawings. Tactual stimuli were composed of 8 independent units not haptically discernible. The computer recorded hand contacts and duration with each unit. Analysis included the mean number of units simultaneously touched, the number and duration of complete explorations during the 10 sec., and the accuracy of the recognition phase. In average, males touched a greater number of units than females ($M=5.56$, $F=4.59$, $p<.02$) and they reexplored more frequently the stimulus ($M=3.75$, $F=2.88$, $p<.05$) with a shorter duration ($M=2.12$ sec., $F=3,07$ sec. $p<.05$). For the 24 subjects, the left hand touched simultaneously more units than the right ($L=5.21$, $R=4.96$, $p<.001$). Neither hand nor sex differences were found regarding recognition accuracy. It is suggested that the strategy is more sensitive to laterality effects than measurement of the accuracy.

DISCHARGE PROPERTIES OF ANTIDROMICALLY ACTIVATED AMBIGUOUS NEURONS DURING VOCALIZATION IN THE AWAKE MONKEY. Y. Yajima* and C.R. Larson. Dept. of Physiology, Hyogo College of Medicine, Nishinomiya, Hyogo, 663 Japan and Dept. of Communication Sciences and Disorders, Northwestern University, Evanston, IL 60208.

As a way of understanding neural mechanisms controlling vocalization, neurons in and near the nucleus ambiguus (NA) were extracelluraly recorded in an awake, vocalizing Macaca nemestrina monkey. Motoneurons within NA were identified by antidromic activation and collision testing from stimulation of the recurrent laryngeal nerve. Peri-event time, interspike interval and auto-correlation histograms were used to further classify the neurons. Other neurons within the NA where antidromic potentials were recorded were classed as respiratory related, swallowing related and unspecified neurons. A variety of discharge patterns such as burst with vocalization or suppression with vocalization were noted. Motoneurons were found at distinct locations in the NA compared with other types of cells. Motoneurons differed from the other cell types on the basis of their pre-vocalization onset times, duration of discharge during vocalization, and time of peak discharge frequency. Most respiratory related neurons discharged in phase with inspiration and also before vocalization. Swallowing related neurons did not discharge with vocalization but were active with swallowing following vocalization. Several other types of neurons related to vocalization close to the NA, which did not show an antidromic response, were also observed.

TACTILE PLACING IN NORMAL CATS IS DIRECTIONALLY DISCRETE: A VIEW FROM DOWN UNDER. N.S. Bradley and S.H. Chambers. School of Physical and Occupational Therapy, McGill Univ., Montreal, PQ, Canada H3G 1Y5.

Spinal lesion studies assuming the view that tactile placing (TP) is a step in isolation have typically treated rostral, caudal, medial and lateral responses as separately controlled behaviors. Observation of forward trajectory of the paw following tactile stimulation of guard hairs has led some investigators to conclude that rostral TP can be controlled by the spinal cord. Our study provides new data that describes the directionally discrete trajectory of the paw in normal adult cats and suggests that responses limited to a single vector space are not equivalent.

Fore- and hindlimb TP was tested in normal adult cats while held with 1 limb relaxed and pendent over a circular opening in a plexiglass testing surface and videotaped from below. Testing fibers (6) were placed at 60° intervals around the paw in the horizontal plane; fiber selection for each trial was randomized.

Of nearly 2,000 trials videotaped to date, forelimb TP (20-40%) was more readily evoked than hindlimb TP (10-20%). Preliminary analyses indicate that nearly all placements were within 30° of the test fiber and half were within 15° regardless of fiber location. Subsequent computer analysis will include polar coordinate representation of paw trajectory leading to paw placement.

PRIMATE LESION FILM COLLECTIONS. J.A. Vilensky, S. Gilman and A. Moore*. Dept. of Anatomy, Indiana Univ. Sch. Med., Ft. Wayne, IN 46805, and Dept. of Neurology, Univ. of Michigan Sch. Med., Ann Arbor, MI 48109.

Interest in the primate motor system was dominated during the early and middle parts of this century by such renowned scientists as Sherrington, Fulton, Hines, Tower, Woolsey, Mettler, Bucy, Denny-Brown and Kuypers. Some of these individuals used film to record the behavior of the lesioned animals. The historical value of these films is undoubted. However, further analyses of these films by contemporary scientists might provide "new" information on motor function, or could be used to evaluate current theories. Accordingly, we have been collecting all the available films of CNS-lesioned monkeys, as well as the accompanying materials (eg, surgical protocols, histological slides, photographs). By far the largest collection is that of Denny-Brown, which consists of approximately 3000 rolls of film of about 450 monkeys. In this presentation we primarily describe the Denny-Brown collection. Briefer descriptions are provided for some of the smaller collections (eg, Woolsey, Bucy, Kuypers with Lawrence). We ask anyone with an interest in using any one of these collections, as well as anyone knowing the whereabouts of additional collections, to contact us. Finally, videotapes of a few of the films from the Denny-Brown collection are available for viewing at this meeting.

NEURONAL PATHWAYS MEDIATING CRAWLING BEHAVIOR IN THE MEDICINAL LEECH, *Hirudo medicinalis*. A. Baader and W.B. Kristan Jr., Department of Biology, UCSD, La Jolla, CA 92093-0322.

Leeches produce two distinct locomotor behaviors: they can swim or crawl towards their targets. While swimming is a rather fixed oscillatory behavior which, once elicited, is hardly influenced by sensory information, crawling consists of many behavioral subcomponents that are strongly sensory-controlled. We are interested in a) finding neuronal pathways participating in crawling and b) the extend to what the nervous system recruits neuronal elements involved in other behaviors to produce crawling.

In freely behaving animals changes in crawling behavior were analyzed after cutting peripheral nerves and transecting the connectives. Deafferentation of several midbody segments (e.g. segments 8 through 18) does not hinder co-ordinated head and tail sucker activity, but it decreases the velocity of body contractions. Transection of both connectives (between segments 11 and 12) blocks the propagation of the elongation wave, but does not prevent contraction of posterior segments and reattachment of the tail sucker, while animals with only one connective cut can still crawl in a co-ordinated manner. Thus crawling seems to be mediated both by central information transfer through the connectives and partly by peripheral pathways.

In tethered crawling leeches, intra- and extracellular recordings were performed in midbody ganglia while the behavior was video-monitored simultaneously. The activity profiles of identified interneurons (e.g 204, 208, S) were determined during crawling. The S-cell, for example, which forms a fast conducting pathway through the whole nerve cord is activated during the contraction phase. The S-cell also excites motoneurons which cause the inhibition of other circular motoneurons producing the elongation of the body during crawling. Supported by a Deutsche Forschungsgemeinschaft grant to AB and a USPHS grant MH43396 to WBK.

CIRCUITRY AND PATTERN GENERATION III

630.1

RESPIRATORY OSCILLATIONS IN MEDULLARY SLICES: CRITICAL ROLE OF EXCITATORY AMINO ACIDS (EAAs). G.D. Funk, J.C. Smith & J.L. Feldman. Systems Neurobiology Lab., Dept. Kinesiology, UCLA, Los Angeles, CA, 90024-1527.

Our previous *in vitro* studies identified a limited region of the neonatal rat ventrolateral medulla, the pre-Bötzinger Complex (pre-BötC), that contains neurons generating respiratory rhythm. Medullary slices (400-600 µm thick) containing this region generate respiratory oscillations in cranial nerves XII and/or IX (Smith *et al.*, SN abs. 465.1, '90), allowing analysis of mechanisms of rhythm generation and rhythmic drive transmission in an isolated, active respiratory circuit. To determine the role of EAAs in rhythmogenesis and synaptic transmission in this circuit, effects of local microinjection of NMDA (MK801) and non-NMDA (CNQX) antagonists were studied. Unilateral injection of 20 µM CNQX solution (10 - 30 nl; 200 - 600 fmoles) into the pre-BötC produced a dose-dependent decrease in respiratory frequency and ultimately eliminated rhythm generation; MK-801 injections (up to 20 nl, 1 mM solution) did not perturb rhythm. CNQX injections 300 µm distant from the site of maximum response did not affect rhythm, confirming site-specificity. Unilateral injection of 20 µM CNQX (2 - 25 nl) into the hypoglossal motor nucleus produced a dose-dependent decrease in burst amplitude, and completely blocked the motor discharge of XII nerve ipsilaterally, without blocking rhythmic discharge on the contralateral nerve. MK801 (up to 50 nl, 1 mM) or AP4 (up to 50 nl, 1 mM) injected into the same site had no effect on XII motor discharge. These results indicate that endogenously released EAAs activating non-NMDA receptors are essential for rhythmogenesis in the pre-BötC, consistent with our hypothesis that depolarization of rhythm generating neurons mediated by EAAs is a necessary condition for rhythm generation. These EAAs may be released at synaptic connections between the rhythm generating neurons, and/or from synapses on these cells from a separate population of neurons. Synaptic transmission of rhythmic drive to hypoglossal motoneurons is also mediated primarily by non-NMDA EAA receptors, consistent with our previous results in *en bloc* brainstem preparations that these receptors mediate transmission in medullary synaptic pathways to cranial motoneurons (Greer *et al.*, J. Physiol. 437: 727-749, '91). Supported by NIH grants HL 40959 and HL 02204 and NSERC of Canada.

630.2

OSCILLATORY PROPERTIES OF NEURONS IN AN ISOLATED RESPIRATORY CIRCUIT ANALYZED BY WHOLE-CELL PATCH-CLAMP TECHNIQUES. J.C. Smith, K. Ballanyi*, D.W. Richter, & J.L. Feldman Systems Neurobiology Lab, UCLA, Los Angeles, CA 90024 & Physiol. Institut, Univ. Göttingen, 3400 Göttingen, F.R.G.

Slice preparations of the neonatal rat medulla have been developed that contain neurons generating respiratory rhythm and a local circuit for motor output generation (Smith *et al.*, Soc. Neurosci. Abs. 16: 1130, '90). These slices provide a novel tool for analysis of rhythm generation and oscillatory drive transmission in an isolated, functionally active motor network *in vitro*. Whole-cell patch-clamp recording techniques were applied to analyze oscillatory properties of neurons in the network. In the pre-Bötzinger Complex of the ventrolateral reticular formation, the region previously identified as the locus for rhythm generation (*ibid*; Smith *et al.*, Soc. Neurosci. Abs. 15: 505, '89), a population of neurons was identified with voltage-dependent pacemaker properties that are candidates for the rhythm generating neurons. These neurons generate 10 - 15 mV regenerative membrane potential oscillations and rhythmic bursts with a voltage-dependent oscillatory frequency when the membrane potential is depolarized into the -55 – -45 mV range under current clamp. When the network is rhythmically active, these neurons receive depolarizing inputs that synchronize the oscillation of the pacemaker neuron population, so that the rhythmic discharge of these cells results from the interaction of synaptic currents and the intrinsic pacemaker properties. Other respiratory neurons in the network do not exhibit intrinsic voltage-dependent oscillatory properties; their rhythmic discharge results from large amplitude synaptic drive currents (400 – 700 pA currents, reversal potentials near 0 mV under voltage clamp). These results are consistent with a model in which respiratory rhythm is generated by a population of coupled, synchronized conditionally bursting pacemaker neurons. The current-voltage properties of these neurons that promote oscillatory behavior also facilitate a rapidly propagating, synchronized depolarization within the pacemaker cell population. Supported by NIH HL 40959, HL 02204, DFG, & the Alexander von Humboldt Foundation.

PLATEAU-POTENTIALS CONTRIBUTE TO THE GENERATION OF RHYTHMIC DEPOLARIZATIONS IN LOCUST FLIGHT INTERNEURONS. J.M.Ramirez and K.G.Pearson, Dept. of Physiology, University of Alberta, Edmonton, Canada, T6G 2H7.

During flight in the locust the membrane potential of interneurons oscillates over a wide amplitude range (up to 25mV). We have found that in many interneurons (e.g. 308, 504, 514, 566 and 567) voltage-sensitive plateau-potentials contribute to the generation of these large oscillations. Hyperpolarizing currents injected into these interneurons caused the amplitude of rhythmic depolarizations to drop suddenly by up to 50% in both intact and deafferented flying locusts. Plateau-potentials could be triggered by short depolarizing pulses and prematurely terminated by short hyperpolarizing pulses. A characteristic feature of these potentials was that they were rarely expressed in the quiescent locust. In the absence of flight activity most neurons displayed only passive membrane properties in response to current injection. These data indicate that plateau-potentials are induced during flight activity. Induction of these active membrane properties during flight may depend on the natural release of octopamine or may be due to octopamine modulating active membrane properties induced by other neuromodulators. This is suggested by the findings that 1) octopaminergic neurons are activated at the onset of flight, and 2) exogenously applied octopamine induces plateau-potentials and endogenous bursting in quiescent locusts. The voltage-sensitivity, the amplitude and the duration of these octopamine induced plateau-potentials are similar to the potentials seen during flight, and the frequency of endogenous oscillations is close to that in deafferented flying locusts.

SEROTONIN DEPENDENT PERIPHERAL SPIKE INITIATION ZONES IN THE AXON OF A MOTOR NEURON. J.M.Weimann, P.Meyrand*, and E.Marder. Biology Dept., Brandeis Univ., Waltham, MA 02245 and Neurobiologie, CNRS, Arcachon, France.

The lateral gastric (LG) neuron of the stomatogastric ganglion (STG) in the crab, *Cancer borealis*, makes inhibitory synaptic connections within the neuropil of the STG, and also projects to the periphery where it innervates muscles that control the movements of the gastric mill. The LG motor neuron has a spike initiation zone close to its neuropilar integrative regions. Spikes initiated here evoke IPSPs in LG followers. During spontaneous gastric activity in semi-intact preparations (muscles attached) spikes can also be initiated at peripheral axonal sites ~2 cm from the LG soma. Peripherally initiated spikes propagate antidromically into the STG where they do not evoke IPSPs onto LG follower neurons and also propagate to the muscles to prolong the contraction of the gm5b muscle. When the muscles are removed, long depolarizations of the LG soma (>3 seconds) together with serotonin applied to the nerve, also evoke peripheral spike initiation. The activity of the peripheral zone can be controlled by current injection into the soma to either initiate or terminate the spikes, suggesting the presence of plateau-like properties in the LG axon. Thus, the LG neuron can send different signals to its peripheral and central targets.

A MODEL NEURON WITH A PERIPHERAL SPIKE INITIATION ZONE. L.F. Abbott*, Barry Feedman*, J.M. Weimann, T. Kepler and E. Marder. Center for Complex Systems, Brandeis University, Waltham, MA 02254.

We have constructed a multi-compartmental, conductance-based model to study the serotonin activated peripheral spike initiation zone found in the Lateral Gastric neuron of the stomatogastric ganglion in *Cancer borealis*. The model neuron consists of two large passive regions representing the soma and primary neurite connected to an axon and a secondary process both of which have active Hodgkin-Huxley sodium and delayed rectifier conductances. The peripheral spike initiation zone located distally on the axon is modelled with an additional current that can produce a plateau potential resulting in a burst of action potentials.

As in the experimental preparation, we find the following features in the model: 1) The orthodromic and antidromic action potentials appear highly attenuated when recorded from the soma and have different shapes. 2) The peripheral zone can be activated by action potentials propagating outward from the primary initiation zone. Activation may require anywhere from one to a large number of spikes. Once activated, the peripheral initiation zone can generate a number of spikes or it can fire continuously. 3) As well as travelling down the axon, orthodromic spikes propagate down secondary processes to inhibitory synapses. Antidromic spikes also propagate along the axon but they fail to propagate down secondary processes.

The third result shows that the postsynaptic effect of an action potential propagating along a neuron depends on the location of the spike initiation zone. Supported by MH46742

PILOCARPINE INDUCES RHYTHMIC ACTIVITY IN LEG MOTOR NEURONS IN ISOLATED THORACIC GANGLIA OF LOCUSTS. Sylvie Ryckebusch and Gilles Laurent. Computation and Neural Systems, California Institute of Technology, Pasadena, CA 91125.

We demonstrate that in isolated thoracic ganglia of the locust, *Schistocerca americana*, leg motor neurons will express rhythmic activity similar to that which occurs during walking in an intact animal. The centrally generated rhythm, induced by bath application of the muscarinic agonist pilocarpine, was recorded both intracellularly from leg motor neurons and extracellularly from leg motor nerves.

The observed rhythm appeared similar to walking in an intact animal, as motor neurons to antagonistic muscle groups in the metathoracic ganglion were active in antiphase, whereas motor neurons to synergistic muscle groups were active in phase. Levators of the trochanter were in phase with flexors of the tibia, and depressors of the trochanter were in phase with extensors of the tibia. The frequency of the observed rhythm was an approximately linear function of the concentration of pilocarpine, and saturated at about 0.2 Hz for a bath concentration of 10^{-4}M. This rhythm was thus slower than that underlying walking. The rhythms expressed by the left and right halves of a ganglion were not necessarily of the same frequency. Some lateral coupling between hemiganglia was observed, however, as depressors of the trochanter on one side were generally in phase with levators of the trochanter on the other.

The preparation we describe will be used to study sensory-motor interactions, since the walking rhythm can be induced reliably in a completely isolated preparation. Supported by the NIH and a Searle Scholarship to GL.

"HOT SPOTS" OF SPIKE-EVOKED CALCIUM ENTRY IN THE MAJOR NEURITES OF CRAB STOMATOGASTRIC NEURONS. K. Graubard, N. Lasser-Ross, D. Baldwin and W.N. Ross, Dept. of Zoology, Univ. of Washington, Seattle, WA 98195 and Dept. of Physiology, New York Medical College, Valhalla, NY 10595

Voltage-correlated changes in $[Ca]_i$ were examined in identified neurons of *Cancer borealis*, by using simultaneous electrical recording and high-speed imaging of Fura-2 fluorescence at 380 nm with a cooled CCD camera. The same somatic microelectrode was used to inject Fura-2, to inject current, and to record membrane potential. Sharp increases in $[Ca]_i$, time-locked to depolarizing potentials, were interpreted as due to entry through voltage dependent channels. Our results extend those previously obtained using arsenazo III and a photodiode array (Graubard and Ross PNAS *82*:5565-5569,1985; Ross and Graubard PNAS *86*:1679-1683,1989). Use of Fura-2 and the camera enabled us to estimate the magnitude of the changes in $[Ca]_i$ and to identify with greater spatial precision the sites of $[Ca]_i$ increase.

For all cells, bursts of intrasomatically evoked action potentials caused calcium entry into the soma and neuropil with distinctly higher levels in a small region of the main process (pre-axon) near the edge of the neuropil just before the axon entered a nerve. Cells with more than one axon had a "hot spot" on each pre-axon. During the spontaneous voltage oscillations and spike bursts of the pyloric rhythm, oscillations of $[Ca]_i$ were observed with the highest amplitudes at the "hot spots". In TTX saline, intrasomatic stimulation caused increases in calcium which were largest in the soma and decremented smoothly in the neuropil; no "hot spots" were seen.

We suggest that 1) during spontaneous bursting the mean variation in $[Ca]_i$ in the neuropil is small; 2) most spike-evoked synaptic transmission comes from the subset of neurites closest to the "hot spots"; 3) the calcium channel distribution along the largest neurites is roughly uniform; and 4) there are few calcium-permeant ion channels in the axon.

Supported by N.I.H. Grants NS16295[WNR], NS25505[KG].

630.8

REGIONAL DISTRIBUTION OF THE FINE NEURITES OF IDENTIFIED NEURONS OF THE CRAB STOMATOGASTRIC GANGLION. D. Baldwin and K. Graubard, Dept. of Zoology, University of Washington, Seattle, WA 98195.

The stomatogastric neuropil of crabs and lobsters can be divided into a central core containing the largest neurites, an intermediate region containing a mix of intermediate and fine neurites, and a peripheral neuropil containing mostly fine neurites (Baldwin and Graubard *Soc. Neurosci. Abstr.* **16**:724, 1990 and King *J. Neurocytology* 5:207-237, 1976). Regions containing fine neurites (fine neuropil) are the sites of intrinsic synaptic interactions and of extrinsic synaptic input (King, 1976). Neurons of the STG participate in two major motor patterns by using two interacting neural circuits. We have examined the regions of fine neurites in neurons that participate in one or both circuits to determine if the circuitry is reflected in a regional organization of the crab fine neuropil.

Identified stomatogastric neurons of *Cancer borealis* were injected with Lucifer Yellow, fixed and examined as whole mounts with a confocal microscope. In some cases, another dye was injected into a second neuron. For each cell, the neuropil was divided into radial arcs and the serial images scored based on the presence of fine neurites within each arc. This representation of the three-dimensional spread of the fine neurites of each neuron was compared with those of the other neurons. Examinations of PD and LP, purely pyloric neurons, and VD, a mixed pyloric/gastric neuron, show small differences in the distribution of regions of fine neurites.

Supported by N.I.H. Grants NS15697 and NS25505 to K. Graubard.

630.9

ELECTROPHYSIOLOGICAL PROPERTIES OF LAMPREY SPINAL NEURONS. J.T. Buchanan. Department of Biology, Marquette University, Milwaukee, WI 53233.

To provide information for locomotor network modeling, the following six classes of previously identified neurons were studied in the isolated spinal cord of adult *Ichthyomyzon unicuspis* with intracellular microelectrodes in normal Ringers: motoneurons (MN), lateral interneurons (LIN), cells with crossed, caudal axons (CC), excitatory interneurons (EIN), edge cells (EC), and giant interneurons (GI). The classes were generally not significantly different from one another in their resting potentials [for all cells (n=58) mean ± S.D. = -77.4±4.3mV], thresholds (-55.6±4.4mV), or action potentials (106.1± 8.5mV). The late after-spike hyperpolarizations were also similar except for the ECs which occurred earlier and were about twice as large as those in other cells. Cell classes varied considerably in their mean input resistances, consistent with known variation in soma sizes. CCs (71±47MΩ) and EINs (72±62MΩ) had the highest means and the most variance.

Most cells fired spikes throughout a 400ms depolarizing pulse with some tendency to adapt. MNs showed more adaptation than the interneurons. LINs and ECs had 20% higher peak first-interval frequencies (100Hz) than other cell types. When input current was normalized to rheobase, CCs had the largest range of firing (10X rheobase). ECs were unusual in their tendency to fire in doublets.

Overall, most resting and firing properties of these classes of lamprey spinal neurons were similar, except for ECs which are intraspinal stretch receptors. Within classes, CCs and EINs showed the most variation, probably indicating further functional diversities.

630.10

THE EFFECTS OF STRYCHNINE ON FICTIVE SWIMMING IN THE LAMPREY. D.R. McPherson and J.T. Buchanan. Department of Biology, Marquette University, Milwaukee, WI 53233.

Previous studies demonstrated that strychnine speeds fictive swimming in the isolated lamprey spinal cord, presumably by reducing glycinergic inhibitory synapses involved in rhythmogenesis. In contrast to these experimental findings, computer simulations of a proposed lamprey locomotor network display slowing of cycle rate when all inhibitory connections are reduced. The effect is dependent on cell type: reduction of only CC synapses (cells with crossed, caudal axons) speeds the rate, while reduction of only lateral interneuron (LIN) synapses slows the rate. This suggests that LIN ipsps may be insensitive to strychnine. This hypothesis is rejected as present results in silver lampreys show that strychnine abolishes the ipsps produced by LINs upon CC interneurons, while bicuculline has no effect.

The effect of strychnine on fictive swimming has therefore been re-examined. Confirming earlier reports, strychnine accelerates the swim rate in adult silver lampreys (*Ichthyomyzon unicuspis*), but in adult sea lampreys (*Petromyzon marinus*), low concentrations (0.5μM) of strychnine produce a slight speeding, while higher concentrations (2μM) elicit extremely slow alternating bursting (10% of control rate). The slow rate appears to developed as a progressive fusing of fast bursts into longer ones.

Thus, there appears to be a species difference in the response to strychnine during fictive swimming, and these results may indicate a need to revise the proposed locomotor network.

631.1

Effects of Ibotenate (IBO) and Quisqualate (QUIS) Lesions of the Nucleus Basalis Magnocellularis (NBM) on Cortical EEG. R.J. Radek, M.W. Decker, D.J. Anderson, M.J. Majchrzak. Neuroscience, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL. 60064

Lesions of the NBM produce deficits in various learning and memory tasks. The several lesion methods used to generate damage result in similar depletions of the cholinergic marker choline acetyltransferase (ChAT), but do not produce similar behavioral effects. For example, IBO lesions impair performance in the standard Morris water maze task, whereas QUIS lesioned rats are relatively unaffected. The purpose of this study was to compare the effects of these two NBM lesions on cortical EEG. Unilateral lesions were made with either IBO (0.06 M) or QUIS (0.12 M) in Long-Evans rats at coordinates (in mm); AP, -0.6, DV 7.5, Lat 2.8. Frontal-parietal EEG was recorded bilaterally and FFT calculated power spectrum analysis is expressed as percent change from the non-lesioned hemisphere. IBO lesioned rats had a significant 51% ($n=6$, $p<0.05$) increase of alpha (8-13 hz) power in the ipsilateral frontal-parietal cortex. Sham ($n=5$) and QUIS ($n=7$) rats had no significant increases or decreases of alpha power, although several QUIS rats did have moderate EEG changes in the ipsilateral cortex. ChAT activity in frontal-parietal cortex was decreased 34% ($p<0.05$) and 45% ($p<0.05$) with IBO and QUIS lesions, respectively. These data may indicate that IBO and QUIS produce differential basal forebrain injury and may be distinguished on the basis of cortical electrical activity.

631.2

COHERENT 40-HZ RESPONSES DURING AUDITORY PROCESSING IN THE HUMAN BRAIN.
U.Ribary, R.Llinas, F.Lado, A.Mogilner, R.Jagow* and L.Lopez. Center for Neuromagnetism, Department of Physiology and Biophysics, New York University Medical Center, New York, N.Y 10016, USA.

A 14- and a 37-channel MEG system (BTi) were used, in order to analyze the spatial and temporal organization of magnetic 40-Hz activity during auditory processing. MEG data was recorded over the right cerebral hemisphere (from 35-37 positions) of 5 normal humans (20-35 years old), before and during an auditory stimulation. The stimuli comprised frequency modulated tones starting at any frequency between 50-350 Hz. This modulation swept randomly upwards or downwards within this range. Responses were averaged and analyzed using various band-pass filters (5-15, 15-25, 25-35, 35-45 and 45-55 Hz). MEG data indicated synchronized activity at around 40-Hz over the entire hemisphere during auditory processing. This activity was coherent over large cortical areas and demonstrated a phase shift from the frontal to the occipital pole. This spatio-temporal pattern, which consisted of a positive/negative field, showed a coherent rostro-caudal sweep lasting for 4-8 msec, repeating every 12.5 msec. Similar magnetic field patterns were also observed in non-averaged single epochs using the 37-channel system. As in the averaged records, the pattern was absent when filtering above or below the 40-Hz band.

Our MEG data suggests that the 40Hz sweep is a major mechanism in the global organization of brain activity, supported by cortico-thalamic pathways, with a focus on the activated sensory area.

631.3

NETWORK MODULATION OF AN INTRINSIC DELTA (0.5-4 HZ) RHYTHM IN THALAMIC NEURONS. M. Steriade, R. Curró Dossi and A. Nuñez. Lab. Neurophysiol., Sch. Med., Univ. Laval, Quebec, Canada G1K 7P4.

Two questions have been addressed in this study: could slowly (0.5-4 Hz) oscillating single thalamocortical neurons become synchronized?; and, what are the potentiating and suppressing modulatory systems of this slow oscillation? Intra- and extracellular recordings of identified cortical-projecting cells were performed in cats under urethane anesthesia. At the resting Vm (-60 mV) cortical stimulation induced spindles (7-14 Hz), whereas at Vm more negative than -65 mV the same stimuli induced delta oscillations (low-threshold spikes and after-hyperpolarizations recurring rhythmically at 0.5-4 Hz). Auto- and crosscorrelograms of neuronal pairs revealed that unrelated cells became synchronized after a series of corticothalamic volleys, with both neurons displaying rhythmic (1-2 Hz) spike bursts. This effect probably involved inhibitory inputs from cortical-driven GABAergic thalamic cells. Stimulation of either mesopontine cholinergic nuclei or specific sensory channels blocked the delta oscillation by depolarizing thalamic cells, thus bringing them out of the voltage range of this slow rhythm.

We postulate a progressive hyperpolarization of thalamic cells with the deepening of quiet sleep, which would account for spindling during early stages and delta waves during late stages. By contrast, brainstem and/or sensory depolarizing inputs would explain the delta blockage at the transition from slow-wave sleep to either arousal or REM sleep. Supported by MRC grant MT-3689.

631.4

DELTA OSCILLATIONS IN PERIGENICULATE (RETICULAR) THALAMIC NEURONS. F. Amzica, A. Nuñez and M. Steriade. Lab. Neurophysiol., Sch. Med., Univ. Laval, Quebec, Canada G1K 7P4.

Cortical inputs potentiate a hyperpolarization-activated slow thalamic rhythm (0.5-4 Hz) and synchronize oscillatory relay neurons that are otherwise uncoupled (Steriade et al., this meeting). Since these facilitatory/synchronizing actions were exerted by volleys arising in cortical areas that were not directly related to the explored thalamic nucleus, we hypothesized that they were due to the conjunction properties of the interposed reticular nuclear complex. We have recorded extra- and intracellularly perigeniculate (PG) thalamic cells of cats under urethane anesthesia. A subpopulation of physiologically-identified PG cells oscillated spontaneously with spike bursts recurring at delta frequencies (between 0.5 and 4 Hz), most often at 3-4 Hz. The oscillation was voltage-dependent. Indeed, it was blocked by depolarizing current pulses or changes in the ambient light eliciting tonic firing, and by bringing the membrane potential below -90 mV. PG neurons displayed delta oscillation despite the fact that they did not possess the I_h current which is required for this oscillation in thalamocortical cells (see Curró Dossi et al., this meeting). As opposed to the barbiturate-induced blockage of delta rhythmicity in thalamocortical cells (Nuñez et al., this meeting), the slow oscillation in PG cells was not sensitive to barbiturates. These data support the hypothesis that PG or other reticular thalamic cells are involved in the cortical-induced potentiation of thalamic delta oscillation. Supported by MRC grant MT-3689.

631.5

SPINDLE OSCILLATIONS PREVENT DELTA OSCILLATIONS IN INTRACELLULARLY RECORDED THALAMOCORTICAL CELLS OF CAT. A. Nuñez, R. Curró Dossi and M. Steriade. Lab. Neurophysiol., Sch. Med., Univ. Laval, Quebec, Canada G1K 7P4.

The interaction between spontaneous spindle (7-14 Hz) and delta (0.5-4 Hz) rhythmic activities of thalamic neurons was studied intracellularly in antidromically identified cortical-projecting cells of cats under urethane anesthesia. Thalamic spindling was induced by cortical stimulation or by barbiturate administration. In other experiments *cerveau isolé* (collicular-transected) preparations were performed to induce spontaneous spindling in the absence of anesthetics. Oscillations within the frequency range of EEG delta waves were present at Vm between -68 to -90 mV, appearing as rhythmic low-threshold spikes alternating with afterhyperpolarizing potentials. These voltages could be reached by inward current injection or after removal of related cortical areas. In both cases the occurrence of spontaneous as well as barbiturate- or cortical-induced spindle sequences prevented delta oscillations, the effect being accompanied by an increase in membrane conductance.

This competitive interaction between spindle and delta oscillations may explain the prevalent appearance of the former and the latter EEG rhythmicity during early and late sleep stages, respectively. Supported by MRC grant MT-3689.

631.6

ELECTROPHYSIOLOGY OF A SLOW (0.5-4 Hz) INTRINSIC OSCILLATION OF CAT THALAMOCORTICAL NEURONS IN VIVO. R. Curró Dossi, A. Nuñez and M. Steriade. Lab. Neurophysiol., Sch. Med., Univ. Laval, Quebec, Canada G1K 7P4.

An intrinsic oscillation in the frequency range of sleep EEG delta waves (0.5-4 Hz) has been studied in cat thalamocortical neurons. Antidromically identified cortical-projecting cells have been recorded intra- and extracellularly in most major thalamic nuclei under urethane or nitrous oxyde-halothane anesthesia. About 80% of cells with intact cortical connections displayed the slow (delta) oscillation as their membrane potential was brought between -68 and -90 mV by DC. The oscillation consisted of rhythmic low-threshold spikes and after-hyperpolarizations, and it was not dependent upon the occurrence of fast action potentials.This rhythm, involving an interplay between the hyperpolarization-activated cation current (I_h) and the low-threshold transient Ca++ current (I_t), was similar to that reported by McCormick & Pape (1990) in a subpopulation of dLG cells in vitro. The oscillatory activity was spontaneously present in virtually all neurons anatomically or functionally disconnected from related cortical areas (Vm > -65 mV), in which case it could be blocked by DC depolarization. Under these experimental conditions focal delta waves built-up during epochs with synchronized rhythmic multiunitary firing. Only anterior thalamic neurons did not display a delta oscillatory capability.

We hypothesize that this intrinsic phenomenon contributes to switch the activity of thalamocortical neurons toward slow delta waves, as their membrane potential progressively hyperpolarizes during late stages of sleep. Supported by MRC grant MT-3689.

TOPOGRAPHICAL ORGANIZATION OF THE AFFERENT CONNECTIONS TO THE CAUDAL SUBDIVISION OF THE LP-PU THALAMIC COMPLEX. M.L. Rodrigo-Angulo and F. Reinoso-Suárez. Departamento de Morfolgía. Facultad de Medicina. Universidad Autónoma de Madrid. Spain.

The caudal subdivision of the lateral posterior-pulvinar thalamic complex (LP-Pu) has been defined histochemically and cytoarchitectonically in the cat, as formed by the lateralis posterior medialis (LPM), lateralis posterior lateralis (LPL), posterior part of the pulvinar (Pu) and lateralis medialis (LM) nuclei. In this study we have distinguished LPM, LPL and Pu on the retrograde cell labeling techniques. Small amounts of a horseradish peroxidase solution (20-40 nl) were injected in LPM (4 cats), LPL (4 cats) and posterior Pu (2 cats) by means of a glass micropipette. After injections in LPM, cortical neurons averaged 70% of the total labeled neurons in the brain and were homogeneously distributed in areas 17, 18, 19, 20, 21, posteromedial lateral suprasylvian (PmLS) and splenial visual (Sp); subcortically labeled neurons were located mainly in the superficial layers of the superior colliculus (SCs) and in the reticular thalamic and ventral lateral geniculate nuclei (RT and GLV), while only scattered neurons were found in locus coeruleus, parabrachial nuclei and oral pontine reticular nucleus. After injections in LPL, cortical labeled neurons averaged 93% and were very abundant in area 17, less numerous in areas 18, 20, 21, posterior suprasylvian (Ps), dorsal lateral suprasylvian, ventral lateral suprasylvian, PmLS and Sp, and scarce in area 7; subcortically labeled neurons occupied mainly the RT and GLV, and the SCs, beeing just a few in the pretectal region (Pt). After injections in posterior Pu a large amount of labeled neurons (89%) was detected in the cortex, mainly in area 7; fewer were found in areas 18, 19 20, 21, Ps, and in all visual areas associated to the suprasylvian sulcus and gyrus, as well as in Sp, and some appeared in areas 35 and 36; subcortically labeled neurons were located in RT, GLV, Pt and SCs. These results confirm that the nuclei of the caudal subdivision of the LP-Pu show a distinct and topographically organized linkage with different visual cortical areas and subcortical structures.

THALAMIC CONNECTIONS OF THE ORBITOFRONTAL CORTEX OF MACAQUES RELATED TO ACETYLCHOLINESTERASE ACTIVITY PATTERNS. C. Cavada, T. Company*, and F. Reinoso-Suárez. Dept. Morfología, Fac. Medicina, Univ. Autónoma de Madrid, Spain.

The thalamic labeling resulting from axonal transport of tracers injected in the orbitofrontal cortex of macaques was compared with the patterns of staining present in the thalamus of adjacent sections processed to reveal AChE activity. Eleven experiments were performed using single or multiple labeling strategies. Aggregates of labeled neurons or terminals were present in the poorly stained anteromedial and paratenial nuclei, and were characteristically in register with the AChE-poor domains in the mediodorsal nucleus (MD). Labeling was also present in a moderately dense AChE zone in dorsal MD. By contrast, the most intensely AChE-stained zone of the ventral anterior nucleus, surrounding the mammillo-thalamic tract, showed a dense aggregation of labeled neurons and terminals. Also the ventromedial part of the paracentral nucleus, which exhibits very rich and uniform AChE staining, was labeled following the orbitofrontal injections. Other nuclei exhibiting high AChE activity and containing labeled neurons included the parafascicular, limitans, and the paraventricular, reuniens, and central (densocellular, latocellular, superior, intermediate, and inferior divisions) midline nuclei. In the medial pulvinar nucleus, labeling was assembled both within the medial part of the AChE-poor matrix, and in close register with patches of moderate AChE staining located in the mediodorsal part of the nucleus. These findings indicate that the thalamic connections of the orbitofrontal cortex are organized according to differential histochemical patterns. This feature must be considered, together with cytoarchitectonic and connectional attributes of the various thalamic nuclei, in understanding the thalamic connections of the prefrontal cortex.

LATERALITY OF INPUT FROM CORTICALLY PROJECTING EXTRATHALAMIC NUCLEI. S.E. Choe*, C. Geula and M-M. Mesulam. Harvard University, Boston, MA.

The laterality of cortical projections from several extrathalamic nuclei which give rise to widespread corticopetal fibers was investigated in the rat. Horseradish peroxidase was injected into two primary sensory cortical areas (somatosensory cortex and visual cortex/area 17) and two limbic areas (dorsal hippocampus and amygdala). Observations in the basal forebrain (Ch1-Ch4), hypothalamus, ventral tegmental area, raphe and locus coeruleus revealed labelled neurons predominantly ipsilateral to the injection site, with varying degrees of contralateral labelling. Overall, the raphe showed the highest percentage of contralaterally labelled neurons (35% of all labelled neurons), while the basal forebrain cholinergic nuclei showed the lowest percentage (less than 1%). In the locus coeruleus, contralateral labelling was considerably higher after limbic cortical injections than after sensory cortical injections. The other nuclei examined in this study did not show consistent differences of laterality in their projections to limbic vs sensory cortex. The laterality of extrathalamic corticopetal projections thus varies from one nucleus to another and, in the case of the locus coeruleus, also as a function of the target projection site.

