SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 17, PART 2

21ST ANNUAL MEETING
NEW ORLEANS, LOUISIANA
NOVEMBER 10–15, 1991

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0–916110–36–2
Part 2 ISBN 0–916110–37–0
Both parts ISSN 0190–5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 17, Part 2, p. xxx, 1991.

Published by:
Society for Neuroscience
11 Dupont Circle, N.W.
Suite 500
Washington, D.C. 20036

CONTENTS—PART 2

*9,416 volunteer abstracts, 18 symposia abstracts, and 64 teaching of neuroscience abstracts.

1991 Program Committee

J. Anthony Movshon, Ph.D., *Chairperson*
New York University

Stanley J. Watson, Jr., M.D., Ph.D.
Incoming Chairperson
University of Michigan School of Medicine

David G. Amaral, Ph.D.
The Salk Institute

James E. Blankenship, Ph.D.
Marine Biomedical Institute

Martha C. Bohn, Ph.D.
National Science Foundation

Dennis W. Choi, M.D., Ph.D.
Washington University School of Medicine

Roland D. Ciaranello, M.D.
Stanford University Medical Center

Antonio R. Damasio, M.D., Ph.D.
University of Iowa College of Medicine

Eberhard E. Fetz, Ph.D.
University of Washington School of Medicine

Karl Herrup, Ph.D.
Eunice Kennedy Shriver Center

Stephen M. Highstein, M.D., Ph.D.
Washington University School of Medicine

Harvey J. Karten, M.D.
University of California School of Medicine

James E. Krause, Ph.D.
Washington University School of Medicine

Irwin B. Levitan, Ph.D.
Brandeis University

James O. McNamara, M.D.
Duke University Medical Center
V.A. Medical Center

Urs S. Rutishauser, Ph.D.
Case Western Reserve University School of Medicine

Elaine Sanders-Bush, Ph.D.
Vanderbilt University School of Medicine

Gerard P. Smith, M.D.
Cornell University Medical College

C. Dominique Toran-Allerand, M.D.
Columbia University College of Physicians and Surgeons

Leslie G. Ungerleider, Ph.D.
National Institutes of Health

Charles J. Vierck, Ph.D.
University of Florida Health Science Center

Monte Westerfield, Ph.D.
University of Oregon

Robert D. Wurster, Ph.D.
Loyola University of Chicago

Richard E. Zigmond, Ph.D.
Case Western Reserve University School of Medicine

Robert H. Wurtz, Ph.D., *ex-officio*
National Institutes of Health

Joseph T. Coyle, M.D., *ex-officio*
Harvard Medical School

Story C. Landis, Ph.D., *ex-officio*
Case Western Reserve University School of Medicine

CHRONOLOGICAL LIST OF SESSIONS

(See page xiv for Thematic List of Sessions.)

WEDNESDAY

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only.)

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
Theme A: Development and Regeneration							
430.	**Activity-Dependent Plasticity: Analysis at the Cell and Molecular Level**	**SYMP.**				**Thu AM**	
508.	**Specification of Cerebral Cortex During Development**	**SYMP.**				**Thu PM**	
137.	**Trophic Agents and the Development and Maintenance of Neurons**	**SYMP.**		**Tue AM**			
26.	Aging processes I	Poster	Mon AM				
155.	Aging processes II	Poster		Tue AM			
308.	Aging processes III	Poster			Wed AM		
454.	Aging processes IV	Poster				Thu AM	
602.	Aging processes V	Poster					Fri AM
22.	Axon guidance mechanisms and pathways I	Poster	Mon AM				
76.	Axon guidance mechanisms and pathways II	Slide	Mon PM				
297.	Axon guidance mechanisms and pathways III	Poster			Wed AM		
363.	Axon guidance mechanisms and pathways IV	Slide			Wed PM		
87.	Cell differentiation and migration I	Poster	Mon PM				
88.	Cell differentiation and migration II	Poster	Mon PM				
19.	Cell lineage I	Poster	Mon AM				
281.	Cell lineage II	Slide			Wed AM		
370.	Cell lineage III	Poster			Wed PM		
589.	Cell lineage IV	Slide					Fri AM
371.	Cell lineage: genetic and biochemical markers	Poster			Wed PM		
20.	Cell shape and differentiation I	Poster	Mon AM				
21.	Cell shape and differentiation II	Poster	Mon AM				
376.	Development and regeneration of motor systems I	Poster			Wed PM		
377.	Development and regeneration of motor systems II	Poster			Wed PM		
305.	Development of cerebral cortex and limbic system I	Poster			Wed AM		
450.	Development of cerebral cortex and limbic system II	Poster				Thu AM	
522.	Development of cerebral cortex and limbic system III	Slide				Thu PM	
298.	Development of neurotransmitter systems	Poster			Wed AM		
97.	Development of sensory systems I	Poster	Mon PM				
449.	Development of sensory systems II	Poster				Thu AM	
300.	Development: ligand-gated channels	Poster			Wed AM		
299.	Development: voltage-gated channels	Poster			Wed AM		
74.	Formation and specificity of synapses I	Slide	Mon PM				
91.	Formation and specificity of synapses II	Poster	Mon PM				
92.	Formation and specificity of synapses III	Poster	Mon PM				
93.	Formation and specificity of synapses IV	Poster	Mon PM				
514.	Formation and specificity of synapses V	Slide				Thu PM	
294.	Gliogenesis and differentiation	Poster			Wed AM		
23.	Growth factors and trophic agents I	Poster	Mon AM				
95.	Growth factors and trophic agents II	Poster	Mon PM				
301.	Growth factors and trophic agents III	Poster			Wed AM		
362.	Growth factors and trophic agents IV	Slide			Wed PM		
446.	Growth factors and trophic agents V	Poster				Thu AM	
518.	Growth factors and trophic agents VI	Slide				Thu PM	
600.	Growth factors and trophic agents VII	Poster					Fri AM
528.	Hormones and development: CNS	Poster				Thu PM	
529.	Hormones and development: motor neurons	Poster				Thu PM	
527.	Hormones and development: steroid receptors	Poster				Thu PM	
530.	Hormones and development: thyroid hormone	Poster				Thu PM	
215.	Molecular and pharmacological correlates of development I	Slide		Tue PM			

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
304.	Molecular and pharmacological correlates of development II	Poster			Wed AM		
224.	Molecular and pharmacological correlates of development in cerebellum and spinal cord	Poster		Tue PM			
153.	Molecular and pharmacological correlates of development: monoamines	Poster		Tue AM			
448.	Molecular and pharmacological correlates of development: peptides	Poster				Thu AM	
12.	Nerve growth factor I	Slide	Mon AM				
94.	Nerve growth factor II	Poster	Mon PM				
283.	Nerve growth factor III	Slide			Wed AM		
373.	Nerve growth factor IV	Poster			Wed PM		
445.	Nerve growth factor V	Poster				Thu AM	
526.	Nerve growth factor VI	Poster				Thu PM	
599.	Nerve growth factor VII	Poster					Fri AM
18.	Neurogenesis	Poster	Mon AM				
524.	Neurogenesis: regulation	Poster				Thu PM	
222.	Neurogenesis: tissue culture models	Poster		Tue PM			
96.	Neuronal death I	Poster	Mon PM				
447.	Neuronal death II	Poster				Thu AM	
223.	Neuronal death: axotomy	Poster		Tue PM			
302.	Neuronal death: disease, drugs, trauma	Poster			Wed AM		
374.	Non-neuronal cells I	Poster			Wed PM		
375.	Non-neuronal cells II	Poster			Wed PM		
601.	Nutritional and prenatal factors	Poster					Fri AM
8.	Pattern formation, compartments and boundaries I	Slide	Mon AM				
303.	Pattern formation, compartments and boundaries II	Poster			Wed AM		
10.	Process outgrowth, growth cones and sprouting I	Slide	Mon AM				
89.	Process outgrowth, growth cones and sprouting II	Poster	Mon PM				
90.	Process outgrowth, growth cones and sprouting III	Poster	Mon PM				
212.	Process outgrowth, growth cones and sprouting IV	Slide		Tue PM			
295.	Process outgrowth, growth cones and sprouting V	Poster			Wed AM		
296.	Process outgrowth, growth cones and sprouting VI	Poster			Wed AM		
372.	Process outgrowth, growth cones and sprouting VII	Poster			Wed PM		
525.	Process outgrowth, growth cones and sprouting VIII	Poster				Thu PM	
598.	Process outgrowth, growth cones and sprouting IX	Poster					Fri AM
591.	Regeneration	Slide					Fri AM
226.	Regeneration: molecular correlates	Poster		Tue PM			
227.	Regeneration: prostheses, therapeutics, function	Poster		Tue PM			
24.	Regeneration: protein correlates	Poster	Mon AM				
378.	Regeneration: tissue correlates	Poster			Wed PM		
145.	Transplantation: animal models of Parkinson's disease I	Slide		Tue AM			
307.	Transplantation: animal models of Parkinson's disease II	Poster			Wed AM		
25.	Transplantation: cortex	Poster	Mon AM				
98.	Transplantation: general	Poster	Mon PM				
229.	Transplantation: genetically engineered cells	Poster		Tue PM			
453.	Transplantation: hippocampus	Poster				Thu AM	
228.	Transplantation: new technology	Poster		Tue PM			
452.	Transplantation: sensory systems	Poster				Thu AM	
99.	Transplantation: spinal cord	Poster	Mon PM				
359.	Transplantation: striatum	Slide			Wed PM		
357.	Visual system: connections	Slide			Wed PM		
306.	Visual system: cortical connections and plasticity	Poster			Wed AM		
585.	Visual system: cortical mechanisms	Slide					Fri AM
154.	Visual system: molecular mechanisms in visual cortex	Poster		Tue AM			
78.	Visual system: retina	Slide	Mon PM				

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
225.	Visual system: retina and transplantation	Poster		Tue PM			
451.	Visual system: subcortical pathways	Poster				Thu AM	
Theme B: Cell Biology							
354.	**How Cells Keep Time: The Molecular and Cellular Basis of Circadian Rhythms**	**SYMP.**			**Wed PM**		
100.	Blood-brain barrier	Poster	Mon PM				
28.	Cytoskeleton, transport, membrane targetting I	Poster	Mon AM				
158.	Cytoskeleton, transport, membrane targetting II	Poster		Tue AM			
457.	Gene structure	Poster				Thu AM	
211.	Gene structure and function I	Slide		Tue PM			
360.	Gene structure and function II	Slide			Wed PM		
513.	Gene structure and function III	Slide				Thu PM	
230.	Membrane composition: cell surface macromolecules I	Poster		Tue PM			
379.	Membrane composition: cell surface macromolecules II	Poster			Wed PM		
27.	Neuroglia and myelin I	Poster	Mon AM				
157.	Neuroglia and myelin II	Poster		Tue AM			
221.	Neuroglia and myelin III	Slide		Tue PM			
455.	Neuroglia and myelin IV	Poster				Thu AM	
456.	Neuroglia and myelin V	Poster				Thu AM	
101.	Regulation of gene expression I	Poster	Mon PM				
159.	Regulation of gene expression II	Poster		Tue AM			
604.	Regulation of gene expression III	Poster					Fri AM
156.	Staining, tract tracing and imaging I	Poster		Tue AM			
590.	Staining, tract tracing and imaging II	Slide					Fri AM
603.	Staining, tract tracing and imaging III	Poster					Fri AM
Theme C: Excitable Membranes and Synaptic Transmission							
205.	**Molecular Mechanisms of Neurotransmitter Secretion**	**SYMP.**		**Tue PM**			
71.	**Regulation of Ion Channels**	**SYMP.**	**Mon PM**				
462.	Calcium channels: conotoxins and other ligands	Poster				Thu AM	
309.	Calcium channels: molecular biology	Poster			Wed AM		
461.	Calcium channels: multiple types	Poster				Thu AM	
310.	Calcium channels: phosphorylation	Poster			Wed AM		
29.	Calcium channels: physiology and pharmacology I	Poster	Mon AM				
142.	Calcium channels: physiology and pharmacology II	Slide		Tue AM			
358.	Calcium channels: physiology and pharmacology III	Slide			Wed PM		
606.	Calcium channels: physiology and pharmacology IV	Poster					Fri AM
535.	Ion channels: cell function	Poster				Thu PM	
607.	Ion channels: chloride and other	Poster					Fri AM
534.	Ion channels: ligand-gated	Poster				Thu PM	
31.	Ion channels: modulation and regulation I	Poster	Mon AM				
383.	Ion channels: modulation and regulation II	Poster			Wed PM		
435.	Ion channels: modulation and regulation III	Slide				Thu AM	
608.	Ion channels: modulation and regulation IV	Poster					Fri AM
161.	Long-term potentiation: models and mechanisms	Poster		Tue AM			
4.	Long-term potentiation: physiology and pharmacology I	Slide	Mon AM				
380.	Long-term potentiation: physiology and pharmacology II	Poster			Wed PM		
533.	Long-term potentiation: physiology and pharmacology III	Poster				Thu PM	
160.	Long-term potentiation: protein kinases and second messengers	Poster		Tue AM			
102.	Pharmacology of synaptic transmission: hippocampus	Poster	Mon PM				
103.	Pharmacology of synaptic transmission: neurotransmitters	Poster	Mon PM				
605.	Postsynaptic mechanisms	Poster					Fri AM
444.	Postsynaptic mechanisms in neurotransmission	Slide				Thu AM	

Session Number	Session Title	Type	Day and Time: Mon.	Tue.	Wed.	Thu.	Fri.
232.	Postsynaptic mechanisms: signalling pathways	Poster		Tue PM			
311.	Potassium channels: molecular biology I	Poster			Wed AM		
510.	Potassium channels: molecular biology II	Slide				Thu PM	
30.	Potassium channels: physiology and regulation I	Poster	Mon AM				
312.	Potassium channels: physiology and regulation II	Poster			Wed AM		
587.	Potassium channels: physiology and regulation III	Slide					Fri AM
532.	Presynaptic mechanisms	Poster				Thu PM	
593.	Presynaptic mechanisms: ion channels	Slide					Fri AM
231.	Presynaptic mechanisms: neurotransmitter release	Poster		Tue PM			
460.	Presynaptic mechanisms: phosphorylation	Poster				Thu AM	
381.	Sodium channels: molecular biology	Poster			Wed PM		
382.	Sodium channels: physiology and pharmacology	Poster			Wed PM		
458.	Synaptic structure and function I	Poster				Thu AM	
531.	Synaptic structure and function II	Poster				Thu PM	
459.	Synaptic structure and function: hippocampus	Poster				Thu AM	
104.	Synaptic transmission	Poster	Mon PM				
	Theme D: Neurotransmitters, Modulators, and Receptors						
507.	**The Cannabinoid Receptor: Biochemistry, Anatomy and Physiology**	**SYMP.**				**Thu PM**	
2.	**Insights into Brain and Spinal Components of the Opiate Withdrawal Syndrome**	**SYMP.**	**Mon AM**				
583.	**"Lipid Mediators" in Synaptic Transmission and Signal Transduction of Neuronal Cells: Physiological and Pathological Implications**	**SYMP.**					**Fri AM**
353.	**Molecular Biology of the Dopamine System: Heterogeneity of the Dopamine Receptors**	**SYMP.**			**Wed PM**		
519.	Acetylcholine and acetylcholine receptors	Slide				Thu PM	
162.	Acetylcholine receptors: muscarinic I	Poster		Tue AM			
233.	Acetylcholine receptors: muscarinic II	Poster		Tue PM			
234.	Acetylcholine receptors: muscarinic III	Poster		Tue PM			
611.	Acetylcholine receptors: muscarinic IV	Poster					Fri AM
610.	Acetylcholine receptors: muscle nicotinic	Poster					Fri AM
105.	Acetylcholine receptors: neuronal nicotinic I	Poster	Mon PM				
384.	Acetylcholine receptors: neuronal nicotinic II	Poster			Wed PM		
14.	Acetylcholine receptors: nicotinic	Slide	Mon AM				
463.	Acetylcholine: CNS systems	Poster				Thu AM	
313.	Acetylcholine: release	Poster			Wed AM		
609.	Acetylcholine: synthesis and degradation	Poster					Fri AM
617.	Adenosine	Poster					Fri AM
41.	Behavioral pharmacology I	Poster	Mon AM				
116.	Behavioral pharmacology II	Poster	Mon PM				
174.	Behavioral pharmacology III	Poster		Tue AM			
597.	Behavioral pharmacology IV	Slide					Fri AM
169.	Biogenic amines and purines	Poster		Tue AM			
619.	Biogenic amines: uptake and release	Poster					Fri AM
35.	Catecholamine receptors: ∂ and ß	Poster	Mon AM				
36.	Catecholamine receptors: dopamine I	Poster	Mon AM				
238.	Catecholamine receptors: dopamine II	Poster		Tue PM			
323.	Catecholamine receptors: dopamine III	Poster			Wed AM		
324.	Catecholamine receptors: dopamine IV	Poster			Wed AM		
432.	Catecholamine receptors: dopamine V	Slide				Thu AM	
539.	Catecholamine receptors: dopamine VI	Poster				Thu PM	
149.	Catecholamine receptors: noradrenergic and dopaminergic	Slide		Tue AM			

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
210.	Catecholamines	Slide		Tue PM			
112.	Catecholamines: ascorbic acid	Poster	Mon PM				
326.	Catecholamines: biosynthesis I	Poster			Wed AM		
391.	Catecholamines: biosynthesis II	Poster			Wed PM		
325.	Catecholamines: dopamine I	Poster			Wed AM		
540.	Catecholamines: dopamine II	Poster				Thu PM	
37.	Catecholamines: dopamine release	Poster	Mon AM				
38.	Catecholamines: general	Poster	Mon AM				
111.	Catecholamines: hormonal regulation	Poster	Mon PM				
615.	Catecholamines: locus coeruleus	Poster					Fri AM
106.	Excitatory amino acids: anatomy and physiology I	Poster	Mon PM				
107.	Excitatory amino acids: anatomy and physiology II	Poster	Mon PM				
356.	Excitatory amino acids: anatomy and physiology III	Slide			Wed PM		
6.	Excitatory amino acids: excitotoxicity I	Slide	Mon AM				
314.	Excitatory amino acids: excitotoxicity II	Poster			Wed AM		
315.	Excitatory amino acids: excitotoxicity III	Poster			Wed AM		
316.	Excitatory amino acids: excitotoxicity IV	Poster			Wed AM		
32.	Excitatory amino acids: pharmacology I	Poster	Mon AM				
108.	Excitatory amino acids: pharmacology II	Poster	Mon PM				
163.	Excitatory amino acids: pharmacology III	Poster		Tue AM			
235.	Excitatory amino acids: pharmacology IV	Poster		Tue PM			
516.	Excitatory amino acids: pharmacology V	Slide				Thu PM	
536.	Excitatory amino acids: pharmacology VI	Poster				Thu PM	
612.	Excitatory amino acids: pharmacology VII	Poster					Fri AM
33.	Excitatory amino acids: receptors I	Poster	Mon AM				
139.	Excitatory amino acids: receptors II	Slide		Tue AM			
317.	Excitatory amino acids: receptors III	Poster			Wed AM		
464.	Excitatory amino acids: receptors IV	Poster				Thu AM	
613.	Excitatory amino acids: receptors V	Poster					Fri AM
109.	GABA receptors: function I	Poster	Mon PM				
209.	GABA receptors: function II	Slide		Tue PM			
318.	GABA receptors: function III	Poster			Wed AM		
465.	GABA receptors: function IV	Poster				Thu AM	
537.	GABA receptors: function V	Poster				Thu PM	
34.	GABA receptors: structure	Poster	Mon AM				
286.	Interactions between neurotransmitters I	Slide			Wed AM		
392.	Interactions between neurotransmitters II	Poster			Wed PM		
393.	Interactions between neurotransmitters III	Poster			Wed PM		
394.	Interactions between neurotransmitters IV	Poster			Wed PM		
367.	Modulation of neurotransmitter receptors	Slide			Wed PM		
620.	Neurotransmitter and hormone receptors	Poster					Fri AM
170.	Neurotransmitter modulation: excitatory and inhibitory transmitters	Poster		Tue AM			
618.	Neurotransmitter transport and release	Poster					Fri AM
470.	Neurotransmitters: molecular neurobiology	Poster				Thu AM	
110.	Opioids: anatomy and physiology I	Poster	Mon PM				
466.	Opioids: anatomy and physiology II	Poster				Thu AM	
538.	Opioids: behavior I	Poster				Thu PM	
614.	Opioids: behavior II	Poster					Fri AM
152.	Opioids: receptors I	Slide		Tue AM			
236.	Opioids: receptors II	Poster		Tue PM			
237.	Opioids: receptors III	Poster		Tue PM			
322.	Opioids: receptors IV	Poster			Wed AM		
385.	Peptides: anatomical localization I	Poster			Wed PM		
386.	Peptides: anatomical localization II	Poster			Wed PM		
387.	Peptides: anatomical localization III	Poster			Wed PM		

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
164.	Peptides: biosynthesis, metabolism and biochemical characterization I	Poster		Tue AM			
165.	Peptides: biosynthesis, metabolism and biochemical characterization II	Poster		Tue AM			
166.	Peptides: biosynthesis, metabolism and biochemical characterization III	Poster		Tue AM			
167.	Peptides: biosynthesis, metabolism and biochemical characterization IV	Poster		Tue AM			
219.	Peptides: biosynthesis, metabolism and biochemical characterization V	Slide		Tue PM			
388.	Peptides: physiological effects I	Poster			Wed PM		
389.	Peptides: physiological effects II	Poster			Wed PM		
390.	Peptides: physiological effects III	Poster			Wed PM		
512.	Peptides: physiological effects IV	Slide				Thu PM	
79.	Peptides: receptors I	Slide	Mon PM				
319.	Peptides: receptors II	Poster			Wed AM		
320.	Peptides: receptors III	Poster			Wed AM		
321.	Peptides: receptors IV	Poster			Wed AM		
171.	Regional localization of receptors and transmitters I	Poster		Tue AM			
172.	Regional localization of receptors and transmitters II	Poster		Tue AM			
289.	Regional localization of receptors and transmitters III	Slide			Wed AM		
471.	Regulation of adrenergic receptors	Poster				Thu AM	
242.	Regulation of dopamine receptors	Poster		Tue PM			
11.	Second messengers I	Slide	Mon AM				
40.	Second messengers II	Poster	Mon AM				
75.	Second messengers III	Slide	Mon PM				
146.	Second messengers IV	Slide		Tue AM			
173.	Second messengers V	Poster		Tue AM			
240.	Second messengers VI	Poster		Tue PM			
241.	Second messengers VII	Poster		Tue PM			
468.	Serotonin I	Poster				Thu AM	
469.	Serotonin II	Poster				Thu AM	
594.	Serotonin III	Slide					Fri AM
616.	Serotonin IV	Poster					Fri AM
287.	Serotonin receptors I	Slide			Wed AM		
467.	Serotonin receptors II	Poster				Thu AM	
39.	Serotonin receptors: $5HT_{1A}$ I	Poster	Mon AM				
113.	Serotonin receptors: $5HT_{1A}$ II	Poster	Mon PM				
168.	Serotonin receptors: $5HT_2$ and $5HT_{1C}$	Poster		Tue AM			
239.	Serotonin receptors: $5HT_3$	Poster		Tue PM			
114.	Transmitters in invertebrates: arthropods	Poster	Mon PM				
85.	Transmitters in invertebrates: coelenterates, annelids, arthropods	Slide	Mon PM				
115.	Transmitters in invertebrates: coelenterates, worms, echinoderms	Poster	Mon PM				
523.	Transmitters in invertebrates: molluscs I	Slide				Thu PM	
541.	Transmitters in invertebrates: molluscs II	Poster				Thu PM	
Theme E: Endocrine and Autonomic Regulation							
141.	Cardiovascular regulation I	Slide		Tue AM			
280.	Cardiovascular regulation II	Slide			Wed AM		
243.	Cardiovascular regulation: brainstem mechanisms I	Poster		Tue PM			
396.	Cardiovascular regulation: brainstem mechanisms II	Poster			Wed PM		
397.	Cardiovascular regulation: forebrain mechanisms and stress	Poster			Wed PM		

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
244.	Cardiovascular regulation: hypertension and endothelins	Poster		Tue PM			
117.	Cardiovascular regulation: peripheral mechanisms	Poster	Mon PM				
245.	Cardiovascular regulation: spinal mechanisms	Poster		Tue PM			
177.	Endocrine regulation I	Poster		Tue AM			
473.	Endocrine regulation II	Poster				Thu AM	
474.	Endocrine regulation III	Poster				Thu AM	
395.	Hypothalamic-pituitary-adrenal regulation I	Poster			Wed PM		
542.	Hypothalamic-pituitary-adrenal regulation II	Poster				Thu PM	
621.	Hypothalamic-pituitary-adrenal regulation III	Poster					Fri AM
42.	Hypothalamic-pituitary-adrenal regulation: glucocorticoid receptors	Poster	Mon AM				
434.	Hypothalamic-pituitary-adrenal regulation: molecular studies	Slide				Thu AM	
284.	Hypothalamic-pituitary-gonadal regulation I	Slide			Wed AM		
361.	Hypothalamic-pituitary-gonadal regulation II	Slide			Wed PM		
175.	Hypothalamic-pituitary-gonadal regulation: LH and LHRH I	Poster		Tue AM			
544.	Hypothalamic-pituitary-gonadal regulation: LH and LHRH II	Poster				Thu PM	
176.	Hypothalamic-pituitary-gonadal regulation: steroids	Poster		Tue AM			
543.	Hypothalamic-pituitary: control of gonadal function	Poster				Thu PM	
327.	Neural control of immune function	Poster			Wed AM		
365.	Neural-immune interactions	Slide			Wed PM		
328.	Neural-immune interactions: innervation and other	Poster			Wed AM		
475.	Neural-immune interactions: interleukins and neural functions	Poster				Thu AM	
476.	Neural-immune interactions: stress and behavior	Poster				Thu AM	
144.	Neuroendocrine regulation I	Slide		Tue AM			
472.	Neuroendocrine regulation II	Poster				Thu AM	
588.	Neuroendocrine regulation III	Slide					Fri AM
436.	Regulation of autonomic functions	Slide				Thu AM	
545.	Regulation of autonomic functions: gastrointestinal control	Poster				Thu PM	
398.	Regulation of autonomic functions: genito-urinary control	Poster			Wed PM		
86.	Regulation of respiration and autonomic functions	Slide	Mon PM				
43.	Respiratory regulation I	Poster	Mon AM				
246.	Respiratory regulation II	Poster		Tue PM			
329.	Temperature regulation and fever	Poster			Wed AM		

Theme F: Sensory Systems

3.	**Activity-Dependent Regulation of Somatosensory Processing at Thalamic and Cortical Levels in Adult Primates**	**SYMP.**	**Mon AM**				
17.	Auditory and vestibular hair cells and epithelia	Slide	Mon AM				
250.	Auditory and vestibular hair cells: ultrastructure, regeneration and tuning	Poster		Tue PM			
123.	Auditory system: central pathways I	Poster	Mon PM				
124.	Auditory system: central pathways II	Poster	Mon PM				
181.	Auditory system: central pathways III	Poster		Tue AM			
182.	Auditory system: central pathways IV	Poster		Tue AM			
592.	Auditory system: central pathways V	Slide					Fri AM
252.	Chemical senses: central pathways I	Poster		Tue PM

DEXFENFLURAMINE INHIBITS BASAL AND CRF-INDUCED ACTH AND β-ENDORPHIN RELEASE DURING IN VITRO PERIFUSION FROM PITUITARIES OF ADULT MALE RAT. B. Kerdelhue, V. Lenoir*, F. Lacour*, S. Melik*, O. Arnaud*, C. Nathan* and J. Duhault*. Lab. for Reproductive Neurobiology, CNRS, 78350 jouy-en-josas ; and IRIS, 92415 Courbevoie, FRANCE.

It has been demonstrated by in vivo experiments that dexfenfluramine (DF) markedly decreases the stimulatory action of environmental stress on corticosterone release. The present study examined in vitro the action of various concentrations of DF on the basal as well on the CRF-induced release of ACTH and β-Endorphin (β-EP). Anterior pituitaries (AP) were removed from 30 days old male rats sacrificed and placed in a perifusion system (1 AP/chamber ;chambers volume : 500 µl ;fraction collection : 10 min ;perifusion rate :500 µl/min ;perifusion medium: medium 199 containing I.B.M.X. : 0.2 mM ; Hepes : 20 mM ; Bacitracin : 0.1 mM ; BSA : 1 mg/ml ; pH : 7.4). After a 90 min equilibration period, DF (10^{-10}M to 10^{-6}M) was added for 60 min during which an application of a 10 min CRF 10^{-9}M pulse was performed at the end. Additional fractions were collected for 90 min after the end of the CRF pulse. ACTH and β-EP concentrations were determined by specific RIA's. The results show a significant reduction of basal ACTH (but not β-EP) release after exposure to DF. The inhibitory effect started at 10^{-10}M of DF and was concentration-dependent. From 10^{-10}M of DF there was a significant progressive reduction (20 % to 50 %) of the amplitude of the CRF-induced ACTH or β-EP surge. These results show that DF inhibits the secretion of ACTH and β-EP in basal and CRF-stimulated conditions. Together with recent observations from our laboratory showing an inhibitory effect of DF on CRF release rate from hypothalami,these results imply that the inhibitory effect of DF on corticosterone secretion is due to an action at the hypothalamo-pituitary corticotropic complex.

THE ANTIDEPRESSANTS FLUOXETINE, IDAZOXAN, AND PHENELZINE ALTER CORTICOTROPIN-RELEASING HORMONE AND TYROSINE HYDROXYLASE mRNA LEVELS IN RAT BRAIN: THERAPEUTIC IMPLICATIONS. L. S. Brady, P. W. Gold, M. Herkenham, A. B. Lynn, and Harvey J. Whitfield, Jr. Section on Functional Neuroanatomy, Clinical Neuroendocrinology. Branch, NIMH, Bethesda, MD 20892.

Antidepressant agents exert their therapeutic efficacy only after prolonged administration. We used *in situ* hybridization histochemistry to examine the effects of short-term (2 weeks) and long-term (8 weeks) administration of activating antidepressants that are preferentially effective in treating atypical depression–a subtype of depression associated with lethargy and hypersomnia–on the expression of genes encoding stress-responsive, arousal-producing neurotransmitters. Daily administration (5 mg/kg, ip) of the 5-HT reuptake inhibitor fluoxetine, the α_2-adrenergic antagonist idazoxan, and the nonspecific MAO A and B inhibitor phenelzine to rats increased tyrosine hydroxylase (TH) mRNA levels by 70-150% in the locus coeruleus (LC) after 2 weeks of drug and by 71-115% after 8 weeks. The drugs decreased corticotropin-releasing hormone (CRH) mRNA levels by 30-48% in the hypothalamic paraventricular nucleus (PVN). The decreases occurred at 8 weeks but not at 2 weeks. In light of findings that CRH appears to be hypersecreted in depression, the time-dependent decrease in CRH mRNA levels in the PVN may be the common element relevant to the therapeutic efficacy of antidepressant drugs in treating major depression. We propose that the therapeutic efficacy of activating drugs in atypical depression may reflect a capacity to increase the expression of TH mRNA in the LC, an effect that could theoretically be utilized in the screening of pharmacologic agents for the treatment of this disorder.

DECREASED SEROTONIN (5-HT) SYNTHESIS METABOLISM AND 5-HT1A RECEPTOR DENSITY IN VARIOUS BRAIN REGIONS OF INFLAMMATORY DISEASE SUSCEPTIBLE LEWIS RATS. Philip W.J. Burnet*, Ivan Mefford[1] Craig C. Smith*, George P. Chrousos [2], Philip W. Gold* and Esther M. Sternberg. Unit of Neuroendocrine Immunology and Behaviour, Clinical Neuroendocrinology Branch, NIMH; [1]Clinical Neuroscience Branch NIMH; [2]Pediatric Endocrinology Section, NICHD, Bethesda, MD 20892.

We have previously suggested that susceptibility of the Lewis (LEW/N) rat to inflammatory disease is related to a hyporesponsive hypothalamic-pituitary-adrenal (HPA) axis. In contrast, the histocompatible Fischer (F344/N) rat's relative resistance to inflammatory disease is due to a hyper-responsive HPA axis. Since serotonin (5-HT) is a major stimulator of the HPA axis we have investigated whether the activity of the axis reflects the activity of the central serotonergic system by measuring 5-HT and 5-HIAA levels and 5-HT1A receptor densities in various brain regions of F344/N, LEW/N and outbred Harlan Sprague Dawley (HSD) rats which are the maternal strain for both the LEW/N and F344/N rats. The cortex and hippocampus of F344/N and HSD rats contained a significantly greater density of 5-HT1A binding sites (approx. 40% in cortex and 20% in hippocampus) than these areas from the LEW/N rat. 5-HT1A receptor densities in the striatum, hypothalamus and midbrain did not significantly differ between strains. Basal 5-HT and 5-HIAA levels in the cortex, striatum and midbrain of F344/N and HSD rats were also significantly greater than these areas from LEW/N rats. The density of the 5-HT1A receptor in the hippocampus but not other brain areas, from F344/N, LEW/N and HSD rats increased after adrenalectomy. In general, 5-HIAA levels in most brain areas from all three strains increased after adrenalectomy. 5-HT levels in the same areas from all three strains tended to be lower. Thus, 5-HT synthesis and metabolism and hippocampal 5-HT1A receptor expression are dependent on glucocorticoid levels. We conclude that the activity of the serotonergic system in the LEW/N rat is decreased in parallel to its low HPA axis activity. Which of these is the primary or secondary event is as yet unknown.

395.8

CRH ALTERS THE BINDING OF ALPHA 2-RECEPTORS ON LOCUS COERULEUS NEURONS. G.K. Weiss, R. Hauger, M. Brown, A. Ratner, D. Savage, and K. Lucero. Univ. of New Mexico School of Medicine, Dept. Physiology and University of Calififormia, San Diego, Dept. Psychiatry.

CRH is known to have effects on the noradrenergic neurons within the locus coeruleus (LC) and it is believed that these effects may mediate some of the behavioral responses to stress. We investigated the possibility that the CRH effects on the LC neurons includes changes in the alpha-2, auto-inhibitory receptors. Rats were injected with 25 µg CRH intracisternally once per day for 4 days while under halothane anesthesia (controls injected with saline). A second group was injected with CRH only on the 5th day (controls injected with saline) and both groups were sacrificed 1 hr. later. The brains were quickly removed, frozen, and stored at -80°C. Eight micron sections cut through the LC were mounted on glass slides. Specific binding of the α_2-adrenergic receptor antagoist H3-Idazoxan was measured using in vitro neurotransmitter receptor autoradiography techniques. The 4-day group (sacrificed 24 hrs after the last injection) showed a significant decrease in the number of α-2 receptors within the LC while the single injection group had a significant increase above its control (Scatchard analysis). Other studies of the A-2 region are in progress. It appears from these studies that one of the effects of CRH on the central noradrenergic neurons includes changes in alpha-2 receptors. This could be a direct effect on LC neurons or indirect via other hormones released in response to the CRH or an autoregulatory response to changes in the activity of the LC neurons to the CRH.

STIMULATION OF HYPOTHALAMO-PITUITARY-ADRENAL (HPA) ACTIVITY BY HYPOTHALAMIC DA NEURONS. B. Borowsky and C.M. Kuhn. Dept. of Pharmacology, Duke University Medical Center, Durham, N.C. 27710.

We have previously demonstrated a role for central DA neurons in the regulation of HPA activity. The administration of the DA uptake inhibitor GBR12909 into the third ventricle (III-V) or the paraventricular nucleus, but not into the lateral ventricle, stimulated ACTH secretion. We now present evidence that this HPA stimulation is mediated by hypothalamic DA neurons. The administration of 6-OHDA into the III-V significantly decreased DA content in the hypothalamus and the caudate and significantly attenuated the ACTH response to GBR12909, administered either i.p. or into the III-V. In contrast, 6-OHDA lesions of the medial forebrain bundle depleted 99% of DA in the caudate but did not decrease DA content in the hypothalamus, and did not significantly attenuate the ACTH response to i.p. GBR12909. Administration of GBR12909 into the III-V did not increase locomotor activity, as compared to vehicle injected controls. Further, examination of [^{3}H]DA uptake in synaptosome-enriched homogenates demonstrated that DA terminals, in the region of the hypothalamus surrounding the III-V, possess GBR12909-sensitive DA transporters. The present findings suggest that an endogenous DA neuronal system terminating in the hypothalamus mediates the effects of stimulants on HPA function and might play a role in the ongoing regulation of HPA function. ARGININE VASOPRESSIN RESPONSE TO BENZODIAZEPINE WITHDRAWAL: POTENTIAL ROLE IN THE WITHDRAWAL SYNDROME. K.T. Kalogeras, J. R. Glowa,* G. Safos,* H. Bowen,* G. P. Chrousos and P. W. Gold.* CNE, NIMH, and DEB, NICHD, National Institutes of Health, Bethesda, MD 20892.

Arginine vasopressin (AVP) and oxytocin (OT) have been demonstrated to stimulate the pituitary-adrenal axis in a synergistic fashion with CRH, while atrial natriuretic peptide (ANP) inhibits cortisol secretion. Our earlier primate studies have shown that the triazolobenzodiazepine alprazolam suppresses plasma ACTH and cortisol in a dose-dependent fashion, by suppressing the CRH neuron, while chronic alprazolam treatment supresses ANP. More recent studies have demonstrated that alprazolam withdrawal is associated with a rebound elevation of plasma ACTH concentrations that was completely abolished by pretreatment with hydrocortisone. In this study we examined AVP, OT and ANP responses in primates during alprazolam withdrawal precipitated by benzodiazepine receptor blockade with Ro 15-1788, a specific benzodiazepine receptor antagonist. This was done by the administration of an iv bolus of Ro 15-1788 (2 mg/Kg) to 5 non-anesthetized tethered rhesus monkeys, 9 days after the initiation of an iv continuous infusion of alprazolam (2 mg/Kg/day). Plasma AVP, OT and ANP measurements were obtained before, and serially for 3 hours after the administration of Ro 15-1788 in the morning of day 10. Ro 15-1788 administration resulted in a profound increase in plasma AVP concentrations from a basal value of 1.5±0.3 pmol/L to a peak value, at 5 min, of 74.6±29.1 pmol/L, ($P<0.01$, ANOVA). No comparable increases in plasma OT and ANP concentrations were observed. In an effort to attenuate the benzodiazepine withdrawal syndrome by suppressing the CRH and AVP neurons a second group of 5 primates received an identical treatment and in addition a simultaneous iv infusion of hydrocortisone (96 mg/m^2/day). While the ACTH response to Ro 15-1788 was completely abolished and the behavioral withdrawal symptoms were significantly attenuated in this group, the AVP response was delayed but not suppressed by hydrocortisone. Plasma AVP concentrations increased from a basal value of 2.1±1.1 pmol/L to a peak value of 78.7±33.9 pmol/L, ($P<0.01$, ANOVA), 30 min after the administration of Ro 15-1788. We conclude that benzodiazepine withdrawal results in a major activation of the hypothalamic-pituitary-adrenal axis and that an AVP rebound elevation may play a role in the precipitation of the withdrawal syndrome.

INTERACTION OF THE BENZODIAZEPINE, ADINAZOLAM, WITH CRF IN RAT NEUROINTERMEDIATE LOBES: IN VITRO STUDIES. L.C. Saland, J.A. Carr, A. Samora*, D. Tejeda* and A. Rael*, Dept. of Anatomy, Univ. of New Mexico Sch. Med., Albuquerque, NM 87131.

Corticotropin-releasing factor (CRF) stimulates release of proopiomelanocortin (POMC) peptides, beta-endorphin (END) or alpha-melanocyte stimulating hormone (MSH) from rat neurointermediate lobes (NILS) in vitro. CRF-induced peptide release is significantly reduced by dopamine (Saland et al, '88, Neuropeptides 12: 59) or by the CRF-antagonist, alpha-helical CRF (Saland et al, '91, Neuropeptides, in press). The benzodiazepine drug adinazolam (ADIN) may modulate hormones which affect anxiety by suppressing CRF effects. Here, we examined the ability of ADIN to modulate CRF-induced END release from incubated rat NILS. Adult male Sprague-Dawley rats were ether anesthetized, rapidly decapitated, and the NILS incubated in vitro for 90 minutes with CRF (10^{-7}M), ADIN (10^{-10}-10^{-6}M) alone, or CRF followed by ADIN. Aliquots of media were taken for radioimmunoassay of END at 15 minute intervals. At 90 minutes, NILS were fixed and processed for light or electron microscopy (EM). Adinazolam added at 30 minutes suppressed the CRF-induced release of END, while ADIN alone showed non-specific modulation of END release. EM showed well-preserved tissue at the 90 minute end point. Adinazolam may act at the level of the pituitary to suppress "stress hormone" release induced by CRF. Supported by The Upjohn Co., NIH NS 21256, GM 08139(LCS) and NS 08447 (JAC).

INCREASED HYPOTHALAMIC [3H]FLUNITRAZEPAM BINDING IN HYPOTHALAMIC-PITUITARY-ADRENAL AXIS HYPORESPONSIVE LEWIS (LEW/N) RATS. Craig C. Smith*, Elizabeth Hauser*, Nicole K. Renaud*, Amy Leff*, Sofia Aksentijevich*, George Chrousos[1], Ronald L. Wilder[2], Philip W. Gold, and Esther M. Sternberg, Unit on Neuroendocrine Immunology and Behavior, Clinical Neuroendocrinology Branch,NIMH; [1]Pediatric Endocrinology Branch, NICHD; [2]Arthritis and Rheumatism Branch, NIAMS, NIH, Bethesda, MD 20892.

We have previously shown that relative LEW/N rat susceptibility and Fischer (F344/N) rat resistance to inflammatory disease, is related to deficient glucocorticoid counter-regulation of the immune response resulting from deficient corticotropin releasing hormone (CRH) responsiveness to inflammatory and other stress mediators. The GABA/benzodiazepine (BNZ) receptor complex is an important negative modulator of CRH responsiveness. We have examined *in vitro* binding of [3H]flunitrazepam to hypothalamic membrane preparations from LEW/N and F344/N rats. LEW/N rats had significantly more hypothalamic BNZ binding sites than F344/N rats, but there were no differences in BNZ binding affinities (Kd) between these two strains. Differences in BNZ receptor number were consistent with the respective plasma corticosterone levels in the two strains, and with previous studies indicating a negative correlation between corticosterone levels and BNZ number. BNZ binding in adrenalectomized (adx) F344/N rats increased to levels comparable to non-adx LEW/N rats, but remained unchanged in adx LEW/N rats. These findings suggest that basal BNZ receptor differences between these strains may be secondary to strain differences in corticosterone levels. Since BNZs attenuate hypothalamic CRH secretion through GABAergic inhibition, we suggest that strain differences in receptor number could therefore also augment strain differences in HPA axis function through differential sensitivity to GABA mediated feedback.

DIFFERENTIAL EFFECTS OF REPEATED OR CONTINUOUS EXPOSURE TO COCAINE ON THE RAT HYPOTHALAMO-PITUITARY-ADRENAL AXIS. German Torres and Catherine Rivier, The Salk Institute, The Clayton Foundation Laboratories for Peptide Biology, San Diego, CA 92186.

Acute exposure to cocaine is known to enhance the secretion of ACTH and corticosterone secretion, but the endocrine consequences of chronic administration of the drug are less well documented. We therefore compared the effects of repeated (1 x day) iv cocaine injections (5 mg/kg) for 6-days via implanted jugular catheters with those of continuous exposure via osmotic pumps (5 mg/kg/day), also for 6-days. ACTH and corticosterone levels were assessed by RIA. Repeated, daily injections of cocaine produced consistent increases in plasma ACTH and corticosterone levels 30 min after the challenge. This rise in hormonal secretion was maintained throughout the 6-days of treatment. In contrast, continuous exposure to cocaine failed to alter basal levels of ACTH and corticosterone, suggesting de-sensitization of the HPA axis to the constant presence of the drug. To investigate whether this lack of response was due to physiological alterations at the hypothalamic or pituitary level, rats implanted with osmotic pumps were acutely challenged with either CRF (5 ug/kg) or cocaine (5 mg/kg) 6-days after continuous infusion of the drug (1 ul/hr). Although both pharmacological treatments enhanced ACTH secretion, such increase appeared to be altered suggestive of tolerance in some component of the rat HPA axis. (Supported by DA 05602)

FUNCTIONAL ANTAGONISM OF MINERALO- AND GLUCOCORTICOID RECEPTOR-MEDIATED RESPONSES TO CORTICOSTERONE IN HIPPOCAMPUS E.R. de Kloet[1], H. Karst[2] and M. Joëls[2]
[1]Center for Bio-Pharm. Sci., Leiden Univ., The Netherlands
[2]Dept. of Exp. Zool., Univ. of Amsterdam, The Netherlands

Pyramidal neurons in the rat hippocampal CA_1 area contain mineralocorticoid (MRs) and glucocorticoid receptors (GRs), which bind the adrenal steroid hormone corticosterone (B) with different affinity. In previous studies we found that a 20-min application of B to hippocampal slices of adrenalectomized (ADX) rats suppressed the hyperpolarization of CA_1 neurons induced by $5HT_{1A}$ receptor stimulation. This effect of B on the 5HT-induced hyperpolarization appeared to be mediated by MRs and involves protein synthesis. Here we report the interaction between MR- and GR-mediated B effects on $5HT_{1A}$ responses: (i) Short GR activation with the selective agonist RU 28362 blocked the attenuating action of the MR agonist aldosterone on the response to 5HT; RU 28362 alone was not affective. (ii) Low steady state concentrations of the mixed agonist B (0.5 nM, at the k_D of MR) suppressed the 5HT response with a delay of 2 h, while a high concentration of B (5 nM, at the k_D of GR) resulted in a transient reduction. (iii) Neurons of moderately stressed rats, which probably have occupied both MR and GR, did not differ from ADX in their 5HT responses.

Summarizing, the data suggest that when the concentration of B rises, occupation of GR results in a functional antagonism of MR-mediated cellular responses. Accordingly, the MR-mediated attenuation of 5HT responses may be limited to conditions of low adrenocortical activity or pathophysiological conditions where the balance of MR- and GR-mediated effects is disturbed.

INTERACTIONS BETWEEN CANNABINOIDS AND STEROIDS IN RAT HIPPOCAMPUS. J.C. Eldridge[1], H-Y Hu*[1], P.J. Extrom[1]* and P.W. Landfield[2]. *Department of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083[1], and Department of Pharmacology, University of Kentucky School of Medicine, Lexington, KY 40536[2].*

In previous papers, we have examined hypotheses that cannabinoids (THC) and corticosterone (CORT) share common loci of action in brain. Administration of THC induced degenerative changes in rat hippocampus resembling those seen with high CORT administration or during normal aging (Landfield, *et al., Brain Research 443*, 1988). We have also reported that THC competes against CORT binding to cytosolic receptors in hippocampus (Eldridge and Landfield, *Brain Research 534*, 1990). With a recent description of binding sites for CP-55,940 (CP), a synthetic cannabinoid, in neuronal membranes (cf. Howlett, *et al., Trends Neurosci. 13*, 1990) we have broadened our studies to include possible interactions between steroids and THC at both sites. [3H]-CP binding was very high in rat hippocampal membranes (K_d = 87 pM, B_{max} = 3000 fmol/mg protein), at levels comparable to whole cerebellum (K_d = 98 pM, B_{max} = 2800 fmol/mg). Injection of adrenalectomized rats with 1 mg CORT per day increased hippocampal CP binding modestly (25%) after 2 days, but decreased binding 50% after 4 days. No effect was seen in cerebellum. Addition of CORT or "neurosteroids" (e.g. alphaxalone and α-pregnanolone) that have gained much recent attention (cf. Baulieu and Robel, *J. Steroid Biochem. 37*, 1990) to hippocampal membranes induced only a slight alteration of CP binding properties *in vitro*. In other experiments, [3H]-CP binding was observed in hippocampal cytosol (45 fmol/mg protein). Binding was displaced by 100-fold molar excess of unlabeled CP but was not by CORT, up to 10,000-fold excess. Furthermore, excess unlabeled CP could not displace [3H]-CORT binding in hippocampal cytosol.

REGULATION OF THE IMMEDIATE-EARLY GENES C-FOS, C-JUN AND JUN B IN RAT ADRENAL GLAND. Å. Dagerlind[1], M. Pelto-Huikko[1,3], J. Koistinaho[3], J. M. Lundberg[2] and T. Hökfelt[1]. Dept. of [1]Histology and Neurobiology and [2]Pharmacology, Karolinska Institute, S-104 01 Stockholm, Sweden and [3]Dept. of Biomedical Sciences, Univ. of Tampere, SF-33101 Tampere, Finland.

Several factors interacts with specific elements in the promotor region of a target gene, thus regulating its mRNA synthesis. We have used in situ hybridization to study the expression of three such factors, c-fos, c-jun and junB mRNA in the rat adrenal gland. Control rats, showed very low levels of c-fos and junB mRNA in the cortical layers fasciculata and reticulata, whereas no detectable labelling was seen in the zona glomerulosa. Low levels of both c-fos and junB mRNA were detected in the medulla. In contrast, the levels of c-jun mRNA were high in zona fasciculata and reticulata, whereas no labelling was found in the zona glomerulosa with no or low levels in the medulla. Capsaicin (CAPS) treatment increased the levels of c-fos and junB mRNA especially in the zona glomerulosa, whereas all three mRNAs were increased in the medulla. After denervation of the splanchnic nerve, no levels of c-fos mRNA were found in the medulla. Denervation did not effect c-jun mRNA levels. When denervated rats were given CAPS, the increase in c-fos and c-jun mRNA seen in the medulla after CAPS treatment was totally abolished. Nicotine treatment induced a rapid increase of both c-fos mRNA and c-jun mRNA especially in the adrenal medulla. Hypophysectomy did not affect the levels of c-fos or c-jun either in the medulla or cortex. However, administration of adrenocorticotropic hormone (ACTH) increased both c-fos and c-jun in the zona glomerulosa. These results indicate that Fos and Jun, although differentially regulated according to time course, magnitude and regional distribution, may play important roles in the regulation of several genes in the adrenal gland. However, especially in the zona glomerulosa, JunB seems to cooperate with Fos. In conclusion we propose that c-fos and c-jun and probably JunB in the medulla are regulated mainly through neuronal activity via the splanchnic nerve, whereas in the adrenal cortex mainly by humoral factors.

FOS EXPRESSION IN CORTICOTROPHS OF THE RAT ANTERIOR PITUITARY. G. Kasof and S. A. DeRiemer. Dept. Biological Sciences, Columbia University, New York, NY 10027.

We are investigating factors leading to the induction of the protein product of the proto-oncogene *c-fos* in the adenocorticotropic hormone (ACTH) secreting corticotrophs. The almost universal elevation of Fos in nerve and endocrine cells suggests a possible role of Fos in either short or long term regulation of secretion. The gene for Fos contains response elements that are induced by Ca^{++}, Protein Kinase C (PKC), and cAMP. We are examining the effect of known secretagogues which act through these second messengers on Fos expression. In order to more effectively examine Fos in the corticotrophs, a 4-fold enrichment of these cells has been obtained using a continuous Percoll gradient. Localization of Fos in this enriched culture was performed by immunocytochemistry using a polyclonal antibody corresponding to a.a. 2-20 (CRB). Western blots of anterior pituitary homogenates confirm the specificity of the antibody for Fos and its ability to be blocked by the peptide to which the antibody was raised. In all cases Fos-like immunoreactivity was seen in both the cytosol and nucleus. There is a significant increase in Fos immunofluorescence following the depolarization of these cells with high external K^+. This stimulation leads to a rise in intracellular Ca^{++} as detected with fluo-3/AM. Fos staining also increased in response to the PKC activator TPA(100nM). Corticotropin-releasing factor (CRF,100nM), which is known to elevate cAMP in corticotrophs, increased Fos immunoreactivity in a number of cells equalling the calculated percentage of corticotrophs in the culture. We are currently working on getting a pure fraction of corticotropes by flow cytometry which will be used to further investigate the factors necessary for Fos induction and its possible role in ACTH secretion.

CARDIOVASCULAR REGULATION: BRAINSTEM MECHANISMS II

396.1

MODELING REVEALS MECHANISMS OF CENTRAL COMPUTATION IN THE BARORECEPTOR VAGAL REFLEX. E.B. Graves*, J.S. Schwaber, J.F.R. Paton, K.M. Spyer†, and W.T. Rogers. Neural Computation Group, E.I. duPont Co., Wilmington, DE 19880-0352 and †Royal Free Hospital School of Medicine, London NW3 2PF.

Computational modeling provides a framework for understanding function in neural systems. We are creating a model of the baroreceptor vagal reflex. This system performs nonlinear dynamical multivariate control, and thus is ideal for comprehending underlying mechanisms for use in artificial systems. Previously (Rogers et. al., Soc. Neurosci. Abs. 16:219,1990) we reported a model of primary baroreceptor afferents which showed how pressure information is encoded and transmitted to the brain. The present work extends this to illustrate how central neurons transform this code by virtue of their intrinsic membrane properties. Model 2^{nd}-order baroreceptor neurons are constructed from modified channel kinetics which account for membrane potential trajectories observed *in vitro;* including delayed response, spike rate accommodation, rebound depolarization and state-dependent response. Baroreceptor afferents are connected to these central neurons with excitatory ligand-gated synapses. Blood pressure recordings drive afferent activity, which in turn modulates central neuronal activity. Resulting patterns are studied in relation to their inputs in order to determine the transformation that is computed centrally. Regarding the 1^{st}-order/2^{nd}-order processing, consequences of different patterns of afferent convergence and timing are being explored in simulation. Our preliminary results indicate the transformation of strongly correlated burst activity on the afferents into low-rate activity of 2^{nd}-order cells due to their intrinsic membrane properties. We are now exploring the significance of population responses for parallel processing.

396.2

ROSTRO-CAUDAL TOPOGRAPHY OF CARDIAC VAGAL INNERVATION IN THE RAT *J.A. Escardo*, J.S. Schwaber, J.F.R. Paton and R.R. Miselis, Neural Computation Group, DuPont Co., Wilm., DE 19880, & U. Penn., Phila., PA.*

Cholera Toxin-Horseradish Peroxidase was injected into four distinct cardiac sites: 1) between the superior vena cava and the aorta; 2) between the aorta and pulmonary artery; 3) at the junction of the aorta and the heart, and; 4) at the crossing of the jugular vein, left ventricle and pulmonary artery. Only the first and fourth sites displayed consistent and abundant retrograde and anterograde transport. Analysis in transverse, sagittal, and horizontal planes revealed that labeled cardiac preganglionic cells typically extend from +1.44mm to -1.68mm with ref. to the obex. Cells were present bilaterally in three distinct fields: 1) scattered cells in the dorsal motor nucleus of the vagus nerve (DMV) from +1.20mm to -1.92mm with ref. to the obex; 2) a dense, rostral group of up to 126 multipolar, stellate cells in the rostral ventrolateral nucleus ambiguus from +1.44mm to +0.48mm, and; 3) a caudal group of up to 123 larger neurons between -0.12mm and -1.68mm distributed in the field between the DMV and the NA. These caudal neurons are often closely packed and have large, tortuously shaped,often intertwined dendrites. While the first injection site preferentially labeled the caudal group, the fourth site exhibited a bias for the rostral cells.

Cardiac afferents are distributed in a continuous column within the NTS from obex to -3.2mm. Caudally, afferents distribute within the medial commissural NTS, and extend ventrally half way to the central canal. More rostrally, the terminal field migrates to include only the dorsal tier of the commissural NTS. Then, at levels of the obex, where labeling is most dense, it spreads laterally and away from the commissural subnucleus into the dorsal subnucleus capping the Tractus Solitarii dorsally and dorsomedially. This distribution appears to largely overlap that of other cardiovascular inputs, specifically that of the aortic nerve. The rostro-caudal range of aortic afferents is less extensive and is shifted somewhat rostrally, extending from +0.2mm to -1.52mm.

396.3

AUTO-ACTIVITY IN THE CARDIOVASCULAR NUCLEUS TRACTUS SOLITARII (NTS): ELECTROPHYSIOLOGICAL, NEUROPHARMACOLOGICAL AND IMMUNOCYTOCHEMICAL ANALYSIS. J.F.R. Paton, J.M. Bradd*, W.T. Rogers & J.S. Schwaber. Neural Computation Group, DuPont Co.,Wilmington, DE19880-0352.

We previously reported neuronal rhythmic activity (~5Hz) in rat brainstem slices localized to the cardiovascular NTS (Paton et al., Soc. Neurosci. Abs. 16:219,1990). This region contains a significant part of the A2 aminergic cell group. In the present study we further characterized these neurons by 1) assessing the importance of glutaminergic synaptic drives for their activity *in vitro*, and 2), testing for the presence of tyrosine hydroxylase (TH). Application of glutaminergic blockers (APV; 0.5mM) or kynurenic acid (1.0mM) produced two distinct types of response. In half of the cells ongoing discharge was either reduced by 0.5 Hz or unaffected, and these are referred to as auto-active cells (AA). In the other cells rhythmic activity was abolished and these are characterized as synaptically driven neurons (SD). During glutaminergic blockade the excitatory response to topically applied glutamate (1mM) and the synaptically evoked response following electrical stimulation of the solitary tract (2-40μA) were abolished. In addition, AA cells maintained their rhythmicity during exposure to cobalt chloride (5 mM). Characterized AA and SD neurons were labeled iontophoretically with 10% lucifer yellow (-2.4nA for 10mins) in the slice and subsequently reacted immunocytochemically for TH. Our preliminary data suggests that both AA and SD neurons appear co-localized with a population of NTS neurons containing TH. Consequently, we are investigating the possibility that either AA or SD neurons belong to the A2 cell group. In summary, the data reveal two populations of rhythmically active cells in the cardiovascular NTS; one intrinsically active and, the other requiring glutaminergic drives for its activity.

396.4

PROJECTIONS OF THE NUCLEUS RETICULARIS PARVOCELLULARIS TO CARDIOVASULAR AREAS OF THE MEDULLA OBLONGATA IN THE RAT. L.D. Mitchell and M.A. Nathan, Depts. of Physiology and Pharmacology, CUNY Med. Sch., New York, NY 10031.

Central control of the circulation by the nucleus tractus solitarii (NTS), rostral ventrolateral medulla (RVLM) and caudal ventrolateral medulla (CVLM) is well documented (Ciriello et al., Brain Res. Rev., 11:359-391, 1986). However, the importance of the nucleus reticularis parvocellularis (NRP) in cardiovascular control is less understood and controversial. Kumada et al. reported that lesions of the NRP substantially decreased mean arterial pressure (MAP) in the rabbit (Circ. Res., 45:63-70, 1979). In contrast, we found that lesions of the NRP did not decrease MAP in the rat, but that combined lesions of the NRP and RVLM caused profound hypotension (Cochrane & Nathan, The FASEB J., 2:A1488, 1988). We also noted that lesions of the RVLM generally eliminated pressor responses normally caused by electrical stimulation of the NRP. In the current study, we investigated the possible anatomical projection of the NRP to the RVLM and other cardiovascular areas of the medulla oblongata.

Projections of the middle third of the NRP (about 10.3 mm caudal to bregma) were studied in Long-Evans rats. A micropipette (20-30 μM tip) was used to inject HRP-WGA (Sigma) into the NRP (1% in 0.5 M NaCl, 12.5-25.0 nL). Survival times after the injections were 24-48 hrs. The tissue was processed according to the method of Gibson et al. (Brain Res., 298:235-241, 1984).

We found that the NRP projected to the midline raphe, contraleral NRP, facial nucleus and the IXth cranial nerve, which agrees with earlier observations of Ruggiero et al. (J. Comp. Neurol., 206:278-292, 1982). In addition, we found dense anterograde ipsilateral projections and lighter contralateral projections to the NTS. A few retrogradely labeled cells were seen in the NTS. We also found labeled terminals in the RVLM. Some terminal labeling was found in the CVLM.

This study demonstrates that cardiovascular control by the NRP may involve projections to the NTS, RVLM and CVLM, areas importantly involved in the central regulation of the circulation.

CARDIOVASCULAR SYMPATHOINHIBITORY CELLS FORM AN EXTENDED LONGITUDINAL COLUMN IN CAT MEDULLA. C.W. Dempesy, D.E. Richardson, and C.J. Fontana*. Lab. of Neurosurgery, Tulane Univ. School of Medicine, New Orleans, LA 70112.

Sympathetic depressor cells have been shown in rat and rabbit to be located in the caudal ventrolateral medulla, just posterior to the plane of the obex. A similarly located area has been assumed to exist in cat, based on cardiovascular depression observed during stimulation of the caudal ventral surface of the medulla (Guertzenstein and Lopes, J. Physiol. 347:345, 1984). However, the sympathoinhibitory area we have reported for cat (Neurosci. Abst. 14: 92, 1988) lies quite anterior to the plane of the obex, in a location dorsal to the rostral ventrolateral medulla. We now report that a survey using glutamate stimulation of the medullary region joining these rostral-dorsal extremes reveals a columnar distribution of cardiovascular sympathoinhibitory cells extending from -1 to +3 mm with respect to the plane of the obex, at laterality 3 to 4 mm and depth -7 to -9 mm (re the cat brain stem atlas of Berman). The greater density of these cells lies in the anterior half of this column. Chemical inhibition of any segment of this column yields hypertension, tachycardia, and partial loss of baroreflex, with muscimol providing greater blocking effectiveness than kynurenic acid.

396.6

CARDIAC ACCELERATION AND MUSCLE CONTRACTION IN THE DECEREBRATE CAT. P.N. McWilliam* and S.E. McMahon* (SPON: European Neuroscience Association). Dept. of Cardiovascular Studies, University of Leeds, Leeds, LS2 9JT, U.K.

The immediate cardiac acceleration at the onset of exercise is mediated by a withdrawal of vagal tone. In contrast, animal studies involving hindlimb contraction elicited by ventral root stimulation have reported only sympathetically mediated increases in heart rate and the latency of these responses has led to the conclusion that a 'central' rather than a 'peripheral' signal is responsible for the immediate cardiac acceleration in the intact organism. The aim of this study was to determine if muscle contraction elicited by ventral root stimulation would lead to an immediate tachycardia mediated by a withdrawal of vagal tone. Brief hindlimb contractions were elicited by electrical stimulation of L7 ventral roots (50 Hz), in cats decerebrated under halothane anaesthesia. With low vagal tone a 5 s contraction significantly reduced R-R interval from 359 ± 25 (mean ± SE, n=8) to 336 ± 24 ms ($P < 0.005$). When vagal tone was increased this response was enhanced ($P < 0.001$, n=8, paired t-test), with contraction reducing R-R interval from 474 ± 45 to 419 ± 47 ms ($P < 0.001$). The minimum latency between the onset of L7 ventral root stimulation and the end of the first shortened R-R interval was just 687 ± 29 ms (n=5). Atropine (0.4 mg kg^{-1}, I.V) prevented a 5 s contraction from producing any change in R-R interval. These results show that 'peripheral' signals, i.e. afferent impulses originating from receptors in contracting muscle, do contribute to the initial vagally mediated heart rate response in the intact organism at the start of exercise.

396.7

RESPONSES OF LATERAL TEGMENTAL FIELD NEURONS IN THE CAT MEDULLA TO STATIC MUSCULAR CONTRACTION. G.A. Iwamoto and T.G. Waldrop. Depts. of Physiology & Biophysics and Veterinary Biosciences, Univ. of Illinois, Urbana, IL 61801

Prior studies have shown that neurons in the ventrolateral medulla are involved in mediating the cardiovascular responses to static muscular contraction; this area is known to have connections with sympathoexcitatory neurons in the lateral tegmental field (LTF). The purpose of the present study was to determine if static muscular contraction alters the discharge frequency of neurons in the LTF. Single unit responses of LTF neurons to static contraction of hindlimb muscles (evoked by stimulation of the L_7 and S_1 ventral roots) were evaluated in anesthetized cats. Computer averaging analyses were used to examine the basal discharge of the studied neurons relative to cardiovascular (cardiac cycle and/or sympathetic nerve discharge) or respiratory (phrenic nerve discharge) activity. Muscular contraction elicited increases in the discharge rate of 59% of the LTF neurons studied; 74% of these neurons had a basal discharge correlated temporally with cardiovascular activity. Thirty-four percent of the LTF neurons had a discharge related to phrenic nerve activity; only ten percent of the neurons with an inspiratory-related discharge were stimulated by muscular contraction. Baroreceptor stimulation (produced by a phenylephrine-induced increase in arterial pressure) elicited a decrease in the firing rate in 58% of the neurons. These results indicate that cardiovascular neurons in the LTF are excited by static contraction of hindlimb muscles. Thus, the lateral tegmental fields may be part of the supraspinal circuitry involved in regulating cardiovascular responses during exercise (Supported by NIH 06296; American Heart Association).

BARORECEPTOR REFLEX FUNCTION IN CHRONIC RVLM-LESIONED SPONTANEOUSLY HYPERTENSIVE RATS (SHR). E.C. Vasquez, S.J. Lewis, K.J. Varner and M.J. Brody. Dept. Pharmacology & Cardiovascular Ctr., Univ. Iowa, Iowa City, IA 52242.

Lesion of rostral ventrolateral medulla (RVLM) produces a marked hypotension in conscious SHR. This study examined the effects of these lesions on baroreceptor reflex function in conscious SHR. Lesions were produced via bilateral microinjections of 30 nmol/200 nl of N-methyl-D-aspartic acid (NMDA). Baroreceptor reflex function was assessed in conscious rats by measuring reflex-mediated changes in heart rate elicited by graded i.v. doses of phenylephrine and sodium nitroprusside. Reflex function was analyzed using exponential curve fitting analysis. One day post-lesion, the RVLM-lesioned rats showed a significant hypotension in comparison to sham rats (98±6 vs 175±5 mmHg) and was still observed 15 days post-lesion (149±5 vs 173±7 mmHg). The baroreceptor reflex gain in the lesioned rats was significantly reduced when compared to sham rats (-2.2±0.3 vs -4.1±0.5 bpm/mmHg) 1 day post-lesion, but completely recovered 6 days post-lesion. These data suggest that RVLM neurons play an important role in baroreceptor reflex function. Recovery of baroreceptor reflex function may reflect increased activity in other spinal or supraspinal networks. (Supported by HL-14388 & 44546)

LESION OF NEURONS IN ROSTRAL VENTROLATERAL MEDULLA (RVLM) ALTER CARDIOPULMONARY REFLEXES IN SPONTANEOUSLY HYPERTENSIVE RATS (SHR). K.J. Varner, E.C. Vasquez, S.J. Lewis and M.J. Brody. Dept. Pharmacology & Cardiovascular Ctr., Univ. Iowa, Iowa City, IA 52242

We previously reported that chronic N-methyl-D-aspartic acid (NMDA)-induced lesion of neurons in RVLM causes profound hypotension in conscious SHR. The aim of the present study was to examine the effects of these lesions on cardiopulmonary reflex function in conscious SHR. Lesions of RVLM were produced by bilateral microinjections of 30 nmoles (200 nl) NMDA. Cardiopulmonary reflex function was tested by intravenous (iv) injection of 5-hydroxytryptamine (5-HT). One day post lesion, low doses of 5-HT (1 μg/kg) elicited reflex tachycardia (49±9 bpm) in sham and bradycardia (-53±22 bpm) in lesion rats. The Bezold-Jarisch reflex (hypotension and bradycardia) elicited by higher doses of 5-HT (2.5-20 μg/kg) was significantly enhanced in lesion rats as compared to sham rats (heart rate: -53% vs -26%; mean arterial pressure: -28% vs -18%). No significant differences in reflex function were observed between lesion and sham rats 6 to 15 days post lesion, even though arterial pressure in the lesion rats was significantly reduced through day 15. These data indicate that neurons in RVLM 1) are responsible for the reflex tachycardia elicited by low doses of 5-HT, and 2) inhibit cardiopulmonary heart rate reflex responses to iv 5-HT. (Support HL-14388 & 44546)

396.10

MEDULLARY SITES MEDIATING SYMPATHETIC RESPONSES FROM THE PARABRACHIAL NUCLEUS IN THE RAT. H. Herbert[1], S.J. Chen[2], and D.F.Cechetto[2]. [1]Univ. of Tübingen, Dept. Animal Physiol., D-7400 Tübingen, FRG; and [2]Robarts Res. Inst., Univ. of Western Ontario, London, Ontario N6A 5K8.

The pathway mediating the prominent pressor response elicited by electrical or chemical stimulation of the parabrachial nucleus (PB) is unknown. We injected the calcium channel blocker cobaltous chloride (COB) which reversibly blocks synaptic transmission into presumed relay sites in the ventrolateral medulla to determine their role in mediating this response. Arterial blood pressure (AP), heart rate and sympathetic (renal) nerve discharge (SND) were continuously monitored in chloralose-anesthetized rats.

Pressor sites in the PB were electrically or chemically (D,L-homocysteic acid; DLH) stimulated before and after bilateral injections of 300 nl COB (10 mM) into the ventrolateral medulla (VLM) at different rostrocaudal levels. COB injections into the rostral VLM (rVLM; 1.5 to 2.5 mm rostral to obex) blocked both the AP and SND increases. The blockage had essentially disappeared by 10 min after the COB injection. COB injections rostral or caudal to the rVLM did not significantly affect the AP and SND responses. Bilateral lesions of the rVLM with the excitotoxin kainic acid (KA; 50 mM, 50 nl) permanently blocked the PB pressor response. DLH injections into the effective areas in the rVLM, prior to COB or KA injections, characterized them as potent pressor sites.

The pressor response originating in the lateral PB is relayed to sympathetic preganglionic neurons in the spinal cord via the pressor region in the rVLM. This suggests that the PB provides an excitatory drive to rVLM pressor cells. (Supported by the Heart and Stroke Foundation of Ontario)

SOMATOSENSORY AND AUDITORY NUCLEI PROJECT TO A DISCRETE SUBREGION OF THE ROSTRAL VENTRAL MEDULLA IN RAT. Y. Zhu, E.J. Van Bockstaele, H. Akaoka, P.H. Luppi[1], G. Luthin[2] and G. Aston-Jones. Hahnemann Univ., Dept of Mental Health Sciences, Philadelphia, PA 19102, [1] CNRS UA 1195, INSERM U52, Lyon, France, [2] Hahnemann Univ., Dept. of Physiology, Phila. PA 19102.

The rostral pole of the nucleus paragigantocellularis (PGi), termed juxtafacial PGi, lies throughout the medial extent of the facial nucleus. This narrow region of the ventral medulla contains many bulbospinal neurons which have been implicated in pain processing, cardiovascular regulation and respiratory related activities. Previous studies, in cat, examining afferents to and efferents of the juxtafacial PGi indicated that somatosensory and auditory structures, such as the dorsal column nuclei and inferior colliculus, project to the juxtafacial PGi and that neurons in this area project to the posterior nucleus of the thalamus. Although certain studies in the rat have examined afferents to the PGi, the juxtafacial PGi has not been examined in detail for its afferents and efferents. Therefore, in the present study, discrete pressure microinjections of a colloidal gold complex of wheat germ agglutinin- conjugated to inactive horseradish peroxidase were placed into the juxtafacial PGi and retrogradely labeled neurons identified throughout the brain. Anterograde transport from selected brain areas was also used to confirm and further detail the innervation patterns of the juxtafacial PGi from its afferents. The present results reveal that the juxtafacial PGi receives input from a variety of somatosensory and auditory nuclei such as dorsal column nuclei, supraolivary reticular formation, inferior colliculus and medial geniculate nucleus confirming results seen with other species. There are also afferents from the retrofacial PGi, the caudal medullary reticular formation, the periaqueductal gray and hypothalamic nuclei. These results support a role of the juxtafacial PGi in the integration of somatosympathetic events. Supported by PHS grant 24698.

DISTINCT POPULATIONS OF NEURONS IN THE SUPRAOCULOMOTOR NUCLEUS OF THE CENTRAL GRAY (SOM) PROJECT TO THE ROSTRAL VENTROLATERAL MEDULLA (RVM) AND ABDUCENS NUCLEUS (Abd) IN THE RAT BRAIN. E. J. Van Bockstaele and G. Aston-Jones. Hahnemann University, Department of Mental Health Sciences, Philadelphia PA 19102.

Retrograde transport studies have indicated that neurons in the SOM area of the rostral ventromedial periaqueductal gray project to the nucleus paragigantocellularis (PGi) in the RVM (Van Bockstaele et al., JCN, 290:561-584, '89). Anterograde tracing studies have confirmed and further detailed this projection (Van Bockstaele et al., JCN, in press), indicating a strong and specific projection to the sympathoexcitatory region of the lateral retrofacial PGi, corresponding to the nucleus rostroventrolateralis. The SOM region has been implicated in oculomotor related activities because neurons in this area have been reported to project to the Abd in the pons. To determine whether SOM neurons projecting to the PGi are part of the same population of neurons innervating the Abd, double retrograde transport experiments were conducted from the PGi and the Abd. Microinjections (50 nl) of fluorescein latex microspheres were deposited into the Abd using glass micropipettes (15 μm tip O.D.) via a controlled pneumatic pressure device. Microinjections (300 nl) of wheat germ agglutinin conjugated to inactive horseradish peroxidase coupled to 15 nm gold particles (WGA-Au) were similarly deposited into the PGi area. Retrogradely labeled neurons were observed either with epifluorescence microscopy for the fluorescein microspheres or darkfield microscopy for the WGA-Au particles. Retrogradely labeled neurons were identified in the contralateral SOM from both nuclei. Labeled neurons from the Abd were found in the more caudal aspects of the ventromedial PAG. Labeled neurons from the PGi were found more rostrally and more dorsally than Abd-projecting neurons. Few doubly labeled neurons were identified in the SOM although these neurons were interdigitated at rostral PAG levels. These results indicate that neurons in the SOM projecting to the PGi are a separate population from those projecting to the Abd and therefore are probably not preoculomotor neurons. Supported by PHS grant NS24698.

LOCALIZATION OF ANGIOTENSIN II BINDING SITES IN THE DORSAL MEDULLA WITH HIGH RESOLUTION AUTORADIOGRAPHY. E. M. Szigethy, K. L. Barnes, D. J Diz and C. M. Ferrario. Dept. of Brain & Vascular Research, Research Institute, Cleveland Clinic Fndn., Cleveland, OH 44195.

Angiotensin II (Ang II) acts in the dorsal medulla to modulate baroreflex function. Moreover, Ang II binding sites are associated with presynaptic vagal afferent fibers in the nucleus tractus solitarii (nTS) and vagal efferent neurons in the dorsal motor nucleus of the vagus (dmnX). High resolution "wet" autoradiography now documents the relationship of putative Ang II receptors to the cytoarchitecture of these nuclei. Serial 14 μm canine medulla sections were processed for film or emulsion autoradiography with 0.5-1 nM ^{125}I-Ang II. Films were quantitated with ^{125}I-Ang II standards. Fixed sections were coated with emulsion, stored (4°C) for 6-8 weeks, developed and counterstained with cresyl violet. Comparison of film and emulsion images revealed a uniform reduction in labeling after emulsion processing with no alteration in distribution. In the nTS, Ang II binding was restricted to regions with heavy vagal afferent innervation. In the dorsal nTS, label was distributed homogeneously over both small, round cell bodies and neuropil. The highest density of binding capped the dorsolateral solitary tract. In the medial nTS, moderately dense label was concentrated over medium-sized oval perikarya, with scattered grains over the intervening neuropil. Dense labeling was seen over the majority of the large, round to oval perikarya and the surrounding neuropil in the ventral dmnX. A band of label lateral to the dmnX overlaid vagal efferent fibers coursing ventrolaterally to exit the medulla. The discrete subnuclear association of Ang II binding in the dorsal medulla with vagal cells and fibers provides support for our hypothesis that Ang II receptors are present on both afferent vagal fibers and intrinsic medullary neurons. REGIONAL HEMODYNAMIC EFFECTS FOLLOWING CHEMICAL STIMULATION OF THE FELINE AREA POSTREMA (AP). P.J. Gatti. Dept. of Pharmacol., Howard Univ. Col. of Med., Washington, DC 20059.

The purpose of the present study was to determine whether chemical stimulation of the AP would evoke increases in renal (RR) and femoral (FR) arterial resistance. Experiments were performed in chloralose-anesthetized artificially respired cats. Blood flow (ml/min) was measured using a transit time blood flowmeter. Bilateral application of the excitotoxin kainic acid (KA;40 mM) to the AP increased mean arterial pressure by 80 ± 13 mmHg in 5 animals. RR increased by 51 ± 16 % and FR increased by 208 ± 24 %. Effects occurred immediately and lasted 10-15 min. The percent change in FR was significantly greater than the percent change in RR ($p<.05$). A previous study has shown that application of KA to the AP resulted in a 43 ± 13 % increase in coronary vascular resistance (CVR) [Gatti, et al. Brain Res. 448(1988)313-319]. These data indicate that the AP controls blood flow to the kidney, heart and skeletal muscle. However, it appears that its control over skeletal muscle blood flow is greater than kidney and coronary blood flow. This preferential effect is similar to the effect seen following stimulation of the subretrofacial nucleus in the ventrolateral medulla in which FR increased more than RR and superior mesenteric arterial resistance. These data raise the possibility that the AP produces its effects via the ventrolateral medulla. Supported by the American Heart Association/Nation's Capital Affiliate.

ETHANOL (EtOH) INHIBITION OF BAROREFLEX BRADYCARDIA: ROLE OF MEDULLARY $GABA_A$ AND $GABA_B$ RECEPTORS. K. Varga* and G. Kunos. LPPS, NIAAA, Bethesda MD 20892

The effects of EtOH on baroreflex bradycardia and on cardiovascular responses mediated by $GABA_A$ and $GABA_B$-receptors in the medullary dorsal vagal complex (DVC) were studied in urethane-anesthetized rats. EtOH, 1-3 g/kg administered i.v. or 25-200 nmol microinjected bilaterally into the DVC attenuated the reflex bradycardia elicited by graded i.v. doses of phenylephrine in control animals but not in rats pretreated with 3-mercaptopropionate, a GABA-depleting agent. Muscimol, 10-40 pmol intra-DVC, caused a pressor response and inhibited baroreflex bradycardia. The pressor response to muscimol was potentiated and a tachycardic response to muscimol emerged after intra-DVC EtOH. Baclofen, 20-80 pmol intra-DVC, caused pressor and tachycardic effects and inhibited baroreflex bradycardia. EtOH potentiated the pressor response to a low dose of baclofen. Bicuculline, 10 pmol intra-DVC, inhibited the responses to muscimol but not to baclofen, and reduced the baroreflex inhibitory action of EtOH. 2-Hydroxy-saclofen, 400 pmol intra-DVC, inhibited the responses to baclofen but not to muscimol, reduced the baroreflex inhibitory action of EtOH, and prevented EtOH-potentiation of the responses to muscimol. It is concluded that EtOH inhibits baroreflex bradycardia through the potentiation of the actions of endogenous GABA in the DVC. Both $GABA_A$ and $GABA_B$-receptors are involved in this action of EtOH.

EVIDENCE FOR A SYMPATHOEXCITATORY FUNCTION OF THE A5 NORADRENERGIC CELL GROUP. **M. B. Hug and J. Ciriello. Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.**

The contribution of the A5 noradrenergic cell group to the control of the circulation remains controversial. In this study a systematic exploration of the A5 region with microinjections (20nL) of L-Glutamic acid was done to investigate whether excitation of somata was responsible for the pressor responses observed during electrical stimulation. Microinjections of L-glutamic acid (1M) into the A5 region were made in chloralose anaesthetized, paralysed and artificially ventilated male Wistar rats. The ventral surface of the brainstem was exposed using a transpharyngeal approach. Increases in mean arterial pressure (22±-8mmHg) were observed at most (70%) of the sites from which cardiovascular responses could be elicited. At the remaining sites a depressor response (9±-4mmHg) was elicited. Pressor responses were associated with either no changes in heart rate or increases of 16±-9bpm (69% of sites). Depressor responses were primarily associated with decreases in heart rate (8±4bpm; 74% of sites). Pressor responses were consistently elicited from regions which overlapped the A5 noradrenergic cell group, whereas depressor responses were elicited from the dorsal aspects the A5 region and the region immediately dorsal to it. Selective destruction of noradrenergic terminals by intraventricular injections of 6-OHDA significantly attenuated the pressor responses (7±3mmHg). As A5 neurons have been shown to directly innervate the intermediolateral nucleus of the thoracic cord, these data are consistent with the proposed sympathoexcitatory role of A5 somata. VENTROLATERAL MEDULLARY PROJECTIONS TO THE PARABRACHIAL COMPLEX. S. Roder and J. Ciriello, Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

The ventrolateral medulla (VLM) and parabrachial (PBN) complex have been shown to be involved in central cardiovascular regulation. This study was done to investigate the distribution of fibers and terminals in the PBN complex originating from neurons within VLM in the rat. Fibers and terminals in PBN from the caudal (c) VLM, rostral (r) VLM and intermediate (int) VLM, were identified using the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L). PHA-L was iontophoresed into the cVLM, rVLM, or intVLM, and after a survival period of 7-10 days, transverse sections of the brainstem were processed immunohistochemically for the demonstration of PHA-L or tyrosine hydroxylase contained in fibers, terminals and perikarya. PHA-L labelled cells within the injection sites were observed to overlap the A1 and C1 catecholaminergic cell groups in the cVLM, rVLM or intVLM. PHA-L labelling in the PBN complex resulting from a cVLM injection was observed primarily in the caudal two third of Kölliker-Fuse nucleus (KF), and the external lateral and central subnuclei of PBN, whereas that resulting from a rVLM injection was primarily observed in the middle third of KF and the dorsal lateral subnuclei of PBN. PHA-L labelled fibers and terminals in PBN resulting from an intVLM injection were primarily found in the rostral two thirds of KF, and the external lateral, central lateral, superior lateral and medial subnuclei of PBN. Projections to the PBN complex were observed bilaterally but with an ipsilateral predominance. These data suggest a functional organization of VLM projections to PBN that may be involved in cardio-respiratory integration. (Supported by MRC and HSFO)

EFFECT OF COMBINED GLUTAMATE AND NEUROTENSIN MIRCOINJECTIONS INTO NUCLEUS AMBIGUUS ON HEART RATE. T. X. Zhang and J. Ciriello, Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

The nucleus ambiguus (AMB) is known to contain vagal cardiomotor neurons. In a previous study we have shown that microinjection of neurotensin (NT) into AMB elicits a vagal bradycardia. In this study, the possibility that NT and L-glutamate (Glu) microinjected into AMB (10-25nl) had a synergistic effect on the heart rate (HR) response was investigated. In addition, the effect of NT or Glu microinjections into AMB on the reflex vagal bradycardia elicited during activation of baroreceptors (l-phenylephrine, 10μg/ml, i.v.) was investigated. Experiments were done in alpha-chloralose anesthetized, paralysed and artificially ventilated male Wistar rats that had their spinal cord cut at the level of C2. Microinjections of Glu (10-25nmol) or NT (50-125pmol) elicited decreases in HR of 51$\pm$7 and 31$\pm$7bpm, respectively. Combined microinjections of Glu and NT elicited a decrease in HR (82$\pm$12bpm) that was not significantly different from the algebraic sum of the individual Glu and NT responses. In addition, microinjection of Glu significantly increased (86$\pm$20bpm), whereas NT did not alter (39$\pm$4bpm), the magnitude of the reflex vagal bradycardia elicited during baroreceptor activation. Taken together, these data suggest that Glu and NT act as neurotransmitters or modulators in the baroreceptor reflex pathway to AMB and that NT may exert a selective effect on vagal cardiomotor neurons whereas Glu may also activate other neuronal systems contributing to the reflex response. (Supported by MRC of Canada and HSFO).

396.19

CAROTID BARORECEPTOR PROJECTIONS TO THE NUCLEUS OF THE SOLITARY TRACT IN THE RAT. J. Ciriello, Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

The medullary connections of the carotid baroreceptors were studied in the rat using the transganglionic transport of cholera-toxin (CT) or wheat germ agglutinin (WGA) horseradish peroxidase (HRP). A small pledget of 0.1% CT-HRP or 2% WGA-HRP was applied into the adventitia of either carotid sinus after cauterizing the blood vessels and carotid sinus nerve (CSN) branches originating from the carotid body. In control animals 100nl of either solution was injected around the carotid bifurcation after cauterizing CSN branches to the carotid body. After a survival period of 48-72 h the animals were sacrificed and brainstem sections were processed using the tetramethyl-benzidine method. In animals with CT-HRP applications, dense terminal and fiber labelling was observed primarily in the caudal nucleus of the solitary tract (NTS); in the regions of the commissural (Com), medial (Sm), and dorsolateral (Sdl) subnuclei of the complex. Additionally, sparse labelling was observed in the area postrema (AP). In animals with WGA-HRP application, dense fiber and terminal labelling was found in the Sdl and interstitial subnuclei of NTS. Sparse labelling was also found in Sm and in Com at the level of AP. These data have provided the first anatomical demonstration of the termination site of carotid baroreceptor afferent fibers in the medulla of the rat and suggest that different types of afferent fibers originating in the carotid sinus may be selectively labelled with conjugates of HRP. (Supported by HSFO and MRC of Canada).

396.20

CARDIOVASCULAR EFFECTS OF PHOSPHATE BUFFERED SALINE MICROINJECTIONS INTO NUCLEUS TRACTUS SOLITARIUS. S. L. Hochstenbach, T. X. Zhang, M. B. Hug and J. Ciriello. Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

The nucleus tractus solitarius (NTS) is known to play an important role in the integration of cardiovascular afferent information. In this study, NTS was systematically explored for cardiovascular responsive sites during microinjections (20nl) of phosphate buffered saline (PBS, pH 7.2) containing 142 mM, 179 mM, 254 mM or 328 mM of NaCl. Decreases in arterial pressure (AP; range of means, 21$\pm$3 to 53$\pm$9 mmHg) and heart rate (HR; range of means, 5$\pm$2 to 40$\pm$8 bpm) were consistently elicited from only the caudal medial subnucleus of NTS in a dose dependant manner. Microinjection of PBS into area postrema did not elicit cardiovascular responses. Administration of atropine methyl bromide had no significant effect on the magnitude of the AP and HR responses. However, administration of hexamethonium bromide abolished both the AP and HR responses. Control microinjections (20nl) into the caudal medial subnucleus of a hypertonic solution of mannitol (400 mM) containing no NaCl of NTS did not elicit cardiovascular responses. These data suggest that within a restricted region of NTS there exists a pool of neurons sensitive to changes in sodium concentrations of the extracellular fluid, and when activated by the sodium these neurons elicit cardiovascular responses as a result of sympathoinhibition. (Supported by MRC of Canada and HSFO).

396.21

FACTORS MEDIATING THE HINDLIMB BLOODFLOW COMPONENT OF THE DEFENCE REACTION AND THEIR SENSITIVITY TO CLONIDINE. L.L. Watkins and W. Maixner. Dept. of Pharmacology and Dental Research Center, University of North Carolina, Chapel Hill, N.C. 27514.

We previously reported that clonidine inhibits the increase in hindlimb bloodflow (HLBF) associated with the cardiovascular defence reaction elicited by periaqueductal gray (PAG) stimulation in the rat (Neurosci.Abs.16:554,1990). The present experiments were designied to examine potential mechanisms contributing to this increase in HLBF and to examine their sensitivity to inhibition by clonidine. First, the role of epinephrine in the HLBF response was evaluated by measuring the effect of β_2-receptor blockade or adrenalectomy on PAG stimulation evoked changes in HLBF. Both β_2-receptor blockade and adrenalectomy mimicked clonidine's inhibitory effect on PAG-evoked increases in HLBF and prevented the inhibitory effect of clonidine on PAG-evoked increases in HLBF. Second, an isolated hindlimb preparation was utilized to examine whether decreased vascular resistance contributes to the HLBF response to PAG stimulation. Blood withdrawn from the left carotid artery was pumped into the rat's left femoral artery at a constant rate and changes in perfusion pressure were used to derive changes in vascular resistance. Rather than producing a decrease in vascular resistance, PAG stimulation produced a marked rise in vascular resistance that was not changed by clonidine. In summary, these results indicate that the HLBF component of the defence reaction is not associated with a neurally mediated decrease in vascular resistance, but rather is more likely due to a fall in hindlimb vascular resistance mediated by an evoked increase in circulating epinephrine or other humoral factors. Furthermore, these data indicate that clonidine's inhibition of this increase in HLBF is possibly associated with inhibition of epinephrine release from the adrenal glands. (Supported by DE08013 & RR05333).

Chemical And Electrical Stimulation Of The Rostral Ventrolateral Medulla (RVL) Increases Plasma ANF. J.H. Jiao*, P. Guyenet and A.J. Baertschi. Physiol. and Pharmacol. Depts., Univ. of Virginia, Charlottesville, VA 22908

Previous studies indicated that neural reflexes may control ANF secretion (Baertschi et al., AJP, '89,'90). The purpose of the present studies was to investigate whether the rostral ventrolateral medulla (RVL), a source of central sympatho-excitatory drive, can modulate the plasma level of atrial natriuretic factor (ANF). In anesthetized, artificially ventilated rats, electrical stimulations were stereotaxically applied to RVL. Unilateral electrical stimulation of RVL caused a 94 - 186% increase in plasma ANF over baseline ($P < 0.01$, $n = 11$), whereas sham stimulations and stimulations rostral and dorsal to RVL had no effect on plasma ANF. Unilateral microinjections of L- glutamate into RVL of artificially ventilated rats also induced a 81 $\pm$ 23% ($P < 0.01$, n=9) increase in plasma ANF compared to baseline and vehicle control injections. This indicates that cell bodies in the RVL and not fibers of passage mediated the ANF response. Glutamate injections into RVL elicited identical ANF responses in scopolamine-pretreated (n=5) and vagotomized (n=6) artificially ventilated rats, which implies that activation of the parasympathetic system does not stimulate ANF secretion. In contrast, injection of L-glutamate into the caudal ventrolateral medulla (CVL), known to inhibit RVL, elicited a 44 $\pm$ 5% decrease in plasma ANF ($P < 0.05$, n= 6). These results suggest that RVL may regulate cardiac ANF secretion via the sympathetic system. (Supported by AHA grant VA-89-F-9 and VA-90-G-8.)

397.1

HYPOTHALAMIC TRANSPORT OF ANGIOTENSIN-(1-7). C.H. Block and H.Vilsack*. Cleveland Clinic Foundation, Cleveland, OH 44195-5070.

Several studies by our group suggest a close anatomical association of angiotensin (Ang)-(1-7) with the hypothalamic vasopressin system. Specifically, Ang-(1-7) is localized by immunocytochemistry in neurons of the paraventricular (PVN) and supraoptic nuclei. Varicose immunoreactive fibers emanate from the PVN in the paraventriculo-neurohypophysial tract (PVT) and project to the neurohypophysis. In this hypothalamo-neurohypophysial system, anatomical changes suggestive of transport of Ang-(1-7) occur in response to 24 hour-dehydration in a manner similar to vasopressin, and Ang-(1-7) is not visualized in the homozygous Brattleboro rat. The current studies address whether Ang-(1-7) is transported from the PVN to the neurohypophysis. Stereotaxic knife-cuts were placed through the PVT in pentobarbital-anesthetized rats. The animals were perfused transcardially 24, 48, or 72 hours later and brain tissue was processed for immunocytochemical localization of Ang-(1-7).

Unilateral knife-cuts placed lateral to the PVN, severing part or all of the PVT, resulted in fibers engorged with Ang-(1-7) immunoreactivity approximately 20-50 μm distal to the knife-cut. The appearance of the fibers beyond 50 μm was similar to the control side. Ang-(1-7)-neurons were diffusely spread throughout the magnocellular PVN and were decreased in number on the side ipsilateral to the knife-cut after the 72-hour survival period. While Ang-(1-7) immunoreactivity in the neurohypophysis was less intense from control animals, no anatomical changes in the peptide distribution were observed.

The data from this study supports the hypothesis that Ang-(1-7) is transported in the PVT to the neural lobe. However, the possibility that angiotensin precursors are taken up and processed to Ang-(1-7) by the neural lobe cannot be excluded. The lack of changes in the neurohypophysis is not surprising since much of the fiber input arises from the supraoptic nucleus.

BAROREFLEX AND VASOPRESSIN RESPONSES IN GUANETHIDINE-TREATED RATS. EE Benarroch, JD Schmelzer*, PA Low. Neurophysiology Lab, Mayo Clinic, Rochester, MN 55905

Guanethidine (Gu) produces chemical sympathectomy in rats (GuSx). We explored baroreflex (BR) and vasopressin (AVP) responses as potential mechanisms for maintenance of arterial pressure (AP) in GuSx rats. Rats (350-450 gr) received Gu (40 mg/kg i.p. for 5-8 weeks) or saline. After 1-4 weeks of treatment, they were cannulated under ether anesthesia for monitoring of AP and heart rate (HR), for IV bolus of phenylephrine (Phe, 0.5-2 ug/kg), and for plasma AVP sampling. In conscious rats, BR was measured as the maximum decrease in HR (ΔHR) in response to increases in AP (ΔAP) induced by Phe. AVP was measured at rest and after 25% blood volume loss. As compared to controls, GuSx showed (a) similar resting AP and AVP (b) decreased BR responses to Phe (Δ HR/Δ AP: -1.10 ± 0.16 vs. -1.89 ± 0.13 beats per min/mmHg, $p<0.01$), and (c) exaggerated AVP response to hypovolemia (Δ AVP: 19.7 ± 2.6 vs. 12.9 ± 1.3 pg/ml, $p<0.05$). In GuSx rats, microinjection of L-glutamate (0.01-100 nmol) into the nucleus of the tractus solitarius (NTS), elicited decreases in AP and HR comparable to controls. Thus (a) GuSx rats have changes in BR and AVP responses which may contribute to maintenance of AP (b) these changes may not be due to altered NTS responsiveness to cardiovascular afferent inputs.

CENTRALLY ADMINISTERED INSULIN ALTERS PLASMA CATECHOLAMINE LEVELS BUT NOT BLOOD PRESSURE OR HEART RATE. L.E. Ohman and J.R. Haywood. Department of Pharmacology, The University of Texas Health Science Center at San Antonio, San Antonio, TX 78284-7764.

The present studies investigated the effect of insulin delivered centrally on plasma norepinephrine (pNE), and epinephrine (pEPI), blood pressure (BP), and heart rate (HR). Insulin (10 μU/min) or artificial cerebrospinal fluid (aCSF) was infused into the third ventricle of male Sprague-Dawley rats (n=6) for 60 min. Neither BP nor HR were significantly altered by aCSF or insulin. Basal levels of pNE and pEPI did not differ between treatments (aCSF: 96.5 ± 15.7, 83 ± 22.2 pg/ml; insulin: 81.3 ± 16.3, 80.6 ± 15.6 pg/ml). The ventricular infusion of insulin increased pNE 88 ± 59 %, and pEPI by 108 ± 63 % ($p=.07$); aCSF produced a 0.05 ± 11 % increase in pNE, and 27 ± 19 % elevation in pEPI. A second study was performed to localize the site of the sympathoexcitatory action of insulin. Insulin (0.1 μU/min, n=5) or aCSF (5 nl/min, n=4) was bilaterally infused into the paraventricular nucleus (PVN) for 30 min. Again, neither BP or HR were significantly altered by aCSF or insulin. Basal pNE did not differ between aCSF and insulin groups (201.7 ± 44.2; 160.2 ± 19.1 pg/ml), but was decreased by both treatments (aCSF: -30 ± 6.5 %; insulin: -19 ± 11 %). Resting pEPI was similar (aCSF: 166 ± 24.6; insulin: 217.6 ± 42.8 pg/ml), and was slightly altered by aCSF (-13 ± 9 %). Insulin significantly decreased pEPI (-36 ± 2.4 %; $p<.01$). Plasma glucose was slightly elevated by both treatments. These results suggest that insulin delivered into the ventricular system has a sympathoexcitatory effect, but appears to be sympathoinhibitory when administered into the PVN. Cardiovascular and Behavioral Effects of Fetal Hypothalamic Grafts in Hypertensive and Normotensive Rats C. A. Murphy, B. G. Yongue, J. Cheng and L. Skaredoff. New York State Psychiatric Institute, Columbia University, New York, NY 10032.

Spontaneously hypertensive (SHR) rats exhibit higher blood pressures, heart rates, salt appetite and activity levels, and lower body weights compared to inbred normotensive Wistar-Kyoto (WKY) rats. To examine the suggested involvement of intra-hypothalamic factors in phenotypic cardiovascular and behavioral traits in these strains, we grafted fetal hypothalamic tissue from SHRs and WKYs into the third ventricle of hypertensive and normotensive hosts. Donor tissue was implanted into the antero-ventral 3rd ventricle of male SHR, WKY or outbred Wistar hosts at either 25 or 90 days of age. Systolic blood pressure, heart rate, body weight, and locomotor activity were monitored at 3-4 week intervals following transplantation. At 5 months of age, intakes of water and .9% saline were recorded in all subjects in sodium-replete and sodium-depleted conditions. Implants of SHR hypothalamus produced higher blood pressures at 30 and 60 days of age in Wistar hosts grafted at 25, but not at 90 days of age. This effect did not persist at later ages. Wistar hosts implanted with SHR hypothalamus drank significantly more water than rats receiving SHR cortex or WKY tissue. Need-free salt intake was decreased in Wistar hosts grafted with WKY hypothalamus compared to Wistar hosts grafted with either SHR cortex or hypothalamus. In contrast, WKY hypothalamic or cortical grafts did not differentially affect SHR hosts for any variable tested. Moreover, heart rate, body weight, body temperature and activity level did not vary as function of graft type in any host. These results indicate that blood pressure and fluid-regulating behaviors can be altered by grafted tissue, in a way that is determined not only by the neuroanatomical source of the graft but by genetic factors in both the donor and host as well. We believe that this manipulation will prove useful for studying neural factors controlling consummatory behaviors and cardiovascular regulation. (BRSG 903-E004X, NIMH 00803, NIMH 45951)

CORTICOSTEROID BINDING IN LIMBIC BRAIN REGIONS OF NORMOTENSIVE AND HYPERTENSIVE SYRIAN HAMSTERS. **X. Chen and B. B. Turner. Department of Physiology, James H. Quillen College of Medicine, East Tennessee State University, Johnson City, TN 37614-0002.**

The Golden Syrian hamster differs from the rat with respect to the distribution of corticosteroid receptor types in limbic brain regions. In this study we used in vitro autoradiography to determine whether differences in either the number of Type I (mineralocorticoid) or Type II (glucocorticoid) receptors in specific brain regions are associated with hypertension in the hamster. Five outbred normotensive and five inbred hypertensive male hamsters were used. Resting blood pressures (hind limb) were 100 ± 4 mmHg for the normotensive and 138 ± 3 mmHg for the hypertensive hamsters. Hamsters were sacrificed (intra-cardiac perfusion) 12 hr after adrenalectomy. Adjacent 20 sections were incubated for 30 min with either 5 nM ^{3}H-corticosterone (B) or ^{3}H-B plus 1.25 μM RU28362; 5 μM B was used for non-specific binding. Sections were exposed for 12 weeks to LKB Ultrofilm. Binding in sixteen hippocampal regions, lateral septum, and central nucleus of the amygdala (Ce) were measured with a MCID image analysis system. Hypertensive hamsters had only approximately one-half the Type I and Type II binding of controls in both the lateral septum and in the region of the Ce. These differences closely approached, but did not reach statistical significance. No differences in binding between normotensive and hypertensive animals were found in any of the hippocampal regions. If these observations are confirmed, the possibility that region specific reductions in receptor number contribute to the development of hypertension will need to be evaluated. Supported by NIH RR05959.

HYPOTHALAMIC DEFENSE AREA MODULATION OF THE BARORECEPTOR REFLEX IN RABBITS. P.M. McCabe, Y-F. Duan, R.W. Winters*, E.J. Green, and N. Schneiderman. Dept. Psychology, Univ. of Miami, Coral Gables, FL 33124.

Previous work from our laboratory has identified the rabbit hypothalamic defense area (HDA). Electrical stimulation of this region elicits tachycardia, a pressor response, increased hindlimb blood flow, increased ventilatory rate (Markgraf et al., 1991), and escape responses (unpublished observations). Some investigators report that activation of the HDA suppresses both the cardiomotor and vasomotor components of the baroreceptor reflex (BRR), whereas others report inhibition of the cardiomotor component only. The present study assessed HDA modulation of the BRR in the rabbit.

New Zealand albino rabbits were anesthetized with isoflurane, and monopolar stainless steel electrodes were implanted in the HDA. The aortic nerve was then exposed and placed on a monopolar silver hook electrode. The HDA was electrically stimulated with a continuous train (125-300 μA, 100 pps) alone for 10 sec, followed by concurrent stimulation of the HDA and aortic nerve (100-150 μA, 32 pps) for 10 sec. After the HDA stimulation was terminated, the aortic nerve was stimulated alone for 10 sec. Histological examination of the hypothalamus revealed that stimulation sites were in the dorsal posterior hypothalamus, medial to the mammilothalamic tract and the descending column of the fornix, previously defined as the HDA.

Stimulation of the HDA produced tachycardia (+12.3 bpm) and a pressor response (+10.6 mmHG). Concurrent stimulation of HDA and the aortic nerve elicited a bradycardiac/depressor response (-8.2 bpm, -15.4 mmHG), whereas stimulation of the aortic nerve alone led to a larger bradycardiac response (-14.1 bpm) but a smaller depressor response (-10.8 mmHG). The data suggest that HDA stimulation attenuates the cardiomotor component of the BRR, but augments the vasomotor component. (Supported by HL07426 and HL36588).

SALT-INDUCED HYPERTENSION IN DAHL RATS IS ASSOCIATED WITH ENHANCED EXPRESSION OF VASOPRESSIN mRNA WHICH IS MODULATED BY ANGIOTENSIN II AND ALPHA-2 ADRENERGIC RECEPTORS. Bang H. Hwang, Timothy Peters* and Prince Chan*. Terre Haute Center for Medical Education, Indiana Univ. Sch. of Med., Terre Haute, IN 47809.

Central mechanisms for salt-induced hypertension are not clear. Dahl salt-resistant and salt-sensitive (SS) rats were fed with high-salt diets. We used ^{35}S-vasopressin (VP) oligonucleotide probe to study VP mRNA after in situ hybridization, and ^{125}I-angiotensin II (AII) and -iodoclonidine ligands to label AII receptors and alpha-2 adrenergic (A2) receptors respectively. VP mRNA, AII and A2 receptors were measured using quantitative autoradiography. Results showed that hypertension was developed in SS rats whose hypothalamic AII receptors and VP mRNAs were significantly increased, whereas A2 receptors were also up-regulated. This study suggests that salt-induced hypertension is associated with enhanced VP mRNA expression which is controlled by AII receptors and modulated by A2 receptors. Supported by PHS grant NS25087.

NEUROTENSINERGIC MODULATION OF NEURONAL RESPONSES IN THE LATERAL HYPOTHALAMIC AREA (LHA) TO STIMULATION OF CARDIOVASCULAR SITES IN THE INSULAR CORTEX (IC). G.V. Allen and D.F. Cechetto. Robarts Research Institute, University of Western Ontario, London, Ontario, Canada, N6A 5K8.

Sympathetic responses elicited from the IC involve a synaptic relay in the LHA (Cechetto and Chen,'90). This study examines, in the anesthetized rat (chloral hydrate-urethane), the effects of iontophoresis of neurotensin (NT) on extracellularly recorded responses of LHA neurons responding to electrical stimulation of the IC (500 μA, 0.5-0.7 Hz). Of 82 spontaneously firing neurons, 32 units (39%) responded to electrical stimulation of cardiovascular pressor or depressor sites in the IC. Of these, 9 units (28%) were excited, 11 units (34%) showed excitation followed by inhibition, 9 units (28%) were inhibited and 3 units (9%) showed inhibition followed by excitation. Iontophoresis of 0.1-1.0 mM NT (25-100 nA) potentiated 11 (34%) of the excitatory responses and attenuated 2 (6%) of the inhibitory responses. Three of the neurons that responded to IC stimulation and six of the neurons that did not respond to IC stimulation exhibited an increased firing rate to NT iontophoresis. These findings indicate that NT may play an important role in the neuromodulation of cardiovascular regulatory commands from the insular cortex. LESION OF THE MEDIAL SEPTAL AREA IMPAIRS THE PRESSOR AND NATRIURETIC RESPONSES INDUCED BY CENTRAL CHOLINERGIC ACTIVATION IN RATS. A.C. Luiz*; Wilson A. Saad; L.A.A. Camargo*; J.E.N. Silveira*; A. Renzi*; L.A. De Luca Jr.*; Willian A. Saad* and J.V. Menani*. Department of Physiology, Dentistry School, UNESP, Araraquara 14800 SP, Brazil.

Intracerebroventricular (ICV) injection of the cholinergic agonist carbachol (CARB) in rats produces natriuresis, kaliuresis, water intake and hypertension. In this study we investigated the effect of lesion of the medial septal area (MSA) in these responses. Male rats with sham or electrolytic lesion of the MSA were implanted with chronic stainless steel cannula into the lateral ventricle. ICV CARB (8 nmol) in sham rats induced pressor (35 ± 5 mmHg), dipsogenic (10.2 ± 1.5 ml/h), natriuretic (551 ± 83 uEq/120 min) and kaliuretic (170 ± 17 uEq/120 min) responses. Acute (1-7 days) MSA lesions reduced the pressor (18 ± 3 mmHg), natriuretic (178 ± 58 uEq/120 min) and dipsogenic (5 ± 1.3 ml/h) responses. Chronic lesions (14-18 days) reduced only pressor and natriuretic responses. Kaliuresis was not changed by MSA lesions. These results suggest that MSA plays an important role on the pressor and natriuretic responses induced by central cholinergic activation in rats.

LESION OF THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS AFFECTS THE DEVELOPMENT OF THE PRESSOR RESPONSE TO COMMON CAROTID OCCLUSION IN CONSCIOUS RATS. M. I. B. Bedran de Castro* and J. C. Bedran de Castro. Department of Physiology, Dentistry School, UNESP, Araçatuba SP 16015, Brazil.

Pressor response to common carotid occlusion (cco) produced by implanted occlusion cuffs during 60 seconds in conscious rat has two components: an initial peak (IP) of carotid reflex origin and a maintained response (MR), that is, a plateau of lower intensity observed during the last 30 seconds of occlusion, which does not depend on carotid innervation and is probably of central ischemic origin. The present study was performed to investigate the role of the paraventricular nucleus of the hypothalamus (PVH) to the development of the pressor response to cco. Acute lesion of PVH (6 hours, MAP = 132 ± 3 mm Hg) decreased IP by 24% (38 ± 3 vs 50 ± 3 mm Hg) and MR by 28% (23 ± 3 vs 32 ± 2 mm Hg). Chronic PVH lesion (6 days) produced similar reductions (MAP = 122 ± 3, IP = 37 ± 5, MR = 20 ± 3 mm Hg). Aortic denervation, performed 6 hours before cco increased the depressed responses observed in chronic PVH lesioned rats (MAP = 125 ± 5, IP = 45 ± 4, MR = 32 ± 5 mm Hg). These data suggest that PVH plays a role in the integration of the pressor response to cco and that the important buffer effect of the aortic baroreceptors on the cco response is still present after PVH lesion.

HYPOTHALAMIC GABAERGIC INFLUENCES ON TREADMILL EXERCISE RESPONSES IN RATS. J.M. Overton*, M.W. Redding*, S.L. Yancey*, and R.W. Stremel. Dept. Physiology & Biophysics and Exercise Physiology, University of Louisville, Louisville, KY 40292.

To test the hypothesis that a GABAergic mechanism within the posterior hypothalamus (PH) mediates the cardiovascular adjustments to dynamic exercise in conscious animals, Sprague-Dawley rats were chronically instrumented with bilateral guide cannula directed at the PH, a carotid cannula, and Doppler flow probes on the mesenteric and iliac arteries. Saline (SAL, 100 nl/side) or the GABA agonist, muscimol (MUS, 125 ng/100 nl/side), were injected into the PH during steady-state treadmill exercise (20 m/min). SAL had no effect on mean arterial pressure (MAP), heart rate (HR), mesenteric resistance (MR) or iliac resistance (IR) during exercise. MUS had no consistent effect on MAP (2 ± 1 % ▲), HR (2 ± 4 % ▲), or MR (-3 ± 4 % ▲), but produced a significant increase (22 ± 7 %) in IR. In addition, hypothalamic muscimol reduced exercise run time and induced behavioral changes (e.g., sedation) most evident post-exercise. The data suggests hypothalamic GABAergic modulation of exercise hyperemia in conscious animals. Supported by Univ. of Louisville Graduate School.

HYPOTHALAMIC STIMULATION MAY INCREASE ADRENO-LUMBAR VENOUS FLOW AND EPINEPHRINE SECRETION IN THE CAT. V.K. Bergdall* and S.L. Stoddard. Dept. of Anatomy, Indiana Univ. Sch. of Med., Ft. Wayne, IN 46805.

This study was designed to determine the effect of electrical stimulation of the preoptic region and hypothalamus on adreno-lumbar (AL) venous flow and catecholamine (CA) secretion in the cat. Electrode sites (N=75) were chosen in awake, restrained cats (N=16) that elicited signs of sympathoadrenal activation (*e.g.*, hissing, pupillary dilatation). Later, under methoxy-flurane anesthesia, cannulae were placed in the left jugular and AL veins and femoral artery. AL venous samples were collected by gravity and the volume measured during 3 consecutive 1-min periods: 2 prior to stimulation and 1 commencing with stimulus onset (square-wave, biphasic pulses; 60 Hz; 0.6 mA; 30 sec). CA levels were determined by radioenzymatic assay using COMT and S-adenosyl methionine [methyl-^{3}H]; secretion was expressed as ng/min. Hypothalamic stimulation most frequently increased the secretion of both NE and EPI, although evidence of preferential secretion was observed. Stimulation of 17 sites, primarily in the medial hypothalamus and nucleus of the diagonal band, increased AL flow > 12% baseline and elicited significantly greater increases in EPI secretion. These data are consistent with the hypothesis that secreted EPI acts locally to increase blood flow through the adrenal medulla.

397.13

CALCITONIN GENE-RELATED PEPTIDE (CGRP) MODULATION OF VISCERAL AND NOCICEPTIVE INPUTS TO THE VENTRAL BASAL THALAMUS (VBT). R.Z. Liang* and D.F. Cechetto. Robarts Research Institute, Univiversity of Western Ontario, N6A 5K8.

Visceral and nociceptive afferents terminate in the VBT. CGRP has been demonstrated in visceral relay neurons from the parabrachial nucleus to the VBT. The effects of iontophoretic application of CGRP on the responses of extracellularly recorded thalamic neurons to activation of visceral and nociceptive receptors was examined in chloralose-anesthetized rats. Few neurons (39/800, 5%) were observed to change their spontaneously firing rate in response to application of CGRP. CGRP enhanced the responses of: 12/20 neurons responsive to baroreceptor activation (phenylphrine i.v.) of a total of 55 tested; 11/22 to chemoreceptor activation (NaCN i.v.) of a total of 53 tested; 6/18 to chemoreceptor activation (10% CO_2 in inspired air) of a total of 48 tested; 6/15 to gastric mechanoreceptor activation (gastric balloon inflation) of a total of 33 tested; 5/12 to taste stimuli (NaCl on the tongue) of a total of 31 tested; 11/18 to pain stimuli (cutaneous pinch) of a total of 59 tested. In addition, nociceptive inputs converged on a large proportion of the visceral responsive neurons. These results suggest that CGRP serves as a major modulator of visceral and nociceptive inputs to neurons in the ventral basal thalamus.

FOREBRAIN 5-HT_1 RECEPTORS CAUSE SYMPATHOEXCITATION IN RATS. A G Ramage, I K Anderson* and G R Martin[1]*. Depts. Pharmacology, Royal Free Hospital School of Medicine, London, NW3 2PF and [1]Wellcome Laboratories, Kent, UK

Lateral ventricular (i.c.v.) application of 5-HT causes a rise in blood pressure which is thought to be due to activation of 5-HT receptors located in the anterior hypothalamus/preoptic region. The nature of the receptors mediating this pressor effect were investigated.

In α-chloralose anaesthetized rats recordings were made of BP, HR, renal (RNA) and phrenic nerve activity (PNA). 5-HT (40, 120 nmol kg^{-1}), 5-CT (3 nmol kg^{-1}), DP-5-CT (0.3, 3 nmol kg^{-1}), 8-OH-DPAT (40, 120 nmol kg^{-1}) and saline were given by microinjection (5μl over 20s) i.c.v.

5-HT, DP-5-CT and 5-CT all caused rises in BP, HR and RNA of 24 ± 3 mmHg, 63 ± 13 beats min^{-1}, 126 ± 33 % and 24 ± 4 mmHg, 63 ± 9 beats min^{-1}, 112 ± 29 % for the highest dose of 5-HT and DP-5-CT respectively, and 14 ± 4 mmHg, 42 ± 4 beats min^{-1}, 142 ± 43 % for 5-CT. 8-OH-DPAT 40 and 120 nmol kg^{-1} only caused a rise in HR of 28±4 and 50 ± 13 beats min^{-1} respectively. 5-HT differed from DP-5-CT and 5-CT in that the rise in blood pressure was associated with an initial decrease in HR and RNA. PNA was only increase by 8-OH-DPAT. Pretreatment with methiothepin attenuated the effects of DP-5-CT on all variables.

These results suggest that activation of 5-HT_1 receptors are responsible for the sympathoexcitation and pressor effects observed when 5-HT is injected i.c.v.

HYPOTHALAMIC EXCITATORY AMINO ACID (EAA) RECEPTORS MEDIATE STRESS-INDUCED TACHYCARDIA. R.P. Soltis and J.A. DiMicco. Dept. of Pharmacology and Toxicology, Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Microinjection of the GABA-A receptor agonist muscimol into the dorsomedial hypothalamus (DMH) in rats prevents the tachycardia and hypertension seen in an air-stress paradigm. Here, we examined the effect of injecting EAA antagonists into the DMH on heart rate (HR) and blood pressure during air stress. Conscious chronically instrumented rats received bilateral injections (100 nl/side) of either artificial CSF (ACSF, Groups I and II, n=12 each), the non-selective EAA receptor antagonist kynurenate (KYN, Group I, n=4 each dose), the NMDA receptor antagonist AP5 100 pmol, the non-NMDA EAA receptor antagonist CNQX 50 pmol or both AP5 and CNQX (Group II, n=4 each treatment). Below are means ± SEM of basal HR (beats/min) and changes from basal HR 3 min after start of stress (5 min post injection).

Group I	Basal	Change	Group II	Basal	Change
ACSF	345±9	+153±6	ACSF	343±7	+154±4
KYN 1 nmol	327±12	+102±15*	AP5	341±5	+104±6*
KYN 3 nmol	330±17	+58±4*	CNQX	342±17	+110±14*
KYN 10 nmol	341±14	+18±9*	AP5+CNQX	338±12	+58±13*

* different from ACSF treatment by ANOVA ($P < 0.05$)

These results suggest that activity at EAA receptors in the DMH is required for the generation of stress-induced tachycardia. (Supported by USPHS grants 5 SO7 RR 5371 and NS 19883, and the American Heart Assoc., Ind. Affil.)

HYPOTHALAMIC PEPTIDERGIC NEUROMODULATION OF THE SPECIFIC CARDIAC EFFECTS OF INSULAR CORTEX PHASIC MICROSTIMULATION: S.M.Oppenheimer, T.Saleh* and D.F.Cechetto. Robarts Research Institute/University of Western Ontario London, Canada N6A 5K8.

Microstimulation of the rat posterior insular cortex in phase with the ECG R wave elicits pure cardiac effects and has demonstrated insular cardiac chronotropic organisation (Oppenheimer and Cechetto'90). As the lateral hypothalamus (LHA) mediates insular pressor effects (Cechetto and Chen '90), insular tachycardia was anticipated to be responsive to LHA manipulations. Insular tachycardia sites were phasically stimulated once during each cardiac cycle with 500 μA for 1 minute before and after microinjections into the LHA. The insular tachycardia response was abolished in chloralose-anesthetised rats by LHA microinjection of the synaptic blocker cobaltous chloride (4mM). LHA microinjection of kynurenic acid (250mM) attenuated insular tachycardia by 95%. Microinjection of naloxone (2.5mg/ml) attenuated the tachycardia by 95%; met-enkephalin (2mg/ml) was without effect on this response. Leu-enkephalin (2mg/ml) and neuropeptide Y (NPY) (0.01mM) doubled the magnitude of the tachycardia response. We suggest that the LHA contains an obligatory synapse mediating insular tachycardia and that glutamate is the likely neurotransmitter at this site. Neuromodulation of insular tachycardia may be effected by opiate and NPY receptors, a finding of considerable clinical relevance.

STRESS-INDUCED HYPERTENSION IN THE BHR: DURATION OF STRESSOR. D. Hatton, J. DeMerritt*, & D. McCarron*, Oregon Health Sciences University, Portland, OR 97201

Daily exposure to 2 hours of shock-shock conflict or 2 hours of air-jet stress (AJS) has been shown to cause sustained elevations of blood pressure in borderline hypertensive rats (BHR). It is of interest to determine whether shorter stress sessions would be effective in causing comparable increases in blood pressure. In the current study, the effect of 20 min of daily AJS on blood pressure was contrasted with the effects of 120 min of AJS. At eight weeks of age, male BHRs were restrained in plexiglass tubes and exposed to either 20 or 120 min of AJS for 5 days/week for five weeks. Air-jet stress consisted of a stream of air directed toward the top of the head. Maturational controls were left undisturbed in the home cage except for weekly measurement of blood pressure. Systolic blood pressure was taken weekly using a tail-cuff method (NARCO). The 20 min group had significantly higher systolic BP than the control group ($p<.001$), and the 120 min group had significantly higher BP than the 20 min group ($p<.001$). By the 5th week systolic BP was 143, 167 and 174 mmHg in the control, 20 and 120 min groups respectively. However, direct measurement of BP in the home cage at the end of the 5 week period showed no difference between the 20 and 120 min groups (117, 130, 127 mmHg for control, 20 and 120 min). Thus, it is questionable whether 120 min of AJS causes a proportionately greater increase in BP than 20 min of AJS in the BHR.

CHOLINERGIC AND ADRENERGIC MECHANISMS IN THE CARDIOVASCULAR RESPONSE TO STARTLE B.K. Taylor and M.P. Printz. Pharmacology 0636, Univ. Cal. San Diego, La Jolla, CA 92093.

Complex cardiovascular (CV) responses consisting of pressor, bradycardia and tachycardia result from airpuff stimuli delivered to conscious, unrestrained, catheterized Wistar-Kyoto rats. To investigate neurotransmitter modulation of the CV response, we used intracerebroventricular (ICV) administration of the acetycholine depletor hemicholinium-3 (HC-3), muscarinic-receptor antagonists scopolamine (Scopol) & 4-DAMP and clonidine. Saline or drug (in 5 μl) was infused via ICV cannula placed one week earlier and responses measured after the time interval shown. Resting blood pressure and heart rate (HR) were not affected by drug treatment except after administration of clonidine (Saline:343±7 bpm, Clonidine: 315±7 bpm). Behavioral (motor) responses were dissociated from the CV responses as shown below. We conclude that for the doses of agents used, the pressor response is influenced by either α-2 adrenergic or imidazole mechanisms while the bradycardia response is modulated by both muscarinic receptor blockade and clonidine.

AGENT	DOSE (μg/kg)	TIME (min)	↓ HR* (bpm)	MOTOR*	PRESSOR* (mmHg)	↑ HR** (bpm)
Saline (9)	—	120	-55±10	49±7	49±3	28±4
HC-3	5	120	-14±6	32±8	39±3	25±3

RANDOM LIGHT/DARK CYCLES INCREASE PLASMA CHOLESTEROL IN RATS. E.S. Halas and L.M. Klevay.* Department of Psychology, University of North Dakota and USDA, ARS, Grand Forks Human Nutrition Research Center, Grand Forks, ND 58202.

Sixty male weanling rats of the Sprague-Dawley strain were divided into four groups. Two groups were illuminated continuously for eight hours, then were exposed to darkness for 16 hours, beginning at midnight, 8 a.m. or 4 p.m. Each light/dark cycle lasted two, three or four days, with cycle duration and onset of illumination being randomized. The other two groups were housed in a standard 12-hour light/dark room. One group in each room was fed a purified diet containing 2 ppm copper (Cu) while the other two groups were fed the same diet containing 5 ppm Cu. This diet (*Am J Clin Nutr 26: 1060, 1973*) was based on sucrose (62%), egg white (20%) and corn oil (10%); it contains all known essential nutrients. The rats were killed after six weeks. Cholesterol measured by an enzymatic, colorimetric method was elevated approximately 11% ($p<0.025$) in the random light/dark cycle groups. This elevation was less than that (33%, $p<0.005$) found in a preliminary experiment done with only the lower Cu diet. The lower Cu diet depressed both hematocrit ($p<0.004$) and body weight ($p<0.009$) approximately 6%. There was no anemia (mean hematocrit > 43%); a diet marginal in Cu may decrease body size and hematocrit. The results suggest shift workers are at risk for elevated plasma cholesterol.

BED NUCLEUS OF THE STRIA TERMINALIS NEURONS RESPOND TO BOTH NOCICEPTIVE AND STRESS-RELATED STIMULI. J.H. Casada and N. Dafny. Department of Neurobiology and Anatomy, The University of Texas Medical School at Houston, Houston, TX 77225.

The bed nucleus of the stria terminalis (BNST) has been shown to modulate the expression of many components of the stress response including corticosterone secretion, autonomic activity, and increases in agonistic and locomotor behavior. The present experiment was designed to determine the degree to which stress is generalized in BNST by determining if BNST neurons would respond similarly to two different stress-related stimuli. In acute experiments, 20 male Sprague Dawley rats (240-350 g) were anesthetized with 1.25 g/kg urethane. A bipolar stimulating electrode was placed in the amygdala and a recording glass microelectrode was placed in BNST. Eighty-four spontaneously active neurons were recorded from BNST. 66% of these cells responded to electrical stimulation of the amygdala, predominantly with driven activity (latency = 17.25 ± 5.41 ms). 33% responded to a noxious stimulus, tail pinch (TP), predominantly with an increase in firing rate, but only 4% responded to cutaneous stroke, a control somatosensory stimulus. A chi-square test of the interaction between amygdala stimulation and TP revealed that the proportion of neurons responsive to each are independent of one another ($p=0.25$). Thus, while the neurons of BNST are responsive to at least two different stress-related stimuli, the pathways by which these reach BNST appear to differ.

IDENTIFICATION OF ANGIOTENSINERGIC PATHWAYS IN THE PVN. K.A. Roberts, J.W. Harding, L.L. Jensen, J. Hanesworth* and J.W. Wright. Departments of Psychology and VCAPP, Washington State University, Pullman, WA 99164-4820.

Previous studies have indicated that the paraventricular nucleus (PVN) is important in the regulation of body water balance and cardiovascular activity. The PVN receives afferent input from the subfornical organ (SFO) (Lind et al., 1985; Gutman et al., 1986) and is important in the regulation of cardiovascular activity (Ishibashi and Nicolaidis, 1981). In an attempt to verify these previous studies, we have utilized the retrograde transport of fluorescent microspheres to map afferent pathways from the SFO to PVN. The use of latex microspheres offered several advantages including low toxicity and minimal diffusion from the injection site. Eight spontaneously hypertensive rats (SHRs) were injected with rodamine labelled latex microspheres. Small volumes, 30nl, of the beads were injected using a 10 ωl Hamilton syringe, via a 33 g injector into the PVN in alert animals. The animals were sacrificed after 48 hrs and brains were extracted, fixed and mounted. The sections were then observed under a fluorescent microscope and slides were taken of the injection site and SFO. Analysis of 30 micron frozen sections confirmed the existence of a strong SPO-PVN pathway. Although we have not yet demonstrated the angiotensinergic nature of this pathway, push-pull cannula studies demonstrated that direct injection of AII into the SFO resulted in massive release of angiotensins in the PVN. In addition, similar levels of release could be observed in the PVN following 48 hours of water deprivation.

REGULATION OF AUTONOMIC FUNCTIONS: GENITO-URINARY CONTROL

398.1

NEURAL REGULATION OF "PSYCHOGENIC" ERECTION: EXPOSURE TO RECEPTIVE FEMALES FACILITATES REFLEXIVE ERECTION IN RATS, EVEN AFTER HYPOGASTRIC NERVE SECTION. B. D. Sachs and Y.-C. Liu. Psychology and Biobehavioral Sciences Degree Programs, Univ. of Connecticut, Storrs, CT 06269-1020.

Sexually experienced male rats received bilateral transections of their hypogastric nerves (HGNx) or sham operations (SHAM). Three weeks later the males were placed for two minutes in an empty cage or in a cage with two inaccessible receptive females, and then were immediately tested for reflexive penile erections (supine position, penile sheath retracted, no further penile stimulation). Exposure to females reduced the erection latency by about 40% ($p<.01$), and other measures of erectile response revealed similar facilitation, irrespective of prior HGNx or SHAM surgery. We infer that (a) stimuli received by receptors in the head of male rats can facilitate reflexive penile erection, and (b) this psychogenic facilitation of reflexive erections is not mediated by the hypogastric nerves, the only nerves previously proven to mediate psychogenic erection.

398.2

PHYSIOLOGY OF MUSCLE AFFERENTS IN THE BULBOSPONGIOSUS AND ISCHIOCAVERNOSUS OF RATS. R.D. Johnson and V.P. Dugan*. Department of Physiological Sciences, College of Veterinary Medicine, University of Florida, Gainesville, FL 32610.

The bulbospongiosus and ischiocavernosus are perineal muscles that have a role in rodent male sexual behavior, specifically functioning in penile glans engorgement (cups), dorsal penile movements (flips), and ejaculation. It has been suggested that sensory receptors in these muscles play a role in these events and possibly also mediate sensations associated with sexual climax. To investigate the physiological responses of these afferents, we recorded from single afferent fibers in urethane anesthetized rats. Single fiber recordings were made from either dorsal root filaments or from the motor branch (MB) of the pudendal nerve. The muscles were exposed for stimulation. Receptors were found in the ischiocavernosus muscle and in all parts of the bulbospongiosus muscle. Conduction velocity measurements indicated they were primarily Group II myelinated afferent fibers. Almost all of the afferents were typical muscle stretch receptors exhibiting a resting discharge, a regular slowly adapting discharge rate, an increased discharge to muscle stretch, and a short silent period during muscle contraction. They also responded to penile extension and preputial retraction (ie. supine penile reflex test). Some afferents were rapidly adapting, located in tendinous tissue, and increased their discharge during muscle contraction. We have recorded from dorsal horn neurons driven by MB afferents. These results suggest that sensory receptors in the ischiocavernosus and bulbospongiosus muscles are activated during penile events and may play a role in the neural control of sexual behavior. Supported by NS27511.

AUTONOMIC NEURONS ACQUIRE INNERVATION IN THE ABSENCE OF PREGANGLIONIC INPUT: A STUDY USING SYNAPSIN AND MET-ENKEPHALIN IMMUNOCYTOCHEMISTRY. N.M. Minorsky and W.G. Dail. Anatomy Dept., Sch of Med., Univ. of New Mexico, Albuquerque, New Mexico 87131

Neurons within the Major Pelvic Ganglion (MPG) supply autonomic innervation to the corpora cavernosa penis in the rat. Previous studies have shown that penile neurons receive the majority of their presynaptic input from preganglionic fibers which are immunoreactive for met-enkephalin (mENK). Whereas mENK innervation of penile neurons is greatly reduced following acute decentralization of the MPG, it is partially recovered in chronically decentralized ganglia. In order to determine whether other fiber populations contribute to penile neuron innervation following decentralization, nerve terminals were immunolabelled with antibodies to synapsin as well as mENK. As expected, the level of synapsin staining was greatly reduced in the acutely decentralized ganglia and the number of innervated neurons was comparable to that seen by mENK immunocytochemistry (approximately 12%). In the chronically decentralized ganglia however, approximately 60% of the penile neurons were innervated by synapsin-IR fibers, compared to 30% described by mENK immunocytochemistry. These findings demonstrate a remarkable capacity for neurons to receive innervation in the absence of preganglionic input. This potential may be important for understanding autonomic control of pelvic visceral tissue following spinal cord injury.

398.4

DISTRIBUTION OF 5-HT AND ITS COLOCALIZATION WITH TRH, SP AND M-ENK IN THE CAT MEDULLA. C. Dean, L. Marson, C. Hermes*, C. Polchow* and J.P. Kampine. Depts. Anesth. and Physiol., Med. Coll. Wis. and VA Med. Center, Milwaukee WI 53295 and Dept. Physiol., Northwestern Univ. Med. School, Chicago, IL 60611.

Medullary neurons containing 5-HT have long since been implicated in the control of the circulation and their distribution has been well described. This immunohistochemical study investigated the co-localization of peptides with 5-HT within the medullary raphe and reticular formation. Cats were anesthetized with sodium pentobarbitol and a laminectomy performed to expose T9-T10 segments of the spinal cord. Rhodamine latex microspheres were injected into the vicinity of the IML using a Hamilton syringe. Cats were allowed to recover for 4-5 wks then reanesthetized and colchicine (100 ug) was injected into the fourth ventricle. Cats were perfused 24 hrs later with paraformaldehyde/acrolein fixative (3/0.5%). Spinal cord sections (20 um) were examined microscopically to identify injection sites. Sections of the medulla (40 um) were processed for 5-HT and TRH or 5-HT and SP or SP and TRH or 5-HT and M-ENK. 5-HT containing neurons were located in raphe pallidus (RP), obscurus (RO) and magnus (RM), and the ventral medullary reticular formation (VLM). In RP and RO 60-90% of cells containing 5-HT also contained both TRH and SP. In VLM 36 and 71% of cells which contained 5-HT also contained SP and TRH respectively. In addition, in these regions M-ENK was found exclusively in cells containing 5-HT. Retrograde labelling was identified in RO, RP and VLM neurons which contained 5-HT. This study demonstrates that spinally-projecting 5-HT neurons in the cat medulla also contain TRH, SP and M-ENK. (Supported by the NSF).

PROJECTIONS OF THE ROSTRAL NPGI: A REGION INVOLVED IN MODULATION OF SEXUAL FUNCTION. *A.M. Peternel*, L. Marson and K.E. McKenna.* Northwestern University Medical School, Chicago IL 60611

The rostral nucleus paragigantocellularis (nPGi) modulates the tonic inhibition of spinal sexual reflexes (Marson & McKenna, 1990). Mapping the projections to and from the nPGi will provide a neuroanatomical basis for understanding these reflexes.

The anterograde tracer PHA-L, retrograde fluorescent tracers rhodamine and Fluorogold, and the anterograde/retrograde tracer HRP-WGA were microinjected into the rostral nPGi. Rats were perfused with a fixative appropriate for the tracing technique and sections through the brainstem and spinal cord (T13-S1) were processed. Anterogradely labelled fibers and terminals were found mainly ipsilateral at L5-L6 in the region of the medial DL motoneurons of the urethral sphincter, as well as in the lateral portion of this nucleus, near the motoneurons of the ischiocavernosus muscle. Fibers were also labelled in the DM nucleus at L5-L6. The motoneurons of the anal sphincter and the bulbospongiosus are interspersed within this nucleus. Fibers were also labelled in the IML and CA of T13-L2, the region of the lateral motoneurons of L4, and the sacral IML. Retrogradely labelled cells were found mainly contralateral in lamina X of T13-L3, lamina IV and V of T13-L1, and lamina IV of L2. Cells were also found in laminae IV, VIII, and X of L4-L5 and in the medial grey and lamina IV of L6. Cells were also found in the laminae IV, V, and X of S1 and the ventral grey of S2. Anterogradely labelled fibers were found in medullary nuclei including the contralateral nPGi, NTS, nGi, facial nucleus and caudal medullary reticular formation. In addition, fibers were found in the raphe, LC and subLC.

398.6

CNS CELL GROUPS PROJECTING TO THE PENIS LABELLED WITH PSEUDORABIES VIRUS (PRV). *L. Marson, K.B. Platt and K.E. McKenna.* Northwestern University Medical School, Chicago IL 60611

Transneuronal retrograde cell body labelling in the spinal cord and brainstem was identified after injection of Bartha's K strain PRV into the penis of 25 rats. Two days later rats were perfused with 4% paraformaldehyde and the spinal cord, pelvic ganglia and brain removed. Sections of the spinal cord, ganglia and medulla were cut (30-50μm) and processed with swine polyclonal antibody to PRV and visualized with avidin-biotin HRP complex. Retrogradely labelled cells were found in a restricted region of the pelvic ganglia. Transneuronally labelled cells were found in sympathetic and parasympathetic preganglionic regions in T13-L2 and L5-L6 of the spinal cord, respectively. In addition, cells were found in intraneuronal areas throughout the lumbosacral cord with cell labelling also in L3/L4. Quantitative analysis of cell distribution was performed. In the medulla cells were labelled in the nucleus paragigantocellularis, parapyramidal region, A5, raphe and in the region of the subcoeruleus. Labelling was consistent with known anatomical organization of pelvic systems. This procedure is a valuable tool in examination of spinal cord circuitry and neural systems involved in sexual function.

ELECTROPHYSIOLOGICAL EVIDENCE FOR BRANCHED PREGANGLIONIC PATHWAYS INNERVATING BOTH THE URINARY BLADDER AND THE URETHRA IN RATS. B.Conte*, M.Kawatani and W.C.de Groat. Depts. Pharmacol., Menarini Richerche Sud.,Pomezia,Rome,Italy & Univ. Pittsburgh,PA 15261.

In d-tubocurarine pretreated rats electrical stimulation (0.5-15V, 1Hz) of the central end of an acutely transected penile nerve or stimulation of the urethra at the level of the external urethral sphincter elicited discharges (mean latency 13.8±2.4) on postganglionic nerves (PBN) to the urinary bladder (UB). The responses were potentiated (20-80%) by repetitive stimulation (7-10 Hz) and by i.v. administration of DMPP (100 ug/kg) or tetramethyl-ammonium (50 ug/kg). Ganglionic blocking agents (hexametho-nium, trimethaphan, i.v.) or tetrodotoxin applied to the nerve abolished the responses. The responses were not eliminated by acute destruction of the lumbosacral spinal cord, or chronic (1 week) removal of the contralateral major pelvic ganglion or the hypogastric nerve. However, chronic transection (1 week) of the ipsilateral pelvic nerve eliminated the evoked discharges on the PBN. Electrical stimulation of the penile nerve (2-10 V, 3 Hz, 30-60 sec duration) produced UB contractions that were blocked by hexamethonium. These observations provide evidence for the existence of a population of preganglionic axons in the pelvic nerve which give rise to two peripheral branches: one providing an input to MPG ganglion cells innervating the UB and another projecting distally to the wall of the urethra. This population of preganglionic axons might function to coordinate UB and urethra function during micturition.

398.8

THE EFFECTS OF GLUTAMATE RECEPTOR ANTAGONISTS ON THE MICTURITION REFLEX IN THE RAT. M. Yoshiyama, J.R. Roppolo & W.C. de Groat. Univ. of Pittsburgh, Dept. of Pharmacol. Pittsburgh, PA. 15261.

Previous studies from this laboratory have shown that MK-801, a non-competitive NMDA receptor antagonist, inhibits rhythmic bladder activity in the intact urethane-anesthetized (UA) rat, while having little effect in the decerebrate animal. The present study extends those initial observations to: (1) examine the effects of MK-801 on bladder cystometrograms (CMG) and external urethral sphincter (EUS) EMG (electromyogram) activity, (2) compare MK-801 to CNQX, an AMPA receptor antagonist and (3) determine the effects of UA on MK-801 inhibition of the micturition reflex. In UA (1.2 g/kg) intact rats MK-801 (0.001-3 mg/kg, iv) reduced bladder contraction amplitude, capacity and EUS activity in a dose dependent fashion, with EUS being somewhat more sensitive than the bladder. In decerebrate rats, MK-801 (0.001-3 mg/kg, iv) had little effect on bladder amplitude but increased capacity and reduced EMG activity by 70%. The effects of MK-801 (0.1-1 mg/kg, iv) administered to UA (0.6 g/kg) decerebrate rats reduced bladder contractions in a dose dependent fashion as with intact animals. CNQX (0.2-1 mg/kg, iv) had no effect on bladder activity in either the intact, UA or the decerebrate rat.

Three conclusions are suggested by these data: (1) EUS reflexes are more sensitive to the effects of MK-801, (2) the AMPA glutamate receptor does not play a major role in micturition, (3) urethane enhances the effect of MK-801 on the micturition reflex in the rat.

398.9

BLADDER AND EXTERNAL URETHRAL SPHINCTER ACTIVITY EVOKED BY MICROSTIMULATION OF THE SACRAL SPINAL CORD. J.R. Roppolo, S. Smerin, A.M. Booth, I. Nadlehaft, W.C. de Groat, Dept. of Pharmacology, U. of Pittsburgh, PA 15261.

Our previous studies demonstrate that microstimulation of the sacral spinal cord (SSC) produces large amplitude (20-50cm H_2O) bladder contractions (BC). This study extends those initial observations to include: (1) an analysis of evoked external urethral sphincter(EUS) activity (2) detailed maps of stimulus sites in SSC and (3) possible neural mechanisms underlying the evoked responses. In intact chloralose anesthetized cats, the bladder and urethra underlying the EUS muscle were cannulated for pressure recording. A laminectomy exposed the SSC and roots. Ventral root (VR) stimulation identified the segments eliciting the largest bladder (S_2-S_3; 60-100cm H_2O) and EUS (S_1-S_2; 50-120cm H_2O) pressure changes. Using "activated" iridium microelectrodes (tip area: 200μm^2 and stimuli of 50-150μA at 15 Hz, 0.2 msec) microstimulation in the S_2 and S_3 segments along penetrations starting near the dorsal root entry zone, produced BC (10-60cm H_2O) at three depths along a 3000μm track: (1) ~250μm from the cord surface, (2) at the level of the preganglionic (PG) neurons (~800μm) and (3) near the PG axons along the lateral edge of the ventral horn (~2000μm). The EUS responses were large during stimulation at the cord surface and diminished at the level of PG neurons and axons. Transection of the spinal cord (T_9), of dorsal roots (S_1-S_3) bilaterally and contralateral VRs (S_1-S_3) did not change BC. However, ipsilateral VR (S_2-S_3) section abolished the BC. These studies suggest that BC can be evoked by microstimulation of the cord in the absence of major descending and afferent input and that stimulation of ipsilateral SSC does not produce contralateral efferent outflow. (Supported by NIH contract NO1-NS-9-2366)

398.10

EFFECTS OF MK-801, NPC 12626 AND HALOPERIDOL ON MICTURITION IN AWAKE AND ANESTHETIZED RATS. P.L. Vera & I. Nadelhaft, VA Medical Center, University of Pittsburgh, Depts. of Pharmacology & Neurosurgery, Pittsburgh, PA.

Female Sprague-Dawley rats were instrumented with chronic intravesical and intravenous catheters under halothane anesthesia. On the next day, saline infusion (0.2 ml/min) into the urinary bladder elicited micturition in the awake rats. NMDA-receptor antagonists, MK-801 (60-120 ug/kg iv) and NPC 12626 (10-100 mg/kg iv), increased the micturition frequency and concomitantly decreased the volume threshold (VT). MK-801 decreased VT to 30% of control whereas NPC 12626 reduced it to 70%. In anesthetized rats (urethane;1.0 mg/kg iv), MK-801 completely inhibited bladder contractions; however, NPC 12626 still decreased VT to 60% of control. MK-801 also abolished external urethral sphincter activity (EMG). Thus the effects of MK-801 are anesthetic dependent. The effects of MK-801 and to some extent also NPC 12626, in both the awake and the anesthetized animals, were reversed by haloperidol (0.4-1.2 mg/kg iv). Therefore, excitatory amino acids acting via NMDA receptors may play a role in modulating micturition. Dopaminergic or sigma receptors may also be involved since haloperidol antagonized the effects of MK-801.

398.11

NEURAL CONTROL OF RAT LOWER URINARY TRACT FOLLOWING SPINAL CORD INJURY. M.N. Kruse, S.L. Erdman*, W.C. de Groat. Dept. Pharmacology, U. of Pittsburgh, PA 15261.

Changes in urinary bladder (UB) and external urethral sphincter (EUS) activity following spinal cord injury (SCI) were studied in decerebrate neonatal rats (P10-P28) and urethane anesthetized adult rats by recording UB pressure and EUS-EMG. In intact rats, the EUS was inactive during bladder filling but exhibited burst activity during voiding. In contrast, 10-20 days following SCI at ~T9 in adult or neonatal rats, voiding was accompanied by a tonic increase in EUS-EMG (no bursting) and incomplete voiding, indicating that SCI rats exhibit bladder-sphincter dyssynergia. Following block of the EUS with pancuronium in intact rats, the amplitude of UB contractions decreased and residual urine volume increased indicating that the EUS burst activity may facilitate voiding. Immunohistochemistry revealed a dense collection of nerve terminals containing corticotrophin releasing factor (CRF) in the L_6-S_1 spinal parasympathetic nucleus (SPN) of adult rats and in neonatal rats older than day 5. These terminals were absent in SCI rats and in 0-2 day neonatal rats. These results indicate that CRF terminals in the SPN may be a marker for the post-natal development of the descending pathway of the spinobulbo-spinal micturition reflex and the elimination of this pathway by SCI. The present findings also indicate that the SCI rat may be a useful preparation for studying bladder-sphincter dyssynergia. This work was supported by grants from the American Paralysis Association and the Spinal Cord Research Foundation.

398.12

MOTONEURONS AND AFFERENT NEURONS INNERVATING THE BULBOCAVERNOSUS MUSCLE: A TRACING STUDY IN THE CAT. S. Smerin, J.R. Roppolo, R. Stewart*, V. Erickson*, W.C. de Groat, Dept. Pharmacol., Univ. Pittsburgh, Pittsburgh, PA 15261.

The afferent and efferent pathways to the cat bulbocavernosus muscle (BCM) were identified using the retrograde tracer cholera toxin B-HRP injected into the BCM under nitrous-oxide/halothane anesthesia. Ninety six hours later anesthetized cats were perfused with fixative. Spinal cord and dorsal root ganglia (DRG) from L_6 to S_3 were processed with TMB to reveal HRP. Motoneurons projecting to the BCM (average, 125) were present predominantly at the S_1 level and almost exclusively in Onuf's nucleus (ON). The neurons were typically elongate, about 30 x 50 microns in size. While neurons were labeled in equal numbers in the dorsomedial and ventrolateral divisions of ON (ON_{DM} and ON_{VL}), neurons in ON_{DM} gave rise to thick dendrites that extended to the intermediolateral (IML) region and to the ventrolateral funiculus. Thin processes extended to the IML, to the central grey, and to the medial, ventrolateral, and lateral funiculi. Labeled DRG cells (~500 per cat) were present mainly at S_2 and gave rise to abundant fibers that extended through the medial and lateral collateral pathways to the dorsal gray commissure. Two main conclusions can be made. First, the ischiocavernosus muscle (ICM) (studied previously) and the BCM motoneurons do not differ in location or dendritic projection, but in the origin of their prominent dendrites; those for BCM being from ON_{DM} and those for ICM being from ON_{VL}. Second, afferent pathways of BCM and ICM are located primarily one segment caudal (S_2) to the location of the motoneurons (S_1) innervating these muscles, indicating that the afferents may interact with visceral reflex mechanisms in this region of the cord. **(Supported by NIH contract N01-NS-9-2366)**

398.13

HYPERTROPHY OF BLADDER PELVIC GANGLION CELLS FOLLOWING CHRONIC PARASYMPATHETIC DECENTRALIZATION. W. DelGaudio*, A.M. Booth, R. Stewart*, S. Smerin and W.C. de Groat. Depts. of Pharmacology and Behavioral Neuroscience, Univ of Pittsburgh, Pittsburgh PA 15261

Previous studies have revealed reorganized synaptic connections in parasympathetic bladder ganglia and increased (2-3X) volume of the rat bladder following chronic parasympathetic decentralizations. This study was directed toward the involvement of ganglion cells in these events.

Unilateral resection of the L_6-S_2 dorsal and ventral roots of halothane anesthetized male rats was preformed and the animals allowed to recover for at least 3 months. Both lesioned and control animals were anesthetized and fluorogold and/or fast blue (10μl 4% W/V) injected into the urinary bladder wall. After 1-4 weeks animals were perfused with fixative, the major pelvic ganglion was removed, whole-mounted and the area of dye labeled cells calculated.

Dye labeled bladder cells on the lesioned side averaged 50% bigger in cross-sectional area (652±32.5 vs. 438±6.7 um^2, mean±sem). This appears to be an increase in the number of cells having a cross sectional area of between 700 and 2000 um^2 ($p < 0.05$, ANOVA) rather than a general increase in the cell size. Unilateral dye injections established the degree of contralateral bladder innervation from normal ganglia (25%) and following chronic interruption of the hypogastric (sympathetic) or pelvic (parasympathetic) nerve or both.

In summary, interruption of the lumbosacral preganglionic outflow to the bladder leads to hypertrophy of MPG neurons. It is possible that trophic factors released from the target organ may play a key role in the neuronal hypertrophy.

398.14

ELECTROPHYSIOLOGICAL STUDIES OF THE EFFECTS OF GLUTAMATE ANTAGONISTS (MK801 AND CNQX) ON THE MICTURITION REFLEX IN THE RAT. T.Suzuki, L.A.Birder, M.Yoshiyama, J.R.Roppolo, W.C.de Groat. Dept. Pharmacology, Univ. Pittsburgh, PA 15261.

Previous studies revealed that MK801, a non-competitive NMDA receptor antagonist, depressed reflex contractions of the urinary bladder (UB). The present experiments have analyzed the effects of MK801 and CNQX, a competitive AMPA receptor antagonist, on reflex firing in bladder postganglionic nerves (BPN) in urethane anesthetized rats. Rats with an intact neuraxis, as well as acute (5-48 hrs) and chronic spinal (T8) rats were studied. Electrical stimulation of afferent fibers in the pelvic nerve elicited short latency spinal (SR; 50-70 msec) and long latency spinobulbospinal (SBSR; 80-150 msec) reflex discharges on BPN. In intact rats, MK801 in low doses (0.1-0.3 mg/kg, iv) reduced and in high doses (1-3 mg/kg, iv) blocked the SBSR. High doses of MK801 reduced the SR in some intact and spinal rats. CNQX (1-3 mg/kg, iv) had no effect on SR and SBSR. MK801 (0.1-1 mg/kg, iv) reduced the asynchronous firing on BPN induced by bladder distension or injection of a irritant (1% acetic acid) into the bladder lumen.

These data indicate that NMDA but not AMPA glutaminergic receptor mechanisms have an important role in the neural control of micturition. Furthermore, since the SBSR in intact animals is considerably more sensitive than the SR to the depressant effects of MK801 it would appear that glutaminergic transmission is only prominent in the supraspinal reflex pathway to the urinary bladder.

398.15

ROLE OF DESCENDING SEROTONERGIC AND NORADRENERGIC PATHWAYS IN THE CONTROL OF MICTURITION IN AWAKE CATS. M.J. Espey, J.W. Downie, and A. Fine. Depts. of Pharmacol. and Physiol. & Biophys., Dalhousie Univ., Halifax, NS B3H 4H7.

The role of spinal serotonin (5-HT) and noradrenaline (NA) in micturition was assessed using neurotoxins and acute antagonists. Cystometrograms were performed in awake cats with chronic indwelling i.t. and bladder cannulae. Parameters followed were: volume threshold for micturition (V_T), postvoid residual volume, voiding contraction amplitude, contraction time and bladder stiffness during filling. Immunohistochemistry for tyrosine hydroxylase (TH) and 5-HT was performed to verify toxin actions. Methysergide (2.5-20μg it) dose-dependently decreased V_T. 5,7-dihydroxytryptamine (1800μg it) depleted 5-HT in the lumbosacral cord and reduced V_T. Other parameters were unaffected. Prazosin (100μg it) was ineffective, suggesting that alpha$_1$-adrenoceptors are not involved in normal micturition (cf. Yoshimura et al, J Urol 139: 423, 1988). 6-hydroxydopamine (500μg it) depleted TH from thoracic to sacral levels and increased V_T and contraction time. The data imply a spinal inhibitory role for 5-HT in modulation of micturition. Although NA may be facilitatory to micturition, it appears not to be required for normal micturition in conscious cats. (Supported by Rick Hansen Man in Motion World Tour Society)

398.16

EFFECT OF 8-OH-DPAT ON THE SUPRASPINAL MICTURITION REFLEX (SMR) IN ANESTHETIZED RATS. A. Lecci, S. Giuliani, A. Giachetti and C.A. Maggi. "Menarini" Pharmacol. Res. Dept., via Sette Santi 3, 50131 Florence, Italy.

The effect of 8-OH-DPAT, a selective 5-HT$_{1A}$ receptor agonist, on SMR has been investigated in urethane-anesthetizd rats. Intravenous administration of 8-OH-DPAT (3.3 μg/kg) induced activation of SMR (bladder contractions > 16 mm Hg) in 67% of rats which bladders were filled with a volume just below that required for evoking SMR. The effect of 8-OH-DPAT was antagonized by hexamethonium. Both intracerebroventricular (icv) and intrathecal (it) administration of 8-OH-DPAT induced activation of SMR. After icv administration, 8-OH-DPAT was about 10 times more potent than after the it route (minimal effective dose, MED icv: 3.3 ng/rat). The activation of SMR induced by icv 8-OH-DPAT was completely abolished by guanethidine and the MED was shifted to 330 ng/rat by 5,7-dihydroxytryptamine (5,7-DHT) administered icv in presence of desipramine. The activation of SMR by it 8-OH-DPAT was prevented by guanethidine, but was unaffected after 5,7-DHT icv administration. These findings indicate that stimulation of 5-HT$_{1A}$ receptor facilitate micturition reflex at both spinal and supraspinal sites. In both cases, removal of sympathetic inibitory mechanisms prevented the action of 8-OH-DPAT suggesting that suppression of sympathetic outflow to the bladder could be involved in the effect of 8-OH-DPAT. In addition, 5-HT neurons seem to be important in the facilitatory action of 8-OH-DPAT on the SMR at supraspinal level.

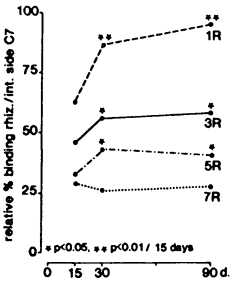
PLASTICITY OF MU OPIOID RECEPTORS IN THE SUPERFICIAL DORSAL HORN OF THE RAT SPINAL CORD AFTER VARYING DELAYS FOLLOWING DORSAL RHIZOTOMIES. D. Besse*, M.C. Lombard and J.M. Besson, INSERM U161 and EPHE, 2 rue d'Alésia, 75014 Paris, France.

Autoradiography of μ receptors (μ rec.) by [^{3}H]DAMGO was performed in laminae I-II at cervical levels following unilateral dorsal rhizotomies of 1, 3, 5 or 7 roots (R) around C7, at 8, 15, 30 and 90 days post-lesion (PL). At 15 days PL, following section of C7 alone, a 37% decrease of binding was observed in the rhizotomized side compared to the intact side of the C7 segment. Sectioning up to 5 and 7 roots increased the loss to a maximum of 70%. The 30% residual binding is attributed to the postsynaptic component of μ rec. (Besse et al. Brain Res, 521, 1990) which remains stable over 3 months. From 15 to 90 days PL after cuts of 1 to 5 roots, a "recovery" of binding occurs which is maximal when only C7 is cut. Because the more deprived the C7 segment is of afferents, the less pronounced is the recovery, the recovery is attributed to the presynaptic μ rec. This neuroplasticity indirectly suggests the occurence of collateral sprouting of fine primary afferent fibers because μ rec. are essentially located on these fibers.



399.2

NEUROPEPTIDE CONTENT AND INTERACTIONS WITH GABA-IMMUNOREACTIVE PROFILES OF PHYSIOLOGICALLY IDENTIFIED LAMINA I AND II MONKEY PRIMARY AFFERENT TERMINALS. F.J. Alvarez, A.M. Kavookjian* and A.R. Light. Dept Physiology. University of North Carolina, College of Medicine, Chapel Hill NC 27599.

Intra-axonally labeled A High Threshold Mechanoreceptors (HTM) terminals identified physiologically had boutons which resemble the Dense Sinusoid Afferents (DSA) previously described in monkey lamina I and II. Using colloidal gold post-embedding immunocytochemical techniques we located CGRP-immunoreactivity (-IR) in some dense-core vesicles found in DSA terminals, but we were not able to unequivocally demonstrate CGRP or SP inside A HTM terminals. GABA-IR was found in vesicle containing profiles that were presynaptic to A HTM terminals and to other non-identified DSAs. CGRP- and SP-IR were predominantly located inside presumed primary afferent profiles which contain numerous large dense-core vesicles (LDCV). GABA-IR profiles were in apposition to LDCV-containing terminals but synaptic contacts were rare. The terminals of two physiologically identifed C fibers also contained CGRP-IR dense-core vesicles. One C-fiber was a polymodal nociceptor. *Supported by grants DA04420, NS16433 and NS14014899 from NIH.*

ULTRASTRUCTURAL CHANGES IN TERMINALS IN THE DORSAL COLUMN NUCLEI OF DIABETIC RATS B.C. Albright, Dept. of Physical Therapy, East Carolina University, Greenville, NC 27858, M.R. Brown* and H.R. Knull*, Dept. of Biochemistry & Molecular Biology, School of Medicine, Univ. of North Dakota, Grand Forks, ND 58202.

The ultrastructure of terminals in the gracile and cuneate nuclei of streptozotocin (STZ) diabetic rats were examined at 1,3,10 and 30 days after the onset of diabetes. Terminals in the gracile nucleus were observed to exhibit a morphology characteristic of neuroaxonal dystrophy in all experimental groups. Only the 30 day diabetic group showed dystrophic terminals in the cuneate nucleus. The dystrophic response was characterized by the decrease in population of synaptic vesicles, the presence and increased accumulation of tubulovesicular smooth endoplasmic reticulum, the increased presence of various forms of cellular debris, and the decrease of synaptic complexes. The proliferation of glial processes was evident in all groups but most notable in the 14 and 30 day groups. Occasionally, terminals which appeared dystrophic were observed in normal and control animals. These findings show that severe diabetes as modeled by the STZ diabetic rat has an early and progressive dystrophic affect on terminals in a somatosensory nucleus of the central nervous system. Many of the dystrophic terminals had a morphology and synaptic configuration similar to primary afferents of the dorsal column nuclei. These observations are in agreement with clinical and experimental findings which often show the initial impairment of long sensory fibers and introduces the concept that the impairment of central transmission may be a contributing factor in the sensory deficits seen in diabetic neuropathy.

CALCITONIN GENE-RELATED PEPTIDE (CGRP) IMMUNOREACTIVITY IN THE CAT SACROCAUDAL SPINAL CORD. C.R. Murray* and L.A. Ritz. Depts. of Neuroscience and Neurosurgery, Univ. of Florida College of Medicine, Gainesville, Fl. 32610.

Our laboratory has been investigating the anatomical, physiological and behavioral organization of the cat sacrocaudal spinal cord, the portion of the neuraxis that innervates the tail. Recently, we have been concerned with the distribution of primary afferent fibers that exhibit CGRP immunoreactivity. CGRP labeling was found, as expected, within the superficial dorsal horn. A dense band formed across the entire mediolateral extent of the superficial portion of the fused dorsal horns. Labeling was localized throughout laminae I-V of the dorsal gray commissure. These fibers expanded rostrocaudally within lamina V. Labeling was also observed in an extensive mediolateral distribution at the level of the dorsal commissure (laminae IV/V). Horizontal sections revealed a 200-300 μm periodicity to the dorsal commissural bundles. There appears to be a greater distribution of CGRP within the deeper portions of the sacrocaudal dorsal horn than in other regions of the spinal cord.

THE DISTRIBUTION OF C-FOS POSITIVE NEURONS IN THE LUMBOSACRAL SPINAL CORD OF THE CAT FOLLOWING ELECTRICAL STIMULATION OF THE PELVIC AND PUDENDAL NERVES. L.Birder, J.R.Roppolo, S.Smerin, V.Erickson*, W.de Groat, Dept. of Pharmacology, U. of Pittsburgh, PA 15261.

The pelvic (PN) and pudendal (PUDN) nerves contain afferent fibers which are involved in sexual and excretory functions. The present study examined the central projections of these afferents by detecting C-FOS in spinal cord interneurons following unilateral electrical stimulation of the PN and PUDN in either decerebrated or urethane (1.2 gm/kg) anesthetized cats. The PN and PUDN were stimulated at 2.5 times the threshold to produce bladder or perineal muscle contractions, respectively (usually 4-8 volts, 0.05 msec, 20 HZ, 10 sec on, 10 sec off, for 1 hour). One hour following the end of stimulation animals were perfused and tissue processed. PN stimulation produced the largest number of C-FOS cells in S_1 and S_2 segments, with fewer cells extending into L_7 and S_3. C-FOS positive neurons were found in the lateral lamina V at the base of the dorsal horn (DH), in the intermedio-lateral grey, in the superficial layers of the DH, and in the dorsal grey commissure (DGC). PUDN stimulation produced a wider distribution of C-FOS positive cells in L_6-S_3 with the densest labelling in S_1-S_2. The superficial lamina as well as laminae IV-VI and DGC contained positive neurons.

This study demonstrates similarities in the distribution of PN and PUDN afferent projections to the spinal cord and identifies possible interneuronal sites involved in the coordination of visceral and somatic components of urogenital function.

GENE DELIVERY TO RAT SENSORY GANGLIA AND SPINAL CORD CELLS USING HERPES VIRUS VECTORS. G.Davar, C. Meaney*, J.K. Andersen, M. Kramer*, W. Bebrin*, B.P. Vos, R. Burstein, D. Garber*, W. Rosenberg, R. Maciewicz, D. Coen*, X.O. Breakefield, Neuroscience. Center., Mass. General Hosp. East, Charlestown, MA 02129; and Neuroscience Program and Genetics Dept., Harvard Med. Sch., Boston MA 02115.

The delivery of genes, to alter the physiology of somatosensory neurons, may be possible using herpes simplex virus (HSV) type 1 vectors mutated by insertion of DNA elements into the thymidine kinase (TK) gene. To achieve gene delivery to peripheral and central neurons, we tested thymidine kinase-negative (HSV TK$^-$) vectors containing the marker gene, lacZ, under the control of different mammalian and viral promoters. Regulatory elements included: HSV promoters classified as immediate-early (alpha 4 in mutant RH105), early (beta 8 in RH116; both from Drs. Ho and Mocarski, Stanford Univ.), and late (gE in vgE26; from Dr. Weir, Walter Reed Hosp.), as well as the putative latency promoter (in tkLATZ1); and non-HSV promoters, the Moloney murine leukemia virus LTR (in tkLTRZ1) and the neuron-specific enolase promoter (in NSE-lacZ). Vectors were applied at an MOI of 0.001-0.1 to neuron-enriched neonatal rat dorsal root ganglion (DRG) cultures and $3x10^8$ PFU (RH116) into rat dorsal spinal cord or snout. In DRG cultures large numbers of positively-staining cells were observed at 4 and 11d after inoculation with all vectors except tkLATZ1. In spinal cord numerous positively-staining cells were observed in the dorsolateral funiculus adjacent to the injection site at 2d after inoculation. At 3d after inoculation onto the snout, a punctate perinuclear staining pattern was observed in a few cells in the ipsilateral trigeminal ganglion. Immunostaining with antibodies to neurofilament and S100 is being used to determine which cell types are expressing beta-galactosidase. Differences in the staining pattern following inoculation into spinal cord or snout may depend on the number of viral particles that entered the cell nuclei, and/or on the relative potency of the different promoters in different cell types.

399.7

GLUTAMATE IMMMUNOSTAINING IN THE DORSAL COLUMN SYSTEM OF RATS. R. Giuffrida, S. De Biasi, M. Bellomo and A. Rustioni, Ist. Fisiologia Umana, Univ. Catania; Dip. Fisiol. Biochim. gen, Univ. Milano; Department. of Cell Biology & Anatomy, University of North Carolina, Chapel Hill, NC 27514.

Immunocytochemical experiments have shown that glutamate-positive neuronal somata in dorsal root ganglia are mostly small. Terminals of unmyelinated and small myelinated fibers in the superficial laminae of the spinal cord were also immunostained by the same glutamate antiserum. In the present experiments, we have investigated whether comparably good correlation exists with another class of primary afferent neurons and their terminals—those ascending in the dorsal columns and terminating in the dorsal column nuclei. At least 75% of terminals identified by anterograde tracing as endings of primary fibers ascending in the dorsal columns are glutamate-immunopositive. However, the majority of dorsal root ganglion neurons with an ascending branch to the the dorsal column nuclei have large somata, and only 20 to 30% of projecting cells are glutamate-immunopositive. The difference in soma size between most dorsal root ganglion neurons that are glutamate-positive and those that project to the dorsal column nuclei suggests that glutamate may be present in cell bodies of large neurons of the dorsal root ganglia in a concentration insufficient to be detected with our present experimental conditions. This and alternative explanations for the apparent discrepancy are currently being explored.

399.8

COEXISTENCE OF GLUTAMATE AND ASPARTATE IN TERMINALS OF PRIMARY AFFERENTS TO THE SUPERFICIAL LAMINAE OF THE DORSAL HORN. K.D. Phend, R.J. Weinberg, and A. Rustioni, Depts. of Cell Biology & Anatomy and. of Physiology, U. of North Carolina, Chapel Hill, NC 27599.

In previous reports we have shown that terminals of dorsal root ganglion afferents in superficial laminae of the dorsal horn are enriched with glutamate, a probable neurotransmitter for these primary afferents. More recently, we have shown that presumed primary afferent terminals may be also enriched in aspartate although it is uncertain whether aspartate is released as neurotransmitter. We have combined double-staining immunocytochemistry with anterograde transport to verify the simultaneous presence of elevated levels of both amino acids in primary afferent terminals. WGA-HRP was injected into the sciatic nerve of anesthetized rats. After 2-7 days, animals were perfused with 2.5% glutaraldehyde/ 0.5% paraformaldehyde/ 0.2% picric acid. Fifty mm Vibratome sections of L4 were cut, reacted for TMB with tungstate stabilizer and embedded in plastic. Nickel mesh grids with thin sections were stained for glutamate and aspartate separately or in combination using different sizes of gold particles (Phend et al., Neurosci. Abst., 1990). Double staining for glutamate and aspartate was commonly observed among terminals of dorsal root afferents likely to be associated with unmyelinated and small myelinated primary afferents. A relation between these observations and the release of glutamate and aspartate from the same terminal of dorsal root fibers remains to be established.

SPROUTING OF THINLY MYELINATED AND UNMYELINATED FIBERS IN THE PARTIALLY DENERVATED PREPARATION. J.X. Bao, J.B. Munson and P.J. Reier Dept. of Neuroscience and Neurosurgery, Univ. of FL, Gainesville, FL 32610.

The goal of this study is to use established CGRP immunocytochemical staining in combination with electrophysiological mapping techniques to examine further the possibility of sprouting of thinly myelinated and unmyelinated fibers in the partially denervated preparation.

Adult Sprague-Dawley rats received unilateral dorsal root ganglionectomies of L1-L4 on the right or left side followed three weeks later by contralateral ganglionectomies. Terminal electrophysiological and subsequent immunocytochemical analyses were performed one week after the second procedure. Recording tracks were made through the dorsal horn with a tungsten microelectrode. The electrode was advanced dorsoventrally while the ipsilateral sural nerve was stimulated at Aαβ, Aδ and C fiber strengths. A series of symmetric tracks was made on the chronically denervated side and on the control side in the same animal.

Preliminary results indicate that the area of CGRP staining fibers was much larger on the chronically denervated side than on the side deafferented one week prior to physiological evaluation. Functionally, more units responded to sural nerve stimulation on the long-term denervated side. These results suggest possible sprouting of thinly myelinated and unmyelinated afferent fibers in the partially denervated rat spinal cord. Supported in part by NS15913 and NS72300.

WINDUP AND SYNAPTIC FACILITATION IN THE NEONATAL RAT SPINAL CORD IN VITRO. C.J. Woolf*, S.W.N.Thompson* and L.Sivilotti. SPON: Brain Research Association, Anatomy Dept., University College, Gower St., London WC 1E 6BT.

Low frequency repetitive stimulation of high threshold primary afferents elicits sustained depolarization and action potential windup in flexor motoneurons in vitro (Thompson et al., Eur.J.Neurosci. 2, 638, 1990). We have now examined the synaptic facilitation associated with the production of this pattern of progressive response increase. Intracellular recordings were obtained with K acetate electrodes from the young rat hemisected spinal cord preparation. In dorsal horn neurons in vitro, windup in response to high intensity stimulation of a lumbar dorsal root (0.5-1 Hz, 20 s) was observed less frequently than in ventral horn neurons in vitro or in dorsal horn cells in vivo. This phenomenon was associated with a facilitation of the synaptic input elicited by activation of low threshold afferents from both the conditioned and the adjacent (test) root, which could not be accounted purely by the cumulative membrane depolarization induced by conditioning. While neurons which generated windup had more prolonged synaptic potentials in response to single shock afferent stimulation, no correlation could be established between the occurrence of windup and the resting membrane potential, input resistance or I/V plot characteristics of a cell. Manipulation of the cell membrane potential by current injection during conditioning or increases in the frequency of the conditioning train failed to elicit windup in cells that did not respond to the control conditioning protocol. These data suggest that both pre and postsynaptic components contribute to afferent-induced sensitization in the spinal cord and that this is a network-related property of spinal responses.

EFFECTS OF ENDOGENOUS GABA ON AXONAL CONDUCTION IN THE NEONATAL RAT DORSAL COLUMN. M. Lee*, K. Sakatani, A.Z. Hassan*, M. Chesler, and W. Young. Dept. of Neurosurgery, NYU Medical Center, New York, NY 10016

We have previously shown that GABA-A receptors activation can modulate axonal conduction in isolated dorsal column of the neonatal rat spinal cord *in vitro* (Sakatani, et al. Brain Res., 542: 273-279, 1991). However, it is not known whether the GABA-A receptors in the dorsal column are activated by endogenous GABA under physiological conditions. We consequently studied the effect of a GABA-uptake inhibitor (nipecotic acid; NPA) and a GABA-A antagonist (picrotoxin; PTX) on axonal conduction in the dorsal column, using whole neonatal (1-5 day-old) rat spinal cord (below T1) *in vitro*. The dorsal column was stimulated (0.5 msec, 2 mA,, 0.2 Hz) by a bipolar platinum electrode, placed on L5 dorsal root entry zone. Orthodromic dorsal column compound action potentials (CAPs) were recorded at two points with glass micropipettes (1 M NaCl).

NPA (1 mM) decreased CAP amplitudes by 12.5 ± 9.6 % of control (mean ± SD, n=4). This effect of NPA was blocked by PTX (1 mM). GABA at 0.1 mM mimicked the effect of NPA. However, the time course of NPA action was slower than that of GABA action, suggesting that NPA increased background extracellular GABA levels which would activate GABA-A receptors in the dorsal column. PTX (1 mM), alone, increased population conduction velocities, calculated from latencies of negative peaks, by 18.7 ± 3.2 % of control (n=3), suggesting that PTX blocks tonic endogenous GABA influences on the dorsal column axons.

These results suggest that pre-myelinated dorsal column axons of the neonatal rat spinal cord are tonically affected by endogenous GABA under physiological conditions. While the biological role of interaction of GABA and GABA-A receptors in the dorsal column is not apparent, these results support our hypothesis that axonal conduction in long tracts of the spinal cord is subject to non-synaptic modulation. Supported in part by NIH grant NS10164.

400.3

DEVELOPMENT OF THE SOMATOTOPIC ORGANIZATION OF THE PRESYNAPTIC NEUROPIL IN RAT SPINAL DORSAL HORN. K. Mirnics and H.R. Koerber. Dept. of Neurobiology, Anatomy and Cell Science, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

In order to examine the development of the topography of primary afferents in the dorsal horn, fibers were labeled in embryos fixed at different stages (E15-P0) with either DiO, DiI or DiA. Dye crystals were placed on isolated dorsal root ganglia (ventral roots cut). Combinations of dyes were used so that the spatial relationships of the central projections of different spinal dorsal roots (L3 and L4) could be examined within the same embryo. The reduced preparations were stored in fixative at 37°C for 2 - 7 days depending upon the diffusion distance. Vibratome sections (50 microns) of the spinal cord were cut in either the transverse, horizontal or sagittal planes. At about E15 primary afferent collaterals extended in the primordium of the dorsal funiculus at least two segments rostral and caudal to their entry zone. In addition, at the level of the entry zone collaterals could be seen coursing medially across the surface of the gray matter. These fibers in turn supported collaterals which penetrated into the medial dorsal horn. Although substantial overlap of fibers from adjacent dorsal roots was observed in the primordium of the dorsal funiculus very little overlap in afferent projections was observed in the gray matter at this stage. The rostrocaudal and mediolateral extent of collaterals in the gray matter increased in successive stages until about E20 when the central projection zones and the degree of overlap was similar to that seen in postnatal animals. These results suggest that although primary afferent fibers have collaterals covering several segments in the dorsal funiculus they first enter the dorsal horn at the level of their entry zone and later expand into their somatotopically appropriate locations. Supported by NS-23725 (HRK).

400.4

SYNAPTIC CONNECTIONS OF FUNCTIONALLY IDENTIFIED INTERNEURONS IN HAMSTER SPINAL NUCLEUS PROPRIUS IN VITRO. S.P. Schneider and D.R. Sandiford*. Department of Physiology, Univ. of N. Carolina, Chapel Hill, NC 27599-7545.

To investigate anatomical substrates underlying synaptic integration in the nucleus proprius (NP), we studied the ultrastructure of synaptic connections of NP interneurons in an isolated spinal cord preparation with intact sensory innervation.

NP interneurons were physiologically characterized and stained intracellularly with horseradish peroxidase (HRP). Terminal axon branches labeled with HRP were unmyelinated or thinly myelinated. Labeled synaptic boutons that were located in proximity to the parent cell body (i.e. within an area comparable to one spinal segment) contained small, round vesicles and contacted small-to-medium sized dendrites (0.3 to 1.5 um in diameter). Labeled boutons that were sectioned serially were sometimes presynaptic to more than one dendrite. Axosomatic contacts were rarely observed. In some cases labeled boutons were postsynaptic to unlabeled axon terminals.

These findings suggest that axonal connections between NP neurons within a spinal segment are established mainly on dendrites, as are the central terminals of cutaneous afferent fibers. Thus, the activity of NP neurons is influenced by both primary afferent and local interneuronal input.

Supported by grant NS25771 from the NINDS.

RELATIVE NUMBERS OF SPINOTHALAMIC, SUPRASPINAL PROJECTION, PROPRIOSPINAL AND LOCAL CIRCUIT NEURONS IN THE SUPERFICIAL DORSAL HORN (SDH) OF THE RAT LUMBAR SPINAL CORD. T.N. Bala,* D.S. Knight, and J.A. Beal. Dept. of Cell Biol. and Anatomy, LSU Medical Ctr., Shreveport, LA 71130.

SDH neurons in the lumbar spinal cord (segment L1) which project to different levels of the neuraxis were labelled via retrograde transported fluorescent tracers delivered at the following sites: 1) the dorsal thalamus to label spinothalamic neurons, 2) a spinal hemisection at spinal cord segment C3 to label all supraspinal projection neurons and, 3) the dorsal gray in spinal segment T12 to label propriospinal neurons with short ascending connections. Cells were counted in each group and numerical estimates of neurons with dual projections, e.g., spinothalamic neurons with propriospinal connections, were determined by comparing the temporal neurogenic pattern of neurons in each group using tritiated thymidine autoradiography. Cell counts indicate that approximately 10% of the neurons in lamina I are supraspinal projection neurons and 50% of these project to the dorsal thalamus. In contrast, less than 1.0% of the neurons in lamina II have supraspinal projections. Short ascending propriospinal neurons are nearly equal in number in laminae I & II and represent 10 to 15% and 2.0 to 3.0% of the total cell populations in laminae I & II, respectively. The remaining SDH neurons, 75% of the lamina I neurons and 95% of the lamina II neurons, are presumed to be local circuit neurons. Supported by NSF grant #BNS-8908601.

400.6

SYNAPTIC ACTIVITY OF FROG SPINAL DORSAL HORN NEURONS. J.A. Meade, H. Tan and V. Miletic. Dept. Comp. Biosci., Sch. Vet. Med., Univ. of Wisconsin, Madison, Wi. 53706.

Dorsal horn neurons were studied in intracellular recordings from isolated hemisected spinal cords of adult frogs (R. pipiens). The average resting membrane potential was -68± 12 mV (S.D.) (n=118, range= -50 to -98 mV). The average membrane input resistance was 117± 68 MΩ (S.D.) (n=61, range=20 to 340 MΩ). Preliminary experiments suggest that the neurons have a membrane time constant of approximately 20 msec. Spontaneous action potentials were observed in 20 of 160 neurons. These action potentials occurred tonically (18/20) or in bursts (2/20). Excitatory postsynaptic potentials (n=77/160), inhibitory postsynaptic potentials (n=7/160), and a combination of both (n=4/160) were observed to occur spontaneously.

Experiments were also conducted in which the dorsal root was stimulated by a suction electrode while the postsynaptic response was monitored in a dorsal horn neuron. The threshold for evoking a response in the dorsal horn neuron was 129± 60 μA (S.D.) (n=78, range=54 to 424 μA). The average latency of response was 7± 11 msec (S.D.) (n=42, range=0.5 to 68 msec). Compound postsynaptic potentials were observed in a few experiments. Preliminary experiments on the reversal potential suggest that the ionic conductances of the evoked postsynaptic potential are similar to those reported for mammalian dorsal horn neurons. (Supported by NIH NS21278).

OUTFLOW OF ENDOGENOUS GLUTAMATE AND ASPARTATE FROM THE RAT SPINAL DORSAL HORN IN VITRO BY SELECTIVE ACTIVATION OF SMALL PRIMARY SENSORY NEURONS. I. Kangrga, R. Cerne and M. Randić. Dept. Vet. Physiol. Pharmacol. Iowa State University, Ames, IA 50010.

Whereas excitatory amino acids glutamate (Glu) and aspartate (Asp) have been implicated as neurotransmitters of the primary afferent fibers (PAF) the contribution of different categories of PAF to the release of Glu and Asp, and the regulation of this release by endogenous opioid peptides at the spinal level have not been characterized as yet. We have investigated whether the rate of outflow of Glu, Asp and glutamine (Gln) from the spinal dorsal horn (DH) is modified in response to selective chemical activation of the small unmyelinated PAF by resiniferatoxin (RTX) and during the perfusion of the slice with a δ-opioid receptor agonist (D-Pen^2,D-Pen^5)enkephalin (DPDPE). In superfused rat spinal cord slice - dorsal root ganglion (DRG) preparation, the DRG were superfused with RTX and the slice superfusate was collected and analyzed for amino acid content by HPLC with fluorimetric detection. RTX (0.1-10 nM for 3-6 min) produced a prolonged (10-15 min), up to three-fold increase in the rate of basal outflow of Glu, Asp and Gln (n=6). Marked desensitization of the RTX effect was observed with the second RTX challenge. Preincubation of slices with DPDPE (10 μM, 12-18 min) effectively attenuated the RTX (2 nM)-evoked outflow of all the three amino acids. Superfusion with DPDPE resulted in a decreased rate of basal outflow of Glu and Asp in a proportion of slices (n=3). It is suggested that a population of small unmyelinated PAF may be an important neuronal source of released Glu and Asp in the spinal DH. A role for δ-opioid receptors in modulation of somatosensory processing at the spinal level is indicated. Supported by NS 26352 and BNS 841 8042.

L-GLUTAMATE AND ADENOSINE-5'-TRIPHOSPHATE ACTIONS ON SUBSTANTIA GELATINOSA NEURONS. J. Li* and E. R. Perl
Physiology, Univ. No. Carolina-CH, Chapel Hill, N.C. 27599.

We sought evidence on whether ATP may be a synaptic transmitter for primary afferent fibers, by comparing actions of L-glutamate (GLU) and adenosine-5'-triphosphate (ATP) on substantia gelatinosa (SG) neurons in superfused 400-500 μm transverse slices of the spinal cord from young hamsters. Whole-cell patch recordings were made with Cs^+ or K^+ filled electrodes. Both bath-applied GLU and ATP (0.4 to 3 mM) caused similar fast depolarizations and generated action potentials in the majority of 70 neurons. TTX blocked the action potentials, but left fast GLU and ATP inward currents unaffected. All but one of 45 cells showing fast excitation by ATP was also excited by GLU; however, 10 of 54 neurons excited by GLU were unresponsive to ATP. ATP-γ-S, a non-hydrolysable ATP analogue, was at least an order of magnitude more potent than ATP in evoking fast inward current while ADP, AMP and adenosine had no effect or were much less potent than ATP. A few neurons exhibited a prolonged depolarizing current to GLU after the initial fast component; a larger number showed prolonged inward current after ATP and ATP-γ-S. Since the SG receives most of its primary afferent input from thin fibers, these observations appear consistent with an ATP-like molecule acting as an excitatory synaptic transmitter for some of these fibers. (Supported by research grant NS-10321 from the NINDS.)

$5HT_3$ RECEPTOR ACTIVATION DEPRESSSES SYNAPTIC TRANSMISSION BETWEEN CUTANEOUS AFFERENTS AND SENSORY INTERNEURONES IN XENOPUS TADPOLE SPINAL CORD. **K.T. Sillar, A.J. Simmers* & J.F.S. Wedderburn.* Gatty Marine Lab., University of St. Andrews, Fife KY16 8LB, SCOTLAND.**

Serotonin acting at the $5HT_3$ receptor subtype may be involved in the modulation of sensory pathway function (Lei & Wilcox, Soc. Neurosci. Abstr, 16,97, 1990). In hatchling Xenopus tadpoles exogenous 5HT suppresses skin sensory activation of locomotor rhythmicity and we have explored the pharmacology and site of action of 5HT in mediating this effect.

5HT (0.5- 5μM) reversibly increases the stimulus threshold for activation of fictive swimming by up to 1000%. Impulses in the primary afferents are not blocked by 5HT, indicating that its effects are mediated centrally. Intracellular recordings from postsynaptic sensory interneurones show that synaptic transmission is reversibly reduced by 5HT with no apparent change in conductance, suggesting a presynaptic site of action. The depression by 5HT is reduced by the specific $5HT_3$ receptor antagonist, MDL72222, but not by methysergide or cyproheptadine. We conclude that in this simple developing vertebrate nervous system $5HT_3$ receptors are involved in the presynaptic inhibition of cutaneous sensory synaptic transmission.

FACILITATION OF THE TAIL-FLICK REFLEX BY INTRATHECAL ADMINISTRATION OF SUBSTANCE P AND BY NOXIOUS CUTANEOUS STIMULATION IS BLOCKED BY CP-96,345, A NONPEPTIDE SUBSTANCE P (NK-1) RECEPTOR ANTAGONIST. J.L. Henry, V. Radhakrishnan and K. Yashpal, Departments of Psychiatry and Physiology, McGill University, Montreal (Quebec)

Substance P has been proposed to regulate the excitability of nociceptive neurons in the dorsal horn of the spinal cord and to facilitate the nociceptive tail-flick reflex. Therefore, we examined the effects of CP-96,345 on facilitation of the tail-flick reflex 1) by intrathecal administration of 6.5 nmol of substance P at the lumbar spinal level in awake rats and 2) by noxious cutaneous stimulation in anaesthetized rats by immersing the tip of the tail in water at 55°C for 1.5 min. Reaction time was decreased by about 70% by intrathecal administration of substance P and by about 40% by tail immersion. Systemic administration of CP-96,345 (0.5 i.v. or 5 s.c. mg/kg), but not of saline, blocked the facilitation induced by intrathecal administration of substance P and by tail immersion. However, neither CP-96,345 nor CSF altered baseline reaction time. These results indicate that while NK-1 receptors do not appear to be involved in mediating the tail flick reflex in either preparation, they may be involved in expression of the facilitation of this reflex by substance P and/or by a related peptide. (Supported by Pfizer Central Research and by the Canadian MRC)

400.11

NOXIOUS CUTANEOUS STIMULATION PRODUCES ANALGESIA IN THE TAIL-FLICK TEST AND DECREASES BINDING OF SUBSTANCE P IN THE DORSAL HORN K. Yashpal, S. Kar, R. Quirion and J.L. Henry, Department of Psychiatry, McGill University, Montreal and Douglas Hospital Research Centre, Verdun, Quebec, Canada

Substance P (SP) has been proposed to play a regulatory role in nociception and both SP-like immunoreactivity and receptors are present in high quantities in the dorsal horn of the cord. However, direct evidence supporting this porposal is still lacking. Therefore a series of experiments was undertaken to examine this proposal. Sprague Dawley rats were anaesthetized i.p. with Na-pentobarbital (20 mg/kg) and chloral hydrate (120 mg/kg). After baseline readings were taken in the tail-flick test, one hindpaw was immersed in water at 55°C for 1.5 min. Readings were taken at 3 min intervals for a subsequent 20 min. For autoradiographic binding studies, rats were decapitated at 1, 10 and 60 min following immersion. The spinal cords were removed and incubated in buffer containing [^{125}]I-BH-SP as described (*Brain Res. 506, 259, 1990*). In the physiological studies, immersion induced an increase in the reaction time to 150 % of the control values at 1 min which gradually decreased over 10 min. Binding of SP was depleted in the superficial parts of the dorsal horn of the lumbar cord in the 1 min group, with partial and full recovery in the 10 and 60 min groups, respectively. Binding around the central canal remained unaltered by immersion. These results indicate that noxious cutaneous stimulation to a hind foot induces an analgesia in the tail-flick test. Furthermore, the decreased [^{125}]I-SP binding is most easily explained as being due to the occupation of NK-1 receptors by endogenously released substance P. (Supported by grants from the Canadian MRC to JLH and RQ)

400.12

RESPONSES OF DORSAL HORN NEURONES TO NOXIOUS CUTANEOUS STIMULATION AND TO IONTOPHORETIC APPLICATION OF SUBSTANCE P ARE BLOCKED BY THE SELECTIVE, NONPEPTIDE SUBSTANCE P (NK-1) ANTAGONIST, CP-96,345. V. Radhakrishnan and J.L. Henry, Departments of Physiology & Psychiatry, McGill University, Montreal, Quebec.

Until recently, the known antagonists at the substance P (NK-1) receptor were all metabolically unstable peptides. Some of them were also known to exhibit agonistic and/or neurotoxic properties. Recently, Snider *et al.* (*Science* 251:435, 1991) and McLean *et al.* (*Science* 251:437, 1991) reported a specific, nonpeptide NK-1 receptor antagonist, CP-96,345, devoid of agonistic property. We tested the effect of CP-96,345 on the responses of dorsal horn neurones to iontophoretic application of substance P (which in electrophysiological studies selectively activates nociceptive neurones) and to noxious cutaneous stimuli. In chloralose-anaesthetized cats, extracellular unit activity was recorded from neurones in segments L_5-L_7 using multibarrelled micropipettes. Neurones were first classified on the basis of their responses to natural stimuli to the skin. Six of the 8 neurones that responded to noxious thermal stimulation also responded to substance P. The slow excitation produced by substance P (80-120 nA), which lasted for 2-3 min, was effectively blocked by CP-96,345 (0.5 mg/kg, i.v.). CP-96,345 also attenuated the responses to noxious heat stimulation in these units, markedly reducing the after-discharge following stimulation. In the case of two substance P-insensitive units, the responses to noxious heat was unaffected by CP-96,345. CP-96,345 also inhibited the response of 2/4 units tested with noxious mechanical (pinch) stimulation. The results support the involvement of NK-1 receptors in the mediation of the after-excitation induced in some dorsal horn nociceptive neurones by substance P and by noxious cutaneous stimuli. (Funded by Pfizer Central Research, the Canadian MRC and NIH).

CP-96,345, A NONPEPTIDE SUBSTANCE P (NK-1) RECEPTOR ANTAGONIST, BLOCKS A SLOW EPSP ELICITED IN DORSAL HORN NEURONES *IN VIVO* BY SUSTAINED NOXIOUS AND BY REPETITIVE C-FIBRE STIMULATION, BUT DOES NOT BLOCK THE *FAST* C-FIBRE EVOKED EPSP. Y. De Koninck and J.L. Henry, Depts. Physiology and Anaesthesia Res., McGill Univ., Montréal, Qué., H3G 1Y6.

As substance P (SP) has been implicated in mediating nociceptive responses in the dorsal horn, the slow time course of action of the peptide when applied exogenously suggests that it may play a role in mediating a slow EPSP to noxious peripheral stimulation. Hence, we attempted to identify a slow nociceptive response which could be tested with a novel SP antagonist, CP-96,345, selective for the NK-1 receptor. In α-chloralose anaesthetized cats, we recorded intracellularly responses of nociceptive dorsal horn neurones to noxious stimulation of the cutaneous receptive field and electrical stimulation of afferent nerves. Noxious stimulation but not innocuous stimulation produced a slow, prolonged EPSP which outlasted the end of the stimulation by 20s to 3min. A similar slow, prolonged EPSP was obtained following a train of high intensity stimulation (10-15Hz for 4-10s) to afferents nerves at intensities recruiting C-fibres, but not at intensities recruiting only Aβ fibres. The slow EPSP in each case was associated with an increase in input resistance and was reduced with hyperpolarization and increased with depolarization as has been described in response to exogenous application of SP. This contrasted with the reversal potential of the C-fibre latency EPSP in response to a single shock stimulation, which was similar to that of excitatory amino acid EPSPs of the non-NMDA type. Administration of CP-96,345 (0.5-2.0mg/kg i.v.) specifically and reversibly blocked the slow EPSP to sustained noxious stimulation, but not the brisk response to innocuous input nor the *fast* C-fibre latency EPSP to single shock electrical stimuli. These results suggest that SP is involved in the mediation of a period of hyperexcitability characterized by a slow EPSP following noxious stimulation in the dorsal horn. This period of hyperexcitability in nociceptive dorsal horn neurones may represent the neuronal substrate underlying central components of hyperalgesia. A LIGHT AND ELECTRON MICROSCOPIC ANALYSIS OF GLYCINE IMMUNOSTAINING IN THE MONKEY SPINAL CORD. G.L. Hargett and S.M. Carlton, Dept. of Anatomy and Neurosciences, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX, 77550.

The inhibitory transmitter glycine is found throughout the mammalian central nervous system. In rat, immunohistochemical studies at the LM and EM level demonstrate glycine-immunoreactive (IR) neurons, fibers and terminals throughout the spinal cord. In the present study, four (4) monkeys (M. fascicularis) were deeply anesthetized and perfused with mixed aldehydes. Portions of the cervical and lumbar cord were removed and sectioned at 25 μm on a vibratome. Glycine-IR profiles were visualized by immunostaining with anti-glycine using the PAP technique or by post-embedding immunogold staining. LM analysis revealed glycine-IR fibers to be present in all funiculi, but most concentrated in the myelinated fibers of the ventral funiculus. Glycine-IR neurons were present in all laminae, but at much lower concentrations in LII, IX, and X. Small diameter, round or oval cells were located in the upper laminae while larger cells with branching dendrites were present in deeper layers. EM analysis of the dorsal horn showed glycine-IR present in axon terminals, cell bodies, and both myelinated and unmyelinated fibers. Glycine-IR terminals contained round, clear vesicles and occasionally dense core vesicles. Glycine-IR terminals synapsed on both glycine-IR dendrites and unlabeled dendrites. Glycine-IR terminals were observed postsynaptic to glomerular primary afferents. Glycine-IR dendrites occasionally contained vesicles and synapsed on unlabeled dendrites. In the ventral horn, several different types of terminals synapsing on motoneurons were immunoreactive for glycine. (Supported by NS11255 and NS27910).

CO-LOCALIZATION OF SUBSTANCE P AND ENKEPHALIN IMMUNOREACTIVITIES IN SYNAPTIC BOUTONS APPOSED ONTO PHYSIOLOGICALLY IDENTIFIED DORSAL HORN NEURONES: AN ULTRASTRUCTURAL MULTIPLE-LABELLING STUDY. A. Ribeiro-da-Silva, Y. De Koninck, J.L. Henry and A.C. Cuello. Depts. Pharmacology & Therapeutics, Physiology and Anaesthesia Research, McGill Univ., Montréal, Qué., H3G 1Y6

The ultrastructural distribution of substance P (SP) and enkephalin (ENK) immunoreactivities was studied in association with identified dorsal horn neurones in the cat spinal cord. In chloralose-anaesthetized cats, intracellular recordings were obtained from dorsal horn neurones at the lumbar level using HRP filled electrodes. Cells were classified on the basis of their responses to natural stimulation of the receptive field. Subsequently, HRP was injected intracellularly and the cats were perfused with an aldehyde mixture. Vibratome parasagittal sections, 50 μm-thick, were obtained and incubated, in a single step, with a mixture of a bi-specific anti-SP/anti-HRP monoclonal antibody and an internally radiolabelled anti-ENK monoclonal antibody. After the diaminobenzidine reaction, the tissue was processed for electron microscopic radioautography. As previously demonstrated in the rat (Ribeiro-da-Silva *et al.*, *J. Neurosci.* 11:1068, 1991), SP and ENK immunoreactivities were co-localized in a population of axonal varicosities, mainly in laminae I and IIo. These double-labelled varicosities contacted either the dendrites or the cell bodies of intracellularly labelled dorsal horn neurones. One enkephalin-immunoreactive, lamina V, wide dynamic range neurone responded with a marked afterexcitation to noxious stimulation of the skin. In addition, this neurone had a large number of synaptic contacts (>30%) from varicosities positive for SP but not ENK; many of these varicosities are likely to be of primary sensory origin. These findings suggest a particular interaction between peptidergic primary sensory fibres and certain physiological types dorsal horn neurones. It also indicates an important participation of neurones colocalizing SP and ENK in the integration of sensory information.

RESPONSE CHARACTERISTICS OF DORSAL HORN NEURONS ROSTRAL TO A UNILATERAL PARTIAL LESION OF THE LOWER LUMBAR SPINAL CORD IN AWAKE, DRUG FREE, CATS. H. Hirata, H. Uchida*, K. Kishikawa, Y. Yamamori* and J.G. Collins. Dept. Anesthesiology, Yale University School of Medicine, New Haven, CT 06510

There is increasing evidence that damage to the peripheral or central nervous system may change the response profile of spinal dorsal horn neurons. The purpose of this study was to examine the effect of a unilateral partial cord lesion on dorsal horn neurons (DHNs) rostral to the lesion site. Cats were implanted with a chronic recording chamber centered over the 4th lumbar vertebra. At the same time electrolytic lesions were made one to two spinal segments caudal to the recording area in the dorsal and ventral gray matter on one side of the spinal cord. Extracellular recordings from the ipsilateral dorsal horn were made, beginning one week after surgery, in awake cats.

Thus far, a total of 19 single DHNs were studied over a period of up to two months. Of these, 17 units (89%) had low rates of spontaneous activity (less than 2 impulses/sec) and most of them n = 13 (68%) fired at less then 0.5 impulses/sec. These values do not appear to be greater than those previously obtained from non-lesioned animals. Of the 15 classified DHNs, 7 units (47%) were wide dynamic range (WDR) and 8 were low threshold (LT). The percentage of WDR neurons found in the lesioned cats was somewhat higher than the values previously obtained in normal animals (11%) but similar to that in cats with complete thoracic spinal cord transection (55%). More samples are necessary to determine if this increase in WDR neurons was due to the spinal cord lesions. An increased population of WDR neurons may contribute to chronic pain syndromes observed in spinal cord injured humans. EFFECTS OF SLEEP ON SPINAL CORD DORSAL HORN LOW THRESHOLD NEURONAL ACTIVITY.