PROJECTIONS FROM THE LATERODORSAL NUCLEUS OF THE THALAMUS TO THE LIMBIC AND VISUAL CORTICES. T. van Groen and J.M. Wyss. Dept of Cell Biology, University of Alabama, Birmingham, AL 35294

Previous studies suggest that the laterodorsal nucleus (LD) of the thalamus projects to both retrosplenial cortex and adjacent visual cortical area 18b. In this study we used the very selective, anterograde tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L) to characterize the projections from LD in detail. A large injection of PHA-L into the middle part of LD labels axons and terminals in caudal infraradiata (IRβ), area 18b, retrosplenial agranular (Rag), retrosplenial granular b (Rgb), retrosplenial granular a (Rga), postsubicular, presubicular and parasubicular cortices. Small terminal fields also are present in the precentral agranular, entorhinal and perirhinal cortices. Smaller injections demonstrated that the LD projection is topographically organized. The projections to IRβ arise from caudoventral parts of LD, predominantly from the medial regions. Rgb receives projections from caudomedial parts of LD, but Rga receives projections only from the rostromedial part of LD. Area 18b is projected upon by medial caudoventral parts of LD. Postsubiculum receives projections from caudal parts of LD. Presubiculum and parasubiculum receive projections from medial parts of LD. Further, the terminations of LD have a distinct laminar pattern in each cortical region. In the visual, Rag, and postsubicular cortices the LD axons end in layers I and III/IV, in Rgb and Rga the terminals are confined to layer I, whereas in presubiculum and parasubiculum and the adjacent entorhinal and perirhinal cortices the terminals are distributed in the deep layers (i.e., layers IV-VI). These results demonstrate that LD projects to retrosplenial, hippocampal, and visual cortices, and that these projections are topographically organized.

DISTRIBUTION OF CALRETININ IMMUNOREACTIVITY IN MONKEY CEREBRAL CORTEX. D.A. Lewis, J.S. Lund, M. Akil, and D.M. Jacobowitz. Depts. of Psychiatry and Behav. Neurosci., Univ. of Pittsburgh, Pittsburgh, PA 15213 and Lab. of Clinical Science, NIMH, Bethesda, MD 20892.

The calcium binding proteins, parvalbumin (PV) and calbindin D-28k (CB), are present in morphologically distinct subpopulations of nonpyramidal neurons in monkey neocortex (*PNAS* 83:2093; *Exp Br Res* 76:476, 1989; *JCN* 293:599, 1990). In this study, we used immunohistochemical techniques to characterize the distribution of immunoreactivity for a related calcium binding protein, calretinin (CR), in cerebral cortex of infant and adult rhesus (*Macaca mulatta*) monkeys. Most CR-immunoreactive (IR) neurons were small nonpyramidal cells with a variety of morphologies; many of these neurons had vertically oriented, oval cell bodies which gave rise to a single ascending and/or descending dendrite. In contrast to CB, CR immunoreactivity was not detected in pyramidal neurons. The greatest density of CR-IR neurons was in layers II-superficial III; a lower density band of labeled neurons was present in deeper cortical layers. Many association regions of cortex contained a high density of radially arrayed CR-IR processes. The morphology and laminar distribution of these fibers appeared to be distinct from that of CB-containing axon fascicles. In some regions, CR-IR axon terminals formed clusters that outlined the somata and proximal dendrites of a subpopulation of pyramidal neurons; the distribution of these pericellular arrays differed from that of PV-IR pericellular baskets. These findings suggest that the role of CR in primate cortical circuitry may be distinct from that of other calcium binding proteins.

LOCAL CIRCUIT NEURONS OF THE PRIMATE PREFRONTAL CORTEX: AREAS 9 AND 46. **J.S. Lund, K.M. Oeth, and D.A. Lewis, Dept. of Psychiatry and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261**

Human neuropsychiatric disorders, such as Alzheimer's disease and schizophrenia, appear to be disturbances of complex behaviors that may reflect disruption of neural circuitry in the prefrontal areas of the cerebral cortex. We have used Golgi and immunocytochemical approaches to characterize morphology, laminar distribution and biochemical specialization of nonpyramidal neurons of rhesus monkey prefrontal cortex. In Golgi impregnations, these neurons can be divided into categories on the basis of their axon distributions: vertically oriented (often a column no more than 100-150um wide), local (innervating 1-2 laminae, with an arbor 200-300um wide) and laterally spreading (up to at least 1mm). Within each of these categories, very different morphological types are found, often with their cell bodies broadly distributed in cortical depth. Matches between classes of Golgi impregnated and immunocytochemically labelled neurons have been made in some instances. For example, neurons making local beaded arbors (found in layers 2-5) may contain calretinin; neurons making local complex pericellular arbors (layers 4-6) and neurons with vertically oriented axon trunks with short curved collaterals (layers 2-4) may both express cholecystokinin; chandelier neurons (layers 2-5) express parvalbumin and corticotropin releasing factor (Lewis and Lund, '90). Probably most of these classes are also GABAergic. These findings begin to reveal the diversity of non-pyramidal cell types in prefrontal cortex with some suggestion of the post-synaptic components with which they may interact. CHOLECYSTOKININ-IMMUNOREACTIVE NEURONS IN MONKEY VENTRAL MESENCEPHALON PROJECT TO PREFRONTAL CORTEX BUT DO NOT CONTAIN TYROSINE HYDROXYLASE. K.M. OETH AND D.A. LEWIS. Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA, 15213.

In rodents, cholecystokinin (CCK)-immunoreactive (IR) neurons in the ventral mesencephalon (VMC) are known to contain tyrosine hydroxylase (TH) and to project to prefrontal cortex (*J Comp Neurol* 279:397, 1989; *J Comp Neurol* 279:415, 1989). In primate VMC, some CCK-IR neurons do not contain TH (*PNAS* 87:8427, 1990). We have observed that the distribution of these CCK-positive/TH-negative cells in monkey (*Macaca fascularis*) VMC follows a rostrocaudal gradient. For example, at very rostral levels, CCK-IR cells are present medially in an area that is almost totally devoid of TH-positive neurons. In more caudal regions of the VMC, the location of CCK-containing neurons overlaps with the position of TH-IR cells, although CCK-positive/TH-negative neurons are still observed. We have previously found that CCK-containing cells in monkey VMC project to prefrontal cortex; however, it is not known if these neurons belong to the class of CCK-positive/TH-negative neurons. Using combined retrograde transport techniques and immunohistochemistry, we found that CCK-containing cells in the VMC which project to prefrontal cortex do not contain TH. These observations were confirmed in double labeling studies in prefrontal cortex which also demonstrated a lack of colocalization of CCK and TH in fibers or terminal fields. These findings demonstrate that a population of CCK-containing neurons in the VMC has the capacity, independent of dopamine, to directly influence prefrontal cortical function.

DOPAMINERGIC (DA) AND NORADRENERGIC (NA) INNERVATION OF THE RAT FRONTAL CORTEX. F.Condé (1), B.Onteniente (2), M.Geffard (3) and F.Crépel (1). 1:CNRS URA 1121, Bat.440, Univ. Paris XI,91405-Orsay, 2: INSERM U 161, Hôpital Henri Mondor, 94010-Créteil, 3: INSERM CJF 88-13, Univ. Bordeaux II, 33076 Bordeaux, France.

In this study we compared on serial adjacent sections the distribution of NA and DA innervation of the rat frontal cortex, as revealed with respectively polyclonal and monoclonal antibodies directed against NA- or DA- glutaraldehyde-protein conjugates (Geffard et al. Brain res., 1986, 363:395-400; Chagnaud et al., J. Neurochem., 1987, 49:487-494). Our results confirmed and extended previous results obtained with different techniques, and emphasized neuroanatomical differences between DA and NA innervation. Regional differences included medio-ventral orbital cortex, in which density of DA and NA fibers was lower than in prelimbic area (PL) and ventro-lateral orbital area in which density of DA fibers is weak whereas NA fibers are numerous; Laminar differences were observed in PL where NA tangential fibers mostly run in the middle part of layer I, whereas DA tangential fibers are mostly in the outer part of layer I. These results suggest morphofunctional differences for NA and DA in frontal areas. A computerized quantitative study of density of NA and DA fibers will be further attempted.

CHOLINERGIC SYNAPTIC ARRANGEMENTS IN THE PRIMATE PREFRONTAL CORTEX. L. Mrzljak*, C. Leranth and P.S. Goldman-Rakic. Sect. of Neurobiology and Dept. of Obstetrics and Gynecology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The prefrontal cortex (PFC) contains neural circuits engaged in working memory and it is of interest to determine how the cortical cholinergic innervation may influence this circuitry. Therefore, cholinergic synapses in areas 9 and 46 of the PFC of three adult rhesus and two cynomolgus monkeys were visualized using a monoclonal antibody against choline acetyltransferase (ChAT; provided by Dr B. Wainer). In addition, a double labeling electron microscopic (EM) method was used in which immunoperoxidase reactive cholinergic synapses were visualized in contact with immunoferritin labeled GABAergic nonpyramidal neurons. Cholinergic synapses in contact with morphologically identified pyramidal neurons were also characterized at the EM level.Cholinergic synapses were found in all layers of the PFC and all synaptic contacts were symmetric. ChAT positive profiles were in synaptic contact with both pyramidal and GABAergic neurons. The predominate postsynaptic targets on pyramidal neurons were apical and basal dendritic shafts and less frequently dendritic spines. Cholinergic terminations on GABA-immunoreactive neurons were restricted to dendritic shafts. These results are the first demonstration of cholinergic synapses in the primate association cortex and are in accord with physiological data showing that cholinergic axons influence principal neurons in the cortex both by direct excitation and indirectly via feedforward inhibition by GABAergic interneurons. These findings elucidate an anatomical substrate for acetylcholine's modulatory role in cortical function. Supported by MH 44866 and NS 26068.

SINGLE UNIT ACTIVITY IN PREFRONTAL CORTEX AND MEDIODORSAL THALAMUS IN THE RAT: BEHAVIORAL CORRESPONDENCE AND EFFECTS OF ETHANOL. Kosobud, A.E., and Chapin, J.K. Hahnemann University, Philadelphia, PA, 19102, USA.

Using chronically implanted microwire electrodes, it is possible to obtain repeated recordings simultaneously from multiple neurons in awake, behaving animals. In the present experiments, multiple bundles containing 4-6 microwire electrodes were chronically implanted in MD thalamus and various sites in medial frontal and prefrontal cortex female rats, 250-300 g. Prefrontal and frontal cortex play a role in planning and organization of behavior, suppression of competing impulses, and in short-term task-related memory. These areas may be important sites for ethanol action, especially its disinhibiting and rewarding properties. Initially, animals were trained to walk on a treadmill with an intermittent cycle. Onset of treadmill movement was signalled by a fixed time interval or a tone cue. In subsequent experiments, rats were trained to press a lever to terminate treadmill movement. A videocamera was used to record behavior throughout experimental sessions. Firing rates were analyzed for individual cells, and in addition, factor analysis was used to assess ensemble properties of multiple neurons. In general, cells developed activity related firing rates, with higher rates of firing either during locomotion (treadmill on) or rest (treadmill off) in the course of an experimental session. Factor analysis suggested that activity levels among the ensemble of cells anticipated onset of the treadmill, and coded initiation and cessation of movement. In the initial 10-20 minutes of intoxication, EtOH consistently reduced or eliminated the difference in firing rate between locomotion and rest. In later stages, cells generally regained their original pattern of firing, but in one case, a cell switched from a higher rate during treadmill on to a higher rate during treadmill off. ORBITAL PREFRONTAL CORTEX IN THE MONKEY: STRUCTURALLY DISTINCT AREAS WITH SPECIFIC INPUTS CONNECTED IN PARALLEL NETWORKS. S.T. Carmichael and J.L. Price, Dept. Anat. & Neurobiol., Wash. Univ. Sch. Med. St. Louis, MO 63110

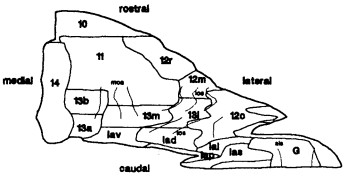
An analysis of Nissl, myelin, AChE and immunohistochemical staining patterns of the orbital cortex and rostral insula of Macaca fascicularis indicates that these two regions encompass 17 distinct areas, as seen in the following unfolded map.



Thirty-five injections of anterograde and retrograde tracers placed within these areas in fourteen monkeys indicate that each area receives a distinct set of limbic, sensory-related or multisensory connections. The limbic input is provided by the amygdala to the agranular insula areas (lav, lad, lal, lap, las) and 12o, 12m and 12l laterally and 11, 13a, 13b and 14 medially; and by the subiculum to areas 11, 13a, 13b and 14. Three areas receive sensory-related inputs: 12m somatic sensory input from SI, SII and 7b; 12l visual input from TE; and lav olfactory input from piriform cortex. Two areas receive a combined sensory input: 13l receives olfactory, gustatory and somatosensory input and 13m receives olfactory, somatosensory and possibly visceral input. lad and 12o receive multimodal input from the dorsal bank of the superior temporal sulcus. These areas then participate in a network of connections within the PFC, with specific projections to the medial wall, area 11 and the principal sulcus. Supported by NIH grant DC00093.

631.18

FUNCTIONAL CORRELATES OF NEGLECT PRODUCED BY UNILATERAL LESIONS OF MEDIAL AGRANULAR CORTEX IN RATS. J.V. Corwin, V. King, D. Paulson*, R.T. Watson*, K. Heilman* and R.L. Reep. Dept. of Psychology, Univ of New Orleans, New Orleans, LA 70148; and Depts. of Neurology and Physiol. Sciences, Univ. of Florida, Gainesville, FL 32610.

Our previous work has demonstrated that unilateral destruction of the medial agranular cortex (AGm), in rodents produces severe multimodal neglect. The present study examined the physiological correlates of severe neglect through the use of 14[C]2-deoxyglucose methodologies.

The functional correlates of neglect were examined in rats which received unilateral lesions of either the left AGm or the left lateral agranular cortex (AGl). Unlesioned controls were also examined. The physiological procedures were performed 4-6 days postop., after the rats were tested for the presence of neglect. Glucose utilization was determined by optical densitometry.

The results indicated that glucose utilization was significantly altered in rats with severe neglect produced by unilateral AGm lesions. Glucose utilization was significantly reduced ipsilesionally in the posterior striatum, the superior colliculus, and thalamus in the nuclei MD and ventralis lateralis. In the cortex glucose metabolism was significantly reduced in the AGl and retrosplenial cortices. These results generally support the pattern of glucose utilization found following physiological studies of frontal neglect in primates.

631.19

POSTERIOR PARIETAL CORTEX IN RATS: BEHAVIORAL ATTRIBUTES AND THALAMIC AND CORTICAL CONNECTIONS. H.C. Chandler*, R.L. Reep, V.R. King and J.V. Corwin. Depts. of Physiol. Sciences and Neurosurgery, Univ. of Florida, Gainesville, FL 32610; and Dept. of Psychology, Univ. of New Orleans, New Orleans, LA 70148.

Our previous anatomical work has demonstrated that a posterior area of parietal cortex lying just lateral to the cingulum bundle is reciprocally connected with medial agranular cortex and ventrolateral orbital cortex. Unilateral lesions of either of these latter two areas produces contralateral multimodal neglect. We now report that severe contralateral neglect also results from unilateral lesions selective to this posterior parietal area.

To delineate the connectivity of this posterior parietal field, rats received microinjections of three different fluorescent tracers, spaced in the anteroposterior or mediolateral direction. Within the a-p series, all cases had cortical labeling in medial agranular and orbital cortex. Thalamic labeling involved the ventral posterolateral, lateral dorsal/lateral posterior, lateral and medial geniculate nuclei. More rostral injections produced heavier labeling in vpl and none in lgn, typical of somatic sensory cortex, while more caudal injections resulted in the reverse, typical of visual areas; all three injection locations yielded labeling in ld/lp. Within the m-l series, more medial injections produced thalamic labeling which included the anterior thalamus, typical of retrosplenial cortex. Middle and lateral placements did not differ in thalamic and cortical labeling patterns. We conclude that a discrete posterior parietal area exists in the rat, based on the behavioral findings related to multimodal neglect, and on a combination of cortical and thalamic labeling patterns.

CORTICAL SENSORY AND LIMBIC INPUTS TO DISCRETE AREAS OF THE SUPERIOR TEMPORAL SULCUS IN THE RHESUS MONKEY. B. Seltzer and D.N. Pandya. Depts. of Psych. and Neurol. and Anatomy, Tulane Univ. Sch. of Med., New Orleans, LA 70118 and V.A. Hosp., Bedford, MA 01730.

Afferent cortical connections of individual sectors of the superior temporal sulcus (STS) were studied using retrograde tracers. The rostral portion of area TPO in the upper bank receives input from the rostral superior temporal gyrus (STG), circular sulcus, perirhinal cortex, and rostral parahippocampal gyrus (area TH). Mid-TPO receives input from the mid-STG, caudal-most inferior parietal lobule, cingulate gyrus (area 23), and retrosplenial cortex. Caudal TPO has afferent connections with the caudal STG, caudal insula and circular sulcus, caudal parahippocampal gyrus (areas TF,TH,TL), lower bank (area LIP) and rim of the intraparietal sulcus, parietal operculum, areas 23 and 24, retrosplenial cortex, medial parietal cortex, and medial extrastriate areas. Cortex in the rostral lower bank of the sulcus (areas TEa and TEm), by contrast, receives input from inferotemporal cortex and the parahippocampal gyrus. Thus discrete subdivisions of the STS have distinct inputs from cortical sensory and paralimbic areas.

631.21

IS THE CORTEX OF CAT ANTERIOR ECTOSYLVIAN SULCUS A POLYSENSORY AREA? H.R. Clemo, M.A. Meredith, M.T.Wallace and B.E. Stein, Depts. Physiology and Anatomy, Medical College of Virginia, Virginia Commonwealth Univ. Richmond, Va 23298.

The anterior ectosylvian sulcus (AES) has been considered a polysensory/multisensory cortical region where convergence of different sensory inputs onto individual neurons occurs. However, three different modality-specific regions have been identified in the AES, suggesting that the degree of multisensory convergence may be less extensive than expected. Therefore, the AES cortex of 9 cats was examined to determine the extent of multisensory convergence. The vast majority (93%, 499/537) of sensory neurons encountered proved to be unimodal and visual, auditory, and somatosensory neurons were segregated from one another: somatosensory in the rostral dorsal bank, visual on the caudal ventral bank, auditory on the caudal dorsal bank which corresponded closely to the identified regions of SIV, EVA and Field AES. Multisensory neurons constituted only about 7% (38/537) of the population, and were found primarily near the borders of adjoining modality-specific fields. Given the paucity of multisensory convergence here it seems inappropriate to retain the designation 'polysensory' cortex. Rather, the AES is best regarded as a composite of three different unimodal areas flanked by strips where sensory convergence sometimes occurs.

631.22

INTEGRATING THE DIFFERENT SENSES IN NEURONS FROM CAT ASSOCIATION CORTEX (ANTERIOR ECTOSYLVIAN SULCUS) M.A.Meredith, M.T.Wallace and B.E.Stein, Depts. Anat. & Physiol. Medical College. Va., Va. Commonwealth Univ., Richmond, VA.

The rules by which neurons integrate information from different senses have been identified in the superior colliculus (Meredith and Stein, J.Neurophysiol 56:640 '86) and their role in multisensory orientation behaviors have been demonstrated (Stein et al., J.Cognit.Neurosci 1:12 '89). However, their general applicability across the neuraxis is not known. The present experiments examined this issue in single neurons in the cortex of cat anterior ectosylvian sulcus. Among the multisensory neurons encountered (n=24/156), all combinations of visual, auditory and somatosensory inputs were identified. When stimuli from different modalities were combined, the responses were dramatically enhanced or depressed. These interactions were often multiplicative and were dependent on the same factors evident in the superior colliculus: receptive fields for the different modalities were spatially aligned; combined stimuli presented within their respective receptive fields evoked response enhancement; a stimulus falling outside its receptive field either depressed or had no effect on an effective stimulus from another modality; the temporal window for integration far exceeded the duration of the unimodal discharge trains; maximal levels of enhancement occur when stimulus onset is adjusted to overlap the peak periods of the discharge trains. These data indicate that the rules governing multisensory integration are independent of structure and apply to neural and behavioral processes throughout the CNS. Supported by NS 22543.

LEARNING AND MEMORY—PHARMACOLOGY: OTHER II

632.1

LEARNING INDUCED CHANGES IN mAChRs IN RAT BRAIN REVEALED BY IN-VIVO (125 I)-4-IODODEXETIMIDE BINDING Ş.Pöğün,U.Scheffel, A.A.Wilson*,M.Stathis*,C. Stainert*,R.F.Dannals*,and H.N.Wagner,Jr.*.Dept.of Physiology,Ege University,İzmir 35100,Turkey and Dept. of Radiology,The Johns Hopkins Medical Inst.,Baltimore MD 21205

The central cholinergic system has been implicated in learning and memory processes. I-125-4-Iododexetimide (I-125-DEX) is a high affinity muscarinic cholinergic receptor (mAChR) antagonist which has been shown to bind to central mAChRs in-vitro and in-vivo. The present study was undertaken to study in vivo I-125-DEX binding to mAChRs in rat brain after learning trials. 11 male Long-Evans rats were trained in a T-maze for a two choice spatial discrimination task;5 controls were handled only. Of tha 11 rats, 6 made more correct choices in more than 55% of the total trials, 5 scored lower. Accordingly, the animals were grouped into good and poor performers. After w2 day learning trials, the rats were injected i.v. with 10 uCi. I-125-DEX and sacrificed 30 min. later. There was a significant difference in I-125-DEX binding to mAChRs in the hippocampus between the three groups (p 0.037,ANOVA) with the good performers showing the highest binding, the controls the lowest. There was also significantly higher I-125-DEX binding in the hippocampus(p 0.001), striatum (p 0.0006), frontal (p 0.002), parietal (p 0.002) and temporal (p 0.026) cortices in good performers when compared to controls (t-test) Our results indicate that learning causes increased mAChR activity in the rat brain and that this is most pronounced in the hippocampus.

632.2

AGE AND SEX RELATED DIFFERENCES IN MORRIS WATER MAZE PERFORMANCE AND BRAIN AChE LEVELS IN RATS. S.Demirgören, S.Temuçin*, S.Amado*, and Ş.Pöğün. Dept. of Physiology, Ege University, İzmir, 35100 Turkey

Young (4 months old) and old (24 months old) male and female Sprague-Dawley rats (n=8 for each group) were trained in the Morris water maze for nine days. There were active controls for each group. 24 Hours after the last trial, the animals were decapitated, their brains removed, dissected and acetylcholinesterase (AChE) levels were assayed in the cerebellum, striatum, hippocampus and cortical areas. Analysis of variance revealed a significant interaction between sex and age in Morris water maze learning performance; young male and old female rats had better scores. Although there was no difference in hippocampal AChE levels in the control groups, experimental groups showed significant variations - higher levels in young males and old females (ANOVA). There was also correlation between performance and hippocampal AChE levels in these groups. In the control groups, the younger animals had higher AChE levels in most of the brain regions studied. In the experimental groups, however, sex differences were observed:young males and old females had higher enzyme levels post-training in some brain regions. Our results imply the sexually dimorphic involvement of the cholinergic system with aging in water maze performance: male rats apperad to be more sensitive to cholinergic impairments as reflected in learning deficits with aging processes.

632.3

MORRIS WATER MAZE PERFORMANCE IN 3 WEEK OLD RATS - SEX DIFFERENCES AND HORMONE EFFECTS.

R.L. Roof, Dept of Psychology, University of Nevada , Reno, NV 89557.

It has been demonstrated that adult male rats outperform females on spatial tasks, including the radial arm maze and the Morris water maze. In addition, this sex difference can be modified with early postnatal administration of testosterone. Testosterone treated females perform better than control females, and in some cases, as well as control males. In human studies of spatial ability, gender differences are not often found in prepubertal populations. It is not known when sex differences for spatial tasks first appear in rats, and whether the administered hormones exert their effects early in life or in a delayed manner. In order to determine whether such sex differences exist in very young rats, male and female rats, both testosterone treated and controls, were trained and tested in the Morris water maze at a young age.

Sprague-Daley rats were treated with 250 ug testosterone proprionate on postnatal days 2 and 4. Controls were given only the oil vehicle. At three weeks of age, these rats were trained and tested on 10 consecutive days in a Morris water maze. The task consisted of finding and remembering the location of a submerged hidden platform in milky water. Sex differences and effects of the testosterone are described in terms of time required to find the platform over trials, as well as time spent in each quadrant on probe trials.

The understanding of the time course of development of sex differences in spatial performance is critical if the anatomical and physiological bases for these sex differences are to be determined.

632.4

EFFECTS OF ZOLPIDEM ON SCHEDULE CONTROLLED BEHAVIOR IN A RADIAL MAZE MODEL OF FORAGING.

G.R. Sessions, J.J. Pilcher, S.A. McBride and E.L. Closser-Gomez*. Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

The effects of the hypnotic imidazopyridine zolpidem on behavior of rats were studied in an effort to discriminate between drug-induced performance deficits and disruptions of schedule controlled behaviors involving memory. Delivery of food was controlled by fixed interval schedules of reinforcement, randomly assigned to each of 8 arms of a radial maze, ranging from 55 to 759 sec. Zolpidem (0.33-3.0 mg/kg ip), administered to well-trained rats immediately prior to test sessions, produced dose-dependent decreases in measures of performance at doses above 0.67 mg/kg, but the overall patterning of responding was altered only at intoxicating doses. The proportion of responses and proportion of time spent in each of the arms relative to the proportion of rewards obtained were relatively unaffected below 2.0 mg/kg. Zolpidem produced performance decrements consistent with its hypnotic actions, but no evidence was obtained to suggest impairment of memory processes required to perform the eight alternative concurrent schedule in effect in the radial maze.

632.5

EFFECTS OF BENZODIAZEPINE RECEPTOR LIGANDS ON THE PERFORMANCE OF AN OPERANT DELAYED MATCHING TO POSITION TASK IN RATS.

B. J. Cole; D. N. Stephens; J. D. Turner*. Department of Neuropsychopharmacology. Schering AG. Berlin. Federal Republic of Germany.

The effects of a series of benzodiazepine (BDZ) receptor ligands, ranging from full agonists through antagonists to partial inverse agonists on short term working memory in the rat were investigated. The behavioral paradigm used was discrete trial, operant delayed matching to position, with delays of 0, 5, 15 and 30 s. These delays generated an orderly 'forgetting' curve in control rats. Diazepam and lorazepam (BDZ agonists) both produced a delay dependent impairment in matching accuracy at certain doses, but delay independent effects at higher doses, which were accompanied by behavioral indices of sedation, including lengthening of reaction times. The BDZ receptor partial inverse agonist FG 7142 also produced a delay dependent impairment in matching accuracy and lengthened reaction times. In contrast, the BDZ receptor antagonist ZK 93426 produced a slight, delay dependent increase in matching accuracy, but also lengthened reaction times. Taken together, these results suggest that an optimal level of GABA activity is necessary for accurate performance of delayed matching to position in rats, and that both increases and decreases in GABA function, effected through BDZ receptor ligands, can impair performance.

632.6

AMNESIC EFFECTS OF CHLORDIAZEPOXIDE IN THE RADIAL ARM MAZE.

J.S. Shumsky and I. Lucki, Departments of Pharmacology and Psychiatry, University of Pennsylvania, Philadelphia, PA 19104

The benzodiazepine (BZ) chlordiazepoxide (CDP) produces amnesia in humans but has been reported to produce variable effects in rats on performance in the radial arm maze in tasks used to measure memory. Chronic pre-trial administration of saline or CDP (5, 10, 20 mg/kg, ip) to food-deprived male Sprague-Dawley rats produced impairment of performance over a 21-day training period. The number of trials required to attain a criterion of 2 or fewer errors on 3 consecutive days and the percentage of animals reaching that criterion was: saline, 7.4 $\pm$ 1.2 (100%); 5 mg/kg, 10.0 $\pm$ 1.6 (87.5%); 10 mg/kg, 11.0 $\pm$ 2.9 (50%); and 20 mg/kg, 12.0 $\pm$ 1.0 (25%). Measures of accuracy (number of errors and task efficiency) were impaired by 10 and 20 mg/kg CDP. Measures of motor responsiveness (latency and rate of response) were unaltered at 10 mg/kg CDP but reduced at 20 mg/kg CDP. In a second experiment, pretreatment with the BZ antagonist flumazenil (5 mg/kg, ip) partially reversed the accuracy impairments of 10 mg/kg CDP, although flumazenil produced no effect on its own. These results are in contrast to the effects in highly trained animals in which CDP (0.3-18 mg/kg, ip) produced no significant alteration in measures of accuracy and a progressive impairment of motor responsiveness in a cumulative dose-effect curve. Therefore, tasks of acquisition appear to be more sensitive than previously acquired tasks to disruption by CDP. Supported by DA 05186.

632.7

GABAERGIC AND CHOLINERGIC INTERACTION IN THE MODULATION OF MEMORY.

S. E. Cruz-Morales and R.A. Prado-Alcala. Behav. Pharmacol. Program, ENEP-Iztacala and Physiol. Dept., Med. Sch., Natl. Univ. of Mexico, P.O.B. 314, Tlalnepantla, Edo. de Mexico, 54030, México.

The aim of this experiment was to study the interaction of GABAergic and cholinergic systems in memory processes. Male Wistar rats (250-350 g) were trained with 2.5 mA, on a passive avoidance task and tested 24 hr later. The rats were assigned to one of 19 groups: two groups were injected 5 min post-training (ip) with scopolamine (SCP) (4 or 8 mg/kg); six groups with picrotoxine (PX) (0.007, 0.015, 0.062, 0.5, 1.0 or 2.0 mg/kg) five groups received 8 mg/kg of SCP in combination with PX (0.007, 0.015, 0.062, 0.25, or 1.0 mg/kg); threee groups received SCP (4mg/kg) with 0.5, 1.0 or 2.0 mg/kg of PX, and three control groups, one injected with isotonic saline, an intact group and a group with no shock. . SCP induced amnesia in a dose dependent way; in contrast PX did not modify performance. Except the group with the smaller dose of PX, all combinations of PX and SCP reversed the the SCP-induced amnesia.

632.8

AGE-DEPENDENT MODULATION OF CORTICAL ACETYLCHOLINE RELEASE BY BENZODIAZEPINE LIGANDS.

H. Moore*, G. Berntson, M. Sarter, and J.P. Bruno, Dept. of Psychology, Ohio State Univ. Columbus, OH 43210.

Administration of benzodiazepines produces bidirectional effects on cognition in animals and humans. Benzodiazepine receptor (BZR) agonists, such as chlordiazepoxide (CDP), impair performance while selective inverse agonists, such as ZK 93 426, enhance performance. These performance changes have been attributed to GABA-cholinergic interactions. Given age-related declines in cognitive processes, we also determined whether these transmitter interactions vary with aging. We have utilized in vivo microdialysis in freely moving animals to determine whether these BZR agents have similar bidirectional effects on cortical acetylcholine (ACh) release.

Fischer-344 rats (4 & 18 mo old) were implanted with unilateral guide shafts into the frontoparietal cortex. Three days later they were equipped with dialysis probes and treated every 2 days, in counterbalanced order, with CDP (3, 5, 10 mg/kg) or ZK 93 426 (1, 5 mg/kg). Baseline ACh release was higher in young (.78 $\pm$ .23 pmol/min) than in old rats (.32 $\pm$ .05 pmol/min). ZK 93 426 increased ACh release in a dose-dependent manner with old rats being more sensitive than young animals. However, old animals were less able than young rats to sustain this increased release. Curiously, CDP did not systematically affect ACh release, suggesting that BZR agonists and selective inverse agonists do not bidirectionally affect cortical ACh release. These data reveal that BZR selective inverse agonists enhance cortical ACh release but the sensitivity and temporal dynamics of this effect vary with age.

632.9

SPATIAL LEARNING IN THE MORRIS WATER TASK AFTER MEDIAL FRONTAL CORTEX LESIONS IN THE RAT: EFFECTS OF DIAZEPAM.
M. S. Weaver, T. Schallert and D. C. James. Inst. for Neuroscience, Univ. Texas, Austin, TX 78713.

Diazepam chronically disrupts recovery from sensorimotor asymmetries caused by unilateral anterior medial cortex lesions if administered continuously during a sensitive 12-96 hour postoperative period (Schallert, Hernandez & Barth, 1986). Diazepam appears to exaggerate secondary degeneration in the striatum which may contribute to the disruption of recovery (Jones & Schallert, 1991). In the present study, bilateral medial frontal cortex lesions significantly impaired spatial learning ability in Whishaw's learning-set version of the Morris water task. Unexpectedly, recovery was greatly facilitated in animals treated post-operatively with diazepam. Preliminary results indicate that diazepam may allow sparing in the CA1 and CA2 regions of the hippocampus. Such a finding suggests that spatial deficits produced by medial frontal cortex lesions may result from secondary damage at the hippocampal level. Depending on the neurological test, diazepam may retard or promote recovery of function after medial frontal cortex lesions.

632.10

EFFECTS OF PERIPHERAL AND CENTRAL INJECTIONS OF GABA AGONISTS ON SPONTANEOUS ALTERNATION PERFORMANCE. C. M. GREY, W. K. K. LAM*, and P. E. GOLD. Neuroscience Graduate Program and Department of Psychology, U. Virginia, Charlottesville, VA 22903.

Peripheral, intraventricular and medial septum injections of glucose attenuate memory deficits caused by opiate agonists and cholinergic antagonists. GABA neurons are associated with cholinergic-opioid interactions in the medial septum, and injection of GABA agonists into the medial septum impair memory (Chrobak *et al*, 1989; Brioni *et al*, 1990). The present experiments examined the efficacy of peripheral and medial septum injections of glucose in attenuating spontaneous alternation deficits produced by GABA agonists.

Mice injected (IP) with either a GABA-A receptor agonist, muscimol (0.5 mg/kg) or a GABA-B receptor agonist, baclofen (5.0 mg/kg) 30 min before spontaneous alternation tests exhibited significantly impaired alternation performance (percent alternation scores: 62.7 ± 2.7 and 58.1 ± 2.6, respectively, vs. saline 69.7 ± 1.6). This deficit was not reversed by co-administration (IP) of glucose (10, 100 or 300 mg/kg). Muscimol injections directly into the medial septum (1 nmole/0.5 ul over 1 minute) impaired alternation performance (42.8 ± 7.3 vs saline 69.0 ± 3.8); this deficit was not attenuated by peripheral (100 mg/kg) or septal (3.3 ug/0.5 ul over 1 minute) injections of glucose.

With parallel findings that glucose does not enhance memory in rats with lesions of the medial septum, the results suggest that glucose effects on memory require the participation of GABA neurons contained in the medial septum, which may contribute to the modulation of memory processing via regulation of opioid and cholinergic systems. 632.11

COGNITION ENHANCING PROPERTIES OF THE BENZODIAZEPINE RECEPTOR SELECTIVE INVERSE AGONIST MDL 26,479. M. Sarter, L.-A. Holley*, and P. Dudchenko. Dept. of Psychology, The Ohio State University, Columbus, OH 43210.

The triazole MDL 26,479 has been shown to displace the cortical binding of Ro15-1788, to reduce the effects of GABA on the activity of Purkinje cells, and to facilitate LTP (Dudley et al. 1990; Sorensen et al. 1990a). In contrast to benzodiazepine receptor inverse agonists (BZRIA), however, MDL 26,479 does not exhibit convulsive effects (Sorensen et al. 1990b), suggesting BZR-selective inverse agonism (BZRSIA; Sarter 1990). We have found that MDL 26,479 (0.1-6.25 mg/kg; 60 min pretest) attenuates the effects of scopolamine (0.03, 0.1 mg/kg (30 min pretest) on performance in a delayed alternation task (0-32 sec). Furthermore, the effects of MDL 26,479 on the acquisition of a conditional visual discrimination task in rats with ibotenic acid-induced (0.06 M) basal forebrain lesions were examined. Sham-lesioned or lesioned rats were treated with vehicle or MDL 26,479 (5 mg/kg; i.p.; daily; 60 min pretest). In comparison to sham-lesioned controls, learning in lesioned rats was drastically impaired. MDL 26,479 did not improve the performance of sham-lesioned animals. However, MDL 26,479-treated, lesioned rats acquired the task as rapidly and accurately as controls. While the extent to which the behavioral effects of the ibotenic acid-induced lesion depended on the destruction of cholinergic neurons remains unclear, we speculate that the beneficial behavioral effects of MDL 26,479 were mediated via an increase in cortical acetylcholine release (as has been previously proposed for other BZRSIAs; Sarter et al. 1990). This hypothesis is supported by the finding that MDL 26,479 stimulates [^{3}H]-hemicholinium-3 binding in cortical but not hippocampal membranes (Miller & Chmielewski 1990). These properties of MDL 26,479 suggest that it represents a potent BZRSIA and a promising therapeutic treatment for the cognitive symptoms that are associated with cortical hypocholinergic functions.

632.12

NMDA LESIONS OF THE AMYGDALA BLOCK DIAZEPAM INFLUENCES ON MEMORY. H. Dickinson-Anson, C. Tomaz and J.L. McGaugh. Center for the Neurobiology of Learning and Memory and Department of Psychobiology, University of California, Irvine, CA 92717.

It is well known that systemically administered benzodiazepines (BZ) induce anterograde amnesia in a variety of tasks. BZ effects are mediated through the GABA-A complex by enhancing GABA-induced synaptic inhibition. Extensive evidence suggests that GABAergic influences on memory are mediated through the amygdaloid complex. As the GABAergic system in the amygdala is a site of action for the anxiolytic effects of BZs, such findings suggest that BZ's may also influence memory through the amygdala. The present experiment was designed to examine this implication.

Male rats received either sham or bilateral amygdala lesions using N-methyl-D-aspartic acid (NMDA). NMDA (8µg/0.8µl phosphate buffer) was injected at a rate of 0.2 µl/min, with injection needle left in place 5 min following injection. One week later, animals were trained to criterion on a continuous multiple-trial inhibitory avoidance task (CMIA) and tested 48-h later (step-through latency). In this task, whenever a rat entered the dark compartment, a footshock was given until the rat escaped to the starting compartment. The number of trials required before the rat remained in the starting compartment for 100 sec in one trial was recorded. Diazepam (DZ) (1.0 and 2.0 mg/kg, ip) or vehicle was injected 30 min prior to acquisition. The results confirmed previous findings: amygdala lesions impair acquisition, systemic DZ impairs retention. The major finding of importance was that the DZ-induced retention deficit was blocked in rats with amygdala lesions. Our results strongly suggest that the amnestic effects of the benzodiazepine, diazepam, are mediated, at least in part, through the amygdaloid complex.

632.13

INTERACTION OF NORADRENERGIC, MUSCARINIC AND GABAERGIC SYSTEMS IN THE AMYGDALA IN REGULATING MEMORY STORAGE. I.B. Introini-Collison, C. Dalmaz*, J. Salinas* and J.L. McGaugh. Center for the Neurobiology of Learning and Memory and Department of Psychobiology, University of California, Irvine, CA 92717.

Previous results from our laboratory have indicated that several neurochemical systems in the amygdala are involved in the modulation of memory storage. These experiments examined the interaction of the amygdala noradrenergic system with muscarinic cholinergic and GABAergic systems. Posttraining intra-amygdala administration of clenbuterol produced a dose-dependent enhancement of retention of an inhibitory avoidance task. The enhancing effects of clenbuterol (3.0 ng) were completely reversed by concurrent administration of atropine (1.0 µg), which by itself had no effect on retention.

In addition, intra-amygdala administration of a low dose of propranolol (0.3 µg), which alone did not affect retention, shifted the dose-response curve of the GABAergic receptor agonist muscimol (0.01, 0.03 and 0.1 ng) toward the left, i.e. lower doses of muscimol were necessary in the presence of propranolol to obtain similar effects.

These findings are consistent with other evidence suggesting that noradrenergic influences interact with GABAergic influences within the amygdala in regulating memory storage and that these influences are mediated through effects involving a muscarinic cholinergic mechanism.

CL 275,838, A NOVEL COMPOUND SHOWING ANTIDEPRESSANT ACTIVITY AND BENEFICIAL EFFECTS ON MEMORY DEFICITS IN THE RAT.
R. Samanin*, M. Carli*, L. Cervo*, A. Vezzani, T. Mennini*
Istituto "Mario Negri", Via Eritrea 62, 20157 Milan, Italy

CL 275,838, 4,5-dihydro-4-{{4-(phenylmethyl)-1-piperazinyl}acetyl}-7-{3-(trifluoro-methyl)phenyl}pyrazolo{1,5a}pyrimidine-3-carbonitrile, reduced rats' immobility in the forced swimming test (5 mg/kg i.p., three injections in 24 h) and counteracted the impairment of rats' performance caused by 1 mg/kg scopolamine in a passive avoidance task (20 mg/kg i.p. CL 275,838 administered before the training trial and the retention test). Similar treatments with oral doses of 40 and 160 mg/kg CL 275,838 respectively reduced rats' immobility in the forced swimming test and antagonized the decrease in retention latency caused by aging (26-28 months old rats) or 5 mg/kg i.p. diazepam in the passive avoidance task. The compound blocks the neuronal uptake of serotonin, increases dopamine release in the mesolimbic system, has moderate affinity and low intrinsic activity for benzodiazepine receptor binding and facilitates the transmission of glutamate on NMDA receptor. These effects can be involved in the favourable effects of CL 275,838 on depression and memory deficits, but clear evidence of their role is not yet available.

632.15

DuP 996 IS A NEUROTRANSMITTER RELEASE ENHANCER WITH COGNITIVE ENHANCING PROPERTIES. V. J. DeNoble, V.J. Nickolson,* K. F. DeNoble, K. W. Rohrbach, S. W. Tam, L. Cook, G. F. Steinfels, M. J. Myers,* and R. M. Scribner.* The Du Pont Merck Pharmaceutical Company, P.O. Box 80400, Wilmington, DE 19880-0400.

DuP 996 (3,3,-bis-C4-pyrindinylmethyl)-1-phenylindolin-2-one) enhances the K^+-stimulated release of acetylcholine, dopamine, and serotonin *in vitro*. DuP 996 is essentially inactive in binding to muscarinic and nicotinic receptors and in inhibiting cholinesterase activity. Behaviorally, DuP 996 was compared to Physostigmine (PH), and Tetrahydroaminoacridine (THA) for its ability to 1) prevent hypoxia-induced amnesia in rats, 2) increase lever press acquisition in rats, and 3) prevent hypoxia-induced disruption of visual recognition in squirrel monkeys. In these tests DuP 996 was found to be superior in that it either produced greater efficacy, was more reliable, and/or had a broader therapeutic window with a better safety margin (Table 1).

Table 1

	Activity in mg/kg		
	DuP 996	Ph	THA
Test			
Hypoxia Passive Avoidance (SC)	0.01-0.1	0.001-0.1	0.3-5.0
Lever Press Acquisition (PO)	0.1-1.0	IA*	IA
Monkey Visual Recognition (PO)	0.3, 0.6	0.1	IA
Tremor Rat (SC)	10	0.3	6.0
Monkey (PO)	5	0.5	3.0**

* IA-Inactive ** Emesis

These results suggest DuP 996 may have therapeutic value in the treatment of diseases which result in cognitive dysfunction.

632.16

[^{3}H]DuP 996 LABELS A NOVEL RECEPTOR SITE INVOLVED IN ENHANCEMENT OF STIMULUS-INDUCED ACETYLCHOLINE, DOPAMINE AND SEROTONIN RELEASE. D. Rominger and S. W. Tam. Central Nervous System Diseases Research, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880-0400.

DuP 996 [3,3-bis(4-pyrindinylmethyl)-1-phenylindolin-2-one] is a novel cognitive enhancer which has been shown to improve learning and memory in rodents and primates. DuP 996 and structural analogs enhance the K^+-stimulated release of acetylcholine, dopamine and serotonin in brain slices without effect on basal release. A novel receptor site labeled by [^{3}H]DuP 996 has been identified with a K_d of 19 nM and a B_{max} of 102 fmol/mg protein. Binding to this site is specific, saturable, reversible, time-, pH-, and temperature-dependent. Specific binding is decreased by treatment with trypsin and not affected by phospholipase C. Specific binding is inhibited by Ca^{2+} and increased by Mn^{2+} but not affected by Na^+, K^+, or Mg^{2+}. The [^{3}H]DuP 996 binding sites are heterogenously distributed in brain with striatum and hypothalamus having highest density and cerebellum lowest. The [^{3}H]DuP 996 binding site is novel because the [^{3}H]DuP 996 binding could not be displaced by a broad variety of standard pharmacological agents and neuropeptides. Physiological significance of this binding site is suggested by the excellent correlation between the binding affinity to this site and the potency to enhance K^+-stimulated release of acetylcholine for a series of DuP 996 analogs. Ligands for this receptor site may have therapeutic potential for the treatment of cognitive deficits and neurodegenerative diseases.

632.17

[^{3}H]DuP 996 LABELS A NOVEL BINDING SITE IN RAT BRAIN INVOLVED IN THE ENHACEMENT OF STIMULUS-INDUCED ACETYLCHOLINE, DOPAMINE AND SEROTONIN RELEASE: AUTORADIOGRAPHIC LOCALIZATION STUDIES. E. B. De Souza, B. L. Rule* and S. W. Tam. Central Nervous System Diseases Research, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880.

DuP 996 [3,3-bis(4-pyrindinylmethyl)-1-phenylindolin-2-one] enhances K^+-stimulated release of acetylcholine, dopamine and serotonin in brain slices without effects on basal release. DuP 996 has significant "cognitive-enhancing" effects in a variety of animal models of learning and memory. A novel high-affinity binding site for [^{3}H]DuP 996 which fulfills many of the criteria of a membrane receptor has recently been identified in homogenates of rat brain. In the present study, we have used in vitro labeling light microscopic autoradiography to localize [^{3}H]DuP 996 binding sites in rat brain. Preliminary experiments were carted out to optimize the binding parameters and to characterize the pharmacology of the [^{3}H]DuP 996 binding site in slide-mounted sections of rat brain. Overall, [^{3}H]DuP 996 binding sites were discretely localized with highest densities present in brain areas (cerebral cortex, hippocampus and amygdala) involved in cognitive processes. A laminar distribution of [^{3}H]DuP 996 binding sites was evident in the cerebral cortex and binding was highly localized in the CA1 to CA3 pyramidal cell layers of the hippocampus. Moderate densities of binding sites were present in the olfactory bulb, olfactory tubercle and amygdala. Lower levels of binding were present in striatum, thalamus and hypothalamus. The localization of [^{3}H]DuP 996 binding sites in brain areas implicated in memory processes and affected in Alzheimer's disease suggest that ligands for this binding site may have therapeutic potential for the treatment of cognitive deficits seen in dementia.

632.18

The Electroencephalographic (EEG) Effects of DuP 996, a Compound with Cognitive Enhancing Properties. G. P. ALBERICI, L. Cook, J.-L. GASKILL and G. F. STEINFELS. The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880-0400 USA.

Using EEG as a measure of brain electrical activity we examined the effects of DuP 996 on the EEG of 3 animal species; rat, rabbit and dog. Frontal-parietal, bipolar recordings were made from rat and dog, and multi-lead (16 electrodes) recordings were made in the rabbit for topographic analysis. EEG activity was collected online (125 Hz) and transformed into power spectra via a fast Fourier transform. The results were then grouped into the following EEG bandwidths: *delta* 1-5 Hz; *theta* 5-9 Hz; *alpha* 9-13 Hz; and *beta* 13-35 Hz for rabbit, *beta-1* 13-25, *beta-2* 25-50 for rat and dog. DuP 996 in a single dose of ≥ 0.085 mg/kg (sc) in rats and ≥ 0.0085 mg/kg (sc) in dogs decreased relative spectral power (RP) in the *delta* EEG band , and concomitantly increased RP in the *beta-1* EEG band. Topographical (rabbit) EEG results (0.85 mg/kg, sc) displayed the following: for mean frequency, a total brain increase in *beta* and a total brain decrease in *theta*. For relative spectral power, an occipital region increase in *beta*, a frontal region increase in *theta* and a frontal region decrease in *alpha*, and for absolute spectral power, a total brain decrease in *delta* and *alpha* and an occipital region increase in *beta*. In some cases these changes parallel those reported in clinical EEG studies of DuP 996 (Saletu, 1989).

632.19

ELECTROPHYSIOLOGICAL EFFECTS OF DUP 996 ON HIPPOCAMPAL CA1 NEURONS. B. W. Lampe and B. S. Brown*, CNS Diseases Research, The Du Pont Merck Pharmaceutical Co., Wilmington, DE 19880

DuP 996 (3,3-bis(4-pyridinylmethyl)-1-phenylindolin-2-one) enhances K^+-stimulated release of several neurotransmitters in various regions of rat brain *in vitro*. To explore its mechanism of action, conventional intracellular recording techniques were used to study the effects of DuP 996 on electrophysiological characteristics of CA1 pyramidal cells in rat hippocampal slices. DuP 996 (5-100 μM) enhanced the slow cholinergic epsp, reduced spike frequency adaptation (SFA), delayed repolarization of action potentials elicited by brief, threshold-level depolarizing pulses and increased the frequency of spontaneous action potentials, but had no consistent effect on resting membrane potential, input resistance, or inward rectification in response to hyperpolarizing current pulses. The effect of DuP 996 on epsp was blocked by atropine. The effect on SFA was not atropine-sensitive nor was it accompanied by a reduction of the cumulative slow afterhyperpolarization. Both facilitation of the cholinergic epsp and reduction of SFA occurred with all tested concentrations of DuP 996. These two effects may be due to a common mechanism, possibly the attenuation of certain K^+ conductances, and may provide the basis of DuP 996-enhanced neurotransmitter release.

632.20

DuP 996, A NOVEL NEUROTRANSMITTER RELEASER, BLOCKS VOLTAGE-ACTIVATED POTASSIUM CURRENTS IN CULTURED NEOCORTICAL NEURONS. J.M. Frey, P.A. Murphy* and B.S. Brown*, CNS Diseases Research, The Du Pont Merck Pharmaceutical Co., Wilmington, DE 19880

DuP 996 [3,3-bis(4-pyridinylmethyl)-1-phenylindolin-2-one] enhances the K^+-stimulated release of a number of neurotransmitters from rat neocortex, hippocampus and striatum *in vitro* without affecting basal release. To determine if increased release could be related to blockade of potassium channels, we examined the ability of DuP 996 to inhibit voltage-activated potassium currents in rat cultured neocortical neurons using the whole cell patch clamp.

In the presence of both Na^+ and Ca^{++} channel blockers (3 μM TTX and 4-5 mM Co^{++}/5 mM EGTA or BAPTA, respectively), depolarizing voltage commands (V_C) above -50 mV evoked outward currents with an early 4-aminopyridine-sensitive transient component (I_A) and a late tetraethylammonium-sensitive component (I_K). DuP 996 blocked both I_A and I_K nonselectively in a concentration-dependent manner above 30 μM; the half maximal inhibitory concentration (IC_{50}) was approximately 300 μM.

When Ca^{++} channels were not blocked by Co^{++}, evoked outward currents were ≈1.5-fold larger (at V_C=25mV) than those observed in the presence of Na^+ and Ca^{++} channel blockers. Under these conditions, 10 and 30 μM DuP 996 significantly blocked outward currents and the IC_{50} was < 100 μM. Our results indicate that DuP 996 is a more potent blocker of voltage activated, Ca^{++}-dependent outward currents than of I_A or I_K in cultured cortical neurons. Whether DuP 996 blocks Ca^{++}-dependent outward currents directly, or indirectly through a block of calcium channels is presently under investigation.

632.21

GLUCOSE FAILED TO REVERSE SCOPOLAMINE-INDUCED DEFICITS IN A WATER-ESCAPE TASK IN RATS. R.D. Holsten* and L.W. Means. Department of Psychology, East Carolina University, Greenville, NC 27858.

Thirteen Sprague-Dawley male rats were trained to escape in a two-choice water maze, where the choice section containing the escape platform was reversed on each trial following a correct choice. Rats were given 1 reference and 10 test trials/day with the trials separated by intertrial intervals of 1-2 min. Incorrect choices were punished by retaining the rat in the incorrect choice section for 30 sec. The rats attained a performance level of 9.2 correct choices/session (CC/S). Injections (s.c.) of .5, 1.0 or 2.0 mg/Kg scopolamine hydrobromide 30 min prior to testing significantly ($p<.01$ in each case) reduced the number of CC/S to 6.4, 6.8 and 7.0, respectively, whereas .5 mg/Kg methylscopolamine failed to affect CC/S (9.5). In a subsequent experiment using the same rats, no injection, injections with .5mg/Kg scopolamine alone, or in combination with 100, 250 or 500 mg/Kg glucose (i.p.) resulted in 9.6, 8.6, 7.9, 8.5 and 8.2 CC/S, respectively. The rats performed significantly ($p<.05$ in each case) worse after all injections than when tested after no injection. Thus, the rats were impaired on the task by the CNS activity of scopolamine, and glucose failed to ameliorate the scopolamine-induced impairment.

PARADOXICAL SLEEP IS SELECTIVELY SENSITIVE TO GLUCOSE IN AMNESIC RATS. W.S. STONE AND P.E. GOLD. Dept. of Psychology, U. of Virginia, Charlottesville, VA 22903.

Poor memory is highly correlated with impaired paradoxical sleep under several conditions. We determined here whether glucose administration, which enhances memory in rodents and humans, also enhances sleep In three amnesic populations: amygdala-kindled, atropine-treated, and old rats. Sleep records (3-hr EEGs) were obtained before and after rats received daily kindling stimulation (biphasic square waves, 1 msec, 60 Hz, 250 uA, 1 sec train) for 4-5 weeks or a single injection of atropine (1 mg/kg, IP). Later, spontaneous alternation performance was assessed after saline or glucose (100 mg/kg, IP) administration. EEGs were also obtained from aged (26 mo) Fischer 344 rats which received saline or glucose (100 mg/kg). These rats were then trained on an inhibitory avoidance task (1 ma, 1 sec) and later tested for generalization of the learned response.

The results were similar despite different designs and subject populations. Glucose selectively increased the duration of paradoxical sleep bouts - and improved memory - in amnesic but not in respective control populations, including within individual rats in these populations which do not exhibit sleep or memory impairments. These results show that paradoxical sleep measures predict the ability of glucose to attenuate memory deficits in 3 amnesic populations, and more generally, they show that the brain becomes significantly more sensitive to the effects of glucose administration in several amnesic populations. URINARY INCONTINENCE AND MEMORY IMPAIRMENT IN RATS WITH BASAL FOREBRAIN LESIONS AND IMPROVEMENT BY TREATMENT WITH A CEREBRAL ENERGY METABOLISM ENHANCER ASSOCIATED WITH RECOVERY OF LCGU. M. Miyamoto, Y. Nagai*, T. Nakayama* and A. Nagaoka*, Biology Res. Lab., Res. and Dev. Div., Takeda Chem. Ind. Ltd., Osaka 532, Japan.

Effects of chronic administration of idebenone on urinary incontinence and learning and memory impairment in rats with basal forebrain (BF) lesions were studied. BF lesions were made by injection of ibotenic acid (24 nmol/0.4 μl/side) into the bilateral BF involving cholinergic neurons projecting to the cerebral cortex. The BF-lesioned rats showed a significant urinary incontinence assessed by area saturated with urine, which lasted for about 4 weeks. Chronic treatment with idebenone (10 and 30 mg/kg/day, p.o.), started 4 days after BF lesions when the score of urinary incontinence became maximum, improved the urinary incontinence in a dose-dependent manner. The drug also ameliorated the impairment of water maze learning, as demonstrated by shortening of the latency to find the platform submerged in the water tank, and decrease in swimming distance until the rat found the platform. After completion of behavioral tests, effects of chronic treatment with idebenone on local cerebral glucose utilization (LCGU) were examined. The BF-lesioned rats showed a significant decrease in LCGU, especially in the cerebral cortex, such as frontoparietal cortex and temporal cortex, striatum and habenula, when compared to sham-operated rats. Idebenone provided a dose-dependent recovery of the decreased LCGU in rats with BF lesions. These results indicated that urinary incontinence and memory impairmment in the BF-lesioned rats may be related to the decrease in cerebral energy metabolism, and suggest that treatment with idebenone improves the deficits in the rats, associated with recovery of LCGU.

LONG-TERM (24 HR) MORPHOLOGICAL CHANGES INDUCED BY cAMP IN PLEURAL SENSORY NEURONS OF *APLYSIA* ARE DEPENDENT ON *DE NOVO* PROTEIN SYNTHESIS. F. A. NAZIF, J. H. BYRNE and L. J. CLEARY. Dept. Neurobiology and Anatomy, Univ. Texas Med. Sch., Houston, TX 77225

Previous studies have shown that long-term sensitization is correlated with morphogical changes in the sensory neurons mediating a defensive withdrawal reflex (Bailey and Chen, 1988). Some of these changes can be mimicked by the intracellular injection of cAMP (Nazif *et al.*, 1991). Since long-term sensitization and long-term facilitation require protein synthesis (Montarolo *et al.*, 1988; Castellucci *et al.*, 1989), we were interested in examining the role of protein synthesis in the induction of these morphological changes by cAMP.

Pleural ganglia of *Aplysia* were preincubated in either anisomycin (10 μM) or its inactive derivative deacetylanisomycin (10 μM) for one hr. cAMP was then iontophoretically injected into sensory neurons from right and left pleural ganglia. One hr after injection the ganglia were perfused with fresh culture medium. About 22 hr after injection the same neurons were pressure injected with HRP and incubated for another 2 hr. After histochemical processing, varicosities in axonal branches within the pleural neuropil were counted. The number of varicosities was greater in neurons whose ganglia were bathed in deacetylanisomycin than in neurons from contralateral ganglia, which were bathed in anisomycin (50 ± 10 SEM vs 23 ± 7 SEM; $P<0.05$; $n=6$).

These data suggest that the morphological changes induced by cAMP are dependent on the production of new proteins during and/or immediately following the injection of cAMP. This conclusion is consistent with the hypothesis that cAMP-dependent regulation of gene expression results in the synthesis of new proteins. Consequently, several mechanisms are affected, including those regulating neuronal morphology.

CHANGES IN PROTEIN PHOSPHORYLATION IN PLEURAL SENSORY NEURONS OF *APLYSIA* VARY DEPENDING ON THE DURATION OF SEROTONIN TREATMENTS. R. Homayouni, R. Zwartjes, J.H. Byrne, and A. Eskin. Dept. Biochem., Univ. of Houston, Houston, TX 77204. Dept. Neurobiol. & Anat., Univ. of Texas Medical School, Houston, TX 77225.

The facilitatory effects of serotonin (5-HT) on tail sensory neurons (SNs) in pleural ganglia of *Aplysia* are due in part to activation of cAMP-dependent protein kinase. The phosphorylation of a number of proteins in pleural SNs was found to be increased both following 2 min 5-HT and 24 h after 2 h 5-HT (Sweatt et al.,1989). The increase in phosphorylation 24 h after treatment did not occur when 5-HT was given with anisomycin, a protein synthesis inhibitor. To study the events responsible for the transition between short-term and long-term facilitation, we investigated the phosphorylation of proteins at the end of 2 min, 25 min, and 1.5 h treatments of 5-HT.

For each experiment 6 pedal-pleural ganglia and their matched controls were isolated and incubated in ^{32}P for 20.5 h. Experimental ganglia were treated during the end of labeling. After treatment, clusters of SNs were removed and the incorporation of ^{32}P into proteins was examined using 2D-PAGE. The phosphorylation of approximately 9 proteins was increased and 1 protein was decreased following either 2 min, 25 min, or 1.5 h 5-HT treatments. Only one protein was affected by all 3 treatments. Different sets of proteins were phosphorylated by different durations of 5-HT. This variation in protein phosphorylation may contribute to the transition between short-term and long-term facilitation.

We examined the effect of anisomycin alone and together with 1.5 h 5-HT on the phosphorylation of proteins. Anisomycin alone altered the phosphorylation of 5 proteins, some of which were the same as those affected by 5-HT. The effect of 1.5 h 5-HT on phosphorylation of one protein, whose phosphorylation was not affected by short 5-HT treatments or anisomycin alone, was blocked by anisomycin. This protein may play a key role in the induction of long-term facilitation.

633.3

EFFECTS OF ANISOMYCIN ON THE LATE CHANGES OF PROTEINS IN PLEURAL SENSORY NEURONS OF *APLYSIA* PRODUCED BY AN *IN VITRO* ANALOGUE OF SENSITIZATION TRAINING. F. Noel, J.H. Byrne, A. Eskin. Dept. of Neurobiol. & Anat., Univ. of Texas Med. Sch., Houston, TX 77225, & Dept. of Biochem. & Biophys. Sciences, Univ. of Houston, TX 77204.

An *in vitro* analogue of sensitization training in *Aplysia* produces early and late changes in the incorporation of label into specific proteins in pleural sensory neurons. Proteins were increased both at the end of (early) and 24 hr after (late) the training procedure. To determine whether the late changes require translation, we studied the effect of anisomycin applied during the training on the incorporation of labeled amino acid into proteins 24 hr after the training.

Experimental pleural-pedal ganglia were exposed to anisomycin (10^{-5} M) for a 3 hr period. One hour after the beginning of anisomycin, peripheral nerves of experimental ganglia were electrically stimulated with 4 trains of shocks for a 1.5 hr period. Twenty-two hours after the last electrical shock the control (C) and experimental (E) ganglia were exposed to ^{35}S methionine for a 2 hr period. The sensory neuron clusters were surgically removed and processed for 2D-PAGE. Control experiments included treatment with anisomycin without electrical stimulation and electrical stimulation without anisomycin.

Anisomycin by itself had a general effect on protein synthesis as well as an effect on specific proteins. The overall ^{35}S methionine incorporation into proteins was significantly decreased both in the presence (Ratio E/C = 0.65, n=12, $p<0.05$) and in the absence (0.69, n=10, $p<0.05$) of the training procedure, whereas it was not affected by the training procedure alone (0.83, n=8, p=0.12). In addition, the incorporation of label into 21 proteins were either increased or decreased by application of anisomycin alone. Most of the late proteins affected by training were also affected by the anisomycin treatment itself. However, the effect of training on one protein which was not affected by anisomycin alone, was blocked by anisomycin. These results indicate that at least one of the late changes was due to increased translation of a specific protein. They also emphasize the importance of controlling for the possible effects of anisomycin alone.

633.4

CALMODULIN SYNTHESIS AND mRNA LEVEL ARE REGULATED IN *APLYSIA* NEURONS BY TREATMENTS PRODUCING LONG-TERM FACILITATION. R. Zwartjes, F. Noel, J. H. Byrne, and A. Eskin. Dept. Bioch., Univ. of Houston, 77204, and Univ. Tex. Med. Sch., Houston, TX 77225.

Both translation and transcription inhibitors block the long-term effects induced by serotonin (5-HT) on cultured sensory neurons of *Aplysia* (Montarolo et al., 1986). Also, the induction of long-term facilitation is blocked by the injection of an oligonucleotide containing the cAMP response element (Dash et al., 1990). A number of studies have shown that changes in the synthesis of specific proteins occur as a consequence of behavioral sensitization training, an *in vitro* analogue of the training procedure, or application of 5-HT (Castellucci et al., 1988; Noel et al., 1989, 1990; Barzilai et al., 1989; Eskin et al., 1989). These results indicate that transcription of new messenger RNA, as well as the production of new proteins, may be involved in long-term changes in sensory neurons associated with sensitization.

To examine whether levels of mRNA change during induction of long-term facilitation, we used *in vitro* translation of RNA isolated from pleural-pedal ganglia, with 2-D PAGE of the labeled protein products. The level of mRNA is proportional to the amount of label incorporated into a protein. We previously reported that *in vitro* incorporation of ^{35}S-methionine into 4 proteins was increased following a 1.5 hr treatment of ganglia with 5-HT (Zwartjes et al., 1990). We have now identified one of the 4 proteins reported above as calmodulin (MW 17,000, pI 3.9). Purified chicken calmodulin comigrates with the *Aplysia* protein on 2-D PAGE, and a rat calmodulin antibody specifically labels this protein on Western blots of pleural-pedal proteins.

Is the increase in calmodulin mRNA accompanied by an increase in protein in stimulated pleural-pedal ganglia? We examined changes in ^{35}S-methionine incorporation into proteins of pleural sensory neurons produced by 1.5 hr electrical stimulation of peripheral nerves. Incorporation of amino acid into calmodulin was consistently increased 24 hr after stimulation (N=4). These findings suggest that calmodulin is transcriptionally regulated during the induction of sensitization and, moreover, calmodulin may be important in the induction or maintenance of long-term sensitization.

633.5

IDENTIFICATION OF PLEURAL NEURONS THAT INHIBIT TAIL SENSORY NEURONS OF *APLYSIA*: CORRELATION WITH FMRFAMIDE IMMUNOREACTIVITY. Y.Xu, L.J.Cleary and J.H.Byrne. Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

Sensory neurons (SNs) in the pleural ganglion are hyperpolarized by mechanical stimulation of the body outside their receptive field. FMRFa is a peptide that has inhibitory effects on SNs, and FMRFa immunoreactive (IR) neurons and processes are present in the pleural ganglion. No FMRFa IR neurons that inhibit the tail SNs have been identified, however.

A cluster of small cells in the right pleural ganglion had inhibitory effects on the SNs. Intracellular stimulation of these cells produced hyperpolarization of SNs. Identified inhibitory cells were injected with Lucifer yellow (LY) and labelled with rabbit anti-FMRFa antibody followed by goat anti-rabbit antibody conjugated to Texas Red. The hyperpolarization in the SNs produced by FMRFa IR cells developed slowly, and upon removal of the stimulation, diminished slowly, but the hyperpolarization produced by non-FMRFa IR cells diminished more rapidly. LY injection demonstrated that the FMRFa IR cells projected out into the pleural-cerebral connective (3 of 3), while most non-FMRFa IR cells (9 of 11) did not. Both FMRFa and non-FMRFa IR cells received strong synaptic inputs from the pleural-abdominal connective and peripheral nerves P8 and P9. The nerve-evoked EPSPs in FMRFa IR cells were always followed by a slow, long-lasting IPSP, whereas this was not always observed for the non-FMRFa IR cells. In one case, the FMRFa cell also received excitatory inputs from the SN it hyperpolarized. Preliminary immunohistochemical staining indicated that myomodulin, another peptide transmitter that inhibits SNs, is not contained in non-FMRFa IR cells.

These results suggest that inhibition of the SNs is produced by a family of inhibitory transmitters, one of which is FMRFa. Further studies are necessary to identify other inhibitory transmitters as well as the physiological role of inhibitory neurons in the mediation and modulation of the reflex responses for which the tail SNs comprise the afferent limb.

A NETWORK MODEL OF THE TAIL-WITHDRAWAL CIRCUIT IN *APLYSIA* J.A. White, L.J. Cleary, I. Ziv, and J.H. Byrne Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77225

The tail-withdrawal reflex is mediated at least in part by a monosynaptic circuit with properties that may be modulated by several forms of learning. The strength of the synaptic connection between sensory neurons (SNs) and motor neurons (MNs) is correlated with strength of the reflex response. However, it is difficult to explain how brief (< 1 s) trains of monosynaptic EPSPs from SNs to MNs can drive extended (> 10 s) activity in MNs and how observed changes in the amplitudes of these EPSPs produce changes in the duration of MN responses. To examine the determinants of intensity and duration of MN responses, we used a simulation program SNNAP (Ziv et. al., this volume) to construct a computer model representing the interactions among neurons of the circuit. Membrane conductances of model neurons are described by H-H type equations. Parameters were derived from electrophysiological and, in some cases, voltage-clamp studies.

Simulations indicate that monosynaptic connections from a number of SNs to a single MN contribute only to the first 1 s of the MN response, even when synaptic efficacies are greatly enhanced. In order to simulate the duration of the MN response, it is necessary to include elements representing recently described excitatory interneurons (INs) that elicit slow, decreased-conductance EPSPs in MNs. Disynaptic connections via as few as two INs can lead to extended (~20 s) response durations (RDs) in MNs at average spike rates (SRs) of about 2 sp/s. Changes in cellular properties of SNs and INs lead to changes in both RDs and SRs in MNs. Enhancement of EPSP amplitude by 100% via spike broadening in SNs leads to a 12% increase in SR and an 18% increase in RD. Synaptic depletion in SNs to 50% of control levels reduces SR by 31% and RD by 11%. Spike broadening in the INs is even more effective than that in SNs in increasing both SR and RD. Effects of spike broadening in SNs and INs are cumulative. We conclude that a network like the one described can account for the relationship between spike width and synaptic depletion in SNs and duration of responses in MNs. The simulations predict that changes in the properties of the INs would prove very effective in modulating the tail-withdrawal response.

SIMULATIONS OF ACTION POTENTIALS, TRANSMITTER RELEASE, AND PLASTICITY OF SENSORIMOTOR SYNAPSES IN *APLYSIA*. C. C. Canavier, D. A. Baxter, J. W. Clark*, and J. H. Byrne. Dept. of Electrical and Computer Engineering, Rice University, Houston, TX 77251 and Dept. of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225.

A Hodgkin-Huxley type membrane model of an *Aplysia* sensory neuron has been combined with a model of transmitter mobilization and release, as well as a model of the synaptic coupling with a follower motor neuron. The membrane currents in the model, as well as their modulation by 5-HT, were largely based on voltage-clamp data from the sensory neuron soma. In addition, material balances on cAMP and Ca^{2+} in the terminal were included. Release was modeled as a cubic function of Ca^{2+} current and a linear function of available transmitter. The population of transmitter vesicles was compartmentalized into pools. In addition to its effects on membrane currents, a facilitatory effect of 5-HT on transmitter mobilization was modeled. The parameters of the transmitter mobilization and release model were adjusted by fitting the simulated EPSP to published data recorded during presynaptic voltage-clamp pulses of varying duration (Hochner et al., 1986). The model of synaptic coupling included transmitter accumulation and removal from the cleft, as well as kinetics associated with the transmitter-gated current in the postsynaptic membrane. Simulations of voltage-clamped sensory neurons produced a good fit to the waveforms and maximum amplitudes of EPSPs under normal, depressed, and facilitated conditions. Simulations of action potentials also accurately predicted the resultant spike-induced EPSP. Moreover, modulation of K^+ channels and mobilization simulated empirically observed 5-HT-induced spike broadening and enhancement of transmitter release. Our goal is to incorporate this model of a sensory neuron and its synaptic terminal into a realistic network in order to simulate the modification of reflex circuits by simple forms of learning.

633.8

SEROTONIN- AND PKC-INDUCED SPIKE BROADENING IN TAIL SENSORY NEURONS OF *APLYSIA*. S.Sugita, D.A.Baxter and J.H.Byrne. Dept. of Neurobiology and Anatomy, Univ. of Texas Med. Sch., Houston, TX 77225.

Serotonin-induced spike broadening in the tail sensory neurons is due to both cAMP-dependent and cAMP-independent mechanisms (Baxter and Byrne, 1990). Since 5-HT translocates protein kinase C (Sacktor and Schwartz, 1990), we have begun to examine the possible role of PKC in the cAMP-independent aspect of broadening.

Application of phorbol 12,13-diacetate (PDAc, 3μM, n=9) led to a 26% increase in the duration of the action potential recorded in ASW (15°C), where spike width was measured as the time from the peak to 10% of the amplitude of the peak. 12-deoxyphorbol 13-isobutyrate (1-2μM, n=6) had similar effects. This spike broadening, like that induced by 5-HT, developed slowly and reached a maximum in 10-20 min. PDAc-induced broadening was blocked by a PKC inhibitor, calphostin C (3μM, n=4). Moreover, inactive phorbols (3μM, n=3) did not produce broadening nor interfere with the ability of 5-HT to induce broadening. Thus, the phorbol ester-induced broadening seems to be specific and due to the activation of PKC. Coapplication (n=8) of PDAc (3μM) and 8-bromo cAMP (1.5-5mM) produced the same level of broadening (25%) as PDAc alone.

We also examined the relationship between 5-HT- and phorbol ester-induced broadening. Application of 5-HT (40μM) after phorbol esters produced further broadening (increase from 25% to 53%, n=15), but was less than the maximal broadening produced by 5-HT alone (82%, n=8). In contrast, application of PDAc after 5-HT did not produce further broadening. These results suggest that spike broadening produced by 5-HT and PKC have some convergent sites or some common mechanism.

633.9

ATTENUATION OF SYNAPTIC STRENGTH PRODUCED BY β-BAG CELL PEPTIDE IS NOT DEPENDENT ON SPIKE NARROWING IN TAIL SENSORY NEURONS OF *APLYSIA*. J.R. Goldsmith and J.H. Byrne. Department of Neurobiology & Anatomy, University of Texas Medical School, Houston, TX 77225.

An extract of the bag cells inhibited the baseline tail-siphon withdrawal reflex and selectively suppressed long-term sensitization of the reflex (Goldsmith and Byrne, 1990). In addition, using an *in vitro* analogue of the reflex, we identified a possible neural site of action for the inhibition of the baseline reflex as well as three bag cell peptides (BCPs) which may produce the effect. β-BCP, ELH and γ-BCP were found to attenuate the synaptic strength of the sensory-to-motor connection underlying the tail withdrawal component of the reflex. The present experiments were designed to explore the possible role of presynaptic spike narrowing in this modulation. The effects of β-BCP, the BCP which produced the most robust attenuation of the EPSP, were examined.

Testing consisted of eliciting a single action potential in a tail sensory neuron (SN) by a brief intracellular depolarizing pulse and recording the monosynaptic EPSP elicited in a tail motor neuron. Ganglia were perfused with ASW containing 100 mM TEA (to facilitate detection of changes in duration of the action potential) and low Na^+ (to reduce spontaneous synaptic activity). Five action potentials were elicited in each of two test periods, the pretest and posttest, at an interstimulus interval of 5 min. β-BCP (1-10 μM) (n=14) or artificial seawater (ASW) (n=14) was bath applied 2.5 min after the last stimulus in the pretest. The posttest was begun 2.5 min after the bath application. Motor neurons were hyperpolarized by 30 mV during each test.

β-BCP produced a small but statistically insignificant narrowing of the SN action potential. However, there was an attenuation of the monosynaptic EPSP produced by β-BCP which became significant at the last trial of the posttest. These results suggest that β-BCP does not attenuate the monosynaptic EPSP by modulating membrane channels that regulate the duration of the SN action potential.

633.10

EFFECTS OF FMRFAMIDE ON INPUTS TO PERIPHERAL SIPHON MOTOR NEURONS IN *APLYSIA*. J. Cooper* and G. A. Clark. Program in Neuroscience, Princeton University, Princeton, NJ 08544.

The connections of *Aplysia* LE siphon sensory cells onto central motor neurons in the abdominal ganglion undergo presynaptic inhibition in response to the neurotransmitter FMRFamide. However, the siphon sensory cells also synapse onto a group of peripheral siphon motor neurons, and the effects of FMRFamide at peripheral connections were unknown. As an initial step toward investigating whether presynaptic inhibition, like presynaptic facilitation, can be synapse-specific in these cells, we have examined the effects of FMRFamide on excitatory postsynaptic potentials (EPSPs) elicited in peripheral siphon motor neurons by stimulation of either individual sensory neurons or the siphon nerve. As with previous work on FMRFamide at central synapses, we found that application of 10^{-6} M FMRFamide strongly inhibited the monosynaptic EPSP elicited in peripheral motor neurons by intracellular sensory neuron stimulation (97% ± 2% decrease, $p < .001$). However, in contrast to this inhibition, we also found that FMRFamide produced facilitation of the EPSP evoked by stimulation of the siphon nerve, which contains the axons of the LE sensory neurons as well as other cells (144% ± 39% increase, $p < .02$). As yet, we do not know whether this facilitation is due to an increase in the number of afferent fibers activated by the extracellular stimulus, or to an increase in synaptic efficacy *per se* (presumably at connections of low-threshold, non-LE cells). Nonetheless, because synaptic facilitation by FMRFamide has not been previously described, these results point to a possible new function for this transmitter, and further suggest that the same neuromodulatory substance can produce both inhibition and facilitation at different inputs onto a common postsynaptic target.