K. Kishikawa, M.D., J.G. Collins, Ph.D., H. Uchida, M.D.,* Y. Yamamori, M.D.*

Dept. of Anesth., Yale Univ. School of Med., New Haven, CT 06510

The purpose of this study was to examine the effects of natural sleep on the response properties of spinal cord dorsal horn neurons to low intensity stimulation of their peripheral receptive fields (RFs). Extracellular recordings of single spinal dorsal horn neurons (n = 6, to date) were made in physiologically intact, awake, drug-free cats during EEG confirmed wakefulness and sleep stages (control awake, eye closed and relaxed stage, slow wave sleep, rapid eye movement (REM) sleep). The size of RF area that was sensitive to light touch and the neuronal responses to brushing the RFs were determined. There was no change in the low threshold RF size of any neuron during any sleep state. One neuron showed an increased response to brushing during REM and slow wave sleep. Two neurons presented decreased response to brushing during various sleep stages. The other three neurons demonstrated no change in response to brushing during sleep. In one of these three neurons, propofol (7.5 mg/kg) was administered intravenously after sleep effects were studied. The response to brushing in that neuron was reduced after propofol. These results indicate that natural sleep itself caused alterations in spinal cord dorsal horn neuronal activity, in a way that may be different from our previous reports of suppressive effects of pentobarbital (Brain Res 525, 189-97, '90.) and propofol (Anesthesiology 73, A 697, '90.) on spinal sensory processing. Supported in part by NIH GM-29065

ASCENDING PROPRIOSPINAL CONNECTIONS TO THE UPPER CERVICAL SPINAL CORD IN THE RAT: POSSIBLE INVOLVEMENT IN FUNCTIONAL RECOVERY FOLLOWING SPINAL CORD INJURY.

R.P. Yezierski and M. Santana*. Dept. of Neurological Surgery and The Miami Project, Univ. of Miami, Miami, FL 33136.

It is well known that a large proportion of spinal neurons belong to a class of cells that interconnect different segments and levels of the spinal cord. Although these propriospinal neurons have been implicated in both sensory and motor function, little is known about the organization or function of the rat propriospinal system, a species often used in studies of the intact or injured spinal cord. The present study was carried out to evaluate the distribution of rat propriospinal neurons projecting to the upper cervical spinal cord and to study their potential involvement in the recovery of function following spinal cord injury.

Fluorescent tracers, including Fluorogold, DAPI and Fast Blue, were injected into cervical segments C2-C3; injection volumes ranged from 0.5-1.0μl. Following survival times of 5-7 days animals were perfused transcardially with 4% paraformaldehyde, tissue sectioned at 35-50μm and viewed with Epi-fluorescent illumination. The distribution of neurons with ascending propriospinal connections included the dorsal and ventral horns, the region around the central canal and the lateral spinal nucleus. Although the majority of labeled neurons were found within 5 segments of injection sites, large numbers of cells were also found throughout the lumbosacral cord. In preliminary experiments, performance on sensory and motor tasks were assessed following mechanical or neurotoxic lesions in the thoracic cord (T7-T12). In these animals functional recovery was found to correlate with the presence of propriospinal labeling from cord levels below the lesions to injection sites in the upper cervical cord. (Supported by NS28059 and The Miami Project).

LABELING OF PRIMARY AFFERENT NEURONS INNERVATING SPINAL CORD AND PERIOSTEUM FOLLOWING SPINAL CORD TRANSECTION. E.L. Hill, H.A. Dancuasse*, and V.R. Holets. Division of Endocrinology and Dept. of Neurological Surgery and The Miami Project, Univ. of Miami, Miami, FL 33136.

Osteoporosis develops after spinal cord injury even with weight-bearing (as in the neonatally lesioned rat). Changes in central and peripheral sensory innervation may affect neuropeptides (such as CGRP) implicated as modulators of bone metabolism and may be involved in bone loss after spinal cord injury. Retrograde tracing techniques were used to demonstrate that primary afferent neurons supplying periosteum in affected bones also project to areas of spinal cord known to undergo reorganization after transection.

Five day old rats received a spinal cord transection at the T8 level. Six months after transection, the retrograde tracer Fast Blue was injected under the periosteum of the right tibia. Rhodamine-labeled latex microspheres were injected into the right half of the spinal cord at L1 5 days later. Rats were euthanized 3 days later. Dorsal root ganglia (DRG) from T8-S1 were examined for labeling. Unlesioned littermates were also labeled.

Fast blue labeled cells were confined to L1-L3. In some animals labeled cells were only observed in a single DRG. Rhodamine labeling was present in T8-S1 and was greatest in T9-L1. Double labeled cells were seen in L1-L3. CGRP immunoreactivity was found in both Fast Blue and rhodamine labeled cells. Many CGRP fibers are found in periosteum and CGRP has been implicated as a modulator of bone metabolism. Primary afferent nerve fibers containing CGRP are altered in the spinal cord after injury. The peripheral processes of these DRG neurons may also innervate bone and be altered after spinal trauma. Supported by The Miami Project to Cure Paralysis and The Daniel Heumann Fund for Spinal Cord Research.

SECONDARY NEURONAL DEGENERATION IN THE RAT SPINAL CORD. S. Saporta. Department of Anatomy. University of South Florida College of Medicine, Tampa, FL 33612.

There has been considerable interest in visualizing neurons in the spinal dorsal horn that undergo secondary degeneration following damage to dorsal root afferents or their cell bodies. With modification of a newly described histochemical technique using esterification followed by ionic silver "development" of damaged neurons described by van den Pol and Gallyas (J. Comp. Neurol. 296:654-673, 1990), it has been possible to visualize both surgically damaged dorsal root afferents within the dorsal horn; and, 2 - 3 weeks after the lesion, neurons in laminae I and II that stained as if they were damaged as a result of deafferentation. It is assumed that this response is a result of the loss of primary afferent synaptic contact, and most of these neurons will continue to undergo secondary degeneration. However, the degree of synaptic loss required to allow these neurons to stain is not clear. No neuronal somata were stained during the first week after dorsal root rhizotomy. It has been possible, moreover, to quantify the distribution of these somata. Of the 103 impregnated neurons studied to date, 36 somata (35%) were located in lamina I and 67 somata (65%) in lamina II. In addition, most of these neuronal somata were sufficiently well impregnated to allow their tentative classification as lamina I type I (n= 10) or type II (n= 26) cells; or lamina II stalked (n=15) or islet (n=21) cells.

PAIN PATHWAYS: SPINAL AND TRIGEMINAL

401.1

SPINAL CORD WIDE DYNAMIC RANGE, BUT NOT NOCICEPTIVE SPECIFIC NEURONS ENCODE INTENSITY OF LONG-DURATION HEAT PAIN. R.C. Coghill[1], D.J. Mayer[1], R.L. Hayes[2], and D.D. Price[3]. Dept. [1]Physiology, [2]Neurosurgery, and [3]Anesthesiology, Medical College of Virginia, Virginia Commonwealth University 23298-0551

A common feature of both clinical and experimental pain is the absence of habituation during prolonged exposure to noxious stimuli. The central nervous system mechanisms coding these prolonged sensations of pain, however, remain poorly understood. The present investigation examines the involvement of single spinal cord wide dynamic range (WDR) and nociceptive specific (NS) neurons to prolonged (20 minute) noxious thermal stimulation and relates them to psychophysical ratings of identical stimuli. Electrophysiological experiments were conduced in paralyzed, T-2 spinal cord transected rats. Neurons whose receptive fields included the distal portion of the hind limb were stimulated by cyclical immersion (5 sec in, 5 sec out) of the hind paw in a heated water bath. The receptive field of each cell was stimulated with a neutral (35° C; 2.5 min), a warm (43° C; 2.5 min), and one noxious temperature (45°, 46°, 47°, 48°, or 49° C; 20 min.). Only one cell was examined per rat.

NS neurons exhibited a temporal response pattern dramatically different from that of WDR neurons. NS neurons stimulated with 49° C temperatures reached a peak discharge frequency during the first two minutes of stimulation and habituated to baseline (35° C) levels in less than 5 minutes. Discharge frequencies of WDR neurons similarly were highest during the first two minutes of stimulation, but, importantly, failed to habituate substantially and were maintained at approximately 70% of peak levels during the subsequent 18 minutes of noxious stimulation. Psychophysical ratings of pain intensity closely parallel the temporal pattern of WDR responses, indicating that WDR neurons, but not NS neurons subserve long-term thermal nociception. Supported by PHS grant NS-24009-1A2 and FIDIA Pharmaceuticals.

ASSOCIATIVE LEARNING OF AN ANTINOCICEPTIVE RESPONSE AT THE LEVEL OF THE SPINAL CORD IN INTACT RATS. P.A. Illich, K.D. Burks*, & J.W. Grau. Dept. of Psychology, Texas A&M Univ., College Station, TX 77843.

Prior work suggests that the circuitry needed to obtain conditioned antinociception exists at the level of the spinal cord. Because our past work used a reduced preparation (spinal) it is not clear whether this type of learning normally occurs in intact subjects. The present study addresses this issue by testing whether subjects that had been trained with the cord intact will exhibit conditioned antinociception after the cord has been transected. Twelve intact rats received differential conditioning (which controls for sensitization and pseudoconditioning). One stimulus (the CS+) was paired with mild tail-shock (2-s, 0.5 mA), while the other (the CS-) was presented alone. Vibro-tactile stimuli to the left or right rear paw served as the CS+ and CS-. Which stimulus served as the CS+ was counterbalanced across subjects.The subjects received 30 CS+ and 30 CS- trials spaced 1 min apart. One hr after training all subjects received a spinal transection at T2. Twentyfour hrs later pain reactivity during the CSs was tested with the tail-flick test. Ten of the twelve subjects exhibited longer tail-flick latencies during the CS+ relative to the CS- ($p < .05$). These results suggest spinal systems can support associative learning in intact subjects. Supported by BNS 881981 to J.W.G.

401.3

SPATIAL DISTRIBUTION OF SPINAL CORD NEURAL ACTIVITY ENCODES THE DISTINCTION BETWEEN NOCICEPTIVE AND NON-NOCICEPTIVE SENSORY EVENTS D.D. Price,[1] R.C. Coghill,[2] R.L. Hayes,[3] and D.J. Mayer,[2] Departments of Anesthesiogy,[1] Physiology,[2] and Neurosurgery,[3] Medical College of Virginia, Richmond, VA 23298

Differences between distributions of spinal neural activity evoked by noxious (45,47,48,49°C) or non-noxious (35,43°C, vigorous mechanical brushing) stimulation were analyzed by the quantitative ^{14}C-2-deoxyglucose (2-DG) technique. Experiments were conducted in unanesthetized, T-2 spinalized rats paralyzed with curare. Stimulation of the whole left hindpaw was produced by cyclical immersion (5 sec in, 5 sec out) in a water bath in the case of temperature stimuli or from a servo-driven mechanical brush stimulus (vigorous mechanical). Each of 7 groups (5/group) were stimulated with one of the above listed stimuli. 2-DG procedures were those previously employed by Coghill et. al. (J. Neurophysiol. 65(1991)133-140). As previously reported, nociceptive stimulation produced somatotopically specific increases in glucose utilization with maximum activity occurring in L4 laminae V-VI. Metabolic activity expanded rostrally and caudally (L1 - L5) within laminae V-VI but not within laminae I-IV as noxious temperature increased. In contrast, vigorous mechanical stimulation evoked significant increases in metabolic activity only within the upper dorsal horn (laminae I-IV) and this activity was restricted rostral-caudally (L3, L4). Finally, although vigorous mechanical stimulation evoked greater activity than gentle mechanical stimulation (35°C water immersion) in the upper dorsal horn, it was much less than that evoked by nociceptive temperatures (45-49°C) in the deep dorsal horn. These findings further support the role of spatial recruitment in spinal mechanisms of nociception by indicating that the distinction between nociceptive and non-nociceptive sensory events may be reflected by both large differences in intensity and spatial distribution of neural activity (supported by NINDS Grant NS-24009-2A2).

401.4

CHARACTERIZATION OF NOXIOUS HEAT-EVOKED FOS PROTEIN-LIKE IMMUNOREACTIVITY IN THE RAT SACRAL SPINAL CORD. S.L. Jones. Department of Pharmacology, University of Oklahoma, Oklahoma City, OK 73190.

The expression of fos-related proteins can be utilized as markers for neuronal activation. The objectives of the present study were: 1) to characterize the expression of fos-like immunoreactivity in the sacral spinal cord evoked by the application of noxious heat to the tail, and 2) to determine if the expression of heat-evoked fos-like immunoreactivity can be modulated by intrathecally administered alpha adrenoceptor agonists. Rats were anesthetized with pentobarbital (45mg/kg, IP) and the tail was immersed in 55-60°C water for 10sec for 30 consecutive trials at 2min intervals. Time course experiments revealed that a 2 hour survival time resulted in optimal expression of fos-like immunoreactivity. The rats were perfused with paraformaldehyde; the sacral spinal cord was removed, vibratome sectioned (50µm, transverse), and processed for fos-immunoreactivity. Neurons demonstrating heat-evoked fos-like immunoreactivity were identified in superficial and deep dorsal horn laminae. Intrathecally administered norepinephrine (60 nmole) inhibits (to 47% of control, n=3) the expression of fos-like immunoreactivity; however, norepinephrine also appears to evoke the expression of fos-like immunoreactivity in a subpopulation of neurons located in the superficial dorsal horn laminae. Supported by Presbyterian Health Fdn. and OCAST.

401.5

THE RELATIONSHIP OF AN AVERSIVE OPERANT BEHAVIOR TO THE EXPRESSION OF *C-FOS* IN THE LUMBAR SPINAL CORD OF THE RAT. C.L.Lee, H.H.Willcockson*, C.J.Vierck, and A.R.Light. Dept of Physiology, UNC-Chapel Hill, Chapel Hill, NC 27599-7545. Expression of the proto-oncogene *C-fos* in spinal cord neurons is induced by stimulation of the skin presumably through activation by primary afferents. This study cor-relates the minimum intensity of electrical stimulation that motivates a rat to turn off this stimulus with the number of spinal neurons which label for *fos* protein immu-noreactivity in the lumbar dorsal horn of an anesthetized rat model. The behaving rat turned off the stimulus by pressing a bar with its forefoot 25% of the time at the lowest stimulus intensity (0.19 mA peak-to-peak) applied through contact electrodes on the dorsal and ventral surfaces of the rat's hindfoot. This corresponded to the production of *fos* immunolabeled neurons in laminae I and II of the dorsal horn which was above background level. At 0.34 mA, the rats pressed the bar 83% of the time and the number of *fos* labeled neurons was approximately twice the number labeled following the lowest level. At still higher stimulus levels (0.57mA and 2.83mA), the rats pressed the bar nearly 100% of the time and more quickly and with more force. These higher levels corresponded to more labeled neurons in laminae I and II as well as labeled neurons in deeper laminae. Thus, the number of *fos* immunolabeled neurons appears to be correlated with the aversive operant behavior. *Supported by NIH grants DA04420, NS16433, NS14899.*

401.6

EFFECT OF SPINAL SOMATOSTATIN OR KAINIC ACID SUPERFUSION AND NOXIOUS SKIN STIMULATION ON IMMEDIATE EARLY GENE EXPRESSION IN RAT SPINAL DORSAL HORN NEURONS *H. Beck and J. Sandkühler*, II. Physiologisches Institut, Universität Heidelberg, Germany.

Noxious skin stimulation causes rapid and temporal induction of immediate early genes such as *c-fos* and releases neuropeptides including somatostatin in the spinal dorsal horn. To test whether somatostatin is involved in the induction of *c-fos* experiments were performed on deeply pentobarbital anesthetized rats. Following laminectomy a pool was formed on the dorsum of the lumbar cord by means of a specially prepared silicon rubber. The pool was filled with artificial CSF before and after superfusion with somatostatin (10 μM, for 30 min) or kainic acid (0,3 mM, for 15 min). In other rats the glabrous skin at a hindpaw was stimulated by radiant heat (twelve 54°C pulses for 20s in intervalls of 1 min). One hour after these stimulations the rats were transcardially perfused with phosphate buffered saline and 4% paraformaldehyde. The FOS protein was detected by immunocytochemistry in free floating 50 μm frontal sections through the lumbar spinal cord. The mean numbers of FOS positive cells per section were determined. No differences in mean number and pattern could be detected following superfusion with CSF and somatostatin. Noxious skin heating and kainic acid superfusion increased the number of FOS positive neurons. These results show that the controlled superfusion of the rat cord dorsum is a useful tool to study the effect of putative neurotransmitters on gene expression in the spinal cord. Somatostatin apparently failed to mimick the effect of natural noxious skin stimulation i.e. failed to induce *c-fos* which further casts doubt on its role as an excitatory neurotransmitter of primary afferent nociceptors. SUPPORTED BY A GRANT FROM THE DEUTSCHE FORSCHUNGSGEMEINSCHAFT (SA 435).

401.7

SUBNUCLEUS INTERPOLARIS NEURONS CONTRIBUTE TO THE CONTROL OF ADRENAL AND AUTONOMIC FUNCTION THAT ACCOMPANIES TRIGEMINAL NOCICEPTION. D.A.Bereiter and A.P.Benetti* Section of Neurobiology & Department of Surgery, Brown Univ./R.I. Hospital, Providence, RI 02903.

The role of neurons in rostral portions of the spinal trigeminal nucleus in mediating sensory and/or autonomic responses to noxious stimulation of orofacial regions is not well defined. To assess the influence of neurons in subnucleus interpolaris (Vi) or in the principal sensory nucleus or in subnucleus oralis (Vp/Vo) on adrenal secretion of catecholamines and on cardiovascular function, cells were stimulated directly by microinjections of L-glutamate (0.5M, 100 nl) in chloralose-anesthetized cats. Microinjections of L-glutamate into Vi evoked prompt increases in the adrenal secretion of catecholamines (CA, P<0.001), total adrenal blood flow (P<0.005), adrenal vascular conductance (P<0.001), mean arterial pressure (MAP, P<0.001) and heart rate (HR, P<0.001), whereas injections into Vp/Vo had no consistent effects. Plasma ACTH was not affected regardless of the site of injection. These results indicate that chemical activation of neurons in different trigeminal subnuclei has an unequal influence on autonomic function. To examine the influence of rostral trigeminal neurons on autonomic responses to noxious trigeminal sensory input, thermal stimuli were applied to the corneal surface before and after local blockade of the ipsilateral Vp/Vo by injections of procaine (2%, 500nl). Noxious (52°C) corneal heat evoked prompt increases in CA (P<0.001), adrenal blood flow (P<0.001), adrenal vascular conductance (P<0.05), MAP (P<0.001) and HR (P<0.05). Ipsilateral blockade of Vp/Vo by procaine did not attenuate any of the thermal-evoked responses. Innocuous (45°C) corneal heat had no significant effects. These results are consistent with a role for neurons within Vi, but not within Vp/Vo, in the integration of sensory information relevant for adrenal and autonomic responses to noxious trigeminal stimuli. Supported by NIH grant NS26137.

ANATOMICAL AND PHYSIOLOGICAL STUDIES OF THE TRIGEMINOHYPOTHALAMIC TRACT. R. Burstein, A.M. Strassman and R.J. Maciewicz. Pain Physiol. Lab., Dept of Neurol., Mass. Gen. Hosp., and the Neurosci. Prog., Harvard Med. Sch., Boston, MA 02114.

A variety of facial and intraoral stimuli can alter the activity of hypothalamic neurons that are thought to participate in the control of autonomic and endocrine responses. Recent studies reported that neurons in the trigeminal nucleus caudalis project directly to the hypothalamus. In the present study we have used anatomical and physiological techniques to describe in greater detail the locations of trigeminohypothalamic tract (THT) neurons, and their physiological characteristics. In rats, injections of the retrograde tracer Fluoro-Gold that were restricted to the hypothalamus labeled several hundered neurons in the trigeminal complex from C1 to the obex. The majority of labeled cells were located in the caudal part of the trigeminal nucleus interpolaris at levels caudal to the obex. Within the medullary and C1 dorsal horn, labeled neurons were found primarily in laminae I and V. Few neurons were found in the trigeminal complex rostral to the obex. Throughout the trigeminal nuclei, labeled neurons were predominantly contralateral (approximately 90%). The nucleus of the solitary tract, the ventrolateral medulla (dorsal and lateral to the lateral reticular nucleus), and the medullary reticular formation also contained large number of labeled neurons. To date, we have recorded from 14 trigeminal neurons that were antidromically activated (<50uA) from the hypothalamus of anesthetized rats. Recording sites were found in the superficial (1 cell) and deep (9cells) laminae of the medullary and C1 dorsal horn. Four of the characterized neurons responded to innocuous mechanical stimuli but were more strongly activated by noxious mechanical stimuli. Five neurons responded only to noxious stimuli. The receptive fields were ipsilateral and covered small areas of the face (6 cells), large areas of the face and neck (2 cells), or the entire body (1 cell). The mean conduction velocity was 7m/s (range=2-13; n=12). In some cases (4), neurons were antidromically activated from both sides of the hypothalamus. The physiological data indicate that THT neurons in the deep dorsal horn carry sensory and nociceptive information directly to the hypothalamus. The anatomical data suggest that THT neurons are located in areas implicated in nociceptive processing, and that the number of these neurons in the trigeminal complex caudal to the obex is similar to the number of spinohypothalamic tract neurons previously demonstrated in individual spinal cord segments.

RETROGRADE LABELING OF NEURONS IN THE SPINAL CORD THAT PROJECT DIRECTLY TO THE AMYGDALA AND THE ORBITOFRONTAL CORTEX. S. Potrebic, R. Burstein and R.J. Maciewicz. Pain Physiology Lab., Dept. of Neurology, Mass. General Hospital, and the Neuroscience Program Harvard Medical School, Boston, MA 02114.

The amygdala and the orbitofrontal cortex have been implicated in motivational-affective responses to noxious stimulation. Nociceptive information is generally believed to reach the amygdala primarily through a relay in the parabrachial nucleus, and the orbitofrontal cortex through a relay in the thalamic nucleus submedius. In a recent study, however, injections of the anterograde tracer PHA-L into the spinal cord labeled fibers and varicosities in both the central nucleus of the amygdala and the medial orbital cortex. In the present study we further pursued these findings by using retrograde tracing techniques to describe the locations in the spinal cord of neurons that project directly to the amygdala and orbital cortex. In 7 cases, restricted injections (200nl) of the retrograde tracer Fluoro-Gold (FG) into the amygdala labeled several hundred neurons bilaterally (60% contra., 40% ipsi.) throughout the length of the spinal cord. About half of the labeled neurons were located in the deep dorsal horn (DDH), 25% in the lateral spinal nucleus, 13% in the gray matter surrounding the central canal (ACC) and 10% in the intermediate zone/ventral horn. More than half of the labeled cells were found in lumbar (L1-3, 32%) and cervical (C1-2, 25%) segments. The lower cervical (C4,5,7,8), thoracic (T4,6,8,12), and sacral (L6-S2) segments contained 18, 16 and 8% of the labeled neurons, respectively. In 3 cases, small injections of FG (100nl) into the orbital cortex labeled a very small number of neurons (approx. 50) in the spinal cord. More than 70% of the neurons were located within the DDH and ACC. About half of the cells labeled from the orbital cortex were found in the upper lumbar cord. Marginal zone neurons were not found to project directly into either the amygdala or the orbital cortex. These findings demonstrate an additional, direct pathway over which sensory and nociceptive information from the spinal cord may reach these regions.

A DOUBLE-LABELING STUDY OF THE CELLS OF ORIGIN OF THE SPINOHYPOTHALAMIC AND SPINOTHALAMIC TRACTS IN RATS. J.T. Katter, R.J. Dado and G.J. Giesler, Jr. Dept. of Cell Biol. and Neuroanat., Grad. Prog. in Neurosci., Univ. of Minn., Minneapolis, MN 55455.

Results of recent studies in rats have demonstrated the existence of neurons in the spinal cord that project directly to the hypothalamus. These spinohypothalamic tract (SHT) neurons are found in many of the same regions of the spinal gray matter as spinothalamic tract (STT) neurons. In the present study, a double-labeling strategy was used to determine whether SHT and STT neurons represent entirely distinct populations of spinal neurons or whether some spinal neurons project to both the hypothalamus and thalamus. Fluoro-Gold (FG) and cholera toxin B (CTB) were injected unilaterally into the hypothalamus and thalamus, respectively, of adult rats. Sections through 18 identified spinal segments were examined for neurons retrogradely labeled with either or both tracers. CTB was visualized using indirect immunocytochemistry. Neurons labeled with only FG, only CTB and with both FG and CTB were observed in each segment examined. Of the total number of neurons observed that were labeled with either (or both) tracers, roughly 40% were SHT neurons, 50% were STT neurons and 10% were neurons that projected to both the hypothalamus and thalamus. Doubly-labeled neurons comprised about 30% of the total number of SHT neurons and about 20% of the total number of STT neurons that were counted. The proportion of SHT or STT neurons that were doubly-labeled and their locations within the spinal gray matter varied with the spinal level. In general, most of the doubly-labeled neurons were located in the superficial dorsal horn, the lateral reticulated area and the lateral spinal nucleus. These results indicate that some spinal neurons project to both the thalamus and the hypothalamus. Supported by NS25932, DA07234 and MH10059.

PHARMACOGENETIC STUDY OF THE ANTINOCICEPTIVE RESPONSIVENESS OF C57BL/6 AND DBA/2 PROGENITOR AND DERIVED MOUSE STRAINS TO NITROUS OXIDE (N_2O). R.M. Quock, J. Mueller*, L.K. Ruppert* and L.K. Vaughn. Univ. Illinois Col. Med. at Rockford, IL 61107 and Marquette Univ., Milwaukee, WI 53233.

We have found that DBA/2 mice are resistant to N_2O antinociception in comparison to various other inbred mouse strains (Quock et al., IBRO 3rd World Congr. Abst., in press). In this study, we investigated the inheritance pattern for this insensitivity by measuring responsiveness to N_2O in C57BL/6 and DBA/2 parent strains, their $B6D2F_1$ offspring, and BXD/Ty recombinant inbred strains created by systemic inbreeding of an F_1 cross of B6D2. N_2O antinociception was measured as percent suppression of acetic acid abdominal constrictions (AC) in 70% N_2O compared to room air. C57BL/6 mice were highly sensitive to N_2O (60% suppression of AC), DBA/2 mice were highly resistant (<10% suppression), and $B6D2F_1$ mice were intermediate in sensitivity (49% suppression). In 19 BXD/Ty strains, responsiveness to N_2O varied from 100% to 0% suppression):

BXD-14 -100%; 25 -100%; 22 - 96%; 05 - 94%; 28 - 90%; 31 - 89%; 01 - 89%; 24 - 88%; 12 - 86%; 09 - 82%; 29 - 78%; 16 - 75%; 02 - 69%; 13 - 62%; 32 - 61%; 21 - 33%; 19 - 29%; 30 - 26%; 27 - 0%.

This pattern suggests that multiple genes may be responsible for the underlying neurobiological anomaly conveying resistance to N_2O antinociception. (Supported by N.I.H. Grant DE-06894 and grants from UIC COMCOR and CRB.)

ADDITIONAL TECHNIQUE FOR DETECTING VISCEROMOTOR RESPONSE TO COLORECTAL DISTENSION IN AWAKE AND LIGHTLY PENTOBARBITAL-ANESTHETIZED RATS. Y.Harada,* K.Nishioka,* L.M.Kitahata and J.G.Collins. Department of Anesthesiology, Yale University School of Medicine, New Haven, CT 06510

Visceromotor response to colorectal distension (CRD) has been demonstrated to be useful in visceral pain studies. While visual determination of visceromotor threshold (T) in response to CRD is easy and reliable, it is a subjective method. For the objective determination of the T, we have been using a newer technique in place of EMG employed by Gebhart and colleagues (Brain Research, 450: 153-169, 1988). In addition to a distension balloon, we insert a detection balloon that enables us to detect increases in intraabdominal pressure when the visceromotor response is evoked. The present study has examined the reliability of this technique in awake and lightly pentobarbital-anesthetized rats. This protocol was approved by the Yale Animal Care and Use Committee. Male Sprague-Dawley rats (280-430 g) were used. Both balloons were inserted intraanally under light halothane anesthesia and T were measured repeatedly every 5-10 min during 20 to 60 min after recovery from halothane. The detection balloon, 1.5 cm in length, was positioned ahead of the distension balloon. In pentobarbital anesthetized rats, T were measured repeatedly every 5-15 min for 1-3 hours after appearance of a clear visceromotor response. The balloon-detected T values in the awake (n=93) and anesthetized (n=22) state were 22.5 ± 4.1 and 23.0 ± 4.4 respectively (mmHg, mean ± SD). These values are comparable to the values reported by Gebhart and colleagues (22.4 mmHg). There was no significant difference between the balloon-detected T values and visual T values (23.3 ± 3.8 - awake, n=93; 23.4 ± 2.8 - anesthetized, n=22). Not only do the techniques seem comparable, but light pentobarbital anesthesia does not change the threshold values. (Supported by NIH grant NS-09871)

CORTICAL POTENTIALS EVOKED BY TOOTH PULP STIMULATION TO STUDY PAIN IN AWAKE RATS. P.J. Danneman[1], I.S. Zagon[4,5], T.J. Morrow[2,3]. Unit for Lab. Animal Medicine[1] and Depts. of Neurology[2] & Physiology[3], Univ. of Michigan Medical School, Ann Arbor, MI 48109 and Depts. of Neuroscience[4] & Anatomy[5], Penn State College of Medicine, Hershey, PA 17033

Behavioral tests to measure antinociception in animals are potentially affected by the sedative as well as analgesic effects of drugs. Accordingly, the cortical potential evoked by electrical stimulation of the tooth pulp is being evaluated as a nonbehavioral measure of antinociception in awake rats. Bipolar stainless steel electrodes are cemented into bur holes in the dentin of the left maxillary incisor. Recording electrodes are attached to skull screws located over the contra- and ipsi-lateral somatosensory cortex and vertex. A screw located over the cerebellum is used as reference. The best results are obtained with a 0.3 msec, 400μA stimulus and an amplifier bandpass of 0.3-90 Hz. The averaged evoked potential consists of a positive component at 34-40 msec (P35), a negative component at 93-102 msec (N100), and a positive component at 165-185 msec (P175). The effects of morphine, an analgesic with sedative effects, and droperidol, a nonanalgesic tranquilizer, were studied. Drugs were administered subcutaneously and recordings were made 30 min later. Morphine (5-20 mg/kg) produced an increased latency and decreased amplitude in P35, N100, and P175. Naloxone (0.5-2 mg/kg) antagonized these effects of morphine. Alone, naloxone had little effect on latency but increased the amplitude of P35 and N100. Droperidol (1.25 mg/kg) increased the amplitude of P175 and had little effect on latency.

These results suggest that this technique will be useful for studying the antinociceptive activity of compounds which may also have sedative or motor-inhibitory effects. (RR00052)+

DEPTH OF PENTOBARBITAL ANESTHESIA ALTERS PREPROTACHYKININ mRNA AND SUBSTANCE P LEVELS IN RAT DORSAL ROOT GANGLIA FOLLOWING CARRAGEENAN INFLAMMATION. D.B. Masters, C.T. Griggs* and C.B. Berde*. Children's Hospital and Harvard Medical School, Boston, MA., U.S.A.

Since biochemical studies of spinal nociceptive processing frequently employ pentobarbital (P)-anesthetized rats, we examined effects of P anesthetic dose on the content of substance P (SP) and preprotachykinin (PPT) mRNA in response to a peripheral inflammatory stimulus.

Male Sprague-Dawley rats (200-250g) were anesthetized by a single intraperitoneal injection of either 37.5 or 75.0 mg/kg P. Carrageenan (Cg; 6mg in 150μl) was injected into the right hind paw footpad 15 min post P injection. At 1 hr and 19hr post Cg injection, animals were sacrificed and lumbar (L4-6) and cervical (C3-5) dorsal root ganglia (DRG) and spinal cord (SC; L4-L6) samples were removed and frozen. Tissue samples were homogenized in urea/LiCl; supernatants were used for SP RIA and pellets were used for specific RNA quantitation by Northern blot analysis on nylon supports using a γ PPT riboprobe, a ß-actin cDNA probe and a 28S oligoprobe. Relative differences in mRNA levels were determined using a novel optical scanning technology and an improved small-sample normalization procedure based on a 28S oligonucleotide probe. Peptides were desalted on C18 columns, measured by RIA, and normalized to eluted protein levels. Data were analyzed by paired t-tests.

At 1hr, relative to contralateral control, there were significant ($p \leq 0.05$) decreases in lumbar DRG levels of PPT (-18.4±3.1%), ß-actin RNA (-27.9±1.7%) and SP (-23.1±6.9%) in 37.5 mg/kg P-anesthetized rats (n=4). No such decreases were seen in rats receiving 75.0 mg/kg P. At 19 hr post Cg, 37.5 mg/kg P-anesthetized rats showed a significant decrease in DRG SP (-23.9±6.7%) while DRG PPT levels showed no decrease (+10.7±6.4%; n=5; p=0.18). SC SP remained stable at all time points. In conclusion, changes in PPT and SP levels in models of nociception may be altered by the depth of P anesthesia. Moreover, normalization of RNA blots using ß-actin cDNA probes alone may be misleading.

STRESS-INDUCED HYPOALGESIA ON THE TAILFLICK TEST IN RESPONSE TO AUDITORY STIMULATION IS ATTENUATED BY BENZODIAZEPINES P.S. Bellgowan, P. Roberson* & F.J. Helmstetter, Department of Psychology, University of Wisconsin, Milwaukee, WI 53211

Exposure to a variety of environmental stimuli, such as a tone that has been paired with electric footshock during Pavlovian conditioning or footshock itself, can activate endogenous antinociceptive systems. The present study indicates that certain auditory stimuli alone are able to unconditionally elicit hypoalgesia. Rat subjects were exposed to a single 30 sec presentation of white noise (95 dB) while being tested for nociceptive reactivity with the radiant heat tailflick test. Noise stress resulted in a significant, time-dependent elevation in tailflick latency relative to both pre-noise baseline and non-stimulated controls. This hypoalgesia was selectively blocked by pretreatment with the benzodiazepine agonist midazolam (2.0mg/kg). Baseline tailflick latencies of groups exposed to noise did not differ from controls when animals were tested in the same apparatus 24 h later. These preliminary results indicate that exposure to white noise results in the activation of descending antinociceptive systems through a benzodiazepine-sensitive process similar to sensitization or anxiety.

402.6

POTENTIATION OF 2-DEOXY-D-GLUCOSE (2DG) ANALGESIA, BUT NOT HYPERPHAGIA BY ZOLANTIDINE, A H_2-FAMINE$_2$ (H2) RECEPTOR ANTAGONIST. J.E. Koch, L.B. Hough and R.J. Bodnar. Dept. of Psych., Queens Col. CUNY, Flushing, NY 11367, Dept. of Pharmacol. Mt. Sinai Sch. of Med. NY NY 10029 and Dept. of Pharmacol. Albany Med. Col. Albany NY 12208.

H2 receptor antagonists inhibit analgesia following morphine and an opioid form of foot shock, but potentiate opioid and nonopioid swim analgesia. 2DG analgesia and hyperphagia are each opioid-mediated, but are dissociable. The present study examined the effects of zolantidine (ZOL), an H_2 receptor antagonist upon 2DG analgesia and hyperphagia in rats. ZOL (0.1-1 mg/kg, sc) dose-dependently potentiated 2DG (450 mg/kg, ip) analgesia on the tail-flick for up to 1 h and the jump test for up to 2 h following either prior or simultaneous administration. The potentiations of 2DG analgesia (100-700 mg/kg, ip) by ZOL failed to shift the dose-response function of 2DG. In contrast, ZOL (0.1-1 mg/kg) failed to alter 2DG (700 mg/kg) hyperphagia which is consistent with previous failures of H_2 antagonists to alter intake. These data provide further evidence for dissociations between 2DG analgesia and hyperphagia, and indicate that the potentiation of this opioid-mediated form of analgesia following H_2 receptor antagonism is similar to opioid and non-opioid swim analgesia.

402.7

INHIBITION OF ANALGESIA FOLLOWING MORPHINE IN THE PERI-AQUEDUCTAL GRAY BY METHYSERGIDE IN THE VENTRAL MEDULLA OF RATS. J.M. Kiefel, M.L. Cooper* and R.J. Bodnar. Dept. of Psychology, Queens College, CUNY Flushing NY 11367.

Supraspinal opioid analgesia is mediated in part by a descending system which originates in the periaqueductal gray (PAG), synapses in the ventral medulla (nucleus raphe magnus (NRM); nucleus reticularis gigantocellularis (NRGC) and projects to the dorsal horn of the spinal cord. Little is known about the nature of the neurochemical link between the PAG and NRM/NRGC. Since a serotonergic pathway projects from the PAG to the ventral medulla, the present study evaluated intracerebral microinjection effects of the serotonin receptor antagonist methysergide (0.5-5 ug) into the NRM/NRGC upon morphine (2.5 ug) analgesia elicited from the PAG on the tail-flick and jump tests in rats. Methysergide administered into the NRM/NRGC significantly reduced morphine analgesia elicited from the PAG by 69% on the tail-flick test and by 50% on the jump test over a 1.5 h time course. In contrast, methysergide administered into adjacent medullary structures failed to alter morphine analgesia elicited from the PAG. Thus, it appears that a serotonergic synapse participates in the transmission of opioid pain-inhibitory signals from the PAG to the ventral medulla.

402.8

PHARMACOLOGIC ASPECTS OF BRAIN STEM HYPERALGESIC AND ANALGESIC PROCESSES IN THE RAT. S.R. Hamann, J.R. Holtman, Jr., S. Parvini, J.S. Fu and W.R. Martin. Dept. of Anesthesiology, Univ. of Kentucky, Lexington, KY.

Previous studies have demonstrated opioid and nicotinic hyperalgesic and analgesic processes in the dorsal posterior mesencephalic tegmentum (DPMT) and posterior medulla (PM) of the rat, respectively (FASEB J., 5:A860, 1991). The hyperalgesic processes appear to exhibit tonic activity since either naltrexone (N) or mecamylamine (M) produced dose related analgesia when microinjected into the DPMT. Using intact conscious rats fitted with indwelling cannulae we have further explored the pharmacology of these different brain stem regions. In the DPMT, three different local anesthetics [lidocaine (L), bupivacaine (B) and cocaine (C)] produced prolongation of low intensity thermally evoked tail avoidance reflex (LITETAR). A selective kappa agonist, U-50-488, produced dose related shortening of the LITETAR in the DPMT which was abolished by N. A selective 5HT-1A agonist, 8-OH-DPAT, produced prolongation of the LITETAR when administered in the PM. These findings support previous hypotheses including 1) presence of tonically active hyperalgesic processes in the DPMT, and 2) presence of opioid kappaergic hyperalgesic processes in the DPMT. Further, the results with 8-OH-DPAT indicate the presence of serotonergic analgesic processes in the PM where opioid and nicotinic analgesia has been previously demonstrated.

402.9

INHIBITION OF PGI_2 FORMATION PREVENTS THE EXCITATORY ACTIONS OF BRADYKININ IN NODOSE NEURONS OF THE GUINEA PIG *IN VITRO*. *G. M. Koschorke, D. Weinreich, G. E. Taylor*, W. C. Hubbard* and B. Undem**. Univ. Maryland Sch. Med. and Johns Hopkins Sch. Med., Baltimore, MD.

Bradykinin (BK) increases neuronal excitability in a subpopulation of nodose neurons by selectively blocking a spike induced slow afterhyperpolarization (AHP_s). This effect is dependent upon the production of a prostagladin (PG) (Europ. J. Pharmac., 132: 61-63, 1986). To identify which PG is mediating this BK effect, PG release from individual nodose ganglia was assayed using GC/MS analysis. Spontaneous PG release ranged between 1 and 20 fmole/ganglion for PGD_2, 9αIIβ PGF_2, PGE_2, $PGF_{2\alpha}$, TxB_2, and PGI_2. Of these PGs, only PGI_2 synthesis was significantly elevated by BK (100 nM) application, from 20 ± 4 to 51 ± 8 fmole (n=5). Tranylcypromine (TCP, 10 μM), a PGI_2 synthetase inhibitor, had no significant effect on spontaneous PG release but it completely abolished the BK-induced increase in PGI_2 formation.

When PGD_2, PGE_2, $PGF_{2\alpha}$, TxB_2, or PGI_2 were superfused onto nodose ganglion neurons, only PGI_2 blocked the AHP_s. TCP (10 μM) did not effect the AHP_s but its presence in the superfusate totally prevented the BK-induced block of the AHP_s (n=6). We conclude that BK blocks the AHP_s by selectively stimulating the synthesis of PGI_2. (NIH grant NS22069 to DW).

BRADYKININ STIMULATION OF DORSAL ROOT GANGLION CELL CULTURES. M.B. Bauer, M.L. Simmons, S. Murphy & G.F. Gebhart Dept. Of Pharmacology, University of Iowa, Iowa City, IA 52242.

Although prostaglandins are traditionally considered to have a peripheral involvement in nociception, they have been implicated as also having a central role. To test for a central role of prostaglandins in nociception, dorsal root ganglion cells were cultured from embryonic 15 - 19 day old rats. After 12 days in culture with Dulbecco's Modified Eagles Medium containing NGF and mitotic inhibitors, the cells appeared to be predominantly neuronal. Ionomycin (10^{-5} M) or bradykinin (BK; 10^{-5} M) stimulated the release of arachidonate (AA) metabolites from [^{3}H]AA-labelled cells. Specific RIA revealed that BK (10^{-8} to 10^{-5} M) stimulated the release of PGI_2 (prostacyclin) but did not stimulate the release of TXA_2. Additionally, it appeared that BK (10^{-6} M) stimulated the release of guanylyl cyclase-activating factor (GAF), the production of which was inhibited by NMA (N-monomethyl arginine). Overall, it appears that BK stimulates the release of prostacyclin and possibly a nitrosyl compound from cultures of embryonic dorsal root ganglia.

402.11

GLUTAMATE RECEPTOR ANTAGONIST DEPRESSION OF A CAPSAICIN-EVOKED NOCICEPTIVE REFLEX. B. Ault & L. Hildebrand. Dept. Neurosciences, Sterling Research Group, 81 Columbia Turnpike, Rensselaer, NY 12144.

The isolated spinal cord-tail preparation of the neonatal rat (Otsuka & Yanagisawa, J. Physiol. 395, 255-270, 1988) provides a model of a nociceptive reflex, in which application of capsaicin to the sensitized rat tail evokes a depolarizing response in lumbar ventral roots (CAP-VR), primarily by activation of C-fibers. Stimulation of the segmental dorsal root evokes a ventral root potential consisting of a monosynaptic reflex (MSR) and polysynaptic activity. Capsaicin (3 μM, 3s) and maximal electrical stimulation (0.4 ms, 0.2-1 mA) were presented at 15 min intervals to avoid tachyphalaxis.

Test drugs were perfused, in cumulative doses, over the spinal cord for at least 15 min. Morphine and clonidine completely suppressed the CAP-VR (IC50s of 200±80 nM, N=3, and 180±70 nM, N=3, respectively) but had little effect on the MSR or early polysynaptic responses. The effects of morphine and clonidine were antagonized by application of naloxone or efaroxan respectively. The NMDA antagonist AP5 (1-100 μM) depressed the CAP-VR, MSR and polysynaptic activity by a maximum of 31%, 31% and 33% respectively (N=3), suggesting a limited role of NMDA receptors in Mg-containing medium. An AMPA receptor antagonist CNQX (0.01-100 μM) suppressed the CAP-VR, MSR, and strongly inhibited polysynaptic responses, with respective IC50s of 0.27±0.09 uM, 1±0.3 uM and 5.2±3 uM, N=3). These data indicate that AMPA receptor-mediated synapses play a critical role in spinal transmission, including nociceptive activity. AMPA receptor subtypes may therefore provide novel analgesic targets.

402.12

INTRATHECAL PHACLOFEN ATTENUATES ANALGESIA PRODUCED BY MICROINJECTION OF GLUTAMATE INTO THE NUCLEUS RAPHE MAGNUS IN THE RAT. M.K. McGowan and D.L. Hammond. Department of Anesthesia & Critical Care, University of Chicago, Chicago, IL 60637.

This experiment examined whether the antinociception produced by chemical stimulation of neurons in the nucleus raphe magnus (NRM) is mediated by $GABA_B$ receptors in the spinal cord. Rats were prepared under general anesthesia with an intrathecal (IT) catheter and a chronic guide cannula aimed at the NRM. After a one-week recovery period, baseline nociceptive sensitivity was determined using the tail flick test. Rats were then injected IT with either 2.5 mmol phaclofen, a selective $GABA_B$ antagonist, or with vehicle (25% Molecusol). Fifteen minutes later, 30 nmol L-glutamate was microinjected into the NRM and tail flick latency (TFL) was redetermined at fixed intervals thereafter. Microinjection of glutamate significantly increased TFL in both vehicle- and phaclofen-pretreated rats ($p < 0.05$). However, TFL in phaclofen-pretreated rats was significantly shorter than that in saline-pretreated animals 1 minute ($t = 2.36$, $p < 0.05$) after glutamate administration. These results suggest that GABA in the spinal cord may modulate descending inhibitory systems from the raphe via its action at local $GABA_B$ receptors.

402.13

OPIOID THERMAL ANALGESIA IN MICE PRODUCED BY SYSTEMIC ADMINISTRATION OF A CCK-B ANTAGONIST. H. Chen* and D.A. Downs. Dept. of Pharmacology, Univ. of Michigan, and Dept. of Neuroscience, Warner-Lambert/Parke Davis Research Inst., Ann Arbor, MI 48109.

PD 134308 is a CCK-B antagonist with high selectivity (Hughes *et al.*, Proc. Natl. Acad. Sci. USA, 1990, 87:6728-6732). Its systematic name is [R-(R*,R*)]4-[[2-[[3-(1H-indol-3-yl)-2-methyl-1-oxo-2-[[(tricyclo[3,3,1,$1^{3,7}$]dec-2-yloxy)carbonyl]amino]propyl]amino]-1-phenylethyl]amino]-4-oxobutanoic acid. An analgesic effect of PD 134308 was obtained in mice using a 50° C. tail withdrawal assay. PD 134308 produced analgesia dose-dependently in a cumulative dose response procedure (10-320 mg/kg). Full effect (20-sec cutoff) was produced by 320 mg/kg. The analgesia induced by PD 134308 was antagonized by 10 mg/kg naltrexone and by 1 mg/kg naltrindole. The analgesic effect of morphine was enhanced by PD 134308, but attenuated by CCK-4; both drug interactions were modest effects.

Recent ligand binding studies (*ibid.*) have shown that PD 134308 is not a direct ligand at opioid receptors. PD 134308-induced anlagesia could be produced through an augmentation of endogenous opioids. *H.C. supported by a Warner Lambert postdoctoral fellowship.*

OPIATE AND NONOPIATE INTERACTIONS IN TWO FORMS OF STRESS INDUCED ANALGESIA. J. Grisel, M. Fleshner, L. Watkins, S. F. Maier Department of Psychology, University of Colorado, Boulder, CO 80309.

Stress induced analgesias (SIAs) have been traditionally classified as either "opioid" or "nonopioid". In 1982 Kirschgessner et al. (*Pharm, Biochem & Beh. 17:1175).* proposed that opioid and nonopioid analgesia systems did not function as independent systems, but rather interacted in a mutually inhibitory fashion. Here we report a number of experiments which further support this model. Cold water swim (4 min. at 14° C) produces a nonopioid analgesia. We exposed rats to 5 daily sessions of cold water swim and found the hypoalgesia to be potentiated by naltrexone (14 mg/kg sc, 20 min before stress). Moreover, administration of a low dose of morphine (1.5 mg/kg sc), 15 min before the swim sessions actually reduced the analgesia that resulted. The combination of morphine and cold water produced less analgesia than did either separately. A similar pattern of findings resulted from the administration of naltrexone or morphine before another stressor that produces nonopioid SIA, social defeat. Intruder rats were exposed to established colonies for 10 min on 5 consecutive days. Naltrexone or morphine was administered before the daily defeat session. Naltrexone potentiated the resulting analgesia, and animals given defeat and morphine were less analgesic than those that received only morphine. These data provide further support to the idea that there is an interactive relationship between opioid and nonopioid analgesia systems. Supported by NSF grant BNS 88-09527.

MONOSIALOGANGLIOSIDE GM1 REDUCES NOCICEPTIVE BEHAVIORS AND SPINAL CORD METABOLISM IN RATS WITH PERIPHERAL MONONEUROPATHY J. Mao[1], R. L. Hayes[2], D. D. Price[3], R. C. Coghill[1], J. Lu[1], and D. J. Mayer[1]. Dept. of [1]Physiology, [2]Neurosurgery, and [3]Anesthesiology, Medical College of Virginia, Richmond, Virginia 23298

Effects of a monosialoganglioside GM1 were examined on nociceptive behaviors and spinal cord metabolic changes in rats with a peripheral mononeuropathy produced by sciatic nerve ligation. Behavioral changes of ligated rats were assessed by the radiant heat foot-withdrawal test and by rating spontaneous hind paw guarding positions. Effects of GM1 treatment on spinal cord metabolic activity were examined by using the 2-deoxyglucose autoradiographic technique. All drug treatments were given daily for up to 9 days postsurgery. 1) Intraperitoneal (IP) GM1 (10mg/kg, n=6/group) reduced thermal hyperalgesia of the rat hind paw ipsilateral to nerve ligation, when initiated up to 24 hrs after nerve ligation (ANOVA, $P < 0.001$); 2) The hyperalgesic response also significantly decreased in a dose dependent manner in ligated rats when intrathecal (IT) GM1 was initially administered 1 hr after nerve ligation at the lumbar spinal cord (10 - 80 nmol, n=7/group), but not at the cervical spinal cord (20 nmol, n=9)(ANOVA, $P < 0.01$), indicating a lumbar spinal mechanism of GM1 action. Moreover, 80 nmol IT GM1 significantly lowered the rating score of spontaneous hind paw guarding positions ($P < 0.05$), suggesting the attenuation of spontaneous pain; 3) IP GM1 (10mg/kg, n=6) initiated 1 hr after nerve ligation significantly reduced the abnormal increase of metabolic activity seen 10 days following nerve ligation in all four sampled regions (laminae I-IV, V-VI, VII, VIII-IX) on both sides of spinal lumbar segments (L2-L5)(ANOVA, $P < 0.01$). This decrease of spinal cord neural activity may also reflect the influence of GM1 on spontaneous pain. Our data suggest that ganglioside treatment may be a promising approach for clinical management of neuropathic pain syndromes. Supported by Fidia Pharmaceuticals.

RETINA AND PHOTORECEPTORS: CIRCUITS AND SIGNALS

NBQX REVEALS A PROMINENT NMDA RESPONSE IN THE RABBIT RETINA. Ethan D. Cohen*, Tage Honore* and Robert F. Miller*, Dept. Physiol., U.of Minn.Med.School,Mpls, USA*, A/S Ferrosan, CNS Div., Soeborg, Denmark*.

NBQX (2,3-Dihydroxy-6-nitro-7-sulfamoyl-benzo(F)quinoxaline) is the most selective antagonist yet developed for non-NMDA vs. NMDA excitatory amino acid transmission. We have studied NBQX in the superfused rabbit retina using bath application of drugs and a combination of intracellular and extracellular electrophysiological techniques. Intracellular recordings from horizontal cells (cone dominant) revealed a near complete suppression of the light response using 5-30μM NBQX. These effects are rapidly reversed when NBQX is removed from the bathing medium. Recordings from depolarizing amacrine cells (AII-like units) show a transient loss of the light evoked response in the presence of NBQX, followed by some recovery. In ganglion cell recordings, the most common observation is a transient loss of the light evoked response, followed by a substantial recovery during a prolonged application of NBQX. In the presence of NBQX, the addition of D-AP7 to block NMDA receptors strongly blocks the light evoked responses. We interpret these results to indicate that NBQX blocks non-NMDA input by selectively interacting at these receptors, leaving (or possibly enhancing) a substantial NMDA mediated synaptic response.

FUNCTIONAL CONSEQUENCES OF MORPHOLOGY IN TYPES A AND B HORIZONTAL CELLS OF CAT RETINA. R.G. Smith and P.Sterling, Dept. Anatomy, Univ. of PA, Phila., PA 19104-6058.

Horizontal cells in cat retina are of 2 morphological types. Type A has thick dendrites (> 2 um), that tend to branch distally; type B has thinner dendrites that tend to branch proximally. Both receive cone synaptic input onto spine heads that connect to dendrites via thin necks (0.1 um dia., 3-5 um long).

To explore what functional differences these morphological differences imply, we simulated, using a compartmental model, isolated horizontal cells with synaptic inputs connected to. dendritic spines. We activated each synapse separately and recorded the postsynaptic potential at the soma to map "synaptic weight" vs. radial distance from soma. Synaptic weight in the type A cell was virtually constant with radial distance, whereas synaptic weight in the type B cell decreased with radial distance. Transfer of voltage from soma to peripheral dendrites was nearly 100% for both types when synapses were inactive. When all synaptic conductances were partially activated (100 pS/synapse), the space constant of synaptic transfer in the type B cell was markedly reduced.

If both cell types contribute to a Gaussian-like surround in the cone, the B type would contribute to the narrow, domed peak, whereas the A type would contribute to the wide, distal skirt. Supported by EY00828 and T32-EY07035.

403.3

SYNAPTIC APPARATUS ASSOCIATED WITH TRANSMISSION OF A SINGLE PHOTON EVENT. R. Rao and P. Sterling. Dept. of Anatomy, Univ. of PA, Philadelphia, PA 19104.

A rod in cat retina contacts 2 rod bipolar cells at a single ribbon synapse. The presynaptic membrane subjacent to the ribbon (arciform density) extends for almost 2 um, demarking an area over which ~100 synaptic vesicles can attach prior to exocytosis. The ribbon surface serves as depot for ~500 vesicles. We reconstructed from electron micrographs of serial sections the corresponding synaptic apparatus at the second stage of the circuit where 2 bipolar axons contact 5 AII amacrine cells. Individual ribbons in the rod bipolar axon are small: length of arciform density = 0.23 ± 0.09 um; surface area = 0.045 ± 0.025 um^2. However, the number of ribbons is great: 59 ± 3 ribbons/2 bipolar axons. Consequently the total area for attachment at the presynaptic membrane can accomodate ~675 vesicles, and the total ribbon surface can accomodate ~1500 vesicles. Thus, the synaptic apparatus at the second stage expands by roughly 5-fold.

The signal in a rod due to one photoisomerization is prolonged (integration time ~250 ms), but at the AII cell it quickens to about 50 ms. If the total length of the arciform density is proportional to the number of vesicle release sites, and the probability of release is the same at each site, then the number of vesicles modulated by one photoisomerization (#release sites x probability of release x integration time) would be similar at both stages. Supported by EY00828.

MORPHOLOGY AND SYNAPTIC INPUTS TO LUCIFER YELLOW INJECTED BIPOLAR CELLS IN RAT RETINAL SLICES. J.F. Muller[1,2], P.D. Lukasiewicz[1] and M.S. Silverman[2]. [1]Dept. Ophthalmol., Washington Univ. Sch. of Med., [2]Sensory Neurosci. Lab., Central Inst. for the Deaf.

The morphology and circuitry of rodent bipolar cells have not been well characterized. We have injected Lucifer yellow into visually identified bipolar cells in rat retinal slices which were lightly fixed in aldehydes. With this technique, a variety of bipolar cells can be labeled efficiently. In most cases, Lucifer yellow clearly labeled bipolar cell dendrites, axons and terminal arbors. In well-labeled cells Lucifer yellow was photoconverted with intense blue light in the presence of diaminobenzidine, to yield a dark, stable, osmiophilic reaction product. Slices were subsequently fixed in more concentrated aldehydes, post-fixed, stained and embedded, similar to Sandel *et al.*, (J. Comp. Neurol. 283:303,1989), for camera lucida drawing and ultrastructural analysis. Four general morphologies of bipolar cell have been distinguished from these preparations: Two terminate in sublamina a of the inner plexiform layer (IPL), (type a, putative off cells), and two terminate in sublamina b (type b, putative on cells). 1) The more commonly found type a bipolar cell has a fine, diffuse terminal arbor, similar to the *cb2* bipolar cell described in cat (Kolb *et al.*, Vision Res. 21:1081, 1981). Our preliminary ultrastructural findings suggest that these cells, as with *cb2* bipolar cells in cat (Nelson & Kolb, Vision Res. 23:1183, 1983), receive cone input through a non-invaginating basal junction. 2) A second morphology of type a rat bipolar cell is characterized by a single terminal swelling close to the amacrine cell layer border. 3) The most commonly found bipolar cell has been a type b cell, terminating in a small calyx near the proximal IPL border, resembling rod bipolar cells described in a number of mammalian species. 4) A second type b bipolar cell has fine, broadly stratified terminals, more distally in sublamina b, similar to *cb6* bipolar cells described by Kolb and coworkers in cat. Further ultrastructural analysis is under way to determine whether these bipolar cell types are contacted by rods or cones.

TWO DIFFERENT EXCITATORY AMINO ACID RECEPTORS IN ON-BIPOLAR CELLS OF THE MUDPUPPY RETINA. W. B. Thoreson and R. F. Miller. Dept. of Physiology, University of Minnesota, Minneapolis, MN 55455.

Whole cell recordings were obtained from ON-bipolar cells in the mudpuppy retinal slice. At a holding potential of -50 mV, L-2-amino-4-phosphonobutyric acid (L-AP4, 5-10 μM) produced an outward current and membrane conductance decrease. In contrast, AMPA (50 μM) produced an inward current accompanied by a conductance increase. A selective non-NMDA excitatory amino acid antagonist, NBQX (2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo(F)quinoxaline, courtesy of T. Honoré, 30 μM), suppressed the conductance increase observed with AMPA, but had no significant effect on the response to L-AP4. Responses to L-AP4 persisted for up to 1 hr. when the patch pipette contained 0.5 mM GTP. Before washout of the L-AP4 response by prolonged dialysis, kainic acid (KA, 30 μM) typically caused a small outward current similar to L-AP4. After washout of the L-AP4 response, KA produced an inward current similar to AMPA. These results suggest that ON-bipolar cells in the amphibian retina possess both L-AP4 and KA/AMPA excitatory amino acid receptors. It is, at present, unclear what role the non-L-AP4 receptors play in normal synaptic transmission. Supported by NIH grants EY03014 and EY06213.

403.6

GLUTAMATE RECEPTOR SUBTYPES IN OFF-CENTER BIPOLAR CELLS. B.R. Maple and F.S. Werblin, Neurobiology Group, Univ. of California, Berkeley

Glutamate activated conductances were studied in bipolar cells isolated from salamander retina. A multibarrel array was used to rapidly deliver known concentrations of glutamate to voltage clamped cells. "Off" cells were selected for, based on their tendency to have relatively short Landolt clubs or displaced morphology. Responses were characterized according to the ranges of activation and desensitization with respect to glutamate concentration, and the effects of glutamate antagonists.

Initial results suggested the existence of at least three types of excitatory non-NMDA receptors, based on the following dose-response profiles observed: 1) Cells for which activation began at about 15 uM GLU, but no desensitization was observed at concentrations up to 40 uM. At concentrations above 40 uM, the initial peak response continued to grow, but the steady state response declined somewhat due to desensitization. 2) Cells with no response to 20 uM GLU, but with a CNQX sensitive response that strongly desensitized at 40 uM. 3) Cells which responded to 10 uM GLU and exhibited CNQX resistant responses that almost completely desensitized at 20 uM GLU.

Some cells displayed both "on" and "off" conductance mechanisms. Typically, in these cells 20 uM GLU elicited a slow conductance decrease associated with a reversal potential near -5 mV, but 40 uM GLU elicited a response dominated by a type 2 excitatory conductance increase. These cells could operate in an opponent fashion with respect to different photoreceptor inputs.

Earlier studies of glutamate responses and osmotically induced transmission in retinal slices (Soc.Neurosci.Abs. 16:297.2) suggest that type 1 receptors may predominate in bipolar cells with axons ramifying in the distal 1/4 of the IPL, whereas type 2 and 3 receptors may predominate in more centrally ramifying bipolar cells. Bistratified cells ramifying in both distal and central "off" sublaminae probably possess both "on" and "off" receptors, as they displayed APB sensitivity and predominantly "on" responses to osmotically induced transmission.

LOCALIZATION OF $GABA_A$ RECEPTOR IN THE OUTER RETINA OF CAT AND MONKEY. P. Masarachia*, N. Vardi, and P. Sterling. Dept. Anat., U. of Penn., Phila, PA 19104.

Horizontal cells in cat retina are thought to be GABAergic because they contain mRNA for glutamic acid decarboxylase (GAD) and endogenous GABA. However, mammalian horizontal cells do not react with antisera to GAD, nor do they accumulate exogenous GABA; monkey horizontal cells are negative for an mRNA probe for GAD. We sought additional evidence on this issue by localizing the $GABA_A$ receptor. Monoclonal antibodies to the β and α subunits (bd-17 and bd-24, kindly donated by J. G. Richards), were applied to aldehyde-fixed retinas of cat and monkey. The binding patterns were revealed as a diaminobenzidine reaction product ("stain"). As reported by others, (Hughes et al., 1991, Vis. Neurosci., 6:229-238) stain was densely distributed in the inner plexiform layer, especially in strata 4 & 5, and in somas of certain amacrine, bipolar, and ganglion cells. A new finding was that stain was consistently present (to both antibodies and in both cat and monkey) in the outer plexiform layer mainly, as a dense, punctate deposit. This stain, observed by EM, filled the extracellular space at the triad but was absent from the space surrounding the horizontal cell terminal bulbs. Stain was also distributed in fine strings of tiny, punctate deposits lateral to the pedicle bases, but rod spherules were not stained. The presence of immunoreactivity to $GABA_A$ receptor in the cone synaptic triad supports the hypothesis of GABAergic transmission at the cone synaptic complex, most likely from the horizontal cell. THE COEXISTENCE OF ENKEPHALIN AND NEUROTENSIN IN AMACRINE CELLS OF THE CHICKEN RETINA: A RE-EXAMINATION USING A MORE SENSITIVE DOUBLE-LABEL PROTOCOL. C.B. Watt. Alice R. McPherson Laboratory of Retina Research, The Center for Biotechnology, Baylor College of Medicine, The Woodlands, Texas 77381.

In an earlier study, less than 50% colocalization was observed between the populations of enkephalin- and neurotensin immunoreactive-amacrine cells in the chicken retina. This lower percentage of coexistence observed in the previous study most likely resulted from the fact that 1) a less sensitive monoclonal antibody against enkephalin was used and 2) the double-label paradigm utilized a combination of a fluorescein- and peroxidase-label. For the present study, a more sensitive double-label paradigm was performed on cryosections collected throughout each of the four retinal quadrants. Primary antibodies were raised in different species, while respective secondary antibodies were conjugated to either fluorescein- or rhodamine- isothiocyanate. An examination of more than six thousand labelled cells in each of the retinal quadrants revealed that all labelled cells express both enkephalin- and neurotensin- immunoreactivity. Therefore, these results indicate the presence of a single population of chicken amacrine cells in which each member contains both of these putative neuroactive peptides.

CHANGES IN HORIZONTAL CELL TEMPORAL FREQUENCY SENSITIVITY RESULTING FROM STEADY ANNULAR ILLUMINATION. I.D. Cadenas and D. Tranchina. Dept. of Biology, New York University, N.Y.,N.Y. 10003.

We have examined the effects of steady annular illumination (I_A) on turtle luminosity-type horizontal cell (L-HC) responses to sinusoidal modulation of the intensity of a small spot around a mean light level (I_0). The presence of a steady concentric annulus leads to enhancement of the sensitivity to high frequency flicker of the spot, an indication of speeding up of response kinetics. Several cells also demonstrated attenuation of low-frequency senstivity under these conditions. The modifications in kinetics is accounted for by a discrete stage model in which the D.C. gain and the time constant of a single stage of low-pass filtering are changed. Across a population of cells, the degree of enhancement observed was uncorrelated with the extent of hyperpolarization when I_A goes from I_A=0 to I_A=I_0. No relationship was apparent between the magnitude of enhancement and L-HC receptive field size. A change from I_A=I_0 to I_A=0 depolarizes L-HCs, but depolarization to approximately the same extent by uniformly dimming a field in which I_A=I_0, does not affect sensitivity to high-frequency flicker of the spot. When in a series of experiments, the light intensity of the annulus is gradually increased from darkness to $2I_0$, there is accompanying increasing enhancement of the sensitivity of high-frequency responses. Repeating this experiment at lower overall light levels, however, diminishes enhancement of sensitivity. The data indicate that neither spatial contrast nor the changes in L-HC polarization produced by the presence or absence of a steady annulus is solely responsible for the changes in sensitivity observed. These results suggest the possible involvement of another neural element.

403.10

A MODEL OF RESPONSES OF CATFISH TYPE C AMACRINE CELLS INVOLVING PARALLEL INPUTS FROM ON AND OFF BIPOLAR CELLS. [1]D. Naylor, [2]D. Tranchina, [3]K.-I. Naka. [1]Dept. of Biomath, Mt. Sinai Sch of Med,N.Y.,N.Y.,10029, [2]Dept. of Biology and [3]Dept. of Ophthal.,New York University,N.Y.,N.Y., 10003

The linear component of the type C cell response to white noise light input accounts for <10% of the power while the 2nd order Wiener kernel contributes >60%. Thus, a successful model of highly non-linear C cells should fit both 1st and 2nd order Wiener kernels. Signal processing measured in bipolar cells is highly linear and we have modelled it as a bandpass filter involving a quotient of polynomials, $B_1^{ON}(\omega)$. In our model, ON and OFF bipolar cells are assumed to have transfer functions of similar form but opposite polarity, $L_1^{ON}(\omega)$ and $L_1^{OFF}(\omega)$. $L_1^{ON}(\omega)\equiv B_1^{ON}(\omega)B_2(\omega)$ and $L_1^{OFF}(\omega)\equiv B_1^{OFF}(\omega)B_2(\omega)$, where $B_2(\omega)$ is a "lead-lag" filter. $B_2(\omega)$ is designed to represent pre-synaptic filtering in bipolar terminals and is identical in each pathway. Each of the parallel pathways then is assumed to have a static non-linearity which intervenes between the bipolar terminals and the post-synaptic ligand gated conductance in the C cell. Finally, linear filtering, $L_3(\omega)$, occurs post-synaptically in the amacrine membrane in this model. While $B_2(\omega)$ and $L_3(\omega)$ cannot be measured directly, they were justified physiologically by indirect means. This scheme enabled us to predict analytic forms for the 1st and 2nd order Wiener kernels of C cells. The parameters of the predicted analytic forms were adjusted successfully so as to fit simultaneously the actual 1st order kernel and diagonal of the 2nd order kernel. These parameters subsequently were able to reconstruct the entire 2nd order kernel as a further support for the model.

COMPARISONS OF VOLTAGE-GATED CURRENTS IN SECOND AND THIRD ORDER NEURONS IN THE SALAMANDER RETINA Z-H. Pan* and M. M. Slaughter. Biophysics, SUNY School of Medicine, Buffalo NY 14214

Whole cell voltage clamp experiments were performed on isolated cells from the tiger salamander retina to characterize and compare the excitable currents. Bipolar cells were found to have large delayed-potassium currents that could be blocked by tetraethyl ammonium (TEA), fast activating and inactivating potassium currents blocked by 4-aminopyridine (4-AP), and an inwardly rectifying current blocked by extracellular barium or cesium, and slightly by TEA or 4-AP. Small inward calcium currents, both sustained and transient, but no sodium current, were observed. The principal voltage gated currents in the physiological range are the potassium currents. Horizontal cells also had prominent delayed potassium currents, though at only about a tenth of the bipolar cell current density. The A-type current was small or absent. These properties may explain the horizontal cell's small contribution to the ERG. There was also a prominent inward rectifying current that activated near the potassium reversal potential. A small, inward current was found that was only partially blocked by TTX. The calcium current in horizontal cells was very small, possibly reflecting the calcium-independent release of transmitter. In contrast, third order neurons have very large inward sodium currents. An A-current was usually present, with faster kinetics than that in bipolar cells, and a large delayed potassium current was found that was similar in current density to bipolar cells. No inward rectifying currents were observed. The calcium currents, both sustained and transient, were much larger than those found in other retinal neurons. Supported by NEI grant #05725.

PHYSIOLOGICAL SUBLAMINATION OF THE INNER PLEXIFORM LAYER (IPL) IN THE TURTLE RETINA. J.Ammermüller*, H.Kolb, R.Normann, R.Weiler. University of Oldenburg, Germany and University of Utah, USA.

We intracellularly recorded and stained 150 amacrine and ganglion cells in eyecup preparations of *Pseudemys* turtle. We have identified 21 of the 29 amacrine cells and 19 of the 21 ganglion cells described by Kolb (1982). This sample allows us a relatively complete description of the physiological sublamination of the IPL by correlating the light responses of the morphologically identified cell types with their stratification levels in the IPL. Thus amacrine cells with processes in distal sublamina a (S1) respond with sustained hyperpolarizations and those in proximal sublamina b (S4,5) with sustained depolarizations. Transient responses are correlated with amacrines stratifying in S2/3 and S3 on the ON-OFF sublamina a/sublamina b border. Ganglion cells mono-, bi- or tristratified from S1-S3.5, give sustained OFF responses. Similarly, ganglion cells mono- or bistratified from S3.5-S5 are sustained ON center. As expected, most bi- and tristratified ganglion cells with dendrites in both sublaminae respond in an ON/OFF fashion while diffuse ganglion cells with branches throughout the IPL gave ON center responses. With the majority of IPL branching neurons being multistratified in the turtle retina, the simple bisublamination of ON and OFF responses seen in cat retina is obviously not as clear cut. Nevertheless our results show that an ON-OFF subdivision is largely valid for amacrine cells and for ganglion cell types with dendrites restricted to one or other of the sublaminae.

VISUAL CORTEX: STRIATE MECHANISMS

404.1

SPATIAL FREQUENCY CHARACTERISTICS OF NEURONES IN FERRET VISUAL CORTEX. N. Port, I.D. Thompson*, M.P. Graham* and A.J. Parker*. University Lab. of Physiology, Oxford, OX3 1PT, U.K.

The ferret is increasingly used in visual neurobiology. We have characterised the spatial properties of the neurones in its visual cortex using drifting sinusoidal gratings. Pigmented ferrets were anaesthetised (70:30 N_2O:O_2, Sagatal 1 mg/kg/hr) and paralysed. Gratings were generated (luminance, 120 cd/m^2; contrast, 0.84) and detailed analysis of spike time and waveform was provided by BrainWave software. Surface normal penetrations were made into cortex representing central visual field.

Hand plots of receptive fields showed orientation tuning and, in the upper layers, marked end-inhibition. When stimulated with drifting gratings, some neurones showed a modulated response, others were unmodulated. A range of acuities could be observed within a single penetration. In one case, there was a change from 1.4 c/deg to 0.18 c/deg for neurones separated by less than 1 mm. It is our impression that neurones with lower acuities were found in the deeper layers. The neurones also varied in the bandwidth of their spatial tuning, from low pass to as narrow as 1.3 octaves. Orientation tuning to drifting sinusoidal gratings at peak spatial frequency yielded bandwidths at half-height that were typically around 60 degrees. Normally, adjacent neurones displayed similar peak orientation tuning but, in one pair of neurones recorded simultaneously, the peak orientations differed by 90 degrees.

RESPONSES OF CELLS IN RABBIT AREA 17 TO DRIFTING SINUSOIDAL GRATINGS

Molotchnikoff S.[1], Durand V.[1*], Hubert F.[1*], Casanova C.[2]
[1] Dépt. Biologie, Univ. de Montréal, C.P. 6128, succ. A, Montréal,
[2] Dépt. Ophthal., Univ. Sherbrooke, Sherbrooke, Canada.

As part of our continuing inquiry into spatial and temporal properties of neurons in rabbit area 17, we measured their responses to sine-wave drifting gratings. Single cell activity in anesthetized and paralyzed rabbits was recorded. Units were identified as simple (S) or complex (C) with light or dark bars and stationary spots. In simple cells (S) (n=45), only 58% responded to gratings with modulated discharges. The remainder (42%) were unresponsive to the same stimuli. On the other hand, 85% of complex cells (C) (n=20) had an unmodulated discharge to sinusoidal gratings, and only two of them were unresponsive. In two C, the discharge was modulated at optimal frequency. Six other cells could not be classified as either S or C, but they responded to gratings. Most units were low-pass to spatial frequency. Few neurons (S=33%, C=20%) were band-pass. So far no high-pass have been encountered. In contrast, most cells were band-pass in the temporal domain (S:mean=3.1 ± 1.5Hz; C: mean=2.8 ± 0.7Hz). In some cells (6%), the temporal tuning curve appeared double-peaked. And another 6% exhibited a U-shape curve below the spontaneous firing level. The influence of the contrast is being evaluated. As demonstrated in other species, cells in rabbit area 17 can be differentiated on the basis of responses to gratings.

404.3

RESPONSES IN STATIONARY TARGETS ARE GENERATED BY DIFFERENT MECHANISMS IN SIMPLE AND COMPLEX CELLS. C. Morin*, F. Hubert*, Y. Michaud, B. Nault, P. McKinley[1], and S. Molotchnikoff, Univ. Montreal, Biologie, C.P. 6128, Succ A, and McGill, Physical & Occupational Therapy[1] Montreal, Canada, H3C 3J7

The goal of this study was to examine the extent to which striate neurons were influenced by neighboring cells in the anaesthetized rabbit. Using single cell recordings, 84 striate units were evaluated for responses to both stationary (on/off) and moving light bars before and after injection of 300nl of either lidocaine or GABA 2mm away from the recorded cell. Surprisingly, responses to stationary spots were affected in 55% of the neurons, while the responses to moving spots were modified in only 36% of the cells ($P<0.02; x^2=7.5; df=2$). When directional index (DI) was < 50%, the on/off response was modified more often ($p<0.01; x^2=45.9$) than in units whose DI was >50%. Amongst the non-directional neurons, simple cells showed mainly decreased responses (67.7%) while the complex cells were mostly increased (62.5%). In contrast, direction selective (DI>50%) simple *and* complex cells maintained unaffected on/off responses (66.6% & 80% respectively). Results suggest that the non-directional cells are more dependent on horizontal cortico-cortical connections and on/off responses are mediated through different mechanisms in simple and complex cells. Supported by an FCAR grant to S. Molotchnikoff and P. McKinley

404.4

EFFECTS OF SUBSTANCE P IN THE CAT STRIATE CORTEX ARE SELECTIVE FOR CELL TYPE AND CORTICAL LAYER.
H.H.A. Chao*1, T.P. Hicks[2] and K. Albus[1]
[1]Dept. Neurobiol., MPI Biophys. Chem., 3400 Göttingen, FRG, and [2]Dept. Psychol. UNCG, Greensboro, NC 27412, USA

In the cat striate cortex Substance P (SP) is contained in intrinsically projecting neurons of layers V and VI. The SP content is high during the first postnatal month and thereafter decreases dramatically (Wahle et al., Soc. Neurosci. Abstr., 14:745, 1988). We tested the effects of SP on single neurons in one month and one year old cortex to seek for a functional role of SP in striate cortex and for possible differences in SP effects between immature and mature cortices. Drugs were delivered microiontophoretically during extracellular recording and visual stimulation in anaesthetized and immobilized animals. SP affected about 20% of the cells tested (N=93). Its main effect was a reversible, strong enhancement of visually evoked responses (VER) and/or spontaneous activity. The affected cells either had complex receptive fields (layers V and VI) or gave sluggish responses to visual stimulation (deep layer VI or white matter). The enhancement commenced after some delay (1-3 min) and generally outlasted the administration of SP. The effect was dose-dependent and did not decrease in strength when SP administration was prolonged or repeated. Complex cells in layers II-IV and unimodal and simple cells in all layers were not affected by SP, or showed only slight changes in spontaneous activity and VER. Differences in SP effects between one month and one yaer old cortices have not been observed so far. Our findings support a role for SP in modulating synaptic transmission in cat visual cortex. The exact mechanism of this action will be elucidated by ongoing experiments.

404.5

MICROIONTOPHRETICALLY-APPLIED NORADRENALINE AND SEROTONIN HAVE FUNCTIONALLY ANTAGONISTIC EFFECTS ON RESPONSE PROPERTIES OF CAT VISUAL CORTEX NEURONS. J. Goyer and M.S. Cynader, Dept Ophthalmology, Univ. British Columbia.

The effects of microiontophoretic applications of noradrenaline (NA) and serotonin (5-HT) on some response properties of visual cortex neurons were assessed in anesthetized, paralyzed cats. Unit responses to single flashes and bidirectional sweeps of bright slits of the optimal orientation, as well as orientation tuning curves were assessed before, during and after NA or 5-HT application.

The signal-to-noise ratio of the activity evoked by single flashes (duration 400 msec) was significantly increased after NA application (16.8 vs 10.5), but was decreased after 5-HT application (4.6 vs 10.5). The direction selectivity of the assessed cells (as measured with bidirectional sweeps along the cell's preferred orientation) was also significantly increased by NA (7.8 vs 4.5), and decreased by 5-HT (1.9 vs 4.5). The sharpness of the orientation tuning curves was again increased by NA and decreased by 5-HT.

These results suggest that NA and 5-HT play functionally antagonistic, modulatory roles on the response of visual cortex cells to different stimuli, NA acting to "sharpen" the cortical cell's response, while 5-HT "smooths" cortical cell response.

404.6

THE ROLE OF GABAERGIC INHIBITION IN THE ADAPTATION OF DIRECTION SELECTIVITY IN NEURONS IN AREA 17 OF THE CAT; Stuart G. Marlin, Robert M. Douglas, and Max S. Cynader, University of British Columbia, Depts. Ophthalmology & Psychology, Vancouver, B.C. Canada.

We investigated a possible mechanism for adaptation of single cortical neurons using iontophoretically applied GABA receptor agonists and antagonists. The adaptation of responses to prolonged unidirectional visual stimulation was compared to the adaptation during iontophoretic application of the GABA antagonists bicuculline ($GABA_a$) and phaclofen ($GABA_b$) as well as the agonists GABA and Baclofen. Bicuculline increased the firing level of all cells by approximately 100%. Both preferred and nonpreferred direction of motion responses increased. In a small number of cells phaclofen increased the responses by about 33%. Neither bicuculline nor phaclofen blocked the adaptation to prolonged stimulation, and the higher responsivity under bicuculline actually increased the rate of adaptation. GABA and Baclofen dramatically decreased the firing of cortical neurons, however, adaptation to prolonged stimulation was still observed. Adaptation-induced changes in the direction selectivity of the neurons were also observed during bicuculline and phaclofen application, even in cells where the nonpreferred direction motion responses had increased to equal the preferred direction responses. Bicuculline alone (without visual stimulation) dramatically increased spontaneous activity, but did not cause an adaptation-like reduction in the response rate suggesting that pre-synaptic depletion of neurotransmitter may be an important part of the mechanism of adaptation in cortical neurons.

Optical Imaging of Cortical Responses to Moving Plaids Reveals Linear Processing of its Oriented Components, in Area 18 of Cat Visual Cortex. *D. Malonek and A. Grinvald.* The Weizmann Institute of Science, Rehovot 76100, Israel, and The Rockefeller Univ., New York, NY 10021.

The spatial organization of orientation tuning was revealed with the use of small oriented bar stimuli (Hubel & Wiesel). Recently optical imaging revealed that orientation tuning maps obtained by large gratings produced functional maps identical to those produced with small bars. Thus, lateral interactions between activities evoked by multiple bars within the gratings did not change the spatial maps.

Here we examine functional interactions among regions, tuned to different orientations, in area 18 of cat visual cortex. We employed plaids stimuli composed of two orthogonal gratings and extending over large visual angle ($>15^0$). Using optical imaging based on intrinsic signals, *in vivo*, we measured activity maps in anesthetized and paralyzed adult cats. Either moving plaids or their individual components were used as stimuli. To determine whether significant interaction exists among regions tuned to different orientations (activated simultaneously), we compared activity maps generated by the above stimuli set. We found that the maps generated by moving plaids stimuli were identical (in shape and intensity) to the sum of maps generated separately by its components.

This finding indicates that, at the level of population activity, the interactions associated with these complex stimuli do not affect the intensity or spatial activation of area 18. If perceptual direction of motion is spatially coded, plaid's motion coding should produce a map which differs from a linear sum of its components. Thus, our results are consistent with a two stage model for motion processing: Area 18 stage codes local motion of oriented components (bounded by the "aperture problem") while the stage of motion integration is performed at higher visual areas. 404.8

CORTICAL DIRECTION SELECTIVITY AS A FUNCTION OF TEMPORAL FREQUENCY. A.B. Saul and A.L. Humphrey. Dept. of Neurobiology, Anatomy and Cell Science, U. of Pittsburgh, Pittsburgh PA 15261.

We had previously speculated that lagged X- and Y-cells in the cat lateral geniculate nucleus provide inputs to direction selective cells in cortex (*J. Neurophys.* 64:206). We noted that convergence of lagged and nonlagged inputs would be expected to produce direction selectivity only at low temporal frequencies, because the quarter-cycle response phase difference between these cells at 1 Hz grows to a half-cycle by about 4 Hz. We expected that cortical cells would resemble their nonlagged inputs at high temporal frequencies, since lagged responses have lower resolution. We have now measured temporal frequency tuning in each direction in 62 cortical neurons.

Direction selectivity in cat visual cortical neurons is indeed strongest at low temporal frequencies. As predicted, selectivity is often lost with increasing frequency even though the cell continues to respond in both directions. Responses in the nonpreferred direction are typically suppressed at 1 Hz, but become stronger by about 4 Hz and sometimes equal or exceed the responses in the preferred direction. About 25% of our sample showed clear increases in the nonpreferred direction response with increasing temporal frequency while the preferred direction response declined or remained relatively constant. We quantified this phenomenon by estimating the optimal temporal frequency in each direction. The preferred direction was tuned to lower frequencies than the nonpreferred direction in about 70% of the cells, and 40% had preferred direction optima at least an octave lower than nonpreferred direction peaks. Average optimal frequencies were 3 Hz in the preferred direction and 5 Hz in the nonpreferred direction. Temporal resolution, on the other hand, differs little between the two directions (13 Hz vs. 16 Hz on average, lower than the resolution of nonlagged cells but not of lagged cells).

In summary, a population of visual cortical cells exists that are direction selective around 1 Hz, lose selectivity around 4 Hz, and respond in both directions out to about 8-16 Hz. These phenomena can be interpreted in terms of the lagged projection from the LGN.

NON-LINEAR RESPONSES TO APPARENT MOTION IN CAT VISUAL CORTEX NEURONS. J.C.Boulton* and C.L.Baker,Jr.
Dept. of Medical Physics, Utrecht University, The Netherlands; and
Dept. of Psychology, McGill University, Montreal, Canada.

Recent human psychophysics has shown that the perception of movement from two-flash apparent motion of random Gabor kinematograms can be predicted from the stimulus spatiotemporal power spectrum *only* when the stimulus onset asynchrony (SOA) is less than 100 ms. For larger SOAs this relationship breaks down, implying nonlinearity (Boulton and Baker, ARVO 1991).

Comparable experiments on direction selective cells in Areas 17 and 18 of cat visual cortex reveal similar behaviour. Two-flash apparent motion of a Gabor stimulus was used to examine direction selectivity across a range of SOAs (0 to 200 ms) and jump sizes (0 to 1 cycle of the cell's optimal spatial frequency, lambda). For short SOAs (< 100 ms) linear behaviour is observed with peak directional responses for small jump sizes (< 1/4 lambda), often followed by reversal for larger jump sizes. However, many cells also showed strong directionally selective responses at long SOAs (> 100 ms) and large jump sizes (> 1/2 lambda). These non-linear responses are compared to human psychophysical performance.

SPATIAL ORGANIZATION OF INHIBITORY INFLUENCES UPON NEURONS IN THE CAT'S STRIATE CORTEX. G.C. DeAngelis*, J.G. Robson†, I. Ohzawa, and R.D. Freeman. School of Optometry, Univ. of California, Berkeley, California 94720, and †Physiological Laboratory, Cambridge CB2 3EG, UK.

Intracortical inhibitory interactions are known to be involved in the generation of receptive fields of neurons in the visual cortex. In addition, there are two main types of inhibitory influences which modulate the responsiveness of striate cortex neurons: end-inhibition (or endstopping) (Hubel & Wiesel 1965) and "cross-orientation" inhibition (Morrone et. al 1982). We have studied the spatial organization of these inhibitory influences through extracellular recordings of single unit responses from the striate cortex of anesthetized and paralyzed cats.

Length-response and width-response curves are constructed using rectangular patches of drifting sinusoidal grating centered on the receptive field. Cells which exhibit an optimum in their length-response curves (end-inhibition) tend to show a similar effect in their width-response curves (side-inhibition). Tests with superimposed gratings of different spatial frequencies suggest that regions eliciting end- and side-inhibition only slightly overlap the excitatory receptive field. In similar tests, superimposed gratings of orthogonal orientations are used to measure the spatial summation of cross-orientation inhibition. For all cells tested, the summation area for cross-orientation inhibition is centered upon the excitatory receptive field and of similar or smaller extent. Thus, cross-orientation inhibition is confined within the excitatory receptive field, while end- and side-inhibition arise from surrounding regions.

End- and side-inhibition may be further distinguished from cross-orientation inhibition through dichoptic measurements. For binocular cells which show end- or side-inhibition monoptically, inhibition can also be elicited dichoptically. In contrast, we were never able to elicit cross-orientation inhibition dichoptically.

A model is proposed to explain the spatial organization of end- and side-inhibition and cross-orientation inhibition in terms of cortical circuitry. (EY01175)

MODULATION OF STEREOSCOPIC PROCESSING IN PRIMATE VISUAL CORTEX V1 BY THE DISTANCE OF FIXATION. Y. Trotter*, S. Celebrini*, S. Thorpe* and M. Imbert. IDN, Lab. Neurosc. Vision, Univ. Paris 6, France.

The question of knowing how far objects appear to be away from us is related to binocular distance perception which has to be distinguished from relative depth perception or stereopsis. Retinal horizontal disparity alone is not sufficient to allow either 1) the true distance of an object to be determined or 2) to make accurate judgments about the 3-dimensional shape of objects. This is because both types of judgments require additional information about the fixation distance which could originate mainly from the angle of vergence and/or the degree of accomodation and/or retinal vertical disparity. We have addressed the question of what happens to the response properties of individual neurons when the distance of fixation is changed. We recorded responses of neurones to static random dot stereograms in cortical area V1 of a monkey trained to perform a fixation task. We first studied 79 neurons for stereopsis at a fixation distance of 40 cm. About half of them (47%) were disparity sensitive. Thirty one neurons were also tested at other fixation distances (20 cm/40 cm/80 cm). By doubling the size of the image on the screen when the fixation distance of this screen was increased by a factor of two, it was possible to maintain the angular size of the stimulus constant. The luminance level was about 1 cd/m^2 at the 3 distances. In 22 cells, disparity selectivity emerged only at certain viewing distances. Consequently, the proportion of disparity selective units was actually higher when the neurons were tested at more than one fixation distance (71%) than when only the 40 cm distance was used. For 9 of the 31 neurones, there were changes in the spontaneous activity of the neurons related to changes of viewing distances. In 6 of these cases, the spontaneous activity was increased when the animal was fixating at shorter distances. Our findings show that retinal horizontal disparity sensitivity of neurons as early as cortical area V1 is influenced by fixation distance and thus by extraretinal factors probably related to vergence.

CHARACTERISTICS OF NEURONS IN MARKED LOCATIONS IN STRIATE CORTEX OF BEHAVING MONKEY. D. M. Snodderly and M. Gur* Eye Res. Inst. and Harvard Med. Sch., Boston MA, 02114; *Biomed. Eng., Technion, Haifa, Israel.

Localization of recording sites in behaving animals has been difficult because the visibility of electrode tracks and lesions declines rapidly with survival time. With currents producing discrete, well-localized damage (1.2 μa for 6 sec), neither electrolytic lesions nor iron deposition clearly marked recording sites. In contrast, coating the electrode with the nontoxic fluorescent carbocyanine dye, DiI, resulted in discretely labeled penetrations visible for at least 10 days.

During recording, electrode depth was monitored carefully. The cortical surface was visualized through a small slit in the dura and blood vessels were avoided to minimize damage. A biopsy was taken, fixed with glutaraldehyde/paraformaldehyde, and sectioned. Sections were photographed with a fluorescence microscope to map the electrode tracks. Then they were reacted for cytochrome oxidase to visualize the laminae, which obliterated the fluorescence. Laminar boundaries were drawn and the fluorescence photographs of the electrode tracks were projected onto the drawings to observe the trajectory of the electrode through the cortical layers. The depths determined in this way corresponded well to microdrive depth readings.

As previously reported (ARVO, 1988), cells in the superficial layers often had small receptive field activating regions with potent inhibitory surrounds. A powerful stimulus for these cells was a moving texture composed of small rectangles oriented to match the preferred orientation of the cell and configured to avoid simultaneous stimulation of the center and the surround. Natural surfaces such as those of vegetation, earth, and animals often are imaged to produce such oriented textures. These patterns could be used by cortical neurons to contribute to the discrimination of objects from backgrounds. This suggests another perceptual role for upper layer neurons, in addition to the commonly mentioned ones of border extraction and spatial frequency analysis.

High Resolution Optical Imaging of Functional Architecture in the Awake Primate. Amiram Grinvald, Ralph Siegel, Eyal Bartfeld and Ron D. Frostig. Laboratory of Neurobiology, The Rockefeller University New York, NY 10021 and The Weizmann Institute of Science, Rehovot, Israel 76100.

Optical imaging of the functional architecture of cortex, based on intrinsic signals, is an useful tool for the study of the development organization and function of the living mammalian brain.

Here we establish that this technique is also suitable for exploring the brain of awake behaving primates. We designed a chronic sealed chamber which was mounted on the monkey skull over the primary visual cortex and permitted imaging experiments through a glass window. Restriction of head position alone was sufficient to minimize movement noise in the awake animal imaging experiments. High resolution imaging of the ocular dominance, and the blobs was achieved simply by taking pictures of the exposed cortex when the awake monkey was viewing video movies. Furthermore, the functional maps could be obtained without the noise reduction procedure of synchronizing the animal respiration and the data acquisition to the EKG. The wavelength dependency and time course of the intrinsic signals was similar in anesthetized and awake monkeys indicating that the signal sources were the same.

We therefore conclude that optical imaging is well suited for exploring functional organization related to higher cognitive brain functions of the primate as well as providing a diagnostic tool for delineating functional cortical borders and assessing proper functions of human patients during neurosurgery.

HETEROGENEITY AND COMPARTIMENTALIZATION IN THE OLFACTORY BULB OF ELASMOBRANCH FISHES.
L. Dryer and P.P.C. Graziadei. Florida State University, Department of Biological Sciences, Tallahassee, Fl 32306.

Anatomical observations reveal that the Elasmobranch olfactory bulb is an elongated structure immediately adjacent to the olfactory organ. Depending on the species, it appears as a succession of swellings (i.e. the Bonnethead shark, *Sphyrna tiburo*) or as two independant subunits (i.e. the Sharp-nosed shark, *Rhizoprionodon terranovae*). We examined several species in order to understand the functional significance of these morphological features.

The olfactory bulb of all specimens stained with Golgi method exhibit two distinct populations of mitral cells: A first type has loose dendritic arborization bearing numerous terminal boutons. The second type of mitral cell, smaller, shows an extremely dense feather-like arborization.

Localized extracellular injections of Biocytin in the olfactory epithelium result in restricted labeling of the bulb, suggesting a topographical arrangement of the olfactory projections onto the bulb. The lateral olfactory bulb would process information coming from the lateral epithelium, whereas the medial bulb would process information coming from the medial epithelium. Several sizes of glomeruli were also observed with this method. Further experiments are in progress to delimit the projection fields with accuracy and define the lateral interconnections between the subdivisions of the olfactory bulb.

CONNECTIVITY OF THE AREA POSTREMA IN THE HAMSTER (*Mesocricetus auratus*).
A.P. Knox, N.L. Strominger, L.D. Savoy* and C.B. Halsell. Departments of Anatomy and BioStructure and Function, Albany Medical College, Albany, NY 12208 and UCONN Health Center, Farmington, CT 06030.

The connectivity of the area postrema (AP) was investigated in the hamster. Iontophoretic injections of WGA-HRP were made into either the central portion of the AP or the parabrachial nucleus (PBN). After 24-48 hours survival time, animals were perfused with phosphate buffered saline followed by a 3% glutaraldehyde solution in phosphate buffer. Brains were removed *in toto*, cut at 50 μm and processed for HRP histochemistry with tetramethylbenzidine. Alternate sections were mounted unstained with the remaining set counterstained with a Nissl stain.

PBN injections resulted in the labeling of numerous neuronal perikarya throughout the AP, medial and commissural subnuclei of the solitary complex. Injections of the lateral PBN were most effective in labeling of AP neurons. Preterminal label was present in the AP but not prominent. Injections in the AP resulted in labeling of perikarya in subnuclei (medial and commissural) of the solitary complex. Afferent label from AP injections was present in the solitary complex at the level of the injection and most prominently in the lateral PBN.

The area postrema of the hamster is in a pivotal position to receive not only primary afferent information but also information from the systemic blood due to a weak blood brain barrier. The AP may play an important role in modulating visceral function by influencing pontine visceral relay centers.

POSTNATAL MATURATION OF THE MITRAL/TUFTED CELLS OF THE RAT ACCESSORY OLFACTORY BULB.
S. Takami and P.P.C. Graziadei. Dept. Biol. Sci. Florida State Univ., Tallahassee, FL 32306-3050.

The mitral/tufted cells (MTCs) of the rat accessory olfactory bulb (AOB) are morphologically different from the mitral and tufted cells of the main olfactory bulb (MOB); the MTCs have more diverse dendritic branching and unique glomerular arbors (GAs). To clarify the developmental sequence of the MTCs dendritic branching and the appearance of the GAs we have studied the MTCs in the rat AOB during the perinatal period.

Using the rapid Golgi and Golgi-Kopsch methods, impregnated MTCs were observed in the rat AOB from postnatal P1 to P29. The mitral and tufted cells of the MOB were also observed at comparable stages. At P1/P2 MTCs had dendrites branching in beaded structures, however, GAs were not present. GAs were instead often observed in the mitral and tufted cells of the MOB. At P8/P10 dendrites of the MCTs began to show branching and early formation of GAs. By P15, GAs and complex branching of the dendrites acquired more complexity; morphological details as observed in the adult were obvious by P22 to P29. Our observations indicate that the MTCs and their specific intraglomerular GAs develop postnatally and at later stages than the GAs of the mitral and tufted cells of the MOB. Supported by a grant from the NIH (NS 20699) to P.P.C.G.

ONTOGENY OF VOMERONASAL NEURONS AND ACCESSORY OLFACTORY BULB IN NEONATAL OPOSSUMS (Monodelphis domestica): A ^{3}H-THYMIDINE AUTORADIOGRAPHIC STUDY.
R. T. Wang, T. L. Soltesz*, T. Hayes* and M. Halpern[1]. Departments of Anatomy, Marshall Univ. Sch. of Med., Huntington, WV 25755 and [1]SUNY Health Sci. Ctr. at Brooklyn, NY 11203.