633.11

SIMPLE NEURAL NETWORK MODELS PROVIDE HEURISTIC TOOLS FOR UNDERSTANDING THE POSSIBLE ROLE OF COMMAND-LIKE NEURONS CONTROLLING BEHAVIORS IN *APLYSIA*. I. Kupfermann, D. Deodhar* and K.R. Weiss. Center for Neurobiolgy and Behavior, and Dept. of Physiology and Biophysics, Columbia U. School of Medicine and Mt. Sinai School of Medicine, New York, N.Y.

Feeding behavior in *Aplysia* involves two different types of responses: a highly stereotyped bite-swallow, and a more diverse orienting response. Bite-swallows are elicted by food stimuli applied to the medial region of the lip-tentacles. Orienting turns are elicited by intermediate or far lateral stimulation of the lip-tentacle region, and the magnitude of the response is a function of the distance of the stimulus from the mouth. If a far lateral stimulus is followed by a more medial stimulus, the response is appropriate to the more medial stimulus. No turns are elicited during the execution of a bite-swallow. The above input-output characteristics was modelled by means of a simple neural network consisting of an input layer (sensory neurons) of 5 units (medial, left and right intermediate and lateral receptive fields); an output layer (motor neurons) of three units (bite, left turn, right turn); and a hidden layer of 5 units. The network was repeatedly presented with 12 combinations of inputs and target outputs, and the connections were adjusted until the circuit produced the desired output for each of the possible inputs. Different networks were generated by varying the intitial conditions and transfer functions for the units. The functional role of individual units was analyzed by "stimulating" and "ablating" individual hidden units. The results indicate that simple tests done on individual neurons can provide misleading information on the actual role of the neuron in generating behavior.(MH 35564 & GM 320099)

633.12

FMRFamide INDUCES AN INCREASE IN Na^+ AND K^+ CONDUCTANCE IN THE LFS SIPHON MOTOR NEURONS OF *APLYSIA*. K.J. Belkin and T.W. Abrams. Dept. of Biol. and Inst. of Neurological Sci., Univ. of Pennsylvania, Phila., PA 19104

The molluscan neuropeptide FMRFamide has an inhibitory effect on at least two sites in the neural circuit mediating siphon withdrawal in Aplysia -- siphon sensory neurons (Piomelli et. al., 1987) and the LFS motor neurons (Belkin and Abrams, 1990). We have analyzed the ionic basis of the response of LFS neurons to FMRFamide. A puff of 2 uM FMRFamide onto the cell body causes a biphasic response: a transient inward current lasting 2-5 sec, followed by a prolonged outward current. The early phase of the FMRFamide response, which involves an increase in membrane conductance, is reduced in low $[Na^+]_o$ saline and is not blocked by 100 uM TTX. The early inward current inactivates with repeated application of FMRFamide. As previously reported, the prolonged outward current is carried by K^+. 2mM 4-AP blocks the late outward current. Neither 100 mM TEA nor the reduction of $[Ca^{++}]_o$ affect this outward current. In the presence of 4-AP, a third component of the FMRFamide response, a small prolonged inward current, is unmasked. Our pharmacological observations indicate that the K^+ current modulated by FMRFamide is distinct from $I_{K\text{-}S}$, which is increased by FMRFamide in the presynaptic sensory neurons of this circuit (Belardetti, et. al., 1987), as well as from $I_{K\text{-}V}$ and $I_{K\text{-}Ca}$.

633.13

cAMP AND ARACHIDONIC ACID INDUCE OPPOSITE MORPHOLOGICAL CHANGES WITH LONG-TERM PRESYNAPTIC FACILITATION AND INHIBITION IN THE SENSORY NEURONS OF *APLYSIA*. P.G. Montarolo*, D.L. Glanzman, E.R. Kandel & S. Schacher. Ctr. Neurobiol. & Behav., Columbia P&S, NYSPI, & HHMI, N.Y., N.Y. 10032.

The long-term changes in synaptic effectiveness with presynaptic facilitation of sensorimotor synapses in culture produced by 5-HT, and with long-term presynaptic inhibition produced by FMRFamide, can be mimicked by their respective second messengers. We now asked: Can cyclic AMP and arachidonic acid also produce structural changes in the sensory cells similar to those produced by 5-HT and FMRFamide? Iontophoretic injection of cAMP (200mM) into sensory cells evoked an increase of 70% ± 11 (N = 8), in the amplitude of the EPSP that was detectable 24 hrs later. This increase in synaptic strength was accompanied by a significant increase of 42% ± 18 in the number of sensory cell varicosities. Similarly, bath incubation (2 hr) of arachidonic acid (10 μM) evoked a significant decrease of -29% ± 3 in the amplitude of the EPSP and a decrease of -19% ± 2 (N = 8) in the number of sensory cell varicosities after 24 hr. Control injection of 5' AMP (200mM) into sensory cells (N = 8) or control incubation of sensorimotor cultures (N = 8) with eicosenoic acid (25 μM) had no significant effect on the EPSP or on the number of sensory cell varicosities (-10% ± 5 or 3% ± 2 for EPSP; -7% ± 3 or 4% ± 4 for varicosities). These results support the idea that the number of synaptic varicosities can be regulated in both directions by the appropriate modulatory transmitters and second messengers involved in presynaptic facilitation and presynaptic inhibition.

633.14

CYPROHEPTADINE BLOCKS 5-HT-INDUCED SPIKE BROADENING BUT NOT 5-HT-INDUCED ANTI-ACCOMODATION: EVIDENCE FOR MULTIPLE 5-HT RECEPTORS IN *APLYSIA* SENSORY NEURONS. Mercer, A.R.* and Carew, T.J. Dept of Psychology, Yale University, New Haven, CT 06520

Serotonin (5-HT) acts as a neuromodulator of pleural sensory neurons (SNs) in *Aplysia*. Two known effects of 5-HT are spike broadening and increased excitability (anti-accomodation). We examined whether these 5-HT-induced effects could be blocked by the 5-HT antagonist cyproheptadine (CYP). Bilateral pairs of pleural ganglia were used: one was tested with 5-HT alone, the other was treated with CYP 10 min prior to and during 5-HT application. SPIKE BROADENING: Brief pulses (2ms, 5nA) were used to elicit single spikes from SNs. 5-HT (5μM) significantly broadened spikes in control cells ($\bar{x}$ =19% increase, $p<.01$, N=5), whereas in the presence of CYP (200μM) SNs showed no significant spike broadening ($\bar{x}$ =-0.7% increase, N=6). A between-group comparison showed that CYP caused a significant reduction in 5-HT-induced spike broadening ($p<.01$). CYP itself had no significant effect on spike duration ($\bar{x}$ =-0.8% increase). 5-HT-induced spike broadening in pleural SNs involves reduction of IKv (Baxter and Byrne, 1990). In preliminary voltage clamp studies, we find that CYP can antagonize 5-HT-modulation of IKv. We are currently examining the effects of CYP on other currents (eg: IKs , Siegelbaum et al, 1982). ANTI-ACCOMODATION: In the same cells as above, 200ms (0.5nA) pulses were used to elicit spikes from SNs. 5-HT produced a significant increase in spike number both in 5-HT alone ($\bar{x}$ increase=200%, $p<.02$, N=4) and in 5-HT+CYP ($\bar{x}$ increase=200%, $p<.02$, N=5) . Thus CYP does not block the 5-HT-induced increase in excitability.

Our results indicate that some of the actions of 5-HT on pleural SNs are mediated by receptors differentially sensitive to CYP. This 5-HT blocker now provides a valuable tool with which to analyze the relative contributions of different receptors to neuromodulation associated with sensitization in *Aplysia*.

SENSORY NEURON SPIKE BROADENING INDUCED BY TAIL NERVE STIMULATION IN *APLYSIA* IS BLOCKED BY CYPROHEPTADINE. Marcus, E.A., Mercer, A.R.*, Emptage, N. J.* and Carew, T.J. Departments of Biology and Psychology, Yale University, New Haven, CT 06520.

Tail shock-induced sensitization in *Aplysia* is known to involve spike broadening in pleural sensory neurons (SNs). This effect on spike duration is mimicked by serotonin (5-HT) suggesting that tail shock-induced sensitization is mediated, at least in part, by 5-HT. We have tested this hypothesis directly by using the 5-HT antagonist cyproheptadine (CYP), which blocks 5-HT-induced spike broadening in SNs (Mercer and Carew, this volume).

Brief pulses of depolarizing current (2ms, 5nA) were used to elicit single spikes from pleural sensory neurons. Modulatory input to SNs was activated by stimulation of the tail nerve P9 (3 sec train of 50 ms pulses at 10Hz). Spike duration was measured before and after P9 stimulation. Ganglia from one side of the animal served as controls; those from the opposite side were treated with CYP (200 μM). P9 stimulation significantly increased spike duration in control SNs ($\bar{x}$ =16%, p<.05, N=6), whereas SNs treated with CYP showed no significant spike broadening ($\bar{x}$ =3%, N=6). Thus, CYP blocks spike broadening induced in pleural SNs by tail nerve stimulation.

Consistent with earlier findings that CYP selectively blocks 5-HT-induced spike broadening without affecting 5-HT-induced changes in excitability (Mercer and Carew, this volume), we have also found that CYP does not affect increases in excitability produced by P9 nerve stimulation. Specifically, in 5 experiments, P9 stimulation in normal sea water produced significant anti-accomodation ($\bar{x}$ increase in spike number=880%, p<.03) that was unchanged in CYP ($\bar{x}$ increase=880%, p<.03).

Our results complement previous work by providing direct evidence that 5-HT acts as a neuromodulator in tail SNs of *Aplysia*. Furthermore, our data suggest that endogenous 5-HT acts at different receptor sites in producing different forms of plasticity.

633.16

THE DUAL PROCESSES OF PRESYNAPTIC FACILITATION PRODUCED BY SEROTONIN ARE INHIBITED BY CYPROHEPTADINE IN SENSORY NEURONS OF *APLYSIA*. J.P. Pieroni and J.H. Byrne. Dept. of Neurobiology and Anatomy, Univ. of Texas Med. Sch., Houston, TX 77225

Serotonin (5-HT)-induced facilitation of transmitter release from sensory neurons mediating defensive reflex responses in *Aplysia* is due to at least two processes, spike broadening and a second process termed mobilization (Gingrich *et al.*, 1985, 1988; Hochner *et al.*, 1986). Since Mercer and Carew (this volume) demonstrated that cyproheptadine, a serotonin antagonist, blocks 5-HT-induced spike broadening in pleural sensory neurons, we were interested in determining whether it also affects 5-HT-induced enhancement of mobilization.

Abdominal ganglia were pretreated with TEA (100 mM) and TTX (250 μM) and connections between LE sensory neurons and follower cells (LFS or other similarly sized cells in the same vicinity) were monitored. In this preparation, application of 5-HT leads to an increase in spike duration and an increase in the amplitude of the monosynaptic EPSP which is independent of spike broadening (Pieroni and Byrne, 1989, 1990). Confirming Mercer and Carew, we found that cyproheptadine (200 μM) inhibited 5-HT-induced spike broadening. Moreover, it inhibited 5-HT-induced facilitation of the EPSP. Cyproheptadine did not appear to block spike broadening or facilitation induced by small cardioactive peptide B.

The inhibitory effects of cyproheptadine were seen when 5-HT was applied at either 5 or 25 μM. Preliminary analyses indicate that cyproheptadine may block spike broadening to a greater degree than it does enhancement of the EPSP, especially at the higher concentration of 5-HT. These results lend further support to the hypothesis that spike broadening and other mechanisms involved in the enhancement of the EPSP can be dissociated. Moreover, just as the facilitatory processes of spike broadening and anti-accommodation seem to be mediated by separate 5-HT receptors (Mercer and Carew, this volume), our results indicate that this dissociation may extend also to other aspects of facilitation, such as mobilization.

633.17

ANNEXINS ARE EXPRESSED DIFFERENTIALLY IN CNS, INCLUDING SENSORY NEURONS, AND EYE OF *APLYSIA*. L.J. Cleary, A. Eskin, J.H. Byrne. Dept. of Neurobiology and Anatomy, Univ. Texas Med. School, Houston, TX 77225.

In pleural sensory neurons and the eye, 5HT affects the synthesis of several proteins. One such protein from eye has been partially sequenced and shown to be a member of the annexin family (Raju et al., '90). An interesting property of the annexins is their high affinity binding to membrane phospholipids in the presence of Ca^{2+}, suggesting that they could play a role in regulating neuronal function. Using affinity-purified polyclonal antibodies against the consensus sequence peptide (αCS; Kaetzel & Dedman, '89), we examined the distribution of annexins in CNS and eye.

αCS-immunoreactivity (IR) was selectively, but not exclusively, expressed in sensory neurons throughout the CNS. In whole mounts, αCS-IR appeared to be present in all neurons in the pleural sensory cluster. Larger medial cells were not labeled. In the abdominal ganglion, neurons in the LE and RE clusters were labeled as well. Only a fraction of neurons in the sensory J cluster of the cerebral ganglion were labeled, and the sensory S cluster of the buccal ganglion was unlabeled. Other labeled cell groups include three medial clusters on the ventral surface of the cerebral and a cluster of 5-7 neurons, including B1, on the caudal surface of the buccal ganglia. In the eye, αCS-IR was present in the rhabdom, neuropil and optic nerve, but seemed to be excluded from the pigment cell layer. The distribution of labeling was clearly different from that of 5HT, which labels only the neuropil, or FMRFa and myomodulin, which each label a subpopulation of small cells in the photoreceptor layer. Western blots of homogenized pleural ganglia revealed one major cross-reactive protein of ~40 kD, and several minor bands.

The differential expression of annexins within the CNS might be related to the functional role of the IR neurons. One common feature of sensory neurons and the eye is sensitivity to 5HT. It is conceivable that annexins contribute to the cellular response to modulatory transmitters through alterations of intracellular calcium.

633.18

CLASS III ß-TUBULIN STAINING OF PERIPHERAL NEURONAL STRUCTURES IN APLYSIA. I.Steffensen*, M.Anctil, D.H.Vandorpe* and C.E.Morris. Biol. Dept., Univ. Ottawa & Neurosciences, Loeb Inst., OCH, Ottawa, Ont. K1Y 4E9.

Aplysia mechanosensory inputs from the tail region make monosynaptic connections with motor neurons in the pedal ganglia. Although synaptic changes associated with learning and memory have been extensively studied at the sensory-motor synapse, the peripheral mechanosensitive terminals have not been characterized. Class III ß-tubulin, a tubulin isotype expressed at the onset of neuronal differentiation in vertebrates, is neuronal-specific. Because it also appears to be neuronally-specific in Aplysia, we have been able to use it here to trace peripheral neuronal structures. The structures were visualized by immunofluorescence, using a monoclonal antibody against class III ß-tubulin on frozen cryostat sections from the tail region and from tentacles (tentacles have been described at the EM level: Emery & Audesirk 1977 J Neurobiol. 9:173). Neuronal structures in the tail region were comparable to those of the tentacles' mechanosensory exterior but not to those in its chemosensory groove. A variety of other ultrastructural and neuronal tracing techniques (eg. 2-deoxyglucose, lipophilic dyes, EM) to reveal mechanosensory endings in the tail region are also being explored. Supported by the Canadian NCE and NSERC.

633.19

SENSITIZATION IN JUVENILE APLYSIA IS AFFECTED BY DIET. J.M.Flinn,S.Kurtz,C.Hong,S.West*,Dols,S.* George Mason Univ,Fairfax,VA; EPA,Gulf Breeze,FL.

Juvenile Aplysia were raised from 50 days post-hatch on algae treated to be low in protein & tryptophan (LO), low in protein but high in tryp. (T), low in tryp. but high in protein (P) and high in both protein & tryp., (HI). Animals were tested for sensitization over a 3 wk period beginning 110 days post-hatching. At the beginning of testing the mean wts. in gms were .09 (LO), .10 (T), .42 (P), .37 (HI). Sensitization was examined by measuring escape behavior following tail shock and comparing control (C) and sensitization (S) groups. Preliminary analyses showed that the greatest sensitization level was seen in the T group at 130+ days post-hatch. The sensitization in this group increased over the 3 wk period and at 130+ days was +235% (S) vs -29% (C). Sensitization in the HI group also increased over the 3 wks and at 130+ days was +69% (S) vs -31% (C). The LO & P groups decreased in sensitization over 3 wks and did not show sensitization at 130+ days. The data suggests that a tryptophan-rich, protein-poor diet produced greater sensitization than a diet rich in both. HPLC analyses will be performed to examine the levels of serotonin and other neurotransmitters.

633.20

INDIRECT MODULATORY EFFECTS ON ANTERIOR FOOT MOVEMENTS BY THE C-PR NEURON IN *APLYSIA*. T. Nagahama, K. R. Weiss and I. Kupfermann. Center for Neurobiol. & Behav., Columbia U. and NYS Psychiat. Inst., New York, N.Y. 10032, and Dept. of Physiol. and Biophysics, Mt.Sinai School of Med., New York, N.Y. 10029

The cerebral neuron C-PR may function to elicit various manifestations of a food arousal state in *Aplysia*. We previously reported that C-PR firing produces polysynaptic EPSPs in neck motor neurons, and polysynaptic IPSPs in anterior foot motor neurons (AFs). We now report that the C-PR firing produces polysynaptic EPSPs in motor neurons innervating the middle and posterior foot. These results are consistent with the suggestion that the C-PR may mediate the appetitive feeding posture in which the animal lifts its head and expands the anterior foot while supporting its body with the middle and posterior foot. C-PR also has indirect modulatory effects on the anterior foot movements produced by the AFs. We previously showed that these effects may be caused by pedal modulator neurons (P1Rs) which receive monosynaptic EPSPs from the C-PR. There appear to be two types of P1R neurons: those (P1R-E) that enhance (or initially reduce and then enhance) contraction, and those (P1R-R) that reduce contraction. P1R-E neurons enhance (or reduce and enhance), whereas P1R-R neurons reduce the size of the synaptic currents produced by AFs. Preliminary data indicate that the P1R-E neurons are immunoreactive to pedal peptide (PEP) (antibody supplied by P.E. Lloyd). PEP applied arterially predominantly enhanced anterior foot movements evoked by AFs and increased the size of synaptic currents produced by AFs. These results suggest that the P1R-E neurons may contain PEP, and that PEP may contribute to the enhancement effect of these neurons. The enhancement effects of PEP and of P1R-E are completely blocked when the muscle is bathed in ASW containing high divalent cations, suggesting that PEP is either acting on a peripheral nerve net or is altering the excitability of the nerve terminals of the AFs.

Two patterns of buccal nerve activity that distinguish ingestion from rejection can be replicated in a reduced preparation in *Aplysia*. D. W. Morton[1] and H. J. Chiel[2,1], Departments of [1]Neuroscience and [2]Biology, Case Western Reserve University, Cleveland, OH., 44106.

We are studying the neural basis of feeding in *Aplysia californica*. Our approach has been to associate *in vivo* patterns of neural activity with specific behaviors and then develop a reduced preparation which produces similar patterns of activity and is suitable for intracellular recording. Using *in vivo* cuff electrode recordings of buccal nerve 2 (BN2) and the ipsilateral radula nerve (RN) with a simultaneous video record, we have associated two patterns of large unit activity with two types of consummatory feeding behavior. Pattern I is associated with ingestion (biting or swallowing), and is characterized by a burst of large units on the RN occurring together with a burst of large units on BN2. Pattern II is associated with rejection, and is characterized by the RN activity preceding the BN2 activity. The burst of RN activity occurs with retraction in pattern I and protraction in pattern II. To investigate the neural basis of these patterns, we have developed a reduced preparation producing two patterns of large unit activity, termed *in vitro* patterns, that are qualitatively similar to the *in vivo* patterns. Using this preparation, we have identified a buccal ganglion neuron that closes the radula when stimulated, appears as a large unit in RN extracellular recordings, and is active during the RN burst in both *in vitro* patterns. These results suggest that this radula closer motor neuron is active with retraction during ingestion and protraction during rejection, consistent with observations of radula closure during these behaviors. Studying this motor neuron's pre-synaptic cells during both *in vitro* patterns could provide insights into the neural control of radula closure during ingestion and rejection in *Aplysia*. Support: BNS-8810757 and 5T32GM07250.

Characterization of Pattern Triggering Neurons from *Aplysia's* Buccal Ganglion *In Situ* and in Culture. H. J. Chiel[1,2] and Jingtao You[1], Departments of [1]Biology and [2]Neuroscience, Case Western Reserve University, Cleveland, OH, 44106.

Pattern triggering neurons have been described in the buccal ganglion of *Aplysia* (Susswein and Byrne, J. Neurosci. 8:2049, 1988). Do these neurons induce bursting due to their intrinsic properties or by their connections to other neurons? To answer this question, we have studied these neurons in the buccal ganglion and in isolated cell culture. Cells were identified using the criteria of Susswein and Byrne. The only neurons which we found that triggered patterns also generated action potentials, and thus might correspond to B33, 35 or 37. In the intact ganglion, cells were injected with lucifer yellow and their morphology was visualized. Of 8 cells filled in 8 different ganglia, 5 showed a single axon which crossed the midline of the ganglion via the buccal commissure; the remaining 3 had axons projecting via peripheral nerves (buccal nerves 2, 3 or the cerebral buccal connective). In the intact ganglion, low calcium solutions blocked the ability of the neurons to trigger patterns, but caused spontaneous bursts to occur in B4. High divalent cation solutions greatly reduced the ability of the neurons to trigger patterns, but fast IPSPs and slow EPSPs from these neurons to B4 were clearly observed. Maps of ganglia were drawn with a camera lucida, pattern triggering cells were identified physiologically, and cells were removed for isolated cell culture. In 10 experiments (one in which the cell was cultured in isolation, and 9 in which it was co-cultured with B4), pattern triggering neurons showed irregular firing in response to large depolarizing currents *in vitro*, but did not burst. These results support the hypothesis that the pattern-triggering neurons induce bursting in the buccal ganglion by means of synaptic connections to other neurons. Supported by NSF grant BNS-8810757.

THE RELATIVE INFLUENCE OF OLFACTORY AND TACTILE STIMULI ON THE FEEDING BEHAVIOR OF THE NUDIBRANCH, *MELIBE LEONINA*. W.H. Watson III and C.M. Chester*. Dept. of Zoology, University of New Hampshire, Durham, N.H. 03824

The nudibranch, *Melibe leonina*, feeds by rhythmically sieving small crustaceans from the water with its large oral hood. Previous studies demonstrated that the frequency of feeding movements is proportional to the concentration of prey. The purpose of this study was to determine what qualities of prey are important in modulating the frequency of *Melibe* feeding.

During a typical experiment 4 animals were placed in an aquarium and exposed to one of the following treatments: 1)*Artemia* at a concentration of 1500/ml; 2) *Artemia*-conditioned seawater; 3) small (350 μm) Sephadex beads in clean, filtered seawater or; 4) Sephadex beads soaked in *Artemia*-conditioned water. The feeding frequency of each animal was then monitored for 20 min.

Both conditioned water (olfactory stimuli) and Sephadex beads (tactile stimuli) caused appetitive behavior (orientation of the oral hood) and a significant increase in the rate of feeding. When both were added together, they produced a larger increase than either did alone, but still not as great a response as the intact *Artemia*. Thus, we conclude that *Melibe* detects the presence of prey using at least three different signals: smell, touch, and perhaps movement of live prey. This study was supported by the U.N.H. BRSG program.

OPTICAL MEASUREMENT OF ACTIVITY IN THE MELIBE LEONINA BUCCAL GANGLION. Larry B. Cohen, Win Watson, Jim Trimarchi, Chun X. Falk and Jian-young Wu. Dept. of Physiology, Yale University School of Medicine; Dept. of Zoology, University of New Hampshire; and Marine Biological Laboratory.

Molluscan buccal ganglia have been used to study the neural basis of feeding behavior. However, detailed information about the underlying neural circuits is lacking for most buccal preparations because of their complexity. The buccal ganglion of Melibe leonina, with only 40-50 neurons, is relatively simple and transparent. Optical recordings from this ganglion might be able to monitor all the action potentials in all of the neurons. Using ganglia stained with a merocyanine (JPW1124) or an oxonol (RH155) dye we tested the completeness of the recording. In one preparation we were able to detect activity in more than 90% of the cells. In a recording made during rhythmic output from the ganglion we detected activity in about 50% of the neurons. However, in many preparations the measuring light led to a photo-stimulation. We plan to try reduced dye concentration and additional dyes to avoid this effect. Supported by NIH grant number NS08437 and a UNH Summer Faculty Scholarship.

633.25

ACQUISITION PHASE OF FEEDING BEHAVIOR IN THE PTEROPOD MOLLUSC CLIONE LIMACINA. T.P. Norekian and R.A. Satterlie. Dept. of Zoology, Arizona State Univ., Tempe, AZ 85287-1501 and Friday Harbor Laboratories, Friday Harbor, WA 98250.

Two types of acquisition responses have been observed in Clione. (1) Buccal cone eversion can be triggered by direct contact with prey. The threshold for such a "fast strike" is very high, and an unsuccessful strike results in immediate withdrawal of the buccal cones. (2) Perfusion of prey extract across the head of a Clione, placement of an animal in the vicinity of feeding animals, or injection of serotonin into the hemocoel of a non-feeding animal triggers buccal cone eversion without direct contact with a prey item. In these cases, buccal cones remain extended for prolonged periods (hunting behavior).

Three classes of cerebral motoneurons have been identified that are directly involved in prey acquisition. One group (A neurons) initiates lip retraction, buccal cone eversion and general contraction of head musculature. A neurons inhibit the other two classes of neurons which retract the buccal cones (B neurons) and close the lips (C neurons). Serotonin activates A neurons and thus favors buccal cone eversion. Dopamine depolarizes both A and B neurons, but the effect is much more powerful in B neurons. Dopamine thus favors buccal cone retraction. Superfusion of GABA produces simultaneous inhibition of B neurons and excitation of A neurons. The difference between a fast strike and hunting behavior may hinge, at least in part, on the interplay between several modulators/transmitters which regulate the excitability of feeding neurons.

DEPLETION OF SOMATOSTATIN BY CYSTEAMINE SELECTIVELY INHIBITS DARK-ONSET FEEDING IN RATS. D. Feifel and F.J. Vaccarino, Department of Psychology, University of Toronto, Toronto, Canada M5S 1A1.

In a previous study we demonstrated that blockade of endogenous GRF by injections of GRF antiserum into rat hypothalamus, selectively inhibited dark-onset feeding, but not feeding at other circadian time points, This suggested that endogenous GRF plays a role in the circadian organization of feeding. We have also reported that inncreased somatostatin activity is an important output for GRF-induced feeding. This study sought to determine if endogenous somatostatin, like GRF, also plays a role in circadian-specific feeding.

Male Wistar rats were housed under a 12:12 light-dark photoschedule and tested for their feeding response to subcutaneous injections of cysteamine (300 mg/kg) (known to deplete body somatostatin). Results indicated that cysteamine injections selectively inhibited food intake (51%) at dark-onset but not at other time point tested.

These findings suggest that somatostatin, like GRF, is involved in the mechanism which organizes the circadian pattern of feeding in rats. This work was supported by NSERC grant 35036 to F.J.V. D.F. was supported by a MRC Postgraduate Scholarship.

THE EFFECT OF Nle^4,D-Phe^7-[α-MSH] AND ITS FRAGMENTS ON CORE TEMPERATURE IN RATS. L.H. Raible*[1] and M. Camacho-Ochoa[2]. Kalamazoo College, Kalamazoo, MI 49007[1], The Upjohn Company, Kalamazoo, MI 49001[2].

The research of Lipton and coworkers indicates that α-melanocyte stimulating hormone (MSH) exerts antipyretic and hypothermic actions in the rabbit. Research on MSH and temperature in the rat has utilized peripheral or ventricular injections and has yielded inconclusive findings. More direct application of MSH or an analog of MSH might produce more conclusive results. The present experiments examined the effects of a potent MSH analog (Nle$_4$, D-Phe$_7$-[α-MSH]; NDP-MSH) and its fragments (NDP-MSH$_{1-7}$, NDP-MSH$_{4-10}$, NDP-MSH$_{7-13}$; all provided by Dr. Tomi Sawyer, The Upjohn Company) on temperature when injected into the anterior hypothalamic/medial preoptic area (AH/POA). Results indicated that rats receiving .5 pmol of NDP-MSH/.5 µl NaCl displayed significantly greater temperatures than those receiving the vehicle, $F(5,30)= 5.00$, $p<.002$. The least amount of variance was observed in those subjects receiving 5 pmol NDP-MSH. The second experiment indicated that AH/POA injections of 5 pmol/.5 µl NDP-MSH and its 4-10 and 7-13 fragments significantly elevated temperature while injections of vehicle and of the 1-7 fragment did not, $F(4,52)=12.72$, $p<.0001$, a finding consistent with other assays. Studies designed to eliminate the possibility of a pyrogenic contaminant in the effective solutions are currently underway.

CENTRALLY INJECTED BOMBESIN ELICITS GROOMING IN DEVELOPING RAT PUPS.
H. Piggins[1] and Z. Merali[1,2], [1]Psychology & [2]Pharmacology, University of Ottawa, Ottawa, Canada, K1N 6N5.
In adult rats intracerebroventricular (i.c.v.) injection of the tetradecapeptide bombesin (BN) elicits a scratching form of grooming behaviour. In this study, we aimed: (1) to ascertain if i.c.v. BN would elicit grooming behaviour in developing rats and (2) to characterize the sequential nature of this response. Briefly, anaesthetized pups of 1-20 days of age were injected i.c.v. with BN (0.01-1.0 µg) or saline (n=7/dose/age) and the videotaped responses scored for grooming and other behaviours. BN dose-dependently induced grooming in rat pups up to 20 days of age. The 20 day olds were the most and 1 day olds the least sensitive to i.c.v. BN. Non-contact scratching activity was prevalent from postnatal day 1 and was replaced in the sequence of grooming behaviour with contact scratching activities by postnatal day 20. Scratching activities appeared to form a subsystem connected to but nonetheless separate from washing behaviours and this was particularly distinguishable at postnatal day 20. Changes in BN-induced grooming reflected the maturation of the motor capabilities of the developing rat. Further, these results indicate that BN binding sites in the developing rat central nervous system are pharmacologically functional from an early stage in ontogeny.

EFFECT OF SYSTEMICALLY ADMINISTERED CERULETIDE ON MOUTH MOVEMENT IN CHRONIC FLUPHENAZINE TREATED RATS. T.Saito, T. Ashizawa, E.Hashimoto, H. Ikeda, H.Ozawa, N.Takahata. Dept. Neuropsychiatry, Sapporo Medical College, Sapporo 060 Japan

The effect of repeated administration of ceruletide (100 ug/kg/day, 1P, 3days) on mouth movement and SCH 23390 binding to striatal membrane were examined in chronic fluphenazine enanthate (FPZ)treated rats(25mg/kg, IM, every 3 weeksx10) and sesame oil treated (control) rats. Three weeks after final FPZ injection, mouth movement (teeth chattering, chewing, licking, opening of mouth, perioral tremor) and an increase in SCH 23390 binding to striatal membrane were observed in the FPZ-treated rats. High amplitude EMG discharge(8c/s),which correlated to perioral tremor was recorded from the masseter in the FPZ-treated rats. Repeated ceruletide injection suppressed mouth movement and normalized SCH 23990 bining to striatal membrane in the FPZ-treated rats. The effects of ceruletide on mouth movement and D_1 receptor continued for 6 days after final ceruletide injection. These findings indicate that systemically administered ceruletide affects the D_1 receptor and that an increase of D_1 receptor function may play an important role in the pathogenesis of tardive dyskinesia.

MIF-1 ALTERS PAVLOVIAN CARDIAC CONDITIONING, CONCOMITANT CORTICAL NEURONAL ACTIVITY, & DELAYS EXTINCTION IN RABBITS
Linda L. Hernández, Philip J. Tollison* & Charles M. Gibbs, Dept. VA Hospital & U. South Carolina, Columbia, SC 29201.

Rabbits received Pavlovian conditioning training in which a tone (CS+) was paired repeatedly with a mild eye-shock and another tone (CS-) was never paired with shock. Separate groups were treated with 10 or 100 µg/kg MIF-1 or saline vehicle (i.v.) prior to training and subsequent extinction testing. Tone-evoked bradycardia was acquired which was larger in response to the CS+ than the CS-; 10 µg/kg MIF augmented the magnitude of these learned responses, compared to saline, whereas 100 µg/kg MIF decreased conditioned response magnitude. Concomitant, tone-evoked multiple unit activity in medial prefrontal cortex (PFCm MUA) showed comparable changes; i.e. evoked PFCm MUA was larger in the group treated with the low dose of MIF, and was smaller in the group treated with the higher dose, than in saline-treated controls. During extinction, both MIF treatments delayed disappearance of the conditioned heart rate discrimination compared to saline; the higher dose reduced the magnitude of responses evoked by both CSs, whereas the low dose reduced the magnitude of responses evoked by the CS- and augmented those evoked by the CS+. These data show that MIF-1 can promote acquisition and delay extinction of conditioned autonomic responses and alter associated PFCm MUA during training. Supported by DVA Research funds and USPHS Grant RO1-DA06676.

EFFECTS OF POSTNATAL ADMINISTRATION OF ACTH AND NICOTINE ON REPRODUCTIVE PARAMETERS OF THE FEMALE RAT. S.E. Alves, H.M. Akbari, F.J. Antonawich, E.C. Azmitia and F.L. Strand. Department of Biology and Center for Neural Science, New York University, New York, NY 10003.

A previous study in our laboratory has shown that *prenatal* administration of ACTH 1-24 or nicotine decreases the lordosis response in female rats tested as virgins (Alves and Strand, 1990; Soc. for Neurosci., #114.8). This study was conducted to investigate whether *postnatal* treatment of these substances would affect the reproductive capacity of female rats. Sprague-Dawley rat pups were injected s.c. with either ACTH 1-24 (0.1mg/kg), nicotine hydrogen tartrate (0.25mg/kg) or saline vehicle once daily from postnatal day one (day of birth) to day 7. Starting at 30 days of age, the females were checked for vaginal opening as a sign of sexual maturation. At approximately 60 days of age, these animals were tested for sexual behavior as virgins. The sexual maturation of ACTH treated animals was significantly delayed when compared to nicotine treated and control animals ($p<0.01$). Animals from both treatment groups displayed decreased female sexual behavior, having significantly lower lordosis quotients and lordotic quality scores compared to control animals ($p<0.01$). Hypothalamic 5-HT fiber density was assessed using high affinity ^{3}H-5-HT uptake. 5-HT uptake was significantly increased in ACTH treated animals ($P<0.02$) but unchanged in nicotine treated animals compared to controls. This increase in hypothalamic 5-HT in ACTH treated animals could account for the decrease in female sexual behavior seen in these animals. Based on this study we suggest that sexual differentiation of the brain in the female rat is also susceptible to *postnatal* manipulation with ACTH or nicotine. We are currently investigating plasma sex steroid levels and immunohistochemistry for the neurotransmitters involved in female sexual behavior. This study was supported by the Council for Tobacco Research.

PEPTIDE T TREATMENT OF COGNITIVE IMPAIRMENT IN HIV+ INTRAVENOUS DRUG ABUSERS. M. I. Rosen*, C. VanDyck*, T. P. Bridge*, C. Duncan, S. S. O'Malley*, H. R. Pearsall*, B. L. Martini*, H. M. Thomas*, P. O'Connor*, H. Brett-Smith*, S. W. Woods, T. R. Kosten*. Yale University CMHC New Haven, CT 06519

Peptide T, an analogue of Vasoactive Intestinal Peptide, has improved cognitive function in patients with AIDS Dementia Complex in open clinical trials. We treated five methadone maintained, cognitively impaired HIV positive patients in a double blind cross-over study for four weeks with Peptide T, 5 Mg intranasally tid, and with placebo for four weeks. The five patients were impaired on at least two tests of neuropsychological function, and had been treated with AZT for at least one month prior to enrollment. The sample was 80% male, with a mean age of 37 and baseline WAIS of 84, verbal IQ of 86, performance IQ of 83.

Our patients showed an average improvement of .4 SD on the following five tests with Peptide T, compared with no change with placebo: Trails B (TMB), the Parker Verbal Learning Test (PVLT), Grooved Pegboard (GPB-N), Stroop Interference Test (STRP-CW), and the Paced Auditory Serial Addition Test (PASAT). Patients improved .7 SD on Peptide T compared with placebo for those tests they were originally impaired on. Our other data suggest improvement in constitutional symptoms with Peptide T.

Methodologic differences between our study and the previous open label trials include; different doses of Peptide T, different routes of administration (IN vs. IV), concurrent administration of AZT, and subject population (methadone maintained substance abusers vs. homosexual men). Further studies will be necessary to determine optimal parameters for Peptide T administration and selection of patients likely to respond to Peptide T.

EFFECTS OF MESENCEPHALIC INJECTIONS OF NEUROTENSIN$_{1-13}$ AND NEUROTENSIN$_{8-13}$ ON CENTRAL GRAY SELF-STIMULATION. P.P. Rompré[1] and A. Gratton[2]. [1]CSBN, Psychology Dept., Concordia University, Montreal, Quebec, H3G 1M8 and [2]Douglas Hosp. Res. Ctr., McGill University, Verdun, Quebec, H3H 1R3.

Results from anatomical, biochemical and electrophysiological studies suggest that mesencephalic dopamine (DA) neurons receive a direct excitatory input from nerve elements that release neurotensin (NT). In this experiment, we compared the effects of mesencephalic injections of NT1-13 and its C-terminal fragment, NT8-13, on central gray self-stimulation (SS). Rats were implanted with a stimulation electrode in the central gray and a guide cannula in the ventral or dorsal mesencephalon and subsequently trained to bar press to obtain a train of cathodal, rectangular pulses of a fixed intensity. Changes in the function relating the rate of bar presses to the stimulation frequency were measured immediately before, and after the injection of 3 nmoles of NT1-13, NT8-13 or its vehicle. Results obtained from thirteen rats with ventral cannula placement, show that the C-terminal fragment, NT8-13, is fully active and is as potent as NT1-13 in decreasing the frequency threshold for SS; the facilitation effect, however, was observed 15 minutes after the injection with NT8-13 compared to 35 minutes with NT1-13. No significant changes in threshold were seen when the peptides were injected in the dorsal mesencephalon.

Supported by a grant from le Fonds de la Recherche en Santé du Québec.

EVIDENCE FOR AN INTERACTION OF NEUROTENSIN WITH THE A-1 SUBTYPE OF ADENOSINE RECEPTORS. **F. B. Jolicoeur and D. Ménard. Depts. Psychiatry and Pharmac., University of Sherbrooke, Sherbrooke Qc. Canada J1H 5N4**

We have reported that pre-administration of the mixed adenosine receptor antagonist, theophylline, systematically abolishes the hypothermic and hypokinetic effects of neurotensin (Soc. Neurosci. Abstr. 1990) In order to better delineate this interaction, we examined the effects of pre-treatment of several adenosinergic drugs purported to act specifically at the A1 or A2 receptor subtype, either as agonists or antagonists. For each drug examined, a dose which was centrally inactive when given alone, was injected SC 15 min prior to the intracerebro-ventricular administration of several doses of neurotensin (0.03 - 50.0 µg). LPIA (A1 agonist) significantly enhanced both the hypothermic and hypokinetic effects of neurotensin. On the other hand, IBMX (A1 antagonist) significantly decreased the hypothermia but not the hypokinesia produced by neurotensin. Prior administration of CPCA and DMPX (A2 agonist and antagonist respectively) did not alter these effects of neurotensin. These results suggest that neurotensin induced hypothermia and possibly hypoactivity might be mediated via an interaction with adenosine A1 receptors. However, an interaction of the peptide with phosphodiesterase might also be of importance, since theophylline and IBMX are well known inhibitors of this enzyme.

THE EFFECTS OF INTRACEREBRAL INJECTIONS OF TWO NOVEL NEUROKININS (NEUROKININ A AND NEUROKININ K) ON THE EXPRESSION OF MALE RAT SEXUAL BEHAVIOR. Peter Malen*, Kevin Short*, and Wayne Dornan. Dept. of Psychology, Illinois Wesleyan University, Bloomington, IL. 61701

Substance P (sP), a member of the tachykinin group of neuropeptides, has been implicated in the neural control of male copulatory behavior. Recently two novel neurokinins, neurokinin K (neuropeptide K) and neurokinin A (substance K), derived from the same gene and precursor molecule (ß-preprotachykinin) as sP, have been identified in the mammalian CNS. At present, however, it is not known whether neurokinin K (NKK) or neurokinin A (NKA) has any role in the neural regulation of male rat copulatory behavior. Therefore, in a series of experiments we examined the effects of bilateral injections of different doses of NKK or NKA into the Medial Preoptic Area (MPOA) on male rat copulatory behavior. In the first experiment, bilateral injections of 10 or 100 ng of NKK into the MPOA had no effect on male copulatory behavior when compared to saline injected controls. Injections of 1 and 2 µg of NKK into the MPOA, however, produced a dramatic disruption in the expression of copulatory behavior in sexually vigorous male rats when compared to controls. In contrast, bilateral injections of 10 or 1000 ng of NKA into the MPOA failed to affect any parameters of male copulatory behavior. The results of the present study provide further support for a role of neurokinins in the neural regulation of copulatory behavior in the male rat. Taken together, these results suggest that at the level of the MPOA, sP and NKK, two neurokinins synthesized from the sP gene, play a differential role in the regulation of male copulatory behavior while NKA, another neurokinin derived from the same sP gene may not be involved in the neural regulation of male copulatory behavior.

CHRONIC ADMINISTRATION OF ANGIOTENSIN II AND DuP 753 INCREASES GROWTH OF EMBRYONIC RAT HEART CULTURED *IN OCULO*. R. Hunt, A. Torres, and D. C. Tucker. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Angiotensin II (AII) is implicated in the development of cardiac hypertrophy. AII may exert a direct trophic effect or act indirectly by potentiating sympathetic neural influences. Little is known about the effect of AII on developing cardiac tissue.

Embryonic rat heart (E-12) was cultured in the anterior eye chambers of male Sprague-Dawley hosts. One eye chamber of each host was sympathectomized by removal of the ipsilateral superior cervical ganglion. Eye chamber sympathectomy significantly decreased graft mass in control animals (4.72±0.71 vs. 1.54±0.81 mg) after 9 weeks *in oculo*.

Chronic administration of non-pressor doses of AII (60 or 120 ng/kg/hr) or the non-peptide AII-1 receptor antagonist DuP 753 (10 mg/kg/day, p.o.) did not alter graft growth in innervated eye chambers. In sympathetically denervated eye chambers, however, both AII and DuP 753 significantly increased graft mass (3.33±0.78 and 3.53±0.62 mg, respectively). Although both AII and DuP 753 caused similar growth in embryonic myocardium cultured in sympathetically denervated eye chambers, we hypothesize that the mechanisms by which this growth was achieved are different.

INHIBITION OF CALCITONIN-INDUCED ANOREXIA BY ANTIDEPRESSANT DRUGS. R. de Beaurepaire*. Laboratoire de Pharmacologie, CHU Côte de Nacre, 14032, Caen, FRANCE.

Calcitonin is a peptide hormone secreted by the thyroid gland, which acts primarily on calcium homeostasis. When injected peripherally or centrally, calcitonin reduces food intake. The effects of chronic antidepressant treatment on calcitonin-induced anorexia were tested in rats.

Daily intraperitoneal injections of 9 different antidepressants, two anxiolytics, and one neuroleptic were made during three weeks, and the daily food intake of the animals were recorded every day during the last week. The drugs were tested in groups of 8 animals, and for each drug a control group of 8 animals was daily injected with saline. On day 21, the animals received an intraperitoneal injection of 40 units of calcitonin.

The results show that calcitonin reduces food intake by more than 90% in all control animals and animal treated by the anxiolytics (meprobamate, 100 mg/kg, clorazepate, 60 mg/kg), and the neuroleptic (chlorpromazine, 10 mg/kg), but not in animals treated with the antidepressant drugs. The most effective drugs were clomipramine (15 and 25 mg/kg), imipramine (25 mg/kg), amitriptyline (25 mg/kg), trimipramine (30 mg/kg), and maprotiline (25 mg/kg). Conversely, fluoxetine (15 mg/kg), fluvoxamine (30 mg/kg), viloxazine (30 mg/kg), and trazodone (100 mg/kg) inhibited the effects of calcitonin in some animals, but the results were not significant.

These results demonstrate that tricyclic antidepressants can have a specific inhibitory effect on a behavior induced by a centrally active peptide.

SELECTIVE ANTAGONISTIC PROPERTIES OF THE C-TERMINAL FRAGMENT OF CALCITONIN GENE-RELATED PEPTIDE, H-CGRP$_{8-37}$. D. Ménard, [1]A. Fournier and F. Jolicoeur. Depts of Psychiatry and Pharmacology, Univ. Sherbrooke, Sherbrooke Qc, Canada J1H5N4 and [1]INRS-Santé, Pointe Claire, Qc, Canada .

Results from our recent studies indicated that a C-terminal fragment of Calcitonin Gene-Related peptide, CGRP$_{8-37}$ could block certain in vivo and in vitro effects of h-CGRP (JPET 254:123,1990). In order to further characterize the antagonistic properties of this fragment, its activity against the following h-CGRP neurobehavioral effects were examined: hypokinesia, anorexia, analgesia, hyperthermia and catalepsy. These effects were obtained following intracerebroventricular (ICV) administration of 20 µg of the peptide. First, CGRP$_{8-37}$ alone injected ICV in several doses (10-80 µg) did not alter any neurobehavioral measurements. However, prior administration of the fragment at 40 µg significantly attenuated and at 80 µg systematically abolished the anorexia and analgesia produced by CGRP. The other neurobehavioral effects of CGRP were not affected. These results support the existence of heterogeneous receptors mediating central effects of CGRP. Follow-up structure activity studies, using various C-terminal fragments of the peptide, indicated that CGRP$_{9-37}$ was the minimal length required to obtain antagonistic activity.

634.14

MOLECULAR AND CELLULAR ORGANIZATION OF THE PEPTIDERGIC NETWORK UNDERLYING MALE COPULATORY BEHAVIOR IN A SIMULTANEOUS HERMAPHRODITE ANIMAL, *LYMNAEA STAGNALIS*. W.P.M. Geraerts, A.B. Smit* and K.W. Li*. Faculty of Biology, Vrije Universiteit, Amsterdam, The Netherlands.

Male mating behavior of the gastropod snail, *Lymnaea stagnalis*, consists of a series of flexible (non-cyclic) behaviors that are a prelude to copulation. To define the distribution of neurons that compose the network underlying male copulatory behavior, retrograde cobalt chloride fillings of the penis nerve were carried out. Several clusters of peptidergic neurons together with individual neurons and a serotonergic cluster ("I-cluster"), all located at the right side of the CNS, were identified.

We used recombinant DNA methodology and peptide chemistry to identify the structural organization of the prohormones and the bioactive peptides that are expressed in the neurons of the network. Large neurons in the lobus anterior of the right cerebral ganglion and several smaller clusters in other ganglia express a gene encoding the APGWa precursor. It contains 10 copies of APGWa and a 36 aa peptide, the C-terminal anterior lobe peptide (CALP). All 10 copies of APGWa and CALP are endoproteolytically processed from the prohormone. The gene is also expressed in the Ring Neuron that affects the egg laying controlling neuroendocrine caudodorsal cells. The lobus ventral neurons in the right cerebral ganglion, which form also part of the network, express the FMRFa gene (Linnacre *et al.*, 1990). Finally, a small cluster adjacent to the I-cluster in the right pedal ganglion expresses the peptide, myo-modulin. Currently, several additional peptidergic neuron clusters are in the process of analysis. All peptides as well as serotonin are transported to the penial complex. Sero-tonin and FMRFa, when applied *in vitro*, evoke contractions of the penis retractor muscle. APGWa antagonizes the serotonin-induced contractions. APGWa has, in addition, excitatory effects on several types of neurons, including those of the I-cluster. These data are sustained by whole-mount and light- and electron-microscopic immunochemical studies, showing intrinsic APGWa-positive axonal branching patterns and synapse-like structures that form connections between the neurons of the network.

We conclude that the male mating behavior of *Lymnaea* is controlled by a, mainly peptidergic, network. The organization of information processing of the network is complex and no doubt further studies of this network will reveal novel means of communication between (peptidergic) neurons that are part of complex networks.

DIFFERENTIAL EXPRESSION OF NEUROPEPTIDE mRNA AS RELATED TO AGE IN *APLYSIA*. M. Kindy*, M. Srivatsan*, and B. Peretz. Depts. Biochem. and Physiol. Univ. of Kentucky Med. Ctr., Lexington, KY 40536-0084.

With increased age the *Aplysia* nervous system manifests behavioral, physiological and morphological changes (Peretz et al., 1984; Peretz, 1989). The basis of these age related changes is unknown. Although environmental factors can influence the effects of age on the *Aplysia* nervous system (Zolman & Peretz, 1987), as yet the role of genetic factors has not been examined. Here we describe age-related differences in the mRNA expression of Phe-Met-Arg-Phe-NH_2 (FMRFamide) and egg-laying hormone (ELH) in the abdominal ganglion, a part of the *Aplysia* CNS. Northern blot analysis of RNA isolated in ganglia from young (ca 80 days old), mature (ca 140 days old) and aged (over 240 days old) animals revealed two mRNA species of 1.4 and 3.2 kb for FMRFamide mRNA and a single mRNA species of 0.8 kb for ELH. In young animals FMRFamide mRNA was exhibited at low levels, with a 1.5 fold increase in the mature group and a 2-3 fold decrease in old animals. In contrast, the ELH mRNA levels increased 2 fold from young to mature animals, but in old animals the increase was ca 25 fold. These studies show that age has a differential effect on mRNA of these two peptides in the abdominal ganglion, thus the differential effect of age on abdominal ganglion neurons reported earlier (Peretz et al., 1984) may well have a genetic basis. Our findings suggest that there is a genetic basis for the age-related change in behaviors mediated by ELH and FMRFamide in *Aplysia*.

CONOPRESSIN G SUPPRESSION OF THE SEROTONIN-SENSITIVE K^+ CURRENT IN APLYSIA SENSORY NEURONS. M. Martinez-Padron, J. Edstrom and K. Lukowiak. Neuroscience Research Group, University of Calgary, Calgary, Alberta T2N 4N1 Canada.

Single-electrode voltage clamp techniques were used to analyze the mechanism of action of the excitability and action potential shape changes caused by conopressin G on *Aplysia* siphon sensory neurons (Martinez-Padron and Lukowiak, 1989). Bath application of micromolar concentration of conopressin G reversibly decreases the total outward membrane current produced by depolarizing voltage commands to -20 mV. The threshold for this action is in the 10^{-8} M range. The reversal potential of the outward current is shifted in the positive direction by about 50 mV per 10-fold increase in the extracellular potassium concentration, indicating that at this range of membrane potentials, the outward steady-state current is carried mainly by potassium ions. changes in the extracellular concentration of sodium or chloride had little or no effect on the reversal potential. Intracellular injection of CsCl blocks the outward potassium current by about 75% and abolishes or greatly reduces the effect of conopressin G, suggesting that the peptide is acting to reduce the outward K^+ current.

The current is highly resistant to tetraethylammonium ions (Kd = 200 mM) and to 4-aminopyridine (Kd = 10 mM). The effect of conopressin G is reduced by prior application of 5-HT and forskolin. Taken together, these data suggest that conopressin G decreases the S-like current in abdominal siphon sensory neurons.

DRUGS OF ABUSE—PRENATAL ETHANOL

635.1

FETAL ETHANOL EXPOSURE ALTERS GLUCOCORTICOID AND ß-ENDORPHIN RESPONSES TO STRESS. J. Weinberg and C. Gianoulakis, Dept of Anatomy, Univ of British Columbia, Vancouver, BC V6T 1Z3; Douglas Hosp Res Center, Dept of Psychiatry, McGill Univ, Verdun, Quebec H4H 1R3.

Prenatal ethanol exposure alters development and response of the hypothalamo-pituitary-adrenal (HPA) axis and the pituitary ß-endorphin (ß-EP) system in the rat. The present study examined effects of fetal ethanol exposure (FEE) on habituation to repeated exposures to a stressor (60 min restraint, once daily).

Sprague-Dawley males and females from FEE, pair-fed (PF) and ad lib-fed (C) conditions were terminated prior to stress (basal) or immediately after 1, 5 or 10 exposures to restraint stress. Plasma levels of corticosterone (CORT) and ß-EP were elevated over basal levels in both males and females following single or multiple restraint periods. In females, CORTs in FEE and PF were higher than levels in C, while ß-EP levels did not differ among groups. In contrast, for males, CORT levels were similar among the 3 groups, whereas FEE males exhibited a greater and more sustained elevation of plasma ß-EP after multiple restraints. These data indicate little or no habituation of CORTS or ß-EP to repeated stress and suggest that prenatal ethanol exposure may differentially affect FEE males and females at different levels of the HPA-axis and ß-EP system. EFFECTS OF PRENATAL ALCOHOL EXPOSURE AND ACOUSTIC TRAUMA ON THE RAT'S AUDITORY BRAINSTEM RESPONSE (ABR). M.W. Church and G.W. Overbeck*. Fetal Alcohol Research Center, Dept. Ob/Gyn, Wayne State Univ. Sch. Med., Detroit, MI 48201.

Sprague-Dawley rats were prenatally exposed to alcohol by giving liquid diets containing 35% ethanol-derived calories to pregnant dams (gestation days 8-22). Pair-fed and non-treated control groups were also used. One pup from each litter was exposed to acoustic trauma (118 dB alarm bell) during the critical period for noise-induced hearing loss (about 20 days of age). To evaluate auditory acuity, ABR latency-intensity profiles were developed for click and tone burst stimuli with intensities of 25 to 100 dB peSPL.

Regarding offspring not exposed to acoustic trauma, the alcohol group showed marked prolongations in ABR latencies as pups but normal ABRs as adults. This suggested that prenatal alcohol exposure delayed otoneurological development. Regarding offspring exposed to acoustic trauma, animals in the alcohol group had longer ABR latencies and higher ABR thresholds as adults. This indicated some degree of permanent hearing loss, suggesting that prenatal alcohol exposure increased the vulnerability to noise-induced hearing loss. (Supported by NIAAA grant AA07606 and NIDA grant DA05536).

635.4

SYNERGISTIC EFFECTS OF SHORT-TERM MATERNAL EXPOSURE TO ETHANOL AND EARLY SENSORY DEPRIVATION ON VISUAL DISCRIMINATION LEARNING IN RATS. M.H. Lee, A. Potempska*, and A. Rabe. NY State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314

Ethanol exposure during cerebral cortical development has been shown to produce cortical thinning and disorganization, but not necessarily a detectable functional deficit. Nevertheless, the animal may have been rendered vulnerable to other adverse influences. Possible synergistic effects of ethanol exposure and light deprivation during development were tested. Offspring of Long-Evans rats who had received a total oral dose of 10g/kg of ethanol on gestation days 14 and 15 (E) and lab chow controls (C) were reared either in a dark room (D) or under a 12-hour light/dark cycle (L) from day 5 to 45. They were then trained in a shock-motivated two-choice box to discriminate between horizontal and vertical alternating black-and-white stripes.

The ED rats were impaired in learning the discrimination: they needed more trials than the CD rats to reach criterion. In contrast, the EL rats did not differ from the CL rats. The results thus indicate that acute maternal consumption of ethanol and adverse early postnatal rearing environment can synergistically produce a functional deficit.

635.5

DEVELOPMENTAL REGULATION OF GABA EXPRESSION IN THE SUPERIOR COLLICULUS OF SWISS WEBSTER MICE IS AFFECTED BY PRENATAL ALCOHOL EXPOSURE. C.S.Zajac and D.L.McGunagle*. Fetal Alc Res Ctr, Wayne State Univ., Detroit, MI 48201.

This study was undertaken to determine the developmental regulation of gamma amino butyric acid (GABA) expression in the superior colliculus (SC) of Swiss Webster mice and the effect of prenatal alcohol exposure (3g/kg) on that regulation. To that effect, newborn (NB) and gestation day (GD) 15 fetal mouse pups were sacrificed by decapitation into liquid nitrogen, lyophylized, and stored at -70°C. GABA levels were determined for lyophylized SC using the "GABAse" method. The SC of NB male pups prenatally exposed to alcohol had significantly greater levels of GABA than all other groups tested including NB females with the same treatment. There were no significant differences between other groups.

The superior colliculus plays an important role in coordinating reflex responses to visual, auditory, vestibular and somesthetic input. The significantly higher GABA levels in newborn male pups (but not in females) confirm other studies showing a sex related difference in the response of neurons to prenatal alcohol exposure.

635.6

SPONTANEOUS BEHAVIORAL ORGANIZATION IN RATS PRENATALLY EXPOSED TO ETHANOL

M. J. Renner[1], A. J. Bennett*[1], D. R. Widman*[2], & B. A. Blanchard*[3] [1]Department of Psychology, Memphis State Univ., Memphis, TN 38152 [2]Department of Psychology, State Univ. of New York, Albany, NY 12222 [3]Department of Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208.

Prenatal exposure to alcohol is associated with deficits in learning, attention, and motor performance. This study was conducted to identify the characteristics of spontaneous behavior that may contribute to these deficits. Pregnant female rats were fed one of three diets from gestation days 6-20: a liquid diet in which 35% of calories were derived from ethanol (35%, $n=6$ pups); liquid diet without ethanol, fortified with sucrose for equivalent caloric intake to the 35% ETOH diet (0%, $n=8$ pups), and standard lab chow (LC, $n=7$ pups). After G20, mothers and pups were given standard lab chow. At 80 days of age pups were videotaped during 3 consecutive nights' access to a trapezoidal arena containing two objects. Tapes were scored for locomotion, general activities (e.g., grooming), and object interactions, using a standard protocol (Renner & Seltzer, *J Comparative Psychology*, 1991, in press). This method minimizes subject stress and maximizes expression of the subjects' behavioral repertoire. Objects with different stimulus characteristics were treated differently, consistent with other studies using these techniques. No effect of prenatal maternal diet was found for any molar-level measure of behavior, including interactions with objects. Microanalysis of behavior sequences used during object interaction, however, revealed increases in behavioral complexity over days for LC group and decreases for the 35% group; the 0% showed different effects for manipulable (decreases) and nonmanipulable (increases) objects. These results are consistent with the hypothesis that prenatal exposure to ethanol exerts its effects on information-processing capability through subtle behavioral and attentional changes.

635.7

THE EFFECT OF EMBRYONIC ETHANOL EXPOSURE ON SENSORY AND MOTOR NEURONAL DEVELOPMENT IN THE CHICK SPINAL CORD. B Mendelson. Dept. of Anatomy, U. of Ark. for Med. Sci., Little Rock, AR 72205.

Embryonic exposure to ethanol often produces motor dysfunction consisting of poor balance, and altered gait. To determine if abnormalities produced in spinal sensory and motor neurons contribute to these symptoms, chick embryos were exposed to physiological concentrations of ethanol during development. Subsequently, the effect of ethanol treatment on neural morphology was determined by retrogradely labeling identified populations of sensory and motor neurons with DiI. After diffusion of the dye, the arborization patterns of afferent collaterals and the cell body positions of the neurons were analyzed. The positions of the cells after ethanol treatment were appropriate for the nerve labeled. Sensory afferents that had peripheral processes in either the lateral femoral cutaneous (LFC) or the sartorius (Sart) nerves were located in appropriate dorsal root ganglia, and motoneurons that supplied the Sart muscle were positioned laterally in the lateral motor column of lumbosacral segments 1 and 2, as in normal embryos. However, LFC afferent collaterals arborized in an abnormal pattern. Normally at E12 (St 38), the vast majority of LFC collaterals enter the gray matter medially, within lamina 3 in the chick. The few fibers that enter laterally, remain lateral in laminae 1 and 2. In ETOH-treated E12 embryos, a large number of LFC collaterals enter the gray matter laterally and many proceed medially into lamina 3. The density of arborization in the medial and lateral regions was similar, whereas in normal E12 embryos the lateral region is almost devoid of processes. Therefore, ETOH-treatment appears to induce inappropriate sensory collateral growth that may lead to abnormal processing of sensory information in the spinal cord. BRAIN CATECHOLAMINE CONTENT DURING RECOVERY FROM STRESS IN FETAL ETHANOL-EXPOSED RATS. P.K. Rudeen and J. Weinberg. Dept of Anatomy & Neurobiology, Univ of Missouri, Columbia, MO 65212; Dept of Anatomy, Univ of British Columbia, Vancouver, BC. V6T 1Z3

Effects of fetal ethanol exposure on brain catecholamine (CA) content during recovery from restraint stress were examined. Sprague-Dawley male and female rats from fetal ethanol-exposed (FEE), pair-fed (PF) and ad libitum-fed (C) conditions were terminated prior to stress (basal), immediately after 60 min restraint, or following 15, 30 or 60 min recovery. Tissue CA were measured in hippocampus (HIP), hypothalamus (HY), and cortex (CX) by HPLC-EC. Restraint resulted in a reduction of HY norepinephrine (NE) content that persisted for at least 30 min following stress termination. NE levels returned toward basal levels by 60 min of recovery. A similar response was seen in CX NE but the decrease was smaller and longer lasting. Cortical NE was reduced overall in FEE and PF compared to C animals, whereas HY NE was reduced in FEE females but not males. There was a sex difference in HIP NE but no sex or treatment effects in epinephrine (E) or dopamine (DA) content of HY or CX. Reduction of neuronal CA content after restraint that continues throughout 30 min of the recovery period suggests that the effects of stress continue following the cessation of the stressor. The differential response seen in FEE animals may be related to the pituitary-adrenal hyperresponsiveness previously observed. (Supported by NIAAA grants AA05893 & AA00107 (PKR) & AA07789 (JW).

EFFECTS OF CROSS-FOSTERING ON THERMOREGULATION DEVELOPMENT AFTER PRENATAL ALCOHOL EXPOSURE.
B. Zimmerberg, A.A. Beliveau*, A.H. Furniss*, Williams College, Williamstown, MA 01267.

One critical variable in neonatal thermoregulation studies is the role of the mother. Prenatal alcohol-exposed (35% EDC) rat pups were reared by their biological dams or fostered to control (LC) dams at postnatal day 1. Control pups were also cross-fostered. On postnatal days 5, 10 and 15, pups were isolated and rectal temperatures taken hourly for 4 hours. Effects of cross-fostering were detected. Alcohol-exposed pups reared by 35% EDC dams had significant thermoregulatory deficits at 5 and 10 days of age compared to all control groups, but fostered alcohol-exposed pups were no different from pair-fed controls, although they did differ from both LC control groups. Both fostered and non-fostered alcohol-exposed pups gained less weight postnatally compared to controls, but LC pups fostered to 35% EDC dams also gained less weight than non-fostered LC pups. These results suggest that maternal behavior by 35% EDC dams should be considered in neonatal state regulation studies that use this animal model.

EVIDENCE THAT MODERATE ETHANOL CONSUMPTION DURING GESTATION DOES NOT ALTER THE METABOLOTROPIC OR IONOTROPIC COMPONENTS OF HIPPOCAMPAL QUISQUALATE RECEPTORS IN RAT OFFSPRING.
S.A. Queen, C.F. Sanchez,* S.R. Lopez,* L.L. Paxton* and D.D. Savage. Department of Pharmacology, Univ. of New Mexico School of Medicine, Albuquerque, NM 87131.

Prenatal exposure to a relatively high maternal blood ethanol concentration (BEC) decreases quisqualate metabolotropic stimulated inositol–1–phosphate (IP_1) accumulation in the hippocampal formation (HPF) of adult rat offspring (*Life Sci.* 45:803, 1989). We have reported reductions in the number of HPF N–methyl–D–aspartate (NMDA) and kainate subtypes of glutamate receptors in rats exposed to a more moderate BEC *in utero*. We investigated whether prenatal exposure to a more moderate maternal BEC would affect either the metabolotropic or ionotropic components of HPF quisqualate receptors in rat offspring.

Rat dams were fed a liquid diet containing 3.35% ethanol (17.5% ethanol–derived calories) throughout gestation. Consumption of this diet produced a peak maternal BEC of 40 mg/dL. Another group of dams was pair–fed a 0% ethanol diet isocalorically equivalent to the 3.35% ethanol diet. A third group of dams was fed lab chow *ad libitum*. Offspring from each group were sacrificed at 45 days of age and the brains processed either for IP_1 accumulation studies or *in vitro* ^{3}H–amino–3–hydroxy–5–methylisoxazole–4–propionate (AMPA) autoradiography.

Quisqualate metabolotropic agonist stimulation of IP_1 accumulation by either ibotenate or trans–1–amino–1,3–cyclopentanedicarboxylic acid (ACPD) was not altered in the HPF of prenatal ethanol exposed rats compared to pair–fed or *ad lib* controls. Furthermore, no differences were observed among the three experimental groups in specific ^{3}H–AMPA binding to the ionotropic quisqualate site in HPF or cerebral or cerebellar cortical regions. These results suggest a differential sensitivity among subtypes of HPF glutamate receptors to the effects of prenatal ethanol exposure. Higher maternal BECs are required to alter HPF metabolotropic quisqualate responses than the BEC required to alter HPF NMDA and kainate subtypes of glutamate receptors. Whether higher BECs are required to alter the ionotropic subtype of HPF quisqualate receptor remains to be established.

ELECTROPHYSIOLOGICAL AND BEHAVIORAL FINDINGS IN RATS EXPOSED TO ALCOHOL PRENATALLY.
W.M. Kaneko*, E. Riley, S.L. Lopez* and C.L. Ehlers. Dept. of Psychology, San Diego State Univ., and Dept. of Neuropharm. Res. Inst. Scripps Clinic, La Jolla, CA 92037

Fetal alcohol syndrome (FAS) is one of the highest known causes of mental retardation in the western world. Previous research has shown behavioral and electrophysiological abnormalities in human infants born to alcoholic mothers, particularly hyperactivity. A rat model for FAS, which has several qualitative similarities to the human condition, has recently been developed. In the present study this rat FAS model was used to evaluate the effects of prenatal exposure on locomotor behavior and two paradigms for the generation of auditory event-related potentials (ERPs). Nineteen Sprague-Dawley adult male rats from two prenatal liquid diet treatment groups: alcohol exposed (35% ethanol-derived calories, 35% EDC) and nutritional control (0% ethanol-derived calories, 0% EDC), were stereotaxically implanted with electrodes aimed at dorsal hippocampus (DHPC), amygdala (AMYG) and frontal cortex (CTX). ERPs were recorded in response to an auditory "oddball" paradigm and an oddball plus "startle" paradigm. Evaluation of ERPs revealed that both paradigms produced consistent results. The prenatal alcohol exposed group had significantly longer P1 and N1 latencies than the control group for the rare tone in both paradigms ($p<0.005$ and $p<0.02$ respectively). Statistical analysis of these animals locomotor behavior evaluated in photocell cages revealed that the prenatal alcohol exposed rats also showed significantly more locomotor behavior (crossovers) in the first four hours of their activity cycle ($p<0.03$). These results suggest that this animal model displays electrophysiological and behavioral findings similar to human FAS and further suggests that this model may provide the substrate to investigate what brain mechanisms may be altered in FAS children.

EFFECT OF IN UTERO ETHANOL EXPOSURE ON THE POSTNATAL DEVELOPMENT OF BERGMANN GLIA IN RAT CEREBELLUM.
A.K. Shetty* and D.E. Phillips. Dept. of Biology, Montana State University, Bozeman, MT 59717.

Animals prenatally exposed to ethanol exhibit a delay in the postnatal migration of cerebellar neurons from the external granular layer to the internal granular layer. Since these neurons use the long processes of Bergmann glial cells across the molecular layer as guides during migration, we have examined the postnatal development of Bergmann glia following prenatal ethanol exposure. Pregnant rats were either fed with an ethanol containing liquid diet in which 37.5% of the total caloric content was ethanol derived or were pair fed with an isocaloric diet throughout gestation. Female offspring were perfused on postnatal day 15 and Bergmann glial fibers in the cerebellar vermis were stained immunohistochemically using an antibody against glial fibrillary acidic protein (GFAP). GFAP positive Bergmann glial fibers stretched from the Purkinje cell layer to the glial limiting membrane in both ethanol treated and control rats; however, the density of fibers per unit length was reduced in lobule I ($p<0.03$), lobule VII ($p<0.0001$) and lobule X ($p<0.1$) of ethanol treated rats. It appears that prenatal ethanol exposure retards the postnatal development of Bergmann glial cells in the cerebellum which may contribute to the delayed migration of granule cells.

THE EFFECTS OF PRENATAL OR POSTNATAL ETHANOL EXPOSURE ON SPATIAL LEARNING IN RATS.
M. D. Bannoura. Florida Atlantic Univ. Boca Raton, FL 33431

The purpose of this experiment was to investigate the effects of pre- and postnatal ethanol (ETOH) exposure on spatial learning in 30 & 60 day old Sprague-Dawley rats (Charles River). Pregnant rats were randomly assigned to one of 3 groups: liquid diet (BioServ) containing 35% ethanol derived calories (EDC), 0% EDC, or ad lib rat chow (Purina). The postnatal exposure group self administered either a 15% sweetened (Nutrasweet) ETOH solution or distilled water from postnatal day 13 to 17. Spatial learning performance was measured over 5 consecutive days beginning on either day 30 or 60, in a Morris swim maze. At both 30 & 60 days, there was a significant difference in performance between the pre- and postnatal exposure groups. At both ages, the postnatally exposed group showed greater deficits in learning. These data suggest that postnatal ETOH exposure produces greater deficits in spatial learning than prenatal ETOH exposure.

MORPHOLOGICAL AND ELECTROPHYSIOLOGICAL EFFECTS OF ETHANOL ON DEVELOPMENT OF DORSAL RAPHE TRANSPLANTS *IN OCULO*.
A-Ch. Granholm and C. Bäckman*. Dept. Basic Sci. Oral Res., Univ. Colorado HSC, Denver, CO 80262. A number of studies have demonstrated alterations in brain serotonin levels in animals after ethanol exposure *in utero*. To investigate the cellular basis for ethanol induced abnormalities in serotonergic neurons, we have transplanted fetal rat tissue of embryonic day 17 from nucleus raphe dorsalis to the anterior chamber of the eye in two groups of adult albino rats. The experimental group received 16% ethanol in the drinking water and the control group received water *ad libitum*. Immunohistochemical analysis revealed a disorganized serotonin immunoreactive innervation of surrounding host iris without axon bundles and with diminished outgrowth area in the ethanol group. Extracellular recording of monoaminergic neurons in grafts showed no difference in spontaneous activity or firing pattern between the two groups. Ethanol, superfused over the surface of grafts, elicited two different responses in both groups; low dose excitations and high dose inhibitions. However, monoaminergic neurons in the ethanol group showed a decreased sensitivity to locally applied ethanol. The dose-response curve was significantly shifted to the right in this group. These results suggest that chronic treatment with ethanol during early development disturbs the normal structure of brainstem serotonergic neurons, as well as their response to acute ethanol. LACK OF RECOVERY FROM MEMORIAL AND NEUROBIOLOGICAL DEFICITS FROM HIGH-PEAK BEC RESULTING FROM EARLY POSTNATAL EXPOSURE TO ETHANOL P. L. Greene, J. L. Diaz-Granados & A. Amsel. Department of Psychology and Institute for Neuroscience, University of Texas, Austin, Texas, 78712

Electrolytic hippocampal lesions at 10-11 days of age (P10-11) (Lobaugh et al., 1989), postnatal hippocampal exposure to x-irradiation (Diaz-Granados et al., submitted) and postnatal exposure to ethanol from P4-10 that results in high daily peak blood ethanol concentration (BEC) (Greene et al., submitted) significantly retard the acquisition of patterned (single) alternation (PA), a form of memory-based learning, with 60-s but not 30-s intertrial interval (ITI) in rat pups tested on P17-18. We examined the effects on PA at P60-86 of early postnatal (P4-10) exposure to EtOH with high- (H) and low- (L) peak BEC. Artificially-reared pups in the H condition were fed a 10.2% EtOH-adulterated diet (control pups received an isocaloric control diet) on 4 consecutive hourly feedings each day and unadulterated diet on the remaining 20 feedings. L pups received a 1.7% EtOH-adulterated diet on all 24 feedings. H pups at P60-86 were impaired in PA learning relative to L and control pups at 60-ITI, the same ITI at which PA deficits were observed in infant rats. Group H brain weights were significantly reduced, relative to Group-L and control weights, at 86 days, mirroring the result at 21 days of age. Morphometric correlates of recovery from specific hippocampal cell damage seen in infants are presented. These results suggest incomplete recovery from the memorial and neurobiological teratologic effects of the high-peak ethanol exposure regimen in infancy. Supported by NIAAA grant AA07052.

DRUGS OF ABUSE—CELLULAR EFFECTS OF ETHANOL

636.1

MARKED INHIBITION OF DOPAMINE RELEASE: A COMMON NEUROBIOLOGICAL SUBSTRATE FOR ABSTINENCE FROM DRUGS OF ABUSE. Z.L. Rossetti, F. Melis, S. Carboni and G.L. Gessa. Dept. of Neuroscience, Univ. of Cagliari, Italy.

Behavioral and biochemical evidence indicates that the dopamine (DA) pathways mediating reward and pleasure are deeply involved in dependence from drugs of abuse. By using the microdialysis technique, we studied the changes in DA efflux from the mesolimbic system induced in rats by repeated treatment with morphine, alcohol, or cocaine, and after withdrawal from these drugs. *Ethanol*. In ethanol-dependent rats (5 g/Kg p.o. every 6 h for 6 days) withdrawal symptomatology was associated with a progressive decrease of DA extracellular levels. DA reached 20% of controls when abstinence symptomatology was fully established. Ethanol (5 g/kg p.o.) suddenly reverted both abstinence symptomatology and inhibition of DA outflow. *Cocaine*. In chronic cocaine-treated rats (15 mg/kg twice per day for 18 days) extracellular DA concentrations were decreased to 35% of controls for at least 5 days after the supension of the treatment. Cocaine (10 mg/kg i.p.) immediately reverted this effect. *Morphine*. In morphine-dependent rats, (s.c. 70-mg morphine pellets for 5 days) the gradual onset of abstinence symptomatology following by pellet removal was paralleled by a progressive decrease of DA levels. DA efflux reached a minimum (23% of controls) when opiate withdrawal symptomatology was clearly manifested. Morphine (100 mg/kg s.c.) suddenly reversed both abstinence symptomatology and inhibition of DA release. Thus, DA system mediating the hedonic and reinforcing actions of drugs of abuse is impaired in drug dependence. The inhibition of DA transmission in the mesolimbic system appears to be a common neurobiological substrate for abstinence from drugs of abuse.

636.2

A GENERAL CELLULAR MODEL FOR TOLERANCE AND DEPENDENCE. A.M. Babey and R.M. Palmour. Dept Biology and Psychiatry & Centre for Human Genetics, McGill Univ., Montreal Que H3A 1A1.

Symptoms exhibited upon withdrawal from various addictive substances differ mainly in magnitude of expression, rather than in basic character, and are unlikely to be explained by changes restricted to the receptor. In cultured murine neuroblastoma cells, chronic theophylline treatment results in an increased production of cAMP in response to adenosine receptor stimulation. A parallel increase in receptor affinity persists, but physiological hypersensitivity disappears by two weeks. Increased responsiveness to forskolin stimulation appears after 4 days of continuous theophylline exposure. Chronic ethanol elicits altered response to adenosine, prostaglandins and opiates; these phenomena are mediated by changes in both G proteins and receptors, and are expressed primarily through altered coupling. We propose that chronic exposure to an addictive or habit-forming substance proceeds sequentially: Changes first to the receptor, then to G proteins signal the onset of tolerance. The development of cellular dependence requires alterations in adenylate cyclase. Withdrawal of drug initiates biochemical rebound only after completion of this sequence. The time lag associated with true cellular tolerance mimics that of physiological tolerance, which rapidly leads to dependence. This model describes the cellular characteristics of a wide range of habit-forming drugs of very different chemical classes, and should provide a useful screening tool for testing the abuse liability of new drugs.