Five groups of neonatal South American opossums at the ages of 1, 3, 7, 14 and 28 days (N=44 total) were injected with a single dose of ^{3}H-thymidine (2 to 5 μCi., i.p.) for tracing the development of their vomeronasal (VN) system. Neonates survived an additional 1, 7, 14, 21 or 28 days following injection and were processed into light microscopic autoradiogram on slides. For 1 day survival groups, injection of ^{3}H-thymidine to neonates on Day 1 or 3 radioactively labeled stem cells throughout the primitive VN organ while injection made after Day 7 selectively labeled stem cells in the developing VN organ at the basal cell layer and some at the apical sustanticular cell (SC) layer. The SC showed a marked reduction in the number of cells to incorporate ^{3}H-thymidine after Day 14. For incorporation time longer than 7 days in all groups studied, labeled VN neurons emerged in the intermediate zone of the sensory epithelium where they sustained a life span exceeding 28 days. Furthermore, telencephalic neuroblasts generated prior to Day 3 first differentiated into mitral cells in the main olfactory bulbs (MOB) by Day 8 and in the accessory olfactory bulbs (AOB) by Day 15. Injection made on Day 7 and thereafter labeled neuroblasts which gave rise to the granule cells predominantly and very few mitral cells in the MOB and AOB. Supported by NIH RR-05870, NS-11713 and MUSOM.

FLUORESCENT TRACT-TRACING STUDIES OF DESCENDING PROJECTIONS FROM THE INSULAR CORTEX TO THE NUCLEUS TRACTUS SOLITARIUS.
T. S. Donta and J. A. London. Center for Neurological Sciences and Dept. of BioStructure and Function, Univ. CT Health Center, Farmington, CT 06030.

This laboratory has been investigating descending cortical projections to the taste-responsive rostral pole of the nucleus tractus solitarius (NTS) in golden Syrian hamsters (Mesocricetus auratus). Previous work in this lab has demonstrated that the contralateral projection is greater than the ipsilateral projection, and that the contralateral projection area extends further dorsally in layer 5 than the ipsilateral projection area. The rostral-pole of the NTS is primarily innervated by the chorda tympani nerve. Here we expand our studies to include descending cortical projections to other regions of the NTS. Injections of retrograde tracers into NTS regions were guided by multi-unit electrophysiology and confirmed by histology. Responses in the NTS were recorded after application of a search stimulus (0.03 M NaCl, 0.1 M KCl and 0.1 M sucrose) to the anterior tongue in order to map a taste active region. Once a taste active region was delimited, a tracer was injected into the center of the active region. The retrograde labels used were latex microspheres filled with either rhodamine or fluorescein. It was found that the same area of the ventral agranular insular cortex projected to NTS areas receiving chorda tympani or glossopharyngeal nerve innervation, or to more caudal areas near obex. The cortical projection cells to these different regions were highly intermingled. However, only cells projecting to the rostral pole of the NTS were found in the dorsal part of the agranular insular cortex and in the granular insular cortex. No differences in the rostral-caudal mapping of the cortex to the NTS were observed.

THE ORGANIZATION OF AFFERENT FIBERS AND LOCAL SYNAPTIC CIRCUITS IN PIRIFORM CORTEX FOLLOWING MITRAL CELL LOSS.
Juan C. Bartolomei and Charles A. Greer. Sections Neurosurg. & Neurobiol., Yale Univ. Sch. Med., New Haven, CT 06510.

The mutant mouse Purkinje Cell Degeneration (PCD) loses all mitral cells (MCs) in the olfactory bulb (OB) over a period of about 30 days beginning at 4 mon. of age. Tufted cells and denervated granule cells subsequently exhibit significant local synaptic reorganization in the OB. Because a primary input of piriform cortex (PC) is derived from the MCs, our current goal is to assess changes in axonal distribution and synaptic organization in the PC after loss of MC axons in PCD mice.

In 5 to 7 mon. old PCD mice a small incision was made in the LOT and a pledget of Horseradish Peroxidase inserted. The distribution of labeled fibers in control and PCD mice was assessed with light microscopy. In control mice there was a prominent rostral to caudal distribution of labeled fibers along the PC with a well demarcated subliminar distribution limited to layer Ia. In PCD mice there was a large reduction in the rostral to caudal extent of axonal distribution. At the rostral levels the sublaminar distribution appeared relatively normal through layer Ia though the density of labeled axons was significantly reduced. Centrifugal axons in the LOT did not appear effected in PCD mice since contributing nuclei were labeled retrogradely. Radially oriented montages of electron micrographs were used as translaminar probes of ultrastructural organization of PC in PCD mice. Preliminary data revealed a substantial decrease in the number of myelinated axons contributing to the LOT. Synaptological analysis of PC showed terminal boutons that correspond to those previously attributed to intracortical and LOT axons (Friedman & Price, 1986). Preliminary counts suggested a dramatic reduction in the number of large pale profiles characteristic of LOT axons. Thus far the findings do not support the notion of extensive denervation induced collateral sprouting of tufted cell axons in the PC of PCD mice. Further studies continue to assess alterations of PC synaptic circuit organization occurring due to MC axon loss.

PARALLEL PROCESSING OF CHEMOSENSORY INPUT IN THE BRAIN OF THE SPINY LOBSTER. M.Schmidt, E.Orona and B.W.Ache. Whitney Lab. & Departments of Zoology and Neuroscience, Univ. of Florida, St. Augustine, FL 32086

The biramous antennules (1st antennae) of decapod crustaceans are complex sensory organs bearing olfactory (aesthetasc), mechano-chemosensory, and mechanosensory sensilla. To analyze the central processing of antennular information we backfilled antennular afferents and intracellularly recorded and stained deutocerebral neurons in the spiny lobster, *Panulirus argus*. The deutocerebrum contains two, distinct pathways for processing antennular input. One pathway includes the olfactory, parolfactory, and accessory lobes (OL, PL, AL), neuropils that process olfactory and mechanosensory information originating in the lateral flagellum of the antennule. Antennular afferents terminate in columnar glomeruli in the OL, where the input is transferred to different classes of multiglomerular local interneurons, one of which connects the OL to the AL, and to pluriglomerular projection neurons. Axons of the OL projection neurons run together with axons of AL projection neurons via the olfactory-globular tract to higher protocerebral centers. The second pathway includes the lateral and medial antennular neuropils (LAN, MAN), which lack glomerular organization and receive mechano- and non-olfactory chemosensory input from both flagella and the basal segments of the antennule. A major output element of the LAN and MAN are antennular motoneurons whose neurites are interwoven with the afferent projections. The second pathway appears to mediate local antennular reflexes (LAN) and coordinate reflexes of the head appendages to antennular stimulation (MAN). The independent processing of olfactory and non-olfactory chemosensory input originating from the same appendage of the spiny lobster further argues that olfaction is a distinct chemosensory modality even in non-vertebrate, aquatic animals. ELECTROTONIC AND DIFFUSION MODELS OF INTERACTIONS AMONG DENDRITIC SPINES OF THE MAMMALIAN OLFACTORY BULB. T.B. Woolf, G.M. Shepherd, and C.A. Greer. Sect. of Neurobiol. & Neurosurg., Yale Univ. Sch. Med., New Haven, CT 06510.

Granule cells in the olfactory bulb mediate lateral and self inhibition of mitral/tufted cells through reciprocal dendrodendritic synapses involving spine heads (gemmules). We recently reported serial EM reconstructions of these spines (*Synapse*, 7:181) and electrotonic models of granule cells based on LM observations in the mouse (*J. Neurosci.* 1991, in press). We describe here detailed compartmental models of spines and short dendritic sections, based on EM morphology, to assess communication between spines via electrotonic spread and diffusion of putative neuroactive compounds.

To model diffusion, diffusion constants were estimated for 16 compounds from a determination of the Stokes radius and an empirical equation for cytoplasmic viscosity (*Biophys J.*, 58:31). Compounds with a relatively high diffusion constant, such as Ca, cAMP, cGMP, or IP_3, decreased to less than 10% concentration change at distances greater than 2 um following a 1 msec pulse of elevated concentration at the spine head. With slower diffusion rates, such as those for calmodulin, PKA, calcineuron, or calpain, changes were less than 10% at distances of only 0.8 um. Since spines are separated by a mean of 7.5 um, it seems unlikely that effective communication occurs by diffusion. In contrast, the electrotonic models, suggested that although voltage differences can develop within a spine, significant communication occurs between nearby spines. The results support the idea that spines form compartments limiting diffusional interactions between spines.

ARBORIZATION CHARACTERISTICS OF OLFACTORY RECEPTOR CELL AXONS IN OLFACTORY BULB GLOMERULI. N. Halasz[1] and C.A. Greer[2,3]. [1]Inst. Biophys., Biol. Res. Ctr., Hungarian Acad. Sci., Szeged, Hungary and Sects. [2]Neurosurg. and Neurobiol., Yale Univ. Sch. Med., New Haven, CT 06510.

To further our understanding of receptor cell projections to the olfactory bulb we studied the arborization of individual axons within glomeruli. Specifically, we wished to address the issue of whether a subglomerular organization may be established by the arborization characteristics of individual receptor cell axons within glomeruli.

Olfactory bulbs from Sprague-Dawley rats were processed with a Golgi-EM procedure chosen for its selective impregnation of individual receptor cell axons. Correlated light and electron microscopic analyses confirmed that individual axons could be resolved with the light microscope and reconstructed with camera-lucida. The terminal arbor of single axons encompassed areas of 41-1840 um^2 (mean $\pm$ S.E.M. = 880.36 $\pm$ 59.91). This accounted for only 3 - 20% of total glomerular area in any single case (mean $\pm$ S.E.M. = 12.12 $\pm$ 1.44). The number of axon bifurcations ranged from 1 - 15 (mean $\pm$ S.E.M. = 6.84 $\pm$ 0.51) and the total number of terminal enlargements or varicosities suggestive of synaptic specializations from 2 -19 (mean $\pm$ S.E.M. = 8.1 $\pm$ 0.51). Further studies revealed that a single terminal enlargement or varicosity could make synaptic contact with more than 1 postsynaptic target. These data show that olfactory receptor cell axons segregate into small subglomerular compartments. This differential innervation could provide a basis for subglomerular organization and perhaps differential synaptic organization.

ANALYSIS OF THE STRUCTURE AND FUNCTION OF INDIVIDUAL HRP-LABELED GUSTATORY NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT (NST) OF THE RAT. W.E. Renehan, S.P. Weaver*, X. Zhang* and L. Schweitzer. Division of Gastroenterology, Henry Ford Hospital, Detroit MI and Dept. of Anatomical Sciences and Neurobiology, University of Louisville.

To enhance our understanding of structure-function relationships in the NST, and as a prelude to future developmental studies, we have begun an investigation of the morphology of taste-sensitive neurons in the adult rat brainstem. Glass micropipettes filled with 6.0% HRP in Tris-KCl buffer were advanced into the rostral NST and a bipolar stimulating electrode was placed on the ipsilateral chorda tympani (CT) nerve. The response properties of neurons driven by the CT stimulating electrode were tested using 0.5 and 0.1 M NaCl, 0.5 and 0.1 M KCl, 0.01 M quinine HCl, 0.01 N HCl and 1.0 M sucrose. Following receptive field characterization the cells were impaled and injected with HRP. Cells were grouped according to soma size and shape, axonal target and dendritic field morphology. Most of the neurons recovered in this initial phase of our study have been quite small, with soma diameters in the range of 10-15 um, and have responded best to NaCl or quinine HCl. The majority of these neurons do not project to rostral targets, but instead appear to terminate in the NST or adjacent regions of the brainstem. Our results suggest that the intracellular labeling technique will permit us to relate the physiological and morphological properties of gustatory neurons in the NST.

THE CONE ELECTRODE: ULTRASTRUCTURAL STUDY FOLLOWING LONG-TERM RECORDING. **P.R.Kennedy, S.Mirra and R.A.E.Bakay. Yerkes Research Center, Emory Univ., VA Med. Center, & Neurosci. Lab., GA Tech, Atl, GA.**

The achievement of long-term recording (LTR) of neural signals has potential clinical and investigative applications. To facilitate LTR a novel cone electrode consisting of an insulated gold wire within a hollow glass cone was developed (Kennedy, J. Neurosci. Methods, 29(1989)181-193). Sciatic nerve segments were inserted into the cones and implanted into cerebral cortex in rats and monkeys. Recordings and light microscopic preparations indicated connections between neurites within the glass cone and surrounding cortical neurons.

Electron microscopic study now further defines the structures within the electrode cones following implantation for as long as 15 months. After removal of electrodes and breaking of the glass cones, tissue within the cones was carefully removed under a dissecting microscope. EM examination revealed centrally myelinated axons, dendrites, synaptic profiles, blood vessels and glial cells. Peripheral nerve was not identified. Neuronal cell bodies were present only in the adjacent neuropil.

These studies suggest that cortical neurites grow into the tip of the cone electrode and remain viable for 15 months as shown by EM studies and by recordings of movement related activity in the same monkey. RR00165 Yerkes; Am. Paralysis Ass.

DISTRIBUTION OF NEUROFILAMENT IMMUNOREACTIVE NEURONS IN THE RHESUS MONKEY MOTOR CORTICES. M.J. Campbell and H. Barbas. Mt. Sinai Sch. Med., NY, NY 10029, and Boston Univ. and Sch. Med., Boston, MA 02215.

A monoclonal antibody to a nonphosphorylated neurofilament protein (SMI-32, Sternberger Monoclonal Inc.) labels a subpopulation of pyramidal neurons in cortex. The distribution of labeled neurons varies substantially across cortical areas (J. Comp. Neurol. 282:191-205, 1989). In this study we focused on the motor and premotor areas. The distribution of labeled neurons varied in a systematic way within architectonic subdivisions of the cortical motor system (J. Comp. Neurol. 256:211-228, 1987). Area 4 had the highest density of immunoreactive neurons both within the frontal and the entire cortex. Anterior to area 4 the density of labeled neurons was still high but decreased gradually in progressively rostral premotor areas. The dorsal premotor sector had a higher density of labeled neurons than the ventral. Within each premotor sector the central parts on the lateral surface had a higher density of immunoreactive neurons than either the supplementary area on the medial surface, or the lower part of ventral area 6. The preponderance of neurons that contain this cytoskeletal protein in the above frontal areas may be related to the specialization of the cortical motor systems.

LAMINAR PATTERNING OF CORTICOCORTICAL CONNECTIONS IN THE RAT. D.H. Wang*, T.W. Deacon, and J. Connell* . Biological Anthropology, Harvard University, Cambridge, MA 02138

Using the tracers WGA-HRP reacted with TMB, PHA-L immunoreacted with DAB, and fluorescent dyes Fast Blue and Fluorogold we have attempted a comprehensive survey of laminar patterns of rat corticocortical connections, and contrasted them with those found in the monkey or cat.

In the rat, unlike cat and monkey, essentially all corticocortical projections include a significant portion of afferent terminations in layer 1. Additionally, labeling of afferents in deeper layers varies depending on the sites of origin and termination of the projection. Quantitative differences in the relative intensity of labeling in deep layer 3 and in layer 4 as compared to labeling in layers 1, 2, and upper layer 3 divide projections into two general classes. I. Projections originating from primary sensory areas, or targeting tertiary or polysensory areas terminate most densely in deep layer 3 and layer 4 and exhibit relatively lighter labeling in upper layer 3. This results in a bimodal distribution of label involving layer 1 and these middle layers. II. Projections from secondary areas to primary areas or from frontal to parietal areas terminate primarily in layer 1 with a decreasing density in layer 2 and upper layer 3, and sparing deeper layers. In general, labeling in infragranular layers is quite sparse, though exceptions do exist.

Placement of different fluorescent tracers into areas that receive projections from a common third area revealed laminar differences in cells of origin. Both extensive overlap and nearly complete segregation of cell groups into layers 3 and 5 were observed in different cases. For example, neurons in the lateral visual area (Oc2L) tend to be segregated according to their axonal targets, with laterally directed projections originating from supragranular and medially directed projections originating from infragranular cells. Although laminar differences are much more subtle and graded in the rat as compared to cat and monkey, it appears that there are corresponding laminar asymmetries.

A COMPARISON OF FRONTAL LOBE INPUTS TO THE PRIMARY, SUPPLEMENTARY AND CINGULATE MOTOR AREAS IN THE MONKEY. R.J. Morecraft and G.W. Van Hoesen. Depts. of Anatomy and Neurology, Univ. of Iowa, Iowa City, Iowa 52242

Although frontal lobe interconnections of the primary (area 4 or M1) and supplementary (medial area 6 or M2) motor areas are well understood, how frontal association cortex influences these or other areas that give rise to the corticospinal tract is not. We investigated the distribution of frontal lobe inputs to M1, M2 and the cingulate motor area (areas 24c and 23c or M3) in the rhesus monkey using fluorescent dyes. M1 received input from area 6, M2 and cingulate areas 24c and 23c. M2 received input from areas 46, 9, 12, 8B, 6, M1 and cingulate areas 24c and 23c. M3 received input from all cytoarchitectural types of cortex within this lobe including areas 10, 46, 9, 12, 8B, 8A, 6, M2, M1 and orbitofrontal cortex. A double labeling experiment demonstrated that less than 1% of all labeled neurons in areas 46, 9, 6, 4C, and M2 send axon collaterals to areas 24c and 23c. The heavy component of dorsolateral prefrontal input to M3 suggests a hierarchy concerning the diversity of frontal lobe inputs. M1 receives the least diverse frontal lobe input which arises exclusively from primary association cortex. M2 receives more diverse input which arises from multimodal association, primary association and primary motor cortices and M3 receives the most diverse and widespread frontal lobe input which includes paralimbic, multimodal association, primary association and primary motor cortices. These patterns of connectivity suggest that frontal association input gains preferential access to the cortical motor areas via M3. (Supported by grant NS14944)

FUNCTIONAL ACTIVITY IN THE CEREBRAL CORTEX OF THE RAT MODEL OF PARKINSON'S DISEASE MAPPED WITH ^{14}C DEOXYGLUCOSE. A. Dispenzieri and L.L. Brown, Dept. of Neurology Albert Einstein College of Medicine, Bronx NY 10461.

An ultimate target of efferent activity from caudate-putamen is the neocortex. To determine the effect of caudate-putamen dopamine loss on general neural activity in the cortex of an animal model of parkinson's disease, we used ^{14}C deoxyglucose autoradiography in rats with a unilateral 6-hydroxydopamine lesion of the substantia nigra. Animals were studied both at rest and with a sensory challenge. Primary motor, sensory and secondary motor regions all showed alterations in local cerebral glucose utilization (LCGU) associated with the lesion, but not more than 15%. Lesion animals showed an overall significant side-to-side difference in glucose utilization not shown in sham lesion controls, with a decrease in LCGU ipsilateral to the lesion. Mean cortical LCGU of all 73 regions analyzed was significantly decreased relative to untreated controls bilaterally (-14%, $p<.001$). The response of the cortex to the sensory challenge was also modified by the lesion. The results demonstrate a small but significant and widespread change in neural function related to dopamine depletion of the basal ganglia.

406.6

PREFRONTAL, PREMOTOR, MOTOR, AND HIPPOCAMPAL CONNECTIONS OF AREA 24 IN THE MACAQUE MONKEY. T. Arikuni, H. Sako*, and A. Murata*. Dept. of Anat. and Neurophysiol., Nihon Univ. Sch. of Med., Tokyo 173, Japan

The present study was undertaken to clarify the organization of transcortical connections between the dorsolateral prefrontal cortex and the hippocampal formation in the macaque monkey. Under direct vision, small amount of 10% solution of wheat germ agglutinin-conjugated horseradish peroxidase (WGA-HRP) was injected into each of several regions of area 24 of the cingulate cortex in the Macaca fuscata. The connections of area 24 with the prefrontal cortex, premotor area, motor area and the temporal cortex connected to the hippocampus were analysed. WGA-HRP-labeled cells and terminals appeared densely in areas 10, 9 and 13 and in the rostral area 46, while labeled cells and terminals appeared patchly in the caudal area 46 and areas 8A and 45. HRP-labeled cells and terminals were distributed more extensively in area 6aβ than in areas 6aα and 6b. Labeling was seen in areas 4a and 4b of the motor cortex and in the prosubiculum of the hippocampal formation. HRP-labeled cells were distributed in layer V of areas 28 (the entorhinal area) and TH, while they were distributed in layers III and V of areas 35, 36, TF, and TE. All of these areas contained HRP-labeled terminals. In summary, the prefrontal cortex and premotor area have strong reciprocal connections with area 24 which is strongly reciprocated with the prosubiculum and parahippocampal areas.

406.7

A DOUBLE LABELING STUDY ON SUBCORTICAL INPUTS TO THE SUPPLEMENTARY MOTOR AREA IN THE MONKEY. H.Tokuno*, J.Tanji, M.Kimura and H.Aizawa. Natl. Inst. Physiol. Sci. Okazaki 444, Japan.

To elucidate subcortical inputs to the supplementary motor area (SMA) precisely, we labeled pallidal or cerebellar terminals in the thalamus using wheat germ agglutinated horseradish peroxidase (WGA-HRP), and labeled thalamic neurons projecting to the SMA using Fast Blue (FB) in the same monkey.

FB was injected into the hand-arm area of the SMA after confirming the somatotopy using intracortical microstimulation. After 3-4 weeks, WGA-HRP was injected into the internal segment of the globus pallidus or the deep cerebellar nuclei. After 3 days, the animals were perfused under deep anesthesia. The sections were processed with tetramethylbenzidine and observed with bright-field and epifluorescent illumination. In pallidal injection cases, numerous FB labeled thalamic neurons were distributed in pallidal terminal areas. In contrast, few labeled neurons were found in cerebellar terminal areas.

The present results indicate that the SMA receives subcortical information mainly from the basal ganglia via the thalamus.

406.8

TOPOGRAPHY AND COLLATERALIZATION OF BRAINSTEM DOPAMINERGIC (DA) PROJECTIONS TO MOTOR CORTEX, SUPPLEMENTARY MOTOR AREA AND LATERAL PREFRONTAL CORTEX. IN OWL MONKEY. P. Gaspar*, I.Stepniewska, and J.H.Kaas. INSERM U106, Paris, France and Vanderbilt University, Nashville TN 37240.

Motor and premotor areas receive a dense DA innervation in primates. We determined the origin of this projection and showed that some neurons project via collaterals to more than one field by injecting different fluorescent dyes in parts of the prefrontal cortex, MI, and SMA, first identified by microstimulation in adult owl monkeys (*Aotus trivirgatus*). The distributions of retrogradely labeled cells were related to the locations of tyrosine hydroxylase immunolabeled (DA) neurons on the same or alternate brain sections. All the cortically projecting DA cells were located in the A8-A10 complex, largely in its dorsal components, the parabrachial pigmented n. of the ventral tegmental area (VTA), pars γ of the substantia nigra (SNc), and the dorsal part of the retrorubral area (A8). Fewer cells were in the midline groups of VTA (LR,LC) and in n. paranigralis. DA neurons projecting to MI, SMA, and prefrontal cortex were largely intermixed, with some collateralization (double or triple labeled cells). Cells projecting to MI were always more numerous than to the other cortical locations.

The topography of the cortically projecting DA cells corresponded in part to a histochemical subdivision of the A8-A10 complex defined by the presence of calbindin-immunoreactive neurons, and by neurotensin and noradrenergic terminal innervation. (Supported by grant NS 16446).

406.9

COMPARISON OF CORTICAL PROJECTIONS TO PRIMARY AND SUPPLEMENTARY MOTOR AREAS IN OWL MONKEYS (AOTUS TRIVIRGATUS). I. Stepniewska, P. Gaspar* and J.H. Kaas. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

We used injections of two different fluorescent tracers to demonstrate that primary motor cortex (MI) and supplementary motor area (SMA) receive some inputs from separate regions of cortex, and some from the same regions, although few neurons project to both fields.

Forelimb representations in MI and SMA were first identified by intracortical microstimulation, boundaries were marked with microlesions and different tracers were injected into the same body part representation in both fields. Brains were sectioned in the coronal plane or parallel to the surface after flattening, and alternate series of sections were stained for myelin, CO or AChE. Injections revealed arrays of short intrinsic connections in both fields and interconnections between the fields. MI had major inputs from areas 3a and 1, while SMA did not; neither area received notable input from area 3b. More caudally cortex in the 2—5 region projected to both SMA and MI, although only a few double labeled neurons were detected. Almost all the projections from SII region and adjoining cortex were to MI. Foci of labeled neurons projecting to MI and SMA from lateral premotor and rostrally adjacent cortex overlapped extensively, but few cells were double labeled. Some regions of cingulate cortex projected to both fields, but rarely via the same neurons. Finally, cortex on the medial wall just rostral to the SMA and more caudal cingulate region sent projections to SMA but not MI. (Supported by NS 16446).

406.10

AREA LIP INPUT TO AREA 7A IN THE INFERIOR PARIETAL LOBULE OF MACAQUE. J.-R. Tian, J.C. Lynch, and S.G.P. Hardy. Department of Anatomy, University of Mississippi Medical Center, Jackson, MS 39216.

Studies of the sources of neural input to area 7a, a higher-order association area in the inferior parietal lobe, have been inconclusive about whether there is a significant projection to 7a from the lateral intraparietal area (LIP), a region in the lateral bank of the intraparietal sulcus that seems to have predominantly visual and oculomotor functions. This question was addressed by making small placements of the retrogradely transported tracers diamidino yellow or fast blue in area 7a and/or LIP in 3 M. fascicularis and 1 M. mulatta. Labeled neurons were counted in evenly-spaced sections through the LIP, cingulate gyrus, and the principal sulcus region of prefrontal cortex (PS). Typically, both cingulate gyrus and PS cortex contained more than twice as many neurons that projected to 7a as did LIP. Neurons in LIP that were labeled by 7a injections were restricted to a single small zone. In contrast, neurons in 7a that were labeled by LIP injections were distributed widely through the area. More neurons were labeled in 7a by the LIP placements than vice versa. These experiments confirm that LIP is a source of neural input to 7a, but suggest that, in spite of the close physical proximity of 7a and LIP, and of their functional similarities, both the cingulate gyrus and the PS region of prefrontal cortex provide more robust neural connections with 7a than does LIP. Furthermore, the data suggest that the projection from 7a to LIP may be considerably more extensive than the projection in the opposite direction. (Supported by PHS grant EY04159)

PATTERN OF PROJECTIONS FROM THE PREMOTOR AREAS ON THE MEDIAL WALL OF THE HEMISPHERE TO THE PRIMARY MOTOR CORTEX. J.W. Holsapple and P.L. Strick. VA Med. Ctr. and Depts. of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syracuse, NY 13210.

The representation of the distal forelimb in the primary motor cortex of macaques is found in 2 regions: 1) a rostral region on the crest of the precentral gyrus and 2) a caudal region in the anterior bank of the central sulcus. The results of prior studies have suggested that anatomical and physiological differences exist between the 2 regions of distal forelimb representation (e.g., Strick and Preston, '82; Holsapple et al., '91). We used retrograde transport of wheat germ agglutinin conjugated to horseradish peroxidase (WGA-HRP) to examine the pattern of interconnections between the arm areas of the premotor areas on the medial wall of the hemisphere and the rostral and caudal regions of forelimb representation in the primary motor cortex of macaques (*Macaca nemestrina*). Tracer injections into the supplementary motor area (SMA, n=2) and the caudal cingulate motor area on the ventral bank of the cingulate sulcus (CMAv, n=2) labeled large numbers of neurons in the rostral region of forelimb representation on the crest of the precentral gyrus. Surprisingly, few neurons were labeled in the caudal region of the forelimb representation in the anterior bank of the central sulcus. In contrast, tracer injections into the caudal cingulate motor area on the dorsal bank of the cingulate sulcus (CMAd, n=2) labeled large numbers of neurons in the caudal region in the central sulcus, as well as in the rostral region. These results support the concept that the rostral and caudal portions of the forelimb representation in the primary motor cortex each have a unique input-output organization. Furthermore, they provide additional evidence that the CMAd is a motor field which is distinct from the SMA and CMAv. Support: VA Med.Res.Serv.; USPHS 2957, 24328, 843902.

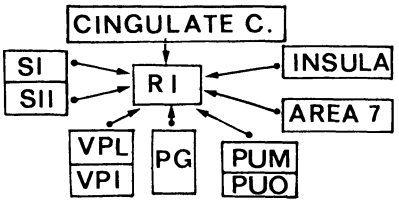
THE INTERCONNECTIONS OF THE RETRO-INSULAR CORTEX OF THE MARMOSET MONKEY. W. Guldin, S. Mirring* and O.-J. Grüsser; Dept. of Physiology, Freie Universität Berlin, 1000 Berlin 33, Germany.

The retroinsular cortex (Ri) is a cortical representation of somatosensory and vestibular input, situated in the posterior Sylvian sulcus of the marmoset monkey (Callithrix jacchus). Different retrograde tracers were placed into the cortical regions around this sulcus. The loci of injection were identified by single unit recordings and subsequent histology.

Thalamic afferences originate mainly in the oral- and medial-pulvinar nucleus (PUO, PUM) in the posterior group PG and in the lateral ventral and the inferior ventral nucleus (VPL, VPI). The cortical input to Ri of the Callithrix monkey comes from the area 7, the cingulate cortex, the somatosensory areas SI and SII and the insula. Our results support in part our former findings on the interconnections of the parieto-insular vestibular cortex (PIVC) of the Squirrel monkeys.



406.13

EFFERENCES FROM THE VESTIBULAR CORTEX TO THE VESTIBULAR NUCLEI IN PRIMATES. S. Akbarian, O.-J. Grüsser and W. Guldin. Dept. of Physiology, Freie Universität Berlin, 1000 Berlin 33, Germany

The parieto-insular vestibular cortex (PIVC) is a vestibular cortical field located in the posterior insula and the retroinsular region. Vestibular neurons were found in the PIVC of Java monkey (Macaca fascicularis) and Squirrel monkey (Saimiri sciureus). Identifying injection sites by recording single unit responses, we placed different retrograde tracers in the vestibular nuclei (VN) of anesthetised Java and Squirrel monkeys. In both species retrograde nerve cell labelling in the PIVC region could be detected. The only other cortical regions with noteworthy labelling after VN injections were area 7 and the cingulate gyrus. These findings indicate that the PIVC is the main cortical region of vestibular signal processing.

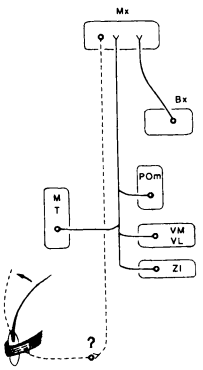
VIBRISSAL MOTOR CORTEX IN THE ADULT MOUSE; ITS CORTICAL AND THALAMIC INPUT.

Ullrich, N.*, E. Welker* and H. Van der Loos.
Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.



In order to study the potential role of a somatosensory pathway in adult plasticity in a related motor pathway we have investigated their interrelationship in the vibrissal system at cortical and thalamic levels. Using platinum-iridium electrodes (kindly provided by Prof.J.Donoghue, Brown University, RI), we delineated a discrete portion of the primary motor cortex where, under light anaesthesia, movements of individual caudal vibrissae could be elicited. At this cortical locus we deposited a fluorescent retrograde tracer (rhodamine beads), while an anterograde tracer (biocytin) was injected in the barrel in SI corresponding to the stimulated whisker (as determined physiologically, in the same animal; n=10). The vibrissal motor cortex receives input from the barrel cortex and the following thalamic nuclei: ventral lateral (VL), ventral medial (VM), medial portion of the posterior complex (PO), zona incerta (ZI) and some of the medial thalamic nuclei (MT). Future analysis will further define the significance of PO as a link between the motor and sensory vibrissal pathways. Support: Swiss NSF 3100.009468.

INTERHEMISPHERIC COMPARISONS OF THE ORGANIZATION OF BRODMANN'S AREAS 44 AND 45 IN HUMAN BRAIN. T.L. Hayes and D.A. Lewis. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15216.

Although motor speech functions are believed to be localized to the left hemisphere in Brodmann's areas 44 and 45, little is known about how the cyto- and chemoarchitecture of these areas compare to their homologues in the right hemisphere. We used Nissl stains to compare the cytoarchitectonic features of these regions in five control human brains. Areas 44 and 45, located in the posterior inferior frontal gyrus, were identified according to published criteria. At its most caudal extent, area 44 is dysgranular. More rostrally, in area 45, the cortex becomes granular, with unusually large pyramidal neurons present in deep layer III. At the most rostral aspect of area 45, the large layer III pyramidal neurons are not seen. These cytoarchitectonic features were identified in both hemispheres. However, measurements of the size of the large layer III pyramidal neurons in caudal area 45 revealed that they were larger in the left hemisphere than in the right ($p<.05$); the largest neurons were 10-20% larger in the left than the right. Further comparisons were made using immunohistochemical markers of non-phosphorylated neurofilament protein (NPNFP) and calbindin. As previously reported (*Soc. Neuro. Abstr. 16:240, 1990*), the large layer III pyramidal neurons in the left hemisphere were immunoreactive for NPNFP but not for calbindin. The present study revealed a similar pattern of immunoreactivity in the right hemisphere. Further investigation of possible hemispheric differences in these regions are underway. These studies may provide insight into the anatomical basis of the lateralization of motor speech function.

RELATIONSHIPS BETWEEN CONNECTIVITY AND CYTOSKELETAL PROFILE OF CORTICOCORTICALLY-PROJECTING NEURONS. J.H. Morrison, P.R. Hof, S.B. Kupferschmid, P.F. Good, W. Janssen*, and N. Archin*. Fishberg Research Center for Neurobiology and Dept of Geriatrics, Mount Sinai School of Medicine, New York, NY 10029.

Previous analyses combining retrograde transport of Fast Blue (FB) with immunohistochemistry have demonstrated that a substantial subpopulation of corticocortically-projecting neurons (CCPN) contain high concentrations of non-phosphorylated neurofilament protein (NPNFP). However, the relative proportion of a given projection that is NPNFP+ varies with its functional role and connectivity characteristics (Campbell et al, *Brain Res*, 1991:**539**). For these analyses, FB injections were placed in one of the following regions: prefrontal cortex ventral to the principal sulcus (vPS), inferior parietal cortex (vIPS) or cortex in the superior temporal sulcus (STS). The distributions of FB only and FB plus NPNFP double labeled neurons were analyzed in regions that provide cortical projections to each injection site. Quantitative analyses revealed that 1) Interconnections between these three association areas vary in the proportion of CCPN that are NPNFP+ such that connections between vIPS and STS have the lowest proportion (30-40%), vIPS and vPS intermediate (40-50%), and STS and vPS the highest (75-90%). 2) Reciprocal connections tend to have a similar proportion of double labeled cells. 3) The incidence of NPNFP+ CCPN from homologous contralateral areas varies from 25-100% depending on the system involved. 4) Analyses within the visual system suggest that CCPN within a given sensory modality may display differential typological characteristics as compared to CCPN interconnecting high-level association regions. Supported by AHAF and NIH AG06647.

INSULAR CORTEX OF THE CAT: THE RETROGRADE TRANSPORT OF HORSERADISH PEROXIDASE TO THE VENTRAL GROUP, MIDLINE NUCLEI, INTRALAMINAR COMPLEX, AND MEDIODORSAL NUCLEUS OF THE THALAMUS. F.G. Martinez-Sandoval and J. de la Rosa. Fac. de Med.,Univ. Autonoma de Guadalajara, Mex.

The cells of origin of projections from the ventromedial, ventrobasal, and intralaminar thalamic complexes, midline nuclei, and mediodorsal nucleus to the orbito-insula, insula proper and insulo-temporal cortex of the cat, were analyzed by means of the retrograde transport of horseradish peroxidase (HRP). After injections in different parts of theses cortical zones, HPRP-positive neurons were found in all experiments in the nucleus ventralis medialis (VM), interventralis (Iv), centralis medialis (Cm), parafascicularis (Pf), subparafascicularis (Spf), reuniens (Re), and mediodorsal (MD). In some experiments labelled neurons were detected in the nucleus ventralis anterior (VA), ventralis lateralis (VL), submedius (S), centre median (CM), paratenialis (Pt), and paraventricularis anterior (Pva). It seems that VA innervates the orbito-insula and most of the insula proper but not the caudal insula nor the insulo-temporal cortex. VL sends projections to the orbito- insula and most of the insula proper but not to the ventral insula nor the insulo-temporal cortex. S, Pc, CL, and CM innervate all regions of the insula except the insulo - temporal cortex. These findings suggest a multidisciplinary participation of the insula in the relay and/or control of modalities such as somato - motor, somato - sensory, visceral-motor, visceral-sensory, and an important role in the limbic system.

CORTEX: LESION AND STIMULATION

407.1

MUSCIMOL INJECTIONS IN MONKEY AREA 4 IMPAIR INDIVIDUATED FINGER MOVEMENTS, IN AREA 6 PRODUCE CONTRALATERAL NEGLECT. M.H.Schieber, L.Kim* and W.T.Thach. Depts. of Neurol. & Neurosurg., Anat. & Neurobiol., Wash. U. Sch. Med., St. Louis, MO. 63110.

What each cortical motor area--including the motor cortex in area 4 (MC), and the arcuate premotor area (APA) and supplementary motor area (SMA) in area 6--contributes to finger movements in any given behavior is uncertain. To investigate, muscimol was injected intracortically, reversibly inactivating each area as a Rhesus monkey performed a visually-cued individuated finger movement task. Muscimol was injected (1-5μg in 1μl over 1-5 min. via a 26-30g needle) at left hemisphere sites where neuron activity was well related to finger movements. MC was injected on 7, APA on 3, and SMA on 2 occasions.

MC injections were followed within 5-15 min. by deterioration of the trained contralateral finger movements. APA or SMA injections, in contrast, had no identified effect on task finger movements. Nor did they disrupt other aspects of the task, even though APA neurons responded briskly to the visual cues, and both APA and SMA neurons were well related to task finger movements. MC injections also rendered the monkey unable to extract raisins from a narrow well with the contralateral fingers, though in walking and climbing this hand appeared normal. Again, neither APA nor SMA injections affected these finger movements. Nevertheless, on bilateral simultaneous presentation of apple pieces, APA and SMA injections each decreased the likelihood both that the monkey would use his contralateral hand to retrieve bait, and that he would take contralateral bait with either hand. APA injections also decreased the likelihood that the monkey would first turn his head contralaterally to examine the bait. MC injections had no effect on laterality of bait retrieval or initial head turning.

MC thus appears necessary for all individuated finger movements, but not for finger control in walking or climbing. If APA and SMA neurons are active during visually-cued finger movements, why does inactivation of these areas not disrupt this performance, and instead produce only a mild contralateral neglect?

MODALITY-INDEPENDENT DEFICITS IN SPATIAL MEMORY TASKS INDUCED BY LOCAL INJECTIONS OF BICUCULLINE INTO THE PREFRONTAL CORTEX OF MONKEYS. T. Sawaguchi and P. S. Goldman-Rakic. Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

To examine the modality-specificity of spatial working memory mediated by the prefrontal cortex (PFC), bicuculline was injected into the dorsolateral PFC of monkeys who were trained on 3 different oculomotor tasks associated with memory-guided saccades to left or right spatial targets: 1) a standard oculomotor delayed response task cued by visual stimuli (VODR); 2) the ODR task cued by auditory stimuli (AODR); 3) a delayed alternation task where the monkeys' previous somatic (S) responses presumably guided alternatively saccades to the left and right targets (SODR). In each daily session, the monkeys performed the VODR and one or two of the other memory task(s) as well as a control task which required the monkeys to make only sensory-guided saccades. Several delays (1-5 sec) were employed in each ODR task. Local injection of bicuculline (1-3μg) into the PFC induced deficits in all of the memory tasks but not in the control task. When the VODR task was impaired, the AODR and SODR tasks were invariably impaired, and vice versa. The deficits were usually restricted to the memory-guided saccades directed toward the target contralateral to the injection site, and the impairment was dependent on the duration of the delay. Further, the effective sites of the injection were clustered in a small region of the dorsal bank of principal sulcus. The data suggest that the same region of the dorsolateral PFC is involved in visual, auditory, and somatosensory working memory for spatially guided behavior and that this region can be considered as a working memory center for spatial cognition.

MICROSTIMULATION STUDIES OF PREMOTOR AND OCULOMOTOR CORTEX IN OWL MONKEYS. T.M. Preuss, J. Stepniewska, and J.H. Kaas. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

We carried out extensive motor mapping studies of the dorsolateral frontal lobe in seven owl monkeys (*Aotus trivirgatus*). Animals were anesthetized with ketamine and xylazine and stimulated intracortically with .5—1 MΩ microelectrodes. Under these conditions, somatic and ocular movements could be elicited from a large territory rostral to primary motor cortex (M1); only the extreme ventrolateral and polar regions were unresponsive at high currents.

A dorsal premotor region lies between the low-threshold (<40 μA) M1 and the oculomotor cortex. This region is agranular in architecture, like M1, but has smaller pyramidal cells; somatic movements could be elicited at currents of ~40—150 μA, and sometimes less An additional somatic zone is located just rostral to the M1 face representation. Forelimb and (more laterally) face movements were elicited from this zone, often with low currents (<40 μA). This zone is dysgranular, rather than agranular, and is probably homologous to the arcuate premotor area (APA) of macaques. Rostral to the premotor zone, eye movements were elicited at low thresholds from the frontal eye field (FEF) and supplementary eye field (SEF), and at higher currents from the cortex located just rostral to FEF (previously described as the frontal ventral area), and also in the territory between FEF and SEF. In the latter region, thresholds typically ranged from ~50—200 μA, and at many points, movements of the face as well as the eyes could be elicited. 407.4

LATE RESPONSES TO TRANSCRANIAL MOTOR CORTEX STIMULATION IN LOWER LIMB MUSCLES OF HEALTHY HUMANS. W.B. McKay, M.R. Dimitrijevic, M.*Kofler Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, Texas 77030.

Short latency motor evoked potentials (MEPs) have been recorded in response to transcranial motor cortex stimulation from skeletal muscles whose spinal motor nuclei are innervated by the stimulated cortical cells. Magnetic stimulation applied at intensities of up to 2.5 Tesla with the coil centered over the vertex of the skull elicited surface EMG recorded MEPs from upper and lower limb muscles in 7 healthy subjects. The mean onset latencies for the early responses recorded from the quadriceps, hamstring, tibialis anterior and triceps surae muscles were 25,26,30 and 32 ms respectively. Second, later responses were recorded with mean latencies of 66, 60, 76 and 75 ms respectively. Two possible mechanisms for the generation of the second response are: 1. a strech reflex elicited by the early contraction or; 2. a longer additional pathway such as cortico-bulbo-spinal mediated response that would require a longer time to arrive.

DYNAMIC MODULATION OF PRIMATE MOTOR CORTEX OUTPUT DURING MOVEMENT J. P. Donoghue and J. N. Sanes Center for Neural Science, Brown Univ., Providence, RI 02912

These experiments tested the hypothesis that motor cortex output is dynamically modulated during skilled arm movements. *M. Fascicularis* monkeys performed a visually guided step-tracking task which required flexion of the wrist against a spring load. During movement preparation and execution the motor cortex was stimulated at one of 11 sites through 70 um Pt-Ir wires that were chronically implanted in areas 4 and 6. The EMG was recorded in 7 arm muscles (biceps, triceps, ECU, ECR, PL, EDC, FCU). Individual sites were stimulated with 30 ms pulse trains below 20 uA in each of 6 epochs: (1) during hold (no load), (2) during the same hold but after target location was displayed, (3) 250 ms after a go cue, (4) during movement initiation, (5) at mid movement, and (6) during hold in target zone

Modulation in the amount of evoked EMG during different epochs was site dependent. Stimulation at sites where digit movements were evoked at threshold showed only suppression or no change in EMG evoked from digit or wrist extensors. Pronounced modulation of FCU, ECU, ECR, or PL (1.5-10 fold increase of evoked EMG above epoch 1) was seen at wrist and shoulder or mixed movement sites, most frequently in epoch 3 (68% of cases). Evoked EMG during epochs 4-6 at these sites were typically equal to or below that evoked in epoch 1, even though the muscles remained active. At 2 sites evoked EMG in wrist muscles paralleled expected changes in the excitability of wrist flexor motor neuron pools. Modulation due to the instruction was uncommon (19% of the muscle observations). The occurrence of evoked EMG could depend on the stimulation epoch occurred: in 39% of 31 cases a muscle was activated from cortex only in ≤3 epochs. These findings suggest that the relationships between groups of cortical neurons and muscles may be temporarily maintained during different movement epochs. This organization may direct feedback onto selected cortical cell groups and could participate in adaptive reorganization of cortical motor maps observed after nerve transections or maintained changes in posture. MUSCLE INHIBITION FROM TRANSCRANIAL STIMULATION IN NORMAL HUMANS. E. M. Wassermann, A. Pascual-Leone, J. Valls-Solé,* L.G. Cohen, and M. Hallett. Human Cortical Physiology Unit, Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892.

We used transcranial magnetic stimulation to study 5 normals for inhibitory motor responses. Subjects activated the abductor pollicis brevis (APB) while we stimulated sites one cm apart on the contralateral scalp with a Cadwell MES-10 stimulator and an "8"-shaped coil. Rectified EMG from APB was averaged. In the area where stimulation produced the largest motor evoked potentials (MEPs), low stimulus intensities (30-35% stimulator output) elicited silent periods (SPs) on 20 trial averages without evidence of preceding facilitation. At slightly higher intensities (40-50%), MEPs followed by SPs were found at a cluster of sites on the central scalp (MEP area). At the same stimulation intensity, averages from 3 to 9 sites just anterolateral to the MEP area yielded SPs without facilitation. SPs without facilitation could not be produced at any other sites at this intensity. At sites further lateral, high intensities (60-100%) evoked robust SPs without MEPs on single trials.

Muscle suppression without preceding facilitation may be mediated by low threshold corticospinal neurons, spinal circuits excitable by weak cortical output, or inhibitory cerebral circuits. The difference between MEP and SP thresholds is greatest anterolateral to the center of the MEP area. This region may correspond to an inhibitory motor area defined by direct cortical stimulation with electrical pulse trains.

CORTICOSPINAL PROJECTIONS TO LOWER LIMB MOTONEURONS IN MAN. **B. Brouwer and P. Ashby* Dept. of Rehab. Therapy, Queen's Univ., Kingston, ON K7L 3N6 and Playfair Neuroscience Unit, Toronto Western Hospital, Toronto, ON M5T 2S8**

The relative strength of the projections from cortical neurons activated by transcranial magnetic stimulation to lower limb spinal motoneurons of the vastus medialis (VM), biceps femoris (BF), tibialis anterior (TA), medial gastrocnemius (MG), soleus (SOL), extensor digitorum brevis (EDB) and flexor digitorum longus (FDL) were examined in 34 normal subjects. The magnitudes of the postsynaptic potentials (PSPs) produced in spinal motoneurons were estimated from the changes in firing probability of single motor units. Strong short latency facilitations were observed in all TA motor units and in 67% of those innervating the small muscles of the foot. Less than 30% of the motoneurons of the triceps surae muscles were facilitated by the cortical stimulus and of those that were, the PSPs were small. The responses in other lower limb muscles were variable. It is argued that the observed pattern and the magnitude of the evoked responses are consistent with the known projections of the rapidly conducting corticospinal tract in subhuman primates.

ACTIVATION OF LOWER LIMB MUSCLES BY MAGNETIC STIMULATION IN SPINAL CORD INJURED (SCI) PATIENTS IS CONTEXT DEPENDENT. M.C.Verrier, B.E. Mustard and C.D. MacKinnon*, Departments of Rehabilitation Medicine and Physiology, University of Toronto., Lyndhurst Hospital, Toronto., CANADA M5T 1W5.

Magnetic stimulation (MS) to motor cortex activates contralateral lower limb compound motor action potentials (CMAPs) in normals during different motor tasks. MS in SCI has been used to determine integrity of the cortical spinal pathway but not as an determinant of neural recovery or therapeutic intervention. Clinically, SCI subjects with incomplete lesions demonstrate an ability to cycle with progressively more phasic and reciprocal activity during the recovery phase. We used MS to activate lower limb CMAPs (biceps femoris BF, rectus femoris RF, tibialis anterior TA, and soleus S) in these patients at rest, during selective muscle activation and during upright cycling to determine whether MS has utility as a therapeutic strategy. In studies using MS to the motor cortex (4 cm posterior; 2 cm lateral to Cz; with a Cadwell MES-10 with a 9.5 cm coil) CMAPs were repeatedly elicited in Q, and S during selective muscle activation but not routinely in BF and TA (n=1). Response latencies for Q and S were 23msec and 31msec respectively. In normals (n=10) BF, Q and TA were reliably elicited in all subjects and S in 8 out of 10 subjects with facilitation. In contrast to normal subjects, CMAPs in SCI subjects were not elicited during active cycling. A single MS stimulus interrupted cyclic S activity and elicited maintained S activity that lasted throughout the trial. The study suggests that the response to MS in SCI patients may be context dependent and indicative of existing spinal motor circuitry.

INHIBITORY INTERACTIONS BETWEEN TRANSCRANIAL BRAIN STIMULI APPLIED OVER THE MOTOR CORTEX IN MAN. T. Kujirai*, M. Sato*, J.C. Rothwell, B.L. Day*, P.D. Thompson*, S. Wroe*, P.T. Asselman* and C.D. Marsden*. MRC Human Movement & Balance Unit, Institute of Neurology, Queen Square, London WC1N 3BG, U.K.

With ethical committee approval, we gave pairs of transcranial brain stimuli separated by intervals of 1-20ms over the motor cortex of 10 normal volunteers. Both electrical (Digitimer D180) and magnetic (Magstim 200 connected to a figure 8 coil) stimuli were used. EMG responses were recorded from surface electrodes over the contralateral first dorsal interosseous (FDI) muscle. In active muscle, responses to electrical stimulation (at 1-1.2 times threshold) were facilitated by a preceding conditioning stimulus (either electric or magnetic), whereas responses to magnetic stimulation were inhibited. This suggests that the inhibition of magnetically-evoked responses occurred at the level of the motor cortex. The amount of inhibition depended upon the intensity of the conditioning stimulus. At high intensities of conditioning shock, the amount of inhibition was reduced, and in some subjects became a facilitation. The position of the conditioning stimulus was important. Moving the conditioning shock away from the motor strip decreased the amount of inhibition. However, conditioning stimulation of the hand area of cortex was not necessary to produce inhibition of responses evoked in the FDI. For example, conditioning stimuli applied at the vertex at an intensity subthreshold for producing EMG responses in the active FDI could still inhibit test responses evoked in the same muscle by stimulation over the hand area. The inhibitory interaction between pairs of stimuli is probably produced by a combination of several mechanisms, including refractoriness of pyramidal tract cells discharged by the conditioning stimulus, recurrent inhibition from pyramidal tract collaterals, and cortico-cortical inhibitory processes.

CORTICAL ACTIVITY PRECEDING SEQUENTIAL HAND MOVEMENTS AFTER BILATERAL LESION OF THE SUPPLEMENTARY MOTOR AREA (SMA)

J. Artieda*, J.A.Obeso
Department of Neurology, Movement Disorders Unit, Clínica Universitaria, Medical School, Pamplona SPAIN

We studied a patient with a chronic bilateral lesion of the SMA. Sequential hand movements (right wrist flexion-left wrist extension) revealed a mean interonset latency of 893±237 (Control 219±38 ms) when self-initiated and 912±283 ms (Controls 199±44 ms) when triggered by a visual stimulus. Back averaging the EEG activity preceding the first EMG discharge (right hand extension) showed absent readiness potential (RP). A motor potential (MP) starting some -70 ms was recorded over the primary motor cortex. Using the second EMG for triggering revealed a MP preceding left wrist extension by -120 ms. The interval between the maximal negativity of both MP was 927±202 ms. These observations indicate that cortical activity preceding sequential movements may be used to estimate the central delay for the assembling of motor programs. Such process appears to depend upon the integrity of the SMA.

INVESTIGATION OF MOTONEURONAL AND PREMOTONEURONAL MECHANISMS OF PUDENDAL REFLEX MODULATION DURING MICTURITION IN THE CAT. B. Fedirchuk, L. Song* and S.J. Shefchyk. Depts of Med. and Physiol., Univ. of Manitoba, Winnipeg, Canada, R3E 0W3.

This work investigates the mechanisms responsible for pudendal reflex suppression during micturition. Intracellular recordings were obtained from antidromically identified external urethral sphincter (EUS) or external anal sphincter (EAS) motoneurons (MNs) in decerebrate male cats. Sacral afferents from the sensory branch of the pudendal nerve and the superior perineal cutaneous nerve were electrically stimulated at $\leq 5T$ (T = minimum stimulus to elicit a cord dorsum potential) to produce postsynaptic potentials (PSPs) in the pudendal MNs during reflex distention or brainstem evoked micturition. In addition, 500μs hyperpolarizing short pulses were injected into the MN to assess MN membrane conductance changes before and during the void.

The membrane potential of EUS MNs hyperpolarized during the bladder contraction and void while EAS MNs depolarized or showed no change. PSPs produced in EUS MNs from both peripheral nerves were reduced in amplitude or abolished when the bladder pressure was elevated and voiding occurring. Preliminary evidence supports the presence of a conductance increase of the MN during voiding, however the magnitude of this conductance change is unlikely to be entirely responsible for the decrease in the PSP amplitude observed.

Recordings made from the proximal end of S2 dorsal root filaments have revealed dorsal root potentials produced by stimulation of sensory pudendal, superior perineal and pelvic afferents. The contribution of primary afferent depolarization to sphincter reflex modulation must be considered along with actions at segmental interneuron sites.

This research was supported by the Medical Research Council of Canada.

THE IDENTIFICATION OF GLYCINERGIC TRIGEMINAL PREMOTONEURONS. J.E. Turman, Jr., S.H. Chandler and R.S. Fisher. Dept. of Kinesiology, Anatomy/Psychiatry and the Brain Research Institute, UCLA, Los Angeles, CA 90024.

A glycinergic innervation of the trigeminal motor nucleus is suggested from physiological studies which investigated the inhibition of masseter motoneurons following peripheral and cortical stimulation. Following stimulation of the inferior alveolar and masseter nerves an early and late hyperpolarization is observed in masseter motoneurons. The early hyperpolarization is blocked by a systemic application of strychnine suggesting that the hyperpolarization is due to glycine (Nakamura, Y. et al., Brain Res., 57:29, 1973). Following repetitive stimulation of the masticatory cortex, rhythmical jaw movements are observed. A large portion of the rhythmical hyperpolarization seen in the masseter motoneurons is blocked by strychnine (Enomoto, S. et al., Neurosci. Res., 4:396, 1987).

We initiated a series of experiments to identify glycinergic inputs to the trigeminal motor nucleus. A retrograde tracer, gold colloidal-bound WGA-HRP (gWGA-HRP) was injected into the trigeminal motor nucleus of male albino guinea pigs. Following a 72 hour survival time, the animals were transcardially perfused with 4% glutaraldehyde and 0.5% paraformaldehyde. Glycine immunohistochemistry was performed using a polyclonal antibody (Chemicon, Inc.). ABC histochemistry with DAB as a chromagen was used to label the immunoreactive complex. Neurons which co-localized the connectivity marker and neurotransmitter marker were identified bilaterally in the parvocellular reticular formation, supratrigeminal nucleus, intertrigeminal nucleus, spinal trigeminal nucleus oralis and lateral paragigantocellularis. Immunoreactive cells, not containing the retrograde marker, were identified in the superior olive, dorsal cochlear nucleus, trapezoid body, vestibular nuclei, nucleus gigantocellularis, perihypoglossal area and spinal trigeminal nucleus interpolaris. Based on these data we conclude that glycinergic inputs to the trigeminal motor nucleus converge from several distinct portions of the brainstem. Funded by NIH-NIDR grant DE06193.

SPATIAL AND TEMPORAL OPTICAL RECORDING OF THE EXCITATION OF SINGLE NEURONS COMBINING A COOLED CCD AND A PHOTODIODE ARRAY. M.G. Rioult+, P. Gogan#*, H.-R. Lüscher+ & S. Tyc-Dumont#. Dept. of Physiology (+), University of Bern, CH-3012 Bern, Switzerland and Unité de Neurocybernétique cellulaire (#), CNRS UPR 418, F-13009 Marseille, France.

Investigations of synaptic integration in complex neurons necessitates simultaneous recording of the spatial and temporal patterns of excitation and inhibition in the entire cell. Optical recording of the membrane potential by means of voltage-sensitive dyes (VSD) and a photodiode array (PDA) gives sufficient temporal resolution but only a CCD-array (CCDA) can provide the necessary high spatial resolution. However, a CCDA cannot provide the necessary speed. In order to overcome the limitations inherent in the two techniques, a combined approach was developed.

Rat sensory ganglia grown in an organotypic culture for 14 days were stained with the fluorescent VSD RH-237. The neurons were impaled with microelectrodes for intracellular stimulation and recording of electrical activity. The concomitant changes in fluorescence intensity were recorded simultaneously by a square 124 element PDA and a liquid nitrogen cooled CCDA, both mounted in the image plane of an inverted microscope. A 40x/1.3 n.a. objective provided a spatial resolution of 15 μm/PD and 1 μm/pixel for the CCDA. The signal from each PD was amplified and digitized at a rate of 3 Khz. The CCDA integrated the fluorescence signal for a period of 10 msec coinciding with the evoked action potential. A second CCD-image was taken for the same time period without stimulation. The difference and the fractional change of the two fluorescence images were calculated.

The fluorescence signals registered from the excited neuron by the PDs reproduced the intracellularly recorded action potential with high fidelity. The CCDA produced an image which localized the electrical activity to the membrane of the excited neuron. This demonstrates that the two optical recording techniques are complementary. The high spatial resolution achieved with the CCDA localizes neural activity to small membrane areas, while the PDA provides the necessary temporal information.

ELECTRICAL INDUCTION AND MODULATION OF RESPIRATION IN VITRO. O. Hamada*, T. Iwahara *, E. Garcia-Rill and R.D. Skinner, Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, Arkansas.

Recently, we described the ability to induce locomotion using electrical stimulation of the brain stem and spinal cord in the neonatal rat in vitro brain stem-spinal cord preparation (J. Neurophysiol. 64, 1990). The purpose of the present study was to determine if electrical stimulation of the spinal cord can be used to induce respiration in vitro. EMGs were recorded from intercostal muscles in the brain stem spinal-cord, rib-attached, 0-3 day rat in vitro maintained in artificial cerebrospinal fluid. All preparations showed spontaneous, rhythmic and synchronized upward movements of the rib cage at a frequency of 0.06±0.01 Hz (range 0.04-0.07 Hz). The threshold for mechanical or twitch contraction-induced respiration was 16.0±13.5 μA, with the frequency of stimulation determining mechanical respiration from 0.1-4 Hz. In most cases, lower current amplitudes (11.0±3.1 μA) increased the frequency of spontaneous respiration to 0.07±0.03 Hz (range 0.06±0.09 Hz). The optimal frequency and duration of stimuli for induced and modulated respiration were 3 Hz (range 0.5-4 Hz) and 1 ms (0.5-2ms), respectively. The optimal stimulation sites were located in the C4 and C5 segments. These preliminary findings suggest that respiration can be induced and/or modulated by cervical spinal cord stimulation in vitro.

A SLOW EPSP CONTRIBUTES TO BURST DISCHARGE OF TURTLE RED NUCLEUS NEURONS REVEALED BY INTRACELLULAR RECORDING *IN VITRO*. J. Keifer and J.C. Houk, Dept. of Physiology, Northwestern University Medical School, Chicago, IL 60611.

The *in vitro* turtle brainstem-cerebellum is a useful model in which to study the circuit and cellular mechanisms underlying central motor commands in the cerebellorubral system. Previously we reported that long duration burst discharges were recorded from red nucleus neurons in this *in vitro* preparation. These bursts are postulated to represent motor commands and are generated by excitatory amino acid neurotransmission mediated by both NMDA and non-NMDA receptors (Keifer & Houk, *J. Neurophysiol.* 65: 454, 1991). It was postulated that burst discharges are triggered by a fast EPSP mediated by QUIS/KA receptors and sustained by an NMDA-mediated slow EPSP whose duration is prolonged by excitation from cerebellorubral recurrent pathways. Here we present evidence from intracellular recordings of red nucleus neurons in the *in vitro* brainstem-cerebellum for the presence of a slow EPSP that may contribute to burst discharge.

Intracellular recordings from 14 red nucleus neurons (RP < -55 mV) were obtained using microelectrodes containing 4 M KAc (D.C. resistance, 80-100 MΩ). Intracellular voltage was measured in the bridge balance mode. A stimulating electrode in the contralateral spinal cord was used to identify rubrospinal neurons by antidromic or synaptic activation. Current-voltage relations having slight inward rectification were obtained from red nucleus neurons and all cells showed anode-break excitation to current offset. Many cells (7 of 14) received spontaneous IPSPs and EPSPs. Responses to synaptic input were assessed by single shock contralateral cord stimulation which activates red nucleus neurons through synaptic pathways. In 6 of 14 cells, a slow EPSP having a mean latency of 11 ms (9-12 ms range) and a duration of 200-600 ms was observed following the stimulus. A higher stimulus intensity evoked an action potential at antidromic or synaptic latency (3-7 ms) followed by the slow EPSP. Action potentials were observed riding on the voltage envelope of the slow potential. The results provide support for the hypothesis that both cellular and circuit mechanisms contribute importantly to the generation of burst discharges in the red nucleus.

DEPRESSION OF TRANSMISSION FROM GROUP II MUSCLE AFFERENTS BY ELECTRICAL STIMULATION OF THE CUNEIFORM NUCLEUS AND SUBCUNEIFORM REGION IN THE CAT. B.R. Noga[1], E. Jankowska[2]* and B. Skoog[2]*Department of Physiology, [1]University of Manitoba, Winnipeg, Canada and [2]University of Göteborg, Göteborg, Sweden.

The effects of electrical stimuli applied within the cuneiform nucleus and the subcuneiform region were examined on transmission from group I and group II muscle afferents to neurones located in mid-lumbar spinal segments. Changes in the effectiveness of transmission from these afferents were assessed from changes in the sizes of the monosynaptic component of extracellular field potentials evoked following stimulation of muscle nerves.

Field potentials evoked from group II muscle afferents in the dorsal horn, intermediate zone and ventral horn were reduced in size when the test stimuli applied to peripheral nerves were preceded by conditioning stimulation (6-8 shocks at 400 Hz, 0.2 ms duration, 1/sec, 50-100 μA) of either the anterior and posterior cuneiform nucleus or the subcuneiform region ipsilaterally or contralaterally to the recording site. The depression of group II field potentials occurred at conditioning-testing intervals of 20-400 ms, being maximal at intervals of 35-70 ms and 40-105 ms for potentials recorded in the dorsal horn and intermediate zone/ventral horn, respectively. At the shortest intervals the depression of these field potentials was combined with a depression of the group I field potentials (maximal at intervals of 20-25 ms) in the intermediate zone. Thoracic spinal cord reversible cooling experiments revealed that the effects of stimulation of the cuneiform nucleus or subcuneiform region at long-conditioning test intervals were mediated via pathways travelling through the ipsilateral ventrolateral quadrant.

Intravenous administration of ketamine was found to antagonize the depression of dorsal group II field potentials evoked following stimulation of the cuneiform nucleus at long conditioning-test intervals. It is suggested that this effect was due to the action of ketamine on NMDA receptors of neurones activated by stimulation of the cuneiform nucleus and was not due to the dissociative anaesthetic properties of this drug since the depression evoked following conditioning stimulation of the raphe obscurus was unaffected and that evoked by Kölliker-Fuse nucleus stimulation was only partially antagonized.

SELECTIVE MODULATION OF THE PAD OF SINGLE Ia AND Ib AFFERENTS PRODUCED BY SURFACE STIMULATION OF THE MOTOR CORTEX IN THE CAT. J. R. Equibar, J. Quevedo*, I. Jimenez and P. Rudomin. CINVESTAV, Mexico DF 07000 and ICUAP.

The possible specificity of the control exerted by the motor cortex on primary afferent depolarization (PAD) of single muscle spindle and tendon organ afferents was studied in 6 anesthetized, paralyzed and artificially ventilated cats. PAD was inferred from the intraspinal threshold changes produced in pairs of single group I afferents either from the gastrocnemius (GS) and/or semitendinosus (ST) nerves. Surface anodal stimulation of motor cortex with trains of 8 pulses, 700 Hz, 200-1500 μA facilitated the PAD produced by group I flexors in 8 Ib fibers and inhibited the PAD elicited in 14 Ia fibers. The lowest threshold regions for the 2 actions were located mainly in the hindlimb area of the posterior sigmoid gyrus, and were usually separated by about 2 mm. With low strengths of cortical stimulation some sites were found that affected the PAD of Ia fibers without affecting the PAD of Ib fibers, while other sites affected to a similar extent the PAD of Ia and Ib fibers. The sites of overlapping actions increased with higher intensities of cortical stimulation. No obvious differences were found in the distribution of the most effective sites affecting the PAD of Ia and Ib fibers originating from the GS and ST muscles. The results suggest that neurons in the motor cortex are organized in discrete ensembles that are able to control the effectiveness of specific sets of group I muscle afferents. Supported by grants NIH NS 09196 and CONACyT 41739.

MODULATION OF SYNAPTIC EFFECTIVENESS OF GROUP I MUSCLE FIBERS BY ARTICULAR AFFERENTS. J. Quevedo*, J.R. Equibar, I. Jimenez, R.F. Schmidt and P. Rudomin. CINVESTAV and ICUAP, Mexico and University of Würzburg, Germany.

Schaible et al. (J. Physiol, 372: 575, 1986) suggested that electrical stimulation of the cat's posterior articular nerve (PAN) produces little or no presynaptic inhibition. We have reinvestigated this issue in the anesthetized, paralyzed and artificially ventilated cat. PAN stimulation with single pulses (<1.6 xT) produced a negative wave (onset latency 5.2±.5 ms) in the cord dorsum but no dorsal root potentials (DRPs). With higher strengths (1.7-4 xT) a second negative wave (peak latency 15.7±1.2 ms) followed by a P-wave and DRPs were recorded. In 2/6 experiments the DRPs were further increased by stimulation of the PAN with intensities (>7 xT) producing a third negative wave (latency 31.8±5 ms). Stimulation with trains (7 pulses 400-700 Hz) lowered the threshold for DRP generation (1.1-1.3 xT). Electrical stimulation of the PAN as well as innocuous and noxious stimulation of the knee joint depressed the DRPs produced by group I afferents of the posterior biceps and semitendinosus (PBSt) nerves. Analysis of the intraspinal threshold changes of single Ia and Ib fibers showed that repetitive stimulation of the PAN (8-10 xT) inhibited the PAD of Ia fibers produced by group I PBSt afferents (n=19). It also produced PAD in some Ib fibers (n=3) and inhibited the PAD in other Ib fibers (n=2). It is suggested that PAN afferents act on Ia and Ib fibers in a similar way as intermediate and high threshold cutaneous afferents. Supported by the VW Foundation, NIH (NS 09196) and CONACyT (41739).

408.9

IS THE PAD EVOKED IN Ia FIBERS RELATED TO THEIR RESPONSES TO STRETCH? M. Enriquez*, O. Hernandez*, I. Jimenez and P. Rudomin. CINVESTAV, Mexico D.F. 07000.

Intracellular recordings were made from single gastrocnemius (GS) afferent fibers in the spinal cord of anesthetized and paralyzed cats. In 17 Ia fibers a detailed analysis was made of their responses to segmental and descending inputs and to longitudinal ramp stretches of the GS muscle (8-16 mm/s). Stimulation of the posterior biceps and semitendinosus (PBSt) nerve (3 shocks, 330 Hz, 2xT) produced PAD in these fibers (mean 370±235 μV). Stimulation of the sural nerve (5xT) produced PAD only in 1 fiber (182 μV), and stimulation of the bulbar reticular formation (4-7 pulses, 331 Hz, 2xT) produced PAD in 4 fibers (mean 405±176 μV). These 2 inputs inhibited the PBSt-induced PAD in other Ia fibers (to 83±13%, n=10 and to 73±10%, n=3, respectively). The amplitude variations of the PAD evoked by PBSt stimulation appear not to be related with the conduction velocity of the Ia fibers (r=0.34). In 3 out of 4 experiments the PBSt-induced PAD of Ia afferent fibers with a low (<20 Hz) dynamic index (DI) was larger than the PBSt-PAD evoked in fibers with a higher (30-60 Hz) DI. The low DI/high DI PBSt PAD ratios were of 1.98, 1.59 and 2.97. The coefficients of correlation between the PBSt-induced PAD and DI derived from the 13 mm/s stretches were of -0.84 (n=5), -0.71 (n=5) and -1 (n=2) in these 3 experiments. It is suggested that the strength and/or density of the connections of the segmental interneurons mediating PAD may vary according to the DI of the target Ia fibers. Partly supported by NIH grant NS 09196 and CONACyT grant PCEXCCNA 41739.

MODULATION OF JAW MUSCLE SPINDLE AFFERENT ACTIVITY BY STIMULATION OF THE VENTRAL DIENCEPHALON. D. Dessem and H. Juang*, Department of Physiology, University of Maryland Dental School, Baltimore, MD 21201

Anatomical studies showing the presence of synaptic contacts on first-order afferent cell bodies in the mesencephalic trigeminal nucleus (MesV) suggest they are subject to central modulation. This study investigated the diencephalic modulation of jaw-muscle spindle afferent activity recorded in MesV. Peri-stimulus time histograms (PSTH) were generated (1000-10,000 stimuli) from the spontaneous activity of single muscle-spindle afferents triggered from bipolar, constant current stimulation (0.1 ms) of the ventral diencephalon. Jaw-muscle spindle afferents were identified by their response during: muscle palpation, ramp and hold jaw displacement, and the infusion of succinylcholine. Twenty afferents were studied in 8 rats anesthetized with pentobarbital and paralyzed. The spontaneous firing of 8 spindle cells was inhibited at latencies of 0.8-1.6 ms ($\bar{x}$=1.26 ms) and persisted for 2.2-8.0 ms ($\bar{x}$=4.7 ms). The inhibition was characterized by a distinct threshold at 50-300 μA and graded with stimulus intensities above threshold. The inhibition gradually decreased as stimulation frequencies were increased above 10-25Hz. PSTH's generated from non-spindle and some spindle cells showed no effect at stimulus intensities up to 1000 μA. Studies are in progress to determine whether this inhibition is mediated via the hypothalamic pathway to MesV reported by Nagy et al., (Neuroscience, 1986).

PHASIC MODULATION OF TRANSMISSION FROM VESTIBULAR INPUTS TO RETICULOSPINAL NEURONES DURING FICTIVE LOCOMOTION IN LAMPREYS. N.Bussières* and R.Dubuc. Dép. de Kinanthropologie, Univ. du Québec à Montréal, Montréal, H3C 3P8 and Centre de Recherche en Sciences Neurologiques, Univ. de Montréal, Montréal, Québec, Canada H3C 3J7.

Reticulospinal neurones (RS) play a key role in the supraspinal control of locomotion in lampreys. They provide excitation to motoneurones and to spinal interneurones involved in the generation of locomotion. In turn, they receive sensory inputs from many sources. For instance, electrical stimulation of vestibular nerve afferents induces di-synaptic responses in RS neurones on both sides (Rovainen *J Neurophysiol* 1979 *42* 745). The present study was aimed at examining whether the transmission of these synaptic responses is phasically modulated during locomotion. The brainstem-spinal cord of lampreys was isolated *in vitro*. Vestibular nerves on both sides were stimulated during different phases of locomotor activity induced by bath application of NMDA (50 μM). Reticulospinal neurones showed phasic membrane potential oscillations related to the locomotor activity with a depolarization during ipsilateral activity and hyperpolarization during contralateral activity in the rostral spinal cord. On top of this modulation, excitatory synaptic responses evoked in RS neurones by ipsilateral stimulation were phasically modulated, reaching a minimum during depolarization and a maximum during hyperpolarization of the RS neurone. Stimulation on the contralateral side induced opposite effects: responses were maximal during depolarization and minimal during hyperpolarization. No phasic changes of the input resistance were observed in these RS neurones, suggesting that the modulatory effects are pre-reticular. Microstimulation of two relay nuclei (intermediate and posterior octavomotorius) induced similar results, although the phasic modulation was slightly less. Responses to ipsilateral stimulations were minimal during depolarization whilst those to the contralateral side were minimal during hyperpolarization. Taken together, these results suggest that a large part of the modulation of vestibular input transmission to RS neurones takes place either at the level of the soma of relay cells and/or at presynaptic terminals innervating RS neurones. THE EFFECTS OF ACOUSTIC STARTLE RESPONSE ON LUMBAR 1A INHIBITORY INTERNEURONS. L.E. Tremblay, U. of Ottawa, Canada and P.J. Delwaide*, U. of Luik, Belgium.

The acoustic startle response (ASR) to unexpected auditory stimulation was studied in 15 healthy subjects aged 23-40 years. The present study was undertaken to investigate the effects of ASR on lumbar motoneurons (MNS) excitability and lumbar 1a inhibitory interneurons (1a IN). The ASR was evoked by a binaurally conditioning test (1000 Hz 120 db tone). The audiospinal facilitation was measured on the soleus H-reflex using a lower conditioning stimulus (1000 Hz 85 db tone). The effect of ASR on soleus was measured from 50 to 300 ms. The effect of ASR on 1a IN was elicited the same way as the soleus H-reflex protocol but preceded by a subthreshold electrical stimulus on the common peroneal nerve. The maximal effect of audiospinal facilitation was at a 100 ms delay 222.9% ± 67.5 expressed in percentage of H-reflex control ($P<0.001$). The audiospinal facilitation on (1a IN) was significant at delays of 100 and 125 ms. The inhibition was facilitated by 20% ± 10 and 18% ± 6 ($p<0.05$) respectively. These results on the ASR confirm the time course and variability of audiospinal facilitation on lumbar MNS. The ASR facilitates the lumbar 1a IN at delays of 100 and 125 ms post-acoustic stimulation. At this time only the activation of the nucleus of gigantocellularis of the reticular formation can explain the facilitation effect on 1a IN.

ANTIDROMIC DISCHARGE OF SINGLE UNITS IN DORSAL ROOTS AND HINDLIMB CUTANEOUS NERVES. A. Niechaj, L. LaBella and S. Rossignol. Centre de Recherche en Sciences Neurologiques, Univ. de Montréal, Québec, Canada, H3C 3J7.

Our previous work on presynaptic mechanisms during fictive locomotion has indicated that some cutaneous and muscle primary afferents, recorded intracellularly at the dorsal root entry level, may discharge rhythmically. In the present series of experiments, spike-triggered averaging (STA) was used to show that action potentials in dorsal roots as well as in cutaneous nerves may be propagated antidromically (AD) in such preparations.

Experiments were performed on 21 spinal cats, 15 of which were spinalized 7-22 days prior to surgery. Single spikes recorded from a dorsal root by bipolar hook electrodes were used to trigger an average of the mass activity recorded from the same root with a second electrode and digitized at 20 KHz. Similar methods were used in the periphery to make STA in the medial (MS) or the lateral sural (LS) nerves. Single units were found to discharge tonically in both intact and cut dorsal rootlets. Such antidromic discharges could last for several minutes. In a few cases, these units were rhythmically active during fictive locomotion induced by Nialamide and DOPA. AD discharges were also found in 17 LS and 10 MS recordings and were also shown in 7 semi-chronic spinal preparations in which the spinal canal was not opened in order to avoid spinal trauma or changes in the temperature of the spinal cord. In a few cases, a weak modulation of such peripheral cutaneous units could be shown during fictive locomotion. It is concluded that, in such acute preparations with or without fictive locomotion, single primary afferents, recorded both in cut or intact dorsal roots, as well as in peripheral cutaneous nerves, may discharge antidromically, either tonically or rhythmically. (Supported by the MRC and by the FRSQ).

POSTURAL AREAS IN THE FROG LUMBAR SPINAL CORD. S. F. Giszter, F. A. Mussa-Ivaldi* and E. Bizzi. Dept. Brain and Cognitive Sciences, M. I. T., Cambridge, MA 02139.

Recently, we have examined the role of the premotoneuronal spinal areas in organizing posture and movement in spinalized frogs. Our investigations revealed that microstimulation of a single site in the upper and middle layers of the frog spinal cord, in conjunction with positioning of the leg in different workspace locations, generated a force field with a single equilibrium point. The equilibrium point is that spatial location at which the leg would be at steady state were it free to move. In the work described here, we have examined the spatial distribution of the convergent force fields (CFFs) in the lumbar cord.

We investigated whether the areas that specify different equilibrium-limb positions are topographically organized. After sampling the premotor area of the lumbar cord, we concluded that there are at least four areas from which four distinct types of CFFs are elicited. These regions form stripes oriented rostro-caudally. Within each region, a qualitatively similar set of x and y forces are produced. We also found that the simultaneous stimulation of two different points in the areas we have outlined results in a force field proportional to the sum of the fields obtained by the stimulation delivered at each point. This result is surprising given the complex nonlinearities that characterize the interactions both among neurons, and between neurons and muscles. We view a superposition mechanism as the simplest way to explain how the spinal cord generates a vast repertoire of force fields from the limited variety of available fields.

DIFFERENTIAL EFFECTS OF SPINAL TRAUMA IN PRIMATES AND CATS. M.Jayachandra* and V.E.Amassian. Dept. of Physiology, SUNY-Health Science Center at Brooklyn,Brooklyn, NY 11208.

We demonstrated changes in direct impulse conduction in the dorsal columns (DC) and corticospinal tracts (CT) following a midthoracic (T6) weight drop in fully anesthetized cats (J.Physiol.(Lond).,426,103P,1990). DC function was assessed by recording the posterior tibial nerve responses monophasically to antidromic epidural stimulation at C1 or T5. A second epidural stimulus was also applied at T10 below the trauma zone and these responses were used to correct (normalize) for any local changes at the recording site over a period of 8-29 hrs. DC population responses showed an immediate conduction loss after submaximal trauma, followed by recovery within 30-60 min and subsequent secondary decay beginning within 2-3 hrs; the normalization process increased the definition of kinetic changes in all the models used. Following trauma, both sensory and motor systems showed latency shifts, decreased amplitudes, and selective conduction loss of the fastest elements of the population responses. In the motor system this sensitivity was seen in population studies of antidromically excited single units recorded from primary motor cortex; the shortest latency units, presumably reflecting the largest diameter fibers, were more affected.

In the cat the DC conducted responses were less vulnerable, recovered faster and to greater extent than the CT. Extending the same paradigm to primates two phases of decay were identified, but the secondary decay took longer to develop. However, unexpectedly, the DC conducted response in primates (n=4) was more sensitive to trauma than the direct CT response (recorded from the pyramid to antidromic stimulation at T10). This finding cautions against extrapolating results derived from models in lower forms to primates.

FORELIMB MOTOR PERFORMANCE FOLLOWING CERVICAL SPINAL CORD CONTUSION INJURY, DORSAL COLUMN LESION, OR DORSOLATERAL FUNICULUS LESION IN THE RAT. G. W. Schrimsher and P. J. Reier. Dept. of Neuroscience, Univ. of Florida, Col. of Medicine, Gainesville, FL 32610.

The focus of this study is to compare the effects of weight-drop contusion injury with either selective dorsal column (DC) or dorsolateral funiculus (DLF) lesions at the C4 spinal segment on the following behavioral tests: forelimb reaching and pellet retrieval, vibrissae-induced forelimb placing, and forehead adhesive sticker removal. Contusion injuries were produced by dropping a 10 gm weight from a height of 2.5 cm onto a 2.5 mm tip diameter impounder resting on the exposed dura. Of 13 rats receiving this injury, 9 failed to recover reaching ability, 3 recovered reaching ability with a greatly reduced retrieval rate, and one rat approximated normal performance levels. The inability to contact an adhesive sticker placed on the forehead or a greater than 50% drop in forelimb placing at one week post-injury were each predictive of permanent failure to recover reaching ability. The DC corticospinal tract was severely disrupted in all animals, regardless of whether or not reaching ability recovered. Animals that recovered reaching ability were found to have a greater sparing of lateral column white matter as compared to animals which failed to recover. Initial results from the surgical lesion studies revealed that reaching ability was spared and pellet retrieval performance approached normal levels even when the DC lesion disrupted the DC corticospinal tract. Confined bilateral DLF lesions, however, produced a profound grasp deficit involving a prominent loss of digit flexion. Lesions which also extended into the ventrolateral white matter produced a marked hypometria in forelimb extension during reaching attempts. These findings indicate possible roles for the rubrospinal tract and the small DLF component of the corticospinal tract in distal limb motor performance in the rat. This work was supported by PHS Award MH15737-12.

EFFECTS OF RETICULOSPINAL INPUT ON MONOSYNAPTIC REFLEXES IN PARTIAL SPINAL CORD INJURY. W. H. Lee*, Y.G. Park, A. Chen*, J. H. Kim, The Miami Project To Cure Paralysis, Dept. of Neurol. Surg., Univ. of Miami, Miami, FL 33136

Rats with a spinal cord (SC) lesion sparing only the ventral quadrant at T6 level recovered coordinated fourlimb locomotion within 2-3 weeks. The time course of the functional recovery of the hindlimb movement is temporally correlated with recovery of reticulospinal nuclei (RtN) input to the lumbar SC. However, the physiological role of RtN in motor function is not clear. The objectives of this study was to investigate effects of RtN activation on monosynaptic reflex (MSR) in the normal and chronically injured SC. Sprague-Dawley rats were used. Under sterile conditions, SC lesions were made at the T6 level sparing one ventral quadrant. Rats survived from one day to ten weeks. During terminal experiments, a laminectomy was performed to expose L1-S1 SC. Left and right L4 dorsal roots (DR) were freed and mounted on two pairs of bipolar stimulating electrodes. MSR was produced by stimulation of DR, and was monitored on the sciatic nerve . Chronic changes in the RtN inputs to the SC were estimated by changes in MSR due to RtN conditioning stimulus. Immediately after partial SC lesion, both MSR and the RtN evoked outputs were depressed on the completely lesioned side of the cord. Within 2-3 days dramatic increases in MSR appeared on the left side and peaked within one week after the lesion. Following the lesion, the excitatory effect was completely abolished on the left, whereas it remained intact on the right where the ventral quadrant was spared. **(Support: NIH NS28059, The Miami Project Research Fund)**

Loss of Hindlimb Stepping after Unilateral Lumbosacral Deafferentation in Cats. M.E. Goldberger E. Coleman-Paige, K.L. Ziegler. Medical College of Pennsylvania, Phila PA, 19129.

We have shown (Goldberger & Ziegler, 1988, Soc Neurosci) that, after unilateral dorsal rhizotomy, L1-S2, the deafferented hindlimb recovers quadrupedal locomotion overground and on a treadmill, but not bipedal treadmill locomotion. In order to test the hypothesis that this failure might be due to the presence of descending inhibition, the spinal cord was transected at L1 in 3 cats with chronic hindlimb deafferentation in order to abolish descending inhibition and perhaps bring back bipedal locomotion. The deafferented hindlimb, however, does not recover bipedal locomotion and even the stepping responses of the afferented limb recovered slowly and were permanently weaker than in transected-only cats. Speculating that pattern generating neurons of the afferented side were unable to acivate those of the deafferented side, we examined c-fos expression in one animal after the chronic combined lesion and treadmill exercise. C-fos was expressed in interneurons on both sides of the cord. The results, taken together suggest that deafferentation reduces critically the input to spinal pattern generators and that even though neurons are activated, activation is inadequate to mediate locomotion unless the influence of descending input is permitted (or specific drugs are used). Supported by NS 228081.

THE EFFECT OF LESIONS TO THE NUCLEUS TRACTUS SOLITARIUS (NTS) ON THE OROPHARYNGEAL SWALLOW IN CATS. M. Kobara-Mates*, J. Logemann, C. Larson, and P. Kahrilas. Dept. of Communication Sciences and Disorders, Northwestern University, Evanston, IL 60208.

Although the NTS area has been shown to be involved in the central control of swallowing, it is unknown whether this area merely initiates the pharyngeal swallow or is involved in the motor programming of the pharyngeal swallow, as well. The purpose of this study was to examine the effect of small lesions in the NTS on the physiology of the oropharyngeal swallow in awake cats through the use of simultaneous videoradiography (VRG) and electromyography (EMG).

Hooked wire EMG electrodes were implanted into six muscles (posterior tongue, mylohyoid, thyrohyoid, thyroarytenoid, inferior constrictor, cricopharyngeus) active during swallowing. Sites in the NTS area near the level of the obex that elicited swallowing upon electrical stimulation were stereotaxically identified and then lesioned by passing anodal DC current. Cresyl violet staining revealed similarly placed lesions in the ventromedial portion of the NTS and surrounding area, near the obex.

Following the lesions, VRG revealed that two of the cats exhibited difficulty initiating pharyngeal swallows of small bolus volumes only. Intra-oral bolus transport was not affected. Post-lesion changes in laryngeal elevation, a pharyngeal stage event, were also found for all three cats. Although amplitude and duration measures of EMG were affected by lesioning, the sequence of EMG bursts was not affected in any of the cats. Thus, the results of this study support the assertion that the ventromedial NTS and immediately surrounding area is not only involved in the initiation of the pharyngeal swallow, but may be involved in programming the duration and amplitude of pharyngeal stage events. Although these results are preliminary, small lesions to the NTS do not appear to affect the sequencing of EMG activity during the pharyngeal stage of the swallow.

CONTROL OF POSTURE AND MOVEMENT I

409.1

STANCE PERTURBATIONS FOLLOWING BILATERAL LABYRINTHECTOMY IN THE CAT. J.M. Macpherson and J.T. Inglis. R.S.Dow Neurol. Sci. Inst., Portland, OR 97209 and Dept. of Anatomy, Queen's Univ., Kingston, Ont., Canada K7L 3N6.

The aim of this study was to determine whether vestibular afferent inputs are critical for triggering the rapid postural responses that are evoked by movements of the support surface under the freely standing cat. Four cats were trained to stand quietly on a moveable force platform. The animal's stance was unexpectedly perturbed by applying a linear ramp-and-hold translation to the support surface in each of 16 different directions in the horizontal plane. The postural responses were quantified in terms of the 3-D ground reaction forces under each paw, and the EMG activity evoked in selected hindlimb muscles. Following the collection of control data, the animals were labyrinthectomized bilaterally in one surgical procedure. The vestibule on each side was opened by drilling into the temporal bone, and the membranous labyrinth was suctioned away, presumably destroying the hair cells.

The cats were able to stand stably on the platform within 2-3 days of the lesion. The responses to platform translation were characterized by normal patterning and latency of EMG activity. Furthermore, all cats continued to use the force constraint strategy that is characteristic of the intact animal (Macpherson, J. Neurophysiol. 60(1988):204-217). The only clear deficit in performance was a transient hypermetria, characterized by an over-response in the forces and often, a subsequent oscillation. The hypermetria disappeared after 8-10 days. Although the cats over-responded, they were still able to maintain their balance successfully. These results suggest that vestibular inputs are not necessary for the triggering or patterning of postural responses evoked by support surface translations.

INTERACTION OF VESTIBULOSPINAL AND SOMATOSENSORY INPUTS IN THE CONTROL OF BALANCE IN MAN. C.W.Y. Hui-Chan, E. Lo Monaco*, N. Paquet*. School of Phys. and Occup. Ther., McGill Univ., Montreal, Canada, H3G 1Y5.

Despite considerable investigations into the control of posture during *slow* perturbations to free standing, there has been few systematic studies directed at the control of balance during *more rapid* whole head-and-body tilts. The objectives of our study were 1) to determine the effects of different magnitude of head acceleration on lower limb muscles responses evoked by sudden whole head-body tilts during stance; and 2) to delineate the modifyability of tilt-evoked responses by foot/ankle somatosensory inputs. Seven young normal subjects were blindfolded and fixed on a tilting apparatus. They underwent sudden forward tilt of 15° from the vertical position at acceleration of 0.5, 0.7, 1.4 and 1.8g without, and at 0.7 and 1.8g with, concommitent passive ankle dorsiflexion. Acceleration was measured with a linear accelerometer mounted on a dental bite, and ankle position with a potentiometer. Surface EMG was recorded from the tibialis anterior (TA), medial gastrocnemius (MG) and biceps femoris (BF) muscles.

Our results showed that the number of respondent to tilt with or without ankle rotation, and the frequency of occurrence of tilt-evoked responses in the respondents, increased progressively in the three lower limb muscles with increasing magnitude of head acceleration. With the addition of ankle rotation, the only change observed was in the relative onset latencies of the two extensor muscles (MG and BF). More specifically, with no ankle rotation, the proximal muscle (BF) was activated before the distal one (MG) in 4 of 5 subjects; while with ankle rotation, this pattern was reversed (MG before BF) in 5 of 6 subjects. These preliminary results suggest that the occurrence of tilt-evoked responses is dependent on the intensity of the vestibular stimulation and that the patterns of muscle activation in the lower limb muscles could be subjected to modification by somatosensory inputs interacting with vestibulospinal influences.

MECHANISM OF γ_D INDUCED SLOW DECAY OF CAT SPINDLE IA RESPONSE TO STRETCH. M. Hulliger, B. Wang*, M.S. Tabet* and E. Otten[1*]. **Dept. of Clinical Neurosciences, Univ. of Calgary, Calgary, Alta., Canada T2N 4N1, and Dept. of Neurobiology, Univ. of Groningen, NL-9712 KZ Groningen.**

The sensitization of spindle IA response to stretch during dynamic fusimotor activation has been attributed to stretch induced excitation of bag1 fibres, and the slow decay of IA firing following dynamic stretch to a slow decay of stretch activation (Boyd, Q.J. Exp. Physiol. 61: 203, 1976). However, experimental assessment of this hypothesis has been inconclusive (Dickson et al., Prog. Brain Res. 80:9, 1989), leaving open the possibility that IA sensitization is due to other mechanisms, including activation of unusual visco-elastic properties of bag1 fibres.

Acute experiments in cat soleus nerve muscle preparation were combined with mathematical modelling of spindle receptor mechanisms (Schaafsma et al., J. Neurophysiol., in press) to explore the nature of the slow decay. Trapezoidal stretch (8 mm) of the parent muscle was combined with quick release (at the end of the dynamic stretch) and with various patterns of γ_D activation. Modelling predicted that slow decay of firing due to slow deactivation should be immune to rapid release steps, regardless of amplitude. In contrast, slow decay due to a visco-elastic force transient would be abolished by release. This was confirmed experimentally. A slowly decaying transient of IA firing (evoked by exponentially decaying rate-modulated γ_D activation) persisted during release steps (up to 8 mm.) In contrast, with tonic γ_D activation the slow decay of IA response after stretch was completely abolished by release steps of around 4 mm.

These findings suggest that the slow decay of γ_D-sensitized stretch response is **not** due to a decay of **stretch activation.** Moreover, modelling indicates that it is most parsimoniously attributed to - exceptional - force-velocity characteristics of activated bag1 fibres. **Supported by AHFMR (Canada).**

RESTRUCTURATION OF THE FICTIVE LOCOMOTOR CYCLE BY TONIC PROPRIOCEPTIVE INPUTS. P. Saltiel, T. Reader and S. Rossignol. Ctr. Res. Sci. Neuro., Univ. Montréal, Québec, Canada, H3C 3J7.

In spinal cats, studies on the initiation of the swing phase have suggested that interactive signals responsible for interlimb coordination might be maximal in mid-stance and mid-swing. Is there evidence, firstly, that such mid-phase events are present in the fictive, centrally-generated, locomotor pattern and, secondly, that these events are involved when restructuration of the fictive locomotor cycle occurs with changes in limb position?

In high decerebrate, spinalized (T13) and paralyzed cats, fictive locomotion was recorded in both forelimbs from cut nerves to long head of triceps (TriLo, shoulder retractor and elbow extensor), lateral head of triceps (TriLa, elbow extensor) and cleidobrachialis (ClB, shoulder protractor and elbow flexor).

At 55% of the extensor phase, three events occur simultaneously: ipsilateral (ipsi) TriLa abruptly rises in amplitude (inflexion point), ipsi TriLo and contra ClB start to decrease in amplitude. When the ipsi shoulder is tonically protracted or retracted or when the elbow is flexed or extended, cycle duration changes little, but burst durations and amplitudes are markedly altered. However, the simultaneity of the ipsi TriLa inflexion point and contra ClB onset of descent is preserved with each kind of perturbation. Restructuration of the cycle is achieved by lengthening or shortening the duration of the bursts components before or after these points. This pattern of cycle restructuration was seen in five cats.

The observations that the ipsi Trila inflexion point and contra ClB onset of descent remain coupled as the cycle is restructured by a change in ipsi forelimb tonic position and that these points distinguish which burst components are modified in this restructuration suggest that these centrally- generated events may be important for interlimb coordination. (Supported by the MRC of Canada).

SPINAL MOTOR CENTER EXCITABILITY CHANGES DURING EXERCISE OF DISTANT MUSCLES AS MEASURED BY TENDON TAP RESPONSE.

M.R. Dimitrijevic, M. Saling, G. Vrbova*, W.B. McKay
Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, Texas 77030.

The Jendrassik's maneuver (strong volitional effort to pull apart clasped hands) will increase stretch reflex responses in muscles not involved in the maneuver. Likewise, maximal volitional contraction (MVC) of a muscle group will increase stretch responses in other ipsilateral and contralateral muscles. Intermittent, graded volitional ankle dorsiflexion at 20, 40,60, 80 and 100% of MVC with visual force feedback on contralateral quadriceps tendon tap responses were studied in six adult subjects. Surface EMG responses to tendon taps delivered with a constant force by an electrodynamic hammer at regular intervals were analyzed. Spinal motor center excitability was increased during the contraction phase at contraction/relaxation cycle rates of 6/4 s and 12/8 s. In contrast, at the 3/2 s cycle rate, increased excitability is present in the relaxation phase as well. This paradigm provides insight into the behavior of sub-components of voluntary motor control.

409.6

DIFFERENCES IN MODULATION OF EXTENSOR AND FLEXOR SPINAL MOTOR CENTERS DURING GAIT.

A.A. Leis*, J.H. Schild*, J.A. Halter, M.R. Dimitrijevic
Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, Texas 77030

Suprasegmental modulation of spinal motor center (SMC) excitability occurs during gait, but little is known about how central mechanisms influence extensor and flexor SMC excitability prior to movement. We studied excitability changes in extensor and flexor SMCs using triceps surae (TS) and tibialis anterior (TA) H-reflexes in 18 healthy subjects during treadmill walking. Stimuli were delivered relative to heel strike at 20 ms intervals across a 500 ms window. We found that facilitation of extensor H-reflex occurred 100 to 300 ms prior to EMG activation of TS, while flexor H-reflex facilitation preceded EMG activity in TA by 0 to 100 ms. These temporal differences indicate that there is a difference in the central mechanisms modulating extensor and flexor SMCs.

SPONTANEOUS ACTIVITY IN VENTRAL SACRAL ROOTS OF ISOLATED SPINAL CORD OF THE ADULT HAMSTER WITH AND WITHOUT 4-AMINOPYRIDINE.

A. J. Dekhuijzen[1], J. Bagust*[2], and V. R. Edgerton[1],
[1]Brain Research Institute and Dept. Kinesiology, UCLA, Los Angeles, CA 90024, U.S.A. and [2]Dept. Physiology and Pharmacology, Univ. of Southampton SO9 3TU, U.K.

In vitro ventral root activity has been recorded from the lumbar isolated spinal cord of hamsters weighing 15-25 g (Bagust, J, et al, *Brain Res.*, 479: 138, 1989). The feasability of recording from the isolated spinal cords of larger hamsters was explored in the present study in order to expand the utility of this preparation to study long term neuroplasticity. Whole isolated spinal cords, bathed in artificial cerebro-spinal fluid were studied in conditions with and without 4-aminopyridine (4-AP) and with and without Mg^{2+}, at temperatures of 18-21 ^{o}C in hamsters weighing 56-65 g. Electrically induced and spontaneous activity was recorded from ventral roots. Although spontaneous bursting activity occurred in 4-AP/Mg^{2+}-free conditions, 4-AP (10^{-5} M) increased the burst frequency from 0.25-0.50 Hz to 1.0-6.0 Hz. The burst durations found in 4-AP/Mg^{2+}-free conditions decreased from 0.5-1.0 s, to 0.02-0.4 s in the conditions with 4-AP. It is concluded that ventral root activity can be recorded in an isolated spinal cord from a sexually mature animal. [1]SUPPORTED BY NIH GRANT NS 16333 AND [2]NUFFIELD FOUNDATION.