636.3

INFLUENCE OF ETHANOL ON NEUROBLASTOMA AND GLIOMA CELLS IN VITRO: GLYCOSPHINGOLIPIDS. *K.C. Leskawa and C.E. Gabe**. Dept. Anatomical Sciences & Neurobiology, University of Louisville, Louisville, KY

The reports of *in vivo* effects of ethanol on brain glycosphingolipids (GSLs) are conflicting. To pursue this, we have recently examined neuroblastoma (NG108-15) and glioma (C6) cells in culture using two experimental paradigms: acute (0.1% for 8 hr) and chronic (0.5% for 24 hr) ethanol exposure. The synthesis of neutral GSLs and gangliosides was analyzed by the addition of ^{14}C-serine to the media during the last 8 hr of exposure. Ethanol exposed NG108-15 cells demonstrated decreased ganglioside synthesis, with the decrease being greater under chronic ($p<0.01$) than acute ($p<0.05$) conditions. Ethanol had no effect on neutral GSL synthesis by NG108-15 cells. Conversely, when C6 cells were exposed to ethanol neutral GSL synthesis doubled ($p<0.01$), few differences were observed between acute and chronic conditions, and ganglioside synthesis was not altered. Further experiments demonstrated that these changes were not due to alterations in the size of the intracellular pool of the ^{14}C-serine precurser. Levels of intracellular free serine equilibrated rapidly (within 1 hr) and neither acute or chronic ethanol treatment had any effect. In addition, we studied the activity of the first enzyme in ganglioside catabolism, sialidase (N-acetylneuraminic acid), using ^{3}H-GM3 as a substrate. Sialidase activity in C6 cells was inhibited only after chronic ethanol exposure ($p<0.05$), whereas ethanol treatment of NG108-15 cells (either condition) had no effect on sialidase activity when compared to control cultures. The results suggest that effects of ethanol on GSLs varies greatly with cell type, and that the response is at the level of GSL synthesis rather than GSL catabolism.

636.4

SELECTIVE EFFECTS OF CHRONIC ETHANOL EXPOSURE ON BRADYKININ-MEDIATED INTRACELLULAR CALCIUM MOBILIZATION IN N1E-115 NEUROBLASTOMA CELLS. T.L. Smith, C. McCollum* and L. Hoerr*. Res.Service, Vet.Affairs Med.Cntr., Tucson, AZ 85723.

Chronic (7day) ethanol (E) exposure has been reported by this laboratory to selectively inhibit bradykinin (BK)-stimulated [^{3}H] inositol phosphate (InP) production in N1E-115 cells, while having no effect on this response to neurotensin (NT). In order to determine whether chronic E also produces selective effects on receptor-mediated increases in intracellular free calcium, [Ca^{2+}]i, N1E-115 cells were exposed to 100mM E for 7 days. In other studies, the effects of acute exposure to 100-400mM E on resting [Ca^{2+}]i were also determined. Confluent cells grown in DMEM with 10% fetal calf serum were incubated in DMEM containing 8μM fluo-3/AM for 30 mins. at 35 C. Aliquots of the washed cells ($5-8x10^{5}$) were resuspended in 3 ml HEPES buffered salt solution and [Ca^{2+}]i determined fluorometrically. Chronic E reduced by 43% the [Ca^{2+}]i response to BK, but had no effect on the same response to NT. Resting [Ca^{2+}]i values (nM) for control and chronic E treated cells were 64±15 and 70±20nM, respectively. Acute E (3-4 mins) as high as 400mM had no significant effects on resting [Ca^{2+}]i. It is concluded that BK-mediated [Ca^{2+}]i is reduced in parallel with InP production after chronic E. Furthermore, in contrast to synaptosomes and PC12 cells, N1E-115 neuroblastoma do not exhibit an increased resting [Ca^{2+}]i subsequent to acute E exposure. (Supported by the Dept.of Vet. Affairs).

ETHANOL-INDUCED CHANGES IN ^{3}H-GABA RELEASE FROM SUBSTANTIA NIGRA AND SUPERIOR COLLICULUS. Joanna Peris, Mia Coleman-Hardee*, and Amy Shawley*, Dept. Pharmacodynamics, Univ. Florida, Gainesville, FL.

An increase in neuronal transmission in the GABAergic striatonigral pathway and a decrease in GABAergic transmission in the nigrocollicular pathway both are correlated with decreases in seizure sensitivity. If the relation is causal, then the anticonvulsant effects of ethanol should have opposite actions on GABAergic transmission in SN and SC and the reverse should occur during ethanol withdrawal. We measured the effects of in vitro ethanol on pre- and postsynaptic measures of GABA transmission in SN and SC both in naive rats and in rats given ethanol in their drinking water for 24 days and then withdrawn for 24 hrs. While ethanol inhibited ^{3}H-GABA release from slices of SC at low concentrations (50-200 mM), 500 mM was required to inhibit release from SN. In fact, release was increased by low concentrations of ethanol in SN. We next measured these parameters in SN and SC from rats that had a mean ethanol consumption of 9.4 g/kg body weight/day. Ethanol inhibition of release in SN from ethanol-treated rats was greater than in the control rats whereas ethanol inhibition of release from SC was less in ethanol-drinking rats compared to control rats. When ^{35}S-TBPS binding was measured using quantitative autoradiography, there was a greater number of binding sites in striatum of ethanol-treated rats compared to controls. Thus when ethanol is acting as an anticonvulsant, it increases release in SN and decreases release in SC, but when animals are sensitized to seizures by ethanol treatment, release is decreased in the nigrostriatal pathway and increased in the striatonigral pathway. EFFECTS OF CHRONIC AND ACUTE ETHANOL EXPOSURE ON CALCIUM CURRENTS IN PC12 CELLS. A.J. Grant, G. Koski[1], and S.N. Treistman. Worcester Foundation for Experimental Biology, 222 Maple Ave., Shrewsbury, MA 01545 and [1]Department of Anesthesia, Massachusettes General Hospital, Boston, MA 02114.

Previous studies, using biochemical assays, have indicated that there is an increase in depolarization-induced calcium influx into PC12 cells which have been chronically exposed to ethanol, as compared with cells not exposed to ethanol. To further elucidate the mechanisms involved, we describe here the effects of acute and chronic ethanol on whole cell calcium currents in PC12 cells using electrophysiological as well as biochemical methods. Undifferentiated pheochromocytoma (PC12) cells were chronically exposed to 200 mM ethanol for six days. Parallel cultures from the same parent passage were maintained, under the identical conditions, without ethanol. Following chronic exposure, whole cell calcium currents were recorded from the two groups using standard patch clamp techniques. Cells chronically exposed to ethanol had significantly larger voltage-gated calcium currents than those grown in the absence of ethanol. The inactivation kinetics of the currents, as well as the voltage protocols used to elicit these currents, suggest that calcium ions were passing primarily through L-type channels. Radiolabelled calcium uptake assays confirm that calcium influx is increased in chronically exposed cells from the same parent passage as those tested electrophysiologically. In contrast to the augmentation of current from chronically exposed cells, acute exposure to low ethanol concentrations greatly reduced the magnitude of the currents. Supported by Grant #AA05542.

636.7

THE EFFECT OF ETHANOL AND NITROUS OXIDE ON CEREBELLAR GRANULE CELLS AND PURKINJE CELLS. C.-F. Hsiao, R. Huang* and C. Huang. School of Basic Life Sciences, Univ. Missouri-Kansas City, Kansas City, MO 64110

Among the initial manifestations of ethanol intoxication are the delay in reaction times, the impairment of fine motor skills, and the deterioration of motor coordination and mental abilities. We previously showed that ethanol or nitrous oxide severely inhibited neuronal activities in the granule cell layer of the cerebellum in the cat. To further identify the effect of ethanol and nitrous oxide on specific cell types, we have combined the method of intracellular recording/injection with ethanol delivery (0.3g/Kg IV) or nitrous oxide anesthesia (66%). Ethanol inhibited the spontaneous discharges and auditory responses of most, but not all, granule cells. The spontaneous discharges of Purkinje cells were either suppressed or enhanced by ethanol. Occasionally, the amplitude of action potentials also seemed to be affected. On the other hand, nitrous oxide abolished the spontaneous discharges and auditory responses of all granule cells. Some Purkinje cells were excited, others were inhibited, and still others showed no effect. In conclusion, ethanol and nitrous oxide have significant but different effects on the spontaneous discharges and responses of most cerebellar granule cells and Purkinje cells. (Supported by PHS grant AA07643.)

636.8

PHENCYCLIDINE POTENTIATES ETHANOL-INDUCED ACTIONS VIA A β-ADRENERGIC MECHANISM IN CEREBELLAR PURKINJE NEURONS, BUT NOT IN PUTATIVE GOLGI NEURONS *IN VITRO*. M.R. Palmer, Y. Wang and R.K. Freund. National Defense Medical Center, Taipei, Taiwan, R.O.C., and Department of Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262.

Previous studies have established that ethanol (EtOH) inhibits firing of Purkinje neurons (PN) both *in vivo* and *in vitro*. It has been reported that β-adrenergic agonists potentiate inhibitory responses to GABA in these cells. Phencyclidine (PCP) has been found to increase catecholaminergic overflow, possibly by increasing catecholamine release and/or by decreasing uptake in various brain regions, including cerebellum. Data from this laboratory and others suggest that EtOH-induced inhibition of PN firing involves GABA mechanisms. In this study we found that PCP potentiated EtOH-induced depressions of spontaneous firing of PN's in cerebellar slices from Sprague-Dawley rats. (-)-Isoproterenol appeared to mimic the effect of PCP on the EtOH response. In preliminary experiments, timolol antagonized the potentiation by PCP of EtOH responses. By contrast to the EtOH response in PN's, the firing of putative Golgi neurons was markedly increased by EtOH, and this effect was attenuated by PCP. We conclude that PCP potentiates ethanol-induced inhibition via β-adrenergic mechanisms in cerebellar PN's, but not in Golgi cells.

636.9

URETHANE POTENTIATES ETHANOL-INDUCED INHIBITION IN RAT BRAIN SLICES. R.K. Freund, Y. Wang, W.R. Proctor and M.R. Palmer. Department of Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262, and National Defense Medical Center, Taipei, Taiwan, R.O.C.

Ethanol (EtOH) has been found to inhibit firing of neurons in several different brain regions *in situ* (e.g., cerebellum, hippocampus, cortex, striatum). One potential complication regards the use of anesthetics in these studies. It is not well-established whether anesthetics may significantly modify the observed EtOH responses. In the present study the effects of urethane (ethyl carbamate), an anesthetic commonly used in animal research, was examined for its possible influence on the inhibitory action produced by EtOH on electrophysiological responses measured in slices from several brain areas. In cerebellar slices, EtOH-induced inhibition of the unit activity (spontaneous firing rate) was potentiated by 20 μM urethane. A similar urethane-induced potentiation of the depressant effects of EtOH was observed with evoked extracellularly-recorded population spike amplitudes from the somal layer in the CA1 region from hippocampal slices. These data indicate that urethane increases ethanol potency (but does not qualitatively alter the inhibitory response) in cerebellum and hippocampus, and thus, suggest that the electrophysiological effects of EtOH in the CNS observed in urethane-anesthetized animals are potentiated by the anesthetic.

Supported by USPHS grants AA05915 and AA00102. MP is supported by an ADMH Research Scientist Development Award.

636.10

EFFECTS OF ETHANOL ON THE SENSITIVITY OF RAT RETINAL GANGLION CELLS TO INHIBITORY NEUROTRANSMITTERS. H.H. Yeh. Dept. Neurobiology & Anatomy, U. Rochester Med. Ctr., NY 14642.

Evidence is accumulating that ethanol can modulate neuronal sensitivity to certain neurotransmitters. We report here our initial findings using the rat retina as a model to determine whether direct exposure of retinal ganglion cells to ethanol can influence their responsiveness to GABA and glycine, the major inhibitory neurotransmitters resident in the retina. This study was motivated in part by our recent demonstration that both $GABA_A$ receptor- and glycine-activated currents in ganglion cells are subject to modulation via interaction with other neuroactive substances.

Solitary ganglion cells, obtained following enzymatic treatment and acute dissociation of the intact rat retina, were selected for whole-cell patch-clamp recording. Current responses to brief pressure pulses of GABA (I_{GABA}, $\leq$20 uM) or glycine (I_{Gly}, $\leq$200 uM) were monitored before, during and after exposure to ethanol (15-150 mM). Toward the higher end of the range of concentration used in this study, a clear-cut potentiation of I_{GABA} could be observed during paired applications of ethanol and GABA. The potentiating effect was reversible, returning promptly toward control (pre-ethanol) levels of I_{GABA} upon termination of ethanol exposure. In contrast, ethanol did not potentiate I_{Gly}. In fact, the tendency was for I_{Gly} to be attenuated upon ethanol exposure. Such a differential effect on I_{GABA} and I_{Gly} could be demonstrated in the same ganglion cell.

Thus, our data suggest that ethanol may exert selective effects on signal processing involving the GABAergic and glycinergic pathways in the retina. The retina should be a useful model system for elucidating the mechanisms of ethanol action on central neurons and circuits.

ETHANOL ENHANCES $GABA_A$ RECEPTOR-MEDIATED CHLORIDE CURRENTS IN CHICK CEREBRAL CORTICAL NEURONS. J.N. Reynolds and A. Prasad, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Nfld., Canada A1B 3V6.

Primary cultures of cerebral cortical neurons were prepared from seven day old chick embryos. The effect of ethanol on GABA-activated membrane currents was examined using whole-cell voltage-clamp recording in cells maintained for 3-25 days *in vitro*. Cells were continuously perfused (1-2 mL/min) with a physiological saline containing (in mM) 140 NaCl, 5 KCl, 2 $CaCl_2$, 1 $MgCl_2$, 10 HEPES, 10 glucose, 0.5 μM tetrodotoxin, pH 7.3. Ethanol was diluted in extracellular solution (final concentration 0.5-50 mM) and applied by bath perfusion. Recording pipettes (3-5 MΩ) contained (in mM) 140 KCl, 2 $MgCl_2$, 10 HEPES, 4 ATP, pH 7.3. GABA (10-50 μM) applied by brief pressure pulses directly to the soma elicited a current which reversed at 0 mV and was blocked by 50 μM bicuculline. In 60% of neurons examined (n > 100) ethanol caused a potentiation of the membrane current elicited by GABA. The threshold concentration of ethanol was 1 mM, and the effect of ethanol was maximal at 10 mM. In many cells, higher concentrations (40-50 mM) of ethanol inhibited GABA currents. These effects of ethanol were all reversible. Cells obtained from individual embryos had similar responses to ethanol, whereas cells obtained from different animals varied greatly in their sensitivity to ethanol. In cultures where ethanol enhanced GABA responses, excessive buffering of intracellular calcium (by including 5-10 mM BAPTA in the recording pipette) attenuated the effect of ethanol.

636.12

THE EFFECTS OF ETHANOL ON CULTURED SEROTONERGIC NEURONS AND ASTROGLIA. D.K. Lokhorst and M.J. Druse Neuroscience Program, Loyola U. of Chicago, Stritch Schoolof Medicine, Maywood, IL 60153.

The effects of ethanol exposure on the development of serotonergic neurons were assessed by examining the influence of 50, 150 and 300 mg/dl of ethanol on cultured fetal rhombencephalic cells. Rhombencephalic cells were removed from rats on embryonic day 14, and cultured for 2 days in the absence of ethanol and an additional 4 days in the presence of ethanol. Cultured rhombencephalic neuronal and astroglial cells were assessed for serotonin (5-HT) uptake, 5-HT content, number of 5-HT immunoreactive cells, and DNA and protein content.

The results of these experiments demonstrate that exposure of cultured rhombencephalic neuronal cells to an ethanol concentration of 50 to 300 mg/dl does not affect 5-HT or DNA content, or the proportion of 5-HT immunoreactive cells. In addition, DNA content is unchanged in ethanol-exposed astroglial cells. However, 300 mg/dl of ethanol significantly reduces protein content and 5-HT uptake per well to approximately the same extent in both neuronal and astroglial cells. Thus, it appears that at the ethanol concentrations examined ethanol does not produce cell death. However, ethanol does inhibit protein synthesis in both neuronal and astroglial cells. This decreased protein synthesis is reflected in decreased 5-HT uptake by both cell types.

CALCIUM-DIACETYL HOMOTAURINE (Ca-AOTA) ALTERS ELECTROPHYSIOLOGICAL PROPERTIES OF HIPPOCAMPAL PYRAMIDAL NEURONS (HPNs) *IN VITRO*. Samuel G. Madamba, [1]Walter Zieglgänsberger,* [1]Marc L. Zeise* and George Robert Siggins. Dept. of Neuropharmacology and Alcohol Research Center, Research Institute of Scripps Clinic, La Jolla, CA 92037 and [1]Max-Planck-Institute for Psychiatry, 8000 München, F.R.G.

Ca-AOTA has shown promise in preventing relapse in abstinent alcoholics. However, its mechanism of action is unknown. As ethanol can alter synaptic transmission and several ionic conductances in hippocampal neurons, we examined the effects of superfusion of Ca-AOTA on rat CA1 HPNs in a slice preparation. We used standard intracellular recording or whole-cell "patch-slice" recording methods, in current- or voltage-clamp mode. Ca-AOTA had small concentration-dependent effects on membrane potential: 1-10 μM Ca-AOTA depolarized, hyperpolarized and had no effect in equal numbers of cells, whereas 100-500 μM Ca-AOTA slightly hyperpolarized most HPNs. Under voltage clamp (-36 to -47 mV holding potentials; 5-25 mV hyperpolarizing steps), Ca-AOTA (10-1000 μM) had little reproducible effect on M-current relaxations (which are reduced by ethanol), but caused an outward current and a large conductance increase. By contrast, Ca-AOTA elicited a net inward current (with conductance increase) in whole-cell recordings with TEA and Cs^+ in the internal and external medium. In conventional intracellular recordings with external TTX, 50-300 μM Ca-AOTA (like Cd^{++} 100 μM) blocked Ca^{++}-dependent action potentials and afterhyperpolarizations evoked by depolarizing current. In whole-cell voltage clamp with TEA and Cs^+, 50-100 μM Ca-AOTA reduced (by 5 to 57%; n= 6) the peak Cd^{++}-sensitive inward currents evoked by 20-65 mV depolarizing steps from holding potentials of -60 mV. These results suggest that Ca-AOTA, like ethanol, has multiple actions on HPNs, including activation of an uncharacterized K^+ conductance and inhibition of a Ca^{++} current. These mechanisms could account for the clinical efficacy of this agent. (Supported by USPHS (AA06420) and LIPHA, France.)

636.14

EFFECTS OF ETHANOL ON RAT HIPPOCAMPAL EPILEPTIFORM ACTIVITY. S.M. Cohen, D. Martin, R.A. Morrisett, W.A. Wilson, and H.S. Swartzwelder*. Departments of Pharmacology, Neurology and Psychology, Duke Univ. Med. Ctr. and V.A. Med. Ctr., Durham, NC 27705.

Activation of the NMDA receptor is a critical requirement in the induction of several forms of neuronal plasticity, including hippocampal electrographic seizures (EGSs). Electrophysiological and biochemical evidence strongly indicates that ethanol specifically blocks NMDA responses. Therefore, we examined the effects of ethanol on the expression and induction of electrographic seizures (EGSs) after kindling-like stimulation of the hippocampal slice.

It has been previously reported (Martin, et al. 1991 Alc. Clin. Exper. Res. in press), that ethanol has multiple effects on EGS expression. Ethanol 33-100 mM increased the threshold for seizure expression approximately 2-4 fold. The NMDA receptor antagonist, D-APV (50 μM) also increased seizure threshold by a similar amount. Lower concentrations of ethanol (10 mM) increased burst frequency and EGS duration. Increasing ethanol concentrations (33-60 mM) had little or no effect on the morphology of the EGSs. Very high concentrations (100-300 mM) suppressed the EGS in a dose-dependent manner.

In another set of experiments, ethanol had minimal effects on EGS induction produced by supra-maximal trains. Control slices were bathed in 75mM ethanol and conventional trains were given. Ethanol did not increase the number of trains required to elicit full EGSs.

These data suggest that phamacologic levels of ethanol have little or no effect on EGS induction or EGS morphology once epileptiform activity is established. However, ethanol clearly increases the threshold for expression of this seizure-like activity. Therefore, the effect of ethanol upon EGS threshold suggests antagonism of NMDA-mediated responses, since NMDA antagonists have a similar effect. The hippocampal EGS model therefore may provide a useful system to analyze the modulation of epileptiform activity by ethanol.

KCl-EVOKED GABA RELEASE UNCHANGED IN *IN VITRO* HIPPOCAMPUS AFTER CHRONIC FLURAZEPAM TREATMENT. E.I. Tietz and X-H. Xie. Department of Pharmacology, Medical College of Ohio, Toledo, Ohio 43699

Electrophysiological studies in CA1 region of *in vitro* hippocampal slices from benzodiazepine (BZ) tolerant rats showed significantly reduced paired-pulse inhibition 48 hr, but not 7 days after 1 week flurazepam (FZP) treatment. Together with the concomitant increase in the ½ decay time of the EPSP, these data suggested a decrease in hippocampal GABA-mediated inhibition in tolerant rats. Hitchcott et al., (1990) reported an increase in GABA release after chronic diazepam treatment. To determine whether altered GABA release could modify the electrophysiological responses measured in hippocampus, [^{3}H]GABA release was examined 48 hr after 1 week FZP treatment (100 mg/kg X 3 dy; 150 mg/kg X 4 dy). 200 μM hippocampal slices from treated (n=6) or control rats (n=6) were preincubated 10 min at 37°C in pregassed ACSF. Slices were incubated in 1.5 ml .23 μM [^{3}H]GABA (50 μM AOAA) for 30 min at 37°C under 95%O_2/5%CO_2. Slices were superfused (1 ml/min) with ACSF + 500 μM nipecotic acid. After 15 min, 20 mM KCl was injected into the chamber (1M, 20 μl/min) for 2 min. 30 μM EGTA blocked KCl-evoked release. [^{3}H]GABA release was calculated as a fraction of the amount remaining. There was no significant difference in the maximal (control:.015±.003;treated:.016±.004) or total fraction released between groups. GABA uptake into slices tended to be greater in control than treated slices but was not significantly different (679.6±87.6 vs. 542.7±69.7 pmoles/mg prot.). GABA uptake will be investigated further in hippocampal synaptosomes from chronic BZ treated rats. Supported by grants RO1-DA04075 and S07-RRO5700.

Ca^{2+} CURRENTS IN THE TERMINALS OF RAT NEUROHYPOPHYSIS ARE REDUCED BY DIFFERENT CHAIN LENGTH ALCOHOLS. X.Wang*, J.R.Lemos and S.N.Treistman. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Effects of ethanol and long-chain alcohols on voltage-activated calcium (Ca^{2+}) channels have been examined in acutely dissociated rat neurohypophysial terminals, which release vasopressin and oxytocin. Using "whole-cell" patch-clamp recordings, two types of high-threshold voltage-activated I_{Ca} (a fast-inactivating and a long-lasting current component) were present in the nerve terminals. We found that amplitudes of both current components were reduced in a dose-dependent manner (concentrations of 0.1-100 mM) after acute exposure to ethanol (EtOH), butanol (BuOH), hexanol (HxOH) and octanol (OcOH). The reduction did not result from a shift in their current-voltage or steady-state inactivation relationships. The order of effectiveness is OcOH > HxOH > BuOH > EtOH. These results, in contrast to those previously obtained with *Aplysia* neurons (Treistman & Wilson, PNAS, 84:9299, 1987), suggest the importance of EtOH's hydrophobicity in its blockade of Ca^{2+} channels in nerve terminals of the rat neurohypophysis. (Supported by PHS AA08003 and NSF 8919790).

EFFECTS OF ETHANOL AND CHLORDIAZEPOXIDE ON INHIBITORY PROCESSES IN THE FASCIA DENTATA AND HIPPOCAMPUS REGIO SUPERIOR Henriksen, S.J., Young, W.G. and Steffensen, S.C.*, Research Institute of Scripps Clinic, La Jolla, CA 92037

Acute intoxicating doses of ethanol producing blood alcohol levels of 120-200 mg% selectively increase paired-pulse (PP) inhibition in the dentate gyrus of anesthetized rats suggesting that ethanol facilitates recurrent inhibitory processes (Wiesner and Henriksen, *Neurosci. Letts.* 79:169, 1987). To further our understanding of the neuronal mechanisms underlying this phenomenon, we studied the effects of acute intoxicating levels of ethanol and the benzodiazepine (BZ), chlordiazepoxide, on extracellular field potentials and single-unit activity in the dentate gyrus and area CA1 of the hippocampus. In the dentate, ethanol: 1) had no effect on population excitatory postsynaptic potentials (pEPSPs), 2) decreased population spike (PS) amplitudes (28%), 3) increased paired-pulse (PP) inhibition, 4) decreased dentate granule cell (DGC) spontaneous activity (58%), 5) had no effect on putative interneuron spontaneous activity and 6) markedly increased post-field potential evoked interneuron discharges (IDs, 218%). In the dentate, chlordiazepoxide had no effect on pEPSPs or PS amplitudes, increased PP inhibition, decreased DGC (62%) and interneuron (72%) spontaneous activity and markedly decreased IDs (89%). In CA1, ethanol had no effect on pEPSP amplitudes, decreased PS amplitudes (29%), had no effect on PP responses, decreased pyramidal cell (PC) spontaneous activity (39%), had no effect on interneuron spontaneous activity and markedly increased IDs (97%). Chlordiazepoxide had no effect on pEPSPs, decreased PS amplitudes (26%), had no effect on PP responses, decreased PC spontaneous activity (41%) and had no effect on interneuron spontaneous activity or IDs. Our results suggest that the BZs decrease principal cell excitability by postsynaptic facilitation of inhibitory processes, whereas ethanol decreases principal cell excitability indirectly by increasing the excitability of inhibitory interneurons. ***IN VIVO* ELECTROCHEMICAL STUDIES OF THE EFFECTS OF LOCALLY-APPLIED ETHANOL ON DOPAMINE NERVE TERMINALS IN RAT STRIATUM.** Y. Wang*, M.R. Palmer and G.A. Gerhardt. Depts. of Pharmacology and Psychiatry, Univ. of Colorado Health Sciences Center, Denver, CO 80262 and *Dept. of Pharmacology, National Defense Med. Ctr., Taipei, Taiwan, R.O.C.

Previous studies have shown that ethanol (EtOH) has effects on the dopaminergic system of the rat striatum, however, few studies have explored the direct effects of locally-applied EtOH on dopamine (DA) nerve terminal function. In the present study, we used high-speed (5Hz) chronoamperometric recording techniques using Nafion-coated carbon fiber electrodes coupled with pressure ejection of ETOH to investigate the effects of this drug on DA nerve terminals in the urethane-anesthetized rat. Local application of EtOH (100mM EtOH with 2.5 mM $CaCl_2$, 25-200nl) from a multibarrel micropipette did not produce a detectable change in the extracellular levels of DA in the anterior striatum. However, potassium (70mM)-evoked overflow of DA was seen to be reversibly inhibited (approx. 50%) by EtOH. In contrast, tyramine (2mM)-induced DA overflow was not altered by EtOH in the same brain region. In addition, the clearance/diffusion of locally-applied DA was reversibly enhanced by EtOH. This effect was partially antagonized by locally-applied nomifensine. Taken together, these data suggest that EtOH exerts its effects on DA-containing nerve endings in the rat striatum by causing an increase in DA uptake. (Supported by USPHS grants NS09199, AG06434, AA05915 and AA00102.)

ETHANOL INCREASES GABA MEDIATED CHLORIDE CURRENT IN CORTICAL NEURONS IN RAT BRAIN SLICES. W.R. Proctor and T.V. Dunwiddie, Veterans Admin. Medical Research Services and University of Colorado Health Sciences Center, Denver, CO.

Previous studies have shown very little effect of acute ethanol application on intracellular responses in rat **hippocampal** slices. In particular, ethanol did not enhance the $GABA_A$ receptor mediated chloride current recorded in CA1 pyramidal neurons; however, depolarizations elicited by local application of NMDA were significantly reduced by 80 mM ethanol superfusion. The present study was designed to examine the effects of ethanol on pyramidal neurons located in the *in vitro* **cerebral cortex**. Using conventional "sharp point" microelectrodes (60-80 MΩ), 80 mM ethanol application did not affect the membrane input impedance, but significant effects were observed on the resting membrane potential (RMP; 2-5 mV hyperpolarizations) and on EPSP responses (approx. 30% decrease in amplitude). Stimulus-evoked $GABA_A$-mediated IPSCs were studied with whole-cell recording from cortical neurons voltage-clamped at depolarizing potentials. Monophasic IPSCs recorded with this procedure were blocked by bicuculline, increased by pentobarbital, and enhanced by ethanol superfusion in a dose dependent manner over the range of 20 - 160 mM. In combination with the observation that ethanol modulates muscimol-induced chloride flux in cortical (but not hippocampal) microsacs, these results suggest that ethanol selectively interacts with the $GABA_A$ receptors expressed in cortex but not with those in the CA1 region of the hippocampus.

ETHANOL DOES NOT ALTER HYPERPOLARIZING RESPONSES TO BACLOFEN IN CA3 HIPPOCAMPAL NEURONS. G.D. Frye and A.S. Fincher*, Department of Medical Pharmacology, Texas A&M College of Medicine, College Station, Texas 77843-1114.

Previous behavioral studies suggest that $GABA_B$ receptors may be involved in the central actions of ethanol (Frye et al., J. Pharmacol. Exp. Ther. 237:478, 1986; Allan and Harris, Life Sci. 45:1771, 1989). To further test this hypothesis the acute and chronic effects of ethanol were examined on a cellular level model of $GABA_B$ receptor function. Intracellular recordings from CA3 neurons in hippocampal slices were used to measure baclofen-induced membrane hyperpolarization. Sequential superfusion of increasing concentrations of (+)baclofen (0.1-100μM), induced reversible, concentration-dependent hyperpolarization. In untreated cells, hyperpolarizing responses to near maximal concentrations of baclofen (30-100μM) were -23.3 ±3.4mV, while responses to baclofen (3μM; approx. ED_{50}) were -13.0±3.7mV. These responses were not changed by bath applied ethanol (30mM). Baclofen responses in cells from ethanol dependent rats or treatment matched controls also were not different from those in untreated cells. These results suggest that neither acute nor chronic ethanol treatment change $GABA_B$ receptor responses of CA3 pyramidal neurons to baclofen. Supported in part by PHS grants AA06322 and AA00101.

PSYCHOTROPHIC AGENTS: ANXIETY

637.1

ANXIOGENIC AND CARDIOVASCULAR EFFECTS OF CCK-4 IN MONKEYS ARE BLOCKED BY THE CCK-B ANTAGONIST LY262691. R. M. Palmour*, F. R. Ervin*, J. Bradwejn* and J. J. Howbert#. *Dept Psychiatry, McGill Univ., Montreal Que H3A 1A1 and #Lilly Research Labs, Eli Lilly & Co., Inidanapolis, IN 46285.

Cholecystokinin tetrapeptide (CCK-4), given i.v. to African green monkeys, has profound and dose-related effects on behaviors thought to reflect anxiety and panic. In awake male monkeys (~5 kg) with indwelling venous catheters, low doses of CCK-4 increase restless behaviors (scratch, fidget, pace), threat and alerting to external stimuli. These changes appear within 30 sec of administration, peak after 2 min and gradually decline through 20 min. Higher doses of CCK-4 engender frozen immobility during the initial 10 min and thereafter a gradual increase in restless behavior and arousal. Blood pressure and heart rate are increased at all doses during the first 5 min. The effect of LY262691 (LY), a non-peptide antagonist of brain type CCK (CCK-B) receptors, was tested on these behaviors. If administered s.c. 1 hr before CCK challenge, LY dose-dependently reduced ($p<.01$) threat, alerting to external stimulus and restless behaviors elicited by 5-10 μg CCK-4, with EC50's of 2.5-4 mg/kg, depending on the behavior. LY also reduced time immobile ($p<.01$) in monkeys given 20-30 μg CCK (EC50 6 mg/kg). LY completely blocked lip smacking, urination, drinking and penile erection typically observed in the first minute after CCK-4. At 12 mg/kg, LY alone reduced frequency of restless behaviors, but lower doses had no detectable effect on baseline behavior. In a separate experiment, 6 mg/kg LY blocked elevations in both systolic and diastolic blood pressure caused by 20 μg i.v. CCK-4. These findings suggest that the anxiogenic effects of CCK-4 are mediated through CCK-B receptors, and further support the idea that CCK-B antagonists may find a role in the clinical treatment of anxiety.

637.2

NEUROCHEMICAL AND PSYCHOPHARMACOLOGICAL PROFILE OF A NOVEL 5-HT1A RECEPTOR-SELECTIVE ANXIOLYTIC SUN 8399. I. Hirotsu, M. Harada*, K. Saito[1]*, M. Shibata[2]*, K. Nomura[2]*, T. Tatsuoka[2]*, T. Ohno* and T. Ishihara[1]*. Laboratories of Experimental and [1]Molecular Pharmacology, and [2]Medicinal Chemistry 1, Suntory Institute for Biomedical Research, 1-1-1, Wakayamadai, Shimamoto-cho, Mishima-gun, Osaka 618, Japan.

Anxiolytic actions of SUN 8399 (4-[4-[4-(2-pyrimidinyl) piperazin-1-yl] butyl]-2,3,4,5-tetrahydro-1,4-benzoxazepin-3,5-dione hydrochloride) was examined in various neurochemical and behavioral pharmacological tests.

In *in vitro* receptor binding assays, SUN 8399 displayed higher affinity for the 5-HT1A receptor site (IC_{50}=3.75 nM) than buspirone (IC_{50}=13.0 nM) and no significant affinity for benzodiazepine receptor (>10 μM). Moreover, SUN 8399 had much lower affinities for 5-HT2, 5-HT3, α1, α2 and D2 receptors (IC_{50}=9.3, 4.4, 0.85, 1.79 and 14.5 μM, respectively). Based on adenylate cyclase studies which measure 5-HT1A receptor-mediated effects in the guinea-pig hippocampus, the agonistic activity of SUN 8399 (10^{-5} M) was equivalent to that of 8-OH-DPAT, a selective 5-HT1A agonist, whereas the effect of buspirone was partial. SUN 8399 (3 mg/kg, i.p.) did not prevent 8-OH-DPAT (3 mg/kg, s.c.)-induced hypothermia in rats, but buspirone inhibited it. Anxiolytic activity of SUN 8399 (10-30 mg/kg, p.o.) was much more potent in the thirsty rat conflict test as compared with that of buspirone. In the social interaction test, SUN 8399 (10 mg/kg, p.o.) and buspirone possessed pro-social effects in rats which was not mimicked by diazepam. SUN 8399 (100 mg/kg, p.o.) lacked in mice and rats not only typical side effects such as sedation, hypnosis, muscle relaxation and ataxia of benzodiazepines but also antidopaminergic effects of buspirone.

Thus, it is concluded that SUN 8399 is a potent and 5-HT1A receptor-selective anxiolytic agent without undesirable effects of benzodiazepines and buspirone.

637.3

THE INTERACTION BETWEEN R(+)- AND S(-)-ZACOPRIDE. M.E.Kelly*, B.Costall*,D.M. Murphy*,R.J. Naylor*. (SPON: Brain Research Association) Studies in Pharmacology, University of Bradford, Bradford, BD7 1DP, UK

The R(+)-isomer of zacopride has been shown to be more potent than the S(-) to reduce aversive behaviour (Barnes et al., 1990). In addition S(-)zacopride can attenuate the actions of R(+) zacopride (R.J. Naylor, personal communication). This study investigates the interaction of R(+) and S(-)zacopride emphasising the duration of the pretreatment time.

Mice received S(-)zacopride (1μg/kg) 0,5,10,20,40 and 60 min before treatment with R(+) zacopride (1μg/kg), 40 min later the mice were tested in a light/dark box. Aversive responding was taken as the % time in the dark.

R(+)zacopride (1μg/kg) reduced aversive responding (time in the dark reduced 61% to 24%, P<0.01). S(-)zacopride (1μg/kg) given as a 0,5 or 10 min pretreatment failed to modify this response (time in dark 35%, 39% and 42% respectively). However, when S(-)zacopride was given as a 20,40 or 60 min pretreatment the reduction in aversive behaviour was abolished (time in dark 63%, 63% and 65% respectively).

This study confirms the ability of S(-)zacopride to antagonise the anxiolytic action of R(+)zacopride and emphasises the importance of selecting a suitable pretreatment time for interaction studies.

EFFECTS OF THE PUTATIVE ANXIOLYTIC AND ANTIDEPRESSANT COMPOUND WY-50,324 ON SEROTONERGIC BEHAVIORAL ACTIVITY FOLLOWING CHRONIC ADMINISTRATION. J. A. Moyer and R. F. Kucharik* Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

WY-50,324, a novel adamantyl piperazine derivative, has a high affinity for 5-HT1A and 5-HT2 receptors. *In vitro* and *in vivo* studies have demonstrated WY-50,324 to be a 5-HT1A partial agonist and a 5-HT2 antagonist. Behavioral characterization has indicated that WY-50,324 has an anxiolytic and antidepressant profile. The primary purpose of the current study was to assess 5-HT1A agonist activity of WY-50,324 during the course of repeated administration by assessing hypothermia and the serotonin syndrome. In addition, 5-HT1A and 5-HT2 antagonist activity after chronic (14 day) administration was determined by assessing the serotonin syndrome and head shake response, respectively. Finally, 5-HT1A and 5-HT2 *in vivo* sensitivity was ascertained after chronic (14 day) WY-50,324 treatment by administering selective agonists for these receptor subtypes and measuring behavioral responses associated with their activation. Standard 5-HT1A and 5-HT2 compounds were examined concurrently. In the rat, WY-50,324 (10.0 mg/kg i.p.) continued to produce a 5-HT1A partial agonist response in the serotonin syndrome as did buspirone (10.0 mg/kg i.p.). At the same doses, WY-50,324 and buspirone also produced a hypothermic response indicative of 5-HT1A agonism, but the magnitude of this response decreased over the course of repeated administration with both compounds. The 5-HT1A and 5-HT2 antagonist activity of WY-50,324 was still evident after chronic administration. As expected, the 5-HT2 antagonist, ritanserin, did not demonstrate 5-HT1A agonist or antagonist activity after repeated administration. Changes in receptor sensitivity, as measured by selective agonist challenges at 5-HT1A and 5-HT2 receptors, did not occur after chronic (14-15 day) treatment with WY-50,324 (10.0 mg/kg i.p.) or buspirone (10.0 mg/kg i.p.) in the rat. Chronic ritanserin (1.0 mg/kg i.p., 14-15 day), however, produced a supersensitive 5-HT1A hypothermic response. These results demonstrate that after repeated administration the *in vivo* pharmacological profile of WY-50,324 is unaltered i.e. 5-HT1A partial agonist and 5-HT2 antagonist activity are still evident.

637.5

EVALUATION OF THE EFFECTS OF PD 134308, A CCK-B ANTAGONIST, ON THE PUNISHED RESPONDING OF SQUIRREL MONKEYS. Powell, K.R.and Barrett, J.E., Dept. of Psychiatry, Uniformed Services University of the Health Sciences, 4301 Jones Bridge Rd., Bethesda, MD 20889-4799. Lever pressing of squirrel monkeys was maintained by a fixed-interval 3-min schedule of food presentation during which every 30th response also produced a brief electric shock. Lever pressing was suppressed during this stimulus(conflict or punishment) compared to that occurring prior to the introduction of shock or, with some monkeys, during an alternate stimulus in which punishment did not occur. PD 134308, administered i.m. (0.03-3.0 mg/kg), increased punished responding but had no effect on non-punished responding. Peak increases of 150% of control occurred at 3.0 mg/kg. There was no indication of sedation at the highest dose of PD 134308 (10.0 mg/kg). By comparison, chlordiazepoxide (1.0-10.0 mg/kg) produced similar effects, except the magnitude of increases in punished responding reached approximately 200% of control performance levels and the higher doses reduced non-punished response rates. PD 134308 produces anxiolytic-like effects in this animal model of anxiety that would suggest potential clinical efficacy in humans of a novel class of compounds with actions at or modulated by cholecystokinin receptors.

637.6

EFFECTS OF BENZODIAZEPINE PARTIAL AGONISTS ON PUNISHED RESPONDING AND ON MIDAZOLAM DISCRIMINATION. S. Gleeson[1], J.M. Witkin[2], C.H. McDonald[1]*, and J.E. Barrett[1]. [1]Behavioral Pharmacology Lab., Uniformed Services University of the Health Sciences, Bethesda, MD 20814 and [2]Psychobiology Lab., NIDA Addiction Research Center, Baltimore, MD 21224.

Novel compounds acting as partial agonists at benzodiazepine (BZ) receptors show only some of the effects typical of full agonists, making them candidates for development as anxiolytics without accompanying sedation, muscle relaxation, or dependence liability. Several partial agonists were examined for anxiolytic activity and degree of similarity to the full agonist midazolam. The BZ derivatives Ro 16-6028 (bretazenil) and Ro 17-1812, and the β-carboline abecarnil produced large increases in punished responding of pigeons, similar to the effects of midazolam. Abecarnil and midazolam were effective across a similar dose range, while the effective dose range for the other drugs was broader. The similarity to midazolam was not apparent in the drug discrimination procedure, however. In pigeons trained to discriminate midazolam (1.0 mg/kg), Ro 16-6028, Ro 17-1812, and abecarnil only partially substituted (<80%) for midazolam, even at higher doses than required to produce peak anti-conflict effects. The results suggest that partial BZ agonists may exert anxiolytic effects across a broad range of doses that do not share subjective effects with full benzodiazepine agonists. Partially supported by DA 02873.

637.7

ANXIOLYTIC ACTIVITY OF FLESINOXAN IN ANIMAL MODELS. B. Olivier, A.M van der Poel*, J. Mos, J.A.M. van der Heyden and J. Schipper. Dept. Pharmacology, Duphar, P.O. Box 900 1380 DA Weesp, The Netherlands.

Flesinoxan selectively binds to the 5-HT_{1A} receptor (K_i= 1.7 nM). Flesinoxan has been studied in anxiolytic models in mice where exploration of a novel environment is suppressed by punishment. In the 4-plate test, where ambulatory activity is punished by a mild foot-shock, flesinoxan and other 5-HT_{1A} agonists show no anxiolytic effects in contrast to benzodiazepines. Similar results are obtained in the light-dark model, where exploration of mice is inhibited by bright illumination. In another anxiety model in mice, which is based on stress-induced hyperthermia, flesinoxan is active at doses of 1 mg/kg p.o. and higher. Also 8-OH-DPAT and buspirone are active in this model (0.3 mg/kg s.c and 10 mg/kg p.o.), whereas ipsapirone does not show an effect upto 20 mg/kg p.o.

Anxiolytic properties of drugs can also be detected by the so-called separation-induced ultrasonic vocalizations of infant rodents. Low doses of benzodiazepines reduce ultrasonic vocalizations in rat pups. 5-HT_{1A} agonists like buspirone and ipsapirone also reduce these separation induced anxiety calls. Flesinoxan is highly active (0.3-3 mg/kg i.p.) and far more potent than buspirone and ipsapirone. Ultrasonic vocalization emitted by adult rats in anticipation of electric footshocks are very effectively suppressed by flesinoxan (0.3 -1 mg/kg i.p.). Benzodiazepines are only marginally active in this test, except for alprazolam, which is fully effective at 3 mg/kg. In a conflict test in pigeons, it has been found that flesinoxan has anxiolytic activity at low doses (0.03-1) mg/kg (Barrett et al., J. Psychopharm. (1989) 3:64-69).

In conclusion, flesinoxan is a highly potent and selective 5-HT_{1A} agonist. Based on the animal pharmacology data there are strong indications that flesinoxan may have potential anxiolytic properties in man.

637.8

PHARMACOLOGICAL PROFILE OF THE 5HT$_{1A}$-ANXIOLYTIC EMD 56551 G.D. Bartoszyk, H. Böttcher*, H. Greiner*, J. Harting*, and C.A. Seyfried*. E. Merck, Pharm. Res., 6100 Darmstadt, FRG.

EMD 56551 (5-methoxy-3-[4-(4-(4-methoxyphenyl)-1-piperazinyl)butyl]indole) exhibited the following binding profile in vitro (receptor and IC_{50}, respectively): 5HT_{1A}: 4 nM; 5HT_2: 750 nM; D_2: 420 nM; affinity to 5HT_{1B}, 5HT_3, BZ, D_1, α_1 and α_2 was ≥ 1 μM. EMD 56551 inhibited forskolin-stimulated adenylate cyclase (IC_{50}: 2 nM), but antagonized the inhibitory effects of 1 μM 8-OH-DPAT in this model at 3 and 10 μM. 5HTP-accumulation in rat n.raphe was inhibited dose-dependently (threshold dose ≤ 0.1 mg/kg po). In the elevated plus maze and social interaction tests in rats, EMD 56551 was anxiolytic with bell-shaped dose-response curves (3-100 and 0.3-100 μg/kg sc, respectively). Foot-shock induced vocalization in rats was decreased with an ED_{95} of 100 μg/kg sc. In drug discrimination studies, EMD 56551 generalized to the 8-OH-DPAT cue with an ED_{50} of 0.6 mg/kg ip. Moreover, EMD 56551 inhibited two-way shuttle box avoidance and prevented haloperidol-induced catalepsy. The results characterize EMD 56551 as a selective partial 5HT_{1A}-agonist with a high potency and a broad dose range as regards anxiolytic activity.

637.9

IN VIVO VOLTAMMETRIC NEUROCHEMICAL PROFILE FOR THE TRIAZOLOBENZODIAZEPINE, ADINAZOLAM. F.T. Phelan and P.A. Broderick, Dept. Pharmacol., CUNY Medical School (Rm. J-910), Convent Ave. & W. 138th St., N.Y., N.Y. 10031, U.S.A.

Adinazolam is a benzodiazepine (BZD) agonist, an anxiolytic compound with demonstrated antidepressant activity (Amsterdam et al., *Psychopharmacol.* 88 (1986) 484). However, adinazolam does not affect either noradrenergic or serotonergic reuptake inhibition (Lahti et al., *Neuropharmacol.* 22 (1983) 1277). To elucidate adinazolam mechanistically, semiderivative voltammetry was used with stearate working electrodes to detect norepinephrine (NE) and serotonin (5-HT) in hippocampus (CA_1) of chloral hydrate anesthetized, male, virus free, Sprague Dawley rats. Specific details for the characterization of the NE and 5-HT electrochemical signals are published (Broderick, P.A., *Neurosci. Lett.* 95: (1988) 275). Additional studies showed that the α adrenoreceptor agonist, clonidine (30 mg/kg ip) significantly decreased the NE signal (36%, $p<0.05$), whereas the α adrenoreceptor antagonist, yohimbine (5 mg/kg ip) significantly increased the NE signal (24%, $p<0.05$). Moreover, the triazolobenzodiazepine, adinazolam (10mg/kg ip) significantly decreased the NE signal by 36.4% ($p<0.05$) and significantly decreased the 5-HT signal by 39.0% ($p<0.05$) at the end of one hour of study. The data are consistent with known mechanisms for the BZD's (Gallagher, D.W., *Eur. J. Pharmacol.* 49 (1978) 133; Sanghera, M.K. and German, D.W., *J. Neural Transm.* 57 (1983) 267). Importantly, the expected increased extracellular concentrations of NE and 5-HT, consistent with measurement of reuptake inhibitory mechanisms, do not occur. Thus, adinazolam regulates presynaptic NE and 5-HT release mechanisms. (Supported in part by an Upjohn grant).

637.10

SELECTIVE SEROTONIN RE-UPTAKE INHIBITORS DECREASE SCHEDULE-INDUCED POLYDIPSIA IN RATS. A. Woods*, C. Smith, M. Szewczak, M. Cornfeldt, P. Conway, and R. Corbett*. Department of Biological Research, Hoechst-Roussel Pharmaceuticals, Inc., Route 202-206, P.O. Box 2500, Somerville, NJ 08876.

Polydipsia was induced in food deprived rats by exposure to a fixed-interval feeding schedule (FI = 60 sec) for 150 min. per day. A polydipsic rat consumed a 3-4 times greater volume of water compared to a food deprived control rat. To determine if selective serotonin re-uptake inhibitors could decrease this schedule-induced polydipsia, animals were treated with either clomipramine (CMI), fluoxetine (FLU) or the noradrenergic re-uptake inhibitor, desipramine (DMI), as a negative control. Each of these agents were administered daily for at least 21 days at a dose of 5 mg/kg, ip, to polydipsic rats 60 min. prior to testing. Animals administered DMI showed no decrease in polydipsic behavior throughout the testing period. However, after chronic dosing, CMI and FLU significantly reduced polydipsia by approximately 50 percent. Since obsessive-compulsive disorder (OCD) and polydipsic behavior both involve an exaggeration of a normal behavior, the polydipsia model may be relevant for the prediction of compounds useful in the treatment of OCD. This idea is strengthened by the finding that CMI and FLU effectively reduce both polydipsic behavior in rats and clinical symptoms of OCD in humans, while DMI does not.

A COMPARISON OF BENZODIAZEPINE (BZ) RECEPTOR AGONISTS IN RAT BEHAVIORAL MODELS OF ANXIETY AND SEDATION. J.V.Cassella and M.D.Crago. Neurogen Corporation, Branford, CT 06405.

Drugs interacting with the BZ receptor reduce anxiety-related behaviors in animals and also produce a variety of side effects. Although some rat behavioral models have accurately predicted anxiolytic effects of these compounds, the measurement of anxiety-related behaviors can be confounded by concomitant sedation or motivational changes. This study compares the effects of the BZ receptor full agonists diazepam and alprazolam and partial agonists RO 16-6028 and CGS-9896 in three very different rat anxiety models (Elevated Plus Maze[EPM], Lick Suppression, and Fear Potentiated Startle) and an independent test of sedation (Locomotor activity). Diazepam (0.5-2.0mg/kg,IV) and alprazolam (0.06-0.5mg/kg,IV) dose-dependently reduced locomotor activity while RO 16-6028 and CGS-9896 depressed activity at some doses (0.125-1.0mg/kg,IV and 0.5-2.0mg/kg,IV, respectively). In similar dose ranges, all the compounds were efficacious in the EPM but sedative effects clearly interfered with the animal's performance in this task. All compounds increased the animal's willingness to take shocks in the lick task, with diazepam and RO 16-6028 clearly superior in efficacy. However, these two drugs also significantly increased drinking from a non-shocked spout. Performance in the Potentiated Startle paradigm also varied among the four test compounds. For the purposes of drug discovery a number of different behaviors, each possessing a minimal and varying sensitivity to different potential side effects should be employed. The overall profile of test results might best predict clinical efficacy of new test compounds.

BEHAVIORAL EFFECTS OF RO 15-4513 RELATED TO ITS INTRINSIC AGONIST ACTIVITY. A.H.Tang and S.R.Franklin. CNS Research, The Upjohn Company, Kalamazoo, MI 49001

Ro 15-4513 (RO) has pharmacological characteristics of a partial inverse agonist at the benzodiazepine (BZ) receptor. RO also reverses some, but not all, of the CNS effects of ethanol, BZ's, and barbiturates. It has a much higher affinity than other BZ's and β-carbolines for a recombinant $GABA_A$ receptor subtype identified in the cerebellum of rats (Luddens *et al.*, Nature 346:648, 1990). This study investigates the intrinsic behavioral effects of RO, and compares them to another BZ inverse agonist, FG 7142 (FG).

In rats trained to lever-press (VI-45 sec) for food reinforcement, both RO and FG suppressed respondings, with the former being 10X more potent. The effect of FG can be completely reversed by flumazenil, diazepam, or the BZ partial agonist, U-78875 (Tang *et al.*, Psychopharmacol. 101: Suppl. S56, 1990). The effect of RO on the food-reinforced behavior was incompletely antagonized by diazepam or flumazenil, although U-78875 was fully effective in reversing this effect of RO.

In rats trained in 2-way avoidance, RO dose-dependently impaired the avoidance response. FG produced only a minimum depressant effect. Again, flumazenil and diazepam partially reversed the avoidance depression by RO, but U-78875 produced a complete reversal. The results indicate that RO has intrinsic behavioral effects other than those of an inverse BZ agonist. U-78875 appears to be an antagonist for this intrinsic effect.

PERSISTENT MIDBRAIN HISTOLOGICAL ALTERATIONS IN ADULT MICE PRENATALLY TREATED WITH DIAZEPAM. A. Márquez-Orozco, M.C. Márquez-Orozco, M.A. Alcantara-Ortigoza* and A. Escobar*. Embryol. Dept. Sch. of Med., Inst. Invest. Biomed. UNAM, P.O.B. 70-553. México 04510 D.F. MEXICO.

Diazepam diffuses through the placental barrier of humans and mice, and accumulates in the mesencephalon, where it produces a delay in the neuroblastic differentiation of fetal mice, and an atypical chromatin distribution and less number of fibers in the neuroblastic nucleus. We investigated if these histological alterations of the fetal mesencephalon occur in adult mice. Single daily doses (2.7 mg/kg) of diazepam were s.c. administered to CD-1 strain female mice, between the 6th and 17th day of gestation. A control group received equivalent volumes of saline sol. The offsprings were wet-nursered by non-treated mice, weaned, and kept for 240 days. The motor activity and swimming patterns were periodically measured from the 6th day until the 8th month. Mice were deeply anesthetized, perfused with 10% formaline, and the brains were removed, fixed, and stained with current and modified fast-Golgy techniques. The sections were observed under a photonic microscope. The experimental animals showed atypical distribution of collicular and red nuclei neurones, less number of fibers, and accumulation of glial cells around vessels. These findings could explain the locomotor activity and swimming pattern alterations.

THE SPONTANEOUSLY HYPERTENSIVE RAT AS AN ANIMAL MODE OF ATTENTION-DEFICIT HYPERACTIVITY DISORDER. T. Sagvolden and B. Wultz. Dept. Neurophysiology, University of Oslo, N-0317 Oslo, Norway.
(SPON: European Brain and Behaviour Society).

About 3% of all children suffer from attention deficit hyperactivity disorder (ADHD). The primary purpose of the present research was to investigate the possibility of using the spontaneously hypertensive rat (SHR) as an animal model of ADHD.

Several experimental paradigms were used: open fields and various schedules of reinforcement.

The results showed that some behavioral changes in SHR are parallel to those of ADHD: SHR as well as ADHD children are hypoactive initially in a novel situation but develop a pronounced hyperactivity as time passes, there are some deficits in "attentive" behavior and both SHR and ADHD show a pronounced variability in their behavior.

SHR show reduced behavioral sensitivity to methylphenidate (Ritalin) compared to controls.

SHR is a promising animal model of ADHD also known as the "hyperkinetic syndrome".

COMPARATIVE STUDIES OF CALCIUM CHANNEL BLOCKERS EFFECTS ON CENTRAL FUNCTIONS AND THEIR PSYCHOLOGICAL DISORDERS. T.Shibuya, Y-Q.Zhang and Y.Watanabe. Dept. of Pharmacology, Tokyo Medical College, Shinjuku, Tokyo 160, Japan.

The modulation of Ca^{++} in the cerebellar granule cells of rats and the behavioral alterations resulting from treatment of Ca^{++}blockers were examined to evaluate the central effect of Ca^{++}blockers on the improvement of psychological dysfunctions. In hyperpotassium-induced Ca^{++} efflux, the fluorescence of Ca^{++} induced by Fura-2am in the granule cells was potentiated about 1.6 times higher than the steady state level. Fifty percent inhibition of this potentiation was seen in $5x10^{-7}$M of flunarizine (Flu), $2x10^{-6}$M of nicardipine (Nic), and concentrations higher than $5x10^{-5}$M of diltiazem, verapamil and nifedipine showed about 20% inhibition. In the behavioral studies, Flu and Nic demonstrated pharmacological properties similar to diazepam, but not chlorpromazine. Also both Flu and Nic treatment remarkably inhibited the hyperactivity of spontaneously hypertensive rats caused by mild audiogenic stress-induced fear, and also prolonged the duration of immobility in forced swimming of both male and female rats. These results suggest that the pharmacological properties of Ca^{++}blockers in the central nervous system are completely different from those in the peripheral nervous system, and some Ca^{++}blockers may be effective in the treatment of anxiety.

PHOSPHATIDYLINOSITOL HYDROLYSIS IN BRAIN MEMBRANES. X. Li, L. Song* and R. S. Jope. Dept. Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

The hydrolysis of phosphatidylinositol (PI) was measured in brain membranes using the method of Wallace and Claro (J. Pharm. Exp. Therap. 255:1296, 1990) in which the hydrolysis of exogenous [^{3}H]PI is measured. [^{3}H]PI hydrolysis was stimulated by GTPγS concentration-dependently with a maximal stimulation of 2 to 3-fold obtained with 3 μM. NaF concentration-dependently stimulated [^{3}H]PI hydrolysis to a greater extent than did GTPγS, with a maximal effect of about 5-fold with 20 mM NaF.

Carbachol alone or with NaF did not stimulate [^{3}H]PI hydrolysis, but with GTPγS carbachol stimulated activity above that obtained with GTPγS alone. Pilocarpine, which is only slightly active in slices, stimulated [^{3}H]PI hydrolysis in the presence of GTPγS to a similar extent as did carbachol. Inclusion of excitatory amino acid agonists with GTPγS and carbachol did not inhibit [^{3}H]PI hydrolysis, in contrast to results in slices, but with GTPγS some agonists effectively stimulated [^{3}H]PI hydrolysis.

In membranes prepared from chronic lithium-treated rats (4 weeks) carbachol stimulated [^{3}H]PI hydrolysis to a similar extent as in controls but activation of G-proteins induced lower stimulation than in controls.

These results demonstrate that membrane preparations are useful to study the modulation of [^{3}H]PI hydrolysis.

637.17

PERTUSSIS TOXIN POTENTIATES SEIZURES INDUCED BY PILOCARPINE, KAINIC ACID AND N-METHYL-D-ASPARTATE. R. S. Jope and G. C. Ormandy. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

Previous studies have shown that lithium potentiated the in vivo response to cholinomimetics in rats, resulting in seizures at otherwise nonconvulsant doses, but did not affect seizure activity induced by other chemical convulsants including kainic acid and NMDA (Ormandy et al., Exp. Neurol. 111:356, 1991). In vitro experiments have suggested that lithium interferes with receptor mediated second messenger production, possibly due to an action at G-proteins. The present study tested the hypothesis that selective inhibition of G-proteins by in vivo administration of pertussis toxin would induce effects similar to those of lithium.

Pertussis toxin (icv, 3 days) mimicked lithium in potentiating the convulsant response to pilocarpine in rats. The effect of pertussis toxin was dose-dependent and the extent of potentiation was over 13-fold, which was remarkably similar to lithium. The seizures were prevented by pretreatment with atropine, phenobarbital or diazepam. L-Phenylisopropyladenosine and MK-801 also demonstrated anticonvulsant activity, with MK-801 also protecting the rats against the rapid death associated with pertussis toxin/pilocarpine-induced seizures. Thus, seizures were cholinergically initiated and were controlled by the same drugs as were lithium/pilocarpine-induced seizures. The results illustrate that in several respects the response to cholinomimetics are modified in a similar manner by lithium and pertussis toxin. However, pertussis toxin lacks the specificity of lithium as it also potentiated the convulsant effects of kainic acid and NMDA.

637.18

SEIZURE-INDUCED PROTEIN TYROSINE PHOSPHORYLATION IN RAT BRAIN REGIONS. M. S. Baird, R. S. Jope and G. V. W. Johnson. Dept. of Psychiatry and Behavioral Neurobiology, University of Alabama, Birmingham, AL 35294.

Phosphorylation of protein tyrosines is an important modulatory process for cell signalling and other cellular functions. Rat brain regions were examined for altered protein phosphotyrosines, using Western blot analysis and microwave irradiation to limit postmortem alterations, after administration of two convulsants, lithium plus pilocarpine or kainic acid. Most phosphotyrosine proteins were unaltered by these treatments, but there was a large, specific increase in the tyrosine phosphorylation of a 40 kD protein. This elevation was evident in all three regions that were examined, the cerebral cortex, hippocampus and striatum. This increase occurred abruptly with the onset of generalized status epilepticus and remained elevated for at least 90 min. The majority of the tyrosine phosphorylated 40 kD protein was found in the cytosolic fraction. These results demonstrate a large, specific effect of chemically induced seizures on a single phosphotyrosine protein in rat brain.

EPILEPSY: BASIC MECHANISMS V

638.1

ANTICONVULSANT ACTION OF GABA BLOCKADE IN SUPERIOR COLLICULUS. A. Pazos, K. Japikse, K. Wetzler*, P. Pritchard*, R. Maggio* and K. Gale. Department of Pharmacology, Georgetown University Medical Center, Washington, D.C. 20007.

Blockade of GABA receptors, or stimulation of glutamate receptors, in superior colliculus (SC) has been shown to protect against maximal electroshock-induced tonic convulsions (Dean and Gale, Brain Res. 477:391-395) and pentylenetetrazol-induced spike-and-wave discharge (Redgrave et al., EJP 158:283-287). In the present study, we determined whether blockade of GABA receptors in SC could also protect against limbic motor seizures as characterized by facial and forelimb clonus with rearing.

Limbic motor seizures were induced by the unilateral focal application of bicuculline methiodide (BIC) (118 pmol in 120 nl) into area tempestas (AT), an epileptogenic site in the deep prepiriform cortex. Control rats (receiving bilateral infusions of saline into SC) all exhibited convulsive seizures following BIC in AT. Rats pretreated (5 min) with BIC (50pmol) bilaterally in the deep SC, were protected against the AT-evoked convulsive seizures. Unilateral application of BIC (50pmol) into the superficial SC, did not alter the convulsive response to BIC in AT.

These results are consistent with the observations made previously in other seizure models and suggest that a reduction of GABA transmission in the deep layers of the SC can decrease susceptibility to convulsive seizures evoked by activation of limbic circuits. As the deep SC is known to be a target of nigrotectal GABAergic projections, and, suppression of the activity of nigral neurons is anticonvulsant against a variety of seizures (including those evoked from AT), it is likely that the anticonvulsant action of BIC in SC is due to interference with the influence of the nigrotectal GABAergic projections.

D1 Dopamine Receptor Agonists Induce Forelimb Clonus. D.R. Britton, K. Asin, L. Yahiro*, P. Curzon, L. Bednarz* J. Williams, Neuroscience Research, Abbott Laboratories, Abbott Park, IL 60064

The D1 dopamine receptor (D1) agonist, SKF38393, has been reported by several groups to potentiate pilocarpine seizures. We report that a variety of D1 agonists induce forelimb clonus in rats and mice independent of cholinergic agonist co-treatment. The compounds tested include isochromans (A68930, A68979, A70620) and the benzazepine, SKF82958. Each produced clonus with an ED_{50} value of from 3 to about 300-fold higher than its ED_{50} for inducing rotation in rats with unilateral 6-OHDA lesions. The response showed enantiomeric selectivity for the active enatiomer of A68930 and there was a significant correlation between potency in inducing clonus and IC_{50} values for stimulating adenylate cyclase or Ki values for binding to the D1 receptor *in vitro*. In male CD1 mice, A68930-induced clonus is sensitive to inhibition by a variety of anticonvulsants including diazepam, clonazepam, valproic acid and acetazolamide. It is also sensitive to D1-selective (SCH23390, A69024, SCH39166) but not D2-selective (haloperidol, YM09151-2) antagonists. Neither D2-selective (LY171555, bromocriptine) nor mixed D1/D2 (apomorphine) agonists produced clonus in the dose range tested. Furthermore, co-administration of LY171555 or bromocriptine provided apparent protection from clonus as evidenced by a rightward shift in the dose-response curve to A68930.

GAMMA-HYDROXYBUTYRIC ACID INDUCED SPIKE AND WAVE DISCHARGES IN RATS: ELECTROPHYSIOLOGICAL AND AUTORADIOGRAPHIC EVALUATION. P.K. Banerjee, O.C. Snead III and E. Hirsch. Div. of Neurology, Childrens Hospital of Los Angeles, Department of Neurology, Univ. of Southern California, Sch. of Med., Los Angeles, CA.

γ-hydroxybutyric acid (GHB), a naturally occuring compound, is synthesized from γ-aminobutyric acid (GABA) and induces bilaterally synchronous spike and wave discharges (SWD) in rats which simulate generalized absence seizures. The GHB model of absence seizure has been well characterized in our laboratory (Snead, Epilepsia 29:361, 1988). The purpose of the present study was to investigate the pattern of SWD generation in different layers of frontal cortex (FCtx) and thalamic nuclei. For this purpose, the animals were implanted with bipolar electrodes in two different layers of FCtx, dorsal hippocampus (CA1 field), ventrolateral (VL) and ventropostereolateral (VPL) nuclei of thalamus. The FCtx (layer one) bipolar recording was synchronous with the other cortical epidural (monopolar) electrode recordings while FCtx (layer two) did not seem to participate in the SWD. In the thalamus VPL synchronously fired with the cortical epidural recording during SWD induced by GHB but VL was found to be silent. Our biochemical findings using quantitative receptor autoradiography suggested that even though the highest density of GHB binding sites (labeled with ^{3}H-GHB) were present in the hippocampus (CA3>CA1>CA2), the bipolar recordings of hippocampus (CA1 field) were silent during GHB-induced SWD. Similarly, the bipolar recordings of VL were silent inspite of the fact that the GHB binding sites were more abundant in the VL than in the VPL, where SWD appeared synchronously with the cortical epidural recordings. Interestingly, the distribution pattern of ^{3}H-GHB in the brains from animals sacrificed dring GHB-induced SWD, showed a significant increase in ^{3}H-GHB binding in both the layers of FCtx (~120%). In the thalamus, the VPL binding rose to ~116% compared to GHB-naive VPL, whereas the increment in VL was approximately 80%. These findings suggest that GHB binding sites in thalamus and cortex are directly involved in the generation of SWD in the model of absence.

THE ELECTROPHYSIOLOGICAL BASIS OF EPILEPTIFORM MAGNETIC FIELDS IN NEOCORTEX: SPONTANEOUS ICTAL PHENOMENA SHI DI and DANIEL S. BARTH *Department of Psychology , University of Colorado, Boulder, CO 80309-0345 (U.S.A)*

In a previous report from our lab., electrical measurements of epileptiform cellular currents produced by physiologically evoked interictal penicillin spikes in rat somatosensory cortex were directly compared to the extracranial magnetic fields these currents generate. The present study uses the same methodology to extend these observations to spontaneous interictal and ictal phenomena in rat auditory cortex, and provides a more realistic empirical foundation for physical models with which to interpret noninvasive neuromagnetic recordings of human focal seizures. These data indicate that seizure foci under 1 x 1 cm^2 in cortical surface area are capable of producing magnetic fields that may be recorded at extracranial distances similar to those used in humans. Furthermore, physical models based on the dipole approximation appear to be appropriate for the interpretation of ictal magnetic field phenomena in neocortex.

IMPAIRMENT OF SPATIAL MEMORY AFTER SUSTAINED HIPPOCAMPAL STIMULATION: THE INFLUENCE OF CA1 CELL DAMAGE AND INTERICTAL SPIKING ACTIVITY. **A. Ylinen, J. Sirviö, T.F. Freund[1] and P. Riekkinen. Dept. of Neurol. and Pathol. Univ. of Kuopio, P.O.B. 1627, SF-70211 Kuopio, Finland and [1]Dept. of Funct. Neuroanatomy, Institute of Exp. Medicene. Hungarian Academy of Sciences, H-1450 Budapest, Hungary.**

Definits in learning/memory found in epileptic patients have been associated with morphological damage of the brain tissue and also with epileptiform electrical activity. Sustained stimulation of the perforant pathway (PP) input to the hippocampus has been shown to cause cell damage and also impairment in spatial learning/memory. In the present experiments we studied spatial learning/memory, hippocampal cell damage and appearance of interictal spikes after sustained stimulation (50 min) of PP in rats pretreated either with the GABAergic inhibition enhancing drug, vigabatrin (500 mg/kg) or with NMDA receptor antagonist, CGP 39551 (5 mg/kg). EEGs were recorded 1 week after the stimulation prior to water maze trials. Finally, the rats were perfused for histology. No defects of spatial learning/memory were found in vigabatrin pretreated rats (n=9). Also CGP 39551 treated rats (n=9) performed significantly better than placebo-treated (n=8) ($p < 0.001$), but slightly worse than nonstimulated controls (n=8). Vigabatrin rats showed neither cell damage in hippocampus nor interictal spiking in EEG, CGP 39551 rats showed cell damage but not spiking and placebo rats showed both. In conclusion, the degree of the impairment of learning/memory depends not only on the degree of cell damage but also on the amount of interictal epileptiform activity.

NONLINEAR DYNAMICS OF ICTAL EEG RECORDS. N.D. Schiff*, A. Canel*, D.R. Labar*, and J.D. Victor. Department of Neurology and Neuroscience, New York Hospital-Cornell Medical Center, New York, New York, U.S.A. 10021.

Mathematical models of the EEG posit nonlinear mechanisms at the level of cell populations. Ictal EEG records have qualitative features such as spike discharges which may reflect these underlying nonlinear dynamics. We sought to quantify nonlinear behavior in the ictal EEG by constructing nonlinear autoregressive models (NLAR). The nonlinear difference equation which represents the EEG in this model has a form which can be treated with methods of dynamical systems analysis.

The NLAR models consisted of linear autoregressive models augmented by a single quadratic or bilinear interaction term. By varying the lags associated with this term, we explored the pattern of nonlinear dynamics. NLAR analysis of ictal records from patients with petit mal seizures revealed a specific dynamical pattern. The pattern of interaction excluded simple cascades of linear and nonlinear systems as models, and indicated an interaction of signals separated by roughly 24 ms, at times from 40 ms to 60 ms in the past. Other patterns were seen in patients with other seizure types. In addition, we treated these models as dynamical systems and analyzed the stability of fixed points and two-cycles.

EFFECT OF YOHIMBINE AND CLONIDINE ON ELECTROSHOCK-INDUCED FOREBRAIN AND BRAINSTEM SEIZURES IN RATS. C. Wang, P. C. Iobe and R. A Browning, Southern Illinois Univ. Sch. of Med., Carbondale, IL 62901 and Univ. of Illinois Coll. of Med. Peoria, IL 61656

Recent studies have shown that electroshock-induced convulsions characterized by facial and forelimb (F&F) clonus represent a model of forebrain seizures, while tonic hindlimb extensor (HLE) convulsions represent a model of brainstem seizures (Browning and Nelson, Exp. Neurol. 93: 546, 1986). In an attempt to evaluate the role of noradrenergic receptors in the regulation of seizures, we have examined the effects of yohimbine, an alpha-2 antagonist and clonidine, an alpha-2 agonist on electroshock-induced F&F clonus (forebrain seizures) and tonic HLE (brainstem seizures) in male Sprague Dawley rats. F&F clonus was induced by a 24 mA, 0.2 sec current (the mean threshold) using a Whalquist stimulator and corneal electrodes, while tonic HLE was produced using the same instrument and a 150 mA, 0.2 sec current. Yohimbine (2.5 - 10 mg/kg, i. p.) produced a significant reduction in the incidence of HLE without affecting F&F clonus 30 min after drug administration. Clonidine (0.5 mg/kg, i. p.) had no effect on F&F clonus and produced a slight, albeit non-significant, inhibition of tonic HLE. The results support the hypothesis that noradrenergic receptors exert different effects in the regulation of forebrain and brainstem seizures. Whether the inhibitory effect of yohimbine on tonic HLE is mediated by an increase in norepinephrine release remains to be determined.

638.8

IP_3, CYCLIC AMP AND CYCLIC GMP IN RAT BRAIN REGIONS AFTER LITHIUM AND SEIZURES. A. G. Faulk, L. Song*, K. Kolasa and R. S. Jope. Department of Psychiatry and Behavioral Neurobiology, University of Alabama, Birmingham, AL 35294.

The concentrations of inositol 1,4,5 trisphosphate (IP_3), cyclic AMP, and cyclic GMP were measured in rat brain regions after acute or chronic lithium administration, as well as after the cholinergic agonist pilocarpine alone or in combination with lithium at a dose which induces seizures only in lithium pretreated rats.

Neither acute nor chronic lithium treatment altered the hippocampal or cortical concentrations of IP_3. Pilocarpine increased IP_3 after 20 min, and this response was enhanced in both acute and chronic lithium-treated rats. At 60 min after pilocarpine IP_3 was elevated further, and with pilocarpine plus lithium the IP_3 concentration remained elevated in the hippocampus but it decreased in the cortex.

Neither acute nor chronic lithium treatment altered the cyclic AMP. During seizures induced by pilocarpine cyclic AMP increased in the cortex with acute and chronic lithium and in the hippocampus with acute, but not chronic, lithium administration.

Acute and chronic lithium treatments both caused some reduction in cyclic GMP. Seizures induced by pilocarpine resulted in large accumulations of cyclic GMP with acute lithium treatment, but these increases were much less with chronic lithium administration.

In summary, chronic lithium treatment appeared only to reduce IP_3 and cyclic AMP concentrations after a long period of stimulation whereas both basal and stimulated cyclic GMP production were reduced by lithium administration.

NIGRAL GAMMA–VINYL GABA INFUSIONS AND FLUROTHYL-INDUCED SEIZURES: DEVELOPMENTAL EFFECTS IN RATS. S. G. Xu, E. F. Sperber, D. S. Garant, H. Y. Liu* and S. L. Moshé, Departments of Neurology, Neuroscience and Pediatrics, Albert Einstein College of Medicine, Bronx, NY 10461.

The GABAergic system within the the substantia nigra pars reticulata (SNR) is involved in the control of seizure as a function of age. In the present study, we investigated the effect of perinigral infusions of γ-vinyl GABA (GVG, an inhibitor of the GABA degradative enzyme, GABA transaminase) on clonic and tonic seizures induced by flurothyl in 16 day old rat pups and adult rats. Bilateral nigral infusions of GVG differentially suppressed seizures in the two age groups. In rat pups, nigrally administered GVG (5-20 μg/0.25 μl) increased the threshold for tonic seizures but not for clonic seizures in a dose-response manner. The optimal dose was between 5-10 μg because the dose of 20 μg produced marked sedation. In adult rats, only the dose of 20 μg elevated the thresholds for both clonic and tonic seizures. Lower doses (5-10 μg) did not protect adults against seizures, but there was a significant effect of GVG dose. In both age groups, the GVG effects were confined to the SNR. These results suggest that nigral infusions of GVG exert specific anticonvulsant effects as a function of age.

ANATOMICAL DIFFERENCES IN THE DEVELOPMENT OF GABA-B RECEPTORS AND RESPONSES. D.S. Garant, E.F. Sperber, P.K. Stanton, and S.L. Moshé, Departments of Neurology, Neuroscience, and Pediatrics, Albert Einstein College of Medicine, 1300 Morris Park Ave, Bronx, NY 10461 (USA).

In two-week-old rats the GABA-B agonist baclofen can attenuate seizures after either systemic administration or infusion into substantia nigra (SN), a structure implicated in seizure control. These treatments are ineffective against seizures in adult rats.

To determine whether receptor differences might explain this developmental disparity, baclofen-displaced ^{3}H-GABA binding to GABA-B sites was assayed in brain regions obtained from adult and 14- to 17-day-old rats. There were no significant differences in K_d between age groups. The SN of rat pups exhibited a 3- to 5-fold higher density (B_{max}) of GABA-B binding sites than the SN of adults. In contrast, the density of GABA-B sites was lower in hippocampal and cerebellar tissue from pups, both approximately two-thirds the density in corresponding adult structures. This anatomically selective increased density of GABA-B receptors in immature SN might underlie the greater anticonvulsant efficacy of baclofen observed in rat pups.