EFFECTS OF PRACTICE OF FAST VOLUNTARY MOVEMENTS IN DOWN SYNDROME INDIVIDUALS. G.L. Almeida*, D.M. Corcos, M.L. Latash
Universidade Estadual de Campinas-Ircamp/Conselho Nacional de Pesquisa, Campinas, SP 13100, Brazil, University of Illinois, Chicago, IL 60612, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612.

The effects of extensive practice of aimed elbow flexions in a standardized experimental situation upon kinematic and electromyographic (EMG) variables in two young adults with Down Syndrome (DS) were studied. The protocol included a pre-test during which DS-subjects performed series of trials including isotonic elbow flexions of varying amplitude "as fast as possible", slower isotonic flexions, maximal isometric flexions and extensions, and different perturbation paradigms. Then, the subjects practiced the 36° elbow flexion movements to a 6° target over 10 sessions (1100 movements). They were encouraged to increase movement speed. The training was followed by a post-test similar to the pre-test.

The following major differences were observed between the pre- and post-tests. In both subjects, there was a nearly three-fold increase in the peak movement speed with a corresponding decrease in movement time. The amount of agonist EMG during the acceleration phase and the amount of antagonist EMG during the movement increased five- to ten-fold. In the pre-test, the standard deviation of the final position (SD_f) did not show any clear relation to movement distance, while during the post-test, in one of the subjects, SD_f increased linearly with distance corresponding to the linear speed-accuracy trade-off. The rates of EMG and acceleration rise were much higher during the post-test than during the pre-test.

We conclude that extensive training of DS-subjects in standardized conditions can lead to a dramatic improvement in their performance which demonstrates the effects of transfer being equally observed during movements over practiced and unpracticed distances. Practice can lead to emergence of previously absent features that were seemingly absent in the DS-individuals, e.g. the linear speed-accuracy trade-off.

The study was supported by a grant from the Down Syndrome Research Fund.

FREQUENCY DEPENDENT MODULATION OF MOTOR UNIT FIRING DURING QUASI-SINUSOIDAL ISOMETRIC MUSCLE CONTRACTIONS.

M.B. Iyer, C.N. Christakos and C. Ghez. Center for Neurobiology & Behavior, Columbia University and the New York State Psychiatric Institute, NY 10032.

This study utilizes time- and frequency-domain analyses to examine the firing behavior of human motor units (MUs) during time-varying isometric muscle contractions. Subjects produced nearly sinusoidal abduction forces with their index finger. Single-MU discharges and multi-unit EMG were recorded from the antagonistic first dorsal and palmar interosseii for several frequencies (range 0.25 to 5 Hz), amplitudes and mean levels of sinusoidal muscle force. As previously reported (Iyer et al., Soc. Neurosci. Abstr. 16, 1990), MU discharge rates are modulated at the frequency of the force oscillation, as indicated by a distinct component in their auto-spectra. Further, the unitary modulations show widespread correlations, as indicated by prominent coherences between single-unit and population activities. The present results extend these findings to the antagonist muscle. In addition, we find a dependence of the modulations on the frequency of the force oscillation. For both agonist and antagonist, the modulating spectral components of MUs increased in size with frequency; and for some MUs, particularly of the antagonist, such components were present only at high frequencies. The unit-to-population coherences also increased with frequency, indicating augmented synchrony (correlations) between the modulations of the MU populations. The observed increase in depth and synchrony of MU rate modulations as well as the increased modulation of the antagonist may serve to counteract the effects of the low-pass filtering property of muscle.

BIMANUAL MOTOR CONTROL IN YOUNG CHILDREN.

J.H.Lee* and H. G.Williams.Motor Development/Control Lab., Univ. of South Carolina,Columbia,SC29208.

Past research on bimanual motor control in adults indicates that the upper extremities to move as a single unit. Dynamical theory of motor control suggests that the motor system can accommodate systematic departures from such linkage and that such deviations depend on both task and environmental demands. The purpose of this study was to examine the development of bimanual motor control in young children and to describe conditions under which linkage of the two hands is more or less likely to occur.

4 age groups (6, 8, 10, & 18+ yrs) performed 4 single & 4 two-hand movements to targets located at different distances (7.5cm, 15cm) under four visual conditions: full, hands-only, targets-only, & hands-targets illuminated. Movement time, reaction time, error, & accuracy of responses were analyzed using repeated measures MANOVA techniques.

Bimanual movements of both children and adults were more tightly linked when movements were to equidistant targets and in asymmetrical movements where the RH covered a long distance. Movements were also more tightly linked under reduced visual conditions. Errors in performance were greatest under limb-only conditions. These data suggest that both task and environment are significant factors in the degree to which the upper extremities are constrained to act as a single unit.

409.11

INDEPENDENCE OF REFLEX AND VOLITIONAL EMG MODULATION DURING SINUSOIDAL TRACKING IN NORMALS.

M. Johnson, A. Kipnis*, T. Ebner, Depts. of Neurol. and Neurosurg., Univ. of Minnesota, MPLS, MN 55455.

Stretch reflex gain and volitional muscle activity are linked in the "automatic (reflex) gain compensation" and "servo-assistance" hypotheses. Experiments are reported illustrating conditions in which the normal comodulation of reflex and volitional EMG is altered, violating hypotheses rigidly linking reflex and volitional muscle activation.

A sinusoidal visually guided wrist tracking task was perturbed by step torque transients every 45° of the tracking phase. Evoked EMG and wrist deflection were acquired and used to assess modulation of the stretch reflex amplitude and wrist compliance as functions of the tracked position. Behavior at odds with a rigid linkage between the reflex and volitional control systems may be summarized as 1) a reflex gain modulation corresponding to joint kinematics, independent of the volitional EMG modulation and 2) a task and load specific shift of reflex gain modulation, independent of the volitional EMG modulation. Four observations underscore these behaviors. First, servo-driven passive joint movement through the sinusoidal tracking cycle produces a normally placed, statistically significant reflex amplitude peak with undetectable volitional EMG modulation. Second, unloaded active tracking in a subset of subjects results in a normally placed single reflex peak and bimodal peaks of volitional EMG serving functions of propulsion and cocontraction through the tracking cycle. Third, the imposition of an anti-elastic load (additive position feedback) retards the volitional EMG by approximately 180° compared to that resulting from an elastic load, yet the reflex peak remains normally situated at maximal velocity in the direction of muscle shortening. Fourth, associated with the inherently unstable external anti-elastic loading and during employment of a "precision" tracking strategy is an increase of reflex activity in tracking phases of homonymous muscle lengthening. This shift of the reflex activity corresponds to a decrease in joint compliance, and is postulated to counter destabilizing loading or increase the precision of movement. The tracking phase sequencing of the reflex and volitional EMG in these experiments points to a flexible relationship between reflex and volitional control systems, altered by peripheral input, external load, and task intent.

ALTERATIONS IN POINTING AND HAND CONTROL PRODUCED BY PRISMS AND BY INTERPOSITUS INACTIVATION IN THE MONKEY.

C.R. Mason, R. R. Carter, J.C. Houk, and J. F. Baker. Institute for Neuroscience/Dept. of Physiology, Northwestern University Medical School, Chicago, IL 60611.

Accurate pointing and hand control is an important action of the neuromuscular system. To test control and adaptation we perturbed the system using either prisms or muscimol inactivation of the interpositus nucleus. A monkey was over-trained to make rapid reaches (time restricted reach) to a 6 by 6 array of touch detectors placed vertically in front of him within easy reach. We compared this to a task in which the monkey reached freely (free reach) for food pieces. Both tasks were performed with the head immobilized. When displacing prisms (8 Δ left or right) were added, changed or removed during either task, the monkey required several trials to adapt. When prism adaptation took place during the free reach task and then the monkey was switched immediately to the time restricted task (prism unchanged), there was only partial transfer of adaptation; 50% as many trials were required to complete adaptation as when the prism was changed during the time restricted reach task. Similarly, transfer from time restricted reach to free reach was also only partial.

Inactivation of the interpositus nucleus by injections of muscimol produced errors in both pointing and overall hand control during the performance of both tasks. While the speed of movement was unimpaired, the monkey made grossly inaccurate reaches, with horizontal and vertical pointing errors on the 6x6 array. A large amplitude tremor was evident and especially pronounced as the target was neared. Visually and/or tactilely locating the target using the unaffected hand reduced these errors. Together these results demonstrate that prism adaptation during performance of a task does not generalize completely to other tasks and that the interpositus nucleus plays an important role in the performance of accurate pointing and hand control.

VOLTAGE-DEPENDENT EXCITATION OF MOTONEURONES FROM SPINAL CENTRES DURING FICTIVE LOCOMOTION IN THE CAT.

R.M. Brownstone, I. Engberg*, J.-P. Gossard, H. Hultborn, Institute of Neurophysiology, Panum Institute, 2200 Copenhagen N, Denmark

It is well known that spinal networks can generate a locomotor rhythm in response to tonic input (either by stimulation of brainstem regions or by systemic application of L-DOPA). It has previously been shown that there is a wide convergence of inputs to these spinal centres including those from the mesencephalic locomotor region, FRA, and Ib afferents (in the mesencephalic cat, Shefchyk & Jordan, J Neurophysiol 53, 1985; in the spinalised L-DOPA treated cat, Conway et al, Exp Brain Res 68, 1987). The excitation of motoneurones from these convergent pathways and hence from the output of the spinal locomotor network was examined in the current study.

Using these two preparations, it was found that the excitatory phase of the locomotor drive potentials (LDPs) in motoneurones showed a voltage-dependent increase in amplitude, and that the EPSPs evoked in motoneurones from both Ib and FRA stimulation showed a similar voltage-dependent increase in amplitude.

Furthermore, the question of whether this voltage-dependent increase in the LDP was secondary to intrinsic properties of the motoneurones such as plateau potentials, or rather due to a voltage-dependency of the synaptic excitation per se such as that seen with NMDA receptor activation, was investigated using iontophoretic application of the NMDA antagonist D-APV. Following such an application, the voltage-dependent increase was reversibly eliminated.

It is concluded that the excitatory half-centres which receive convergent inputs from multiple sources project to motoneurones leading to a voltage-dependent excitation of these cells. It is suggested that this is at least in part due to activation of NMDA receptors.

NEURAL COORDINATION DYNAMICS OF SINGLE, MULTIJOINT LIMB MOVEMENTS: SPATIAL BIFURCATIONS AND HYSTERESIS.

J. J. Buchanan and J. A. S. Kelso. Program in Complex Systems and Brain Sciences, Center for Complex Systems, Florida Aatlantic Univ. , Boca Raton FL 33431.

Recent work (Kelso, Buchanan and Wallace, Exp. Brain Res. 1991) has identified relative phase as an order parameter for the neural organization of single, multijoint limb movements. Phase transitions (or bifurcations) were observed when a temporal control parameter, movement frequency, was systematically varied. In KBW (1991) we hypothesized that bifurcations may also result when a spatial parameter, forearm orientation, is manipulated. To test this hypothesis, six subjects rhythmically coordinated flexion and extension of the elbow and wrist joints of the right arm under the following initial conditions: 1) forearm supine (0° of orientation): wrist flexion with elbow flexion and vice versa; and 2) forearm prone (160° of orientation): wrist flexion with elbow extension and vice versa. Starting in (1) or (2) subjects rotated the forearm in eight 20° steps, each step consisting of 15 cycles of motion at a constant frequency of 1.25 Hz. Switching from pattern (1) to pattern (2) and vice versa was observed at a critical spatial orientation. Loss of stability appears as the chief transition mechanism: a) Fluctuations in the relative phasing between the joints were observed en route to the transition in both directions; and b) The critical point depended on the direction of forearm orientation change, revealing the hysteretic nature of the phase transition.These results show that the coordination dynamics of the nervous system are highly nonlinear, both temporally and spatially, thereby assuring stability and flexibility of function.

THE DYNAMICS OF SPONTANEOUS TRANSFER IN LEARNING NOVEL PHASE- AND FREQUENCY-LOCKED COORDINATION PATTERNS. P.G. Zanone and J.A.S. Kelso. Center for Complex Systems, Program in Complex Systems & Brain Sciences, Florida Atlantic University, Boca Raton, Fl. 33913.

The tendency toward phase and frequency synchronization is ubiquitous in neurobiology and behavior, ranging from studies in visual cortex, hippocampal learning, central pattern generation, and human sensorimotor coordination. Previous work in humans [1] has shown that learning a *novel* coordination pattern may involve a nonequilibrium phase transition, or bifurcation. This qualitative change in the coordination dynamics corresponds to the emergence of the to-be-learned pattern (e.g., a frequency-locked bimanual coordination pattern with relative phase, $\phi = \pi/2$ rad., between the oscillating components) as an *attractor* (i.e., an asymptotically stable state) accompanied by destabilization of intrinsically attractive states (e.g., $\phi = \pi$ rad.).

The present study reports *spontaneous* transfer of learning in which the pattern symmetric (e.g., $\phi = 3\pi/2$) to the pattern learned becomes stable and attractive as well. Subjects learned a visually-specified phase relation between the hands of either $\phi = \pi/2$ or $3\pi/2$ rad. Probes of the phase diagram, the set of relative phase patterns in the interval 0 to 2π rad., were conducted during the learning process. When $\pi/2$ rad. was the pattern to be learned, spontaneous generalization to its symmetric partner, $3\pi/2$ rad., was found, and vice-versa. Thus, learning and transfer of relative timing patterns are governed not by specific lead-lag relations between the components, but by intrinsic dynamical constraints founded on symmetry.

RELATIONSHIP BETWEEN STIFFNESS AND NET JOINT TORQUE DURING BALLISTIC ELBOW JOINT MOVEMENT. D.J. Bennett. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Previously we demonstrated that the stiffness of the elbow joint drops to as low as 5 $N \cdot m/rad$ during slow arm movements. We hypothesized that stiffness changes may be proportional to changes in the net joint torque (muscle torque) used to accelerate the limb inertia, but we were unable to fully test this hypothesis because of the limited range of movement speeds studied, and the confounding influence of co-contraction induced by the perturbations. The objective of the present study was to measure the stiffness changes over a large range of movement speed and load conditions, while minimizing and controlling for the effects of co-contraction. Subjects executed ballistic movements (1 *rad*) with strict velocity constraints (< 10 % error). On occasional movements a torque motor applied a small pseudo random binary (PRBS) *position* perturbation (< 0.1 *rad*), servoed about the mean unperturbed trajectory. In contrast to the random torque perturbations that we used previously, the position perturbations did not obligate the subject to co-contract, or otherwise stiffen the joint, to remain near (< 0.1 *rad*) the nominal trajectory. EMG recordings indicated that during the movement the reflex activity contributed to the joint stiffness, but little co-contraction was induced by the perturbations. As found previously for slow movements, the stiffness dropped during movement, with a minimum (< 6 $N \cdot m/rad$) at the zero crossing in the net joint torque. This phenomena persisted even for very fast movements. After compensation for the passive stiffness, the peak stiffness was found to increase proportionally to the peak joint torque. Unlike the net joint torque, the stiffness changes were often abrupt, dropping steeply at the movement onset and rising gradually as the target was approached.

A MODEL OF MOTOR UNIT RECRUITMENT WHICH RESULTS IN INDEPENDENT CONTROL OF EQUILIBRIUM POSITION AND STIFFNESS OF THE JOINT. D.J.Reed and D.R.Humphrey.Lab of Neurophysiology,Emory Univ.Sch.of Med.,Atlanta,GA30322.

We have previously proposed separate descending cortical systems for the control of co-contraction and joint position(Humphrey and Reed, Neurosci. Abstr.,7:740,1981). The present paper discusses a hypothetical model which could provide such control at the level of the motor pool. The model separates the motor pool innervations into common mode(co-activation) and reciprocal components. It assumes that the motor units are recruited according to size(Henneman,JN 28,1965) with the increment being proportional to the existing recruitment, resulting in a logarithmic recruitment function. As a direct result joint stiffness and equilibrium position become independent and are functions of the common mode and reciprocal components respectively.

For the direct control of Alpha motor units(open loop) the model was first developed for an antagonist pair acting about a single joint, then the results were shown to be general for any arbitrary muscle-joint arrangement(multi- muscle,multi- articular). For the reflex case it was assumed that that both Gamma and Alpha motor units are recruited alike,innervated by the same reciprocal component, as suggested by Alpha-Gamma coactivation(Valbo,Acta Phys Scand 80,1970). For this situation the model predicts that the reciprocal component of the net stretch reflex (static) output is null at the Alpha(open loop) equilibrium point. Thus the equilibrium points of Bizzi(Polit&Bizzi,JN 42,1979) and of Feldman(J Motor Behav. 18,1986) would occur at the same joint position. (Supported by NIH Grants NS 10183 and NS20146 to DRH.)

CONTRIBUTIONS OF THE PERONEI, THE TRICEPS SURAE, AND TIBIALIS ANTERIOR TO ANKLE TORQUE IN THE CAT. J. H. Lawrence,III*, T. R. Nichols, and A. W. English. Depts. of Physiology and Anatomy and Cell Biology, Emory University Atlanta, GA 30322.

Although locomotion in quadrupeds and bipeds occurs largely through sequences of flexion and extension, the full repertoire of movement requires torques in three dimensions. Abraham and Loeb (Exp. Brain Res. 85, 580-593, 1985) showed coactivation of peroneus longus (PL) and brevis (PB) with ankle extensors during walking. However the relative contributions of the peronei to eversion and to sagittal plane movements are not known. We stimulated muscles crossing the ankle joints in cats deeply anesthetized with pentobarbital, and used a multiaxis force-moment sensor to measure the resulting isometric torques. The directions of torque and relative magnitudes were as follows:

Soleus	plantarflexion
PL	dorsiflexion and eversion
PB	eversion > toe out > plantarflexion
MG,LG	plantarflexion > toe out > eversion
TA	dorsiflexion > toe in > inversion

(MG,LG: medial & lateral gastrocnemius; TA: tibialis anterior) The eversion torques via LG and MG were each comparable to those from PB and PL combined. MG and LG gave relatively large toe out torques, but less than that of the peronei group. Therefore,with respect to the inversion/eversion axis, MG and LG were both synergistic to the peronei and antagonist to TA.

EVIDENCE THAT REFLEXES BETWEEN PLANTARFLEXORS AND EVERTERS DECOUPLE ACTIONS OF THESE MUSCLES AT THE CAT ANKLE JOINT. S.J. Bonasera* and T.R. Nichols. Department of Physiology, Emory University, Atlanta GA 30322.

It is well established that the peroneal muscles of the cat hindlimb are coactivated with the triceps surae during stance and locomotion (Rasmussen et al., *J Morphol* 155:253-270, 1978). Additionally, while the major action of peroneus brevis (PB) is to provide eversion and toe out at the ankle joint, gastrocnemius (G) also provides a major component of toe out and eversion at the ankle (Lawrence et al., *Soc Neurosci Abst* 19, this volume).

Since both PB and G act in ankle eversion, we investigated stretch-evoked reflex interactions between PB and G, as well as soleus (S), tibialis anterior (TA), and other lateral and posterior compartment muscles in decerebrate cats. At low forces, reflex interactions between PB and G were weak, while interactions between PB and S were asymmetric, with PB contributing a stronger inhibition onto S. However, at high forces, mutual inhibition occurred between PB and both G and S. Reflex interactions between PB and TA were weak. The inhibition observed between the plantarflexors G and S, and the everter PB may serve to decouple actions of G and S from actions of PB under high force conditions, and thus partially compensate for the significant eversion torque generated by G and the slight plantarflexion torque generated by PB.

GENERATING MOTOR REPERTOIRES BY FORCE FIELD SUMMATION. F.A. Mussa-Ivaldi*, S.F. Giszter and E. Bizzi. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

The purpose of this work is to investigate how motor outputs might be combined by the central nervous system for generating a wide repertoire of behaviors. Recent experiments in the spinal frog have shown that the focal microstimulation of the premotor layers in the lumbar grey results in a field of forces acting on the frog's ankle. We have observed this field by measuring the isometric forces induced at different ankle locations by the stimulation of the same spinal site. Our experiments have produced three major resuts. (1) The stimulation of the premotor layers induces a field of forces converging toward an equilibrium point at which the ankle force is zero. (2) There are at least four distinct regions in the lumbar grey matter. Microstimulation of these four areas generates four distinct fields with different equilibrium points. (3) We found that simultaneous stimulation of two different spinal sites generates a field that is proportional to the vector sum of the fields elicited by stimulating each site independently. These results suggest that the neural circuits in the spinal cord "store" a few limb postures in the form of fields acting on the limb's end-point. Using computer simulation, we have investigated the competence of vector summation to provide a larger repertoire of behaviors using such fields. Our approach is equivalent to combining a number of predefined functions for approximating the shape of an unknown surface from a set of sampled points. The simulation results indicate that by a simple vector summation of motor outputs the CNS may generate a wide variety of force patterns and postures from the combination of four convergent force fields. Thus, the combination of force fields is an appropriate framework for motor planning, adjustment and control.

CONTROL OF BODY MOMENTUM DURING STANDING LEG FLEXION MOVEMENTS IN MAN. M.W. Rogers and Y.C. Pai.* Physical Therapy, Northwestern University Medical School, Chicago, IL 60611

The organization of postural responses underlying dynamic transitions in stance support during single leg flexion movements was examined in man. Previous observations led us to hypothesize (1) an invariant structure of the impulse-linear momentum (LM) relationship of the body center of mass over a range of flexion speeds, and (2) an intralimb and interlimb coupling of hip abductor (AB) and adductor (AD) muscle activations for the control of lateral body momentum. Eight adults stood on 2 separate force platforms and performed rapid and slower leg flexion movements. Surface EMG was recorded from the knee flexor biceps femoris and AB and AD muscles. Kinematic data was obtained via motion analysis.

The findings generally supported both hypotheses. First, the normalized time when the peak LM occurred and the absolute magnitudes of the force-time integrals for propulsion (P), braking (B) and P/B components remained constant across speeds. Second, EMG responses revealed an apparent reciprocal organization of bilateral hip AB and AD muscle pairs linking anatomically antagonistic but functionally synergistic interlimb postural muscle elements related to the control of body momentum in the frontal plane.

HEAD AND NECK KINEMATICS DURING VERTICAL PLANE ROTATIONS. E.A. Keshner, R. Cromwell*, G. Rovai*, and B.W. Peterson. Dept. of Physical Therapy, Univ. of IL at Chicago and Dept. of Physiology, Northwestern Univ. Medical School, Chicago, IL 60611.

In our previous study of rotations about the vertical axis, longer latency, voluntary mechanisms dominated stabilization at frequencies < 1 Hz while reflexes and biomechanics contributed at higher frequencies (Keshner & Peterson, Soc. Neurosci. Abstr. 14:1235). In this study, we recorded chair and head velocities, and surface EMGs from bilateral semispinalis (SEMI) and sternocleidomastoid (SCM) muscles. Seated subjects underwent pitch rotations in the dark about a horizontal, bitemporal axis. A triaxial angular rate sensor and a laser pointer, affixed to a headband worn by the subjects, were positioned at the vertex of the head. Stimuli were predictable sine waves and a random sum-of-sines stimulus with 5 frequencies ranging from 0.35 to 3.05 Hz which should be high enough to elicit vestibulocollic (VCR) and cervicocollic responses. One test condition required voluntary attempts at head stabilization (VS), and the second used mental arithmetic to minimize voluntary intervention (MA). Gain and phase of head velocity and EMG responses were calculated using a best fit sinusoid and analyzed with respect to chair velocity. **At 0.3-1 Hz** the head was well stabilized in VS and had stabilizing responses with gain ~ 0.3 in MA. Both SEMI and SCM EMG responded in phase with chair position. **At 1-2 Hz** good head stability was seen in both conditions. SEMI was modulated in phase with chair velocity indicative of a VCR response but SCM continued to have a position-related response. **Above 2 Hz** mechanical responses dominated head motion in both conditions and large EMG responses related to this motion were recorded in SEMI and SCM. Thus, compensatory responses appeared at lower frequencies and were sustained over a greater frequency range than during horizontal rotations. EMG data were consistent with the idea that SEMI is dominated by vestibular, SCM by neck receptor input. *Supported by grant NS22490.*

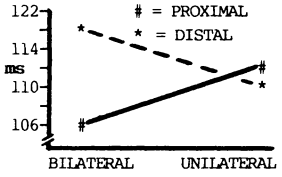
FRACTIONATED REACTION TIME IN SIMPLE, BILATERAL, UNILATERAL, PROXIMAL, AND DISTAL MOVEMENTS. J.G. Anson and Y. Bird*. School of Physical Education and Neuroscience Research Centre, U. of Otago, Dunedin, New Zealand.

Effects on simple reaction time of initiating unilateral vs bilateral and proximal vs distal responses were investigated in 12 college-aged females. Distal responses were unilateral or bilateral index finger extension; proximal responses were unilateral or bilateral elbow flexion. Two blocks of 20 trials were obtained for each condition. EMG from the agonist muscles was demeaned, rectified and smoothed before fractionation into premotor- (PMT) and motortime components. Early results show an interaction between proximal-distal and bilateral-unilateral conditions for PMT. An explanation based on differences between the neuromuscular structure and motor program demands for each condition is proposed.



409.24

KINESTHETIC INPUTS AND MOVEMENT SEQUENCING. L. Bevan, L. G. Carlton*, M. J. Carlton* and P. J. Cordo. R. S. Dow Neurological Sciences Institute, Portland, OR 97209.

The present experiment examined how kinesthetic inputs from one joint are used to trigger movement at other joints in activities requiring movement sequences. Human subjects were required to open their right hand as their right elbow was passively rotated. The criterion elbow angle for hand opening was fixed at 145 deg (180 deg equals full elbow extension). The elbow was rotated at one of seven constant velocities (18-85 deg/s) and from one of seven different starting angles (111-129 deg). Both velocity and starting angle were presented in random order. The results were compared to control trials where the elbow starting angle was held constant, and velocity was randomly varied. The arm and hand were screened from view, but information about hand opening errors was presented after each trial.

The results indicated that there was a large and systematic bias in opening angle when starting angle was randomly varied. Hand opening occurred before reaching the target with longer movement distances (111-117 deg starting angle), and after the target for shorter distances (123-129 deg starting angle). This finding was independent of the velocity manipulation. These results suggest that kinesthetic inputs representing absolute elbow angles are not used to trigger hand opening, rather, the movement is triggered by components of velocity and time, or the angular distance from the starting angle.

RECRUITMENT ORDER OF MOTOR UNITS IN WRIST EXTENSOR MUSCLES. K.E. Jones*, S. Riek* and P. Bawa. Kines., S.F.U., Burnaby, B.C., V5A 1S6.

Extensor carpi radialis (ECR) contributes to wrist extension and radial deviation, while its neighbour, extensor digitorum communis (EDC) contributes to extension of the wrist and extension of various fingers. The following study examined recruitment order of motor units within various task groups of ECR and EDC in human subjects. ECR units tested for wrist extension and radial deviation did not show separate subpopulations contributing to the two tasks. Motor units were recruited in an orderly fashion both for wrist extension and radial deviation. EDC motor units were seen to fall into 3 subpopulations, one contributed to middle finger (MF) extension, the second contributed to ring finger (RF) extension, while the third group (common) contributed to both MF and RF extension. When the fingers were disengaged, EDC motor units were recruited in an orderly fashion for wrist extension. All subpopulations of EDC contributed together towards wrist extension. Similarly, for MF extension, 'MF' and 'common' subpopulations pooled together to show an orderly recruitment.

THE EFFECT OF VARYING PURE INERTIAL LOADS ON THE MECHANICAL PERFORMANCE OF CAT SOLEUS MUSCLE. D.C. Lin and W.Z. Rymer. Depts. of Biomedical Eng. and Physiology, Northwestern Univ., Chicago, IL 60611.

The objective of this project was to evaluate the mechanical performance of eccentrically contracting soleus muscle under different sizes of pure inertial loads and in reflexive and areflexive conditions. Specifically, our aim was to examine the dissipative properties of muscle, assessing its performance by using kinematic variables such as energy and momentum. Pure inertial loads were simulated by a motor and analog circuit using force feedback. The force was integrated twice and referred to the motor which acted as a length servo. The resulting gain and phase of the simulated load plotted as a function of frequency corresponded exactly to a mass.

In the first class of experiments the soleus muscle with the reflex intact from a decerebrate cat was attached to the motor and the crossed-extension reflex was used to elicit a background force of 5N. An initial stretch velocity was set and then the muscle was free to move under the simulated mass, which is equivalent to giving a force impulse to the mass. Both the initial velocity and magnitude of the mass could be independently specified. In the second class of experiments the protocol was repeated except the muscle was originally inactive and then the nerve was electrically stimulated for two pulses, providing a transient force in an open loop condition.

The first experiment shows that the damping coefficient increased with increasing mass. (Usually in a linear spring-mass system with damping, the damping coefficient decreases with increasing mass). In the second set of experiments, both the energy and momentum transferred to the mass were measured. It was found that the momentum transferred always increased with inertial size and the energy transferred also increased with inertial size if the initial velocity was above a certain value.

The end result of the project is to measure the contribution of intrinsic muscle properties in compensating for changes in inertial loads, which has been proposed by Partridge (1965). These inertial-dependent dissipative properties of eccentrically contracting muscle promote smoothness in movements and can simplify the control mechanism needed for the damping of voluntary movements, thus helping to solve the inverse dynamics problem associated with changes in inertial loads.

FUNCTIONAL CLASSIFICATION OF NERVE FIBERS VIA SCALE-INVARIANT CLUSTER ANALYSIS ALGORITHM. M. Maltenfort*, T.S. Buchanan, and W.Z. Rymer, Sensory Motor Performance Program, Rehabilitation Institute of Chicago, and Departments of Rehabilitation Medicine & Biomedical Engineering, Northwestern University, Chicago, IL 60611.

This study tested a new method of identifying active fibers in an intact peripheral nerve bundle by performing cluster analysis to group spikes in the multi-unit record. The analysis was similar to that of Camp and Pinsker [1]: two electrodes are placed along the nerve, and the clustered data vectors consist of the amplitude of the spike on the proximal channel; the amplitude of the spike on the distal channel; and the conduction delay between them. In the new method, modified mode analysis is used to identify initial cluster centers and the determinant of the covariance matrix is a scale-invariant measure of distance. The spikes were pre-processed by low-pass differentiating (LPD) digital filters to resolve overlapping spikes.

Analyses were performed on real data sets from a medial gastrocnemius nerve bundle in a barbiturate anesthetized cat, and on simulated data in which the clusters were known *a priori*. To test the effects of the LPD filter, parallel analyses were performed using a low-pass Butterworth filter instead of the LPD. The sorting of the real data was compared to physiologic expectations, while the analyses of the simulated data was compared to the known input. For both types of data, an FFT-based template matching algorithm was used to find within-cluster scatter and between-cluster scatter for the spike waveforms.

It was observed that although mathematical criteria for a successive clustering of the real data were met (amplitude and conduction velocity correlated, amplitudes on both channels correlated, within-cluster scatter less than between-cluster scatter) it was difficult to justify a one-to-one correspondence between fibers and individual clusters. The LPD filter did aid in spike detection, but it somehow reduced the number of Type II fibers clustered and also reduced the ratio of between-cluster scatter to within-cluster scatter.

The new algorithm is recommended as a way of estimating relative changes in total fiber activity at different time periods, and in applications where correlations between spike amplitude and velocity are not necessarily present.

This work was supported by NIH grant NS-19331.

MODIFICATION OF RESPIRATION AND MASTICATION DURING DEGLUTITION IN THE ADULT HUMAN. D. McFarland, C. Valiquette*, and J.P. Lund. Centre de recherche en sciences neurologiques, Université de Montréal, Montréal, Canada, H3C 3J7.

Previously, we have described the interactions that occur between respiration, mastication, and deglutition in the awake, unanesthetized rabbit (Neurosci. Abstr. 16:50.5, 1990). We concluded that changes in respiration and mastication to accommodate swallowing are accomplished through independent commands from the swallowing central pattern generator. We extend these findings by describing the interrelationships between swallowing, respiration, and mastication in the adult human.

Movements of the jaw, rib cage, and larynx were recorded during spontaneous breathing and the mastication of apple, sausage, and candy. The laryngeal signal was used as a marker for swallowing, and three characteristic patterns were observed. Interposed (I) swallows occurred during the sequence, Terminal (T) swallows ended the sequence, and Spontaneous (S) swallows occurred sporadically between masticatory sequences. The present report focuses on the first two swallow types.

Respiratory pauses usually occurred during the expiratory phase (versus inspiration in the rabbit) of the breathing cycle, before or during elevation of the larynx for swallowing. Jaw movements typically paused during the opening phase and after changes in respiration and movements of the larynx. There was no direct linkage between the onset of pauses in respiration and mastication. Unlike the rabbit, the durations of perturbed respiratory and masticatory cycles in man were related to the phase in which swallowing occurred.

PERTURBATION PRIOR TO TWO-JOINT POINTING MOVEMENTS. G.F. Koshland & Z. Hasan Dept. Of Physiology, Univ. of Arizona, Tucson, AZ 85724.

The aim of this study was to measure reflex responsiveness to a perturbation, delivered just prior to the onset of voluntary pointing movements in different directions. We expected that the EMG response to the perturbation would be systematically modulated with direction, and in particular, would be least when the intended direction coincided with the perturbation direction.

Motion of the arm was restricted to rotations about the shoulder and elbow joints in the horizontal plane, and in some trials, a force perturbation (30 ms) was unexpectedly applied to the forearm, extending the elbow joint and to a lesser extent the shoulder joint. A clear response to stretch in elbow flexors was observed over the period 30-60 ms from the start of the perturbation, and response amplitude was relatively constant for all intended directions. Soon after this short-latency response, the perturbation consistently elicited an earlier and faster target-reaching movement, also evidenced by earlier and larger EMG activity in the agonist and antagonist muscles appropriate for moving in the target direction. Indeed, in the case where the directions of the perturbation and intended movement coincided, a switch occurred from short-latency activity in flexor muscles to activity in shoulder and elbow extensor muscles, initiated as early as 60 ms after the perturbation. This early onset was always observed despite variations in the experimental paradigm (amplitude and timing of perturbation, type of Go signal, presence of warning tone), suggesting that subjects were not jumping the gun before the Go signal.

The findings suggest that apart from the short-latency response in a stretched muscle, the choice of muscles activated in response to a perturbation reflects the pattern that has already been selected for the upcoming volitional movement. This is consistent with other studies in which perturbations by themselves elicited non-monosynaptic EMG responses that mimicked multijoint voluntary patterns. THE PREDICTED DIRECTIONAL TUNING OF CELLS WHICH ARE CORRELATED WITH MUSCLE KINEMATICS. S. A. Ellias. Parkinson's Disease and Movement Disorder Unit, Roger Williams Med. Center, Providence RI. 02908

The activity of many movement related cells in primate motor cortex are characterized by a 'tuning' curve (TC) that varies as the cosine of the difference between the direction of hand movement and a preferred direction (Georgopoulos et. al. 1982;1983; Kalaska et. al. 1989). However, some cells exhibit a TC that is too skewed to show a good fit to a sinusoid (Kalaska et. al. 1989). Here, I will show that broadly sinusoidal and sharply tuned and skewed TC can be created by cells which either command or are correlated with muscle velocities. The TC of these cells are calculated by computer simulation for 1 cm to 8 cm primate arm movements with a bell shaped hand velocity profile in a horizontal plane. The instantaneous firing rate is assumed proportional to instantaneous muscle velocity. Muscle moment arms are kept constant to isolate the effects of arm geometry. Average firing rates are computed for different portions of the movement for different muscles and for different starting locations. The TC show the following properties: 1) The TC for the instantaneous firing rates are sinusoidal for movements of less than 4 cm regardless of starting location. This is consistent with results derived analytically by linearizing the arm kinematics (Mussa-Ivaldi, 1988). 2) The TC for the instantaneous firing rates are more skewed and sharply tuned for movements larger than 5 cm. This skewing is enhanced for movements starting with the elbow more flexed for both single-joint and double-joint related cells. 3) The TC for the average firing rate reflects these same properties: for the first half of the movement it is sinusoidal, but it can be very skewed if the average includes the last half of the movement. 4) The amplitude of the TC for shoulder related cells increases with elbow flexion, and decreases for elbow related cells and some double-joint cells. These TC characteristics may help to subclassify movement related cells, and should be applicable to some sensory cortical cells. Since force commands may be realized by changes in rest length, a distortion of some of these TC properties may also be found in cells which influence muscle force.

CONTROL OF POSTURE AND MOVEMENT IN HUMANS

410.1

RESTORATION OF PRECISION GRIP USING TACTILE FEEDBACK AND FUNCTIONAL ELECTRICAL STIMULATION. J.A. Hoffer and M. Haugland. Dept. Clin. Neurosci., Univ. Calgary, Calgary, Alberta T2N 4N1, Canada; and Dept. Med. Informatics and Image Analysis, Aalborg Univ., Aalborg, Denmark.

In the intact human, cutaneous mechanoreceptors are essential for the control of precise manual tasks. Of particular importance is the high sensitivity of glabrous skin mechanoreceptors to small slips of a gripped object that can occur if the grip force declines, or if a load is added to the object. By 80 ms after the start of a slip, a spinal reflex of cutaneous origin can recruit sufficient additional force to hold the object securely again (Johansson & Westling, Exp Br Res 71:72, 1988).

In persons paralyzed by stroke or spinal cord injury it has been possible to restore some motor function with Functional Electrical Stimulation (FES) of limb muscles. However, fine motor control with FES is difficult because the forces produced with electrical stimulation depend markedly on muscle length, external load, and prior history of activation. We have investigated whether skin mechanoreceptor signals, recorded chronically from sensory nerves, can provide feedback information suitable for *closed-loop* control of FES, an approach that is likely to approximate more closely the performance of the intact motor system.

The cat footpad served as a model of human glabrous skin. Cats were implanted with tripolar nerve cuff electrodes on the tibial nerve and four bipolar intramuscular stimulating electrodes in the heads of triceps and plantaris. In experiments under anesthesia, the leg was secured with atraumatic clamps. When the plantarflexor muscles were stimulated, the footpad pressed against an object that would fall if not held by the paw. In runs simulating fatigue, the force produced with FES was made to decline gradually until the object slipped. In other runs a weight was dropped, causing the object to slip. In both cases, the ENG signal showed a large burst as the object started to slip, that was invariably detected by a computer within 10 ms. The controller responded with an immediate increase in the stimulation of the muscles that allowed the paw to reliably and reproducibly stop the object after only a 1-2 mm fall.

We suggest that feedback signals generated by skin mechanosensors could be similarly recorded from human nerves, and used for automatic regulation of the activation of paralyzed muscles with FES in quadriplegia, paraplegia or hemiplegia.

410.2

OPTIMIZED STIMULATION OF MUSCLE AFFERENTS IN HUMANS WITH A SERVOCONTROLLED TENDON VIBRATOR S.C. Gandevia, P.J. Cordo, D. Burke*, J.P. Hales*, The Prince Henry Hospital and University of New South Wales, Sydney, Australia

Tendon vibration is known to be an effective stimulus for muscle receptors. In reduced preparations, vibration can be delivered directly to and in the same axis as the excised tendon. In humans, however, vibration must be delivered through the skin, perpendicular to the tendon, making it more difficult to control precisely the mechanical characteristics of the stimulus. We have constructed a tendon vibrator for humans in which the force and displacement of vibration can be controlled, even when the muscle and tendon move over short distances during active contractions and joint rotations.

We recorded the activity of single muscle afferents in the nerves supplying the tibialis anterior (TA) in humans using microneurography. We classified afferents as muscle spindles or tendon organs using muscle twitches produced by intrafascicular stimulation and as group Ia or II spindle afferents with ramp stretches delivered by the vibrator. We defined the optimal force and displacement of vibration to entrain each afferent at vibration frequencies of 20, 40, 80 and 120 Hz in the passive muscle, during isometric contractions, and during passive and active changes in the length of the TA.

We were able to entrain these receptors (especially Ia afferents) in the passive limb as well as during active contractions. Our determination of optimal vibration parameters will allow this vibrator to be used to investigate quantitatively how proprioceptive input is used to control human movement.

TRANSIENT DYNAMICS IN MOTOR CONTROL OF PATIENTS WITH BASAL GANGLIA OR CEREBELLAR DISEASES. A. Beuter, C. Labrie*, K. Vasilakos*. Université du Québec à Montréal, CP 8888, Station A, Montréal, Qc, H3C 3P8 and Centre for Nonlinear Dynamics in Physiology and Medicine, McGill University.

Experimental observations of movement disorders including tremor and voluntary microdisplacements recorded during a simple visuomotor tracking task in patients with Parkinson's disease and in patients with lesions of the cerebellum are analyzed. The task required the patient to maintain a constant index position relative to a stationary baseline displayed on an oscilloscope. The displacement signal of the finger was delayed up to 1400 ms, recorded for 80 s and digitized at 102 Hz. Typically in control subjects, insertion of a time delay produces large amplitude low frequency oscillations (with a period two to four times the delay) superimposed over physiological tremor. The performance of patients with Parkinson's disease (whose tremor amplitude is large) and of patients with cerebellar disease (with more severe deficits) is characterized by the intermittent appearance of transient dynamics or by the presence of sudden transitions in the amplitude and/or frequency of the signal. The need to (1) develop new tools to characterize changes in dynamics (i.e., transitions) and (2) redefine movement pathologies following neurological degeneration, in terms of qualitative changes in oscillatory behaviors is emphasized.

ANALYSIS OF VARIABLITY IN KINEMATIC CONTROL IN ASSESSMENT OF LANDING STRATEGIES IN CHILDREN. L.Pelland and P.McKinley. Physical, Occupational Therapy, McGill, Montreal, Que., H3G 1Y5

Landing from a knee-height jump down was studied in 10 children 7-13 yrs of age under normal vision. Subjects (Ss) led with the left leg and landed with both feet simultaneously onto a rigid surface. The jumps were videotaped (60Hz) and analyzed off-line (Peak Performance). Hip, knee, and ankle angles for each subject were normalized to flight time duration, and a 95% confidence interval was obtained at 1% bin widths. For each subject, the bins were normalized to maximum variability (100%) and classified into epochs of ***Low*** (<30%), ***Average*** (30-70%) or ***High*** (>70%). From previously defined categories (Pelland et al., *Xth Intl. Symp. Posture and Gait,* pp 549-552,1990) Ss were placed into one of three developmental categories: ***Adult***, ***Transitional***, or ***Proximal to distal***. In Ss classified as *adult*, 2 points of modulation were identified for all three joints prior to landing: **Low** variability when the limb was in maximum extension, and **high** variability for the 30-42ms (90% of flight time) prior to landing. For the *transitional* group, modulation was less specific although all subjects showed some modulation during 1 of these epochs. For the *Proximal to Distal* group, there were no specific adjustments except at the ankle in the prelanding epoch for 2/5Ss. It is concluded that ability to modulate variability in limb position during landing approach is another important descriptor in categorization of development. Supported by NSERC and FRSQ

POSTURAL CONTROL IN ALZHEIMER'S DISEASE

S. Glatt and J. Sissel*, Department of Neurology, University of Kansas Medical Center, Kansas City, Kansas 66103

While a motor degenerative syndrome is observed in endstage dementia of the Alzheimer type (DAT), clinical motor abnormalities are uncommon in patients with mild to moderate dementia. However accidental falls are commonly observed in this population. We used a mechanical force plate to measure the maximal fore-aft excursion of the center of pressure (CP) in response to a self-paced forward lifting task in 28 patients with mild to moderate DAT (Mini-Mental State Exam >10) as compared to 34 elderly (EC) and 30 young controls (YC). Appropriate anticipatory postural adjustments would minimize CP excursion. Mean maximal fore-aft CP excursion was greater in patients with DAT (3.07 ± 1.59 cm.) as compared to EC (2.41 ± 0.84) and YC (2.13 ± 0.77) ($p < .05$). As these patients do not have neuromuscular deficits, we suggest that disordered postural control is reflective of defective anticipatory postural responses to minimize the postural perturbations associated with voluntary movements of the extremities. The anticipatory response requires an estimate of this perturbation. We suggest frequent falling in DAT is reflective of this deficit in postural control.

410.6

MEDIUM LATENCY STRETCH REFLEXES ARE NOT ENLARGED IN NEUROLOGICALLY NORMAL HIV-POSITIVE PATIENTS.

D.J. Beckley, B.R. Bloem*, V.P. Panzer, and M.P. Remler. Depts. of Neurology, UC Davis, Davis, CA, University Hospital Leiden, The Netherlands, and NeuroCom, Clackamas, OR.

Patients with the AIDS dementia complex frequently manifest features of parkinsonism which may be related to lesions in the basal ganglia. Damage to these brain areas is also associated with enlargement of medium latency (ML) stretch reflexes. To determine whether ML enhancement may serve as an early electrophysiological marker for CNS involvement by HIV-1, we studied amplitudes of these reflexes in legs of neurologically asymptomatic HIV-positive patients (ADC Stage 0) (8 males, 1 female; age range 26-59, mean 38.7) and 10 controls (5 males, 5 females; age range 25-41, mean 34.3). Free-standing subjects received ten toe-up perturbations of 4^{o} amplitude at 50^{o}/sec of a movable forceplate. ML reflexes were recorded from the left medial gastrocnemius with surface EMG electrodes and corrected for background activity. There was no significant difference in ML amplitudes between the two groups ($p > 0.22$, t test). These results show that enlargement of the ML stretch reflex is not present in neurologically normal HIV-positive individuals. While assessment of ML reflexes is unlikely to be useful as a preclinical electrophysiological marker of HIV-induced CNS involvement, we cannot exclude the possibility that ML reflex abnormalities may parallel clinical manifestations in more advanced disease stages.

RELATIONSHIP BETWEEN TREMOR AND THE ONSET OF RAPID VOLUNTARY CONTRACTION IN PARKINSON'S DISEASE

G. Staude*[1], M. M. Wierzbicka, J. Schwarz*[2], R. Dengler*[3] and W. Wolf*[1] [1]Bundeswehr University, Munich, West Roxbury VA Medical Center & Harvard Medical School, Boston MA, [2]Ludwig Maximilian University, Munich, [3]University of Bonn, Bonn, Germany.

Hallett et al. hypothesized that "some of the delay in initiating movement in patients with tremor-at-rest might come from 'waiting to get into correct time of the cycle'" (J Neurol Neurosurg Psychiatry 1977 40: 1133). We tested this hypothesis by examining the onset of the voluntary rapid response in relation to tremor in 5 patients with Parkinson's disease (PD). Isometric index finger abductions were performed to two targets (20% and 60% of subject's maximum voluntary force) in selfpaced (SP) and reaction time (RT) trials. Each subject produced 200 contractions acquired in blocks of 50 trials per condition. The time intervals between the last two consecutive tremor peaks prior to the voluntary response and also from the last tremor peak to response onset were evaluated. Corresponding intervals between tremor EMG bursts and the phasic EMG burst were calculated from surface EMG. The last-peak-to-response-onset interval was 35% ± 18% (mean ± SD) of the length of the peak-to-peak interval (all subjects and experimental conditions). Therefore subjects most often (69% ± 3.5% of trials) initiated their voluntary contraction during the descending phase of tremor cycle, both in SP and RT trials. The phasic EMG burst usually occurred in synchrony with the tremor burst. This systematic phase relationship between resting tremor and the onset of voluntary motor response might indeed contribute to the prolongation of RT in patients with tremor at rest in PD. (Supported by DFG grant)

SENSORY-MOTOR PERFORMANCE CHANGES IN HEALTHY AGING SUBJECTS.

B. Myklebust, J. Myklebust, T. Prieto, D. Kreis. Lab. Sensory-Motor Performance, VA Med. Ctr. & Medical College of Wisconsin, Milwaukee, WI 53295

Disorders of balance and stability are among the most significant health problems of the aging population; falls are a major cause of mortality, morbidity, immobility, and premature nursing home placement). The annual incidence of falling for persons living in the community is 30% of those over the age of 65. The "elderly" (65 years and older) face increased risk of death from a fall; they are also more likely to suffer severe nonfatal injuries from falling than younger persons. Falls account for 87% of all fractures in the elderly. Among people age 65 years or older, approximately 9500 deaths per year are attributable to falls; the incidents in which a fall initiates or contributes to a chain of events that culminates in death is probably greater.

The objective of this comprehensive, multi-dimensional study is to identify the neurophysiologic and biomechanical determinants of functional changes associated with aging. The true effects of growing old are often difficult to distinguish from disease processes that may appear or become more pronounced with time but are not necessarily related to the underlying processes of aging. Because many changes associated with aging reflect a reduction in adaptability and performance that may also characterize a specific disease, the effects of aging and disease are often difficult to separate. Consequently, conflicting reports are often found in data on "normal aging" individuals.

Research on 62 healthy elderly subjects in our laboratory has identified 46 subjects whose measurements are different from normal young adult subjects, using standard tests of functional performance (gait and balance), motor control (ankle joint compliance and reflexes), sensory processing (somatosensory evoked potentials), and physical and neurological examinations. However, none of our subjects had deficits in all measures. Twenty-three subjects had deficits in at least one motor control test, without abnormalities in sensory processing or functional measures. Six subjects who reported a history of unsteadiness also had deficits in motor control tests, the neurological examination, and in gait or standing balance.

COORDINATE TRANSFORMATION BETWEEN VISUAL AND MOTOR SYSTEMS: COMPATIBILITY EFFECTS BASED ON VISUAL FIELD, NOT MUSCLE SYNERGY DIRECTIONS. C.J. Worringham and D.B. Beringer.* Department of Movement Science, The University of Michigan, Ann Arbor, MI 48109; Department of Psychology, New Mexico State University, Las Cruces, NM 88003.

Most natural reaching and manipulation take place with gaze directed at the limbs, but many artificial tasks require humans to look at a display while the limbs are neither within view nor aligned with the display. What is the underlying principle spontaneously used by the nervous system to select the limb movement direction necessary to move an object (e.g. a cursor) in the display? Young adult male and female subjects (n=128) performed a target acquisition task with a joystick in one of eight conditions, involving combinations of "Control-Display", "Visual Field", and "Muscle Synergy" compatibility. Results show significant advantages in reaction and execution times and in error minimization when the required movement was in the same direction in the subject's "virtual" visual field as was the required display motion in his or her actual visual field. This effect was independent of limb positions, muscle synergy, and control-display relationships. The results suggest "visual field compatibility" is a universal principle of directional compatibility.

MOTOR LEARNING IN OLIVO-PONTO-CEREBELLAR ATROPHY: SCHEMA FORMATION, ADAPTATION TO ALTERED GAIN, AND USE OF ERROR INFORMATION. A.L. Smiley-Oyen, C.L. Cross* and C.J. Worringham. Department of Movement Science, The University of Michigan, Ann Arbor, MI 48109.

Animal work shows a crucial olivo-cerebellar system role in motor learning, but there is little equivalent human data. In this study, 7 Olivo-ponto-cerebellar atrophy (OPCA) patients and age-matched controls attempted to learn a task requiring linear arm movements proportional in length to bars presented on a screen. Error feedback was given initially on alternate trials. Tests of retention (no feedback), extrapolation (responses to longer bars than practiced), and gain change (same targets requiring longer movements than previously learned) were given. Measured by absolute constant error, OPCA group improvement during acquisition, retention scores, ability to extrapolate, and adaptation to altered gain did not differ significantly from controls. All OPCA patients could use error information from one trial to improve on the next, and could detect and correct errors even without error feedback. Despite motor control deficits, OPCA patients showed little sign of impaired motor learning in this task.

ALTERED MOTOR UNIT DISCHARGE PATTERNS IN SPASTIC PARETIC MUSCLES. J.J. Gemperline, D. Walk*, and W.Z. Rymer. Department of Biomedical Engineering, Northwestern University, Sensory Motor Performance Program, Rehabilitation Institute of Chicago, and Department of Neurology, Michael Reese Hospital. Chicago, IL 60611.

The paresis associated with cerebral and spinal lesions is usually attributed to a loss of descending excitation of the affected muscles. However, previous studies from our laboratory on patients with spastic hemiparesis show an increased amount of EMG in the spastic limb for a given level of motor output, suggesting that other mechanisms may be responsible as well (Tang and Rymer, 1983). In particular, abnormally low motor unit rates in the spastic limb may contribute to the decreased ability of the muscle to produce force.

Patients with spastic hemiparesis were asked to perform a series of contractions at different force levels using both the affected and unaffected limbs. Elbow torque, surface EMG from several major muscles acting at the elbow, and intramuscular EMG from either the biceps or brachioradialis muscle were recorded. Off-line analysis of the intramuscular signals was performed in order to determine the firing patterns of several motor units which contributed to the EMG signal.

As in previous studies, the spastic limb was seen to generate more EMG in order to obtain a given torque output. However, motor unit rates were approximately 30% lower in the spastic limb for matched torques. For matched EMG, motor unit rates were lower by approximately the same amount. Recruitment rates of some units in the paretic muscle were over 50% lower than recruitment rates on the unaffected side. Units on the affected side were regularly observed to fire at rates below the recruitment rates of the motor units of the unaffected side.

The lowering of motor unit rates in the paretic muscle suggests that the motor units in that muscle are being driven inefficiently, producing reduced amounts of force. This necessitates the recruitment of additional motor units in order to produce a given level of force, which is reflected in the elevated surface EMG levels. The recruitment of previously high-threshold units at even very low force levels may have implications regarding the fatiguability of spastic muscle.

CHANGES IN THE STRETCH REFLEX THRESHOLD IN SPASTIC MUSCLE AS A RESULT OF ELECTRICAL STIMULATION. J.D. Given*, J.P.A. Dewald, C.J. Heckman and W.Z. Rymer. Sensory Motor Performance Program, Rehabilitation Institute of Chicago, Chicago, IL 60611.

Prolonged electrical stimulation of spastic muscle (for example as utilized for FES treatment of spinal paraplegia) has been reported to reduce the severity of spastic hypertonia. In an effort to study the effects of electrical stimulation on spastic muscle we compared pre- and post- electrical stimulation elastic properties of a spastic muscle.

A hemiparetic stroke subject was seated next to a servo controlled DC motor. Elbow joint extensions of 1 radian at velocities of 0.25 or 0.5 rad/s were used to determine the passive and reflexive stiffness of the spastic elbow flexors. The stretch reflex threshold was defined as an increase in the torque-angle slope (i.e. joint stiffness) in combination with an increase of rectified EMGs from the Biceps and Brachioradialis muscles. Subsequent to the determination of the stretch reflex threshold, the subject's Biceps muscle was stimulated for 10 minutes (20 Hz, duty cycle of 2.5 s on, 2.5 s off). Within 10 s after stimulus termination, 3 elbow extensions were imposed to determine changes in the threshold of the stretch reflex and/or slope of torque-angle relations. The elbow extensions were repeated every 3 min for up to 20 min after cessation of the electrical stimulation.

Compared to the pre-stimulation case, in 2 subjects tested, peak torques were 50% higher at the end of the ramp-stretch immediately after electrical stimulation of the spastic biceps muscle. However, no slope changes of either the passive or reflexive stiffness were observed, indicating that the increase in peak torque was due to a marked reduction of the stretch reflex threshold. This threshold shift persisted for at least 20 min.

The decrease in stretch reflex threshold could be related to the stimulation of cutaneous and Ia afferents, resulting in an increase in the excitability of the flexor motor nuclei. The inhibitory Ib force feedback on these same nuclei appears to be less effective under these stimulatory conditions. Our results contradict several clinical reports claiming a reduction in spasticity after stimulation of the spastic muscle.

410.13

INHIBITORY EFFECTS OF MAGNETIC CORTICAL STIMULATION IN MAN I: NORMAL SUBJECTS. DP Cros*, WJ Triggs*, RAL Macdonell*, KH Chiappa*, BJ Day*, JJ Fang*, BT Shahani.
Clin. Neurophysiology Lab., MA Gen. Hosp., Boston, MA 02114

We studied inhibitory effects of magnetic cortical stimulation (MCS) in 6 healthy subjects using a magnetic stimulator (Magstim 200) with 9cm coil centered and fixed over the vertex. Electromyography (EMG) was recorded with disk electrodes during monitored 10% contraction of abductor pollicis brevis (APB) or flexor carpi radialis (FCR) muscles with subjects immobilized in bivalve fiberglass casts attached to a force gauge. MCS produced motor evoked potentials (MEPs) followed by a period of EMG silence. The duration of this silent period (SP) increased with MCS intensity, but abbreviated with effort. An SP never occurred without preceding MEP, however SP duration was not a direct function of twitch amplitude. The amplitude of the H-reflex (APB 1 subject; FCR 3 subjects) was facilitated at the beginning of the SP relative to the response at rest, showed progressive inhibition as the SP evolved, and recovered with facilitation after the SP ended. In some subjects, F-wave amplitudes were similarly altered; however inhibition of the F-wave tended to begin after inhibition of the H-reflex. Neither response was ever completely abolished during the SP. Analysis of post-stimulus time histograms of single motor units activated voluntarily at 10Hz revealed that those units that fired in direct response to a threshold magnetic stimulus showed an interval to resumption of firing in excess of the inter-unit interval preceding MCS. Together, these observations suggest MCS has both excitatory and inhibitory effects, which may manifest at both cortical and spinal levels.

INHIBITORY EFFECTS OF MAGNETIC CORTICAL STIMULATION IN MAN II: LESSONS FROM PATHOPHYSIOLOGY. WJ Triggs*, DP Cros*, RAL Macdonell*, BJ Day*, JJ Fang*, M Hayes*, KH Chiappa*, BT Shahani, A Beric. Clin. Neurophysiology Lab., MA Gen. Hosp., Boston, MA 02114

We studied responses to magnetic cortical stimulation (MCS) in 3 patients with spasticity secondary to motor neuron disease (MND), and in 1 patient with a deafferentation syndrome secondary to sensory neuropathy. We used a magnetic stimulator (Magstim 200) with 9cm coil centered over the vertex. Electromyography (EMG) was recorded with disk electrodes during isometric contraction of abductor pollicis brevis (APB) and abductor digiti minimi (ADM) muscles. In these MND patients, MCS failed to elicit motor evoked potentials (MEPs), but produced a period of silence in the EMG after a latency of 45-50 ms. The duration of this silent period (SP) increased with intensity of MCS. In 1 of these spastic patients, the amplitude of an ADM H-reflex was inhibited during the SP relative to the H-reflex evoked with voluntary facilitation, but not relative to the H-reflex produced at rest. In the deafferented patient, MCS produced normal MEPs with accompanying SPs indistinguishable from responses obtained in normal subjects. This patient showed no SP with supramaximal electrical stimulation of mixed and cutaneous peripheral nerves. These observations indicate that the inhibitory effects of MCS are not due to preceding MEP or changes in muscle length, and indeed are not mediated by Ia peripheral afferents.

THE USE OF ADVANCED INFORMATION IN MOTOR RESPONSES BY HUNTINGTON'S DISEASE PATIENTS. D. B. Willingham[1], W. J. Koroshetz[2], & J. Treadwell*[1]. [1]Dept. of Psych., Williams College, Williamstown, MA 01267.[2] Huntington's Disease Clinic, Mass. Gen. Hosp., Cambridge, MA

Previous studies have shown that patients with striatal abnormalities do not benefit from a warning signal prior to a GO signal in a two-button choice response time (CRT) task, or that patients are not faster in a simple RT task than a CRT task. We compared the abilities of Huntington's disease (HD) patients and normal controls (NC) on three CRT tasks offering different types of advance information: *Watch*, in which a warning appeared; *None* in which the word "Where?" appeared instead of the warning; and *Push*, in which a warning appeared, subjects pushed a button in response to it, and then pushed again when the GO signal appeared. Subjects also performed a simple RT task, *Single*, in which there was one stimulus and one response button. Time between the warning and GO signal was varied from trial to trial, but trials were blocked by type of warning.

The benefit of the warning in the *Watch* and *Push* conditions was the same for HD patients and NC. Both groups responded more quickly in the *Push* than the *Watch* condition. Patients did not show a normal benefit in the *Single* condition, while NC responded as quickly in this condition as they did in the *Push* condition. The results are discussed in terms of simple model of a motor output buffer.

410.16

AGING AND EXTRAPYRAMIDAL MOTOR FUNCTION. MP Caligiuri Department of Psychiatry, University of California and the VA Medical Center, San Diego, CA 92161.

Mild extrapyramidal motor signs such as rigidity, hypokinesia, tremor and postural disturbances are often associated with "normal" aging leading some to suggest that Parkinson's disease (PD) may serve as a model for the understanding of the aging motor system. Objective data supporting this contention are not available to compare with patients who exhibit clinically overt PD. The present study was designed to test the hypothesis that age-related changes in extrapyramidal motor function do not parallel the cardinal motor signs seen in PD. Sensitive electro-mechanical devices were used to examine the motor systems of over 100 non-parkinsonian individuals. Subjects ranged in age from 21 to 90 years. Correlational analyses between motor function and age failed to reveal a relationship for tremor amplitude (r=0.21), movement time (r=0.04) and rigidity (r=0.18). However, the age-motor function relationship was stronger for females than males suggesting an age-gender interaction. These findings suggest that aging-related motor declines play an inconsequential role in the pathogenesis of idiopathic Parkinson's disease.

LOWER ARM ELECTROMYOGRAPHY IN SCHIZOPHRENICS WITH TARDIVE DYSKINESIA. P. B. Vrtunski, K. Kwon* and H. Y. Meltzer. VA Medical Center and Dept. of Psychiatry Case Western Reserve University, Cleveland, OH 44141.

There are numerous descriptions of motor manifestations in schizophrenics with tardive dyskinesia (TD). The neuromuscular substrate of this impairment, however, is not well known. The aim of this study was to examine the EMG activity in agonist and antagonist muscles of the lower arm during a button-press response in a force control task. Seven schizophrenics with TD and 8 without dyskinesia participated in study. The task consisted of matching a target by generating the appropriate force with the index finger of the dominant hand, and maintaining this force for 6 seconds. There were 10 targets ranging from 5 to 560 cN in 90 quasi-randomly ordered trials of the test. The EMG was recorded from m. extensor dig. and m. flexor dig. superficialis. Results indicated that in most subjects a predominant EMG pattern reflected a reciprocal amount of activity along the force continuum, i.e., the antagonist activity was highest at low force targets and lowest at high force targets, while the reverse held true for agonist activity. In four TD patients, the antagonist activity was proportional to that in agonist, i.e., a substantial amount of cocontraction was observed. The increase in cocontraction may represent one of the markers of motor impairment in tardive dyskinesia. (Supp. by VA and MH-46630).

REACTIVE AND PREDICTIVE SCALING OF POSTURAL RESPONSES IN PARKINSONIAN PATIENTS F. Horak, J. Frank, J. Nutt*, C. Shupert R.S.Dow Neurological Sciences Inst., Good Samaritan Hospital, Portland, OR 97209

We investigated whether parkinsonian patients' postural deficits could be related to an inability to scale the magnitude of responses to center of mass (CM) displacements. Fifteen parkinsonian and elderly control subjects were exposed to backward surface displacements to determine whether they could use sensory feedback and prior experience to scale postural responses to displacement velocities or amplitudes.

Although parkinsonian patients scale postural responses, their torque responses were less sensitive to fast and large displacements and more sensitive to slow and small displacements than controls. Parkinsonian EMG responses were normal latency but EMG magnitudes saturated at 50-80% of control values for the fastest and largest displacements. Agonist burst durations were shorter with multiple bursts and antagonists were larger and earlier than controls. Although peak center of pressure (CP) initially moved beyond the peak CM, CP was not sustained to maintain equilibrium for large perturbations. Thus, the primary postural deficit was in sustaining tonic postural force and not in reactive or predictive scaling of the initial triggered postural patterns. (Supported by NIH AG0647 and DC00205.)

MOTOR PREPARATION IN YOUNG AND OLD ADULTS. J.R. Burke[1] and G. Kamen[2]. (Motor Control Laboratory, Indiana University, Bloomington, IN). [1]Department of Exercise Science, University of South Carolina, Columbia, SC and [2]Department of Physical Therapy, Boston University, Boston, MA.

Motor preparation was assessed in young (n = 20) and old (n = 20) adults by eliciting a right leg tibial nerve H-reflex (50% of the maximum H-reflex) prior to the onset of a voluntary response. The motor task was a right plantar flexion in response to a visual stimulus. A visual warning stimulus preceded the response stimulus by 1 second. The motor preparation test intervals were incremented by 50 ms between the presentation of the response stimulus and the onset of the voluntary response. On each trial, a H-reflex was elicited at one of the motor preparation test intervals. Control H-reflexes were elicited between randomly selected trials. The results supported a delayed onset of alpha motoneuron facilitation prior to a voluntary movement with age, as shown for H-reflex amplitude.

CHANGES IN MOTOR STRATEGIES WITH NORMAL HUMAN AGING. A.S.Buchman,*G.L.Gottlieb,D.M.Corcos,C.H.Chen,G.L.Almeida, Rush-Presbyterian St.Lukes Medical Center,Chicago,IL 60612, University of Illinois, Chicago, IL 60612, Universidade Estadual de Campinas, Ircamp/Conselho Nacional de Pesquisa, Campinas, SP 13100, Brazil

Recent studies of single-joint movements in healthy young normal subjects have led to the development of a Dual Strategy hypothesis for voluntary control of single joint movement. This hypothesis postulates that tasks can be performed by one of two strategies: speed-insensitive (SI) or speed-sensitive (SS). It is proposed that the SI strategy is generated by modulating the duration of the excitation pulse to the motor neuron pool while the SS strategy modulates the intensity of the excitation pulse. In light of ongoing changes in the motor unit with normal aging we have compared 8 normal subjects older than 50 years with 8 sex-matched subjects less than 35 years old.

To elicit the SI strategy, subjects performed discrete elbow flexions in the horizontal plane from a stationary initial position to visually defined targets at different distances with a constant inertial load. To elicit the SS strategy, subjects made discrete elbow flexion movements over a fixed distance with changes in movement speed elicited by explicit instructions to the subject and also knowledge of results concerning their movement time. Joint angle, acceleration, and electromyograms from two agonist and antagonist muscles were measured.

Younger subjects all demonstrated both SI and SS strategies. In contrast, only three of eight older subjects exhibited both strategies. The other five exhibited SS appearing behavior for both paradigms.

These findings are consistent with the loss of neuromotor control with normal aging that has been suggested by studies of motor unit firing changes in normal aged. The loss of motor units and changes in motor unit firing with normal aging may limit excitation pulse duration modulation necessary for generating the SI strategy.

RELATIONSHIP BETWEEN FUNCTIONAL DEFICITS IN SENSORY AND MOTOR SYSTEMS AND POSTURAL DYSCONTROL IN MULTIPLE SCLEROSIS (MS) PATIENTS. C. A. Pratt, F. B. Horak, and R. M. Herndon. Dept. of Neurology and R.S. Dow Neurological Sciences Institute of Good Samaritan Hospital, Portland, OR 97209

Because the distribution of demyelinating lesions varies across MS patients, we hypothesized that *different forms* of postural dyscontrol exist among MS patients depending on the relative impairment of functional systems involved in postural control. In this study, we have used a battery of clinical and electrophysiolgical tests to assess function of three sensory systems (somatosensory, visual, and vestibular) and the corticospinal tract in 10 mild-moderately disabled, ambulatory MS subjects aged 39-52 yrs. Functional deficits were correlated with postural control abnormalities revealed by horizontal translations of a posture platform.

One subgroup (N=6) consisted of MS subjects with significant (> 2 S.D.) bilateral delays in the onset of postural responses, recorded electromyographically (EMG) in the leg muscles. In these subjects, there was a high correspondence between bilateral delays in the onsets of postural responses and bilateral delays in central afferent conduction time (ACT), as revealed by somatosensory evoked potentials, but not with delays in central motor conduction times (MCT), evoked by magnetic stimulation of the cortex. EMG latencies were normal in MS subjects with normal ACT or impaired ACT on just *one* side, indicating that normal somatosensory inputs from just one leg are sufficient to trigger postural responses of normal latency bilaterally. A second subgroup (N=3) consisted of MS subjects who had normal VORs but had abnormally low gains in tests of fixation suppression, thought to involve the cerebellum. This subgroup may have impaired feedforward control of posture, similar to previously tested cerebellar patients.

AUTOMATIC & VOLUNTARY POSTURAL RESPONSES IN PARKINSON'S DISEASE. V.P. Panzer*, L.M. Nashner and T.N. Chase, NINDS, NIH, Bethesda, MD 20892 and NeuroCom International, Clackamas, OR 97015.

Limited success has been derived from the study of automatic postural responses in Parkinson's disease (PD); whereas more revealing, though contradictory results are reported in studies of voluntary limb movement. We therefore used a battery of tests of automatic and voluntary postural movements to evaluate 10 PD patients and 10 age-matched controls. Automatic response tests included 6 conditions of posturography and 3 sizes of platform translation. To examine voluntary postural control, patients made single weight shifts to random targets and continuous weight shifting movements. Measures of COG displacement, response latency, movement speed and amplitude were evaluated. Automatic response latencies to translations and COG displacement were normal. In contrast, measures of voluntary movement amplitude were significantly abnormal ($p<.005$). Postural reaction time in single weight shifts was improved by optimal dose levodopa therapy. While automatic postural responses are in the normal range in PD, voluntary movements are abnormal and may be responsive to drug therapy.

OPTICAL REFLECTANCE IN THE CAT DORSAL HIPPOCAMPUS CORRELATES WITH SLOW ELECTRICAL ACTIVITY G. R. Poe*, D. M. Rector*, S. S. Chirwa, and R. M. Harper, Department of Anatomy and Cell Biology and the Interdepartmental Neuroscience Program, UCLA School of Medicine, Los Angeles, CA, 90024-1763.

We monitored optical reflectance at 700 nm from the dorsal hippocampus using a previously described fiber optic probe. Under surgical anesthesia, electrodes were placed to record cortical EEG, and the image probe was lowered to the surface of the dorsal hippocampus. Fine wires were attached to the side of the optic probe to record hippocampal slow electrical activity. Diaphragmatic leads were placed to record respiratory and ECG activity.

To assess optical activity, images from the dorsal hippocampus were gathered at 2 second intervals in synchrony with the ECG R-wave for 2 hour periods which incorporated both sleep and waking states. Recordings of hippocampal and cortical EEG, EOG, diaphragm EMG, and ECG were digitized simultaneously with the images and scored for sleep state. Epochs of particular EEG spectral composition (slow waves, desynchronized) were selected within each state. Images within similar epochs were averaged, then compared by subtraction and ANOVA analysis with an alpha of .05. The dorsal hippocampus exhibited spontaneous fluctuations in optical activity coincident with slow electrical waveforms. Maximal reflected activity occurred during desynchronized EEG activity from phasic REM sleep and during spindling discharge of quiet sleep. The least reflected activity was observed during desynchronized EEG associated with particular waking epochs.

CHOLINERGIC GATING OF AUDITORY RESPONSE IN THE HIPPOCAMPUS. R. Freedman, V. Luntz-Leybman, P. Bickford-Wimer, and L. Olson, Center for Neuroscience and Schizophrenia, Denver VAMC and Univ. of Colorado Health Sciences Center, Denver, CO 80262 and Karolinska Institute, Stockholm, Sweden

Decreased response to repeated sensory stimuli is characteristic of the hippocampus. Innervation from the medial septal nucleus has been shown to be necessary for such gating of auditory response, which is observed in the evoked activity of pyramidal neurons in the CA3 region. The purpose of this study was to determine if cholinergic neurotransmission is critical to this effect and to identify which of the several cholinergic receptor types are involved. Sprague-Dawley rats were anesthetized with chloral hydrate, and recordings of auditory-evoked N40 responses were made from microelectrodes in the CA3 pyramidal layer. Auditory stimuli were presented in a paired-pulse or conditioning-testing paradigm, with 0.5s intrapair interval. In control recordings, the test N40 response was less than 40% of the amplitude of the conditioning N40 response. Cholinergic antagonists were subsequently infused into the lateral ventricle. The muscarinic antagonist scopolamine and the nicotinic ganglionic antagonist mecamylamine were without effect. However, the neuromuscular antagonist curare blocked gating of the test response in a dose-dependent fashion, as did α-bungarotoxin (α-BT). κ-BT had no effect. α-BT infused into the lateral ventricle binds to large neurons outside the CA3 pyramidal layer. There is also binding in the stratum oriens of CA1, but little drug reaches the dentate. Some of the α-BT-labelled neurons in CA3 also stain for GABA by immunocytochemistry. The results suggest that gating of response to auditory stimuli in the hippocampus is mediated by cholinergic activation of GABA-ergic interneurons in CA3 through an α-BT-sensitive receptor.

411.3

FINE STRUCTURE AND CELLULAR CORRELATES OF HIPPOCAMPAL SHARP-WAVE BURSTS. Z. Horváth, R. Urioste*, J. Hetke*, K. D. Wise* and G. Buzsáki, Center for Neuroscience, Rutgers University, Newark, NJ 07102 and Center for Integrated Sensors and Circuits, University of Michigan, Ann Arbor, MI 48109[1]

Neuronal correlates and bilateral synchrony of hippocampal sharp-waves were investigated with single and integrated multisite microelectrodes in the awake rat. The probability of single pyramidal cell firing in CA1 and CA3 during the sharp-wave burst varied from 0 to 55 percent. The probability that 2 or 3 pyramidal cells fired within a time window of 100 msec was several-fold higher during sharp-waves than during sharp-wave-off periods. Interneurons in the stratum oriens selectively increased their discharges during the population bursts, whereas some feed-forward interneurons in CA3 were not affected at all. This finding suggests that sharp-wave bursts are not triggered by subcortical inputs. A spindle-like oscillation (ripple) with 150-250 Hz and 1 mV amplitude was riding on the peak of each sharp-wave. Action potentials were associated with the negative phase of the ripple. The amplitude of ripples was maximal in the pyramidal layer. Ripples were synchronous within 2 msec in the two hippocampi. Ripples may represent a series of population spikes and/or fast repetitive IPSP events. These findings suggest that "epileptiform" fast oscillation is a normal feature of the intact hippocampus.

SPONTANEOUS AND EVOKED THETA FIELD AND THETA-RELATED CELL ACTIVITY OF THE ENTORHINAL CORTEX IN THE URETHANE-ANESTHETIZED RAT. C.T. Dickson and B.H. Bland. Beh. Neurosci. Res. Grp., Dept. Psyc., Univ. of Calgary, Calgary, AB, Canada T2N 1N4.

Theta (θ) is a near-sinusoidal waveform generated by the hippocampal formation and is associated with a well documented nosology of θ-related hippocampal cellular activity. Retrohippocampal areas, such as the entorhinal cortex, also generate θ but the theta-related cell activity is less well known. This study extends the classification system for hippocampal θ-related cell activity to the entorhinal cortex and to examine the control of cell and field activity by cholinergic agents. Both cellular and field activity were sampled from this region using an approach normal to its laminar structure and the effects of various cholinergic agents on both field and cell activity were monitored. Thus far, θ-on cells (i.e., those which fired more during θ) and one θ-off cell (i.e., one which fired less during θ) have been found. θ-on cells were found to have either rhythmic or non-rhythmic firing properties and to be either linearly or nonlinearly related to the frequency of θ in hippocampus. Systemic and intrahippocampal administration of cholinergic agonists activated entorhinal θ and at a lag, θ-on cell discharge. Thus, the nosology of θ-related units in the entorhinal cortex and their control via cholinergic agents seems to be similar to that seen in the hippocampus.

411.5

EFFECTS OF A REVERSIBLE BLOCKADE OF THE DORSO-MEDIAL POSTERIOR HYPOTHALAMUS ON HIPPOCAMPAL FIELD ACTIVITY. S.D. Oddie, L.V. Colom, and B.H. Bland. Beh. Neurosci. Res. Grp., Dept. of Psyc., Univ. of Calgary, Calgary, AB, Canada T2N 1N4.

The effects of dorsomedial-posterior hypothalamic (DMPH) stimulation and inactivation on hippocampal field activity was investigated in urethane-anesthetized rats. Hippocampal theta (θ) could be elicited with either tail pinch or electrical stimulation of DMPH in the range of 0.1-1.0 mA. Reversible blockade of DMPH by micro injection of procaine hydrochloride abolished spontaneous, tail pinch, and stimulation elicited θ and resulted in a reduction in the power of hippocampal field activity. Frequency, amplitude, and power measures of hippocampal field activity showed progressive recovery during the post-procaine period as tested by tail pinch and DMPH stimulation. A second series of experiments investigated the effects of DMPH stimulation and blockade on hippocampal θ elicited by intra-hippocampal microinjection of carbachol. Contrary to Colom, et.al. (1991) where blockade of medial septum abolished carbachol elicited θ, blockade of DMPH did not abolish θ elicited by carbachol in the hippocampal formation or lower the pre-procaine power level of the field activity. After recovery, electrical stimulation of DMPH at appropriate levels resulted in an upward modulation of the carbachol-induced hippocampal θ frequency.

411.6

DORSOMEDIAL-POSTERIOR HYPOTHALAMIC INFLUENCES ON THE SEPTO-HIPPOCAMPAL PATHWAY IN THE GENERATION OF HIPPOCAMPAL THETA. B. H. Bland, L. V. Colom and S. D. Oddie. Beh. Neurosci. Res. Grp., Dept. Psyc., Univ. of Calgary, Calgary, AB, Canada T2N 1N4.

We have hypothesized that the dorsomedial-posterior hypothalamic (DMPH) region may form part of the ascending synchronizing brainstem pathway originating in the pons region and projecting to the medial (MS)/vertical limb of the diagonal band of Broca (vDBB). The influence of the DMPH on the generation of hippocampal formation theta (θ) field activity was thus investigated in urethane-anesthetized rats. Microinfusion of procaine (PRO)-hydrochloride (HCl) into the DMPH blocked tail pinch elicited θ, spontaneously occurring θ, and θ produced by electrical stimulation of the nucleus pontis oralis. Systemic administration of eserine was able to generate hippocampal formation θ field activity during reversible PRO-HCl blockade of the DMPH. Microinfusion of carbachol into the DMPH resulted in intense activation of hippocampal θ. The results suggest that the DMPH forms part of the ascending brainstem synchronizing system. Furthermore, at least part of the influence of DMPH in the generation of hippocampal θ is mediated by cholinergic receptors.

411.7

PONTINE AND DORSOMEDIAL-POSTERIOR HYPOTHALAMIC INFLUENCES ON THETA-RELATED CELLS IN THE MEDIAL SEPTUM. L. V. Colom and B. H. Bland. Beh. Neurosci. Res. Grp., Dept. of Psyc., Univ. of Calgary, Calgary, AB, Canada T2N 1N4

The effects of electrical stimulation of the nucleus pontis oralis (PO) and dorsomedial-posterior hypothalamic (DMPH) region, along with reversible inactivation of the DMPH with procaine hydrochloride (PRO-HCl), on the discharge rates of theta (θ)-related cells in the medial septum (MS)/vertical limb of the diagonal band of Broca (vDBB), were investigated in urethane-anesthetized rats. Electrical stimulation of either the PO or DMPH resulted in intense activation of θ-on cells in the MS/vDBB. The microinfusion of PRO-HCl into the DMPH abolished the activation of MS/vDBB θ-on cells produced by electrical stimulation of the PO. The spontaneous discharge rates of θ cells in the MS/vDBB showed two types of responses to reversible inactivation of the DMPH. Some θ-on cells reduced their discharge rates significantly while others increased their discharge rates significantly, compared to the rates accompanying hippocampal θ conditions. Microinfusion of carbachol into the DMPH also produced intense activation of θ-on cells in the MS/vDBB which was abolished by subsequent microinfusion of atropine sulfate into the DMPH.

411.8

ATROPINE-RESISTANT AND ATROPINE-SENSITIVE HIPPOCAMPAL THETA IN THE FREELY MOVING RAT DEPENDS ON SEPTAL AFFERENTS. V.H. Lawson and B.H. Bland, Beh. Neurosci. Res. Grp., Dept. Psych., Univ. Calgary, Calgary, AB, T2N1N4

The role of the medial septum (MS)/vertical limb of the diagonal band of Broca (vDBB) in hippocampal theta (θ) generation and behavior was assessed using microinfusions of drugs into the MS/vDBB. Rats were chronically implanted with electrodes in the stratum moleculare of the dentate gyrus and a microinfusion guide cannula above the MS/vDBB. Microinfusion of procaine-HCl (PRO) produced a bilateral reversible suppression of θ. The beginning of the PRO infusion was characterized by increased motor activity followed abruptly by an immobility state resembling catatonia, associated with the suppression of θ. The duration of suppression was dose-dependent and recovery was associated with intense feeding. Microinfusion of carbachol also initially produced motor activity followed by long periods of immobility which were associated with θ activity at a constant dose dependent frequency. Any voluntary movements resulted in upward θ frequency shifts. Subsequent microinfusions of either PRO or atropine sulfate abolished immobility related θ and in the case of atropine, movement correlated θ was re-instated. Thus, the septo-hippocampal pathway is critical for the generation of both atropine-resistant and atropine-sensitive θ and their behavioral correlates.

411.9

FIRING RELATIONS OF ENTORHINAL NEURONS TO THE HIPPOCAMPAL THETA RHYTHM IN WALKING AND URETHANE ANESTHETIZED RATS. M.Stewart, M.Barry*, G.J.Quirk and S.E.Fox. Dept. Physiol., SUNY Health Sci. Ctr., Brooklyn, NY 11208.

Recordings from afferent neurons, together with data on the anatomical targets and the excitatory/inhibitory nature of the input, aids the interpretation of field potentials underlying the hippocampal theta rhythm. Extracellular recordings were taken from single entorhinal neurons in rats during the two most widely studied theta mode conditions: walking and urethane anesthesia. Cell firing in relation to the simultaneously recorded theta rhythm was examined. In walking rats, 22/23 histologically identified cells from layer II/III of medial entorhinal cortex (MEC), were significantly phase-locked to the hippocampal theta rhythm with a mean phase of 5° (0°=dentate theta pos. peak). In contrast, only 8/23 layer II/III MEC cells in urethanized rats were phase-locked with a mean phase of 90°. The firing of 4/8 layer II/III cells from lateral entorhinal cortex (LEC) in urethanized rats was significantly phase-locked to the theta rhythm with a mean phase of 134°. The rhythmic firing of one MEC cell (layer II), driven at constant latency from the hippocampal fissure, was reversibly abolished by cooling the supracallosal striae at the genu of the corpus callosum, suggesting that septo-entorhinal projections rhythmically excite these cells.

MEC cells tend to fire near the positive peak of the dentate theta rhythm in both walking and urethanized rats. Hippocampal pyramidal cells also fire on this phase. Distinguishing the two preparations, a larger proportion of MEC cells are phase related to the theta rhythm during walking. Although the MEC phase data are consistent across preparations, they cannot completely account for hippocampal field potentials at the depth of the MEC afferents. The firing of LEC neurons near the negative peak of the dentate theta rhythm may account for the large current sink near the hippocampal fissure. (Supported by NIH NS17095.)

HOMO- AND HETEROSYNAPTIC PAIRED-PULSE MODULATION OF PERFORANT PATH TRANSMISSION: ROLE OF CONDITIONING PULSE INTENSITY.

B. Srebro*, V. Doyère* and N.W. Milgram Dept. Physiology, Bergen, Norway; Dept. Psychophysiology, CNRS, Gif-sur-Yvette, France; Div. of Life Sciences, Scarborough College, Toronto, Canada.

To study short-term synaptic modulation in the lateral (LPP) and medial (MPP) perforant path we have adopted a paired-pulse (P-P) procedure of varying the level of C pulse and keeping the intensity of T pulse constant. The effect of C pulse intensity and interpulse interval was studied in urethane anesthetized rats. Stimulation electrodes were placed in the LPP and MPP and the recording electrode at the granule cell layer. Analysis of the population spike revealed homosynaptic facilitation in the MPP at levels of C pulse below threshold for firing granule cells (100-200% interpulse intervals 15-100ms). At higher intensities of C pulse there was inhibition at the shortest (15-30ms) and the longest (above 300ms, "late inhibition") intervals. In the LPP, homosynaptic facilitation was seen but there was no evidence of inhibition at any intensity of C pulse. Heterosynaptic facilitation was present at all levels of C pulse in both pathways except for the highest intensity of MPP C pulse, which induced heterosynaptic inhibition at shortest intervals. These results reveal a wide dynamic range of the short-term modulation in both the LPP and MPP which has not been reported using conventional P-P procedures.

INTRACELLULAR RECORDINGS OF RAT SUBICULAR NEURONS. J.S. Taube and C.W. Cotman. Department of Psychology, Dartmouth College, Hanover, NH 03755 and Department of Psychobiology, University of California, Irvine, CA 92717.

The electrophysiological properties of CA1 pyramidal neurons have been well-characterized. These cells send a major projection to the subiculum, which in turn projects to the presubiculum. Although recent studies have determined the behavioral/spatial correlates of neurons in the subiculum and presubiculum, little is known about the electrophysiological properties of subicular neurons. Using the in vitro slice preparation and intracellular recording techniques, the present study was conducted to assess the basic properties of subicular neurons.

Potentials recorded from subicular neurons in response to intracellular depolarizing current pulses differed from CA1 pyramidal neurons. Following a 100 msec, 0.5 nA depolarizing current pulse, subicular neurons responded with an initial burst of 3-4 spikes contained in a 40-50 msec depolarizing envelope, followed by the discharge of 1-2 single spikes not contained in a depolarizing envelope. This initial burst of spikes appeared to be mediated by calcium. Subicular cells showed an EPSP/IPSP sequence in response to electrical stimulation of CA1 radiatum, oriens, or alveus. The EPSP was blocked with addition of CNQX to the bathing medium. In a Mg^{++} free, CNQX bathing solution, a longer lasting depolarization was recorded, which was blocked with application of AP5. Iontophoretic application of glutamate or quisqualate into the apical or basal dendritic layers of subiculum lead to a short-latency depolarization. Application of GABA produced a short-latency hyperpolarization when it was applied near the recording site, but a depolarization when it was applied in the apical dendritic region. These results illustrate common properties of CA1 and subicular neurons, with the exception of their response to a depolarizing current pulse.

411.12

SHORT TERM ALTERATIONS IN RESPONSES OF ENTORHINAL CORTICAL NEURONES DURING ACTIVATION OF SYNAPTIC INPUTS *IN VITRO*. R.S.G. Jones. Department of Pharmacology, University of Oxford, Oxford OX1 3QT.

The perforant path, which arises from neurones in layers II-V of the entorhinal cortex (EC) is pivotal in controlling hippocampal functions. To understand these functions it is important to know how the EC processes information which is destined for the hippocampus. The present experiments have examined responses of neurones in layers IV/V and II of the medial EC (MEC) to repetitive activation of afferent inputs at different frequencies. Slices of EC were prepared from Wistar rats and maintained in an interface chamber. Synaptic responses were evoked in layer IV/V neurones by stimulating in the lateral EC and recorded with conventional intracellular electrodes. Responses were evoked in layer II neurones by stimulating in layer V/VI of the MEC or the parasubiculum. Stimulation at relatively low frequencies (<1.0 Hz) elicited a fast, AMPA/kainate mediated EPSP in layer IV/V neurones which was often followed by a slow NMDA mediated EPSP. In some cells (20 %) the NMDA EPSP showed dramatic enhancement during low frequency stimulation and elicited bursts of action potentials. Cessation of stimulation resulted in a rapid (1 min) decline of the slow EPSP to control levels. Higher stimulation frequencies usually resulted in failure of the slow EPSP. The fast EPSP was little altered by changes in frequency. Responses of layer II neurones were dominated by fast ($GABA_A$) and slow ($GABA_B$) IPSPs although an NMDA mediated depolarization often intervened. Both IPSPs showed a frequency dependant decrement and could practically disappeared at higher frequencies (> 2.5 hz). Simultaneously, the NMDA EPSP was enhanced and could elicit action potentials. These effects reversed rapidly (1-2 min). 2-AP5 blocked the enhanced slow EPSP but not the fading of the IPSPs. The results indicate that the routes taken by synaptic information through the EC and therefore its destination in the hippocampus are probably dependant on the frequency of the inputs.

A MODEL OF THE EXTRACELLULAR FIELD POTENTIALS GENERATED BY POPULATIONS OF HIPPOCAMPAL PYRAMIDAL CELLS. R. Costalat*, S. Genet*, E. Thiels, T.W. Berger and G. Chauvet. *Inst. de Biologie Théorique de l'Ouest-Atlantique, 49100 Angers, France, and Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.*

In order to analyze some of the determinants of extracellular field potentials generated by activation of hippocampal CA1 neurons upon stimulation of commissural afferents, a two-neuron model of variation of field potential in space and time was expanded to a population of neurons. The model uses the Laplace equation to describe intra- and extracellular potentials, and Hodgkin-Huxley and linear cable equations to describe active and passive membrane currents, respectively. Computer simulations of the two-neuron system served to derive ionic current lines between sources and sinks and determine from them dynamics of extracellular field potentials. Because the field potential of a population of neurons at a given point in the extracellular space depends on the summation of the extracellular field potentials of all neurons of that population, the ionic current lines for individual neurons were used to deduce population field potentials.

Comparison of the thus derived waveforms with ones obtained from extracellular recordings of CA1 pyramidal cells activated by stimulation of commissural fibers in intact rat hippocampus indicate that the model can predict qualitatively the changes in waveform observed as a function of: (1) location along the dendrite-cell body extent, (2) magnitude of commissural fiber stimulation, (3) efficacy of commissural-CA1 synapses, varied experimentally by induction of LTP, and (4) blockade of commissural-CA1 synapses located deep vs superficial to pyramidal cell bodies, varied experimentally by microinjection of the quisqualate receptor antagonist CNQX in the respective dendritic zones. We conclude that the two-neuron model is sufficient to describe extracellular field potentials generated by populations of neurons.

OPEN-LOOP NONLINEAR RESPONSE PROPERTIES OF RABBIT HIPPOCAMPAL DENTATE GRANULE CELLS RECORDED FROM THIN AND "MINI" *in vitro* SLICES. T. Patrick Harty, German Barrionuevo, Robert J. Sclabassi and Theodore W. Berger. *Depts. of Behavioral Neuroscience, Neurosurgery and Psychiatry, University of Pittsburgh, Pittsburgh, PA, 15260.*

The objective of these experiments was to use nonlinear systems analytic techniques to characterize the input/output properties of dentate granule cells in an open-loop condition, i.e., when feedback from other hippocampal subfields and feedforward or feedback modulation from dentate interneurons is eliminated. Although this condition is at least partly met by the *in vitro* hippocampal slice preparation, populations of interneurons exist in a slice that may contribute to granule cell response properties. Two additional experimental manipulations were used in an attempt to isolate granule cells from all but perforant path input. First, slice thickness was reduced from 600 µm to the minimum thickness that reliably produced detectable population spikes (300 µm). In 600 µm slices, second order nonlinearities were characterized by facilitation of population spike amplitude when a preceding impulse occurred with an interval of 10-100 ms, and suppression when the interval was 150-800 ms. The $GABA_A$ antagonist bicuculline (BMI) increased facilitation, demonstrating an influence of GABAergic interneurons. Although 300 µm slices exhibited similar second order nonlinearities, they were insensitive to BMI. The second manipulation involved physically separating approximately 40% of the dentate gyrus from the rest of a 600 µm slice. Compared to intact slices, granule cell nonlinearities in these "mini" slices were unchanged, and were sensitive to BMI. These results strongly suggest that feedback from interneurons in the deep hilus and from areas CA3 and CA1 do not contribute to nonlinear response properties of granule cells in the *in vitro* slice preparation. In addition, the contribution of GABAergic interneurons is eliminated in a 300 µm slice, suggesting that open-loop conditions for granule cells can be achieved. COMPARISON OF THE FUNCTIONAL PROPERTIES OF DORSAL VERSUS VENTRAL DENTATE GYRUS OF THE *in vitro* HIPPOCAMPAL SLICE USING NONLINEAR SYSTEMS ANALYSIS. Theodore W. Berger, Choi Choi*, T. Patrick Harty, Robert J. Sclabassi. *Departments of Behavioral Neuroscience and Neurological Surgery, University of Pittsburgh, Pittsburgh, PA 15260.*

Neuroanatomical studies of the hippocampal formation have shown that circuitry as well as cell density vary along the dorso-ventral axis. To what extent anatomical differences maintained within the reduced circuitry of the transverse hippocampal slice result in functional differences is the focus of this study. Nonlinear systems analytic techniques were used to compare the input-output functions of the dorsal versus the ventral dentate gyrus in the rabbit hippocampal slice.

Slices of 600 µm thickness were cut transverse to the longitudinal axis of the hippocampus from the dorsal third and the ventral third of the left hippocampus. The perforant path projection to dentate granule cells was stimulated with a train of 4064 electrical impulses with randomly distributed interimpulse intervals. The resulting extracellular potential was recorded from the granule cell layer. The relationship between the interimpulse intervals and the amplitudes of the resulting population spikes were expressed as the kernels of an orthogonalized functional power series. The second order kernel represents the changes to the population spike amplitude due to any preceeding impulse with interval Δ, and the third order kernel represents the changes to the population spike amplitude due to any two preceeding impulses of intervals Δ_1 and Δ_2.

Second and third order kernels were computed for responses from dorsal/ventral slice pairs from the same hippocampi. Preliminary results show no significant differences between the dorsal and ventral slices with respect to either second or third order kernels. These results suggest that the functional dynamics of the transverse dentate gyrus slice, in response to perforant path input, remain constant along the dorso-ventral axis. Supported by ONR, AFOSR, and MH00343.

CLOSED LOOP COMPUTATIONAL EVALUATION OF HIPPOCAMPAL MODEL CONTAINING UNOBSERVABLE ELEMENTS

R.J. Sclabassi, J. Paul*, B.Kasonovich*, D.Krieger, G.Barrionuevo, and T. Berger
Departments of Neurosurgery, Electrical Engineering, and Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15213

Nonlinear systems analytic techniques are being utilized to experimentally characterize the transformational properties of the hippocampus by recording electrophysiological responses to random impulse train stimulation and by expressing the relationship between the input and output activity as the kernels of a functional power series, which are interpreted as nth order impulse responses. In-vivo and in-vitro experiments have been performed to characterize both the closed- and open-loop properties of this system. However, some elements cannot be isolated experimentally and their input/output properties must be inferred from their effect on the other directly observable groups of neurons. To accomplish this the nth order Laplace transforms of the impulse responses are computed and algebraically manipulated. Models of the observable and unobservable subsystems, as well as the entire system, may then be computed in terms of nth order convolution operators.

This paper presents an example utilizing data from three sets of experiments: the intact hippocampal formation, with the dentate granule cell layer considered as a feedforward element, and the remainder of the ipsilateral hippocampus as a feedback element; a partially closed-loop system, where the contralateral hippocampus has been removed, the ipsilateral trisynaptic pathway is open, and the local GABAergic pathways have been blocked, in which: (1) the properties of unobservable elements are estimated, and (2) the response properties of the entire system are computed based on combining the observable and unobservable elements. THREE-DIMENSIONAL SPATIAL DISTRIBUTION OF PERFORANT PATH-EVOKED FIELD POTENTIALS IN HIPPOCAMPUS RECORDED SIMULTANEOUSLY *in vivo* BY MULTIPLE ELECTRODES IN CA1 AND DENTATE. Andrew J. Nowak and Theodore W. Berger, *Depts. of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pgh, PA 15260.*

Excitatory perforant path fibers arising from the entorhinal cortex innervate the distal dendrites of dentate granule cells, as well as the apical dendrites of CA1 and CA3 pyramidal cells. The present study examined the three-dimensional spatio-temporal distribution of CA1 pyramidal and dentate granule activated by perforant path stimulation in the *in vivo* rabbit hippocampus. The laminar profiles of extracellular field potentials evoked by perforant path stimulation were recorded simultaneously by an array of electrodes advanced in 100 μm steps through the CA1 and dentate regions of the dorsal hippocampus of halothane-anesthetized rabbits. Electrode arrays consisted of 3-5 insulated, finely-etched insect pins cemented together with tips separated by 500 or 1000 μm. Perforant path axons were stimulated at the level of the angular bundle with two intensities, one which was subthreshold for eliciting a population spike and the second which evoked a 50% maximum amplitude population spike in the dentate. During withdrawal of the array, current was passed through each electrode at the reversal points of the field potentials for histological reconstruction of the electrode tracks.