Whether this maturational difference in GABA-B receptors between SN and hippocampus results in a difference in responses to GABAergic stimulation, is being investigated by electrophysiologic studies.

BRAINSTEM-EVOKED SYNCHRONOUS DISCHARGE IN THALAMIC NEURONS DURING SLEEP IN NORMAL AND PENICILLIN-TREATED CATS. M.N. Shouse, R. Szymusiak and D. McGinty. VAMC, Sepulveda, Dept. Anat. & Cell Biol., UCLA.

Some periods in the sleep-waking cycle are more seizure prone than others. One seizure prone period is the slow-wave sleep (SWS)-REM sleep transition. Discharge of pedunculopontine (PPT) and paramedian midbrain reticular formation (MRF) neurons accelerates during these transitions, while the thalamocortical EEG remains synchronized. Coincidence of moderate brainstem activation with thalamocortical EEG synchrony is hypothesized to contribute to enhanced seizure susceptibility during SWS-REM transitions.

In untreated cats, low intensity, single-pulse stimulation of the PPT or MRF delivered during waking or REM sleep typically evoked a single, short latency action potential in thalamic neurons. Stimulation during SWS commonly evoked a high frequency burst followed by a period of suppressed discharge and, in some cases, a second burst. High frequency bursts were more reliably elicited by PPT stimulation. Following systemic penicillin-G (100,000 IU/kg), brainstem stimulation during SWS reliably evoked high frequency bursts followed by 1-2 pause-burst cycles with a periodicity of 147 ± 12 ms (n=7). This was similar to the interburst interval of these same thalamic neurons during spontaneous EEG spike-wave discharges (156 ± 14 ms, n=7).

Enhanced PPT- or MRF-evoked synchronous thalamic discharge in SWS supports the hypothesis that brainstem activation during SWS-REM transitions contributes to enhanced seizure susceptibility.

EFFECTS OF db-CAMP AND Na AND K CONCENTRATION IN MEDIUM ON THE Na,K-ATPase ACTIVITY AND INTRACELLULAR Na AND K CONTENTS OF CULTURED ASTROCYTES OF DBA and C57 MICE. D.M. Woodbury, S.Y. Chow, E.J.K. Noach and J. Li. Div. of Neuropharmacology and Epileptology, Univ. of Utah Sch. of Med. Salt Lake City, UT 84108.

The Na,K-ATPase activity in primary cultures of astrocytes derived from the cerebral cortex of audiogenic-seizure-susceptible mice (DBA) was higher than that of audiogenic-seizure-resistant mice (C57). Intracellular Na of DBA astrocytes was lower than that of C57 astrocytes whereas there was no difference in intracellular K. The Na,K-ATPase activity in astrocytes with db-CAMP pretreatment during the third week in culture was much lower than that without db-CAMP pretreatment in both DBA and C57 mice. Varying the concentration of K and Na in either culture medium or buffer solution altered the Na,K-ATPase activity and intracellular Na and K contents of cultured astrocytes. As K in medium increased from 1.2 to 10 mM, Na,K-ATPase activity gradually increased. It plateaued when K in medium was between 10 and 30 mM. The Na,K-ATPase activity declined as the K in medium exceeded 30 mM. These changes were accompanied by the expected changes in intracellular Na and K contents in both DBA and C57 mice. It appears that astrocytes from the hyperexcitable DBA mice are better able to transport Na than are the seizure-resistant C57 mice. Supported by NIH grants #NS21255 and #NS21834.

CHOLINERGIC MECHANISMS OF EPILEPTIC SEIZURE GENERATION IN THE RAT BRAIN. J.W.Cruickshank*, R.S.McLachlan, and S.M.Brudzynski. Departments of Physiol. and Clinical Neurol. Sci., Univ. of Western Ontario, London, Ontario, Canada N6A 5A5

Direct intracerebral application of cholinomimetic agents into the brain can cause motor seizures. The present study was designed to determine the types of acetylcholine receptors involved in cholinergic initiation of seizures from the basal forebrain and diencephalon in rats. Unilateral intracerebral microinjections of a mixed muscarinic and nicotinic agonist, carbachol (3μg), caused reproducible generalized seizures in 10 of 13 rats mostly from zona incerta. Local pretreatment with pirenzepine (7μg), an M1 receptor antagonist, abolished carbachol-induced seizures following 78% of injections compared to 14% following pretreatment with methoctramine (12μg), an M2 receptor antagonist. Pretreatment with the nicotinic blocker, mecamylamine (3μg), abolished seizures in 28%. Saline pretreatment prevented seizures in 23%. The results suggest that the activation of M1 muscarinic receptors is involved in the mediation of generalized seizures in the basal forebrain and diencephalic regions.

CHOLINERGIC MODULATION OF SOMAN-INDUCED SEIZURES. J.H. McDonough and T.-M. Shih, Pharmacology Div., US Army Med. Res. Inst. Chem. Def., APG, MD 21010

Exposure to the nerve agent soman can produce prolonged recurring seizures and brain damage. Previous work has shown that the initiation and early phases of these seizures are mediated by cholinergic events. The purpose of this study was to determine how long seizure activity needed to progress before anticholinergic treatment became ineffective. Rats implanted with cortical and depth electrodes were pretreated with the oxime HI-6 (125 mg/kg, ip), to prolong survival, 30 min before soman (180 ug/kg, sc; an ED100 for eliciting seizures). EEG activity and behavior were monitored for the occurrence of seizure activity, operationally defined as the first continuous train of spike activity ≥ 10 sec. Scopolamine HBr (SCOP) was administered iv, over a range of doses, at selected times after seizure onset. At 2.5 and 5 min after seizure onset, low doses of SCOP (0.05-0.1 and 0.2 mg/kg, respectively) were capable of terminating the seizure; at 10 min after onset, only higher doses (≥ 0.8 mg/kg) of SCOP were completely effective. If the seizures progressed for 20 min, doses up to 3.2 mg/kg SCOP were incapable of stopping seizure activity. The results show that cholinergic control of soman-induced seizures is of a relatively brief, but discrete, duration, and that within this period of time there is a continual increase in the ED50 of SCOP.

LOSS OF GABA-MEDIATED INHIBITION IN LITHIUM-PILOCARPINE MODEL OF STATUS EPILEPTICUS. J.Kapur, E.W. Lothman[1] and R.J. DeLorenzo. Department of Neurology, Medical College of Virginia, Richmond, VA and [1]Department of Neurology, University of Virginia, Charlottesville, VA.

Convulsive status epilepticus (SE) is a neurological emergency. The pathophysiology of SE is poorly understood. This study uses a combination of electrophysiological and biochemical methods to compare the state of GABA-mediated inhibition in rats injected with lithium and pilocarpine to cause SE, with that in naive and lithium-treated controls. Paired pulse inhibition technique is used to evaluate GABA-mediated inhibition in the CA1 region of the hippocampus of urethane-anesthetized rats. There is a left shift of inhibition vs interpulse interval curve in test animals when compared with the curve from the two control groups. High affinity ^{3}H muscimol binding sites in rat forebrain synaptic plasma membrane (SPM) fraction are defined by generating a saturation curve. The SPM from control (naive or lithium-treated) groups showed a high affinity for ^{3}H muscimol and saturation of binding sites as reported in the literature. No high affinity binding site for ^{3}H muscimol or their saturation were detected in SPM derived from the test (SE) animals. These results demonstrate a loss of GABA-mediated inhibition in lithium-pilocarpine induced SE. Loss of GABA-mediated inhibition may result from post-translational modification of the GABA receptor and can play an important role in emergence of SE.

DIFFERENTIAL CHANGES IN EARLY AND LATE PHASE OF INHIBITION IN DENTATE GYRUS FOLLOWING SYSTEMIC ADMINISTRATION OF KAINIC ACID. Moshe Khurgel, E. Pagani* and N.W. Milgram. Life Sciences Division, Scarborough Campus, U. Toronto, Scarborough, Ontario, Canada, M1C 1A4.

Following activation of dentate gyrus granule cells by perforant path stimulation, both an early and a late phase of inhibition of the population spike measure can be demonstrated with the paired pulse technique. These two inhibitory phases are decreased by use and such changes in inhibition are thought to contribute to seizure development. We have monitored both phases during the development of status epilepticus following systemic administration of kainic acid. Subjects were freely moving rats which had been chronically implanted with perforant path stimulation electrodes and dentate gyrus recording electrodes. Consistent with previous reports, prior to the occurrence of the initial afterdischarge activity we found a progressive decrease in the early phase of inhibition measured at an interpulse interval (ipi) of 25 msec. In contrast, there was an unexpected increase in the late phase of inhibition which measured at a 300 msec ipi. We also observed a progressive broadening of the field potential, which was similar to a previously reported late NMDA component and can provide an explanation for the increase in the late phase of inhibition.

KYNURENATE AND ETHANOL WITHDRAWAL
F. Moroni, P. Russi*, G. Lombardi & #R. Pellicciari*
Department of Pharmacology, University of Florence, 50134 Florence ITALY. #Institute of Medicinal Chemistry, 06100 Perugia, ITALY.

Ethanol withdrawal in dependent rats reduced the cortical content of kynurenic acid (KYNA) from 41.5±8 pmol/g tissue to 24.0±3 pmol/g tissue. KYNA is a tryptophan metabolite able to inhibit glutamate neurotransmission by interacting with glycine at the level of the NMDA receptor ion channel complex. In order to understand whether brain KYNA decrease was associated with the symptoms of ethanol withdrawal we administered nicotinylalanine (NAL) to dependent animals. We have previously shown that NAL administration (200 mg/kg i.p.) to rats significantly potentiates tryptophan (200 mg/kg i.p.) induced accumulation of KYNA in their brains. Furthermore NAL administration (100-400 mg/kg i.p.) to audiogenic susceptible DBA/2 mice prevented sound and kynurenine (300 µg/kg i.c.v) induced seizures. The administration of NAL (200-400 mg/kg i.p.) to ethanol dependent C57 black mice was able to prevent withdrawal seizures, tremors and changes in body temperatures, evaluated according to Ritzmann and Tabakoff, J. Exper. Ther., 199, 158-170, 1976.
It appears therefore that by correcting the withdrawal induced decrease of brain KYNA it is possible to prevent symptoms of ethanol withdrawal.

FUNCTIONAL IMPROVEMENT DEMONSTRATED AFTER MYOBLAST TRANSFER THERAPY IN EXTENSOR DIGITORUM BREVIS MUSCLES OF BOYS WITH DUCHENNE MUSCULAR DYSTROPHY . J.A. Florendo, D.S. Kirby*, B.C. Schafer*, T.G. Goodwin*, and P.K. Law. Cell Therapy Research Foundation, Memphis, TN 38117.

Duchenne muscular dystrophy (DMD), an inherited, lethal disease of young males, has no known cure or treatment. Myoblast transfer therapy (MTT), intramuscular injections of normal myoblasts into diseased muscles, has been developed as a possible treatment to alleviate the symptoms of DMD. In this double-blind, first clinical trial of MTT, eleven male volunteers with DMD, aged 5 to 11, received normal myoblast injections in randomly selected extensor digitorum brevis (EDB) muscles. Sham-injected EDBs served as control muscles. All the subjects received Cyclosporine (CsA) for the duration of the trial, and no adverse reactions occurred. This study aimed to demonstrate functional improvement in DMD muscles after MTT.

To evaluate muscle function of EDB muscles, an apparatus was designed and a procedure was developed whereby isometric twitch and maximal voluntary contraction (MVC) tensions could be measured. Twitch tensions were evoked by supramaximal, indirect electrical stimulation. A study of eleven normal adult volunteers was conducted to demonstrate the reproducibility of the technique before testing the DMD volunteers. Six measurements of twitch and MVC amplitudes were obtained before and at 3 and 6 months after MTT on test and control DMD muscles. After MTT the test muscles demonstrated functional improvement, whereas the control muscles showed a loss in strength. (Supported by MDA, Sandoz, and Walgreens.)

THE EFFECT OF AMITRIPTYLINE ON MUSCLE WEAKNESS AND MYOTONIA IN MYOTONIC DYSTROPHY. S. Milner-Brown, Department of Kinesiology. University of Colorado, Bouler, CO 80309.

The objective of this study was to quantify the degree of muscle weakness and myotonia in 12 patients with myotonic dystrophy (MD), and to quantitatively determine the effects of a 6-month therapeutic trial of the antidepressent drug amitriptyline. Muscle weakness was quantified by comparing the 5-sec maximum voluntary contraction (MVC) in newtons (N)/bodymass (Kg) of 12 patients and 20 healthy subjects; knee extensor, elbow flexor, and first dorsal interosseous (FDI) muscles were compared. Myotonia was quantified by measuring relaxation times (RT) at the end of the 5-sec MVC produced by FDI, as the time taken for the MVC to decrease to 50% and 75% (referred to as 1/2 and 3/4 RT). The results were as follows: (1) the mean muscle strength of each of the 3 muscles of the patients was significantly ($p < 0.001$) reduced compared with healthy subjects; knee extensors 3.3 ± 1.9 N/Kg vs 7.8 ± 1.4 N/Kg, Elbow flexors 1.25 ± 0.6 vs 3.3 ± 0.9 N/Kg, FDI 0.27 ± 0.05 vs 0.46 ± 0.08 N/Kg; and (2) 1/2 and 3/4 RT means of the MD patients (vs healthy subjects) were significantly ($p < 0.01$) prolonged; 328 ± 87 vs 135 ± 28 msec and 44.5 ± 116 vs 185 ± 51 msec.

After the 6-month therapeutic trial of amitriptyline (50 mg/day), the mean muscle strength of FDI improved from 0.27 to 0.33 N/Kg ($p < 0.05$); both the mean 1/2 RT and 3/4 RT were reduced from 328 to 142 msec and from 445 to 187 msec, respectively ($p < 0.01$). It is concluded that amitriptyline may provide therapeutic benefit to patients with myotonic dystrophy.

639.3

AMINOGUANIDINE ON NERVE BLOOD FLOW, VASCULAR PERMEABILITY, ELECTROPHYSIOLOGY, AND OXYGEN FREE RADICALS. J. D. Schmelzer*, M. Kihara*, J. F. Poduslo, G. L. Curran*, K. K. Nickander*, and P. A. Low. Dept. Neurol., Mayo Clinic, Rochester, MN 55905

Since advanced glycosylation endproducts have been suggested to mediate hyperglycemia-induced microvascular atherogenesis, and because aminoguanidine (AG) prevents their generation, we examined whether AG could prevent or ameliorate the physiologic and biochemical indices of streptozotocin (STZ) induced experimental diabetic neuropathy. Four groups of adult Sprague-Dawley rats were studied: Group I, STZ + 25 mg/kg/d AG; Group II, STZ + 50 mg/kg/d AG; Group III, STZ alone; Group IV, Controls. We monitored conduction serially in sciatic-tibial and caudal nerves, nerve blood flow, oxygen free radical activity (conjugated dienes and hydroperoxides), and the permeability coefficient-surface area product to ^{125}I-albumin. STZ diabetes (Group III) caused a 57% reduction in nerve blood flow, abnormal nerve conduction and amplitudes, and a 60% increase in conjugated dienes. Nerve blood flow was normalized by 8 weeks with AG (Groups I, II) and conduction was significantly improved, in a dose-dependent manner, by 16 and 24 weeks in sciatic-tibial and caudal nerves, respectively. The permeability coefficient was not impaired, suggesting a normal blood nerve barrier function for albumin, and oxygen free radical indices were not ameliorated by AG. We suggest that AG reverses nerve ischemia and more gradually improves their electrophysiology by an action on nerve microvessels. AG may have potential in the treatment of diabetic neuropathy.

639.4

HIND LIMB PARALYSIS INDUCED BY INTRASPINAL CORD INJECTION OF COLCHICINE: IMPROVED RECOVERY BY CALCIUM CHANNEL BLOCKERS. **M.Baraldi, P.Zanoli*, P.Guidetti*, C.Truzzi*. Chair of Pharmacology and Pharmacognosy, Modena University, 41100 Modena, Italy.**

The intraspinal cord injection of small doses (5-10 ug/rat) of colchicine (C) at the lumbar level induces urine retention and hind limb paralysis in a dose related fashion. The onset of paresis occurs 1 day after the injection of 5 ug of C. By 2-3 days the hind limbs are completely flaccid. Thereafter the condition begin to improve behing almost normal by 21-24 days. Hence this model was used as a tool to study the neurochemical mechanisms of the paralysis due to spinal cord injury and to test new pharmacological treatments. The motor and sensory deficits in C treated rats were evaluated 1,3,6,8,10,13 and 15 days after C injection by actimetric system and neurological scores. By day 3 after the C injection, when the paralysis reaches its maximum score, we found by RIA a decrease of Sub P in the spinal cord (0.51 vs 7.82 pmol/mg prot. of controls) without changes of Dynorphin. This finding seems to be in line with the reduction of Sub P described in spinal cord injury and with the notion that Sub P antagonists may produce paralysis after their intrathecal administration. By radioreceptor binding assay we found also a reduction of the NMDA-related receptors labeled by ^{3}H-TCP and of sigma receptors labeled by ^{3}H-SKF 10047 associated with an enhancement of calcium binding sites labeled by ^{3}H-PN 200-110 in the spinal cord of C treated rats (35.3 vs 16.1 fmol/mg prot. in controls). Since both Sub P and glutamatergic system are involved in calcium homeostasis, we performed pharmacological challenges by chronically injecting the NMDA noncompetitive antagonist MK 801 or calcium channel antagonists (PY 108-068 and PN 200-110). While MK 801 worsened the spontaneous recovery, the calcium channel blockers strongly facilitated the motor and the neuronal recovery of the C- induced paralysis.

ELEVATED MECHANOSENSITIVE CHANNEL ACTIVITY IN INTACT SKELETAL MUSCLE FROM *mdx* MOUSE. A. Franco Jr., and J.B. Lansman. Department of Pharmacology, UCSF, San Francisco, CA. 94143.

Cell-attached recordings were made from the surface of *mdx* myotubes and acutely dissociated intact fibers. Mechanosensitive channels in skeletal normal muscle are closed at rest and open when the membrane is stretched. However, a subset of the mechanosensitive channels observed in *mdx* myotubes are highly active at rest. The channels which show the highest resting activity in *mdx* myotubes are open at rest but close, rather than open, with stretch.

As an extension of our earlier results we also examined the activity of mechanosensitive channels in fibers acutely dissociated from the flexor digitorum brevis (FDB) muscle. In contrast to the two forms of mechanosensitive channel activity seen in myotubes, a single class of mechanosensitive channels are observed in FDB fibers. However, surveying the surface of FDB fibers for channel activity, similarly shows that mechanosensitive channel activity is higher in *mdx* FDB fibers when compared with normal fibers.

A process was observed in ~15% of the patches containing channels in *mdx* myotubes and FDB fibers, in which stretch first activated channels which then subsequently became inhibited with stretch. This may be interpreted as a switch in mechanosensitivity from being activated to inactivated with stretch. Thus, although FDB fibers do not show stretch-inactivated channel from the onset of recording, as is the case for myotubes, they do, however, show channels that are inactivated with stretch after a process of conversion. There is, therefore, a correlation between the percentage of channels which are inhibited with stretch and the elevation in resting activity in *mdx* muscle.

DECREASED CELLULAR ENERGY CHARGE AND INTRACELLULAR ENZYMES IN THE CARDIAC AND SKELETAL MUSCLES OF CHF-146 DYSTROPHIC HAMSTERS (DH) WITH CARDIOMYOPATHY. R.K. Handa, S.K. Bhattacharya, P.L. Johnson, M.P. Gupta, and T.A. Adamec*. Surgical Research Lab, Univ. of Tenn., Memphis, TN 38163.

Membrane-mediated excessive intracellular calcium accumulation (EICA) plays a fundamental pathogenetic role in hereditary muscular dystrophy in animals, as well as in Duchenne muscular dystrophy (DMD). Since efflux of intracellular enzymes (ALD, CPK and LDH) with high plasma activities, decreased adenine nucleotides (ADN) with reduced cellular energy charge (CEC) are the inevitable biochemical fate of the dystrophic tissue with EICA, these variants were measured in the ventricular myocardium (HT) and rectus femoris muscle (RF) of 1 and 12-month-old male DH, and CHF-148 normal hamsters (NH). Glucose-6-phosphate (G6P) level was also monitored to assess the efficacy of glycolytic pathways in DH. Plasma ALD, CPK and LDH were increased in both young and old DH, however the plasma activity fell significantly with age. Correspondingly, these intracelluar energy producing enzymes were significantly diminished both in HT and RF of older DH, but not in younger animals. G6P was reduced progressively in DH ($p<0.05$). In respose to accelerated Ca^{2+}-pumping in dystrophic tissue, ADN and CEC were significantly lower in the HT and RF of older DH, but not in younger hamsters showing considerably less EICA. Thus, ADN and CEC inversely correlated with EICA in DH. **We conclude that** membrane-mediated efflux of intracellular enzymes and depletion of cellular ADN and CEC occur in DH. The glycolytic pathway in DH appears to be suppressed significantly. (Supported by NIH AR-38540)

639.7

INCREASED LIPID PEROXIDATION AND ANTIOXIDANT ENZYME ACTIVITIES IN THE CHF-146 DYSTROPHIC HAMSTERS (DH). M.P. Gupta, S.K. Bhattacharya, P.L. Johnson, T.A. Adamec*, and R.K. Handa. Surgical Research Lab, Univ. of Tenn., Memphis, TN 38163.

Membrane-mediated chronic cellular degeneration plays a fundamental pathogenetic role in hereditary muscular dystrophy. We have shown EICA, efflux of intracellular enzymes and aberrant sarcolemmal dystrophin distribution in DH. We studied whether this genetic membrane insufficiency is associated with enhanced lipid peroxidation and altered antioxidant enzyme activities in muscle of 1 and 12-month-old male DH and CHF-148 strain age and sex matched normal hamsters (NH). Lipid peroxidation (LP), glutathione (GSH), glutathione peroxidase (GSH-Px) and glutathione reductase (GR) were measured in post 10,000 X g supernatant of rectus femoris muscle. Compared to NH, LP increased by 38% ($p<0.01$) and 43% ($p<0.02$), concomitant to decreased GR activity of 43% ($p<0.003$) and 34% ($p<0.001$) in young and old DH, respectively. However, GR activity was higher in older DH ($p<0.01$), compared to younger. GSH level increased by 38% in older DH ($p<0.01$), perhaps in response to cellular adaptive mechanism and regeneration, but not in younger DH. GSH-Px activity was comparable in younger hamsters, but a 21% drop was noted in older DH ($p<0.02$). **We conclude that** chronic pathobiology in DH is inherently linked to cellular antioxidant enzyme-mediated lipid peroxidation of membranes. Increased LP in dystrophic muscle is accompanied by decreased GR and GSH-Px activities. Elevated GSH content in older DH appears to provide insufficient protection against inevitable peroxidative damage and progressive cellular degeneration. (Supported by NIH Grant #AR-38540)

SKELETAL MUSCLE LACTATE DEHYDROGENASE IS DECREASED IN MURINE MOTOR NEURON DISEASE. R. N. Mandler and J. M. Baca*. Dept. Neurology, The University of New Mexico School of Medicine, Albuquerque, NM 87131.

Lactate dehydrogenase (LDH) is the glycolytic enzyme that converts pyruvate into lactate and regenerates NAD^+ in active skeletal muscle. Skeletal muscle LDH activity decreases after surgical denervation. Based on this fact we explored whether LDH might be decreased in affected skeletal muscles of the Wobbler mouse, a natural murine model of denervation due to degeneration of spinal cord motoneurons. LDH activity was determined by an enzymatic spectrophotometric assay performed on homogenized biceps muscle samples from matched pairs of Wobbler and normal littermates at 3, 7, and 15 weeks after birth. In each age group, LDH activity was lower in the Wobbler. The lowest activity occurred in the oldest age group. Differences were statistically significant by paired t-test in the 7-week and 15-week age groups ($p< 0.05$), with no difference in the 3-week age group. These results demonstrate a progressive alteration of muscle energy metabolism in a natural model of motor neuron disease.

Supported by grant R29NS27698 from NINDS, NIH to RNM.

Differential staining of rat pudendal motoneurons with an antibody specific to somatic motoneurons. David G. Wells[1], Arlene Y. Chiu[2] and Cynthia J. Forehand[1]. [1]Dept. of Anat. and Neurobiol., Univ. of Vermont, Burlington, VT 05405 and [2]Div. of Neurosci., Beckman Research Inst. of the City of Hope, Duarte, CA 91010.

In amyotrophic lateral sclerosis (ALS), somatic motoneurons, but not preganglionic neurons, undergo degeneration. In humans with ALS, the nucleus in the sacral cord that innervates the external sphincters of the anus and urethra (Onuf's nucleus), is spared (Mannen et al., J. Neurol. Neurosurg. Psychiatry 40:464, '77). This observation has led to the suggestion that these neurons are similar in some way to preganglionic neurons.

Recently, an antibody (MO-1) has been developed that specifically recognizes cholinergic somatic motoneurons in the rat brain stem and spinal cord. This antibody does not stain preganglionic neurons (Urakami & Chiu, J. Neurosci. 10:620, '90). We have applied this antibody to the rat lumbosacral spinal cord to investigate the antigenicity of pudendal motoneurons that correspond to Onuf's nucleus. In the rat, Onuf's nucleus is segregated into two distinct motoneuron nuclei: the dorsomedial (DM), which innervates the external anal sphincter and m. bulbocavernosus, and the dorsolateral (DL), which innervates the external urethral sphincter and the m. ischiocavernosus (Schrøder, J. Comp. Neurol. 192:567, '80).

All motoneurons that contribute to the sciatic nerve abundantly express this antigen; this is not the case in either DM or DL. Two populations of cells were observed in both nuclei. One group was similar to preganglionic neurons in that they expressed the antigen minimally, if at all. The second group of cells, interspersed with the first group, clearly expressed the antigen, but to a lesser extent than motoneurons that project via the sciatic nerve. Whether these two groups reflect differential staining between sphincter and non-sphincter motoneurons is currently being investigated by retrograde labeling in conjunction with MO-1 immunohistochemistry.

639.10

SPECIFICITY OF THE LAMBERT-EATON MYASTHENIC SYNDROME (LEMS) AUTOANTIBODY FOR NERVE TERMINAL Ca CHANNELS. S.J. Hewett and W.D. Atchison, Dept. of Pharmacol./Toxicol., Mich. State Univ., E. Lansing, MI 48824

LEMS is a presynaptic, neuromuscular disorder characterized by impaired nerve-evoked release of acetylcholine. An autoantibody to prejunctional Ca^{2+} channels has been suggested to mediate the pathogenesis of this disease. We demonstrated previously that acute exposure of rat forebrain synaptosomes to plasma from a patient with LEMS reduced depolarization-dependent uptake of $^{45}Ca^{2+}$ (Soc. Neurosci. Abst. 15: 1035, 1989). The objective of this study was to assess the specificity of the autoantibody by comparing the ability of acute application of IgG isolated from the plasma of a patient with LEMS to reduce depolarization-dependent uptake of Ca^{2+} and Na^+ into synaptosomes. Prior to the initiation of uptake, synaptosomes were incubated under pure O_2 for 90 min with varying concentrations of control or LEMS IgG. Synaptosomes were then incubated for 1 sec with resting (5 mM KCl) or depolarizing (41.25 mM KCl) solution to determine depolarization-dependent uptake of $^{45}Ca^{2+}$. Alternatively, following a 10 min incubation with veratridine (150 μM), 5 sec influx of $^{22}Na^+$ was determined in the absence and presence of tetrodotoxin. Net K^+-stimulated $^{45}Ca^{2+}$ uptake was inhibited 36.5±14.5% and 44.5±9.8% by 2 and 4 mg/ml LEMS IgG, respectively. The same concentrations of LEMS IgG did not affect voltage-dependent uptake of $^{22}Na^+$ into veratridine-depolarized synaptosomes. It is possible that normal activation of Ca channels was prevented by IgG-induced alterations in synaptosomal membrane potentials (E_m). Accordingly, we measured E_m using the fluorescent, potentiometric dye (DiS-C2(5)) following acute application of 2 mg/ml LEMS or control IgG. No alterations in dye fluorescence were evident. These results suggest that IgG from patients with LEMS bind selectively to Ca^{2+} channels of presynaptic nerve terminals. (Supported by the Muscular Dystrophy Association.)

639.11

FUNCTIONAL ASPECTS OF PREGANGLIONIC SYMPATHECTOMY BY CHOLINESTERASE ANTIBODIES. V. Moser[1], S. Padilla*[2], P. Hammond*[3] and S. Brimijoin[3]. [1]ManTech Environ. Tech. and [2]US Environ. Prot. Ag., Res Tri. Pk. NC 27709 and [3]Mayo Clinic, Rochester MN 55905.

Systemically administered antibodies to acetylcholinesterase (AChE) cause a unique complement-mediated destruction of preganglionic sympathetic nerve terminals (Brimijoin and Lennon, PNAS 87: 9630, 1990). To further assess neurological integrity in this disorder, 19 rats given murine monoclonal AChE-antibodies or normal mouse IgG (1.5 mg, i.v.) were repeatedly examined over 4 mo with a neurobehavioral test battery (FOB and motor activity). Antibody-treated rats developed permanent eyelid-drooping (ptosis) within 4 hr, reflecting loss of preganglionic sympathetic terminals. Persistent pupillary constriction (miosis) was noted, in accord with previous evidence of preserved parasympathetic function. Weight gain was also depressed. Essentially normal functions included neuromuscular performance (e.g., grip strength, landing foot-splay, gait), excitability (e.g., arousal, reactivity), locomotor activity, and sensorimotor responsiveness to specific stimuli. These results confirm the autonomic focus of immunologic damage. Enzyme assays at 4 mo showed reduced AChE activity in sympathetic ganglia (35%) and adrenal glands (30-40%), while choline acetyltransferase activity, a marker of cholinergic cytoplasm, was largely absent. The enzymatic data were nearly identical with those from an earlier study, one week after antibody injection. Parallel failure of functional and biochemical recovery demonstrates the permanent nature of the neural lesions induced by AChE antibodies. (NS18170).

GLOBAL BLOCKADE OF CATECHOLAMINE-RELEASE AFTER PREGANGLIONIC SYMPATHECTOMY BY ACETYLCHOLINESTERASE ANTIBODIES. S. Brimijoin[1] and G. M. Tyce[2], Depts. of [1]Pharmacology and [2]Physiology, Mayo Clinic, Rochester MN 55905.

Previous results in rats treated with antibodies to acetylcholinesterase (AChE) demonstrated complement-mediated destruction of preganglionic terminals in sympathetic ganglia with survival of postganglionic neurons. To assess the resulting deficit of sympathoadrenal function, experiments were designed to measure stress-induced release of catecholamines. Rats (6 per group) received injections of murine monoclonal antibody to AChE, or normal mouse IgG (1.5 mg). Four days later a cannula was placed in the femoral artery. On day 5 a 1.5 ml basal blood sample was taken from the awake, unrestrained animals. Later that day the rats were subjected to 10 min of mild stress by forced immobilization in padded restrainers, a second blood sample was drawn, and the rats were killed by pentobarbital overdose. Catecholamine determinations by HPLC in all basal samples showed very low levels of norepinephrine and epinephrine (< 0.2 ng/ml) and moderate levels of the deaminated product, 3,4-dihydroxyphenylethylene glycol (DOPEG, 0.7-1.1 ng/ml). In controls, immobilization-stress increased plasma norepinephrine and epinephrine up to 25-fold (net increase 2.0 & 4.6 ng/ml respectively). The norepinephrine-response in antibody-treated rats was much smaller (15% of control) and the epinephrine-response was nearly abolished (5% of control). Antibody-treatment also markedly reduced the stress-induced rise in DOPEG, although it did not lower basal levels. We conclude that preganglionic immunosympathectomy leads to sustained blockade of neurotransmission throughout the sympathetic nervous system. (Supported by NS18170).

639.13

MECHANISM OF SELECTIVE PREGANGLIONIC SYMPATHECTOMY BY ACETYLCHOLINESTERASE ANTIBODIES. P. Hammond*[1], V.A. Lennon[2], and S. Brimijoin[1]. Depts. of [1]Pharmacology, [2]Neurology, and [2]Immunology, Mayo Clinic, Rochester MN 55905.

Preganglionic sympathetic nerve terminals are selectively destroyed in rats treated with monoclonal antibodies to acetylcholinesterase (AChE). Previous work demonstrated rapid loss of AChE and ultrastructurally defined synapses from ganglionic neuropil, but morphological and biochemical abnormalities at motor endplates were minor. The present experiments were undertaken to clarify the basis for selective immunological attack on ganglionic terminals. Immunofluorescence cytochemistry of superior cervical ganglia, 12 hr after iv injection of AChE antibodies, showed abundant punctate deposits of murine IgG presumably bound to AChE-rich synapses. Unexpectedly dense IgG deposits were also found at motor endplates, demonstrating antibody-access to these structures as well. Monoclonal antibody to component C3 revealed intense complement-fixation in perikaryal ganglionic neuropil. This evidence for complement-mediated lysis of ganglionic terminals is consistent with our earlier finding that ganglionic damage is prevented by depletion of complement with cobra venom factor. However, specific C3-immunofluorescence was also found at the neuromuscular junction, where it colocalized with rhodamine-labeled α-bungarotoxin. The basis for a selective cytodestructive lesion of sympathetic terminals remains uncertain. Topologic features of the neuronal target enzyme may render the preganglionic plasma membrane particularly vulnerable to complement-mediated lesions. (Supported by Grants NS18170 and NS23537).

EFFECTS OF ACETYLCHOLINESTERASE ANTIBODIES ON CHOLINERGIC SYSTEMS IN NEWBORN RAT BRAIN. Z. Rakonczay* and S. Brimijoin, Dept of Pharmacology, Mayo Clinic, Rochester, MN 55905.

Acetylcholinesterase (AChE), an extracellular, membrane-associated enzyme, is a possible target of autoimmunity. When injected systemically in adult rats, antibodies to AChE irreversibly damage some peripheral cholinergic structures (preganglionic sympathetic neurons), but brain and spinal cord are protected by the blood-brain barrier. Because barriers to IgG may be more permeable in immature mammals, we undertook to determine whether AChE-antibodies would enter brain and disrupt central cholinergic systems in newborn rats. Antibodies (ZR 2,3,4,5,6) were given *ip* (equal mixture, 50 µg IgG each), 1 day postnatally (d1). Control animals received saline solution or normal mouse IgG. Body and brain weights and cholinergic markers (AChE, choline acetyltransferase, ChAT) were measured at days 3, 7, 12, and 21 in serum, brain and other tissues. The outward effect of antibody was an almost complete cessation of growth. Antibody-treatment also caused an immediate 90% decrease of serum AChE which was sustained through d21. Brain AChE decreased by 30% at d3, reflecting virtual disappearance of the tetrameric G4 form. At d7, this form began to recover but was still only half as abundant as in controls. Body and brain weights also remained subnormal. At d12, the pattern of AChE molecular forms in whole brain extracts was nearly the same as in controls, but total AChE and ChAT activity were still reduced by 50%. Persistent deficits of G4 AChE were noted in cerebral cortex at d12 and d21. This finding may be evidence for delayed maturation of AChE-expressing cortical neurons. (Supported by NS18170).

AN ELECTRON MICROSCOPIC STUDY OF NEUROMUSCULAR ALTERATIONS IN PARANEOPLASTIC PHENOMENON. H.J. Finol, I. Rodríguez*, A. Márquez*, I. Montes de Oca* and B. Muller*. Sciences, Medicine and Dentistry Faculties, Universidad Central de Venezuela, Apartado 47114, Caracas 1041 A, Venezuela.

Several clinic and pathologic alterations have been described in skeletal muscle in patients suffering from cancer with no muscle metastases. Some of these changes have been considered of neural origin. In support of this point of view, we describe in this work the nerve and muscle ultrastructural pathology in a case of paraneoplastic phenomenon associated with a carcinoma of cervix. A needle biopsy was taken from quadriceps femoris muscle in a 65 year-old female who presented proximal muscular weakness and wasting, associated with a carcinoma of cervix. The patient was treated only with radiotherapy. The changes observed were: some muscle fibers showed different degrees of atrophy and others looked normal. Atrophied fibers presented in motor end-plates destruction of axon terminal with preservation of subsynaptic regions. Neural damage was also observed in myelinated fibers outside the end-plate. Vascular alterations and mononuclear cell infiltration formed by lymphocytes, macrophages and mast cells were also seen. Our findings suggest that muscular damage in this case probably has a dual etiopathogenic mechanism, vascular and neural. Supported by CDCH of UCV, Fundación Polar and The British Council Venezuela.

ABNORMAL ISOMETRIC MUSCLE FORCE CONTROL IN REFLEX SYMPATHETIC DYSTROPHY. C.J. Hunker* and M. Backonja. Dept. of Neurology, U. of Wisconsin, Madison, WI 53792.

The etiology and specific pathophysiology of movement disorders associated with reflex sympathetic dystrophy (RSD) are unknown; central nervous system mechanisms and psychogenic origins have been proposed. Freund and colleagues (1978, 1984) have shown that submaximal isometric contractions provide a means of relating muscle force control to involuntary motoneuronal activity. Hunker et al. (1991), have demonstrated that submaximal isometric contractions can distinguish pathological from somatoform tremors. Maximal and controlled voluntary contractions were examined in 10 RSD patients via isometric wrist and thumb/index finger tasks along with accelerometer recordings from affected and unaffected limbs. RSD patients presented muscle weakness and motor abnormalities of dyskinesia, dystonia, synkinesia and 6.0 Hz tremor localized to the affected limb. Since movement disorders of central origin result from abnormal motor unit activity, involuntary muscle force aberrations are salient during submaximal isometric contractions; in contrast, psychogenic movement disorders, which are not due to involuntary motor unit activity, are absent under isometric conditions. These data support putative CNS pathophysiological substrates for the movement disorders associated with RSD.