Results showed, as described previously (Yeckel and Berger, PNAS, 1990), simultaneous monosynaptic excitation of CA1 pyramidal and dentate granule cells with subsequent polysynaptic excitation of CA1 via the trisynaptic pathway. In addition, a medio-lateral gradient of excitation across the CA1 and dentate regions was indicated by: 1) a longer peak latency and decreased slope of population EPSPs for more lateral recording sites in CA1, and 2) longer latency population spikes for more lateral recording sites in dentate. Finally, a significant disparity was found between the locations of orthodromically and antidromically driven CA1 pyramidal cells. Supported by ONR, AFOSR, MH00343.

EFFECTS OF YOHIMBINE ON THE NONLINEAR RESPONSE CHARACTERISTICS OF HIPPOCAMPAL DENTATE GRANULE CELLS IN THE ANESTHETIZED RAT. Michael J. Mana, Robert J. Sclabassi, and Theodore W. Berger. *Departments of Behavioral Neuroscience, Neurological Surgery, and Psychiatry, University of Pittsburgh, Pgh, PA 15260.*

Nonlinear systems analytic techniques were used to study the effects of the α-2 antagonist yohimbine on the input/output dynamics of hippocampal dentate granule cells to perforant path stimulation involving a random interval train of 2026 electrical impulses; interimpulse intervals (Δ) were determined by a Poisson process with a mean frequency of 2 Hz. Yohimbine (4 mg/kg, i.p.) was administered after the first train; 30 min later, a second train was delivered. First, second, and third-order kernels describing the relationship between Δ and the amplitude of the evoked granule cell population spikes were computed for each train.

Yohimbine produced a 40-50% increase in the magnitude of first order kernels, (h_1), which reflect the average population spike for all impulses in a train. Second order kernels reflect the influence of any preceding impulse on granule cell response to a later impulse in the train, as a function of Δ. The increase in second order facilitation produced by yohimbine when Δ = 60-200 ms was proportionally greater than the drug-induced increase in h_1; the magnitude of suppression when Δ < 50 ms was maximum both pre- and post-drug (i.e., postdrug suppression increased in absolute terms to match the increase in h_1). Yohimbine did not change the Δ associated either with peak facilitation or peak suppression. Third order kernels reflect the influence of any pair of preceding impulses occurring Δ_1 and Δ_2 ms earlier. A marked suppression was observed both pre- and post-drug when Δ_1 and Δ_2 < 200 ms. Yohimbine also enhanced the magnitude of third order nonlinearities, with the increase again being proportionally greater than the increase in h_1. These results suggest that yohimbine increases both the number of granule cells excited by a perforant path volley, as well as the relative contribution -- though not the time course -- of the majority of mechanisms providing feedforward and feedback modulation of granule cell activity. AUTONOMOUS AND RHYTHMICALLY DRIVEN THETA-LIKE OSCILLATIONS IN A COMPUTER MODEL OF THE *IN VITRO* RODENT HIPPOCAMPAL CA3 REGION. R.D. Traub, G. Buzsáki and R. Miles. IBM T.J. Watson Research Ctr., Yorktown Heights, NY 10598; Center for Neuroscience, Rutgers Univ., Newark, NJ 07102; Institut Pasteur, Paris, France.

MacVicar and Tse (*J. Physiol.* 417: 197, 1989) have reported a 4-10 Hz *C*arbachol-*D*riven *P*opulation *O*scillation ("CDPO") in the isolated CA3 region *in vitro*. CDPO is characterized by 1) large synchronized EPSPs in pyramidal cells with superimposed bursts in many cells; 2) decrease in amplitude but unchanged frequency after low dose kynurenic acid; 3) insensitivity to bicuculline and phaclofen. We built a network of 1000 pyramidal cells (19 soma-dendritic compartments, 6 voltage-dependent currents - see Traub, Wong and Miles, *Soc. Neurosci. Abstr* 16: 1297, 1990), 100 inhibitory cells (i-cells) producing $GABA_A$ IPSPs and 100 producing $GABA_B$ IPSPs. This network generates population waves similar to CDPO, provided 1) AHP conductance is reduced; 2) EPSP conductances are reduced; 3) IPSPs are blocked; 4) pyramidal cells are depolarized. These requirements are consistent with known actions of carbachol and with MacVicar and Tse's data. In contrast to CDPO, *in vivo* walking theta is characterized by 1) infrequent firing of pyramidal cells with rare bursting; 2) pyramidal firing leads i-cell firing; 3) short bursts in many i-cells during each theta wave. Our network produces this pattern when, at 5 Hz, pulses of excitation are delivered to a small subset of pyramidal cells, followed by (external) phasic depolarizing-hyperpolarizing stimuli to most or all of the i-cells. The i-cell input is consistent with anatomical evidence for cholinergic and GABAergic synapses on these cells. The physiological timing and actions of these i-cell inputs remains to be confirmed.

AMPA RECEPTORS ARE INVOLVED IN EXCITATORY RESPONSES OF PREFRONTAL CORTICAL CELLS INDUCED BY STIMULATION OF THE HIPPOCAMPAL FORMATION. T.M. Jay, A.M. Thierry* and J. Glowinski*. Lab. de Neuropharmacologie, INSERM U114, Collège de France, 11, Place Marcelin Berthelot, 75231 Paris Cedex 05, France.

In previous studies we have demonstrated that field CA1 and subiculum project to the prelimbic portion of the rat prefrontal cortex (PFC) and that this direct unilateral pathway is excitatory and shows long-term potentiation (Jay et al., Br. Res. 505: 337, 1989; Laroche et al., Neurosci. Lett., 114: 184, 1990).

It was therefore of interest to determine whether the transmitter of the hippocampo-prefrontal cortex pathway is an excitatory amino acid and whether excitatory responses of PFC neurones induced by the hippocampal (HIP) stimulations are mediated by NMDA or non-NMDA receptors. Extracellular single unit recordings were obtained from neurones in the prelimbic area of the PFC in urethane anesthetized rats and low frequency stimulation (1Hz) was applied in the ipsilateral field CA1 or subiculum. The effects of iontophoretic application of agonists and antagonists of NMDA and non-NMDA receptors on PFC cells showing an excitatory response to the HIP stimulation (n=16; latency=18 ms) were analyzed. In 15 of these cells, the application of either CNQX or DNQX (10-80 nA) which antagonized the AMPA evoked excitation, completely and reversibly blocked the HIP-induced excitatory responses. In contrast, the application of APV (6-50 nA), which antagonized the NMDA but not the AMPA evoked responses, failed to reduce the HIP-induced excitatory responses in the same cells.

These results demonstrate that the excitatory responses of PFC neurones to stimulation of the hippocampus are mediated by AMPA receptors and suggest that the transmitter of the hippocampo-prefrontal cortex pathway is an excitatory amino acid.

IMMUNOGOLD CYTOCHEMISTRY FOR OXYTOCIN AT THE ULTRASTRUCTURAL LEVEL: REEVALUATION OF THE PLASTICITY IN THE RAT SUPRAOPTIC NUCLEUS (SON) AFTER CHRONIC DEHYDRATION: F. Marzban, C.D. Tweedle and G.I. Hatton. Dept. of Anatomy, Neuroscience Program and Michigan State University, East Lansing, MI 48824.

Vasopressin (VP) and oxytocin (OX) hormones are synthesized in separate magnocellular neurons (MN) in the supraoptic nucleus. These cells show profound plasticity when hormone secretion is elevated by stimuli such as lactation and dehydration. Plasticity of MN was previously seen using EM-immunogold cytochemistry for VP. Both VP(+) and VP(-) neurons underwent ultrastructural changes after chronic dehydration. Here we studied the changes in the cells of the same animals using OX antibody to confirm our findings. Middle portions of SON of chronically dehydrated (10 days 2% saline treated) and control (normally hydrated with tap water) rats were studied. Glial coverage of either type of MN cell body did not change. Percentage of soma-somatic/dendritic membrane contact significantly increased by 11-fold and 3-fold in both (+)-labelled (OX) and (-)-labelled (most probably VP) cells respectively. Percentage of axo-somatic contact significantly decreased by (36%) in OX(-) cells, possibly due to an increase in cell size rather than to a decrease in synaptic contact, with no change in OX(+) cells. Percentage of soma/soma-dendritic multiple synapses per cell significantly increased by (70%) only with OX(+) cells. Multiple synapses only occurred between the (+)- cells or (-)-cells, but not between (+) and (-) cells. Such changes may help synchronization of OX and VP hormonal secretion under the physiological stimulation. The similarity of our findings compared to VP immunolabelling indicates that our technique is adequate and both types of the cells do show plasticity with chronic dehydration. Supported by NS 09140.

OBSERVATIONS ON A NEW VESICULAR-LIKE STRUCTURE IN THE AXON TERMINALS OF POSTERIOR PITUITARY OF THE FEMALE RAT. J.E. Smith, P.J. Rusch, L.E. Koran, G.I. Hatton, Neuroscience Prog., Michigan State University, E. Lansing, MI 48824.

Large vesicle-like structures were observed ultrastructurally in the axon terminals of posterior pituitaries of female rats. These vesicle-like structures are either round or ovoid, range in size from 0.5-1.9μm diameter, with an average diameter of approximately 1.3μm (typical peptidergic granules in the posterior pituitary axon terminals of these animals ranged in diameter from 0.1-0.25μm), and there are an average of 2-3 per terminal. They are usually not bounded by membrane, although occasionally small segments of membrane form their borders. These structures appear to contain particulate material of the same density as the small peptidergic vesicles in the terminals. Approximately 50% of terminals containing these large vesicle-like structures abut against pituicytes, while approximately 20% are adjacent to basal lamina and approximately 30% are intermingled among other axon terminals (p<.005, Chi Square). 75% of terminals containing these structures are located in the center of the posterior pituitary and 25% are located around the periphery of the pituitaries (p<.005, Chi Square). Alonso and Assenmacher (Cell Tissue Res, 1981, 219:525) have shown that supraoptic nucleus sends terminals primarily to the center of the posterior pituitary, with scattered projections to the periphery, while paraventricular nucleus projects terminals only to the periphery. To the best of our knowledge this is the first report of these large vesicle-like structures in the posterior pituitary of the female rat. Supported by NS 09140 and Trgr NS 07279.

RAPID SYNAPSE FORMATION AND NEURONAL/GLIAL PLASTICITY IN RAT SUPRAOPTIC NUCLEUS IN RESPONSE TO A SINGLE HYPERTONIC SALINE INJECTION. G.H. Beagley & G.J. Hatton. Psych. Dept. & Neurosci. Program, Michigan State Univ., E. Lansing, MI 48824.
Neurosecretory neurons of the supraoptic nucleus (SON) manufacture, transport and secrete the neuropeptide hormones oxytocin and vasopressin. These neurons have been shown to be osmotically activated by administration of hypertonic NaCl. We examined, ultrastructurally, changes in several morphological parameters in response to an acutely induced rise in plasma osmotic pressure. Male rats were given intraperitoneal injections of isotonic (0.15M) or hypertonic (1.5M) NaCl solution and sacrificed 5 h after injection. Electron micrographs of the SON of 14 NaCl injected rats (6, 0.15M; 8, 1.5M) were compared to determine morphological differences in the magnocellular neuroendocrine cell (MNC) somata in the two conditions. In the SON cell body zone significant decreases were found in the extent of glial contact with the MNC membrane (0.15M=73%, 1.5M=57%, p<.001); amount of nerve terminal contact with MNC membrane increased (0.15M=10%, 1.5M=13%, p <.01); and amount of apposition of MNC membrane with other MNC cell bodies or dendrites increased (0.15=7%, 1.5=19%,p<.001). Number of multiple synapses (one terminal contacting 2 or more cells) per 100 um of somatic membrane in the 1.5M NaCl condition was double that found in the 0.15M NaCl condition. Both size of nucleoli and overall cell body size were significantly larger in the animals injected with 1.5M NaCl. The 1.5M injection increased the amount of Golgi apparatus from 16% to 28% of the cross sectional profile of MNCs (p<.001). These changes accompany the known increased activation of the MNCs of the SON by intraperitoneal injection of 1.5M NaCl. That these morphological changes all occurred within five hours of the injection indicates a degree of plasticity heretofore unappreciated. Supported by NS 09140 and NS07279.

OSMOTICALLY INDUCED CHANGES IN NEURONAL/GLIAL RELATIONSHIPS IN RAT NEURAL LOBE ARE DEPENDENT ON SYSTEMIC EPINEPHRINE. G.J. Hatton & G.H. Beagley. Neurosci. Program & Dept. of Psychology, Michigan State Univ., E. Lansing, MI 48824.
Posterior pituitary glial occupation of the basal lamina (BL) decreases and neural occupation increases with stimuli that elevate neuropeptide release into the blood. Since the origin(s) of the catecholamines thought to be involved in the glial movement are unknown, we investigated the possibility that blood borne epinephrine might provide a signal. Three groups of male rats were given intraperitoneal injections of either hypertonic (1.5 M) or normal (0.15 M) NaCl and were sacrificed five hours after the injection. One group was given 1.5 M or 0.15 M NaCl with no additional treatment, one group was anesthetized from the time prior to the injection until perfusion, and one group was bilaterally adrenal-medullectomized (MDX) 7 days prior to the NaCl injections. Morphometry on electron micrographs revealed that 1.5 M NaCl alone produced a significant increase in neural occupation of the BL compared to 0.15 M NaCl (63% and 36%; p<.001). Rats given 1.5 M NaCl under anesthesia showed no change in neural occupation when compared to anesthetized rats given 0.15 M NaCl (38% and 34%). Neural occupation of the BL in MDX animals given 1.5 M NaCl injection was the same as in MDX rats receiving 0.15 M NaCl: 33% and 36%, which was no different from neural occupation shown by either anesthetized group or untreated rats receiving 0.15 M NaCl. We conclude that both anesthesia and adrenal-medullectomy prevented glial retraction under a condition that normally changes its occupation of the BL and that systemic epinephrine is involved. Supported by NS 09140.

412.5

RAPIDLY INDUCED SUPRAOPTIC DENDRITIC SYNAPSES: THE SAME AS THOSE FORMED IN PARTURITION? C. D. Tweedle, K. G. Smithson and G. I. Hatton, Neurosci. Prog., Michigan State University, East Lansing, MI 48824.
The magnocellular neurosecretory cells of the adult rat supraoptic nucleus show dramatic ultrastructural synaptic and astroglial changes under several conditions of increased hormone demand. Parturition (mainly involving oxytocin release) is accompanied by increase both in contact of dendrites by multiple synapses (DMS, one pre-synaptic terminal contacting more than one post-synaptic dendrite) and in direct dendro-dendritic contact ("bundling") in the mother rat. We also found evidence for similar changes in the same parameters with 25 min of transcardial perfusion of etherized male rats with high (325 mOsm) vs. lower (302 mOsm) warmed, oxygenated ACSF (Neurosci. Abstr. 15:1224). Further detailed observations and point intersection analysis of electron micrographs now demonstrate that, with parturition or high osmolality perfusion, the percentage of DMS to total number of dendritic synapses significantly increased with increased bundling. Interestingly, the novel synapses are identical with the two stimuli (symmetrical with clear and dense core granules). The time course of the rapidly formed DMS following perfusion indicate they must form by astroglial withdrawal from between dendrites allowing previously single terminals access to new post-terminal dendritic membrane. (Supported by NS 09140)

412.6

LONG-TERM INHIBITION OF VASOPRESSIN (VP) EXCRETION BY USING CENTRAL INJECTION OF AN IMMUNOCONJUGATE (ANTIBODY TO VP LINKED TO RICIN A CHAIN. A.Burlet, M. Chapleur*, B. Haumont-Pellegri*, F. Jansen**, B. Fernette*, J.P. Nicolas* and C. Burlet*. INSERM U 308, Nancy, **Clin-Midy, Montpellier, France.
A monoclonal antibody (MAb) to vasopressin (VP) was specifically taken up and transported in VP producing neurons, when it was injected near the supraoptic nucleus (SON) of the rat brain. At the same time, the diuresis was increased, urine osmolality and VP excretion decreased whereas the ^{35}S-cysteine incorporation was prevented in the target neurons. The duration and the amplitude of these effects depended on the injection site, VP-MAb isotype and activation of the complement cascade, but did not last more than 24hrs. In order to amplify these effects, an immunoconjugate (IT) constructed with purified VP-MAb (IgG1k isotype) and ricin A chain has bilaterally been injected near SON and different parameters measured in freely moving rats. One injection of IT was less efficient than one injection of an ascites fluid containing IgG2a isotype of VP-MAB to increase diuresis and decrease VP excretion. A long-term inhibition of VP excretion was induced by the addition of monensin and plasma complement to IT. Ten days after the last injection of this mixture, the diuresis was high, urine osmolality reduced and urine content of VP lowered (177±35pg/ml vs 648±108pg/ml). Immunocytochemical observations confirmed dramatic disturbances of VP producing neurons at the level of injected nuclei whereas VP producing neurons of other hypothalamic regions were activated.

412.7

DEVELOPMENT OF THE HYPOTHALAMIC CATECHOLAMINERGIC SYSTEM AND ITS PHARMACOLOGICAL DEPLETION DURING ONTOGENESIS. A. Trembleau*, M. Ugrumov*, J. Bernabé*, A. Calas. Lab. Cytol. IDN-CNRS, Lab. Physiol. Reprod., Univ. P. & M. Curie, Paris, France ; Inst. Develop. Biol., Acad. Sci. Moscow, USSR.
The development of the hypothalamic catecholaminergic (CA) system has been studied in rats from the 13th fetal till the 11th postnatal day with the combination of ^{3}H-thymidine radioautography and TH-immunocytochemistry as well as with HPLC of CA. Moreover, HPLC has been used to evaluate the reaction of the hypothalamic CA system in fetuses and in neonates following the treatment of pregnant rats (from the 13th day of gestation) and of neonates (from the 2nd day of life) with the inhibitors of catecholamine synthesis, either α-methyl-m-tyrosine or α-methyl-p-tyrosine. It has been demonstrated that the hypothalamic CA neurons were mainly originated between the 14th and 16th fetal day, that was followed by the synthesis and accumulation of dopamine. The parallel accumulation of noradrenaline (NA) and in a lesser extent of adrenaline (Ad) apparently showed the ingrowth of the NA and Ad fibers to the hypothalmamus via the medial forebrain bundle. By the end of fetal life, the content of dopamine reached the level observed at the 11th postnatal day. On the contrary, NA increased four folds over the same period. Ad remained at the lowest level in each age group. The long-term treatment of pregnant rats and neonates with the inhibitors of CA synthesis did not change the hypothalamic level of dopamine both in fetuses and neonates. On the contrary, the level of NA decreased more than 50% in fetuses and 70% in neonates. It means that this pharmacological model could be valuable to study the role of noradrenaline in the brain development and particularly in the differentiation of the target neurons. This model is currently used to study the possible role of NA in the differentiation of vasopressin and oxytocin neurons using *in situ* hybridization and northern blot methods.

412.8

A T-TYPE CALCIUM CURRENT IN VASOPRESSIN (AVP) AND OXYTOCIN (OT) NEURONS IN GUINEA PIG SUPRAOPTIC NUCLEUS (SON). K.R. Erickson, O.K. Ronnekleiv and M.J. Kelly. Dept. of Physiology, Oregon Health Sciences University, Portland, OR 97201-3098.
Single-electrode voltage clamp studies were performed in SON neurons with biocytin-filled electrodes. A T-type calcium current was characterized in AVP and OT neurons, which were identified with a double labeling procedure (Ronnekleiv et al., BioTechniques 9:432-438, 1990). The T-type calcium current was TTX-insensitive, and was blocked by 100-500 μM NiCl in a dose-dependent manner. The activation threshold was -64 ± 1 mV (N=9), and peak current occurred within 30-50 ms. The T-type current appeared to be a requisite feature for a depolarizing potential (DP) to occur, which in AVP cells was critical for phasic firing. Hyperpolarizing pre-steps elicited a damped oscillating potential (DOP) following the offset of the hyperpolarizing step in cells exhibiting a T-type calcium current (N=10). Cells without a T-type calcium current exhibited no such oscillations (N=12; χ^2: p=.0001, df=2). Since later components of the DOP resembled the DPs observed in phasically-firing neurons in time course and amplitude, it appeared that the T-type calcium current underlies the DP measured in current clamp, and therefore is necessary for phasic firing to occur in AVP neurons of guinea pig SON. (Supported by PHS grants DA05158 and HD00718).

412.9

CONVERGENCE OF μ-OPIOID AND $GABA_B$ RECEPTORS AT AN INWARDLY RECTIFYING K^+ CONDUCTANCE IN HYPOTHALAMIC NEURONS: MODULATION BY ESTROGEN. M.J. Kelly, M.D. Loose and O.K. Ronnekleiv. Dept. of Physiology, Oregon Health Sciences U., Portland, OR 97201-3098.

The effects on neurons of the arcuate nucleus, including β-endorphin neurons, of the $GABA_B$ agonist baclofen and the μ-opioid agonist Tyr-D-Ala-Gly-MePhe-Gly-ol (DAMGO) were compared in hypothalamic slices from guinea pigs (GP) and rats. Intracellular recordings (3% biocytin) were made in hypothalamic slices prepared from proestrous rats or ovariectomized GP which were treated with estradiol benzoate (EB) or oil for 24 hr. Baclofen hyperpolarized all of the cells (GP:12$\pm$2 mV, N=12; rat:8$\pm$3 mV, N=11). DAMGO hyperpolarized all of the GP (N=6) and 4 of 7 rat neurons. Both baclofen and DAMGO caused a decrease in R_{in}. The baclofen-induced current reversed at $\approx E_{K+}$ and exhibited inward rectification as did the DAMGO-induced current. The response to either baclofen or DAMGO was occluded by a maximal dose of the other agonist. EB treatment caused a rightward shift in the dose-response curve for baclofen which was similar to the 3.4 fold shift in the DAMGO dose-response curve. It appears that μ-opioid and $GABA_B$ receptors open the same inwardly rectifying K^+ channels and that estrogen alters a component (G-protein, channel) that is activated by and common to both of these receptors. (PHS grant DA05158).

412.10

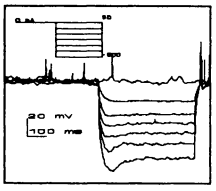
INTRINSIC MEMBRANE CURRENTS IN GUINEA PIG VASOPRESSIN (AVP) NEURONS DICTATING PHASIC FIRING. O.K. Ronnekleiv, K.R. Erickson and M.J. Kelly. Dept. of Physiology, Oregon Health Sciences U., Portland, OR 97201-3098.

Single-electrode voltage clamp studies in AVP-immunoreactive magnocellular neurosecretory cells in the supraoptic nucleus (SON) of guinea pigs revealed that these cells displayed two membrane currents not reported in rat SON, which were associated with phasic firing. The I_h was expressed in a greater percentage of AVP neurons (83%) than OT neurons (40%). The I_h was blocked by 2 mM CsCl (N=24) but not by 100-500 μM $BaCl_2$ (N=8). The time constant of activation followed a single exponential and decreased at more hyperpolarized membrane potentials (700-200 ms). The I_h was modulated by forskolin, an adenylate cyclase activator, which shifted its activation range to more depolarized levels (4 of 6 AVP cells). The I_h appeared to interact with a T-type calcium current by depolarizing the cell into the range of activation of the T-current, which produced a regenerative, depolarizing potential (DP). The DP was associated with phasic firing in guinea pig SON AVP neurons (N=34; χ^2: p=.0004, df=2), and was present only in neurons possessing a T-type calcium current. While both currents were present in oxytocin neurons, these cells did not fire phasically, suggesting that the presence of the I_h and T-type calcium current are necessary but not sufficient for phasic firing to occur. (Supported by PHS DA 05158).

412.11

WHOLE CELL RECORDING OF NEURONS OF THE SUPRA-CHIASMATIC NUCLEI (SCN) STUDIED IN RAT BRAIN SLICE. E.A. Gallman, P.C. Nolan*, T.G. Waldrop and M.U. Gillette. Depts of Cell & Structural Biology and Physiology & Biophysics, University of Illinois, Urbana, IL, 61801.

The SCN in rat are the neuroanatomic substrate for the biological pacemaker underlying circadian rhythmicity. This rhythmicity is expressed *in vitro* in the hypothalamic brain slice preparation as a daily oscillation in overall firing frequency of SCN neurons, with peak activity occurring near the middle of subjective day. The intracellular mechanisms responsible for changes in firing frequency are unknown. As these cells are small (6-15 μm), they have proved hard to study with conventional intracellular techniques, and few such studies exist. We have begun examining these cells using whole cell patch recording in slice. Typically, these cells had resting potentials -40 to -60 mV, after-hyperpolarization (AHP) -5 to -15 mV, and overshooting action potentials of 55 to 85 mV amplitude. Our results also indicate that at least some SCN neurons have an inward rectifier current and many exhibit post-inhibitory rebound (PIR). Support: AFOSR-90-0205 & PHS NS 22155.



BRAINSTEM SYSTEMS

413.1

PATTERNS OF INNERVATION OF LOWER BRAINSTEM AND NODOSE GANGLION CELLS TO THE LIVER AND THE PANCREAS IN NORMAL AND DIABETIC RATS STUDIED BY A DOUBLE LABELING TECHNIQUE. T. Kono, M. Takada, and S. T. Kitai, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

Innervation patterns of the dorsal motor nucleus of the vagus (DMV) and the nucleus ambiguus (NA) to and the nodose ganglion (NG) from the liver and the pancreas were studied by a fluorescent double labeling technique in normal (N=5) and spontaneously diabetic Wistar BB rats (N=10). Under pentobarbital-chloral-hydrate anaesthesia, the cut end of each hepatic and pancreatic nerve was inserted into polyethylene tubings containing either 2μl of 5% True blue (TB) or 3% Diamidino yellow (DY) solution. After four days, animals were anaesthetized (pentobarbital 60 mg/kg) and perfused. The brainstem and NG were sectioned in coronal plane with 40μ thick and labeled neurons were examined under a fluorescent microscope.

In the normal rat, 3-5% of cells were double labeled and 92-95% single labeled in DMV and 40% of cells double labeled and 60% single labeled in NA. In diabetic rats, the number of double labeled neurons remained almost the same in DMV while in NA, they were reduced to only about 6%. In NG, around 40% of the neurons were double labeled in normal while only less than 10% double labeled in diabetic rats. Reduction in double labeled neurons in NA was due to a lack of labeling by pancreatic nerve and in NG due to hepatic nerve. These data indicate that in diabetic rats a strong central control of pancreatic action and sensory inputs on blood sugar from the liver are much reduced. Supported by USPHS grant NS20702.

413.2

COLLATERAL ORGANIZATION OF PARATRIGEMINAL AND SPINAL TRIGEMINAL NUCLEUS PROJECTIONS: A FLUORESCENT RETROGRADE TRACER STUDY IN THE RAT. D.W. Saxon and and D.A. Hopkins. Department of Anatomy, Dalhousie University, Halifax, NS B3H 4H7.

The paratrigeminal islands (PTI) and the marginal layer of the spinal trigeminal nucleus pars caudalis (SpV I) have complex efferent projections to the ipsilateral nucleus of the tractus solitarius (NTS), ipsilateral parabrachial nucleus (PBN) and contralateral ventrobasal complex (VBC) of the thalamus. In order to elucidate the collateral organization of the PTI and SpV I in the rat, fluorescent retrograde tracers (Fluoro-gold, True Blue, Diamidino Yellow and fluorescent latex beads) were injected in combinations into the NTS, PBN and VBC. Injections into the rostral NTS produced labelled neurons throughout the ipsilateral PTI and SpV I. After injections in the VBC labelled neurons were located predominantly in the caudal part of the PTI while after injections in the PBN they were dispersed throughout the PTI and were more numerous . SpV I neurons projecting to the VBC were abundant in the dorsal part of lamina I and tended to be located superficial to those projecting to the PBN. Small numbers of double labelled neurons were found in the PTI and dorsal SpV I following combined injections into the ipsilateral PBN/NTS and VBC/PBN. The topography of afferent projections to and the organization of projections from the PTI suggest that the PTI is distinct from SpV I. The collateralization of the PTI and the known visceral and somatic afferent input to the nucleus support the idea that the PTI plays a role in somatovisceral reflexes. Supported by MRC of Canada, Grant MT-7369.

413.3

PROJECTIONS FROM THE NUCLEUS PARAGIGANTOCELLULARIS IN THE VENTROLATERAL MEDULLA TO THE NEOCORTEX: A DOUBLE-LABELING STUDY IN THE RAT

R. Jaslow*, M. A. L. Nicolelis, R. C.S. Lin, J. K. Chapin and B. D. Waterhouse. Department of Physiology and Biophysics. Hahnemann University, Philadelphia, PA 19102-1192.

The rat paragigantocellularis (PGI) nucleus located in the ventrolateral medulla is known to be a site of convergence for projections arising from nuclei related to the control of autonomic and sensory functions. A broad range of anatomical and physiological studies had suggested that this structure may play a significant role in controlling cardiovascular function, specifically sympathetic tone. Recently, special attention has been drawn to the efferent projections of the PGI since this structure was shown to be one important source of afferents to the locus coeruleus (LC). Here, we provide evidence that the PGI is also a source of direct projections to multiple cortical areas. In this study, adult rats received small injections (0.2-0.4 µl) of two different retrograde fluorescent tracers, fluoro-gold (FG) and rodamine coated microspheres (RCMs), into the frontal and visual cortices respectively. Following a short survival period we observed that in all animals FG injections in the frontal cortex produced bilateral (with ipsilateral predominance) labeling in different nuclei of the ventrolateral medulla, including the PGI. RCMs injections centered in the visual cortex produced less dense labeling in the PGI. Moreover, double-labeled cells were also observed in the PGI, indicating that a small percentage of PGI neurons may give rise to projections to both frontal and visual cortices. These results suggest that PGI neurons have direct access to cortical circuits, providing a possible pathway through which autonomic and sensory information conveyed through this nucleus may influence cortical activity. *Sponsored by grants NS 29161 NS 26722 and FAPESP 88/4044-9.*

413.4

TOPOGRAPHIC ORGANIZATION OF PROJECTIONS FROM THE RAT DORSAL RAPHE TO THE PRINCIPAL NUCLEUS OF V, VPM THALAMUS, AND BARRELFIELD CORTEX. M.L. Kirifides, M.A.L. Nicolelis, R.C.S. Lin and B.D. Waterhouse. Department of Physiology and Biophysics. Hahnemann University, Philadelphia, PA 19102-1192.

Previous studies have demonstrated the existence of a crude topographic organization of the projections from the dorsal raphe nucleus (DRN) to selected target nuclei in the mammalian forebrain. The goal of the present study was to examine the distribution of DRN cells that project to sensory specific structures. In addition, the degree of collateralization of individual DRN cells to multiple sensory modality specific targets was assessed. Adult Long Evans hooded rats (250-350gms) received unilateral injections (.3-.5ul) of fluorescent retrograde tracers (Fluoro gold, rhodamine or fluorescein coated microspheres) into the principal nucleus of V (Vp), ventral posterior medial thalamus (VPM), and the "barrelfield" of the primary somatosensory cortex (BC). Following these injections, coronal sections (80um) through the DRN were examined using fluorescence microscopy. Following injections in VPM and Vp, retrogradely labeled cells were consistently observed in the ventromedial zone of the DRN and to a lesser extent in the dorsomedial region of DRN. Cells projecting to BC were concentrated in the dorsomedial zone of DRN but were also scattered in ventromedial and lateral wing regions of the nucleus. In the sagittal plane, cells labeled from each of the 3 injection sites were found throughout the rostrocaudal extent of the nucleus, with those projecting to VPM more concentrated rostrally and those projecting to Vp more concentrated caudally. Double labeled cells from a paired injection in the VPM and contralateral Vp were observed in the dorsomedial zone of the caudal DRN. In summary, DRN cells that project to different levels of the ascending somatosensory path are distributed within partially overlapping zones of the nucleus. The demonstration of double labeled cells in the DRN suggests that activation of individual dorsal raphe neurons may simultaneously influence efferent targets that are processing the same sensory information. These data are consistent with the notion that DR efferents are organized with respect to the sensory function of target structures. Supported by No. AFOSR-87-0138.

PROJECTIONS FROM THE DORSAL RAPHE NUCLEUS TO THE PEDUNCULOPONTINE AND LATERODORSAL TEGMENTAL NUCLEI. T.L. Steininger and B.H. Wainer. Dept. of Pharm and Phys. and Comm. on Neurobiology, University of Chicago, Chicago IL 60637.

The pedunculopontine (PPT) and laterodorsal (LDT) tegmental nuclei provide widespread cholinergic innervation of the thalamus, as well as other forebrain and brainstem regions, and are believed to participate in behavioral state control. Previous retrograde tracing studies have demonstrated putative projections to the PPT from the dorsal raphe nucleus (DR) (Steininger and Wainer, '89, Soc. Neurosci. Abstr. 15:452). To confirm DR innervation of the cholinergic PPT and LDT neurons, we have utilized the anterograde transport of *phaseolus vulgaris* leuko-agglutinin from the DR, in combination with choline acetyltransferase immunohistochemistry. Light microscopic examination revealed anterogradely-labeled fibers in the tegmentum. In the PPT and LDT, thin varicose fibers formed numerous pericellular contacts on soma and proximal dendrites of the cholinergic neurons. Innervation of the PPT was particularly denser in the pars compacta than in medial diffuse regions. Similarly, labeling in the LDT was denser in lateral regions. In future studies, putative contacts will be examined at the ultrastructural level to ultimately confirm synaptic innervation. Since the serotonergic DR has been implicated in sleep/wake control as well, the demonstrated projection from the DR to the PPT and LDT may serve as the anatomical substrate for behavioral state changes. Origin and function of spiral fiber input to the axon cap of the goldfish Mauthner cell. J.W. Scott[1], N.P. Beatty[2], S.J. Zottoli[2], and H. Korn[3]. Dept. Anatomy, Emory Univ., Atlanta, GA[1], Dept. Biology, Williams College, Williamstown, MA[2], Institut Pasteur, Paris, France[3].

The axon cap is a specialized region enclosing the Mauthner cell (M-cell) axon initial segment. Interneurons entering its periphery inhibit the M-cell by a "field effect" followed by conventional synaptic transmission. Other axons enter the central portion of the cap and spiral around the M-cell initial segment. Some of these axons make a morphologically mixed synapse, but their function is unknown.

HRP placed in the axon cap filled spiral fibers whose somata (about 15µm in diameter) lay contralaterally at the level of the Vth motor nucleus, 300-780µm rostral to the M-cell and 300-540µm lateral to the midline, their dendrites extending ventrally. Electrical stimulation near these somata produces a short latency intracellular M-cell depolarization, which can bring the cell to threshold, with an associated extracellular negativity that is maximal in the axon cap.

MORPHOLOGICAL PROPERTIES OF NUCLEUS TRACTUS SOLITARIUS NEURONS RECEIVING SENSORY INPUTS FROM UPPER AIRWAY RECEPTORS. R.D. Sweazey. School of Dentistry, University of Michigan, Ann Arbor, MI 48109.

Morphological characteristics of lamb nucleus tractus solitarius (NTS) neurons receiving taste and tactile information from the epiglottis and aryepiglottal folds were investigated using electrophysiological mapping, Golgi impregnations and immunohistochemical techniques. Areas of the NTS responsive to chemical or mechanical stimulation of upper airway receptors occupied about one-third of the total superior laryngeal nerve termination zone in the NTS. Within this NTS area was a region of chemical and tactile sensitivity surrounded by a region of tactile sensitivity. Large multipolar neurons with 3-10 primary dendrites predominate in areas of tactile sensitivity. Smaller multipolar neurons with 3-5 primary dendrites and elongate neurons having 2-3 primary dendrites predominate in NTS areas which responded to both chemical and mechanical stimulation of upper airway receptors. Within this latter region preliminary results suggest that GABA is primarily associated with elongate neuron while aspartate is most often localized in multipolar neurons. These results suggest that NTS neurons processing upper airway sensory information have morphological properties similar to neurons located in rostral NTS areas which process information from oral receptors. Supported by N.I.H. Grant DC00735.

PEPTIDE CONTAINING NEURONS WITHIN THE NUCLEUS OF THE SOLITARY TRACT OF THE PIGEON. M.L. Berk and L.A. Mullins*. Dept. of Anatomy, Marshall Univ. Sch. of Med., Huntington, WV 25755.

The distribution of neurotensin (NT), leu-enkephalin (LENK), cholecystokinin (CCK), and substance P (SP) containing neurons within the nucleus of the solitary tract (NTS) was determined immunocytochemically in colchicine treated pigeons. Each of these peptides has a unique distribution within the various NTS subnuclei. Many cell bodies containing LENK and NT were observed within the anterior parts of subnuclei medialis dorsalis and medialis intermedius. Fewer cell bodies containing LENK were also found within the posterior parts of subnuclei medialis dorsalis, medialis intermedius, medialis ventralis, lateralis dorsalis, and the caudal most NTS (posterior to the obex). Most of the CCK containing cell bodies were found at the level of the obex in subnucleus medialis superficialis and the adjacent caudal subdivision of NTS. Most of the SP containing cell bodies were located within all anterior-posterior levels of NTS subnucleus medialis ventralis. The peptide containing neurons in these NTS subnuclei may function as interneurons or as long ascending projection neurons in the transmission of visceral sensory information. The anterior divisions of subnuclei medialis dorsalis and medialis intermedius, which contain NT and LENK neurons, are the primary recipients of esophageal afferent fibers (Katz and Karten, '83). These LENK and NT cells probably have local connections based on previous tracing studies. The CCK containing cells in the caudal NTS and subnucleus medialis superficialis pars posterior may have ascending projections to the forebrain and parabrachium (Berk, '87; Arends et al., '88). The SP neurons in the posterior part of subnucleus medialis ventralis may also have ascending projections. Double-labelling experiments are in progress. Supported in part by grants NSF R11-8922106 and NIH RR05870.

DISCHARGE PROPERTIES OF MEDIAN RAPHE NEURONS IN FREELY-MOVING RATS DURING SLEEP-WAKING STATES. R.P. Vertes and B. Kocsis. Center for Complex Systems, Florida Atlantic Univ., Boca Raton, FL 33431

We previously demonstrated that median raphe (MR) stimulation desynchronizes the hippocampal EEG, and MR lesions have been shown to produce continuously-running theta independent of behavior. We propose that the MR may control the hippocampal desynchronization of quiet waking and slow-wave sleep (SWS). Previous reports in cats have shown that serotonergic MR neurons fire at low rates in all behavioral states (i.e., < 2-3 spikes/sec) and at progressively lower rates from waking (W) to SWS to REM sleep, while nonserotonergic MR neurons discharge at high rates in waking (W) (19-20 spikes/sec) lower rates in SWS (4-5 spikes/sec) and relatively high rates in REM sleep (9-10 spikes/sec).

Adult male rats were permanently implanted with electrodes for recording the cortical and hippocampal EEG, the neck EMG and single unit activity in the MR during sleep-waking states. To date we have sampled the activity of 18 MR neurons; 17 of the 18 cells exhibited discharge characteristics of nonserotonergic MR neurons. The majority of non-5-HT cells fired at very high spontaneous rates during the waking state (i.e., > 30 spikes/sec). Of the non-5-HT cells analyzed across all behavioral states, three populations emerged: (1) cells that fired at approximately equivalent rates in W and REM (21.7) and low rates in SWS (11.3); (2) cells that maintained high rates in W (18.9), very low rates in REM (1.05) and low rates also in SWS (2.4); and (3) cells that discharged at high rates in SWS (29) and low rates in both W and REM (5.1). All of the above values in spikes/sec. The third type of cell may be involved in controlling states of hippocampal desynchronization.

RESPIRATORY NEURONS IN THE CAUDAL MEDULLA OF THE FROG, *RANA CATESBEIANA*. K. Kogo, S.F. Perry* and J.E. Remmers, Dept. of Medical Physiology, Univ. of Calgary, AB, Canada T2N 4N1.

To better understand the neural mechanisms underlying the coordinated cyclic movements of buccal and lung ventilation in the frog, we have begun classifying in the caudal medulla "respiratory neurons", the activity of which correlated with this rhythmic activity. Decerebrated, unanesthetized, paralyzed bullfrogs were used. We recorded the motor output from cranial nerves (CN) V, X and XII as well as the intra- or extracellular activity of respiratory neurons. In addition, the response of these neurons to stimulation of CNIX and X was investigated.

We found respiratory neurons, including motoneurons and non-antidromically activated neurons, from the area in and around the motor nuclei of CNIX, X and XII. Neurons which were active during both buccal elevation (Be) and lung ventilation (L), and others active during both buccal depression (Bd) and during the phase immediately preceding lung ventilation (preL) were designated Be&L and Bd&preL neurons, respectively. Motoneurons which projected to the main branch of CNXII were of the Be&L type, whereas, those projecting to the sternohyoid branch of CNXII were Bd&preL neurons. Some neurons were active (L+), or inactive (L-) only during the L phase. Motoneurons projecting to the laryngeal branch of CNX were either L+ or L-. In addition, we demonstrated Bd-Be neurons which were active during the transition between phases, and a special type of L+ neuron with cardiac modulation. Some of the above neurons could be excited by stimulation of CNIX and X. (Supported by PBF Foundation)

SYNAPTIC POTENTIALS IN MESOPONTINE CHOLINERGIC NEURONS EVOKED BY LOCAL STIMULATION *IN VITRO*. C.S. Leonard and R. Sanchez, Center for Neural Science, NYU 6 Wash. Pl. NY, NY 10003.

The synaptic activation of pedunculopontine (PPT) and laterodorsal tegmental (LDT) neurons was studied with intracellular recording methods in a guinea pig brain slice preparation. Brain slices were cut in the coronal plane and local stimulation was delivered through an electrode placed at the midline or in the central grey ipsilateral to the recording side. Cholinergic neurons were identified by combined intracellular injection of biocytin and histochemical staining for NADPH-diaphorase. Constant current pulses evoked a sequence of graded psps consisting of a fast epsp followed by a fast ipsp and slow ipsp. The epsp could be large enough to evoke an orthodromic spike and displayed both facilitation and post-tetanic potentiation with stimulus trains (100Hz for 0.3-1S). In normal Ringer (3mM Mg) the epsp was completely abolished by 10uM DNQX suggesting that a major component is mediated by non-NMDA receptors. Blocking the epsp uncovered the fast ipsp which reversed near -75mV and was blocked by picrotoxin suggesting activation of $GABA_a$ receptors. Trains of stimuli also produced facilitation and potentiation of the fast ipsp. The slow ipsp fluctuated considerably following single stimuli. Trains of stimuli enhanced the slow ipsp which could be evoked by stimulus trains at strengths below those necessary for fast psps. The slow ipsp was insensitive to picrotoxin and in the presence of DNQX reversed at more hyperpolarized potentials than the fast ipsp suggesting the slow ipsp was mediated by activation of a K conductance. Since conditions were found to evoke each of these potentials independently, it is likely that mesopontine cholinergic neurons receive projections from both rapid signalling and modulatory systems.

VOLTAGE-DEPENDENT MEMBRANE CURRENTS IN ACUTELY DISSOCIATED BRAIN STEM NEURONS OF RATS, C.Jiang, T.R. Cummins and G.G. Haddad, Section of Respiratory Medicine, Dept. of Pediatrics, Yale Univ. Sch. of Med., New Haven, CT 06510

In order to elucidate fundamental mechanisms underlying the neural control of cardio-respiratory function, it is essential to identify the inherent membrane properties of brain stem neurons. To study these properties in isolation, neurons from the hypoglossal (XII) nucleus (n=45) and the dorsal motor nucleus of vagus (DMX, n=105) were freshly dissociated separately and studied under whole-cell voltage clamp. Using specific blockers, reversal potentials and ion substitutions, several membrane currents were characterized. XII neurons showed only one TTX-sensitive Na^+ current and two outward currents: one sensitive to TEA (40 mM) and the other to Cs^+ (1 mM), suggesting that there are a delayed rectifier (K_V) and an inward rectifier (K_H) in XII neurons. In contrast to XII neurons, DMX neurons had two inward currents. TTX (3 μM) and Na^+ removal decreased but did not abolish the inward current. Addition of Co^{++} (1-2 mM), however, eliminated all the remaining inward current, indicating that both Na^+ and Ca^{++} (high threshold) currents are present in DMX cells. Two transient outward currents were observed in DMX neurons. One was 4AP-sensitive and the other was Co^{++} but not apamin sensitive. The remaining outward current was blocked by extracellular TEA (40 mM) and Cs^+ (1 mM) suggesting that K_A, K_{Ca}, K_V and K_H exist in DMX cells. We conclude that 1) XII and DMX neurons have different membrane currents and these currents underlie their different repetitive firing properties and 2) these results substantiate our previous data in slices since the same voltage-dependent conductances were also observed in isolated neurons.

RESPONSES OF RAPHESPINAL NEURONS TO VESTIBULAR NERVE STIMULATION IN THE CAT. B.J. Yates, T. Goto* and P. Bolton. Lab. Neurophysiology, The Rockefeller Univ., New York, NY 10021

Although vestibulosympathetic reflexes have long been known to exist, and to be potentially important in compensating for orthostatic hypotension [Doba and Reis, Circ. Res., 1974], little is known about the neural pathways which relay vestibular signals to sympathetic preganglionic neurons. The caudal medullary raphe nuclei are possible mediators of these reflexes, as considerable evidence suggests they contain many neurons which project to the thoracic intermediolateral cell column [Morrison and Gebber, J. Neurophysiol., 1985]. We tested whether neurons in raphe pallidus and raphe magnus of the decerebrate cat that projected to the thoracic spinal cord responded to electric stimulation of the vestibular nerve. Twenty of 28 raphespinal neurons with conduction velocities between 1 and 4 m/s received vestibular inputs; 13 of the 20 were inhibited, and 7 were excited. Raphe neurons which make synapses upon sympathetic preganglionic neurons have similar slow conduction velocities [Morrison and Gebber, 1985]. In addition, 34 of 42 raphespinal neurons with more rapid conduction velocities (6-78 m/s) also received vestibular signals; 26 were excited, and 8 were inhibited. Raphespinal neurons with conduction velocities > 5 m/s are known to terminate in both the dorsal (laminae I, II, V and X) and ventral horn (lamina VII) of the spinal cord [Light, J. Comp. Neurol., 1985] and therefore are potentially involved in modulating excitability in both sensory and motor pathways.

Slowly-conducting raphespinal neurons thus appear to be a possible route through which vestibular signals can reach sympathetic preganglionic neurons. In addition, rapidly-conducting raphespinal neurons may be in part responsible for vestibular-elicited effects on sensory and motor pathways in the spinal cord.

FOS-LIKE IMMUNOREACTIVITY (FLI) IS INDUCED IN NEURONS OF THE MEDULLA OBLONGATA AFTER STIMULATION OF THE CAROTID SINUS NERVE (CSN) IN AWAKE OR ANESTHETIZED RATS. J.T. Erickson and D.E. Millhorn (*University of North Carolina, Chapel Hill, NC*)

Expression of the protooncogene c-fos has been used as a metabolic marker for tracing polysynaptic neuronal pathways after discrete central or peripheral stimulation (Science 237:192.1987). In this study, CSN afferent fibers were stimulated either electrically or via hypoxia in anesthetized or awake rats. After a suitable recovery period, the medulla was perfused, sectioned, and processed immunohistochemically to detect FLI. A discrete distribution of Fos-labeled cells was observed within nucleus tractus solitarius, area postrema, ventrolateral medulla, nucleus raphe pallidus, and superficially on the ventral medullary surface. We believe these cells represent higher order neurons within the baro- and chemoreceptor reflex pathways. FLI in surgically prepared but unstimulated animals and in animals breathing a normoxic gas mixture was substantially reduced compared to stimulated animals. Studies using immunohistochemical double labeling techniques suggest that some of these functionally activated cells colocalize serotonin or tyrosine hydroxylase, the rate-limiting enzyme for catecholamine biosynthesis. BEHAVIORAL AND BIOCHEMICAL STUDIES ON THE ROLE OF GABA-B RECEPTORS IN THE MEDIAN RAPHE NUCLEUS. D. Wirtshafter, T.R. Stratford, M. Pitzer & J.C. Krebs. Dept. Psychology, Univ. Ill. at Chicago, Box 4348, Chicago, Il 60680.

We have shown that injections of the GABA-A agonist muscimol into the median raphe nucleus (MR) produce hyperactivity, a reduction of hippocampal serotonin metabolism and an acceleration of dopamine metabolism in the nucleus accumbens. We examined here whether similar effects could be produced by stimulation of GABA-B receptors. Microinjections of 62.5-500 ng of the GABA-B agonist baclofen into the MR resulted in dose dependent hyperactivity which was immediate in onset. Injections into the the adjacent dorsal raphe nucleus or the ventral tegmental area resulted in smaller, delayed, increases. The baclofen effect was stereospecific and could be eliminated by coinjection of the GABA-B antagonist 2-hydroxy-saclofen. These findings support the anatomical and pharmacological specificity of the baclofen effect. Baclofen produced only small effects on hippocampal serotonin metabolism, but resulted in a large increase in accumbens dopamine metabolism.

The current findings suggest that GABA-B receptors play a functional role within the MR.

413.16

EFFECT OF GABA ON NEURON TYPES IN GUSTATORY ZONE OF RAT NUCLEUS TRACTUS SOLITARIUS USING WHOLE CELL RECORDINGS IN BRAIN SLICES. R. M. Bradley, S. Boucher and Wang Limei*. School of Dentistry, University of Michigan, Ann Arbor, MI 48109-1078.

We have used whole cell recordings in brain slices to characterize the biophysical and pharmacological properties of neurons in the gustatory zone of the nucleus tractus solitarius (NTS). Three neurons types have been characterized using a current injection paradigm which hyperpolarized and then immediately depolarized the neuron. The hyperpolarizing pulse resulted in an irregular pattern of action potentials initiated by depolarization in Type I neurons. In Type II neurons the hyperpolarizing pulse either delayed the initiation of the first action potential or resulted in a long first interspike interval in the spike train initiated by the depolarizing pulse. The hyperpolarizing pulse had no influence on the spike train initiated by depolarization of Type III neurons. When GABA (1 mM) was superfused over the slices, the resting membrane potential of all three types of neuron was hyperpolarized. This was accompanied by a fall in membrane resistance and marked reduction in excitability. These results demonstrate that GABA alters membrane properties of all three types of neurons in gustatory NTS. Supported by N.I.H. Grant DC000288.

NEURONS RECORDED EXTRACELLULARLY FROM KOELLIKER-FUSE AND PARABRACHIAL REGIONS OF A RAT IN VITRO BRAINSTEM PREPARATION. V.M. Tronnier*, P.C. Rinaldi and R.F. Young. Div. of Neurological Surgery, University of California, Irvine, CA 92717.

As part of ongoing work to study the role of the Koelliker-Fuse (KF) nucleus in pain modulation a slice preparation was developed to define cellular characteristics of KF and parabrachial (PB) neurons and to confirm anatomically described projections to the trigeminal system. Extracellular recordings of the activity of PB and KF neurons were carried out in rat brainstem coronal sections (400 uM). To aid in visualization of anatomic landmarks fast green was initially added to the recording chamber with the slice in static bath conditions. Once appropriate locations for recordings were determined, the slice was maintained and recordings obtained in submerged conditions. Standard extracellular techniques with both pipettes and tungsten microelectrodes were used and signals were recorded digitally for later off-line computer analysis. Stimulation was accomplished with a 50 uM twisted Nichrome wire bipolar electrode. Both spontaneous and evoked unit activity was monitored.

To date, 20 cells have been examined. 15 of these were localized in KF, 3 in the external medial parabrachial and 2 in the external lateral parabrachial subnuclei. In 8 of the cells amplitudes ranged between 20 and 35 uV and in 12 cells amplitudes ranged from 10 to 15 uV. According to frequency pattern, 4 cell types could be distinguished: 4 showed a constant discharge frequency of 10/sec; 6 of 1-3/sec; 6 of 6-8/sec; and 3 cells showed rhythmic patterns of firing. Interestingly, evoked activity could be found in only 2 of 20 cells after stimulation of the motor trigeminal nucleus. Stimulation of principal sensory trigeminal neurons had no influence on the spontaneous activity of KF or PB cells although connections between these structures have been described.

413.18

NICOTINIC PROLONGATION OF HALOTHANE ANESTHESIA BY THE INTERPEDUNCULAR NUCLEUS. R. Wojcik, K. Abate, M. Andresen* and I. D. Hentall. Univ. of Ill. Coll. of Med., Rockford, Illinois, USA 61107.

The metabolic rate of the interpeduncular nucleus (IPN) has been shown to be higher in anesthetized than awake animals. This phenomenon is associated with an increased release of acetylcholine (ACh) (see accompanying abstract). The effect of increased cholinergic activity on the state of anesthesia is thus an important question.

Through a chronically implanted guide cannula, nicotine (2 µl 10^{-5} to 10^{-1} M) or saline was microinjected near the IPN of 300 g female rats (n=20) immediately after discontinuation of 10 min of 3% halothane anesthesia. Fast green dye marks allowed histological verification of injection sites. A dose-dependent prolongation of the time taken to recover righting reflexes was seen; mean prolongation for 10^{-2} M nicotine was 65%. The number of breaths taken by the rat before recovery was similarly increased. The duration of anesthesia was shortened 17% by microinjection of the nicotinic antagonist hexamethonium (2 µl 10^{-1} M, n=10). The nicotinic antagonist mecamylamine (2mg/kg) given intramuscularly prior to anesthesia blocked the effect of 10^{-2} M nicotine (n=10).

These data suggest that ACh release from the IPN contributes to the maintenance of anesthesia.

(Supported by NINDS grant 26116.)

413.19

ACETYLCHOLINE RELEASE IN THE INTERPEDUNCULAR NUCLEUS IS MODULATED BY SUBSTANCE P, PENTOBARBITAL, KETAMINE, AND HALOTHANE. K. Abate, R. Wojcik, K. Taguchi, M. Andresen*, T. Shibuya, Y. Suzuki* and I. D. Hentall. Univ. of Ill. Coll. of Med., Rockford, Illinois, USA 61107.

Many afferents to the interpeduncular nucleus (IPN) contain acetylcholine or substance P. Since the IPN has an unusually high metabolic rate during anesthesia, we tested how the release of ACh is affected by diverse anesthetic agents and by substance P.

Microdialysis tubes were stereotaxically implanted in the rat's IPN, and the extracted ACh was measured by HPLC. In pentobarbital-anesthetized acute preparations, mean [ACh] was 1.32 ± 0.73 pmol (15 min samples of 25 µl). This level was not affected significantly by electrical stimulation (3 Hz, 0.2 ms, 100 µA for 15 min) of the fasciculus retroflexus, which is a major input pathway to the IPN. In chronic awake rats, mean [ACh] was 0.62 ± 0.27 pmol. This value subsequently increased 298% by 100 mg/kg i.m. ketamine (n=3), 212% by 50 mg/kg i.m. pentobarbital (n=2), and 230% by inhaled 3% halothane (n=2). The presence of substance P in the dialysis tube's inflow reduced ACh release in awake animals (20 ± 5% for 10^{-5}M).

We conclude that more ACh is released from the IPN in anesthetized than awake rats, and that substance P directly or indirectly inhibits this release.

(Supported by NINDS grant 26116.)

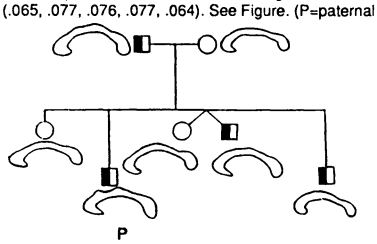
PRENATAL RISK AND CORPUS CALLOSUM DEVELOPMENT IN LANGUAGE AND LEARNING IMPAIRED CHILDREN. P.E. Cowell, T.L. Jernigan, P.A. Tallal and V.H. Denenberg. Biobehavioral Sciences Graduate Program, Univ. of Connecticut, Storrs, CT 06269, Dept. Psychiatry, UCSD, La Jolla, CA 92093 and Center for Molecular and Behavioral Neurosciences, Rutgers Univ., Newark, NJ 07102.

Jernigan et al. (Arch. Neurol., 1991) have shown that regional cortical volume asymmetry patterns differ between language and learning impaired (LLI) children and age matched controls. Since LLI children had substantial aberrations in cortical anatomy, regional differences in callosal (CC) size were investigated. Subjects were 20 LLI males and females (ages 8-10 years). Prenatal risk scores were also available. Callosal drawings were rendered from midsagittal MRIs and digitized using the computer-aided program Stereology. Parameters obtained included callosal area, axis length, perimeter, and 99 widths. The widths were divided into seven clusters defined by previous factor analysis and consisted of averaged widths 3 through 18 (W3-18), W22-39, W49-62, W65-74, W77-85, W89-94, W95-99. Analyses compared LLI subjects on the basis of high vs. low Prenatal risk defined by a median split of scores. In an ANOVA including all Widths, Prenatal risk was highly significant. Overall, high risk children had smaller CCs than low risk children. There was also a marginally significant Sex x Prenatal x Width interaction indicating that the pattern of affected CC regions was not identical for males and females. In addition, there were significant correlations between Prenatal risk score and CC parameters. Sensitivity of this fiber tract to Prenatal risk factors appears to be an important characteristic of LLI children.

414.2

INHERITANCE OF CORPUS CALLOSUM SIZE AND SHAPE IN FAMILIES WITH DEVELOPMENTAL DYSLEXIA.. A.Kushch*, R.Duara, B.Jallad*, H.Lubs*, M.Rabin*,B.Levin*. Univ. of Miami Sch. of Med., Miami, FL 33101.

As part of a three generation familial dyslexia study, 63 members from 8 different families were scanned using magnetic resonance imaging. The corpus callosum and mid-sagittal brain areas were traced in T-1 weighted mid-sagittal slices. Planimetric measures were taken of the genu, splenium, total corpus callosum, and mid-sagittal brain areas. One family showed an inheritance pattern in the total normalized corpus callosal area that was suggestive of autosomal dominant inheritance: with the father and one son having a larger corpus callosal size (.096, .086) and the mother and remaining 4 children having average sizes (.065, .077, .076, .077, .064). See Figure. (P=paternal size)



The corpus callosal size did not distinguish between dyslexics and non-dyslexics in this family. Currently, sib-pair analysis on both corpus callosal angulation and area measurements are in progress on the overall sample.

414.3

ANATOMY OF THE PLANUM TEMPORALE IN RELATION TO SIDE, HANDEDNESS AND SEX S.F. Witelson and D.L. Kigar*, Dept. of Psychiatry, McMaster Univ., Hamilton, Ont., Canada, L8N 3Z5

To assess the relationship of neuroanatomical and functional asymmetries, the planum temporale (PT), part of the posterior language region, was measured in 67 postmortem brains from 24 ♂ and 43 ♀ whose hand preference [consistent-right-handed (CRH) and nonCRH] was tested prior to death. PT was defined as the extent of the dorsal surface of the superior temporal gyrus from Heschl's main transverse sulcus to the end of the Sylvian fissure (SF), and a vertical (V) segment was measured in addition to a horizontal (H) segment when the SF bifurcated in the posterior region. (1) Area of H was greater in the left (L) hemisphere; area of V was greater, to the same extent, in the right (R), making overall size of PT equal in the two hemispheres, although morphologically asymmetrical. (2) Area of H varied with handedness and sex; in contrast, area of V did not differ among the 4 hand-sex subgroups. H was larger in CRH than nonCRH and tended to be larger in ♂. (3) A laterality score for H (L-R/L+R) showed that among ♂, nonCRH had a greater anatomical asymmetry than CRH; among ♀ there was no difference between hand groups. (4) The greater asymmetry in nonCRH men was due to a smaller H in the R hemisphere compared to CRH men; there was no difference between the L hemispheres. To sum, these results indicate that there is marked L-R asymmetry in PT; that PT anatomy is related to hand preference and, by inference, to the pattern of functional asymmetry; but that this relation of structure to function holds only for ♂, not ♀ (as found for the anatomy of the corpus callosum in relation to handedness, Witelson & Goldsmith, 1991). Supported by U.S. NINDS.

RADIAL ARM MAZE MEASURES DEVELOPMENT OF SPATIAL MEMORY IN YOUNG CHILDREN. A. Peuster*, W.H. Overman, S. Caulfield*, R. Hakan. Psychology Dept., UNC-Wilmington, Wilmington, N.C. 28403.

The radial arm maze (RAM) has been used to measure spatial memory and hippocampal function in animals; however, it has rarely been used with humans. In this study, children (20-151 mo.) and adults searched for food rewards in a 8-arm RAM. Experimental conditions were: (1) one day of search in 8 open, baited arms followed by (2) 15 days of forced-choice search. In condition 2, four of the arms were closed and the subject searched the four open arms; then, after a delay (30-120 sec.) all arms were opened and the subject searched for the remaining baited arms. In condition one, there was a developmental progression: youngest children (20-40 mo.) performed at chance levels and older children (approx. 100 mo.) and adults performed at near perfect levels. In condition 2 adults significantly improved (trials 5-8) over the first 4 days of forced choice testing, but the youngest children failed to improve (trials 5-8) in 15 days of testing. However, since all subjects performed nearly perfectly on trials 1-4 of forced choice testing, this indicates that even the youngest children can remember at least four locations for a short period of time.

USE OF AN ODDITY TASK IN CHILDREN TO ANALYZE THE SOLUTION OF DELAYED NON-MATCH TO SAMPLE (DNMS). W. H. Overman, M. Miller*, K. Moore*, W. Kilpatrick*, C. Rogers* Psychology Department, UNC-Wilmington, Wilmington, N.C. 28403

The DNMS task has been used to measure hippocampal function in animals and man. Infant monkeys (Bachevalier and Mishkin, Beh. Neurosci. 98, 1984) and infant humans (Overman, Ann. N.Y. Acad. Sci.608,1990) are impaired in learning a DNMS task which has both a recognition memory and rule learning component. The trial-unique, simultaneous oddity task has a rule similar to DNMS but requires no recognition memory. Children (16-74 mo.) and adults were tested longitudinally and non-verbally on oddity. Oddity required significantly more trials to learn than DNMS, suggesting that impaired rule learning played a major role in the previous findings with DNMS. Subjects who failed to learn simultaneous oddity were then tested on two-part oddity (which was learned quickly), followed by retesting on simultaneous oddity (which was not learned quickly). Given the ABA design, the results suggest that two solutions are available for two-part oddity: win-shift and rule-learning (go to "odd").By inference, DNMS may be learned by infants on the basis of "win-shift", not on the basis of a rule "go to novel".

MEMORY SKILLS IN YOUNG SUBJECTS WITH CEREBELLAR TUMORS. J.A. Lazareff* and E. Castro-Sierra. Dept. of Neurosurgery and Lab. of Psychoacoustic Hospital Infantil de Mexico. 06720 Mexico, D.F. MEXICO.

Children (N=4; avg. age=10:7) with tumors of different etiologies of the cerebellum were studied for their abilities for carrying out visually- or auditorily-presented instructions and for naming and remembering visual images. These studies were undertaken before and after surgical treatment of the tumors by ablation. Results obtained were compared with those from children (N=2; avg. age=10:6) with cerebral tumors of different etiologies, both before and after ablation, and with those from normal children (N=2; avg. age=10:11). Subjects in the cerebellar tumor group manifested a distinct impairment for remembering and carrying out auditorily-presented instructions after surgical intervention. This impairment was especially noticeable in one female subject with an astrocitoma of the cerebellar vermis who suffered from total aphasia for 2 months after surgery. The abilities of the different groups for carrying out visually-presented instructions were at a par among all the groups tested. The results suggest the existence of auditory processing in cerebellar structures.

IMPAIRED MEMORY CAUSED BY HERPES SIMPLEX VIRUS INFECTION.
D.R. Beers*[1], J.S. Henkel*[2], W.G. Stroop*[2], S.F. Basinger[2]. [1]Program of Neuroscience, University of Utah, Salt Lake City, UT 84112; [2]Department of Ophthalmology, Baylor College Medicine, Houston, TX 77030.

Deficits of impaired intellectual function associated with herpes simplex encephalitis (HSE) have not been extensively investigated. Survivors of HSE experience intellectual impairment and an inability to store and recall information. These deficits are postulated to correlate with the stereotypic post mortem temporal lobe necrosis seen in this disease. Because olfactory and limbic system structures are central to storage and retrieval of memories, injury to these areas is believed to cause behavioral and learning disabilities. Therefore, an animal model is needed to explore the correlation between memory impairment and temporal lobe pathology. We have developed a rat model that mimics the physical and behavioral aspects of human HSE and does not involve invasive delivery of virus to the brain. Fifty-one percent of rats shed virus from their nose but rarely from their eyes following intranasal inoculation with 1.4 X 10^6 $TCID_{50}$ of syncytial forming herpes simplex virus type-1. Similar to HSE patients, these animals developed behavioral abnormalities and motor seizures. Memory dysfunctions were evaluated using a radial arm maze test to quantitate the acquisition of information of a learned task. Infected rats (N=8) performed at chance levels which was statistically different than controls (N=8). At different times post infection, rats showed histopathologic changes within the amygdala, hippocampus, and the entorhinal cortex. Viral antigens were also detected within these structures by immunohistochemistry. This model will allow neuroanatomic correlation between memory dysfunction with site-specific HSV replication, and provide a system to test compounds with potential antiviral or cognitive enhancing properties. *Supported by the Department of Veteran Affairs.*

LEARNING AND MEMORY—PHYSIOLOGY IV

LONG TERM RETROGRADE AMNESIA ON INHIBITORY AVOIDANCE AND CONDITIONED TASTE AVERSION LEARNING TASKS BY INSULAR CORTEX LESION. C.E. Ormsby*, A.L. Piña and F. Bermúdez Rattoni. Instituto de Fisiología Celular, UNAM. México, D.F. México. 04510

Previous works have described deficits in acquisition and consolidation of inhibitory avoidance (IA), spatial learning, and acquisition of conditioned taste aversion (CTA) produced by pre- and post-training reversible lesions of the insular cortex (ICx) (Bermúdez-Rattoni et al. PNAS. In press). Male Wistar rats were tested to observe the effects of ICx lesions on long-term memory of IA and CTA tasks. Twenty-six animals were trained in CTA and 48 hr later in IA, then assigned to 3 subgroups: one group (LxG) received bilateral electrolytic lesions of the ICx 48 hr after the IA training to allow consolidation, another, was sham operated the same day (ShG) and the third group served as control (CtlG). All animals were tested four days later for IA, and 11 days later for CTA. Results showed that the lesion of LxG significantly impaired IA, assessed by response latency and time spent in either compartment when compared with both the ShG and CtlG groups. Similarly, the CTA test showed significant impairment of the LxG in the recall of the aversive reaction to saccharin. These results confirm that ICx is necessary for the storage of long-term memory of previously learned avoidance conditionings.

415.2

Temporally graded retrograde and anterograde amnesia following ibotenic entorhinal cortex lesion in mice.
Y. H. CHO*, D. BERACOCHEA and R. JAFFARD. Lab. Neurosciences Comportementales et Cognitives , CNRS URA 339, Univ. Bordeaux I, Ave des Facultés, 33405 Talence, France.

The purpose of the present experiment was to study **retrograde amnesia** in mice by using a **spatial discrimination task** performed in 2 different 8-arm radial mazes. Animals learned successively, one at a time, and every 2 weeks, 5 pairs of adjacent arms (2 in the first maze and 3 in the second one). Bilateral ibotenic acid lesion of the entorhinal cortex (E. C.) was performed 1 hour after subjects reached the criterion on the 5th pair.

As compared to sham-operated animals, E.C. lesioned mice were severely impaired at remembering the 2 last pairs learned within **2 weeks before surgery** but had normal performance on those learned beyond this time period (**Retrograde Amnesia**).

Animals were trained on the second maze until they reattained the criterion on the each of 3 pairs learned before surgery. They were also trained on the 4th pair not previously used. Experimental subjects learned this 4th pair at the same rate as controls but when tested 2 weeks later, a significant forgetting was observed on the 3 pairs relearned post-operatively (**Anterograde Amnesia**).

These results confirm previous findings (Zola-Morgan and Squire, Science, 250, 288-290, 1990) and suggest that the hippocampal formation is required for **only a limited period of time after learning**. Beyond this critical period, normal performance would be supported by extra-hippocampal structures, thus suggesting a "**translocation**" of the internal representation. In addition, as shown by additionnal behavioral data, it seems that a **change in the code** of its representation might occured. This research was supported by Centre National de la Recherche Scientifique and by the Fondation pour la Recherche médicale Française.

INTRACELLULAR RECORDINGS FROM NEURONS IN THE FRONTAL CORTEX OF RATS PERFORMING LICKING CONDITIONED TO A LIGHT CUE. M.P. Kristensen and C.D. Woody. UCLA Medical Center, Los Angeles, CA 90024.

Male Sprague-Dawley rats were trained to lick for water when prompted by a light cue. Intracellular as well as extracellular recordings were obtained from neurons in the frontal cortex of animals performing the conditioned behavior in response to the light stimulus. The electrophysiological characteristics of the neurons were investigated with regard to discharge pattern for all cells and furthermore resting potentials and input resistances for intracellularly studied units, and the correlation of these parameters with the conditioned stimulus, the behavioral response or the reinforcement was analyzed.

Neurons showing increased discharge during and preceding licking were found. Intracellular recording disclosed depolarization of the baseline prior to the onset of licking and hyperpolarization at the cessation of licking.

INSTRUMENTAL CONDITIONING FOLLOWING SELECTIVE LESIONS OF THE NUCLEUS ACCUMBENS. B.W.Balleine* and A.S.Killcross* (SPON: Brain Research Association). Dept of Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB, UK.

Several investigators have suggested that the nucleus accumbens mediates the effects of the instrumental reinforcer and, as such, is involved in the control of instrumental performance. This hypothesis was assessed by examining the effects of bilateral ibotenic acid lesions (0.06M; 0.7 µL) of the nucleus accumbens on the instrumental performance of hungry rats in a free operant situation. In support of this proposal it was found that lever press responding for a food reward on a variable interval (VI) schedule was significantly impaired in lesioned animals relative to sham controls. Two potential accounts for this deficit were then examined, one associative and the other motivational. The associative account assumes that the lesion interferes with learning the response-reinforcer contingency. However, shifting reinforcer delivery from a contingent VI schedule to a noncontingent variable time (VT) schedule was found to produce a comparable decline in performance over trials in both the lesion and sham groups, suggesting that the lesion did not affect sensitivity to the instrumental contingency. Secondly, motivation to respond was assessed by shifts in primary motivation achieved by varying the number of hours of food deprivation prior to test sessions. This manipulation induced deprivation dependent changes in performance which were, again, similar in both the lesion and sham groups - indicating that the deficit in performance in lesioned animals was also not due to a change in the motivational significance of the instrumental reinforcer. These findings support the hypothesis that the nucleus accumbens is involved in instrumental conditioning but suggest that this involvement is not derived from a sensitivity to the instrumental contingency or the motivational significance of the reinforcer.

415.5

ACTIVATION OF THE VENTRAL TEGMENTAL AREA AFFECTS HIPPOCAMPAL EEG. K.B. Austin, Department of Psychology, McGill University, Montreal, Canada, H3A 1B1.

Dopamine (DA) neurons in the ventral tegmental area (VTA) project to the basal forebrain, and are known to mediate brain stimulation reward. The septal nuclei receive input from the VTA and also strongly influence the electrical activity of the hippocampal formation. In intact rats, lesions of the medial septum will abolish hippocampal theta rhythm and disrupt performance on spatial memory tasks. In addition, infusions of DA into the medial septum of chloral hydrate anesthetized rats will result in the generation of hippocampal theta rhythm. In freely-moving rat preparations, VTA activation using the GABA antagonist picrotoxin (PTX) produces compelled, stereotypical locomotion which is accompanied by hippocampal theta rhythm. To dissociate the behavior from the EEG changes, we recorded hippocampal EEG from chloral hydrate anesthetized rats and used local injections of PTX to activate the VTA. Intra-VTA PTX (15 ng in 0.5 uL) injections produced in an increase in EEG synchrony. FFT analysis revealed an increase in EEG power in the 3-5 Hz frequency band. This theta rhythm could be abolished by increasing the anesthetic infusion rate. Subsequent applications of PTX (up to 300 ng) could not reestabish theta, however, numerous sharp-wave complexes were observed at higher doses of PTX. This data demonstrates that the hippocampal EEG can be modulated by activation of the VTA. The VTA may play an important role in the generation of hippocampal theta and, thus, this experiment represents an important step in determining the interaction between reward and memory systems in the brain.

415.6

SUBJECTIVE REWARD MAGNITUDE AS A FUNCTION OF TRAIN DURATION AND STIMULATION STRENGTH

Terry Mark* and C. R. Gallistel Dept of Psychology, UCLA, Los Angeles, CA 90024-1563

We measured the subjective reward magnitude of electrical brain stimulation as a function of train duration and stimulation strength (where strength is defined as current x pulse frequency), using the matching law in two different ways. In the first method (trade-off method), the relative magnitudes of the rewards received from two different levers was estimated by the magnitude of the difference in the mean interreward intervals required to offset the difference in stimulation parameters. When the difference in mean interreward intervals offset the difference in reward magnitudes, the rat allocated its time equally between the levers. In the second method (direct method), the ratio of the reward magnitudes at the two levers was assumed to be directly given by the ratio of the rat's time allocations (after correction for side bias). The results of the two methods agree. They show that: i) Reward magnitude grows steeply up to train durations of about 1 s, then saturates (stops increasing). ii) The stronger the stimulation, the steeper the growth and the higher the asymptote. iii) The saturating duration is approximately the same at different strengths of stimulation. [Supported by NSF Grant BNS 89-96246.]

415.7

Subjective Reward Magnitude as a Function of Stimulation Strength Varies Within Rats as a Function of Site of Stimulation.

Matthew Leon*, C. R. Gallistel and John Liebeskind, Dept. of Psychol., UCLA, Los Angeles, CA 90024-1563

Gallistel and Leon (in press) measured the subjective magnitude of a brain stimulation reward by manipulating the mean interreward interval on one lever and determining the current or pulse frequency required on a second lever to produce equal preference between the levers. At equipreference, the difference in the subjective magnitudes of the two rewards compensates for the difference in the mean interreward intervals. They found that subjective reward magnitude increases approximately as a power function of the strength of stimulation (current x pulse frequency), but the power varied from 2 to 10 between subjects and/or sites of stimulation (subjects and sites were confounded). We have now determined subjective reward magnitude as a function of stimulation strength for electrodes in the ventral tegmental area and right and left lateral hypothalamus in the same rats. We find that the exponent of the power function varies between stimulation sites within a rat, suggesting that the subjective scaling of reward magnitude is a characteristic of individual anatomical sites. [Supported by NSF Grant BNS 89-96246.]

415.8

HABITUATION OF THE ACOUSTIC STARTLE RESPONSE IS NOT FREQUENCY SPECIFIC. W. P. Jordan, L. H. Poore*, J. M. Clayton*, and J. Belcher*, Psychology, St. Mary's College of Maryland, St. Mary's City, MD 20686.

The acoustic startle reflex is mediated by a four synapse reflex circuit in the caudal brainstem. Short-term habituation of startle probably occurs within this reflex arc, but long-term habituation (LTH) relies on an accruing inhibition of the reflex by brain areas extrinsic to the reflex arc. Damage to the midbrain reticular formation either before or after habituation training severely attenuates LTH, placing the site of plasticity underlying LTH outside of the reflex arc. It is unknown whether this inhibition is activated by each stimulus presentation (phasic) or whether it chronically damps the startle reflex. A chronic mechanism likely would be unable to support frequency specificity of LTH. A phasic LTH mechanism poses no such restrictions.

Fifteen male rats received 10 trials per day for 8 days of either a 10k-Hz or a 22-kHz pure tone stimulus (97dB SPL, 400ms). Animals habituated equally well to either stimulus across days. When the stimulus was switched to the other frequency on Day 9 or Day 10, no recovery was found. A subsequent same/difference test of the two frequencies under varied interstimulus intervals revealed no specificity for short-term habituation.

The lack of frequency specificity does not rule out either a chronic or a phasic mechanism for LTH.

415.9

DISCRIMINATIVE CONDITIONING OF ORIENTING HEAD MOVEMENTS IN CATS. M. Penttonen* and T. Korhonen, Dept. of Psychology, Univ. of Jyväskylä, P.O. Box 35, SF-40351 Jyväskylä, Finland.

Habituation of orienting responses to auditory stimuli has been studied quite extensively. The purpose of this study was to develop a paradigm for studying the neural mechanisms of orientation. Miniature loudspeakers were attached at a distance of 2 cm from both ears in cats. During a habituation session two tones of different pitches were presented randomly either to the left or right ear. The cats oriented with head turns towards the tones at 10 trials before the habituation. Discriminative conditioning began on next day and lasted for 5 days. CS+ tone was randomly presented to the left or right ear and was paired with the medial forebrain bundle stimulation. Left or right ear CS- tones were not paired with the stimulation. The cats learned discrimination between these two tones: they turned their head significantly more to the CS+ than CS- and increased responding to the CS+ over sessions and maintained the responding at an asymptotic level during last 2 sessions. Evoked responses recorded from the cingulate cortex also showed a differentiation between discriminative stimuli. It is concluded that with this paradigm it is possible to modify orienting responses and maintain these responses at a constant level so that the analysis of underlying neural systems becomes feasible.

415.10

EFFECTS OF REPEATED MEASURES AND STIMULUS INTERRUPTIONS ON INDUCING PERSISTING HINDLIMB FLEXION (SPINAL FIXATION) IN RATS. M. J. Bartelt, E.S. Johnson*, and M.M. Patterson, Dept. of Psychology and College of Osteopathic Medicine, Ohio Univ., Athens OH 45701.

Steinmetz *et. al.*, (JCPP, 1981) demonstrated that persisting hindlimb flexion may be induced by 40 minutes of stimulation (2-4 mA) to a spinalized rat's hindlimb. The present study investigated the effect of repeated asymmetry measurements (within individual animals) and interruptions of the inducing stimulus on the fixation process. If feasible, a repeated measures design would require fewer animals.

Fifty rats were anesthetized (Nembutal 50 mg/kg i.p.), spinalized at T7, randomly assigned to one of five groups, and stimulated (3.5 mA, 100-pps, 7msec repetitive dc pulses) on the right hindlimb. Immediately following each stimulation we assessed the amount of weight needed to remove the persisting hindlimb flexion. Group 1 was assessed at 20, 30, and 40 minutes; group 2 at 20, 25, 30, 35, and 40 minutes; group 3 had the stimulus terminated for 2 minutes at 20 and 30 minutes and was assessed at 40 minutes; the control groups 4 and 5 were assessed only at 30 and 40 minutes.

We found the following: 1) both the 5 and 10 minute repeated measures groups displayed significantly less flexion than the corresponding control groups, 2) the repeated measures group displayed significantly less flexion than the stimulus interruption group, 3) the variances of the repeated measures groups were greater than the variances of the corresponding control groups or the stimulus interruption group.

The repeated measures study of the persistent spinal reflex alteration may show potential but the greater variability induced makes it's use questionable. From the present study a number of questions arose regarding the lessening of the flexion; for example, what mechanism lowered the persisting flexion, muscular or neural? Further investigations utilizing neural preparations are required to address these questions. Supported by American Osteopathic Association grant 90-08-319.

415.11

INHIBITION OF PERSISTING RAT HINDLIMB FLEXION (SPINAL FIXATION) BY CONTRALATERAL HINDLIMB STIMULATION. M.M. Patterson, M.J. Bartelt, and E.S. Johnson*, Dept. of Psychology and College of Osteopathic Medicine, Ohio Univ., Athens, OH 45701.

Steinmetz *et. al.*, (JCPP,1981) demonstrated that persisting hindlimb flexion may be induced by applying 40 minutes of stimulation (2-4 mA) to a spinalized rat's hindlimb. We explored the possibility that the spinal reflex alteration producing persisting hindlimb flexion could be inhibited by sensory input from the contralateral hindlimb.

Twenty-four rats were anesthetized with Nembutal (50 mg/kg i.p.) and spinalized at T7. Twelve animals were randomly assigned to each of the experimental and control conditions and all then received stimulation (3.5 mA, 100-pps, 7msec repetitive dc pulses) to the right hindlimb for 40 minutes. The amount of weight needed to remove the ensuing persisting hindlimb flexion was then measured. The experimental animals' then received stimulation to the left hindlimb for 40 minutes while control animals received no stimulation. Weight necessary to remove persisting flexion of the right hindlimb was then again measured in both groups.

The results indicated that the contralateral stimulation appeared to lower the persisting flexion by a small (2.1 grams) but consistent and significant ($p< 0.01$) amount. This finding suggested that the spinal fixation produced by the stimulation could be altered at least slightly by presumably the crossed extensor reflex pathways from stimulation of the opposite limb. The results suggest that there may be some possibility of reversing the persisting effects of altered reflex excitabilities by utilizing opposing inputs. Support: Am Osteo Assn 90-08-319

415.12

DOSE-RESPONSE EFFECTS OF d-AMPHETAMINE ON PERSISTING HINDLIMB FLEXION (SPINAL FIXATION) IN RATS. E.S. Johnson*, M.J. Bartelt, D.A. Johnson and M.M. Patterson, Dept. of Psychology & College of Osteopathic Med., Ohio Univ., Athens, OH 45701.

Steinmetz *et. al.*, (JCPP,1981) demonstrated that persisting hindlimb flexion may be induced by applying 2-4 mA of electrical stimulation for at least 40 minutes to the hindlimb of spinalized rats. In 1989 and 1990 Bartelt *et.al.(Soc. Neuro. Abs.)* found that d-amphetamine significantly increased the persisting hindlimb flexion. This study examined the effects of various doses of d-amphetamine on persisting hindlimb flexion.

Forty rats were anesthetized with Nembutal (50 mg/kg i.p.) and randomly assigned to one of four groups receiving either 0.0, 2.0, 5.0 or 10.0 mg/kg i.p. of d-amphetamine. The d-amphetamine was injected 15 min. prior to stimulation and the rats were subsequently spinalized at T7. Immediately following 40 minutes of 3.5 mA. (100 pps) hindlimb stimulation, we assessed the amount of weight needed to remove the persisting hindlimb flexion.

The results showed an increase in hindlimb flexion which generally increased with increasing dosage. This outcome supports Bartelt *et.al.*, 1989, and suggests that d-amphetamine effects may be maximal at 10.0 mg/kg. However, it may be that greater doses of the d-amphetamine accentuate the flexion even more but doses greater than 10.0 mg/kg were not used due to the difficulty of maintaining anesthesia. This work further supports involvement of catacholamine in the persisting alteration of spinal reflexes. Further studies will evaluate specific centrally acting NE and DA agonist effects on persisting postural asymmetry. Supported by American Osteopathic Association grant 90-08-319.

415.13

SYNAPTIC PLASTICITY IN THE ELECTROSENSORY LOBE MAY MEDIATE A MODIFIABLE COROLLARY DISCHARGE IN MORMYRID FISH. C. Bell, A. Caputi, K. Grant, and J. Serrier*. R.S. Dow Neurol. Sciences Inst., Portland, OR 97209 and Lab. de Physiol. Nerv., C.N.R.S., Gif sur Yvette, France 91190.

The mormyrid electrosensory lobe may be a useful site for studying the mechanisms and roles of synaptic plasticity. Corollary discharge signals in the lobe are associated with the electric organ discharge (EOD) motor command and are modified by pairing the command with sensory stimuli. The purpose of this study was to determine whether the plasticity takes place within the lobe.

Single cells were recorded intracellularly in the ampullary region of the electrosensory lobe. Intracellularly injected current pulses (instead of sensory stimuli) were paired with the EOD command. Clear changes in the synaptic effect of the corollary discharge were observed following pairing with depolarizing current pulses. Such pulses evoked both short (1 msec) and long (15 msec) duration spikes. The short duration spikes are presumed to be axonal or somatic and the long duration spikes are presumed to be dendritic. The long duration spikes appeared to be critical for plastic change but the short duration spikes did not. Only the short duration spikes are probably propagated down the axon to other cells.

Thus, modifications in the synaptic effect of the corollary discharge appear to result from pairing with postsynaptic events that are restricted to the cells of the electrosensory lobe. Supported by NSF Grant BNS-8919627.

415.14

CHRONIC FLUMAZENIL (RO 15-1788) FACILITATES HABITUATION TO NOVEL ENVIRONMENT AND ANTAGONIZES SCOPOLAMINE INTERFERENCE WITH ACQUISITION OF PASSIVE AVOIDANCE BEHAVIOR. T.J. Marczynski and M. Urbancic*, Dept. of Pharmacol. Univ. of Illinois Coll. of Med., Chicago, IL. 60612.

Adult rats were treated with flumazenil (FL; 4 mg/kg/day in drinking water) or drug vehicle (0.5% water solution of ethylen glycol). On day 12 of treatment, there was no effect on locomotor activity, but pairs of rats (n=5) spent more time in active, non-aggressive, social interactions, as scored in 1 min intervals ($p<.008$) than the control pairs (n=6). When retested 24 hrs later in the same and now familiar environment, the control group matched the behavioral scores of the FL group. However, the introduction of a 3 min lasting "white" noise inhibited social interactions in the control group, relative to the pre-noise condition ($p<.008$), while the FL-treated rats, after initial inhibition, resumed their interactions, which was higher than in the control pairs ($p<.007$). In another group of animals, on day 22 of FL treatment, the drug protected the animals against amnesic action of scopolamine HBr (0.4 mg/kg s.c.) injected 15 min prior to tests for acquisition of behavior avoiding a dark compartment, in which, every 5 sec, the animal received a mild 0.85 mA electric shock. The FL group (n=11) needed less shocks ($p<.03$) and less often re-entered the dark compartment (1.0±0.6 SE) than the controls (2.5±0.6; n=11; $p<.03$). FL had no effect on retention of avoidance behavior, as tested 24 hrs later. Since habituation to novel stimuli (noise) depends on cognitive functions and muscarinic cholinergic mechanisms (Carlton, Prog. Brain Res. 28: 1968, 48), and since scopolamine has amnesic actions, these results indicate that chronic FL increases the tone of the cholinergic systems, by uncoupling the postsynaptic GABA-A receptors from the benzodiazepine recognition sites (Urbancic & Marczynski, Europ. J. Pharmacol. 171:1989, 1-7) that control these systems. Supported by USAF grant 87-0364.

RELATIONSHIPS BETWEEN CARDIAC RESPONSE VARIABLES, URINARY CATECHOLAMINES AND MEASURED INTELLIGENCE IN EIGHT-YEAR-OLD CHILDREN. C. J. McCallister, N.-S. Jiang*, N. H. McArthur, W. R. Nash* and C. R. Reynolds*. Depts. of Educational Psychology and Veterinary Anatomy, Texas A&M University, College Station, TX 77843 and Dept. of Laboratory Medicine, Mayo Clinic, Rochester, MN 55905.

As part of a larger study, 24 eight-year-old subjects (12 males, 12 females) were administered a standardized intelligence test, the Kaufman Assessment Battery for Children (K-ABC). Height, weight, blood pressure and heart rate were measured immediately before testing. Catecholamines were measured by high pressure liquid chromatography in one 24-hr unstressed sample at least two days before or after the testing and these data were normalized using creatinine values. Diastolic (DBP) and systolic blood pressure (SBP) and heart rate (HR) were all significantly different by gender, as were norepinephrine and epinephrine. Dopamine, age, IQ, height and weight were not significantly different by gender although weight approached significance. Correlations between SBP and IQ for both boys and girls were negative ($r=-0.60$, $p<.03$, $r=-0.59$, $p<.04$ respectively). DBP correlated negatively with IQ for boys ($r=-0.67$, $p<.01$) and positively for girls ($r=0.48$, $p<.10$). No significant correlations were found between any urinary catechols in the 24-hr unstressed sample and IQ although epinephrine exhibited a trend toward significance for girls only. No significant correlations were found between any urinary catechols in the 24-hr unstressed sample and cardiac response variables although HR and norepinephrine showed a trend toward significance for girls only. Exploratory data analyses using stepwise regression revealed that blood pressure was the best predictor of test performance for both boys and girls; further regression analyses will be utilized following the completion of the larger sample (n=100).

DEVELOPMENT OF A BRAIN-COMPUTER PARALLEL INTERFACE. D.J. McFarland, G.W. Neat, and J.R. Wolpaw, Wadsworth Labs, New York State Department of Health and State University of New York, Albany, NY 12201.

Individuals can learn to modify the amplitude of the 9-12 Hz mu rhythm in the EEG recorded over primary sensorimotor cortex in order to move a cursor quickly and accurately to a target located at the top or bottom of a video screen (Wolpaw et al, Electroenceph clin Neurophysiol 78:252-259, 1991). We are now exploring development of two-dimensional control.

Bipolar EEG is recorded from the scalp over central sulcus of each hemisphere. Right and left mu rhythm amplitudes are assessed 5 times/sec by fast Fourier transform. A cursor appears in the middle of the screen and a target appears in one corner. The cursor moves in two dimensions as a function of the right and left mu rhythm amplitudes. The individual's task is to move the cursor to the target.

Initial results suggest that individuals can develop two-dimensional control and use it to reach targets with greater accuracy than accounted for by one-dimensional control.

An EEG-based brain-computer interface may provide a significant new communication and control channel for severely disabled individuals.

A COMPUTER-BASED ANALYSIS OF PAVLOVIAN BEHAVIOR USING DORSAL MIDBRAIN STIMULATION AS THE UNCONDITIONAL STIMULUS. M.G. Laubach, R.C. Gonzalez*, and E. Thomas. Depts. of Biology & Psychology, Bryn Mawr College, Bryn Mawr, PA 19010

We have developed a method for the direct quantification of conditioned behavior. A CCD camera reports the position of an LED above the animal's head every 0.1s. Movement, defined as a change in LED position, was determined during pre-CS, CS, US, and post-CS periods in a light/tone discrimination paradigm, using Sprague-Dawley rats. "Freezing" was defined as less movement during the CS than during the pre-CS period. Electrical stimulation (EBS) of the dorsal midbrain (DM) was the US. The UR was movement: jumping forward or sideways, circling. Animals consistently "froze" on CS+ trials and were active on CS- trials. The difference between CS+ and CS- period behavior was significant. The difference between pre-CS activity and activity during the CS+ was significant from 0. These results, together with a measure of EBS efficacy in a conflict paradigm, suggest that DM EBS is an effective stimulus for aversive Pavlovian conditioning. The method will be expanded with a second camera and will quantify the different qualitative aspects of conditioned responding, currently assessed by judgement using video-tapes.

MOTIVATION AND EMOTION III

NEUROLEPTICS BLOCK HIGH DOSE, BUT NOT LOW DOSE, HEROIN CONDITIONED PLACE PREFERENCES. K. Nader, A. Bechara, F. Harrington* and D. van der Kooy. Dept. of Anatomy, University of Toronto, M5S 1A8.

We hypothesize that two separate motivational systems in the brain underlie the rewarding effects of opiates, one that functions in drug naive rats and the other that dominates in drug dependent animals. These two systems can be double dissociated by lesions of the brainstem tegmental pedunculopontine nucleus (which block conditioned place preferences for environments paired with opiates only in drug naive rats) and by neuroleptic induced dopamine blockade (which abolishes conditioned place preferences for opiates only in drug dependent animals). Recently, we found that the neuroleptic pimozide (0.5 mg/kg i.p.) blocked the conditioned place preferences produced by 500µg/kg(s.c.) heroin in drug naive rats, but had no effect on similar preferences produced by a 50µg/kg (s.c.) dose of heroin . Are four place conditioning trials with 500µg/kg sufficient to produce a dependent motivational state? We independently tested for dependence induced motivational effects of withdrawal in rats receiving only four 500µg/kg injections of heroin using a modified place conditioning procedure. Rats received four exposures to only one of the two place conditioning environments, an environment which was paired with the absence of opiates 23 hours after the animals' most recent heroin injection . When tested in a drug free state by providing free access to both environments, dependent rats show an avoidance of the withdrawal paired environment, while naive rats show no significant conditioned preference or aversion to the environment paired with the absence of opiates. Rats given four 500µg/kg heroin injections showed significant avoidance of the environment paired with the absence of heroin, however no such avoidance was seen in rats given four 50µg/kg heroin injections or one 500µg/kg injection. We conclude that after only four 500µg/kg heroin injections animals are in a dependent state and therefore, as our model predicts, their preferences were subject to neuroleptic blockade. Animals trained with one 500µg/kg or four 50µg/kg heroin doses are non dependent and their preferences were therefore immune to neuroleptic challenge. These findings further support a two system model of the motivational properties of opiates.

416.2

Neuroleptics Block The Aversiveness Of Withdrawal In Opiate Dependent Rats, But Not The Aversiveness Of Naloxone In Drug Naive Rats. A.Bechara and D.van der Kooy. Neurobiology Research Group, Dept. of Anatomy, Univ. of Toronto, Toronto,Ont.,Canada,M5S 1A8.

Morphine produces rewarding effects (as assessed by place conditioning) in drug naive animals,that are blocked by bilateral lesions of the tegmental pedunculopontine nucleus (TPP) of the brainstem, but not by dopamine blockade (i.e. neuroleptics). However, in drug dependent animals (chronically treated with morphine, a total of 60 mg/kg/day for a minimum of 14 days), similar doses of morphine produce rewarding effects that are blocked by neuroleptics, but not by TPP lesions. These results double dissociate two motivational processes mediating the rewarding effects of opiates. Just as the activation of opiate receptors in drug naive versus drug dependent animals produce fundamentally different mechanisms of reward, we now report that reduced activity on these opiate receptors produce fundamentally different mechanisms of aversion. Morphine dependent, but 16 hour abstinent, rats were injected with saline vehicle and then placed in a distinct environment. When later tested in a drug free and non withdrawan state, these rats avoided the environments previously paired with opiate withdrawal (i.e. saline). These conditioned place aversions were blocked by the neuroleptic alpha-flupenthixol (0.8 mg/kg i.p.) administered to animals prior to withdrawal conditioning. Morphine naive animals that were place conditioned with the opiate antagonist naloxone (10 mg/kg s.c.) avoided the places previously paired with naloxone. However,these conditioned place aversions were not blocked by neuroleptic treatment. Although spontaneous withdrawal in dependent animals and naloxone effects in drug naive animals both reflect an attenuated opioid action on opiate receptors, the motivational mechanisms underlying these two types of aversive effects may be fundamentally different. The important neurobiological fracture line in motivational processes may not lie between reward and aversion, but between the drug dependent and drug naive states.

HALOPERIDOL, QUININE ADULTERATION, AND EXTINCTION PRODUCE ELEVATIONS IN THE FORCE EXERTED DURING OPERANT RESPONDING BY RATS

E.O'S. Hammond, P. Baskin*, & A. Ettenberg

Behavioral Pharmacology Laboratory, Department of Psychology
University of California, Santa Barbara, CA 93106

Previous studies have shown that animals responding in a food-rewarded paradigm exert increased force in the presence of neuroleptic drugs. Is the neuroleptic-induced elevation in emitted force a result of reward attenuation or, as others have suggested, a motoric-postural phenomenon? In this study, 3 groups of rats were trained to press a force-sensing operandum for 2.5 sec access to sweetened condensed milk. Testing consisted of two 5 min sessions separated by a 50 min intertrial interval. When animals responded during the second session under conditions of 0.075 mg/kg haloperidol, no reward, or quinine-adulterated (0.025%) reinforcer, all experimental animals emitted significantly greater levels of peak force than controls. These preliminary results suggest that neuroleptic-induced increases in peak force may reflect reductions in the rewarding quality of food reinforcement.

EFFECTS OF HALOPERIDOL ON PROGRESSIVE-RATIO PERFORMANCE MAINTAINED BY LOW AND HIGH LEVELS OF SUCROSE REWARD. P. Skjoldager, P. Pierre* and G. Mittleman. Department of Psychology, Memphis State University, Memphis, TN 38152.

To determine whether haloperidol effects the reinforcing efficacy of sucrose reward apart from its effects on motoric function, Long Evans rats were reinforced with either a low (1 pellet) or high (3 pellet) magnitude of sucrose reward under an arithmetic progressive-ratio 5 schedule of reinforcement. Sessions terminated when subjects failed to respond for 5 minutes. Baseline performance of subjects in the low-reward condition was characterized by lower break points (the value of the last reinforced ratio), longer pauses following reinforcer delivery (postreinforcement pause), lower running rates (response rate exclusive of postreinforcement pause), and longer operant response durations than subjects in the high-reward condition. Haloperidol (0.0, 0.04, 0.08, 0.16, 0.32 mg/kg, injected ip 45 min before an experimental session) differentially affected performance depending on the magnitude of the reward maintaining behavior. Subjects in the low-reward condition evidenced a dose-dependent decrease in break point, whereas subjects in the high-reward condition had higher break points at the 0.04 mg/kg haloperidol dose followed by a steep monotonic decrease in break point as haloperidol dose increased. Surprisingly, haloperidol did not effect other performance measures including postreinforcement-pause time, running rates, or operant response durations. These results suggest that haloperidol attenuates the reinforcing effects of sucrose reward without affecting response measures that are believed to be largely motoric in nature.

416.5

IBOTENIC ACID LESION OF THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS PRODUCES OVERWEIGHT AND MODULATES THE PREFERENCE THRESHOLDS FOR SACCHARIN.

K.Touzani*, B. Cardo and L. Velley - Lab. Neurosciences comportementales et cognitives, CNRS URA 339, Univ. Bordeaux I, Av. des Facultés 33405 Talence France.

In previous studies we showed that bilateral ibotenic acid (IBO) lesion of the lateral hypothalamus (LH) in the rat results in an increase of gustatory preference-aversion thresholds for saccharin, associated with body weight and water intake deficits.

In the present experiment, we studied the preference for saccharin in rats after lesions of the hypothalamic paraventricular nucleus (PVH), which are known to produce certain changes (namely hyperphagia and obesity) opposite to those produced by LH lesion.

Bilateral injection of IBO into the PVH destroyed the parvicellular cells but not the magnocellular cells of the nucleus. As compared with the normal weight gain of the sham-lesioned, lesioned rats exhibited a significantly higher increase in body weight from the third day after surgery. The lesioned rats also showed decreased preference thresholds for saccharin. These findings together with the results obtained after LH lesions indicate that some gustatory signals are controlled in an antagonistic fashion by the LH and the PVH. This control may depend, at least in part, on descending LH and PVH inputs to the first two gustatory relay-stations, the nucleus of the solitary tract and the parabrachial area.

(Supported by INSERM grant 89.6.016 and FRMF).

416.6

LESIONS OF LATERAL HYPOTHALAMIC NEURONES ALTER THE EFFECTS OF MORPHINE INJECTED INTO THE PARABRACHIAL AREA ON PREFERENCE FOR SACCHARIN

S. Moufid*, C.Besson* and L.Velley - Lab. Neurosciences comportementales et cognitives, URA CNRS 339, Univ. Bordeaux I, Av. des Facultés 33405 Talence France.

In previous studies, we showed that ibotenic acid lesion of the lateral hypothalamic neurones (LH) alters the effects of peripherally-administered morphine on rats' preference for saccharin.(Touzani & Velley, Pharmacol. Biochem. Behav., 36, 585, 1990). Furthermore, we identified the gustatory relay, the parabrachial area (PBA) as one of the central sites of the effect of morphine (Akarid et al., Soc. Nsci Abstr., 16, 600, 1990).

In the present study we sought to determine whether lesions of the LH could also modulate the effects of morphine injected into the PBA. During the preference tests, lesioned and sham-lesioned rats were placed either on ad libitum or restricted access to water. Increasing doses of morphine (50 ng to 800 ng) were bilaterally injected into the PBA 15 min before the preference test.

In parallel with our initial studies, we observed that (1) morphine injected into the PBA increased or decreased saccharin preference depending on sweetener concentration; (2) lesioned rats exhibited altered preference response in the presence of morphine. Furthermore, the effects of the LH lesion were stronger when rats were placed on restricted access to water.

(Supported by INSERM grant 89-6-016 and FRMF).

416.7

EXCITOTOXIC LESIONS OF THE RAT LATERAL HYPOTHALAMUS ENHANCE ACQUISITION OF SCHEDULE-INDUCED POLYDIPSIA.

G. Parker*, J. Clark*, A. Clark*, and P. Winn. Dept. Psychology, Univ. St Andrews, Fife KY16 9JU, Scotland.

Schedule-induced polydipsia (SIP) is seen when hungry animals are exposed to the intermittent presentation of food. Electrolytic lesions of the LH abolish SIP. In the present experiment, the ability of rats bearing fiber-sparing NMDA lesions of the LH to acquire SIP was examined. Following surgery, 11 rats lesioned with 1.0ul 0.06M NMDA lost weight and were hypophagic and hypodipsic compared to 6 sham lesioned rats. None of the lesioned rats required wet mash or intragastric intubation. LH-lesioned rats showed an impairment in drinking over 1 h following i.p. injection of hypertonic saline. For SIP testing all rats were placed on a food restriction regime to reduce body weight to 85% of normal. At the start of this regime the LH rats had a lower body weight than controls, but this was not statistically significant. Throughout the 21 days of SIP testing the LH rats were mildly (but significantly) hypodipsic in the home cage. SIP was examined in 60 min sessions every other day; one 45mg food pellet was delivered every 60 sec, while water was available ad lib via a burette protruding into the operant chamber. There were significant differences between the groups over the first 6 sessions (groups $F(1,14)=5.10$ $p<0.04$; interaction $F(5,70)=2.34$ $p<0.05$), LH lesioned rats acquiring SIP more quickly than controls. These data show that there is no motor impairment in LH lesioned rats; and that the LH may be involved in higher-order processes relating to the control of motivated behavior.

416.8

WATER DEPRIVED RATS REMAIN THIRSTY DURING DOPAMINE RECEPTOR BLOCKADE.

J.C. Horvitz and A. Ettenberg. Dept. of Psych., Univ. of Calif., Santa Barbara, CA 93106.

In order to determine whether dopamine receptor blockade would attenuate thirst, the drinking behavior of rats under 23, 16, 12, 4, and 0 hr water-deprivation was compared to that of 23-hr deprived animals under the influence of either 0, 0.5, 0.75, or 1.0 mg/kg of pimozide. Reductions in levels of water-deprivation produced a) increased latencies to initiate drinking, b) changes in the pattern of licking over the course of the session, and c) decrements in the total number of licks during the session. In contrast, administration of pimozide to 23-hr deprived animals produced no effect on either a) initiation latencies or b) lick patterns, and c) only marginally reduced the total number of licks during the session. Further, individual lick durations and interlick intervals were not affected by the neuroleptic. These data suggest that neither thirst mecanisms not motoric processes underlying drinking behavior are disrupted by dopamine receptor blockade.

416.9

REINFORCING PROPERTIES OF DRINKING WATER: ROLE OF OPIOIDS AND DOPAMINE.

Veronica Navarro*, Irith Federman* and Anders Agmo. Dept. of Psychology, Universidad Anahuac, Mexico City.

We have previously reported that sucrose drinking in non-deprived rats produces conditioned place preference. Consumption of the sucrose solution was taken to represent its rewarding properties and the place preference was taken to represent reinforcing effects. A dopamine antagonist blocked reinforcement but not reward, while an opiate antagonist blocked reward but no reinforcement.

The purpose of the present experiment was to evaluate whether drinking water in deprived rats and the reinforcement produced by this event responded in the same way to dopamine and opioid antagonists as sucrose drinking and reinforcement. Male rats were deprived of water for 24 h and then allowed to drink for 8 min in a lickometer. Immediately thereafter they were placed in place preference cages. The reinforced cage was the initially non-preferred cage. After a total of three reinforced and three non-reinforced sessions, the test was made.

Drinking produced a place preference that was blocked by pimozide, 1 mg/kg, administered before the reinforced sessions. A slight reduction of drinking was also observed. Naloxone, 16 mg/kg, administered before the reinforced sessions produced place aversion and considerable and progressive reduction of drinking. These data suggest that dopamine affects reinforcement and opioids reward.

416.10

SCOPOLAMINE BLOCKADE OF AMPHETAMINE-INDUCED CPP.

M.R. Lynch and E.M. Scala Rodriguez*, Research Serv., VAMC and Dept. Psychiatry, SUNY HSC, Syracuse, NY 13210

Neurochemical and behavioral investigations support the existence of a DA-ACh reciprocal interaction in the neostriatum, which is apparent from opposite changes in turnover and in behavioral consequences of pharmacological challenge. While data have been reported implicating ACh in DA-mediated behaviors from from dorsal (catalepsy) and ventral (hyperactivity) striatum, exact nature of the DA-ACh limbic interface is not known; reports can be cited suggesting either a reciprocal relationship or no interaction. Amphetamine-CPP arises from DA activation in the (limbic) NAS region. DA in this structure has been repeatedly implicated in reinforcement/motivational processes. In the present study, 4 groups of (n=6-8) rats were conditioned with 1.5 mg/kg d-Amp to the nonpreferred side of a CPP chamber. Amp conditioning induced a significant increase in time spent on this NP side (6.33% to 26.8% over 15-min). Conditioning with 0.1 mg/kg scopolamine co-administration blocked the increase, although failing to induce a significant aversion itself. Locomotor activity data suggested that Sc also blocked conditioned hyperactivity but the magnitude of these changes failed to reach significance. These findings implicate a cholinergic component in the limbic circuitry generating Amp-CPP, and suggest the possibility that this component opposes DA as with striatally-mediated behavior.

AUDITORY FEEDBACK MAINTAINS CRYSTALLIZED SONG IN ADULT ZEBRA FINCHES. K.W. Nordeen, and E.J. Nordeen. Dept. Psych., U. Rochester, Rochester, NY 14627.

Birds use auditory feedback in learning song, but differ in their use of this feedback in maintaining adult song. Earlier work suggested that zebra finches, and other birds that learn song during critical periods, eventually attain songs that are independent of auditory feedback. It had been presumed that these species establish a central motor program as adult song patterns "crystallize". However, we have found that the crystallized songs of zebra finches change substantially following long-term deafening.

We recorded the songs of 25 adult (>120d) male zebra finches and then removed the cochleae from 11 of these birds. Songs were recorded up to 16 weeks following surgery (deaf) or after 15-68 weeks (control). By 16 weeks after surgery deaf birds accurately reproduced only 36% of the song syllables produced initially. In contrast, control birds retained 90% of their syllables. Also, the percentage of syllables that were unmatched or only slightly similar in phonology to previously recorded syllables was higher in deaf birds than in controls. Usually, these effects of deafening took 6-8 weeks to develop. We do not yet know where auditory feedback acts to maintain the neural circuits supporting adult song behavior, but preliminary data suggest that lesioning the lMAN, which disrupts song development, does not compromise the long-term maintenance of adult song.

417.2

BRIEF EXPOSURE SONG LEARNING IN ZEBRA FINCHES: ACQUISITION AND PRODUCTION OF A MODEL WITH ONE DAY OF TUTORING. A. Lombardino. Rockefeller University, Field Research Center, Millbrook, NY 12545

Juvenile male zebra finches, *Taeniopygia guttata*, normally learn the complex vocalizations of courtship song from an adult conspecific male with whom they can interact. Song learning in this species consists of two overlapping phases: an early sensitive period for acquisition of a model, and an extended period of vocal development during which the model is imitated. It is not known what minimal amount of song exposure is sufficient for imitation to occur. Here the auditory and social environments of male zebra finches were manipulated from one week after hatching until sexual maturity (day 90) in an attempt to narrow the period of model acquisition. Six zebra finch males ("scholars") were raised by their mothers until day 28; on that day each bird was placed singly with an unrelated adult female. On day 35 an adult male ("tutor") was placed in the scholar's cage for 24 hours. The scholars heard no other male zebra finch until day 90. Six control juveniles were treated in the same manner but had no access to a tutor male. The process of song development in both groups was followed by tape recording vocalizations at days 45, 60, 75, and 90. Visual inspection of sonagrams of each juvenile's song and his respective tutor revealed moderate to marked imitation of the model in four of the six scholars, whereas controls produced none of the complex syllables found in the tutors' songs, often incorporating the female companion's calls into a male song structure. The song of scholars and controls had similar introductory notes, which probably are not learned from male tutors. Experimentally restricting the time frame in which zebra finches acquire their song should greatly facilitate study of the mechanisms of song learning.

SONG INDUCES "IMMEDIATE EARLY" GENE EXPRESSION IN SONGBIRD FOREBRAIN. C. Mello*, D. S. Vicario and D.F. Clayton. Lab of Animal Behavior, The Rockefeller University, NY, NY 10021, & Beckman Institute, University of Illinois, Urbana, IL 61801

We identified a gene induced in songbird associative forebrain in response to the sound of birdsong. The gene ("ZENK") encodes the canary homolog of an "immediate early" transcription factor known to be induced by signals for neuronal growth and depolarization (Mello & Clayton, Soc Neurosci Abstr 16:657, 1990). By in situ hybridization, ZENK mRNA levels increased ~10-fold in the forebrain of canaries or zebra finches that heard tape-recorded birdsong after 1 day of acoustic isolation. The most marked induction occurred in the medial caudal neostriatum (NCM) when birds were exposed to song of their own species. Little or no induction occurred in response to pure auditory tones, or in the defined song control circuit or Field L. NCM may represent a site for: 1) auditory discrimination; 2) song storage; or 3) multimodal associations involving the song stimulus.

417.4

DEVELOPMENT OF AUDITORY RESPONSES IN NUCLEUS HVc WITH REDUCED AUDITORY FEEDBACK DURING SONG ACQUISITION. S.E. Volman. Dept. of Zoology, The Ohio State University, Columbus OH 43210.

The sensorimotor stage of song learning in white-crowned sparrows lasts for about 1 month. During this period, birds match their own "plastic song" to a stored memory of a song model. Before this stage, auditory neurons in the song-control nucleus HVc show no evidence of selectivity for the song model, and auditory responses habituate easily. During plastic song, HVc neurons become more responsive to song in general, and they also become preferentially responsive to a bird's own song (Volman and Konishi, Soc. Neurosci. Abst., 1987). This study asked: Is auditory feedback necessary to produce these changes in the auditory responses of HVc, or might they, at least in part, just be a consequence of maturation and activation of the song system? Four juvenile sparrows were individually isolated, and starting from when they first produced early plastic song, they were devocalized for at least 30 days. Devocalization was accomplished by puncturing the interclavicular air sac, which surrounds the syrinx. The air sac heals in 5-7 days, so vocalizations were monitored every day to determine both when repeat operations were necessary and what sounds the birds were producing. Each bird was able to hear himself sing for a total of about 4 days during this time. The responses of HVC neurons, recorded after the 30+ days of devocalization, were compared on a variety of measures to those in normal birds at an equivalent time after vocalization begins. The HVc neurons in devocalized birds gave robust responses to song and showed some song selectivity, but this was markedly less than that in normal birds. These results suggest that auditory responsiveness may develop in HVc in the absence of auditory feedback, but the mature pattern of song-selectivity requires such feedback, and does not simply reflect the activation of response patterns established during the acquisition of the song model.

A TEST OF THE AERODYNAMIC WHISTLE HYPOTHESIS FOR THE PRODUCTION OF BIRDSONG. R. A. Suthers and M. X. Zuo*. Medical Sciences, Indiana Univ., Bloomington, IN 47405.

Birdsong is often assumed to be generated by the vibration of tympaniform membranes in the avian vocal organ--the syrinx. However, an alternate mechanism of sound production based, on the principle of an aerodynamic whistle, has also been hypothesized to generate certain vocalizations in some species such as pigeons and doves (Columbidae) (Gaunt and Gaunt & Casey, Auk 99:474, 1982). According to the whistle hypothesis, sound is produced by a series of stable vortices in the expiratory air downstream from a constricted slot which acts like a hole-tone whistle in the vocal tract.

We have attempted to distinguish between these two mechanisms of sound generation by inserting a bundle of small diameter, parallel, straight stainless steel tubes into the trachea of male hubble pigeons immediately craniad to the syrinx. These tubes were designed to produce laminar airflow downstream from the syrinx and eliminate any turbulent vortices in the trachea. Vocalizations in which the syrinx functions as an aerodynamic whistle should be eliminated by this "flow straightener" whereas sounds produced by vibrating membranes should be little affected. Subsyringeal air sac pressure and tracheal pressure were monitored with miniature piezoresistive pressure transducers during vocalizations with and without this flow straightener. The rate of airflow through the trachea and through the mouth and nostrils was also measured using heated microbead thermistors. Insertion of the tracheal flow straightener had no significant effect on the coo-like vocalizations produced by male pigeons when presented with a female. This result suggests that cooing is not produced by an aerodynamic whistle in the syrinx. (NSF BNS 8720192)

417.6

INTRINSIC OSCILLATORY PROPERTIES OF VOCAL PREMOTOR NEURONS IN THE ZEBRA FINCH FOREBRAIN. R. Mooney. Div. of Biology 216-76 Caltech, Pasadena, CA 91125.

The zebra finch brain contains several nuclei that are specialized for vocal control during singing. Nucleus RA, located in the caudal forebrain, contains neurons that project directly onto the motoneurons controlling the syringeal musculature used in song. To learn how these neurons contribute to vocal motor control, their intrinsic electrophysiological properties were studied in an *in vitro* brain slice preparation. RA neurons fire highly regular trains of action potentials upon depolarization. These action potential trains exhibit little or no frequency adaptation even when depolarized for hundreds of milliseconds; the spike discharge rate increases as a linear function of the injected current pulse amplitude (ca. 63 Hz/ nA). Subthreshold membrane potential oscillations are a regular feature of the RA neuron's behavior near spike threshold, and increase in frequency with depolarization. Several ionic mechanisms contribute to the observed electrophysiological behavior of RA neurons. When impaled with intracellular electrodes containing 75 mM QX-314 (a sodium channel blocker) in 2 M potassium acetate, RA neurons rapidly lose their ability to fire fast action potentials upon depolarization. However, depolarization still evokes broader oscillations of the membrane potential. The major frequency component of these QX-314-insensitive oscillations also increases with greater depolarization, but disappears in nominally calcium-free solution, suggesting that these oscillations are Ca^{2+}-dependent. When RA neurons are depolarized beyond spike threshold without QX-314 in the recording electrode, the firing frequency increases and the interspike hyperpolarization diminishes in the Ca^{2+}-free solution. These experiments indicate that RA neurons have features that would be well-suited to their role in vocal motor control: the lack of frequency adaptation could be essential for the control of vocal muscle tension during singing, and their linear frequency response could render them quite sensitive to modulation by synaptic inputs both from within RA, and to synaptic inputs arising from other forebrain song control nuclei. 417.7

NONLINEAR RESPONSE PROPERTIES OF AUDITORY NEURONS IN THE ZEBRA FINCH'S SONG SYSTEM: A QUANTITATIVE APPROACH.

D. Lim, A. J. Doupe, and M. Konishi. Division of Biology, California Institute of Technology, Pasadena, CA 91125.

Auditory forebrain song nuclei of the male zebra finch (*Poephila guttata*) contain neurons sensitive to the bird's own song. These neurons respond best or exclusively to a certain configuration of song acoustic elements (E. S. Fortune, D. Margoliash, 1989 Abstr Soc Neurosci). The response of these neurons to the effective configuration does not appear to be a simple addition of their responses to individual elements presented in isolation, indicating the involvement of non-linear processes. To quantify these nonlinear interactions, we used a matrix-based optimization method (D. Lim and R. R. Capranica, 1990 J Acoust Soc Am Sup). This procedure made it easier to see interactions between a neuron's responses to various acoustic stimuli. Furthermore, it lent itself well to generating the set of most meaningful acoustic components for a particular group of neurons. Thus, the selectivity of forebrain nuclei for a given set of stimuli could be represented in terms of their nonlinear dependencies. For example, we studied responses of single HVc neurons to harmonically related tones and their combinations such as f1, f2, f1+f2, f1+f3, f1+f2+f3 etc. The results showed different degrees of inhibitory and facilitatory interactions between the neuronal responses to different tones. This work was supported by the McKnight Foundation and the Lucille P. Markey Charitable Trust.

417.8

SOURCES OF AUDITORY INPUT TO THE VOCAL MOTOR PATHWAY IN THE ZEBRA FINCH. D.S. Vicario and K. Yohay*
The Rockefeller University, New York, NY 10021.

Songbirds learn their vocalizations by imitating auditory models. Auditory responses can be recorded in many vocal motor structures of the songbird brain, including the robust nucleus of the archistriatum (RA). The two principal inputs to RA are from forebrain nuclei HVC and LMAN, both of which also respond to auditory stimuli, especially to the bird's own song.

We assessed potential sources of auditory input to RA in adult male zebra finches. 1) Multi-unit auditory responses in RA of anesthetized birds were examined before and after lesioning nucleus LMAN or the pathway connecting it to RA. Following these lesions, robust auditory responses continued to be recorded from cells in RA, although in some cases the latency of the response increased by about 10ms; the characteristic spontaneous bursting activity in RA was not changed. 2) Retrograde tracer injections were made in RA in an attempt to identify a pathway into RA from the "cup" region rostro-ventral to RA (that may receive auditory input from areas near Field L); these injections failed to label cells in the "cup" region. 3) The auditory responses of single HVC cells identified as projecting to RA by antidromic activation were examined.

The results show that the pathway to RA from LMAN is not required for auditory information to reach RA. Consistent with the earlier demonstration by Williams that HVC lesions abolish auditory responses in RA, the results further suggest that the direct projection from HVC carries this information. However, it is not excluded that, under some circumstances, auditory information travels through both pathways and is compared in RA. We are currently examining this intriguing possibility, using recordings in RA of awake birds. (Supported by MH40900)

EFFECTS OF AREA X LESIONS ON SONG DISCRIMINATIONS IN ZEBRA FINCHES. J. Cynx, C. Scharff, and F. Nottebohm. Rockefeller Univ. Field Res. Ctr., Millbrook, NY 12545

Area X is part of the recursive pathway in the circuitry controlling song behaviors. Lesions in this pathway disrupt the learning of song, while having no effect on adult song production (Bottjer et al., 1984; Scharff & Nottebohm, 1991; Sorabji et al., 1990). The recursive pathway has thus been characterized as involved only in song development. We hypothesized the function of the recursive loop might involve the correct discrimination of songs. To test this, we compared the performance of intact and Area X lesioned birds in operant discrimination tasks. Twelve adult male zebra finches were divided into six pairs. In each pair, one bird was given a bilateral Area X lesion. The intact bird in each pair served as a control. They were then trained on a number of operant discrimination tasks. In the first task, birds were trained to discriminate between pieces of hetereospecific (canary) song. There were no consistent differences between Area X lesioned and control birds. In the second task, birds in each pair were trained to discriminate between their own two songs. All Area X lesioned birds required more trials than their respective controls. In the last task, the birds were trained on a second canary song discrimination. Again, there were no differences between Area X lesioned and control birds. We conclude that Area X plays a role in conspecific song discriminations in adult zebra finches.

417.10

LATERALIZATION OF BIRD SONG DISCRIMINATION IN THE ZEBRA FINCH. H.Williams[1,2] J. Cynx[1] and F. Nottebohm.[1]
(1) The Rockefeller University Field Research Center, Millbrook, NY 12545, (2) Biology Dept., Williams College, Williamstown, MA 01267.

Lateralization of bird song production has been documented for a number of species. This is the first report that song discrimination is also lateralized. Fourteen adult male zebra finches were divided into seven pairs. In each pair, a bird was given a right- or left-side lesion of a thalamic auditory relay nucleus (nucleus ovoidalis), effectively deafening the respective telencephalic song control circuitry. This operation did not affect song production, but it affected performance in song discrimination tasks. Left-lesioned birds in each pair required more trials to reach a learning criterion when trained on an operant discrimination task between the pair's two songs. However, when the same birds were asked to discriminate between songs varying only in the placement of one frequency component in a harmonic structure, then left-lesioned birds in each pair mastered the task much faster.

This suggests that the hemispheres of the songbird brain may process song signals in different ways, paralleling inter-hemispheric perceptual differences reported in humans and other primates.

417.11

SONG CONTROL NUCLEI OF THE HOUSE SPARROW (PASSER DOMESTICUS) ARE PHOTOPERIODIC AND PHOTOREFRACTORY. M.G. Rucker*and V.M. Cassone. Dept. Biology, Texas A&M University, College Station, TX 77843.

The house sparrow is a well-studied species for photoperiodism. Song control nuclei have been shown to be seasonal in several avian species. The following study was to determine whether the song control nuclei of house sparrow were dependent upon photoperiodism and/or gonadal growth.

Adult male sparrows were housed in three separate light cycles (N=8/group). Group 1 was maintained in LD 6:18 for 6 wks and in LD 18:6 for 14 wks. Group 2 was maintained in LD 6:18 for 12 wks and in LD 18:6 for 8 wks. Group 3 was maintained in LD 6:18 for 20 wks. Body weight and bill color were recorded weekly. At the end of 20 weeks all animals were anesthetized, intracardially perfused with saline, then Bouin's fixative, and their brains removed. Gonads were also removed, weighed and paraffin embedded. Brains were processed for paraffin embedding and sectioned at 10μm. Tissue samples were then Nissl-stained for morphometric analysis on a computer-image analysis system (JAVA).

As previously determined in this species, gonads were small in photoinhibited Group 3 (21.9 $\pm$ 4.0 mg), large in photostimulated Group 2 (254.1 $\pm$ 11.2 mg), and small again in photorefractory Group 3 (65.1 $\pm$ 65.1 mg). As shown in other species, song control nuclei HVC and RA were smaller in photoinhibitory Group 3 than in photostimulatory Group 2. These nuclei were also reduced in size in photorefractory Group 1, indicating that in the house sparrow, song control is both photoperiodic and photorefractory. Mechanisms of this photorefractoriness is currently under study.

MOTOR BASES OF BEHAVIORAL STEREOTYPY IN SWAMP SPARROW SONG NOTE PRODUCTION. S. Nowicki and S. Peters*. Depts. of Zoology and Neurobiology, Duke University, Durham, N.C. 27706.

Swamp sparrows (*Melospiza georgiana*) incorporate a limited set of minimal units ("note types") into their trilled songs. These note types are species-specific and highly stereotypic. We asked whether birds that share identical note types in their repertoires also use similar motor programs to produce these note types. In other words, does stereotypy in song production on the level of behavior correspond to a comparable degree of stereotypy on the level of motor control? We addressed this question by quantitatively comparing the effects on song notes of identical experimental manipulations, both between and within individuals. Twelve adult males were subjected to denervation of either the left or right tracheosyringealis nerve, and within-treatment comparisons were made for all levels of note identity. We found in a significant proportion of cases evidence that identical note types are produced by different motor patterns. This result suggests that multiple pathways may be taken in the motor development of this stereotypic, species-specific behavior. Supported by DC 00402.

REGIONAL LOCALIZATION OF MK-801 BINDING IN ZEBRA FINCH SONG NUCLEI S.M. Aamodt, M.R. Kozlowski[1], E.J. Nordeen, and K.W. Nordeen. Dept. Psych., U. Rochester, Rochester, NY 14627 and [1]Bristol-Myers Squibb, Wallingford, CT 06492.

Effects of early sensory experience on neural and behavioral plasticity have been linked to activation of N-methyl-D-aspartate (NMDA) receptors. Early auditory experience is crucial for normal song learning in zebra finches, and the physiology of one song control area, the robust nucleus of the archistriatum (RA), indicates the presence of NMDA receptors in young males (Mooney and Konishi, '89). To further localize NMDA receptors in the song system, we measured glycine/glutamate-enhanced binding of 3H-MK801, an NMDA receptor antagonist, in brain sections from adult (>120 day) male zebra finches using film autoradiography.

Specific MK-801 binding was quite low in RA, the higher vocal center (HVC) and the lateral magnocellular nucleus of the anterior neostriatum (lMAN). In fact, binding within all of these regions was distinctly less than in adjacent tissue. In contrast, specific MK-801 binding was high throughout the parolfactory lobe, including Area X, a region critical for song learning. We are currently examining MK-801 binding in 30d and 50d old juveniles to determine whether NMDA receptor densities in these song related nuclei are higher during the sensitive period for song learning than in adulthood.

IMMUNOREACTIVE ESTROGEN RECEPTORS IN A SONG NUCLEUS IN FEMALE CANARIES. E. Brenowitz, B. Nalls*, and G.T. Smith. Departments of Psychology & Zoology, University of Washington, Seattle, WA 98195.

In songbirds estrogen (E) is important for the growth of forebrain song nuclei, juvenile song acquisition, and the activation of adult song behavior, (Gurney 1981; Harding et al. '83; Nordeen & Nordeen '89; Marler et al. '87). The accumulation of sex steroids by cells in song nuclei is thought to mediate hormonal effects. Gahr et al. (1987) showed that cells in the caudal nucleus of the ventral hyperstriatum (HVc) of male canaries have E receptors (ERs). We asked if female canaries also have ERs in HVc. Because female canaries can sing, but do so only rarely and more simply than males, they provide a test of the hypothesis that the ability of both sexes of a species to sing requires E accumulation by HVc cells in both sexes (Brenowitz & Arnold '89).

The brains of 4 male and 4 female canaries in breeding condition were cryosectioned at 18-25 µm. Sections were incubated with the H222 monoclonal antibody raised against human ERs (Abbott Labs), processed by the ABC method, and visualized with DAB.

Cells immunoreactive with the ER antibody were observed throughout HVc in both sexes. The proportion of ER (+) cells in HVc did not differ between females ($X \pm SD = 29.4 \pm 5.9\%$) and males ($30.8 \pm 5.6\%$). The absolute number of ER (+) cells in HVc was greater in males, however, because they have a larger HVc than females. The nuclei of ER (+) cells did not differ in size between females ($33.6 \pm 6.4\ \mu m^2$) and males ($31.1 \pm 7.5\ \mu m^2$).

These results support the hypothesis that the presence of ERs in HVc cells of both sexes is a necessary preadaptation for bisexual song. HVc also acts in song perception as well as song production (Margoliash '86; Brenowitz '91). Therefore, sex steroids may influence the activity of neurons important for both the production and perception of song. NEUROGENESIS IN CANARY FOREBRAIN IS INDEPENDENT OF GONADAL STEROID LEVELS. S. D. Brown, F. Johnson, M. L. Godfrey* & S. W. Bottjer. Dept. Biol., USC, Los Angeles, CA 90089

The number of neurons in vocal-control circuits of adult canary brain varies as a function of season and circulating levels of sex steroids. Although the rate of incorporation of newly generated neurons into vocal-control circuits varies seasonally, this difference could reflect a higher rate of neurogenesis, a lower rate of cell death, or an altered migration. We are interested in the factors that control the rate of cell proliferation, and have looked for changes in the incidence of thymidine-labeled cells in the forebrain ventricular zone of adult canaries as a function of variations in hormone levels.

Adult female canaries maintained on short days were anesthetized and gonadectomized. Four separate groups of birds received systemic exposure to either testosterone, estradiol, a combination of an anti-androgen (flutamide) and an aromatase inhibitor (ATD), or nothing. All birds were also implanted with an osmotic mini-pump that released ^{3}H-thymidine at the rate of 1 uL/hr (c. 1.5 uCi/g/day) for three days and were killed four days following the onset of treatment. Analysis of autoradiograms revealed no differences between groups in the incidence of labeling within the ventricular zone at forebrain levels around the anterior commissure. Preliminary analysis of similarly treated birds allowed to survive 7 days following onset of treatment yielded comparable results. These results suggest that sex steroids do not directly regulate the rate of cell division in the ventricular zone. Differences in the incorporation of labeled cells into vocal-control nuclei may therefore be due to regulation of neurogenesis by other factors or to some other cellular mechanism.

417.16

TESTOSTERONE REGULATES THE DISTRIBUTION AND NUMBER OF ANDROGEN TARGET CELLS IN CANARY HVc. F. Johnson & S. W. Bottjer. Dept. Biol., USC, Los Angeles, CA 90089

Male canaries modify their songs seasonally, adding new and losing old syllables at a time when serum testosterone (T) levels are low (Nottebohm et al '87). Evidence that serum T levels vary seasonally and correlate positively with seasonal variation in the Nissl-defined volume of HVc (a brain region necessary for song production), suggests that T may regulate the size of specific cell populations in HVc (Nottebohm '81). However, at least two sub-populations of HVc cells show no seasonal variation in their distribution: estrogen target cells and neurons which project to Area X (Gahr '90). We have measured the incidence of androgen target cells in HVc and asked whether the distribution and/or number of these cells could be influenced by exposure to T.

Adult males were maintained on short days, gonadectomized, and treated systemically with either T or a combination of an anti-androgen (flutamide, FL) and an aromatase inhibitor (ATD). One month later birds were processed for ^{3}H-dihydrotestosterone (DHT) autoradiography. T treatment increased both the Nissl-defined volume of HVc and the proportion of DHT target cells in HVc. Thus, FL/ATD birds have a smaller HVc with many fewer DHT target cells. Moreover, in contrast to estrogen target cells, the distribution of DHT target cells matched precisely the Nissl-defined borders of HVc in both T- and FL/ATD-treated males. These data suggest that T can regulate the size of a population of androgen target cells in HVc, and in this way might influence seasonal relearning and modification of song.

417.17

LESIONING AFFERENT INPUT TO A FOREBRAIN NUCLEUS DISRUPTS VOCAL LEARNING IN ZEBRA FINCHES. K.A. Halsema & S.W. Bottjer. Dept. Biol., USC, Los Angeles, CA 90089

Vocal behavior in songbirds is controlled by a system of interconnected brain nuclei. Previous studies indicate that discrete portions of this neural system are instrumental during song learning, but are not needed for maintenance of song. Lesions of either lMAN or Area X in juvenile birds disrupt vocal performance whereas ablations of either forebrain nucleus in adults do not disturb the stable song pattern. Area X projects trans-synaptically to lMAN through the thalamic nucleus DLM, which appears to provide the sole source of afferent input to lMAN. In order to examine the effect of lesions at different levels in the X-DLM-lMAN circuit, DLM afferents to lMAN were ablated by knife-cut in young males before 50 days of age and in adult males between 70 and 100 days old. Damaging only DLM afferents disrupts the developing vocal pattern in juvenile males but has no effect on the stereotyped song of adults, as is true for lesions of lMAN and X. However, the nature of the song deficits appears to vary in relation to the level of interruption in the X-DLM-lMAN circuit. Zebra finches receiving lesions of lMAN at a young age produce only a few grossly abnormal notes. In contrast, severing the DLM input to lMAN in juvenile males renders a poorly modulated song consisting of an unstable sequence of 5 to 7 notes. These results indicate that removing the input to lMAN is less disruptive to the development of vocal behavior than are lesions to lMAN itself. This difference in the nature of the behavioral disruption may reflect the neural processing within each portion of the X-DLM-lMAN circuit.

SONG ACQUISITION IN ADULT FEMALE CANARIES REQUIRES N. L-MAN. K.M.Hill*, A.J.Carlson* and T.J.DeVoogd, Dept. Psych. and Field of Neurobiol. and Behav., Cornell Univ., Ithaca, NY 14853

The avian song system can be divided into two subsystems: a caudal group of nuclei that has a large role in crystallized song production, and a rostral group that has a large role in song acquisition. Song acquisition typically consists of an early phase of auditory learning and a later phase of auditory-motor integration. In development, major changes in the morphology of the rostral system occur during the initial auditory phase, suggesting that these regions play a role in this phase of song acquisition.

We now find that one rostral nucleus, l-MAN is also needed for the later phase. Adult female canaries were implanted with testosterone (T). This makes them produce a stereotyped song like that produced by adult males (but with a repertoire of c. 8 syllables rather than 20-30). After the birds were singing, we lesioned l-MAN bilaterally. In a second set of females, l-MAN was lesioned first and T was then given. Vocalizations of both groups were analysed. In birds that were already singing, the lesions do not appear to alter the number of syllables in the repertoire, the stereotypy of syllable production or the patterning of syllables (although a few syllables appear modified after the lesion). In contrast, birds that received the lesion before T, put together a song with only 2-3 simple syllables. These are less stereotyped than in the other group, and the birds appear to perseverate in producing them. These data suggest that l-MAN plays a role in the auditory-motor phase of song acquisition, even when song is acquired as an adult. As in males, l-MAN is not needed for stereotyped female song. Thus auditory-motor integration can be induced and studied in adult animals, perhaps making it possible to determine neural changes responsible for this aspect of song learning. Supported by HD21033-05.

DOPAMINE RECEPTORS IN THE SONG CONTROL SYSTEM: AREA X IS DEFINED BY THE D2 BUT NOT THE D1 DOPAMINE RECEPTOR SUBTYPE.
J.M. Casto, G.F. Ball and J. Balthazart Dept. of Psychology, Boston College, Chestnut Hill, MA 02167; Univ. of Liège, Liège, Belgium

Songbirds possess a system of sexually dimorphic brain nuclei that mediate the production and acquisition of complex vocalizations (i.e. song). One of these nuclei, area X, is a subdivision of the parolfactory lobe (LPO), the caudate homologue. Area X is markedly sexually dimorphic and is known to receive a dopaminergic projection from the area ventralis of Tsai (AVT, Lewis et al. 1981 J.Comp. Neurol.). To better understand this dopaminergic input to area X and LPO we mapped by in vitro quantitative autoradiography the distribution of D1 and D2 dopamine receptors in two songbird species, the zebra finch (Taeniopygia guttata) and the European starling (Sturnus vulgaris) and one non-songbird, the Japanese quail (Coturnix coturnix japonica). D1 receptors were labelled using [^{3}H] SCH 23390 (SA 87 Ci/mmol) at 2.0 nM ± 2 mM (+) Butaclamol. D2 receptors were labelled using [^{3}H] Raclopride (SA 84.7 Ci/mmol) ± 2 mM (+) Butaclamol (to define non-specific binding). In all species the highest receptor density for both receptor types was observed in parts of the basal ganglia such as LPO and paleostriatum augmentatum (PA) the putamen homologue. No difference in the pattern of D1 and D2 binding was discerned within the quail LPO. In the songbird species, Area X, in the LPO, was clearly defined by a high density of D2 receptors as compared to the surrounding LPO. In the case of the D1 subtype there was no apparent difference between area X and the surrounding LPO. In female zebra finches area X is not visible in Nissl stained sections and it was not discernible when examining the pattern of D2 receptor density. Area X is known to be necessary in songbirds for the acquisition but not the production of song; quail do not learn their vocalizations and have no apparent differentiation of LPO into a subregion such as area X.

417.20

AUTORADIOGRAPHIC LOCALIZATION OF NMDA RECEPTORS IN THE AVIAN SONG CONTROL SYSTEM USING [^{3}H] MK-801
G.F. Ball and J.M. Casto, Dept. of Psychology, Boston College, Chestnut Hill, MA 02167

The N-methyl-D-aspartate (NMDA) receptor type has been implicated in the control of learning and memory in several vertebrate species. Songbirds possess a set of interconnected brain nuclei that are involved in both the acquisition and the production of vocal behaviors. To assess the possible involvement of this receptor subtype in song learning, we mapped, by in vitro quantitative autoradiography, the pattern of NMDA receptor binding in the songbird brain. The non-competitive antagonist [^{3}H] MK-801 was used to label the receptors (32 nM ± 5 mM ketamine to define non-specific binding). Two songbird species, the zebra finch (Taeniopygia guttata) and the European starling (Sturnus vulgaris) and one psittacine, the bugerigar (Melopsittacus undulatus) were used in this study. In the songbirds, 3 song control areas, the magnocellular nucleus of the anterior neostriatum (MAN), the caudal part of the ventral hyperstriatum (HVc), and the robust nucleus of the archistriatum (RA) were defined by a low density of MK-801 binding (e.g. 3 to 4 pmol/mg protein) in comparison to the surrounding structures (e.g. 7-10 pmol/mg p). The boundaries of Area X could be clearly discerned by the high density of binding (e.g. 4 to 6 pmol/mg p) in comparison to the surrounding parolfactory lobe (e.g. 2 to 3 pmol/mg p). The putative homologues of these nuclei could not be discerned in the budgerigar. The physiological significance of the relatively low density in three telencephalic nuclei mediating vocal learning and production remains to be investigated.

INVERTEBRATE LEARNING AND BEHAVIOR II

418.1

NEURAL CORRELATES OF EXPLORATORY BEHAVIORS IN FREELY-MOVING *NAVANAX INERMIS* (MOLLUSCA; OPISTHOBRANCHIA).
J.L. Leonard, Mark O. Hatfield Marine Science Center, Oregon St. Univ., Newport, OR 93765.

Navanax is a predatory hermaphrodite whose normal sexual behavior involves bouts of copulation in which a pair of individuals repeatedly alternate sexual roles. In an attempt to elucidate the role of the CNS in these long-term behaviors, I have used 2-14 h observation periods on 2-4 consecutive days to record repeated instances of whole behavioral sequences from animals with chronically implanted bipolar cuff electrodes. Use of a split-screen technique makes it possible to record, visualize, and playback, CNS activity on intact nerves or commissures, simultaneously with behavioral data. The high degree of cryptic neural activity and the fact that *Navanax* behavioral states are not mutually exclusive, make it difficult to identify one-to-one correspondences between behaviors and neural patterns. Also, individuals with lesions of major nerves often show few behavioral deficits. However, recordings from the 5th pedal nerve show a pattern of low frequency bursts of medium amplitude (~0.2-0.5 mv) which appears to be associated with investigation (presumably chemosensory) of the substrate. It may be related to flaring of the Hancock's organ. These spikes are normally absent during contact with prey and may therefore be associated with recognition of, or searching for, conspecifics. There is little overlap between spikes making it possible to identify single units. This suggests that it will be possible to identify the neurons responsible for these spikes. More variable patterns of activity on P5 are associated with head-turning. Supported by NIMH and NSF.

418.2

INTERACTIONS BETWEEN MOTIVATIONAL STATE AND CHEMOSENSORY STIMULATION OF SKIN ACID SECRETION IN *Pleurobranchaea*.
S.D.Grunder and R.Gillette. Dept. of Physiology and Biophysics, University of Illinois, Urbana Il 61801.

Mechanical and chemical stimuli elicit defensive acid secretion from the skin of *P. californica* (Gillette *et al.*, J. Exp. Biol. 156, 335 (1991)). Skin acidification potentiates aversive withdrawal of the affected body part and potentiates aversive turns and locomotion. It was shown that stimuli that elicit acid secretion also suppress feeding behavior and raise feeding thresholds. We have now found that appetitive food stimuli also stimulate acid secretion at the oral veil, suggesting that acid secretion could interact with an animal's motivational state to regulate feeding behavior. To test this, skin acid secretion was recorded while appetitive stimuli (squid homogenate or trimethylglycine) were applied to the oral veil of animals before and after satiation. Feeding thresholds rose by an average of 1.75 log units, but oral veil acidification (avg. 1.19 ± 1.09) was not significantly affected by satiation. These data suggest that food chemosensory stimulation of acid secretion interacts with satiation state to limit meal size. Differential chemosensory conditioning may help to further clarify the role of acid secretion in regulation of feeding behavior.

418.3

NETWORK MODEL OF AVERSIVE DISCRIMINATIVE CHEMOSENSORY CONDITIONING IN *Pleurobranchaea*.
J.R.Payne and R.Gillette. Neuroscience Program, University of Illinois, Urbana Il 61801.

P. californica learns to discriminate chemosensory stimuli such as squid homogenate, sea anemone homogenate, and beer extract (Davis *et al.*, J. Comp. Physiol. 138, 157 (1980); Mpitsos and Cohan J. Neurobiol. 17, 487 (1986)). A simple computational model has been constructed to study possible mechanisms by which complex olfactory stimuli are encoded and discriminated. The model incorporates 1) broadly but distinctly tuned olfactory receptors, 2) simple contrast enhancement mechanisms, 3) documented interactions of neural circuitry for appetitive and aversive behavior, and 4) simple learning mechanisms tied to nociceptive and reward pathways. Results so far suggest that expression of a repertory of relatively complex behavior may be appropriately and specifically altered by simple heterosynaptic modification of sensory paths to specific motor network elements.

418.4

LEARNING CORRELATED CHANGES IN A CALCIUM-ACTIVATED K CURRENT IN HERMISSENDA TYPE A CELLS.
Y. Han and I. Farley. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Previous research has determined that Type A photoreceptors in the eyes of Hermissenda exhibit reduced light-induced depolarizing generator potentials and resting input resistances for several days following pairings of light and rotation, when compared to results from random control or untrained specimens (Behav. Neuroscience., 1990). Voltage-clamp studies indicate that a TEA- and 4-AP resistant calcium-dependent K current ($I_{K\text{-}Ca}$)is an important determinant of a Type A cell's light response. In the present study, generator potential amplitudes of synaptically-isolated Type A cells from trained and control specimens were measured in normal and calcium-free ASW on retention days following learning. The ~ 5.0 mV training-associated difference in generator potential amplitude in normal ASW (3 min post light-onset) was virtually eliminated when calcium was removed from the bathing media. Measurements of I_A failed to reveal any training-associated difference in this component of K current, while measurements of $I_{K\text{-}Ca}$ revealed greater current amplitudes (by ~ 25% for potentials > -25 mV) in A cells from trained vs. control specimens. Collectively, these results demonstrate that long-term training-associated differences in Type A cells' light responses are due in part to training-associated increases in $I_{K\text{-}Ca}$, a mechanism which is the converse of that which underlies learning-associated changes in Type B photoreceptors.

418.5

IDENTIFICATION OF A $GABA_B$ RECEPTOR THAT CONTRIBUTES TO VISUAL-VESTIBULAR INTERACTIONS IN *HERMISSENDA*

L.D. Matzel and D.M. Fass
Department of Psychology, Rutgers University, New Brunswick, NJ 08903

Stimulation of vestibular hair cells induces a hyperpolarization and cessation of firing in ipsilateral B photoreceptors in the mollusk *Hermissenda*. This response is mediated by a GABAergic synapse, the function of which cannot be exclusively attributed to an inward Cl^- conductance at the B cell soma (e.g., Matzel & Alkon, *Brain Research*, 1991). At resting membrane potentials (-50 to -60 mV), pressure microapplication of either GABA (12.5 μM) or the $GABA_B$ agonist baclofen (125 μM) to the terminal branches of the B cell induced a hyperpolarization analogous to that induced by haircell stimulation, though the hyperpolarizing response to baclofen was reduced relative to the hyperpolarizing response to GABA ($\approx$ 4 mV and 8 mV, respectively). The GABA-induced hyperpolarization was reduced, but not eliminated, by the $GABA_A$ antagonist bicuculline (300 μM) or the $GABA_B$ antagonist 2-hydroxysaclofen (450 μM), but was eliminated by the combined application of each antagonist (150 μM and 225 μM, respectively). Moreover, the potential at which GABA induced no net voltage response shifted from -90 mV to -70 mV when either bicuculline (300 μM) or 2-hydroxysaclofen (450 μM) were added to the extracellular solution. To determine the conductance changes underlying these voltage responses, the B cell was voltage-clamped at -55 mV, and GABA application was found to induce a net inward current. Following application of 2-hydroxysaclofen (450 μM), the magnitude of the inward current increased, while application of bicuculline (300 μM) revealed an outward current in response to GABA, consistent with the persistence of an outward K^+ flux induced via stimulation of a $GABA_B$ receptor. In total, these results indicate that the voltage response of the B photoreceptors to GABA is the sum of an inward and an outward current, which arise from dual activation of both $GABA_A$ and $GABA_B$ receptor subtypes.

418.6

CORRELATES OF CONDITIONING IN PAIRS OF IDENTIFIED TYPE A & B PHOTORECEPTORS IN HERMISSENDA: EFFECTS OF ADAPTATION, LIGHT INTENSITY AND SYNAPTIC INTERACTIONS.

R.J. Frysztak & T. Crow. Dept. Neurobiology & Anatomy, Univ Texas Medical School, Houston, TX 77030

Type A & B photoreceptors have been shown to exhibit intrinsic cellular modifications in conditioned *Hermissenda*. Here we report that the effect of conditioning on the light responses of identified pairs of Type A and B photoreceptors depends on light intensity and light adaptation. The light-elicited spike frequency during the first 30s of a bright light (-2.0, -1.0 N.D.) was enhanced for lateral A cells from conditioned animals ($\bar{x}$= 7.67 spikes/s, $\bar{x}$= 5.51 spikes/s) compared to backward (BW) controls ($\bar{x}$= 5.5 spikes/s, $\bar{x}$= 2.84 spikes/s). However, the discharge frequency during the last 30s of a five min light step was less for conditioned animals (-2.0 N.D.)($\bar{x}$= 0.77 spikes/s) compared to BW controls ($\bar{x}$= 1.44 spikes/s). Medial Type A cells from conditioned animals exhibited a decrease in light response to bright light (-1.0 N.D.)($\bar{x}$= 4.46 spikes/s) compared to the BW control group ($\bar{x}$= 7.06 spikes/s) during the first 30s of the light step. The response of medial Type A cells from conditioned animals during the last 30s of a 5 min light step was decreased to bright light ($\bar{x}$= 0.64 spikes/s) compared to BW controls ($\bar{x}$= 1.80 spikes/s). The amplitude of the transient peak of the generator potential of intact medial A's from the conditioned group was enhanced in response to the brightest light intensity ($\bar{x}$= 43.8 mV) compared to normal controls ($\bar{x}$= 38.9 mV) and BW controls ($\bar{x}$= 40.0 mV). However the transient peak of the generator potential of lateral A's was reduced in conditioned animals ($\bar{x}$= 36.3 mV) compared to both normal controls ($\bar{x}$= 42.7 mV) and BW controls ($\bar{x}$= 47.0 mV). Preliminary studies of mutually inhibitory synaptic connections between pairs of A and B photoreceptors measured by Type B spike evoked IPSP's in Type A cells did not reveal significant changes in IPSP amplitude produced by conditioning.

418.7

EVALUATION OF MALE REPRODUCTIVE FUNCTION IN THE PULMONATE SNAIL MELAMPUS BIDENTATUS AFTER PENIAL COMPLEX EXCISION AND NERVE AND GANGLION LESIONS.

S. B. Moffett. Department of Zoology, Washington State University, Pullman, WA 99164.

The penial complex of Melampus is innervated by two clusters of neurons, a right cerebral cluster that is excitatory, and a right pedal cluster that is inhibitory (Moffett, Neurosci. Abs. 1989). Specific reinnervation of the penial complex occurs after the axons are severed (Ridgway et al., Neurosci. Abs. 1988) and the penial complex regenerates if at least part of its innervation is intact. The copulatory success in these hermaphroditic animals is tested in snails with 1) regenerated penial innervation or 2) regenerated penial complex (vas deferens, penis, penial sheath and prepuce). Snails with the same lesion history are maintained together and egg development is observed. Physiological and anatomical evidence of reinnervation appears within 2 weeks and snails with the penial nerve transected 3 weeks before onset of egglaying produced fertile eggs. Regeneration of the penial complex requires 4-6 weeks; snails did not produce fertile eggs at three weeks postoperative but will be monitored for the remaining 2 months of the reproductive season.

418.8

ODOR RESPONSES AND OUTPUTS OF AN OSCILLATING OLFACTORY PROCESSING NETWORK IN A TERRESTRIAL MOLLUSK.

A. Gelperin and J. Flores*. Molecular Biophysics Research Department, AT&T Bell Laboratories, Murray Hill, N.J. 07974

Odor processing networks in a variety of species are being explored from both a cellular and computational perspective to determine how molecular recognition and categorization are accomplished and how the resulting information is interfaced to behavioral subsystems which require processed odor information, such as navigation and odor learning. The procerebral (PC) lobe of the terrestrial slug *Limax maximus* is such an odor processing network. The PC lobe receives direct input from both inferior and superior noses and displays coherent network oscillations at 0.7 Hz which are modulated in waveform and frequency by natural odor input (**Nature** 345:437, 1990). The natural odorant 2-ethyl-3-methoxypyrazine (potato odor) produces comparable changes in the PC lobe oscillation when applied to the neuroepithelium of the superior nose in solution (10^{-4} % in saline) or as the vapor phase of a 10^{-5} % aqueous solution. Candidate outputs of the PC lobe were identified by application of the fluorescent carbocyanine dye $DiIC_{12}(3)$ to the neuropil of the PC lobe and incubation of the tissue at room temperature for 12 to 36 hours. A small number of labelled fibers (4 $\pm$ 2, N = 15)(mean $\pm$ std.dev.) appeared in the cerebropedal connective as did labelled cells in the pedal ganglion (8 $\pm$ 5, N = 13). The pedal cells appeared in 1 - 3 clusters. By analogy to similar cells in *Achatina* described by Chase and Tolloczko, the *Limax* pedal cells with processes in the PC lobe are likely to carry output from the PC to locomotor control centers in the pedal ganglion.

418.9

FOOD DEPRIVATION INCREASES THE CURVATURE OF SYNAPSES CONTACTING A MOLLUSCAN FEEDING INTERNEURON.

R. Chase and B. Tolloczko. Department of Biology, McGill Univ., Montreal, Quebec, H3A 1B1 Canada.

The purpose of this study was to investigate the plasticity of the synapses on the Giant Cerebral Neuron (GCN), a molluscan serotonergic cell that is known to respond to food stimuli and to facilitate feeding behavior. Snails (Rumina decollata) commonly experience extended periods of time without food. Therefore, we fed one group of snails ad lib, while a second group was starved for 5 days. Synapses converging onto the GCN were identified, within the brain, after injecting the GCN with hexamminecobalt. The principal result was that the ratio of curved synapses to flat synapses was significantly greater in the starved animals than in the sated animals. There were no significant differences between the groups in regard to the numerical densities of labelled synapses, the vesicle numerical densities, or the synaptic lengths. The results imply that sensory information about food is transmitted more effectively to the GCN in hungry snails than in sated snails.

418.10

BEHAVIOURAL ANALYSIS OF INTERACTIONS BETWEEN TWO ANTAGONISTIC REFLEXES IN *C. ELEGANS*.

C. H. Rankin, Department of Psychology, University of British Columbia, Vancouver, BC V6T 1Z4.

In response to a mechanical tap the nematode *Caenorhabditis elegans* shows a withdrawal reflex, swimming backwards for some distance. This reflex is capable of habituation, dishabituation and sensitization, as well as both short and long term memory. In addition, we have discovered two antagonistic reflexes in *C. elegans*.

Antagonistic reflexes that use the same final common path cannot be activated simultaneously; as a consequence one reflex often inhibits the expression of the other. In adult *C. elegans* tail-touch normally elicits forward movement, while tap normally elicits backward movement. When tail-touch was delivered one second before a tap, reversals to the tap were inhibited and the magnitude of any reversal that did occur was reduced. The relative magnitude of the two stimuli, tail-touch and tap, affected the amount of inhibition observed. Habituating the response to tail-touch decreased the inhibition of reversal to tap following a tail-touch. The tail-touch induced inhibition of reversal to tap diminished over an interval of at least 10 seconds; however, following the inhibition an enhancement of responding to tap was seen. Inhibition of reversal to tap was present in worms of all stages of development including newly hatched worms.

CIRCUIT ANALYSIS OF INTERACTIONS BETWEEN TWO ANTAGONISTIC REFLEXES IN *C. ELEGANS* . S. R. Wicks and C. H. Rankin, Department of Psychology, University of British Columbia, Vancouver, BC V6T 1Z4.

In order to investigate the mechanisms underlying a behavior, it is first necessary to determine the neural elements involved in the behavior. In this research we have focussed on the neural circuit underlying the withdrawal reflex made by the nematode worm *C. elegans* in response to a mechanical tap. Using mutant analysis and laser ablation techniques we have determined that the touch withdrawal circuit described by Chalfie and colleagues also mediates the tap withdrawal reflex.

Our behavioral experiments showed that the tail-touch withdrawal reflex inhibits the tap withdrawal reflex. Investigations into how these antagonistic responses can be reconciled within the touch circuit followed three lines. First, mutants specific for identified neurons within the circuit have been identified. For example, *deg-1* is a mutant in which the interneuron PVC degenerates between the first and second larval stages. This mutant failed to show the tail-touch induced inhibition to tap suggesting that plasticity is afferent to PVC. Second, laser ablating individual neurons within the circuit confirmed and extended the genetic studies. Finally, many of the worms neurons arise postembryonically. That the worm shows inhibition prior to the formation of some synapses argues against the possibility of those synapses mediating the response.

418.12

THE EFFECTS OF AGING ON NON-ASSOCIATIVE LEARNING IN THE NEMATODE *CAENORHABDITIS ELEGANS*. C. D. O. Beck and C. H. Rankin, Department of Psychology, University of British Columbia, Vancouver, BC, Canada V6T 1Z4.

In *Caenorhabditis (C.) elegans*, there are changes with age in habituation and recovery from habituation. Worms were tested at 4 days (peak of egg-laying), 7 days (after completion of egg-laying), and 12 days (shortly before death) of age. While the frequency of reversal withdrawal responses to single taps to the holding dish (vibrational stimuli) did not change with age, the magnitude of the reversals diminished.

In post-reproductive development, worms at all ages habituated to trains of taps delivered at a 10s interstimulus interval. However, worms tested at 7 and 12 days continued to make small responses throughout stimulation while 4 day olds often stopped responding entirely. All ages showed dishabituation in response to a mild electric shock. However, spontaneous recovery from habituation (measured 30s, 10min, 20min and 30min after the last habituating stimulus) was seen only in the worms tested at 4 days and 7 days. The deficit in recovery at 30min in worms 12 days of age cannot be accounted for by motor fatigue as worms of the same age dishabituated after habituation training.

Describing the changes in non-associative learning with age in normal wild-type worms will allow an analysis of the effects of treatments which alter the aging process in *C. elegans*.

418.13

AN ANALYSIS OF THE TAP WITHDRAWAL REFLEX IN MALE *CAENORHABDITIS ELEGANS*. K. B. Mah and C. H. Rankin, Department of Psychology, University of British Columbia, Vancouver, BC, V6T 1Z4.

Caenorhabditis elegans is a simple soil dwelling nematode which exhibits sexual dimorphism. The male *C. elegans* is differentiated from the hermaphrodite by the addition of 14 sensory structures in the tail. In this study, we compared the behavioural responses of the male to that of the hermaphrodite. It was hypothesized that the anatomical difference in mechanosensory structures might result in behavioural differences in the reversal response to vibratory stimulation (a tap to the side of the holding dish).

The adult male *C. elegans* shows a higher incidence of spontaneous reversals than the hermaphrodite. In response to differing intensities of tap there were no apparent differences between the responses of males and hermaphrodites. Further, the male was shown to be capable of simple non-associative learning: it demonstrated habituation, dishabituation and recovery from habituation in much the same manner as the hermaphrodite. Tail-touch induced inhibition of the reversal response appeared to be similar in males and hermaphrodites.

Thus, there appeared to be no behavioural differences between the male and hermaphrodite in the tap withdrawal reflex despite the presence of additional neuronal structures in the male.

418.14

Behavioral Development in the Embryonic Medicinal Leech, *Hirudo medicinalis*. S.A.Reynolds*, G.K.Bryan, A.Baader, and W.B.Kristan Jr., Department of Biology, U.C.S.D., La Jolla, CA 92093-0322.

The neuronal bases of several behaviors have been characterized in the adult medicinal leech. As a preliminary to studying the development of these behavioral circuits, we have been studying the normal course of behavioral development in the embryos between developmental days 10 and 30. We have determined the time of onset and the maturation of 14 different behaviors, both spontaneous and evoked, using microscopic observations and micro-cinematography with frame-by-frame analysis of behavior. We have found that the behaviors develop along a consistent course. For instance, spontaneous lateral movements of the head appear earlier than shortening can be evoked, and both appear earlier than swimming. There is also a rostrocaudal gradient of development for some behaviors, particularly the ones, such as lateral bending, which develop first. Complex behaviors develop in stages. For instance, in the development of crawling, the embryo masters the coordinated elongation and contraction phases of the step cycle before it can use the front and rear suckers to initiate and complete each step. In leeches, as in other poikilotherms, the overall rate of development depends on temperature. We are investigating whether the sequence of behavioral development is also temperature-dependent. This work was supported by USPHS research grant MH43396 to WBK.

418.15

CELLULAR ANALYSIS OF PREDICTABILITY IN THE LEECH. A. M. Horgan * and C. L. Sahley. Dept. Bio Sci, Purdue Univ., W. Lafayette, IN 47907.

Pairing and predictive relationships between stimuli are critical variables in associative learning for both vertebrate and invertebrate species including the leech, *Hirudo medicinalis*. We previously reported that the Retzius cell (R) may be implicated in the phenomenon (1988,*Soc. Neurosci. Abs.,14*, 838). That is, the R cell, driven by the US, continues to fire to throughout training for leeches experiencing paired CS-US presentations. In contrast, the response of the R cell decrements to repeated US alone presentations as well as to paired CS-US presentations with added unpredicted US alone trials. Learning only occurs following paired training.

Previous experiments have indicated that the long term inhibition of the R cell by serotonin (5HT) occurs via enhancement of IA (1989, *J. Exp. Bio., 145*, 403-17). We now report that pretreatment with FMRF replaces the 5HT induced inhibition of the R cell with an excitatory response consisting of a depolarization and barrage of action potentials. Voltage clamp analysis suggests that inward current is activated at a more negative potential in the presence of FMRF than in the control.

KILLING A SINGLE INTERNEURON ELIMINATES SENSITIZATION AND REDUCES DISHABITUATION IN THE LEECH. B. K. Modney#, K. J. Muller# & C. L. Sahley*. Dept. Physiol. & Biophysics#, U. Miami Sch. Med., Miami, FL 33136 and Dept. Bio. Sci.*, Purdue Univ., West Lafayette, IN 47907

Shortening, a defensive reflex of the leech, exhibits dishabituation and sensitization in response to a noxious stimulus. A chain of coupled interneurons (S cells) that forms the Fast Conducting System of the leech has an uncertain role in this reflex. In this study an intracellular pronase injection was made in vivo to kill a single S cell in segmental ganglion 4 to establish the role of the S cell in sensitization and in dishabituation of the shortening reflex. Control leeches underwent surgery without S-cell pronase injections. The effect of the lesion was assessed in semi-intact leeches using the protocols described previously (*J. Neurosci.*, 1988, 8, 4621).

No differences were found between control and S-cell killed animals in the shortening reflex or its habituation. S-cell kills disrupted, but did not eliminate dishabituation; i.e. animals showed significantly less dishabituation than control animals ($F_{(4,52)}=3.7$, $p<0.01$). In contrast sensitization was completely eliminated by S-cell kills ($F_{(1,12)}=5.62$, $p<0.05$). Thus, the S cell appears to be important in non-associative learning of the shortening reflex, but is not required for the reflex itself. The differential effect of S-cell killing on dishabituation and sensitization is added evidence that these types of learning may operate by different mechanisms.

GIANT FIBER ACTIVATION OF AN INTRINSIC MUSCLE IN THE MESOTHORACIC LEG OF *DROSOPHILA*. J.R. Trimarchi and A.M. Schneiderman. Section of Neurobiology and Behavior, Cornell University, Ithaca NY 14853.

Many of the muscles and neurons recruited during the escape response in *Drosophila* have been characterized. In particular, the tergotrochanteral muscle (TTM) which adducts the femur provides the force which propels the fly from its substrate during the initial jumping phase of the behavior (Mulloney, 1969, *Z. vergl. Physiol.*, **64:** 243-253). The present study focuses on the synergistic role in jumping of the tibial levator (TL), an intrinsic leg muscle.

During activation of the escape response by stimulation of the giant fiber pathway (Tanouye & Wyman, 1980, *J. Neurophysiol.* **44:** 405-421), muscle potentials are recorded from the TL with characteristic latencies of 1.3 ± 0.01 msec. They occur 0.48 and 0.04 msec after muscle potentials appear in the TTM and the dorsal longitudinal indirect flight muscles (DLMs), respectively. The threshold voltage of brain stimulation required to elicit a response in the TL is the same as that required for the TTM and DLMs. As stimulus voltage increases, the responses of the TTM and DLMs undergo a distinctive shift from long to short latency (Levine & Tracy, 1973, *J. Comp. Physiol.* **87:** 213-235). We observed that the response of the TL maintains its temporal delay with respect to the responses of the TTM and DLMs during this shift.

HRP backfills of the TL motor neuron indicate that it has both a dendritic arborization in the leg neuromere and a medially directed neurite. We are extending these studies to characterize the neuronal circuitry underlying activation of the TL by the giant fiber pathway.

418.18

EFFECTS OF cAMP ON GROWTH CONE MOTILITY IN CULTURED CNS NEURONS: ANALYSIS OF *DROSOPHILA* MEMORY MUTANTS, *dunce* AND *rutabaga*. Yun-Taik Kim* & Chun-Fang Wu
Department of Biology, University of Iowa, Iowa City, Iowa 52242

Learning and memory capacity of animals depends on cellular mechanisms underlying functional plasticity of neurons. This plasticity may involve morphological modifications of nerve terminal arborization and synaptic contact between neurons. The *Drosophila* mutants *dunce (dnc)* and *rutabaga (rut)* perform poorly in learning tasks, and are known to have elevated or reduced levels of intracellular cAMP, respectively. Since the growth cone plays a critical role in axonal elongation, branching and synaptogenesis, morphological and behavioral characteristics of growth cones may be altered during neural development in these learning mutants. The dissociated larval CNS culture system (Wu *et al.*, *J. Neurosci.* 3:1888, 1983) was employed in video microscopy examinations of mutant growth cones to investigate the role of cAMP in growth cone morphology and motility. We found that growth cones in *dnc* and *rut* were similar to wild type in several morphometric parameters, including the number and length of filopodia, and area and roundness of lamellipodia. However, the motility of growth cones, characterized by motility index and boundary flow plots (Kim & Wu, *J. Neurobiol.* 22: 263, 1991), was significantly lowered by *dnc* and *rut* mutations. Since *dnc* and *rut* affect cAMP-specific phosphodiesterase or Ca^{2+}-calmodulin activation of adenylate cyclase, respectively, we examined the effects of 10-50 μM forskolin or dibutyryl cAMP in the perfusion medium. The treatment resulted in retraction and thickening of lamellipodia which led to lower motility of growth cones and triggered the transformation of lamellipodia into club-shaped neurite endings. The fact that either elevated or lowered cAMP in *dnc* or *rut* had similar effects on growth cones suggests that an optimal level of cAMP is required to maintain growth cone motility, which may be important to neural plasticity underlying learning behavior.

418.19

SUPPRESSION OF ACTIVITY-DEPENDENT SYNAPTIC PLASTICITY IN NERVE TERMINAL ARBORIZATION BY MEMORY MUTANT *rutabaga* IN *DROSOPHILA*. Y. Zhong and C.-F. Wu Dept of Biology, Univ. of Iowa, Iowa City, IA 52242

Previous studies on hyperexcitable and *dnuce* mutants suggest that the cAMP cascade may be a crucial biochemical pathway in mediating activity-dependent enhancement of motor nerve terminal arborization in *Droasophila* larvae (Budnik et al., 1990, J. Neurosci. 10: 3754; Zhong et al., 1990, Neurosci. Abst. 16: 594). We investigated the effect of the *rutabaga* (*rut*) mutation, which eliminates Ca/CaM activation of adenylate cyclase, on hyperexcitable mutation- and temperature-induced enhancement in larval motor terminal arborization.

In larvae reared at 25 °C, the numbers of motor terminal branches and varicosities were increased in hyperexcitable *Shaker* (*Sh*) mutants with a reduced or eliminated transient K current (mean±SD of branches/varicosities in fiber 12 and 13, abd. segment 3, from 8-12 larvae: Sh^{120}; 22+3/332+51; Sh^{M}; 22±3/392±56; normal; 14±3/243±29). When rearing temperature was increased to 30 °C, expanded nerve terminal projection was also seen in normal larvae (26±5/392±38) as compared to those reared at 25 °C. This hyperexcitability- and temperature-induced enhancement in terminal arborization was suppressed by the *rut* mutation as shown in *rut* Sh^{120} (15±3/255±36) and *rut* Sh^{M} (19±3/298±28) double mutants reared at 25 °C as well as in *rut* single mutant reared at 30 °C (18±45/276±57).

Elevated cAMP in *dnc* mutants has been correlated to enhanced terminal arborization. Our results further support that the activation of cAMP cascade is a critical biochemical step in mediating synaptic plasticity.

LATHEO, A NEW SINGLE-GENE MUTANT AFFECTING LEARNING AND MEMORY IN *DROSOPHILA MELANOGASTER*. S. Boynton* and T. Tully. Department of Biology, Brandeis University, Waltham, MA. 02254

We have begun a screen for new mutations affecting classical conditioning or retention of olfactory avoidance responses in *Drosophila*. Use of P-elements as the mutating agent will ultimately expidite molecular cloning of the relevant genes. One strain isolated from this mutagenesis, $latheo^{P1}$, shows reduced learning and memory. Behavioral analyses indicate that the behavioral deficit of $latheo^{P1}$ flies is not caused by an inability to smell the odors (conditioned stimulus) used during training or by an inability to sense and escape from electric shock (unconditioned stimulus).

Genetic analyses of *latheo* indicate that the behavioral deficit in *latheo* flies is attributable to a single gene. Flies heterozygous for the $latheo^{P1}$ insertional mutation and for chromosomal deficiencies of the second chromosome show abnormal memory of olfactory avoidance conditioning. Two percent of *latheo* alleles generated by P-element excision were lethal, and the lethality mapped to a single, lethal complementation group in the *vestigal* region. More severe alleles of *latheo* show pleiotropic effects on several behaviors reflecting the fact that the normal *latheo* gene product is necessary for survival. In particular, locomotor ability is reduced in $latheo^{P1}$ flies hemizygous for $latheo^{P1}$ or $latheo^{P1}$ flies heterozygous with a lethal allele. The isolation of several hypomorphic excision alleles, however, allows a specific link between *latheo* and learning/memory to be established.

THE RHYTHMIC MOTOR PATTERN CONTROLLING OVIDUCT CONTRACTIONS IN *LOCUSTA MIGRATORIA*: DESCENDING NEURAL CONTROL AND TRACING OF EFFERENT TARGETS. G. Facciponte* and A. B. Lange. Dept. of Zoology, University of Toronto, Erindale College, 3359 Mississauga Road, Mississauga, Ontario, Canada, L5L 1C6.

The oviduct and associated muscles of the reproductive system of *Locusta migratoria* are innervated by neurons in the VIIth abdominal ganglion which project along the oviducal nerves (OVNs). Interruption of *Locusta* during egg-laying results in rhythmic neural activity recorded extracellularly from the OVNs.

The rhythmic neural activity consists of up to five discernable efferent units and no afferent units. All units fired with temporally interrelated patterns. The motor pattern persists in isolated VIIth abdominal ganglia of disturbed egg-layers indicative of a central pattern generator. In non-egg-laying females, where neural activity at the OVNs is normally very low, the rhythmic motor pattern was initiated by transection of the VIth-VIIth abdominal connectives.

Units within the motor pattern were traced to their respective muscle targets. One unit was recorded from a branch of the OVN innervating the lower lateral and common oviduct. Other units were recorded from branches of the OVN innervating skeletal muscles in the VIIIth abdominal segment lying in close association with the ovipositor muscles. The motor pattern therefore coordinates the activities of both a visceral muscle and skeletal muscle groups.

These results suggest that contractions of the lower lateral and common oviduct as well as associated skeletal muscles are controlled, at least in part, by motor pattern generating circuits located in the VIIth abdominal ganglion. These circuits appear to be under descending inhibitory control with the inhibition being removed during the disruption of egg-laying.

418.22

DIFFERENTIAL SENSITIZATION OF THE HONEYBEE'S PROBOSCIS EXTENSION REFLEX. M.Hammer and G.Braun-Weninger*. Inst. für Neurobiologie, Freie Universität Berlin, FRG

We examined the effects of three different stimuli (sucrose solution to the antenna, to proboscis, or to both) on the response to an odor (carnation) in a sensitization paradigm. Responses to the control stimulus (carnation), the sensitizing stimulus (sucrose solution), and test stimuli (.5, 1, 2, 5 min later) were monitored by extracellular recordings from a muscle involved in proboscis movement. The number of muscle spikes per trial served to judge the response-intensity. Also, the percentage of successfully sensitized animals was compared among the different experimental groups. During the control trial we could discriminate animals which showed a response (spontaneous animals) and non-responsive animals (not spontaneous). In both groups a sensitizing effect was apparent with either treatment at the test trial at .5 min, but among the different experimental groups we found no differences for spontaneous animals. The results reported below refer to not-spontaneous animals.

At the first test trial the percentage of successfully sensitized animals was significantly greater when sensitized by antennal stimulation. In contrast, the response-intensity (i.e. muscle-spikes per trial) to the sucrose solution stimulus and during the first test trial was lowest. The experimental groups receiving stimulation to proboscis or to both proboscis and antenna did not show profound differences.

The combined results reveal that intensity and probability of the sensitizing effect are not linked in a trivial way. As a functional interpretation we suggest that antennal sensitization facilitates the sensory components of the reflex, while the procedures involving stimulation of the proboscis facilitate components of the motor program.

418.23

DIFFERENTIAL TONIC INHIBITION OF CRAYFISH LATERAL GIANT ESCAPE TO STIMULI IN DIFFERENT SENSORY FIELDS. F.B. Krasne, E.T. Vu, and S.C. Lee. Neuroscience Program, Dept. of Psychology, and Brain Research Institute, University of California, Los Angeles, CA 90024.

Crayfish lateral giant escape is subject to suppression by a "tonic inhibitory" pathway that descends into the abdomen from more rostral ganglia. Recent physiological evidence (Vu and Krasne, these abstracts) indicates that tonic inhibition is due to remote postsynaptic inhibition of the lateral giant command neurons. Remote postsynaptic inhibition theoretically has the capability to inhibit selected regions of a dendritic tree. As a preliminary test of whether the tonic inhibitory pathway can suppress responses to selected stimulus fields, we simultaneously monitored restraint-induced inhibition in two different abdominal segments to see if differential onsets or offsets could be observed. We found that inhibition tends to turn on at about but not exactly the same time in different segments. Thus, the different segments are subject to independent control. Experiments to search for differential inhibition of different fields within a hemisegment are planned.

Supported by USPHS grant NS08108 (FK) and a Predoct. NSF Fellowship (EV).

OCTOPAMINE INCREASES EFFICIENCY OF COMMISSURAL TRANSMISSION BETWEEN CRAYFISH LATERAL GIANTS. S.C. Lee and F.B. Krasne. Dept. of Psychology and Brain Research Institute, University of California, Los Angeles, CA 90024.

Octopamine is known to increase transmission between primary afferents and first order interneurons of the crayfish lateral giant escape reflex circuit and has been conjectured to mediate behavioral sensitization of the lateral giant escape reflex. Evidence that it also affects the lateral giants directly is now provided by the finding that octopamine ($8x10^{-5}$ - $3x10^{-4}$ M) decreases the time needed for one lateral giant to recruit its contralateral homologue by up to 20%. This effect is antagonized by the octopamine antagonist, phentolamine (10^{-4} M). The presence of functional octopamine receptors on LGs may facilitate analysis of octopamine's mechanism of action in this system.

Supported by USPHS grant NS08108 (FK).

HORMONAL CONTROL OF BEHAVIOR II

THE ONTOGENY OF BEHAVIORAL ASYMMETRY IN THE RAT: INFLUENCE OF SEX & PRENATAL TESTOSTERONE. K.J. Schultz and J. Quinn*. Psychology Department, University of Winnipeg, Winnipeg, MB, Canada R3B 2E9.

Behavioral asymmetry exists in rats and tends to be more strongly exhibited by females than males. Tail posture asymmetries assessed at Day 1 (birth=Day 0) have been found to be predictive of adult turning preference. This study assessed the development of behavioral asymmetries from Day 1 to Day 21 in male (N=44) and female (N=52) Sprague-Dawley rats with varying levels of prenatal testosterone exposure. Testosterone levels were inferred from ano-genital (AG) distance measurements taken on Day 0. The development of behavioral laterality was evaluated using measures of tail posture and negative geotaxis turing direction, while adult patterns of behavioral laterality were assessed on a circling, a swimming and a head turn task. Laterality measures taken on Day 1 revealed no turning preferences and did not reliably predict adult laterality. A rightward turning preference did emerge over the next two weeks, particularly for negative geotaxis, and over this period tail posture varied with sex and AG as well as with age. Measures taken on Days 3 to 15 were significant predictors of adult turning preference and adult behavior also varied as a function of sex and AG distance. Neural mechanisms underlying these changes are being explored.

419.2

RAPID NEUROPHYSIOLOGICAL ACTIONS OF CORTICOSTERONE RELATED TO STRESS-INDUCED INHIBITION OF SEXUAL BEHAVIOR IN AN AMPHIBIAN. J. D. Rose, F. L. Moore and M. Orchinik. Dept. of Psychology, University of Wyoming, Laramie, WY 82071 and Dept. of Zoology, Oregon State University, Corvallis, OR 97331.

Acute stress inhibits courtship clasping by male rough-skinned newts due to a rapid effect of corti-costerone (CORT). A binding site in neuronal membranes from newt brain, with properties correlated with the CORT inhibition of clasping has recently been characterized (Orchinik, Murray and Moore, Science, in press.) In the present study, neural actions of CORT were examined in male newts by microelectrode recordings from medullary reticulospinal neurons that were backfired (antidro-mically-activated) by spinal cord stimulation. Systemic administration of a behaviorally-effective dose of CORT produced an increase in antidromic spike amplitude within 5 min that was followed immediately by a progressive de-cline in excitability, in which spikes exhibited slowed rise rates and fragmentation of components. Topical medullary CORT application also depressed neuronal exci-tability, but more rapidly than systemically-administered hormone. The time course of CORT effects on these neurons corresponds well with the rate of onset of the hormone's inhibition of clasping and is consistent with a membrane mechanism of action. Supported by NIH grant NS13748 (J.R.) and NSF grants BNS8901500 and BNS8909173 (F.M.).

419.3

STEROID HORMONE MEDIATION OF THE EFFECTS OF ENERGETICS ON MALE FROG REPRODUCTIVE BEHAVIOR. C.A. Marler*, M. Ryan* and W. Wilczynski. Depts. of Zoology and Psychology, University of Texas, Austin, TX 78712.

Energetic factors might influence reproductive success in male túngara frogs (*Physalaemus pustulosus*) by limiting the best predictor of male mating success: time spent in chorus activity. We manipulated food intake and found that males with lower food intake called for fewer hours, even though their lipid reserves were not greatly decreased. Average lipid stores in males provided energy for calling approximately six hours a night for six nights.

Hormonal mechanisms potentially mediating this effect of energetics on behavior were also examined. One potential mechanism for decreasing calling is through lower testosterone (T) levels, possibly through increases in corticosterone (B) levels. Males with lower food intake had lower T-levels. Male reproductive behavior was associated with T-levels: calling males had higher T-levels than noncalling males. Two lines of evidence suggest that B might influence T levels; (1) B-levels were negatively correlated with T-levels, and (2) B-implants caused a decrease in T-levels. B may inhibit reproductive behavior directly. B-implants decreased calling behavior, but there was no difference in B-levels between fed and unfed males. However, levels were high in all groups, potentially masking a difference. These data suggest that plasma steroid levels may be mediating effects of energetic factors on reproductive behavior. (supported by Smithsonian Tropical Research Institute and NIMH grant T32 MH18837-01)

419.4

POSSIBLE ROLE OF ANDROGENS IN THE LOSS OF SECONDARY SEX CHARACTERISTICS IN BORNEAN VOICELESS FROGS C.N. Rowsemitt, S.B. Emerson*, and D.L. Hess*. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112, and Oregon Reg. Primate Ctr, Beaverton, OR 97006

Four species of Bornean frogs lack a suite of behavioral and morphological secondary sex characteristics which occur in breeding north temperate and tropical frogs (enlarged fore-limbs, advertisement calls, vocal sacs, nuptial pads). We have examined plasma steroid levels in reproductively active males of one species of voiceless frogs (Rana blythi) to test the hypothesis that decreased circulating androgens could be at least part of the explanation for the unusual loss of these characteristics. Frogs were captured in Sabah, Malaysia, in 1989 and 1990 and immediately bled. Plasma androgens were lower in R. blythi than those reported for other species in the literature where comparable blood sampling techniques were used. We suggest that lowered androgen levels may be at least part of the explanation for the loss of behavioral and morphological secondary sex characteristics in voiceless frogs. [NSF grant #BSR-8822630 (SBE) and NIH grant #HD18185(DLH)]

TESTICULAR SECRETIONS MASCULINIZE VOCALIZATIONS IN FEMALE *X.LAEVIS*. J T. Watson and D. B. Kelley, Dept. Biol. Sci., Columbia Univ., NY, NY 10027

Male *Xenopus laevis* frogs produce a song consisting of alternating fast and slow trills while adult females do not sing. We examined the ability of testicular hormones to induce singing in females. Adult male and female frogs were gonadectomized and implanted with Silastic tubes which contained either testosterone propionate (TP) or nothing, and then tested after 13-17 months with sexually unreceptive females. While TP restored singing in castrated males, it did not induce singing in ovariectomized females. Since previous studies have shown that long-term TP treatment fully masculinizes laryngeal muscle contractile properties, these females' larynges were capable of song. Male and female frogs at various ages from metamorphosis to early adulthood (20-50 g B.W.) were gonadectomized and implanted with testes, grown to sexual maturity (as evidenced by growth of nuptial pads), and tested for singing. All testes-implanted females sang. The number of songs and total duration of singing were not significantly different from identically-treated or intact adult males. Females implanted early in post metamorphic development produced fully masculinized trills (53-70 Hz), but females implanted after 15 g B.W. produced trills which were slower (45-50 Hz). This study provides the first evidence that testicular hormones can induce singing in female *X. laevis*. Supported by NS23684 and NS08304.

419.6

CASTRATION DISRUPTS MALE RAT'S ABILITY TO RECOGNIZE FEMALE CONSPECIFICS. T. Mencio Wszalek and V.D. Ramirez, Beckman Institute, University of Illinois, Champaign, Illinois, 61820

We have previously reported that adult male rats are capable of recognizing sexually receptive adult female rats with whom they have previously interacted. Using the time spent in female-directed olfactory investigation as an index of recognition, we have observed that recognition is significantly disrupted 2, 22, and 44d post-castration; i.e., castrate males, in contrast to intact males, fail to exhibit less olfactory investigation of a familiar female. (▲T=Change in time spent investigating female from the first to the second interaction period, sec±SEM ; ▲T = 2±9, 10±14, and -5±13 sec for the 2, 22, and 44d castrates respectively; n=6 in each group.) Testosterone propionate (TP) (100ug/rat) replacement via subcutaneous injections at 24 and 1 hour prior to interaction test restored the 2 and 44d castrate males ability to recognize a familiar female conspecific (▲T= -35±7 sec for the 2d castrate + TP, n=5; and ▲T= -32±10 sec for the 44d castrate + TP, n=6). The recognition exhibited by the 2d castrates + TP persisted for more than three hours, while that of the 44d castrates + TP began to deteriorate after 2h. In addition, the 44d castrates + TP failed to exhibit mounting behavior during any of the interaction trials, while the 2d castrates + T mounted the familiar female significantly more rapidly during the second, third, and fourth interaction periods as compared to the first, (latency to mount in seconds±SEM = 255±29, 97±29, 129±70, and 127±71.) Thus, it appears that testosterone is a necessary requirement for the adult male rat's exhibition of recognition of a familiar female conspecific.

419.7

DISASSOCIATION OF JUVENILE PLAY FIGHTING AND ADULT DOMINANCE IN MALE RATS TREATED NEONATALLY WITH TESTOSTERONE PROPRIONATE. S. M. Pellis and V. C. Pellis. Dept. Psychology, Univ. Lethbridge, Lethbridge, AB. T1K 3M4

It is known that juvenile female rats play less than juvenile males and that neonatal treatment with testosterone proprionate (TP) elevates the frequency of play of females to that of males. Such treatment to males increases their play to levels above that shown by controls. Studies have indicated that the effects of such neonatal exposure to androgens have a masculinizing effect on brain and behaviour. In the present study, neonatal male rats were injected with TP (two injections of 0.05 ml each, one/day, of 250 µg/ml, s.c. in the nape) and a control group received an equivalent volume of the oil vehicle. At weaning, each injected male was paired with a male littermate, and they were housed together until 100 days old. At 30-40 days and at 80-90 days, they were isolated from one another for 24 h and then re-paired in a test exclosure, and their play behaviour was videotaped. This was repeated twice at each age. At the 30-40 day age class, TP treated rats played 2-3 times more frequently than the oil injected controls. This is comparable to other studies. When housed together, male pairs form a dominant-subordinant relationship which becomes more clearly asymmetrical in the weeks following sexual maturity (i.e., 50-60 days). Behavioural and physical measurements at 80-90 days clearly identified the dominant pairmate in each pair. TP treated rats were no more likely to become the dominant pairmates than were their untreated pairmates. Therefore, while neonatal exposure to additional androgens masculinizes play behaviour, it does not appear to influence other masculine behaviours related to aggression and dominance.

EMG ACTIVITY OF THE SEXUALLY DIMORPHIC SPHINCTER CLOACAE MUSCLE DURING COPULATION AND FOAM PRODUCTION. J.S. Park,* C.M. Seiwert, and E. Adkins-Regan, Departments of Psychology and Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

The foam gland complex (FGC) of Japanese quail (*Coturnix japonica*) is a large sexually dimorphic structure located in the dorsal wall of the cloaca which produces foam that is transferred to the female during copulation. The FGC consists of an aggregate gland whose units are interdigited with fibers of the large, circular sphincter cloacae muscle (mSC; Klemm et al., 1973). The major muscle of the cloaca, mSC is involved in copulation and defecation and may play a role in foam production by mechanically whipping the clear fluid secreted by the gland into its final form. Chronic EMG recordings from freely moving male quail were used to study potential mSC involvement in foam production and copulation, and to determine if the muscle is differentially active during these behaviors. A silastic "tophat" containing a female connector was implanted in the lumbosacral area of the back. Electrode wires were passed subcutanously to the cloacal region, where the wires were inserted into dorsal mSC. Different mSC movements accompany copulation and foam production. The mSC is responsible for elevation of the cloaca and extension of the vent during the cloacal contact movements (CCM; King, 1981) that characterize copulation. A series of spontaneously occuring rhythmic waves (SRW) of contraction are associated with foam production. EMG activity during CCM and SRW is composed of a series of high frequency waves, with bursts during CCM possessing a greater amplitude than those during SRW. SRW activity is rhythmic, although bursts occur more frequently immediately prior to mounting. Thus mSC exhibits different patterns of activity during copulation and the SRW associated with foam production in male Japanese quail. Future work will address whether mSC activity is necessary for the production of foam and whether manipulation of androgen levels alters mSC activity during either of these behaviors. A SEX-DEPENDENT INFLUENCE OF TESTOSTERONE ON THE DORSO-MEDIAL NEURONAL POPULATION OF THE JAPANESE QUAIL INTERCOLLICULAR NUCLEUS. G.C.Panzica, N. Aste, J.Balthazart and C.Viglietti-Panzica, Dept. Human Anatomy & Physiology, Univ. of Torino, I-10126 Torino, Italy and Lab. Biochemistry, Univ. Liège, B-4020 Liège, Belgium.

The nucleus intercollicularis in quail is implicated in the control of a number of vocalizations. It is also a target structure for steroids and includes high numbers of cells containing androgen and estrogen receptors. We recently demonstrated that in another steroid target, the medial preoptic nucleus, the effects of testosterone are paralleled by significant changes in the neuronal size (J. Comp. Neurol., 303, 443-456, 1991). A morphometrical analysis of the nucleus intercollicularis was therefore undertaken in male and female Japanese quail (*Coturnix coturnix japonica*) that were either gonadectomized or gonadectomized and treated with testosterone or left intact as controls. This showed that, in males, testosterone increases the cellular size in the dorso-medial part of the nucleus: the mean neuronal area was larger in intact and testosterone-treated males than in castrates. Such an effect was not observed in females nor in the adjacent nucleus mesencephalicus dorso-lateralis which was taken as control structure because it is devoid of steroid receptors. The changes observed in the nucleus intercollicularis of males represent a morphological marker for the cellular actions of the steroid. They could provide a useful tool to analyze the mechanisms by which testosterone activates vocalizations in male quail. *Supported by EEC (SC1-0230C/TT), CNR (89.03043.04, 90.02456.04), MURST 40%, and FRFC (9.4601.90 and 2.9003.91).*

LOCALIZATION OF MOTONEURONS INNERVATING THE MAJOR MUSCLES OF THE CLOACA IN JAPANESE QUAIL. C.M. Seiwert and E. Adkins-Regan, Department of Psychology, Cornell University, Ithaca, NY 14853.

Four major striated muscles are associated with the dorsal cloaca in birds: the sphincter cloacae (mSC), the transversus cloacae (mTC), the levator cloacae (mLC), and the constrictor cloacae (mCC). By far the largest of these is the sexually dimorphic, hormone-sensitive mSC. Motoneurons responsible for the innervation of mSC lie in the lateral motor column of synsacral segments 7, 8, and 9 or 8, 9, and 10 (Seiwert and Adkins-Regan, 1987). The variability in rostral-caudal location reflects individual differences in which segments of the cord contribute to the pudendal nerve. We now report that the motoneurons supplying mTC, mLC, and mCC also lie in the lateral motor column in the same segments as those innervating mSC. A single small injection of cholera-toxin conjugated to horseradish peroxidase (CT-HRP) was made into the dorsal musculature of the cloaca [mSC-- 0.5 µl, n=7; mTC-- 0.3 µl, n=8; mLC-- 0.25 µl, n=2; mCC-- 0.25 µl, n=3]. Animals were sacrificed 48±3 hours later. Regardless of the muscle injected, labelled somata with multiple primary dendrites were located in the lateral motor column of synsacral segments 7, 8, and 9 or 8, 9, and 10. Bilateral label was observed after injections into mSC and mCC, while in mLC and mTC labelled somata were present only ipsilateral to the injection site. No differences existed in the proportion of labelled somata present in any given segment. Thus the motoneuron pools which innervate mTC, mLC, and mCC are distributed thoughout the larger pool of motoneurons innervating mSC. Work in progress addresses the following questions: 1) Are cloacal muscles other than mSC sexually dimorphic?; 2) Does a sex difference in muscle fiber type exist in cloacal musculature?; 3) Are cloacal motor neurons, like cloacal muscle, sensitive to sex steroids? [Supported by NSF # BNS 88-09441.]

ASYMMETRIC LESIONS OF THE SEXUALLY DIMORPHIC AREA AND RETRORUBRAL FIELD IMPAIR SEXUAL BEHAVIOR IN MALE GERBILS. P.D.Finn and P.Yahr. Dept. of Psychobiology, University of California, Irvine, CA 92717.

Bilateral radiofrequency (RF) lesions of the lateral part of the sexually dimorphic area (lSDA) of the gerbil hypothalamus disrupt male sex behavior (Commins & Yahr, '84). The lSDA projects to two midbrain areas, the retrorubral field (RRF) and the ventrolateral central gray (CGvl; Finn et al., unpub.) that are implicated in the control of male sexual behavior in rats (Brackett & Edwards, '84; Hansen et al., '82). To determine if pathways between these areas and the lSDA are involved in male sexual behavior, asymmetric lesions were used. Gonadally intact male gerbils were given unilateral RF lesions of the lSDA and contra- or ipsilateral RRF or CGvl, or sham lesions at both sites. They were tested for 3 weeks for male sexual behavior. The lesions were small and rarely destroyed the entire target area. An analysis of variance revealed that males with unilateral lesions of the lSDA and contralateral RRF were impaired on most parameters of copulation. Thus, pathways between the lSDA and RRF appear important in the control of male sexual behavior. Since RF lesions destroy both cell bodies and fibers of passage, we are now studying sexual behavior in male gerbils given unilateral RF lesions of the SDA combined with cell body lesions of the contralateral RRF. PELVIC AND HYPOGASTRIC NERVES CO-PARTICIPATION IN THE MEDIATION OF MALE RAT SEXUAL BEHAVIOR. R.A. Lucio, J. Manzo and P. Pacheco. CIRA, Univ. Auton. Tlaxcala; CIB Univ. Veracruzana; IIB-UNAM México, D.F.

Erection is controlled by the pelvic nerve (PN) while hypogastric nerve (HgN) controls emission and the fertility potential. Transection (Tx) of PN viscerocutaneous branch (PNVB), but not of HgN, alters some copulatory parameters. We analyzed the co-participation of both nerves in male rat sexual functions. Copulatory behavior and penile reflexes were tested before and after PNVB, HgN or PNVB+HgN Tx. One ejaculatory series plus penile reflexes or two ejaculatory series plus seminal plug presence (SPP) were scored. RESULTS: a) PNVB Tx increases the number of mounts and the intromission latency, while decreases the number of intromissions, the hit rate, the SPP, and the frequency of penile reflexes. All but SPP values recover progressively. b) HGN Tx reduces even more the SPP (to 20±10% vs to 50±8% of PNVB Tx); again this value never recovers. c) PNVB+HGN Tx produces similar effects than PNVB Tx, but eliminates SPP and penile reflexes; also with this Tx procedure neither parameters nor SPP recover. CONCLUSIONS: a) HGN participates in the regulation of copulatory parameters by compensating the alterations produced by PNVB Tx. b) HgN besides controlling seminal emission, participates in erection. c) PNVB besides controlling erection participates in emission. d) both nerves plays a decisive role on SPP. SEP C91 (P.P.); SEP C91; CONACyT D111903850 (J.M.).

THE MALE RAT LEVATOR ANI: EVIDENCE FOR A SEXUAL FUNCTION FOR A MODEL ANDROGEN-SENSITIVE MUSCLE. G.M. Holmes and B.D. Sachs. Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269-1020.

The levator ani (LA) of most species is involved in defecation. The sexual dimorphism and androgen sensitivity of the male rat LA has implied a reproductive function for the LA, but there has been no direct evidence for such a function. These experiments addressed the role of the LA in sexual and defecatory reflexes of the male rat. Penile bulb and rectal pressure changes were monitored during contraction of the LA and proximal bulbospongiosus (pBS). LA stimulation produced moderate increases in penile bulb pressure and negligible rectal pressure changes. LA denervation produced a 48% decrease in the pressure generated by the pBS relative to pBS muscle contraction with the LA intact. Removal of the denervated LA muscle reduced pressure further. EMG recordings from the LA and pBS during copulation revealed similar and coordinated activity in the two muscles. These data show that the levator ani (a) is an active component in a highly coordinated muscle system augmenting penile erection in the rat and (b) is unlikely to participate in defecation.

EFFECTS OF DISCRETE CELL BODY LESIONS ON SEXUAL AND SCENT MARKING BEHAVIOR IN MALE GERBILS. H. Hershey, T.R. Akesson, and C. Ulibarri, Dept of VCAPP, College of Veterinary Medicine, Washington State University, Pullman, WA 99164-6520.

Previous research demonstrates that the medial preoptic area accumulates gonadal steroids and plays a major role in the control of male scent marking and sexual behavior in Mongolian gerbils (Meriones unguiculatus). Other areas of the brain that also accumulate estrogens and/or androgens are suspected to be involved in the control of scent marking and sexual behavior in gerbils. This study focuses on the roles of the nucleus accumbens (ACC), bed nucleus of the stria terminalis (BST), medial nucleus of the amygdala (MeA), and ventral premammillary nucleus (PMv).

Adult male gerbils were evaluated for scent marking and sexual behavior in test arenas containing four raised blocks to elicit scent marking. The number of marks in the five minutes preceding sexual behavior testing were assessed. During sexual behavior testing the time to initiate a mount, the number of mounts, the time to show an intromission, the number of intromissions, the time required to ejaculate, and post-ejaculatory interval were also recorded. Gerbils were tested several days apart until each completed 3 ejaculations or 5 test sessions, whichever came first. Bilateral cell body lesions were then made by infusion of excitotoxin into the following areas (N = 10/group): ACC, BST, MeA, PMv, or control lesions. Behavior testing was repeated 2 days, 5 days, 1 wk and 2 wk after lesions were produced. Gerbils were then castrated and implanted with testosterone (T) capsules and tested 3 days, 1 wk and 2 wk to determine if behavior changes were the result of decreased T secretion following brain lesions. After behavior testing, lesion placement was confirmed histologically. Analysis of data was performed utilizing analysis of variance followed by orthogonal comparisons. Supported by HD 22869.

INDUCTION OF c-fos IMMUNOREACTIVITY WITHIN THE NEURONAL CIRCUITRY UNDERLYING COPULATORY BEHAVIOR IN THE MALE SYRIAN HAMSTER. S.S. Kollack and S.W. Newman. Department of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109-0616.

We have analyzed the patterns of c-fos immunoreactivity within the neuronal circuitry underlying mating behavior in the male Syrian hamster (*Mesocricetus auratus*) in order to identify specific subpopulations of neurons involved in the mating behavior response. Three groups of adult male hamsters were studied: (1) sexually-naive hamsters as controls, (2) mated hamsters killed immediately after behavioral testing, and (3) mated hamsters killed one hour after behavioral testing. All hamsters were perfused with 4% paraformaldehyde and 40 um frozen sections were processed for immunocytochemistry using a polyclonal c-fos antibody (Oncogene Sciences). Compared to controls, mating induced at least a five-fold increase in the number of c-fos immunoreactive neurons in the caudal aspect of the medial preoptic nucleus, the magnocellular medial preoptic nucleus, and the medial subdivision of the bed nucleus of the stria terminalis. No difference was observed in the patterns of c-fos immunoreactivity between the two mated groups. These data provide a dynamic demonstration of the functional significance of specific neuronal populations to the mating behavior response. We are currently analyzing patterns of c-fos immunoreactivity in other brain areas to obtain the neuroanatomical distribution of neurons activated with mating behavior. IMMEDIATE EARLY GENES INDUCED FOLLOWING SEXUAL BEHAVIOUR IN MALE RATS: DIFFERENTIAL EXPRESSION OF C-FOS IN LIMBIC STRUCTURES. M.J. Baum[1] and B.J. Everitt. Dept. of Anatomy, Cambridge University, Cambridge CB2 3DY, England & [1]Dept of Biology, Boston University, Boston, MA 02215.

The protein products of immediate early genes (IEGs: *c-fos, egr-1, c-jun)* were visualized immunocytochemically in the brains of male rats following different degrees of sexual interaction.

One hour following ejaculation, FOS was expressed prominently in the medial preoptic area (mPOA), bed nucleus of the stria terminalis, the medial amygdala (especially a cluster of cells in the posterodorsal part of the nucleus) and in a large group of neurons in the mesencephalic central tegmental field (CTF). Restricting interaction to 1 or 5 intromissions resulted in proportionally fewer FOS-immunoreactive (IR) neurons in these structures. Prolonged olfactory investigation during interaction with oestrous females induced FOS-IR generally in the medial amygdala, but not in the posterior dorsal nuclear cluster, minimally in the mPOA and not at all in the CTF. Olfactory investigation of females caged in a perforated Perspex compartment did not result in the appearance of FOS-IR in these structures. FOS-IR was detectable as quickly as 15min after ejaculation; the response increased through 30min and was maximal at 1h, but began to dissipate by 3h and was virtually undetectable by 6h.

The results suggest that IEG induction may be used to visualise a widespread neural system associated with the display of sexual behaviour in male rats. This activity-dependent response may provide a means by which to analyse the hormone-dependence and sensory determinants of such neural activity.

MOTONEURONS OF THE GUINEA PIG RETRACTOR PENIS ARE SEXUALLY DIMORPHIC IN SIZE BUT NOT NUMBER. Louise M. Freeman & S. Marc Breedlove, Psychology Dept., U.C. Berkeley, Berkeley CA 94720.

The retractor penis (RP) attaches between the penis and the pubis in male guinea pigs; a much smaller counterpart, the retractor clitoris (RC), is present in females. We previously reported that the associated motoneurons occupy the central region of the ventral horn from the L5 to S1 regions of both sexes (Freeman & Breedlove, Soc. Neurosci. Abstr. 115.4, 1989). To determine whether these motoneurons were sexually dimorphic in number or size, we counted and measured cells labeled by large muscle injections of horseradish peroxidase (HRP) into the muscle.

Under ketamine anesthesia, six adults of each sex were injected bilaterally with HRP (Sigma VI, 30%). After 3 days, we perfused the animals intracardially with saline, followed by 1% paraformaldehyde. Cords were frozen sectioned longitudinally at 50 µm, mounted and counterstained with neutral red. All HRP-labeled neurons with a visible nucleus were counted, and raw counts were corrected for split nuclei error by the method of Konigsmark. Nuclear and soma area were measured from camera lucida drawings of 12 motoneurons/animal.

	SOMA AREA ± SEM (μm^2)	MOTONEURON # ± SEM
Males	1292 ± 181	35±7
Females	908 ± 127	32±8

ANOVA shows a sex difference in MN size ($p<.002$) but not number ($p=.413$). The presence of a sex difference in size but not number is in agreement with our findings for the motoneurons innervating the guinea pig bulbocavernosus (BC) and ischiocavernosus (IC) (Freeman & Breedlove, Soc. Neurosci. Abstr. 380.15, 1990.

Supported by a NSF predoctoral fellowship (LMF) and March of Dimes (SMB).

EFFECTS OF BRAIN LESIONS ON PENILE REFLEXES. Edward P. Monaghan, Jamshid Arjomand & S. Marc Breedlove, Psychology Department, Univ.Calif., Berkeley CA 94720.

Motoneurons in the spinal nucleus of the bulbocavernosus (SNB) innervate striated perineal muscles which mediate reflexive cup-like erections of the penis. Midthoracic spinal transections potentiate these reflexes, indicating that brain regions modulate their expression (Sachs & Garinello, 1980). Brain areas which were previously implicated as afferents of the SNB (Monaghan & Breedlove, in press) were ablated to determine their role in mediating penile reflexes. Lesioned sites included the raphe, paraventricular (PVN), and lateral vestibular (LVN) nuclei of adult male rats. Ablation of the median raphe nucleus ($n=8$) increased the display of penile cups and flips ($p<.02$). PVN lesions ($n=6$) increased the latency to the first erection ($p<.05$) but did not otherwise affect penile reflexes. In animals with complete lesions of the LVN ($n=4$), penile reflexes were eliminated, however these lesions had a generally debilitating effect on the animals. These results suggest that the raphe, LVN, and PVN provide spinal projections which influence the expression of penile reflexes.

EFFECTS OF INTRATHECAL TESTOSTERONE ON PENILE REFLEXES. Jamshid Arjomand, Edward P. Monaghan & S. Marc Breedlove, Psychology Department, Univ. Calif., Berkeley CA 94720.

The spinal nucleus of the bulbocavernosus (SNB), spanning L5 and L6 of the spinal cord, innervates perineal muscles involved in penile reflexes. Castration decreases the reflexes (Hart, 1967) and changes the morphology of motor neurons (Breedlove & Arnold, 1981; Kurz et al, 1986). To begin an investigation of the site of androgen action for these effects, we examined the concentration of spinally administered androgen required to maintain penile reflexes in castrated rats. Osmotic mini-pumps attached to intrathecal catheters administered testosterone (T) to the lumbosacral spinal cord in castrated adult males. T treatments were 4.8, 9.6, and 14.4 µg/day for two weeks. The 4.8µg/day dosage was not sufficient to maintain the reflexes, whereas the animals receiving 14.4µg/day dosage displayed reflexes comparable to precastration levels. Animals receiving 9.6µg/day of T displayed an intermediate response level. These results indicate that the T concentration necessary for maintaining these behaviors may be higher than previously suggested.

Currently underway is a study of the efficacy of intrathecal versus systemic T administration. In addition to gathering behavioral data, we will examine whether the various T treatments affect the morphology of SNB cells.

INTRACRANIAL ANDROGENIC AND ESTROGENIC STIMULATION OF SIGNALING BEHAVIORS IN MALE RATS. J. A. Matochik and R. J. Barfield. Dept. Biol. Sci., Rutgers Univ., New Brunswick, NJ 08903.

Previous research in our laboratory has identified neural sites of steroid hormone action regulating copulatory behavior in the diagonal band of Broca (DBB)-anterior hypothalamic (AHA) continuum. The present study investigated the effects of central implants of testosterone (T) or estradiol (E2) in the restoration of scent marking and 50 kHz ultrasonic mating vocalizations (US) in castrate male rats. Signaling behaviors were tested for 10 min in the presence of estrous odor cues. After the pretest, males were castrated and tested for the absence or reduction of behavior; the animals then received stereotaxic implants of T or dilute E2 (1/100 cholesterol) with systemic DHT and were tested over four weeks for restoration of behavior. Central sites investigated with T were: DBB, AHA, and ventromedial hypothalamus; E2: DBB, lateral preoptic area, and medial preoptic area. Only implants of T or E2 in or near the DBB were effective in restoring scent marking (94% of pretest levels for E2 and 110% for T), an area we previously identified as important for E2 restoration of copulatory behavior. No significant restoration of US was observed in any of the implant groups. Blank cannulae or cannulae filled with cholesterol were completely ineffective in restoring either behavior. This preliminary study suggests that the neuroendocrine substrates for marking and US are different in the male rat. **(Supported by NIH grant HD-04484)**

PASSIVE ELECTRICAL PROPERTIES OF BULBOSPONGIOSUS MOTONEURONS IN GONADALLY INTACT AND CASTRATED ADULT MALE RATS. W.F. Collins, III Dept. of Neurobiology & Behavior, SUNY at Stony Brook, NY 19104.

Bulbospongiosus motoneurons (BS MNs) are smaller in castrated, as compared to gonadally intact, adult male rats (Kurz, et al., Science 232:395,1980). The present study was undertaken to evaluate possible changes in the passive electrical properties of BS MNs following castration. Gonadally intact and castrated (30-45 days) Sprague-Dawley rats (350-400 gm) were anesthetized, and *in vivo* intracellular recordings were obtained from BS MNs (1-8/rat) using conventional techniques. All lumbar and sacral dorsal roots were cut bilaterally. Passive membrane properties were assessed by injecting 1 nA of hyperpolarizing current (30-50 ms) and averaging ($n=32$-64) the resulting change in membrane potential. Following correction for anomalous rectification, input resistance (Rn) was measured. Estimates of membrane (T_0) and equalizing (T_1) time constants were made from the voltage transient following cessation of the current and used to calculate the electrotonic length (L). The data were analyzed using a two-level nested ANOVA, and the results are summarized below. Although mean Rn was larger in castrates, no significant difference was observed in any of the parameters. These results indicate that the passive electrical properties of BS MNs are relatively unaffected by castration. Supported by NIH NS24206 (WFC) and NS16996 & NS14899 (L.M. Mendell).

FEMALE HAMSTER VAGINAL SECRETION STIMULATES C-FOS EXPRESSION IN THE VOMERONASAL AND OLFACTORY MATING BEHAVIOR PATHWAYS IN THE MALE GOLDEN HAMSTER. J.M. Fiber and J.M. Swann. Dept. of Biological Sciences, Rutgers University, Newark, N.J. 07102.

Olfactory and vomeronasal chemosensory input is essential for arousal and execution of mating behavior in male golden hamsters. Precopulatory anogenital investigatory behavior exposes the male to Female Hamster Vaginal Secretion (FHVS) which stimulates copulatory behavior in males. FHVS is composed of volatile and hormonally regulated non-volatile components that stimulate the main olfactory system and the accessory olfactory system respectively. The chemosensory pathway regulating mating behavior and precopulatory anogenital investigation include the vomeronasal organ, the accessory olfactory bulb (AOB), medial (ME) and anterior cortical (C1) nuclei of the amygdala, medial preoptic area (MPOA), and the bed nucleus of the stria terminalis (BNST). Destruction of these nuclei abolish mating in male hamsters.

In the current experiment we determined which brain regions were stimulated by FHVS using c-fos immunocytochemistry as a marker of cell stimulation. Adult male golden hamsters were given FHVS on a swab 1-1.5 hours prior to sacrifice. Controls were given no stimulus. Exposure to FHVS stimulated regions that regulate mating behavior, including, the AOB, bed nucleus of the accessory olfactory tract, medial nucleus of the amygdala, BNST, and MPOA. Exposure to FHVS also stimulated regions of the main olfactory system, not directly involved in the regulation of mating behavior. These include the main olfactory bulb, anterior olfactory nucleus, endopyriform nucleus, horizontal and vertical limbs of the diagonal band of Broca (HDB and VDB), and pyriform cortex. In addition, regions which receive projections from the main and accessory olfactory systems or which are motor output regions also stimulated by FHVS include the anterior and lateral hypothalamus, paraventricular, reuniens and anterodorsal nuclei of the thalamus, cingulate and orbital cortex, frontal and insular cortex, raphe nuclei, central grey, and tegmentum. Brains of control animals showed very light diffuse staining in the main and accessory olfactory bulbs, medial preoptic area, anterior olfactory nucleus -medial, BNST, HDB, VDB, central, basolateral, C1 and ME, and frontal, pyriform, and parietal cortical regions. Our results show that exposure to FHVS stimulates regions known to regulate mating behavior as well as regions involved in arousal, motivation and motor function.

UNILATERAL LESIONS OF THE SEXUALLY DIMORPHIC AREA (SDA) OF THE GERBIL HYPOTHALAMUS DISRUPT MALE SEXUAL BEHAVIOR WHEN COMBINED WITH CONTRALATERAL LESIONS OF THE MEDIAL AMYGDALA-AMGYDALOHIPPOCAMPAL AREA (MA-AHi) OR MEDIAL BED NUCLEUS OF THE STRIA TERMINALIS (mBST). N. Sayaq* & P. Yahr. Dept. Psychobiol., U. Calif., Irvine, CA 92717.

N-methyl-d,l-asparate (NMA) lesions of the SDA impair mating in male gerbils given exogenous testosterone (T; Yahr & Gregory, unpub.). To learn more about pathways that may mediate male sexual behavior, we identified the afferents (DeVries et al., '88) and efferents (Finn et al., unpub.) of the SDA. Here we wanted to determine if any of three areas that are reciprocally connected to the SDA influence sexual behavior via these connections. Male gerbils given exogenous T were infused with NMA in the left SDA. Some received contralateral infusions in the MA-AHi, mBST or ventrolateral septum (vLS). Controls received both lesions on the left. Every control (13/13) mounted during at least one of four tests given 1-3 weeks after surgery; overall, they mounted in 75% of the tests. Males with lesions aimed at the SDA and contralateral vLS behaved similarly (13/14; 75%). In contrast, only half of the males with lesions aimed at the SDA and contralateral MA-AHi (6/10) or mBST (5/12) mounted (% tests with mounts = 40% and 29%, respectively). Thus the MA-AHi and mBST may affect male sexual behavior via projections to the SDA or by relaying the effects of SDA efferents. (Supported by MH26481 and MH00478).

FUNCTIONAL CHANGES INDUCED BY HABENULA CELL TRANSPLANTS FOLLOWING LESION OF THE FASCICULUS RETROFLEXUS. E.W. Thornton*†, M. Murray, T.C. Eckenrode* and F. Haun (SPON: European Neuroscience Association). †Dept. of Psychol., Univ. of Liverpool, U.K. and Dept. of Anat., Medical Coll. Penn., Philadelphia, PA 19129.

Lesions of the fasciculus retroflexus (FR) de-afferent the interpeduncular nucleus (IPN) of both its cholinergic and peptidergic (Substance P) input from the habenula. Cell suspension transplants of embryonic habenula cells have been shown to restore normal Substance P staining in target sub-nuclei of the IPN and to restore normal REM-stage sleep behavior. We now show FR-lesioned rats are hyperactive relative to sham-operated controls in open-field tests over 3 months of testing, an effect potentiated in lesioned rats with transplants. In contrast, motor behavior assayed in a rotating-rod and a forced swimming test was similar to controls for both the lesion-only and transplant animals. The data indicate that transplants providing partial reinnervation of target IPN result in improvement or impairment of behaviors depending on the specific test paradigm. Supported in part by NATO, Burroughs Wellcome Fund and Wellcome Foundation.

LHRH AND SUBSTANCE P MODULATE *IN VITRO* ELECTROPHYSIOLOGICAL RESPONSES OF PERIAQUEDUCTAL GRAY NEURONS TO GABA AGONISTS AND NOREPINEPHRINE IN ESTROGEN-TREATED FEMALE RATS. Sonoko Ogawa, L.-M. Kow, S. Schwartz-Giblin & D.W. Pfaff. The Rockefeller University, New York, NY 10021.

LHRH and substance P (SP) are both known to facilitate lordosis behavior of estrogen-primed females rats by acting on periaqueductal gray (PAG). Previously, we have reported that SP excites PAG neurons through a neurotransmitter-like action whereas LHRH rarely acts this way (Ogawa et al., Soc. Neurosci. Abst., 16, #114.7, 1990). In the present study, we searched for modulation of responses by PAG neurons to lordosis-relevant neurotransmitters, as could be involved in behavioral effects of these neuropeptides. Extracellular single-unit activity was recorded from dorsal PAG in brain tissue slices prepared from estrogen-primed ovariectomized female rats. Effects of $GABA_A$ (THIP) and $GABA_B$ (baclofen) agonists and norepinephrine (NE) on firing rates (spikes/sec) were compared before and after LHRH (10^{-7}M) or SP (10^{-8}M: this dose of SP rarely excited PAG neurons) applications.

It was found that both LHRH and SP can modulate PAG neuronal responses. LHRH could either potentiate or attenuate inhibitory responses to THIP and baclofen, and tended to potentiate both excitatory and inhibitory responses to NE. These LHRH effects persisted over a long period of time (up to 60min). SP also had long-lasting neuromodulatory actions. It tended to potentiate excitatory action of NE and attenuate inhibitory action of NE. Finally, SP potentiated THIP and baclofen effects, consistent with facilitatory effects of SP and GABA on lordosis behavior in the PAG.

EFFECTS OF OPIATE-AMPHETAMINE CROSS-SENSITIZATION IN CONDITIONED REINFORCEMENT ARE MEDIATED BY MU- BUT NOT DELTA-SELECTIVE OPIATE RECEPTORS IN THE NUCLEUS ACCUMBENS. S.T. Cunningham and A.E. Kelley. Dept. of Psychology, Northeastern University, Boston, MA. 02115.

Chronic peripheral administration of opiates induces sensitization in various behavioral responses such that following repeated treatment, subsequent treatment elicits a potentiated response. Repeated intra-cranial injections of opiates into distinct midbrain regions also induce behavioral sensitization. In the following experiments, we investigated opiate sensitization and opiate cross-sensitization to *d*-amphetamine in the conditioned reinforcement (CR) paradigm, following infusion into a striatal subregion. In the CR paradigm, hungry rats (N=38) were trained to associate a compound stimulus (light/click) with delivery of a food pellet (primary reinforcement). During the test phase, a lever is introduced and when depressed, results in the compound stimulus (secondary reinforcement) alone. Each test session is 45 min. in duration, in which total lever presses for secondary reinforcement is recorded. All drugs were delivered into the nucleus accumbens (N. Acc.) over a volume of 0.5 µl per side. Microinfusion of drugs occurred over 6 test sessions, each separated by one day. The first 4 test days consisted of infusion of 0.9% saline, morphine (µ-selective, 0.5 µg), DAGO (µ-selective, 1.0 µg) or DPEN (∂-selective, 2.0 µg), and on the 5th and 6th test days, 2.0 and 10.0-µg doses of *d*-amphetamine were administered, respectively. CR responding was not enhanced by any of the opiate infusions, nor was there any indication of behavioral sensitization. However, animals given either of the µ-selective opiates for chronic treatment showed potentiated lever responding following *d*-amphetamine (2.0 and 10.0 µg), relative to either the chronic DPEN or saline-treated animals. The current results suggest that multiple injections of opiates in the N. Acc. induce an alteration in dopamine transmission, and that this effect is mediated by the mu-selective opiate receptor subtype.

REGULATION OF VENTRAL PALLIDAL-STIMULATED LOCOMOTION BY THE NUCLEUS ACCUMBENS DEPENDS ON ENKEPHALIN AFTER DOPAMINE DEPLETION. L. Churchill and P.W. Kalivas. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Locomotor activity initiated by picrotoxin in the ventral pallidum (VP) is blocked by inhibiting dopamine receptors in the nucleus accumbens (NA). However, blocking opioid receptors with naloxone did not affect the picrotoxin-initiated locomotion in the VP. In this study, we depleted dopamine levels in the NA by >80% and analyzed the locomotor responses to pictrotoxin (0.17 nmol/0.5 µl/side) in the VP at least 10 days after 6-hydroxydopamine lesions (5 µg/3 µl/side/12 min) in the NA or a sham lesion with 0.2% ascorbic acid in sterile saline (3 µl/side/12 min). Locomotion was measured as horizontal photocell counts using an Omnitech photocell cage for a maximum of 6 trials with a minimum intertrial interval of 3 days. Surprisingly, after dopamine lesions, picrotoxin still increased locomotion from the VP. This locomotion was blocked by haloperidol (0.1 mg/kg, i.p.) or naloxone (1 mg/kg, s.c.). To demonstrate that the opioid receptors in the NA were responsible for the block by naloxone, naltrexone (0.6 µg/0.5 µl/side) was microinjected into the NA while picrotoxin was injected into the VP. Locomotor activity returned to control levels in the presence of naltrexone in the lesioned rats, but not in the sham-lesioned rats. These results suggest that <20% of the normal dopamine levels in the NA is sufficient to regulate VP-induced locomotor activity, but that enkephalin in the NA also regulates the VP-induced locomotion after dopamine lesions.

DIFFERENTIAL EFFECTS OF A CCK_A and CCK_B ANTAGONIST AGAINST MORPHINE CONDITIONED PLACE PREFERENCE (CPP). G.A. Higgins and E.M. Sellers. Departments of Pharmacology, Medicine and Psychiatry, University of Toronto and Clinical Research and Treatment Institute, Addiction Research Foundation, Toronto, Ontario, Canada M5S 2S1.

Experimental evidence consistently supports the involvement of the dopamine (DA) mesolimbic pathway in behaviours underlying drug-induced reward (e.g. morphine CPP). CCK is also closely associated with this system and accordingly may modulate a number of DA dependent behaviours. We have previously reported (Higgins et al, Eur J Pharmacol, 1991 [in press]) that pre-treatment with the CCK_A antagonist, devazepide, blocked the acquisition of a morphine CPP. In the present report we describe the effects of L365-260 (L), a selective CCK_B antagonist, on this behaviour. (L) was administered (0.001-10 μg/kg s.c.) 30 min prior to morphine (1.5 mg/kg s.c.). The CPP procedure was as described previously (Higgins et al, Eur J Pharmacol, 1991 [in press]). At no dose did (L) block morphine CPP, instead a mild potentiation was recorded. To study this further we examined the interaction between (L) (10 μg/kg) and a subthreshold dose of morphine (0.3 mg/kg). At these doses neither drug elicited CPP alone, however, when co-administered, a CPP was recorded ($p < 0.01$). In addition, a higher dose of (L) (1 mg/kg) also induced a significant CPP when administered alone ($+120 \pm 45$ sec, $p < 0.05$).

It is concluded that antagonism of CCK_A receptors may attenuate a behaviour indicative of opiate reward, while antagonism of the CCK_B subtype potentiates this response. These effects might be related to the differential roles of these receptors on DA release within the nucleus accumbens (Marshall et al, J Neurochem 56: 917-922, 1991).

MEDIAL PREOPTIC AREA CHOLECYSTOKININ INFUSIONS BLOCK BETA-ENDORPHIN INDUCED DISRUPTION OF MATERNAL BEHAVIOR IN LACTATING RATS. L.F. Felicio, P.E. Mann and R.S. Bridges. Dept. Comparative Medicine, Tufts University School of Veterinary Medicine, North Grafton, MA 01536.

Recent work has demonstrated that intraventricular infusions of cholecystokinin octapeptide (CCK-8) prevents the disruptive actions of beta endorphin (βE) on maternal behavior in lactating rats. Maternal care is also blocked when βE is infused directly into the medial preoptic area (MPOA). In the present study we investigated the possibility that CCK-8 might antagonize βE's action on maternal behavior at the level of the MPOA. Day 5-6 lactating rats previously implanted with bilateral cannulas in the MPOA were infused on Day 5 with saline and on Day 6 with βE (0.145 nmol) or βE plus CCK-8 (1.45 nmol). Testing for maternal behavior began 30 minutes after each infusion and responses were scored throughout the 1 hr test session and again at hourly intervals until all females were fully maternal. Approximately 50% of the βE plus CCK-8 rats were fully maternal within 60 min., whereas none of the βE alone rats responded during this period. In addition, animals treated with βE plus CCK-8 had significantly shorter latencies than βE animals to retrieve, group, and crouch over their pups. These results demonstrate that the administration of CCK-8 directly to the MPOA blocks the inhibitory actions of βE, and suggest that the MPOA is one site of dual peptidergic regulation of maternal behavior. [Supported by NIDA Grant #DA04291 to RSB].

ESTROGEN REGULATION OF PREPROENKEPHALIN-A IN TACHYKININ-CONTAINING CELLS IN THE RAT VENTROMEDIAL NUCLEUS OF THE HYPOTHALAMUS. C. A. Priest, P. Popper and P. E Micevych. Dept. of Anatomy and Cell Biology and the Laboratory of Neuroendocrinology, Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024-1763.

Regulation of lordosis behavior by the ventromedial nucleus of the hypothalamus (VMN) involves the interaction of estrogen with steroid-sensitive neuropeptide circuits, such as those which contain enkephalin (ENK) and the tachykinin substance P (SP). Estrogen induces ENK expression in the VMN but doesn't appear to affect expression of SP, although populations of estrogen-concentrating cells have been described that show ENK-like or SP-like immunoreactivity. Additionally, a previous immunohistochemical study (Priest, Popper and Micevych, Soc. Neurosci. Abst., *16*:325, '90) identified a population of neurons in the VMN that contained both ENK-like and SP-like immunoreactivity. The commercially obtained antisera used in that study, however, showed extensive cross-reactivity with other opiate and tachykinin peptides. To verify the protein content of the doubly-labelled cells, the current study was performed using the combined techniques of *in situ* hybridization and immunohistochemistry. Preproenkephalin-A (PPE-A) mRNA was localized to SP immunoreactive neurons of the VMN using a ^{35}S-labelled single-stranded cRNA probe complementary to the entire coding sequence of the PPE-A mRNA. The probe was transcribed from a 935 bp PPE-A cDNA inserted into a pSP6 vector (gift from Drs. Yoshikawa and Sabol, NIH, Bethesda, MD). The study also examined the quantitative effects of ovariectomy and estrogen replacement on protein expression in the doubly-labelled population of neurons. Supported by NS21220.

ANTIBODIES RAISED AGAINST sCCK-8 MIMIC sCCK-8 INDUCED INHIBITION OF LORDOSIS BEHAVIOR. P.E Micevych, C.A.Priest, R. K. Bittner and P. Popper. Dept. of Anatomy & Cell Biology and the Laboratory of Neuroendocrinology, Brain Research Institute, UCLA, Los Angeles, CA 90024.

Microinjections of sCCK-8 into the ventromedial nucleus of the hypothalamus (VMH) inhibit the display of lordosis behavior in estrogen primed male and female rats (Babcock et al. Physiol Behav, *43*:195,'88; Ulibarri et al. Neuroendocrinol. 52:70, '90). Since CCK tissue levels are higher in males than in females and the levels of CCK binding sites in the VMH are similar in both males and females, we hypothesized that endogenous CCK may act at the VMH of the male to inhibit the display of lordosis behavior. To test this, we microinjected 1 μl of undiluted polyclonal anti-CCK-8 serum (R183E, R. Elde, Univ. MN) into the VMH of gonadally intact males and castrated males that had been injected with 30 μg estradiol benzoate/day for 7 days. R183E attenuated the display of lordosis behavior in castrated rats 48 hrs after estrogen priming, thus mimicking the effects on lordosis behavior of microinjections of exogenous sCCK-8 peptide into the VMH of male and female rats. To examine whether R183E contained anti-idiotypic antibodies that interact with the CCK receptor, we sequentially incubated VMH tissue sections with R183E and then with ^{125}I-sCCK-8. There was no effect on levels of CCK binding in the VMH, suggesting that R183E did not displace ^{125}I-sCCK-8 from its binding sites. In a parallel experiment, ^{125}I-sCCK-8 binding at the VMH was attenuated in a dose dependent manner after incubation with a cocktail of ^{125}I-sCCK-8 and 1:50, 1:100, 1:200, 1:400 or 1:800 dilutions of R183E antiserum. The levels of ^{125}I-sCCK-8 binding increased with greater antibody dilution, indicating that R183E bound the ^{125}I-sCCK-8 and prevented interaction of the ligand with its receptor. Together, the results of these experiments refute the hypothesis that R183E contains sufficiently high titers of anti-idiotypic antibodies to account for its behavioral effects. Supported by NS21220.

THE EFFECTS OF SEX HORMONES ON CHOLECYSTOKININ RECEPTOR BINDING IN THE RAT BRAIN. P. Popper, C. A. Priest and P. E Micevych. Dept. of Anatomy and Cell Biology and the Laboratory of Neuroendocrinology, Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024-1763.

We investigated the effects of sex hormones on cholecystokinin (CCK) receptor binding in the ventromedial nucleus of the hypothalamus (VMN) and cingulate cortex of male and female rats. Female rats were ovariectomized (OVX) for two weeks and assigned to the following treatment groups: untreated, rats given estrogen benzoate (EB, 5 μg) 24 h and progesterone (P, 500 μg) 4 h before decapitation or implanted at OVX with silastic capsules containing testosterone propionate (TP). Males were intact, castrated for 4 weeks or castrated for 4 weeks and implanted at castration with TP silastic capsules. Thirty μm sections through the VMN were obtained and were processed for CCK receptor autoradiography using ^{125}I sulfated CCK octapeptide. Consecutive sections were processed identically with the addition of 50 mg/ml EB to the incubation buffer. In the VMN of EB+P treated rats, the level of receptor binding was reduced compared to untreated or TP treated OVX rats, thus mimicking previously reported binding following EB treatment alone. The latter two treatment groups did not differ in receptor binding. Castration reduced receptor binding in the VMN compared to intact or castrate+TP males. In the cingulate cortex, CCK receptor binding was not influenced by any of the treatments. However, when EB was added to the buffer, receptor binding increased in both the VMN and cingulate cortex. These results indicate that EB modulates CCK binding in the VMN. *In vivo*, EB reduces CCK binding, suggesting that EB may affect CCK receptor expression, while the *in vitro* effects of EB suggest that EB affects binding of the ligand to its receptor. TP *in vivo* facilitates expression of CCK receptors in the VMN. Supported by NS21220.

REGULATION OF PREPROCHOLECYSTOKININ mRNA IN MOTONEURONS OF THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS IN THE RAT. L.A. Abelson, P. Popper and P.E Micevych. Dept. of Anatomy and Cell Biology, Laboratory of Neuroendocrinology, Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024-1763.

Motoneurons of the spinal nucleus of the bulbocavernosus (SNB) are known to be regulated by androgens. Castration of a male rat reduces the size of SNB somata as well as both the size and number of chemical and electrical synapses onto SNB somata. Castration also regulates the expression of calcitonin gene-related peptide (CGRP) in SNB motoneurons by causing an increase in both mRNA and peptide levels (Popper and Micevych, Neuroendocrinol., 50:338-343, 1989; Popper and Micevych, Mol. Brain Res., 8:159-166, 1990). In this study we determined the effect of androgen on expression of preprocholecystokinin (preproCCK) mRNA in SNB motoneurons. In situ hybridization was done with a ^{35}S-labelled single-stranded cRNA probe complementary to the entire coding sequence of the preproCCK. Adult male rats were castrated for four weeks and compared with normal males as well as with males that were castrated and implanted with a silastic capsule filled with testosterone propionate (TP) for four weeks. Analysis of the in situ hybridization was done with both bright and darkfield optics and silver grains were counted on the Cue-2 image analysis system (Olympus Corp.). Motoneurons were considered labelled if the density of silver grains was 3X background. Overall, treatment had a significant effect on the level of preproCCK mRNA as measured by the density of silver grains over SNB motoneurons ($p < 0.01$). The density of silver grains over SNB motoneurons (mean $\pm$ S.E.M. x $10^2 \mu m^{-2}$) in castrate + TP was 60.3 ± 12.85 which was significantly higher ($p < 0.005$) than in castrates (14.04 ± 3.64) or in intacts (22.34 ± 4.17). This research was supported by NS21220.

ANXIOLYTIC-LIKE EFFECTS OF THE CCK-B ANTAGONISTS LY 262691, LY 262684 AND LY 247348 ON PUNISHED RESPONDING OF SQUIRREL MONKEYS. J.E. Barrett[1], M.C. Linden*[1], H.C. Holloway[1], M.J. Yu*[2] and J.J. Howbert[2]. [1]Dept. of Psychiatry, Uniformed Services University of the Health Sciences, Bethesda, MD 20814 and [2]Lilly Research Labs., Eli Lilly & Co., Indianapolis, IN 46285.

Cholecystokinin (CCK) has been proposed as an etiologic factor in anxiety, since the tetrapeptide form (CCK-4) induces panic attacks in humans and CCK antagonists have demonstrated anxiolytic-like effects in animal models of anxiety. In this study, two structurally distinct series of potent, selective antagonists for the brain CCK receptor (CCK-B) were assessed for anticonflict effects in a primate model of anxiety. Lever press responses of squirrel monkeys were maintained under a two-component schedule. During one component, a response produced food after a 3-min interval elapsed; during the second component, every 30th response during the 3-min interval resulted in the delivery of a mild electric shock (punishment or conflict procedure). At 0.3-10 mg/kg, p.o., the CCK-B antagonists LY 262691 and LY 262684 (pyrazolidinone class) and LY 247348 (quinazolinone class) all increased punished responding, with peak increases reaching approximately 150% of control performance levels at the 1.0 to 3.0 mg/kg doses. These doses had little effect on unpunished responding occurring in the alternate component. Agents with clinical efficacy in anxiety have been shown widely to produce increases in punished responding in this type of model. These results suggest that CCK-B antagonists of diverse structural types may be useful in the treatment of anxiety. The lack of suppressed responding in either component further suggests that such treatment could be accomplished without accompanying sedative activity.

420.12

CHOLECYSTOKININ RECEPTOR SUBTYPE ANTAGONISTS MODULATE EXPLORATORY LOCOMOTION IN THE RAT MESOLIMBIC PATHWAY. J.N. Crawley. Unit on Behavioral Neuropharmacology, Experimental Therapeutics Branch, National Institute of Mental Health, Bethesda, MD 20892.

High affinity compounds selective for the central cholecystokinin (CCK-A) or for the peripheral (CCK-B) receptor subtype now permit direct pharmacological analysis of the receptor subtypes mediating the actions of CCK. These compounds also provide critical tools for investigating the functional role of endogenous CCK. L-364,718, a CCK-A antagonist, L-365,260, a CCK-B antagonist (both gifts from Merck, Sharp and Dohme), and CI-988, a water soluable CCK-B antagonist (gift from Parke-Davis), were administered to male Sprague Dawley rats in several behavioral paradigms previously used to analyze CCK-dopamine interactions.

1) Antagonists were microinjected 5 minutes before saline, dopamine, or dopamine+CCK, into the a) nucleus accumbens, or b) ventral tegmental area, immediately before a 15 minute session in the Digiscan exploratory activity monitor. 2) Antagonists were microinjected into the a) nucleus accumbens, b) ventral tegmental area, or c) intraperitoneally, to test for modulation of dark-induced hyperlocomotion. Comparisons of anterior versus posterior nucleus accumbens and ventral tegmental area will be drawn, in an attempt to delineate the postulated contribution of endogenous CCK to the activity of the mesolimbic dopamine pathway.

420.13

HEART RATE CHANGES FOLLOWING ADMINISTRATION OF PUTATIVE PANICOGENIC CHEMICALS IN SQUIRREL MONKEYS. J.D. Newman and L.J. Crepeau. Laboratory of Comparative Ethology, NICHD, NIH, Poolesville, MD 20837-0289.

Clinical studies have determined that intravenous sodium lactate and cholecystokinin tetrapeptide (CCK-4) induce panic episodes in susceptible human subjects. Studies of the physiological changes accompanying panic attacks in humans indicate that heart rate is accelerated (tachycardia) following both spontaneous and lactate-induced panic episodes. We used chair-restrained squirrel monkeys (Saimiri) to test the effects on heart rate of slow iv infusions of sodium lactate, CCK-4, and a muscarinic receptor antagonist (benactyzine) shown in previous work to enhance alarm responses in squirrel monkeys. Eight adults (four males and four females) were adapted to chair restraint following institutional ACUC guidelines. During weekly experiments, the monkeys were removed from their home cages and given a light sedative dose of ketamine, after which an intravenous catheter was introduced into the saphenous vein and cardiac electrodes were affixed to the chest. Lactated Ringers/5% dextrose solution was slowly dripped into the vein throughout the experiment. After recovery from ketamine, a 20 minute period of undisturbed heart rate data was collected, followed by infusion of 0.5 M DL-sodium lactate (High dose), 0.25 M sodium lactate (Low dose), or High lactate plus a high or low dose of CCK-4. Lactate was infused at a rate of 0.5 ml/ min. for 20 minutes. CCK was infused at a rate of 0.05 ml/min in a concentration of 20 or 100 ug/ml. We found that the higher dose of sodium lactate with or without CCK produced a similar pattern of heart rate change, consisting of a transient tachycardia over 2-5 min., followed by incremental bradycardia over the remainder of the 20 minute trial. The low dose of sodium lactate failed to produce transient tachycardia but did result in bradycardia. We conclude that DL-sodium lactate at a dose that triggers panic attacks in susceptible humans produces a reliable pattern of heart rate change in a nonhuman primate model consistent with expected changes during panic episodes.

420.14

INTRAPERITONEAL INJECTIONS OF CHOLECYSTOKININ INCREASE [^{14}C] 2-DEOXYGLUCOSE UPTAKE IN THE AREA POSTREMA AND SOLITARY NUCLEUS OF THE RAT. M. R. Alberro, J. A. Deutsch* and M. F. Gonzalez. Department of Psychology, UCSD, La Jolla, CA 92093

The gastrointestinal octapeptide cholecystokinin (CCK-8) has been hypothesized to act as a satiating agent. There is still some controversy regarding its putative mechanisms of action since there is also evidence that it can produce conditioned taste aversion learning. In this study we investigated the pattern of [^{14}C] 2-deoxyglucose (2-DG) uptake in brain areas involved in the perception of nausea following CCK-8 injections. Twenty-hour-fasted Sprague-Dawley rats (300-400 g) were used as subjects. CCK-8 (10 mg/kg, Bachem) or control saline injections were administered intraperitoneally and placed in a restraining cage. Ten minutes later the rats received an injection of 2-DG (167 µCi/kg) via the lateral tail vein. Forty-five minutes later the rats were sacrificed, their brains removed, sectioned, and autoradiographed using standard procedures. The brain sections of CCK-8-treated subjects exhibited an increase in 2-DG uptake in the area postrema (AP) and the nucleus of the solitary tract (NTS). The effect encompassed the entire the AP, but was obvious only in the most caudal region of the NTS. The brains of animals that received injections of a similar volume of isotonic saline did not show apparent increases in 2-DG uptake in these regions. The present findings suggest that the decreases of food intake observed by other investigators following systemic injections of this neuropeptide, can be attributed to the activation of neural substrata that mediate malaise. Whether lower doses of CCK-8 that produce reductions in eating also alter the metabolic activity of the area postrema and solitary nucleus is to be determined by further experimentation.

420.15

INTRA-ACCUMBENS NEUROPEPTIDE Y PRODUCES REWARD: A CONDITIONED PLACE PREFERENCE THAT IS BLOCKED BY PRE-TREATMENT WITH A DOPAMINE ANTAGONIST. S. A. Josselyn and R. J. Beninger. Dept. of Psychol., Queen's University, Kingston, K7L 3N6, CANADA.

Neuropeptide Y (NPY) has been localized in the nucleus accumbens (N. Acc.) and may influence dopamine (DA) neurotransmission. Extensive data implicate N. Acc. DA in the neurochemical substrate of reward. This raises the possibility that NPY microinjected into the N. Acc. may produce rewarding effects that are mediated by DA. Two experiments replicated the previous findings that systemic (2.0 mg/kg, ip) or central (10.0 ug in 0.5 ul, bilaterally in the N. Acc.) amphetamine produced a conditioned place preference (CPP). The third experiment examined whether NPY would produce a similar CPP and if this preference would be influenced by a dopamine antagonist. Each experiment consisted of three distinct phases; pre-conditioning, conditioning and test. An increase in the time spent in the drug-paired conditioning compartment from the pre-conditioning to the test phase was accepted as evidence for a CPP. Intra-accumbens NPY (0.1 ug in 0.5 ul, bilaterally) produced a CPP. Furthermore, this preference was blocked by pre-treatment with a dose of cis-flupenthixol (20.0 ug in 0.5 ul, bilaterally in the N. Acc.) that, alone, produced no effect. These results strongly suggest that NPY exogenously applied to the N. Acc. produces reward. In addition, the NPY reward effect may be mediated by DA.

420.16

HIPPOCAMPAL AND VENTRICULAR ADMINISTRATION OF NEUROPEPTIDE-Y MODIFIES DELAYED MATCHING-TO-SAMPLE ACCURACY.

J. R. Thomas and S. T. Ahlers. Naval Medical Research Institute, Bethesda, MD 20889.

There is increasing evidence that neuropeptide-Y (NPY), one of the most prevalent neuropeptides in the brain, is important in memory processing. As one of the highest concentrations of NPY and NPY receptors is in the hippocampus, a structure important in normal short-term or working memory, the purpose of the study was to examine the effects of central NPY administration on working memory in rats. A delayed matching-to-sample (DMTS) task was used to assess working memory. The subjects, Long-Evans rats, performed on the DMTS daily in an operant chamber for 180 trials. Each trial began with the illumination of a cue-light over one of two response levers on the front chamber wall. The rat had to press the lever under the cue-light which turned off that light and initiated a delay interval of 2 to 60 sec. During the delay interval the rat was required to respond on a lever located on the rear chamber wall. At the end of the delay interval both cue-lights were illuminated over the two front wall levers. A response to the previously responded to cued-lever was recorded as a correct response and was followed by delivery of a food pellet. NPY was administered bilaterally into the dentate gyrus of the hippocampus (0.06 - 4.0 µg) immediately before a session or into the lateral ventricle (0.3 - 20.0 µg) 45 min before a session. Low doses of NPY consistently increased accuracy of performance at longer delays while higher doses decreased accuracy. No NPY effects were obtained on acquisition or reference memory. These data shown that NPY can profoundly modulate short-term or working memory as measured by accuracy of performance on DMTS.

EFFECTS OF BENEXTRAMINE, A PUTATIVE NPY RECEPTOR ANTAGONIST, ON SEXUAL BEHAVIOR IN MALE AND FEMALE RATS. J.T. Clark and A. Keaton*. Dept. Physiol., Meharry Medical Coll., Nashville, TN.

Adrenergic transmitters and NPY have been implicated in the regulation of sexual behavior. We assessed the effects of benextramine (BXT), an α-adrenergic and NPY receptor antagonist, on sexual behavior. For males, sexually experienced rats received either benextramine (3 mg/kg, IP) or vehicle, 30 min prior to mating tests. BXT induced a selective increase in the copulatory rate (decreased ICI). In a second study, BXT pretreatment (3 mg/kg, 30 minutes prior) failed to attenuate the suppressive effects of clonidine (250 μg/kg, 5 min prior to mating tests). However, clonidine administration reversed the effects of benextramine on the copulatory rate. In ovariectomized females, progesterone (P) treatment typically exerts a biphasic effect on copulatory behavior, initially (4-10 h) there is a synergy with estradiol (E) which is followed (>20h) by a profound inhibition. We hypothesized that this inhibitory effect of P could be due to increased release of NPY. Rats were tested for female sexual behavior 4h post-P (52h post E) following which they were administered BXT (0, 3 or 15 mg/kg, IP). Subsequent tests were administered 24,48,72, and 96h post-BXT. BXT treatment attenuated the inhibitory effects of P on receptivity (lordosis quotients and percent of responding animals) without affecting either proceptive or rejection behaviors. These data indicate that blockade of NPY (and α-adrenergic) receptors is associated with selective enhancements of specific components of sexual behavior in male and female rats. Taken together with previous data on the effects of central administration of NPY, a physiological role for this peptide is suggested.

HYPERAMMONEMIA DECREASES NPY-INDUCED FEEDING. W.T.Chance, F.S.Zhang*, T.Foley-Nelson and A.Balasubramaniam*. Dept. Surgery, Univ. of Cincinnati Med. Ctr. and VA Med. Ctr., Cincinnati, OH.

We reported that feeding to neuropeptide Y (NPY) is reduced in anorectic tumor-bearing (TB) rats (Ann. NY Acad. Sci., 611:497,1990) and that hyperammonemia may be a primary cause of experimental cancer anorexia (Brain Res. 486:316,1989), In this study we tested the effect of hyperammonemia on NPY-induced feeding in normal rats. Two weeks after the implantation of cannulae into the periventricular hypothalamic area, the external jugular vein of adult, male, F 344 rats was cannulated. Normal saline (SAL) was infused (2 ml/hr) for four days, after which half of these rats were switched to infusion of 0.2-0.3 M ammonium acetate + ammonium bicarbonate (pH = 7.7). On the 4th day of ammonia infusion, noninfused (n=5), saline-infused (n=5) and ammonia-infused rats(n=7) were tested for feeding to 1 ug NPY. Compared to saline-infused rats, food intake was reduced by 65% (1 hr) and 58% (4 hr) in ammonia-infused rats. Although 0.2 M ammonium salts had no significant effect on twenty-four hr feeding, infusing 0.3 M ammonium reduced ad lib. food intake by 44%. These results indicate that hyperammonemia reduces NPY-induced feeding and suggest that the increase in blood ammonia concentration may be responsible for decreased feeding to NPY in TB rats.

ALZHEIMER'S DISEASE: EXPERIMENTAL MODELS

421.1

REAGGREGATING CULTURES OF MOUSE TRISOMY 16 BRAIN. D.E. Bredesen, D.J. Kane*, D.M. Holtzman*, C.J. Epstein*. Reed Neurological Research Center, UCLA, Los Angeles, CA 90024-1769; and Depts. of Neurology and Pediatrics, UCSF, San Francisco, CA 94143.

The development of an in vitro model of Alzheimer's disease would be advantageous in the analysis and treatment of neurodegenerative diseases. Because Down's syndrome (trisomy 21) patients over the age of 40 develop the pathology of Alzheimer's disease in virtually all cases, and mouse chromosome 16 is syntenic with HSA 21 over a large region of the long arm of HSA 21, we have been analyzing long-term reaggregating central nervous system cultures of trisomy 16 mice and control euploid littermates. Cultures were reaggregated at embryonal day 15, and followed for 11 months. Within four months after reaggregation, marked differences were noted between control and trisomy 16 cultures. Lipid-laden cells appeared in the trisomy, but not control, cultures. Immunohistochemistry, using an antibody directed against residues 1-28 of human beta-amyloid peptide (anti-BAP; a gift from D. Serban), produced vascular and parenchymal staining of trisomic but not control cultures. The parenchymal staining occurred in foci of amoeboid microglia and in a second, as yet unidentified, cell type. To distinguish between staining of beta-amyloid precursor protein and beta-amyloid peptide, electron microscopy was performed on sections of the reaggregating cultures. Abundant extracellular fibrils of approximately 10-15 nm diameter were detected in the trisomy 16 cultures, whereas only very rare extracellular fibrils were detected in euploid cultures. Immunoelectron microscopy demonstrated binding of anti-BAP antibodies to some, but not all, of the fibrils in the trisomy 16 cultures. Pre-adsorption with mouse beta-amyloid peptide prevented the binding. These findings are compatible with previous suggestions that cells of the macrophage lineage may play a key role in amyloid formation.

421.2

EXAMINATION OF ALZHEIMER-TYPE PATHOLOGY IN MOUSE TRISOMY 16 NEURONS MAINTAINED BY TRANSPLANTATION. J. Stoll, B. Ault, A. Balbo*, S. I. Rapoport and A. Fine, Laboratory of Neuroscience, National Institute on Aging, Bethesda, MD 20892 & Dalhousie Univ., Halifax, NS, CA.

Hippocampal tissue from day 15-17 fetal mice, trisomic for chromosome 16, or their normal littermates, was transplanted with or without dissociation into the striatum or the lateral ventricle of 6-8 week old female C57Bl/6 mice. After 2 weeks to 18 months of survival, host brains were sectioned and the grafts were examined by *in situ* hybridization or by immunocytochemistry for antigens present in pathological brain structures of Alzheimer's disease patients. The grafts contained a layer of large neurons similar to the pyramidal cell layer of the normal adult hippocampus. No obvious morphological difference was detected by cresyl violet staining between trisomic and control transplants. RNA's for amyloid precursor protein (with and without the KPI domain), for GAP-43 and for somatostatin, genes located on Mu16, were assayed by *in situ* hybridization at 2 weeks and 4 months of survival and showed similar patterns of expression. Antibodies against ubiquitin, neurofilaments and tau failed to demonstrate the presence of Alzheimer type pathology in the trisomic or control grafts. These results differ from those of Richards et al., EMBO J. (1991) 10, 297-303, who reported Alzheimer type degeneration in trisomy 16 transplants.

421.3

PHORBOL ESTER-INDUCED ABERRANT SPROUTING IN THE RAT NEOCORTEX AS A MODEL OF AD NEUROPATHOLOGY. E. Masliah, M. Mallory*, N. Ge*, R.D. Terry*, T. Saitoh, University of California, San Diego, La Jolla, CA 92093

Previous studies in Alzheimer disease (AD) have shown that synapse loss and aberrant sprouting are prominent features of AD neuropathology (*Neuron*, 1991, in press). To further explore these aspects of AD, we developed a rodent model by combining denervation and neurointoxication. The rationale is that AD pathogenesis may be a multi-step process, such as a widespread synapse loss followed by a neurotoxic event that eventually will lead to an ineffective and abnormal repair process in the denervated regions. The main neurotoxin that we tested was phorbol 12-myristate 13-acetate (PMA) which has been described to activate and eventually down-regulate PKC and promote the expression of amyloid genes in the rat. Preliminary studies have shown that the administration of multiple injections of 2mM PMA in the denervated neocortex of the rat promotes, in the first week post-injection, a widespread vacuolization of the neuropil with a subsequent disruption of the synapses in the injection site followed by aberrant sprouting and dystrophic neurite formation at day 15 (in 7 of 10 rats). These neuropathological changes are similar to the synaptic abnormalities observed in AD. Control experiments (n=7) where the vehicle was injected, with or without contralateral lesion, failed to show aberrant sprouting with dystrophic neurites. Immunohistochemical analysis indicated that the dystrophic neurites in the areas of denervation and PMA administration were anti-synaptophysin and anti-GAP43 positive with an increased APP immunoreactivity surrounding them. APP immunoreactivity was mostly associated with pyramidal neurons in the cortex. At the ultrastructural level the PMA-induced abnormal neurites contained abundant dense and laminated bodies as well as synaptic vesicles. These organelles displayed synaptophysin immunoreactivity in their outer membranes.

SELECTIVE EXCITOTOXIC NEURONAL LOSS IN THE RAT ENTORHINAL CORTEX CAUSES MEMORY DEFICIT AND ALZHEIMER-LIKE CHOLINERGIC SPROUTING IN THE DENTATE GYRUS OF THE HIPPOCAMPUS

Levisohn,L.F., S.R. Bossi* and Isacson, O. Dept. Neurology and Program of Neuroscience, Harvard Med. Sch., Neuroregeneration Laboratory, McLean Hospital, Belmont MA 02178.

The entorhinal cortex (EC) is one of the most severely afflicted brain regions in Alzheimer's disease (AD), in Down's Syndrome, and in aging; it is the earliest to exhibit the classic neurofibrilary tangles (NFT's) and continues to exhibit the greatest number of NFT's throughout the progression of disease. While previous anatomical and behavioral research has included primarily surgical or electrolytic lesions, in the present study we used NMDA to cause selective bilateral neuronal loss in the EC, as an approach to model the early neurodegeneration of AD and aging. Lesioned, sham lesioned and intact control rats learned a novel reference memory task involving a brightness discrimination for water reward. Rats were trained over 1 week until reaching criteria and tested for retention after a 10 day interval. In the retention test, EC-lesioned rats were significantly impaired ($p<.05$) compared to control and sham lesioned groups. Anatomical analysis confirmed excitotoxic lesions of EC and also showed evidence of denervation plasticity in the outer molecular layer of the dentate gyrus, by extensive cholinergic sprouting into this region, similar to that seen in AD. This functional and anatomical study of the EC demonstrates EC's role in reference memory and raises the possibility of functional deficits resulting from partial and selective neuronal loss in this area.

AN ANIMAL MODEL OF ALZHEIMER'S DISEASE: IMPLICATIONS FOR SPATIAL DISORIENTATION, MEMORY LOSS AND WANDERING BEHAVIOR. D. Hoffman*, & J. P. Ryan, Department of Psychology, State University of New York at Plattsburgh, Plattsburgh, NY 12901

Spatial information from cortical areas is received and processed by the dentate gyrus of the hippocampus. We have found that degeneration of this area in rats results in spatial memory impairments and mimics the wandering behavior in Alzheimer's disease. The present study measured spatial memory impairments using the Morris water maze task. A baseline of maze performance was recorded for twenty-two Long-Evans hooded rats for a period of six days (36 trials). The experimental group (N = 11) received bilateral intradentate injections of colchicine (15 µg/µl), while a sham group received bilateral intradentate injections of saline. Ten days following surgery, both groups were behaviorally tested in the maze for a period of three days (18 trials). By changing the platform location of the maze (i.e. the goal) a new task was introduced and tested for three days (18 trials). In comparison to the control group, the lesioned animals learned the behavior equally as well during baseline. However, they failed to recover their memory for the maze after surgery and also failed to learn a new task, whereas the control group consistently located the platform across all testing conditions. The results indicate that disruption to the spatial information processing system (dentate gyrus) interrupts and impairs recently acquired spatial memory, while impeding new learning of a spatial task. This suggests that in Alzheimer's disease, spatial disorientation in familiar environments could be related to degeneration of the dentate gyrus. Furthermore, the introduction of a new environment may exacerbate an already disoriented condition.

421.6

BEHAVIORAL AND MORPHOLOGICAL EFFECTS OF ASTROCYTE TRANSPLANTS IN RATS WITH NUCLEUS BASALIS LESION. L. Lescaudron, Z. Fulop*, R. Sutton, H.M. Geller and D. Stein. Brain Research Lab., Rutgers Univ., Newark NJ 07102 and UMDNJ-Robert Wood Johnson Med. School, Piscataway, NJ 08854.

Adult male rats received transplants (TP) of dissociated 30-day old cultured cortical astrocytes [AST: labeled with bisbenzamide (BIS)] into the nucleus basalis magnocellularis (NBM) or into the frontal and parietal cortex (CX) immediately after ibotenic acid lesion of the NBM. Nine days after surgery rats with AST-TP into NBM or CX were as impaired in the acquisition of a passive avoidance (PA) task as untreated counterparts. No effects were found for PA retention. Brains were processed for BIS, GFAP-ICC, ACh-E and cytochrome oxidase (CO) 14 days after TP. Host brain gliosis, but no surviving AST-TPs, were observed in the NBM. AST-TPs had no effect on size of the lesions. Concentrations of ibotenic acid used to lesion the NBM killed AST in vitro within 24 hours, suggesting a similar fate for AST-TPs in NBM. BIS-labeled AST were observed in CX, but these AST-TPs produced severe laminar disruption, gliosis and decreased ACh-E and CO staining.

BEHAVIORAL AND PHYSICAL DISTURBANCES OF RATS WITH IBOTENIC ACID LESION OF BASAL FOREBRAIN. C.Hara and N.Ogawa. Dept. of Pharmacol., Ehime Univ. Sch. of Med., Ehime-ken 791-02, Japan.

In this study, characteristics of behavioral and physical disturbances of rats with ibotenic acid lesions of the bilateral nucleus basalis of Meynert (NBM) were analyzed in connection with physical disability or abnormal behavior in patients of Alzheimer's disease. Male Wistar rats (9 weeks old) were used. They were maintained in the air-conditioned room with 12:12 LD cycle, and were housed in the running wheel or the activity meter (Scanet SV-10, Toyo-sangyo) cages. Ibotenic acid (Sigma; 5µg/0.5µl/2 min) was injected into the NBM (Paxinos & Watson;A:7.7,L:2.3,V:7.1) under pentobarbital anesthesia (50 mg/kg, i.p.). After the surgery, rats were forcedly given milk daily. In the results, the NBM-lesioned group revealed body weight loss, disruption of food-intake, and disturbance of circadian rhythm of activity with the increased daytime activity. These disturbances recovered within 1 week accompaying with recovery of body weight in most of the rats. However, several rats showed no recovery with urinary incontinence. The results suggest that these disturbances may be attributable to damage to the adjacent lateral hypothalamus, and are interested in the physical disability model.

MEMBRANE DEFORMATIONS IN A CELLULAR MODEL FOR ALZHEIMER AMYLOIDOSIS. G.E. Maestre, R.E. Majocha, B. Tate, E.M. Sajdel-Sulkowska, and C.A. Marotta. Massachusetts General Hospital, McLean Hospital and Harvard Medical School, Boston, MA 02114.

PC12 cells were permanently transfected with DNA corresponding to the ß/A4 to C terminal region of the amyloid precursor protein of Alzheimer's Disease. Integration of human amyloid DNA was confirmed by Southern blotting. Transfected clonal cell lines and controls were examined at both the light and electron microscopic levels. Many morphological parameters are similar between transfected and control cell lines, including number and size of mitochondria and number of lipofuscin inclusions. However, transfected cell lines exhibited numerous membrane extensions not seen in similar quantities in the control cell lines. Membrane extensions include ruffles and blebs. Extensions may be related to reorganization of membrane proteins and/or the cytoskeleton. Similar cellular deformations, if present in Alzheimer brain cells, may indicate disturbances in membrane-associated functions, including cell-cell interaction. Senile plaques do not support neurite outgrowth *in vitro*. M.K. Carpenter[1], K.A. Crutcher[2], S.B. Kater[1]. [1]Dept. of Anatomy and Neurobiology, Colorado State Univ., Fort Collins. CO 80523; [2] Dept. of Neurosurgery, Univ. of Cincinnati Med. Ctr., Cincinnati, OH 45267.

Although senile plaques represent a consistent neuropathological feature in Alzheimer's brains, it is not known what role plaques play in the etiology of the disease. Both growth-promoting and growth-inhibiting influences have been postulated. One of the major components of plaques, namely ß-amyloid, has been shown to affect neuron survival and neurite outgrowth *in vitro*. Since plaques consist of other components in addition to ß amyloid, we undertook the present study to determine whether neurite outgrowth is affected by senile plaques in culture. This was accomplished using a novel technique in which embryonic rat hippocampal neurons are cultured on cryostat sections of the postmortem-derived cerebral cortex of patients diagnosed with Alzheimer's disease. Using this paradigm, neurons growing on a substrate with a high density of plaques can be examined. The cultured cells were visualized using a vital fluorescent dye (the acetoxymethyl ester form of carboxyfluorescein). After imaging the cultured neurons, the section was then fixed and stained with thioflavin S to identify plaques. Using computer analysis of superimposed images, the morphology of neurons that associate with plaques was examined. Living neurons are found on senile plaques, suggesting that plaque components are not toxic under these culture conditions. However, such cells rarely extend processes or, and if processes are present, they are shorter in length than processes of cells attached to non-plaque regions. In addition, neurites that extend from neurons adjacent to plaques appear to turn away from the plaques.Supported by NIH-NS26819, MKC supported by NIH postdoctoral fellowship NS08842.

QUISQUALATE INJECTION INTO THE NUCLEUS BASALIS MAGNOCELLULARIS INDUCES SEIZURE-RELATED BRAIN DAMAGE. M.T. Price, D. F. Wozniak, S. Sun*, and J. W. Olney Washington Univ, St. Louis, MO 63110.

Ibotenate (Ibo), quisqualate (Quis) and N-methyl-DL-aspartate (NMA), are excitotoxins that have been used to destroy neurons in the area of the nucleus basalis magnocellularis (NBM) in adult rats. NBM lesions produced by Ibo and NMA are associated with reliable learning/memory deficits. This is consistent with the hypothesis that cholinergic neurons play an important role in memory, and that loss of these neurons may contribute to memory impairment in Alzheimer's disease (AD). However, recent reports that Quis produces at least as great a reduction in cortical choline acetyltransferase activity as Ibo or NMA, without producing consistent learning/memory deficits, raises the important question whether some factor other than loss of cholinergic neurons might account for the Ibo/NMA-induced memory impairment. In the brains of AD patients, a marked loss of somatostatinergic (Som) as well as cholinergic neurons has been reported, and we have recently found that Som-immunopositive neurons in the rat basal forebrain are readily destroyed by NMA (Wozniak et al., Neurosci Abs. '91). The present study was undertaken to determine what effect Quis has on basal forebrain Som neurons. Addressing this question proved rather difficult because unilateral injection of Quis into the NBM (n=10) caused sustained seizures and disseminated brain damage in all rats. While Som neurons were destroyed in these brains, it is impossible to know whether this signifies sensitivity to Quis or to sustained seizure activity. Since the dose of Quis and injection parameters we used were the same as those used by others who did not report seizure pathology as a complication, we are currently exploring relevant variables to clarify the discrepancy. Our results indicate that Quis poses the same kind of problem as kainic acid -- instead of producing a simple excitotoxic lesion confined to the injection site, it induces persistent seizures and seizure-mediated brain damage near to and far from the injection site. Supported by AG05681 (DFW & JWO) and RSA MH38894 (JWO).

421.11

SENSITIVITY OF BASAL FOREBRAIN SOMATOSTATINERGIC NEURONS TO N-METHYL ASPARTATE NEUROTOXICITY. D. F. Wozniak, G.R. Stewart, S. Sun*, and J. W. Olney. Dept. of Psychiatry, Washington Univ. Sch. Med., St. Louis, MO 63110.

Various excitotoxin agonists, including ibotenate (Ibo), quisqualate (Quis) and N-methyl-DL-aspartate (NMA), have been used as lesioning agents to destroy cholinergic nucleus basalis magnocellularis neurons in adult rats. Destruction of these neurons by Ibo and NMA is associated with similar learning/memory deficits. This is consistent with the hypothesis that cholinergic neurons play an important role in memory, and that loss of these neurons contributes to memory impairment in Alzheimer's disease (AD). However, recent reports that Quis deletes at least as many basal forebrain cholinergic (BFC) neurons as Ibo or NMA, without producing consistent learning/memory deficits, raises the important question whether some factor other than BFC neuronal loss might account for the Ibo/NMA-induced memory impairment. It is not known whether injection of excitotoxins into the basal forebrain destroys somatostatinergic (Som) as well as cholinergic neurons, but in the brains of patients with AD, both of these transmitter systems are reportedly affected. The present study was undertaken to determine what effect NMA has on basal forebrain Som (BFS) neurons. Injection of NMA into the basal forebrain caused a lesion which, by routine histopathological evaluation, appeared well confined to the injection site. The largest and most conspicuous group of BFS neurons are those in the entopeduncular nucleus (EpN) located 1-1.5 mm from the center of the injection site. The NMA injection destroyed 100% of these BFS-EpN neurons but only ≤ 70% of the BFC neurons within a sphere of equal radius from the injection. Moreover, in nearby portions of caudate nucleus there was a 30% loss of Som neurons and no loss of cholinergic neurons. Our findings signify the following: 1) BFS neurons are extremely sensitive to excitotoxin-induced degeneration; 2) An excitotoxic mechanism could account for loss of either BFS or BFC neurons in AD; 3) The learning/memory deficits associated with an NMA lesion (or with AD) could be due, in part, to loss of BFS neurons. Supported by NIH grants AG05681 (DFW & JWO) and RSA MH38894 (JWO).

RADIO-FREQUENCY LESIONS OF THE NUCLEUS BASALIS (nbM) INDUCE LONG-LASTING DEFICITS IN STIMULUS-PROCESSING ASPECTS OF DIFFERENTIAL CONDITIONING PERFORMANCE. J.E. Dencoff, A.E. Butt, & G.K. Hodge. Department of Psychology, University of New Mexico, Albuquerque, NM 87131.

Previously, we have reported that bilateral radio-frequency lesions of the nbM resulted in deficits in differential conditioning performance. As compared to control animals, rats with bilateral nbM lesions showed impaired discrimination (i.e., reduced successes, increased errors, and increased session time on a bar-press task). Lesioned and control animals did not differ with respect to overall rate of responding. Results suggested that nbM-lesioned animals had an impaired ability to attend to and use stimulus cues in accurately guiding behavior. In the current study, we now report that such deficits persist months after lesions are induced.

Twelve months post-lesion, ten months after their last exposure to the task, animals were retested. In the interim, animals received no experimental manipulations. Initially, both lesioned and control animals showed poor discrimination, but on successive days, control animals improved whereas lesioned animals showed consistently poor discrimination ability.

INDUCTION OF THE BETA AMYLOID PRECURSOR PROTEIN IN THE SUBCORTICALLY LESIONED RAT CORTEX. V. Haroutunian, V. Bragin*, K. Davis, W. Wallace; Dept. Psychiatry and Center for Neurobiology, Mt. Sinai School of Medicine, New York.

We have reported that NMDA lesions of the rat nucleus basalis of Meynert result in the increased synthesis of beta-amyloid precursor protein (B-APP) in the cortex. In order to determine the normal physiological function of B-APP in the intact brain, we have further characterized this induction. This induction is common to other cortically projecting neurotransmitter systems. Lesions of the dorsal raphe nuclei, which targets serotonergic innervation and ascending noradrenergic bundle, which targets adrenergic innervation, similarly induce the cortical B-APP. Thus, the induction of B-APP appears to be a general response of the lesioned cortex. However, treatment of naive rats with the acetylcholinesterase inhibitor, physostigmine does not alter B-APP synthesis, showing that increased levels of acetylcholine do not result in this induction. The elevated B-APP synthesis is accompanied by increased B-APP mRNA indicating increased gene transcription. The induction occurs as early as one hour after lesion and persists for at least seven days. These observations suggest that B-APP may be interacting with other neurotrophic factors in the cortex in response to the loss of subcortical innervation.

421.14

ALTERATIONS IN THE CIRCADIAN RHYTHMS OF RATS RECEIVING SCN IMPLANTS OF PC12 CELLS OVER-EXPRESSING ALZHEIMER'S DISEASE ß-AMYLOID. B.Tate, K.S. Aboody, A.M. Morris, R.E. Majocha and C.A. Marotta. Mass. General Hospital and Harvard Medical School, Boston, MA 02114.

Patients suffering from Alzheimer's Disease (AD) display a number of abnormalities in circadian rhythms. In order to model this uniquely human disorder, permanently transfected PC12 cells containing the ß-amyloid to C terminal region of the amyloid precursor protein have been developed. The cells were stereotaxically placed in the suprachiasmatic nuclei (SCN) of adult female rats and circadian rhythms in body temperature and activity were monitored using indwelling radio transmitters (Mini-mitters). Controls included animals receiving vehicle, normal PC12 cells or PC12 cells transfected with vector only, or no surgery. On light/dark cycles of 12:12, animals receiving amyloidotic cells showed activity rhythms but not temperature rhythms that differed significantly from all control animals ($p<0.001$). The data support an association between a behavioral disruption and amyloid. Similar mechanisms may be relevant to the clinical manfestations of AD. Supported by NIH AG02126 and Milton Fund Grant.

421.15

ALZHEIMER DEFICITS DEVELOP IN AGED RATS AFTER CHRONIC CEREBROVASCULAR INSUFFICIENCY. J.C. de la Torre, G.A.S. Park*, T. Fortin*, J. Katnick*, J. Saunders*, K. Butler*, P. Kozlowski*, B. Pappas, M. Richard*. Univ.of Ottawa, Ontario Canada K1H 8M5.

Alzheimer's disease (AD) is initially characterized by reduced CBF, spatial memory dysfunction, increased formation of senile plaques (SP), neurofibrillary tangles (NT), glial fibrillary acidic protein (GFAP) and by hippocampal cell loss. ^{31}P- NMR spectroscopy of AD brains also shows a phosphomonoester (PME) elevation which indicates an increase in membrane phospholipid synthesis.

We subjected aged rats to cerebrovascular insufficiency (CVI) for 9 weeks as we have described (Brain Res. Bull. 26:365, 1991). At 3, 6, 9 weeks after CVI, we measured CBF and tested rats for spatial memory, ^{31}P- ^{1}H- NMR spectroscopy/imaging using ISIS localization for the hippocampus. Post-mortem tissue was examined for CA1 sector cell counts and GFAP reaction. Results show that CVI rats but not matched controls developed spatial memory impairment in the Morris Water Maze test and elevation of PME in the hippocampus following ^{31}P- NMR spectroscopy. In addition, aged CVI rats had significant cell damage to CA1 and increased GFAP immunoreaction throughout the hippocampus. Rats had cortical and hippocampal CBF reduction 3 weeks after chronic ischemia but only hippocampal blood flow remained low for 6-9 weeks after CVI (equivalent to 4-6 human years).

These results suggest that membrane phospholipid synthesis is increased in CVI rat hippocampus possibly due to proliferation of reactive GFAP-positive astrocytosis.

We conclude that chronic CVI in aged rats induces a syndrome that mimics the cognitive, metabolic and morphologic changes seen in AD. It is tempting to speculate that the pathologic deficits seen in the early course of AD could also be triggered by chronic CVI.

ATROPHY OF BASAL FOREBRAIN CHOLINERGIC NEURONS IS MODELED BY MOUSE TRISOMY 16 TRANSPLANTS. D.M.Holtzman, Y.Li*, S.J.DeArmond*, F.H.Gage, C.J.Epstein*, W.C.Mobley. Depts. of Neurology, Pediatrics, and Biochemistry, UCSF, San Francisco, CA 94143 and Dept. of Neurosciences, UCSD, La Jolla, CA 92093.

Vulnerability of specific brain regions and neuronal populations is a characteristic feature of Alzheimer's disease (AD) and Down syndrome (DS). One of the vulnerable populations includes cholinergic neurons in the basal forebrain. We transplanted brain tissue from mouse trisomy 16 (Ts 16), an animal model of DS, in order to develop a model to study the neuronal degeneration which occurs in AD and DS. Suspensions of fetal Ts 16 or control septum were injected into hippocampus of young adult mice. At one month post-transplantation, there was good neuronal survival and neurite outgrowth from all grafts. However after six months, Ts 16 cholinergic neurons and their proximal neurites frequently appeared shrunken and atrophic. They were significantly smaller than controls (125.9 vs. 166.2 μ^2). The atrophy of cholinergic neurons was selective in that no significant difference was found in comparing the size of non-cholinergic neurons. Some mice were given bilateral lesions of the fimbria-fornix. Fornix lesions increased the size of all cholinergic neurons; controls remained larger than Ts 16. Our findings indicate that one can model a genetic disorder leading to cholinergic atrophy. It should allow for dissection of the chromosomal region(s) responsible for degeneration of these neurons. This model may also be used to understand early molecular events important to the pathogenesis of AD. In addition, it provides a means to study potential therapies to prevent genetically determined neurodegeneration.

421.17

CHRONIC NEUROFIBRILLARY DEGENERATION INDUCED BY ALUMINUM FLAVONOL, A UNIQUE LIPOPHILIC ALUMINUM CHELATE COMPLEX. R.N.Katz*, A.Hsu*, P.F.Good, D.E.Wolfe and D.P.Perl. Fishberg Research Center for Neurobiology, Mt. Sinai Medical Center, New York, NY 10029.

Orvig and coworkers (J.Amer.Chem.Soc., 108:5033, 1986) have shown that aluminum-related neurotoxicity can be increased by an order of magnitude by administering aluminum as aluminum maltol. Following this lead we have prepared a lipophilic complex, tris(3-hydroxyflavonato)-aluminum (aluminum flavonol, $AlFl_3$), and have demonstrated acute and chronic neurotoxic effects in rabbits when administered intraventricularly as a single injection. $AlFl_3$ is not water soluble but a stable suspension can be prepared using a Brinkman tissue homogenizer. Intraventricular injection of 0.1mL of a 75mM suspension in New Zealand albino rabbits produced seizures at 18 days, and SMI-31 (monoclonal antibody to phosphorylated medium and heavy neurofilament proteins) immunoreactivity (*ir*) revealed extensive neurofibrillary degeneration in cortical layers III and V. Additional animals remained asymptomatic after four weeks but had numerous SMI-31*ir* neurons in the neocortex and subiculum. Animals exposed to 0.1mL of 7.5mM $AlFl_3$ showed only subtle symptomatology after five months. These animals also demonstrated neocortical neurofilamentous tangles. An interesting property of $AlFl_3$ is its autofluorescence, and using fluorescence microscopy we have observed particles of the compound in macrophages within the ventricles. $AlFl_3$ and other novel aluminum chelate complexes represent important new tools for developing animal models of chronic aluminum neurotoxicity. ALZHEIMER'S DISEASE: CYTOSKELETON

422.1

EXPRESSION OF TAU AND ALZ-50 IN HUMAN CORTICAL CELL LINE HCN-1A AND NON-HUMAN NEUROBLASTOMA CELL LINES. S.A.Enam, J.T.Megerian, & W.L.Klein. Northwestern University Institute for Neuroscience, Evanston, IL 60208

The relationship between tau and Alz-50 was studied by immunofluorescence in HCN-1A, and N1E-115, B103, and the F3 variant of PC12 cells. Results were as follows:

	Neurites	Alz-50	Tau
HCN-1A (Differentiated)	Yes	Negative	+ all neurites & soma
HCN-1A (Un-differentiated)	No	Negative	Very weak
N1E-115	Yes	+ all cells	+ all neurites & soma
B103	Yes	+ all cells	+ all neurites & soma
F3	No	Weak	+ all cells

In some cell lines, Alz-50 was present in all the cells, suggesting that Alz-50 is not a marker of cell death. The difference between the expression of Alz-50 in B103 and F3 cell lines is interesting when considered with the fact that almost all of the B103 cells constitutively express neurites in vitro, whereas F3 cells rarely express neurites. This interesting contrast is consistent with the hypothesis that Alz-50 may be associated with the process of neuritogenesis. These cell lines may be a valuable source for further understanding the role of Alz-50 in Aging and normal development.

422.2

BRAIN TAU LEVELS ARE ELEVATED IN ALZHEIMER DISEASE. S. Khatoon*, I. Grundke-Iqbal* and K. Iqbal, NYS Institute for Basic Research, Staten Island, N.Y. 10314

Microtubule associated protein tau which stimulates the assembly of α-β tubulin heterodimers into microtubules is abnormally phosphorylated in Alzheimer disease (AD) brain, and is the major component of paired helical filaments. In the present study, the levels of tau, abnormally phosphorylated tau and of tubulin were determined in brain homogenates of AD and age-matched normal cases. A radioimmuno slot blot assay was developed using a primary monoclonal antibody (mAb), Tau-1 and anti-mouse ^{125}I-IgG as secondary antibody. For assaying the abnormally phosphorylated tau, the blots were treated with alkaline phosphatase prior to immunolabeling. Amounts of α and β tubulin were determined by an ELISA using mAb YL1/2 to α and mAb KMX-1 to β tubulin. The levels of total tau were about 6-fold higher in AD (5.9 ± 1.3 ng/μg protein) than in control (1.0 ± 0.2) cases. Most of the tau in AD brain was abnormally phosphorylated (4.3 ng/μg protein). In contrast there were no significant changes in the levels of tubulin in AD brain. These studies show (1) that there is a marked increase in brain levels of tau in AD, and (2) that this increase is due to the accumulation of abnormally phosphorylated tau in the affected tissue. (Support by NIH grants AG05892, AG08076, NS18105 and AG04220 and a grant from AHAF).

A TAU POLYMER MODEL OF THE PAIRED HELICAL FILAMENT. D.M. Wilson* and L.I. Binder. Dept. of Cell Bio., Univ. of Alabama at Birmingham, 35294

The paired helical filament (PHF) is the basis of the intracellular neurofibrillary pathology observed in Alzheimer's Disease. The microtubule-associated protein tau is widely accepted as contributing to the structure of the PHF. Recent advances in purifying populations of PHF amenable to standard solubilization tecniques, revealed that tau isoforms are the only proteins isolated following filament dissociation. Therefore, believing that tau is the only integral component of the PHF, we have constructed a tau polymer model for these filamentous structures. Our tau polymer has the appearance of paired filaments, with a total mass/unit length of 55-60 kDa/nm. Its dimensions and cross-sectional mass distribution are consistent with data reported for PHF. Our model also accommodates the demonstrated beta-pleated sheet content of the PHF. Three mechanisms of tau self-association are invoked to generate the tau polymer. One of these mechanisms is phosphorylation dependent, and the model predicts specific phosphorylation sites and appropriate kinases which would be involved in producing assembly competent tau.

FUNCTIONAL STUDIES OF ALZHEIMER'S DISEASE TAU PROTEIN. Q. Lu* and J.G. Wood. Dept.of Anatomy and Cell Biology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

In vitro assays were used to monitor and compare the kinetic behavior of microtubule assembly induced by tau proteins isolated from Alzheimer's disease (AD) and non-demented age matched control brains. Tau from 4 of 5 AD cases induced slower assembly and a steady state assembly approximately 50% of that stimulated by tau from 3 control cases. Tau from the most severe cases was least effective at promoting assembly. Dark field microscopy of the control samples indicated abundant microtubule formation and many microtubule bundles. Fewer microtubules were observed in the AD samples and bundling could not be detected. There was no obvious difference in the ultrastructure of microtubules formed in both cases. SDS-PAGE analysis revealed lower amounts of tau in microtubule pellets from experimental compared to controls which supports the assembly data. AD tau is modified by phosphorylation (PNAS, 83:4040-4043; 4913-4917). These results indicate that tau modification compromises its function in helping provide a population of stable neuronal microtubules needed for critical functions such as axonal transport. AG 06383; NS 17731.

CASEIN KINASE II BINDS PAIRED HELICAL FILAMENTS. L. Baum and T. Saitoh. Department of Neurosciences, 0624, University of California, San Diego, La Jolla, CA 92093.

In Alzheimer's disease (AD), neurofibrillary tangles (NFT) and dystrophic neurites contain paired helical filaments (PHF) composed largely of abnormally phosphorylated tau, a microtubule-associated protein. The kinases that phosphorylate tau in vivo are not yet known. Casein kinase II (CK-II), a highly conserved serine/threonine kinase, phosphorylates tau in vitro. NFT exhibit CK-II immunoreactivity, and purified CK-II can bind NFT on AD brain sections. We explored the nature of this binding using purified CK-II and purified PHF. To detect any PHF-associated CK-II, PHF was purified by a relatively gentle method (Greenberg and Davies). Immunoblots of PHF showed no CK-II, indicating either that: the amount of CK-II present was too little to detect; CK-II does not bind PHF; or detergent in the PHF purification removes CK-II. To determine whether CK-II can bind PHF, CK-II was added to centrifuge tubes containing PHF, spun to pellet the PHF, and the amount of CK-II pelleting with the PHF was measured on immunoblots. Although some CK-II, which can form filaments in vitro, pellets in control tubes, more CK-II pellets in PHF tubes. Low salt enhances co-pelleting, suggesting an ionic interaction. Thus, CK-II binds PHF in vitro. In vivo, the normal functions of CK-II might be disrupted by its abnormal localization in AD. In addition, since the phosphorylation of a substrate by CK-II can be enhanced by previous phosphorylation of the substrate, CK-II might contribute to the overphosphorylation of tau in PHF.

CYTOSKELETAL mRNAs IN ALZHEIMER'S DISEASE TEMPORAL CORTEX AND CEREBELLUM. KM Chan, JR Goss & DG Morgan. Gerontol. Ctr. & Dept. of Biol. Sci., Univ. Southern Cal., Los Angeles CA 90089-0191

We have shown previously by northern hybridization that glial fibrillary acid protein (GFAP) RNA prevalence increased in Alzheimer's Disease (AD) cortex. In this study, we have examined three other cytoskeletal RNAs: vimentin, the low molecular weight neurofilament (NF-L), and β-tubulin. RNA prevalence in 8 AD and 8 control specimens from each region was measured by a solution hybridization method (RNase-protection assay), carried out in triplicate using six concentrations of total RNA per sample. The mass of each specific message per unit mass of total RNA was calculated (pg/μg).

Marker	TCX (C)	TCX (AD)	CBL (C)	CBL (AD)
GFAP	6.7±0.5	29.8±7.2	11.7±1.4	8.2±0.8
Vimentin	1.6±0.1	2.6±0.6	0.8±0.1	0.68±0.07
NF-L	2.0±0.04	1.9±0.03	0.8±0.1	0.56±0.05
β-Tubulin	4.3±0.5	3.5±0.4	3.8±0.4	4.1±0.4

The 4.5 fold increase in GFAP message between AD and control cortex was the only statistically significant change. Two cortical AD samples had 4 fold elevations of vimentin RNA suggesting microglial/macrophage proliferation, but other samples were within the control range. No change in NF-L or β-tubulin were detected, although northern analysis suggested a different size for the NF-L mRNAs in AD T-CX. As expected, no changes were observed in the relatively intact AD cerebellum. We thank SA Johnson for organizing the brain tissue samples and CA Zarow for modifying the NF-L clone. Supported by AG-07892, AG-00093, AHA-GIA 891079, and AHA-EIA 890173.

CHARACTERIZATION OF HMW TAU IN THE PERIPHERAL AND CENTRAL NERVOUS SYSTEM N.Taleghany* and M.M.Oblinger Dept. of Cell Biology & Anatomy, The Chicago Medical School, North Chicago IL 60064

Tau is a complex family of neuron-specific microtubule-associated proteins that are encoded by a single gene. The major tau proteins in brain are a complex of low molecular weight (LMW) proteins (50-70 kDa). However, a HMW tau isoform (110 kDa) has been found in peripheral nervous tissue as well as in PC12 cells. Little is known about the distribution of this HMW tau form in the nervous system. Is this isoform restricted to the PNS, and are the properties of HMW tau different from those of other isoforms? In order to address this issue immunoblotting analysis with the tau-1 antibody was employed and such studies revealed that while LMW tau was present throughout CNS samples, HMW tau was largely restricted to tissues that were obtained from the PNS. An intermediate-sized tau isoform (MMW tau, 90-110 kDa), was also identified in this study. This isoform was localized in the optic nerve (ON) as well as the cerebellum. To explore some of the molecular properties of HMW tau, we examined its behavior under a series of conditions, namely its gel mobility after treatment with phosphatase, its heat stability and its partitioning when exposed to cold-calcium and Triton extraction paradigms. Interestingly, HMW tau partitioned with the soluble fraction while LMW & MMW tau partitioned mainly with the stable microtubule pellets. Immunocytochemical studies revealed that DRG cell bodies stain with tau specific antibodies. This is in sharp contrast to previous findings that neuronal cell bodies in brain don't exhibit staining with tau-1 antibody. Since immunoblots show that the dorsal roots & DRG contain only the HMW tau form we can suggest that the DRG cell bodies contain HMW tau and that the tau-1 epitope is not the masked in these cell bodies. Northern blot analysis of total RNA from different regions of the adult nervous system revealed different sized tau mRNA's (6-8 kb). This suggests that alternative splicing of tau mRNA is a significant factor in generating tau heterogeneity. The HMW tau generated by such a mechanism has unique characteristics from other tau forms.

MAP-2 mRNA LEVELS ARE DECREASED IN PRIMARY MOTOR CORTEX IN ALZHEIMER'S DISEASE. K.E. Rogers*, H. A. SantaLucia*, and P. D. Coleman. Dept. of Neurobiol. & Anat., University of Rochester, Rochester, NY. 14642

Morphometric studies have suggested that dendritic plasticity is altered in Alzheimer's Disease(AD). MAP-2, a microtubule associated protein, has been shown to be a dendritic specific protein whose levels may parallel the volume of the dendritic compartment. Thus, measurement of MAP-2 mRNA levels could reflect the state of the dendritic compartment. Total RNA was extracted from AD and control tissue taken from Brodman's area 4. MAP-2 message prevalence was measured by solution hybridization to a MAP-2 cRNA. mRNA content was determined by oligo-dT slot blot hybridization. Data analysis demonstrated that there was a 57% decrease in MAP-2 messages in AD when compared to age-matched controls. Area 4, primary motor cortex, has not previously been thought to be significantly affected in AD. (Supported by R35 AG 09016, P01 AG 03644, R01 AG 01121, P30 AG 08665(PDC) AND ADRDA PRG-89-120(KER).

422.9

TIME-DEPENDENT EFFECTS OF INTRAHIPPOCAMPAL NMDA ON THE MICROTUBULE PROTEINS TAU AND MAP2. D.K. Rush[1], R.K. Lartius[2], S.H. Aschmies[1]* & E.Uemura[2]. [1]Dept. Biol. Res., Hoechst-Roussel Pharmaceuticals Inc., Somerville, NJ, 08876 and [2]Dept. of Anat., Iowa State Univ., Ames, IA 50011.

The plaques and tangles characteristic of Alzheimer's disease (AD) are composed in part of microtubule associated proteins (MAPs). Since excitatory amino acid neurotransmission may play a role in AD neurodegeneration, we examined the effects of intrahippocampal N-methyl-D-aspartic acid (NMDA) on the MAPs, tau and MAP2. NMDA (20 nmoles in 1 µl dH_2O) was unilaterally injected into the dorsal hippocampus of rats under chloral hydrate anesthesia. The animals were sacrificed 1, 3, or 7 days later and brain sections immunohistochemically stained for either MAP2 or tau with HM-2 or Tau-1 monoclonal antibodies. The pattern of MAP2 and tau staining differed in terms of both regional specificity and time course. One day post-lesion, tau staining was significantly increased in all three layers of the CA1 region (strata oriens, moleculare, and pyramidale) in the NMDA as compared to the vehicle injected hippocampus. MAP2 staining was unchanged. At 3 and 7 days post-lesion, tau staining had returned to normal but MAP2 staining was decreased in all three CA1 layers of the lesioned hippocampus. The cell necrosis and effects on microtubule associated proteins found in the present study differ from the pattern of neuropathological changes in AD; tau did not remain elevated as it does in the disease state. The pattern of effects does support previously reported findings of NMDA on MAP2 and tau staining in cortical culture (Bigot & Hunt 1990) and suggests a modulatory effect of NMDA on the neuronal cytoskeleton.

422.10

SUBPOPULATIONS OF MICROTUBULES REVEALED BY EXPRESSION OF INDIVIDUAL HUMAN TAU ISOFORMS AND PERTURBATION BY COLCHICINE, COLD, AND CALCIUM.
T.E. Norris, A.F. Fieles*, C.B. Caputo, C.W. Scott, M. Goedert*, and M.M.S. Lo. ICI Americas, Inc., Wilmington, DE 19897 and MRC Laboratory of Molecular Biology, Cambridge CB2 2HQ, England.

The neuronal cell contains subpopulations of microtubules (MT) as defined by their composition and function. Different MAPs, and their isoforms are associated with different MT populations. In addition, these distinct MT show selective sensitivities to different MT depolymerizing conditions.

In order to investigate the early events in MT degeneration, we have used 3T3 cells stably transfected with single isoforms of human tau. These cell lines have revealed that MT behavior depends on the specific tau isoform present. Expression of individual tau isoforms confers unique cellular morphologies as well as different MT stabilities to depolymerizing conditions. These morphology differences are further accentuated by the MT depolymerizing conditions of colchicine. Degradation of MTs resulting from various treatments shows that the MT subpopulations depolymerize via different mechanisms. Colchicine causes a loss of cell processes, however, an intracellular MT matrix remains intact in the cell body which contians concentrated "pools" of tubulin. In contrast, cold treatment causes a progressive degradation of MT into small fibers without altering the cellular morphology. Increased levels of intracellular calcium causes a redistribution of the MT networks into bundles yet does not change the cell's morphology. The different cytoskeletal changes caused by these MT depolymerizing conditions, as well as the morphological changes caused by expression of different tau isoforms, reveals that there are numerous subpopulations of MTs. We will be focusing on the effects of elevated intracellular levels of calcium as it relates to cell morphology, cytoskeleton and organelle redistribution, and the calcium regulated phosphorylation events of tau.

422.11

TAU PROTEIN INDUCES BUNDLING OF MICROTUBULES IN VITRO. C.W Scott, A.B. Klika, M.M.S. Lo, T. Norris and C.B. Caputo, Dept. of Pharmacology, ICI Americas, Inc. Wilmington, DE 19897.

Expression of tau protein in non-neuronal cells results in the redistribution of the microtubule (MT) cytoskeleton into thick bundles of tau-containing MTs (Lewis et al., (1989) Nature, 342:498). The molecular basis for tau-induced bundling of MTs is not understood, therefore experiments were performed to reconstitute MT bundling using purified bovine tubulin and recombinant human tau isoforms. Tubulin was assembled into MTs by incubating with taxol in assembly buffer. The MTs were isolated by centrifugation, mixed with various concentrations of T4 (tau isoform containing four MT binding domains), and examined by negative stain electron microscopy. In the absence of tau the MTs were randomly distributed. When MTs were incubated with T4 at tubulin:tau molar ratios of 1:0.9 the MTs appeared as loosely- and tightly-packed parallel arrays. At molar ratios of 1:1.5 the MTs condensed into thick bundles containing multiple layers of tightly packed parallel arrays. MT bundling was observed with porcine tau and other human tau isoforms, and was blocked by the addition of 0.5M NaCl or 0.3mM estramustine phosphate. A tau deletion construct that contained only the four MT binding domains plus 19 amino acids to the C-terminus was capable of bundling MTs. These data further refine the region of tau required for MT bundling in vitro and demonstrate that bundling can be reconstituted using only tubulin polymers and tau protein.

422.12

PHOSPHORYLATION AND METABOLISM OF TAU. G.V.W. Johnson and J.M. Litersky. Depts. of Psychiatry and Cell Biology, Univ. Alabama at Birmingham, Birmingham, AL 35294.

The phosphorylation state of tau has been postulated to modulate its interactions with other cytoskeletal components and also may regulate its susceptibility to proteolysis. We are examining these processes because an inappropriately phosphorylated tau is an important component of paired helical filaments (PHFs), which are found in Alzheimer's disease brain. In this study we examined the in vitro phosphorylation of bovine tau by cAMP-dependent protein kinase (cAMP-PK), Ca++/calmodulin-dependent protein kinase II (CamKII), and protein kinase C (PKC), and how phosphorylation by these kinases modulates its hydrolysis by calpain or binding to microtubules.

Phosphorylation of tau by each of the kinases produced distinct 2 dimensional phosphopeptide maps. cAMP-PK phosphorylated unique sites, as well as sites phosphorylated by CamKII. Little overlap existed between the sites phosphorylated by PKC and either CamKII or cAMP-PK.

Phosphorylation by CamKII or cAMP-PK, but not PKC, retarded the migration of the tau isoforms on SDS-polyacrylamide gels. Phosphorylation of tau by cAMP-PK significantly inhibited its hydrolysis by calpain. In contrast, phosphorylation of tau by CamKII did not alter its susceptibility to calpain. Phosphorylation of tau by these kinases also altered the binding of tau to microtubules. These results suggest a role for cAMP-PK phosphorylation in regulating the degradation of tau. Abnormal phosphorylation could result in a protease-resistant tau population which may contribute to the formation of PHFs in Alzheimer's disease.

422.13

PHOSPHORYLATION MODULATES DEGRADATION AND FUNCTION OF INDIVIDUAL HUMAN TAU ISOFORMS. J.M. Litersky, C.W. Scott and G.V.W. Johnson. Depts. of Psychiatry and Cell Biology, Univ. of Alabama at Birmingham, Birmingham, AL. 35294 and ICI Americas Inc., Wilmington, DE 19897.

Individual human tau isoforms purified from an E. coli system expressing each specific clone (Goedert and Jakes, 1990) were used in this study. Of the six isoforms cloned, the three used in this study were tau with either three or four microtubule-binding repeats in the carboxy-terminal half of the molecule (T3R, T4R) and a four repeat tau with the 58 amino acid insert in the amino-terminal region of the molecule (T4RL). The isoforms were phosphorylated by cAMP-dependent protein kinase (cAMP-PK) and Ca++/ calmodulin-dependent protein kinase II (CamKII), and subjected to one-dimensional polyacrylamide gel electrophoresis (1D PAGE), two-dimensional nonequilibrium pH gradient electrophoresis (2D NEPHGE), 2D phosphopeptide mapping, calpain hydrolysis and a binding assay. Phosphorylation by either kinase retarded the migration of all three isoforms on 1D PAGE. cAMP-PK produced two slower migrating species, the slower of which aligned with the single band produced by phosphorylating with CamKII. 2D NEPHGE revealed that T4R existed as one isovariant, while T3R and T4RL appeared to exist as 5 and 7 isovariants, respectively. Phosphorylation also increased the microheterogenity of the isoforms on 2D NEPHGE. The 2D phosphopeptide maps demonstrated that the isoforms were all phosphorylated in a similar manner, with the two kinases producing distinct peptide maps. The three tau isoforms were all susceptible to calpain hydrolysis, however T3R was proteolyzed at a slower rate than either T4R or T4RL. The hydrolysis of the isoforms by calpain was significantly increased after phosphorylation by CamKII. Phosphorylation by cAMP-PK did not alter calpain-induced proteolysis. In addition, phosphorylation appears to modulate the binding of the tau isoforms to tubulin. Supported by NIH grants NS27538 and AG06569 and a grant from the American Health Assistance Foundation.

422.14

ASSOCIATION OF TAU(τ) WITH RIBOSOMES IN ALZHEIMER'S DISEASE. S.Ch. Papasozomenos and Y. Su*. Univ. of Texas Med. Sch., Houston, TX 77225.

We showed that in Alzheimer's disease (AD) τ immunoreactivity is associated not only with the abnormal filaments but also with ribosomes (Lab. Invest. 60:123, 1989 and 60:375, 1989). We also observed that in chromatolytic Pick's cells and in Pick's bodies τ immunoreactivity is associated with ribosomes. In this study, we have isolated ribosomes from six AD cases and controls and used four monoclonal anti-τ antibodies (Tau-1, Tau-2, Tau-5 and T46), immunoblot analysis and EM immunogold labeling to further investigate the association of τ with ribosomes. In immunoblots of SDS extracts, three τ polypeptides of 60-, 62- and 66-kDa were present but only in regions that in parallel histologic preparations contained τ immunoreactivity. Dephosphorylation was necessary to demonstrate these three τ polypeptides with Tau-1 and enhanced staining with Tau-5. Also, the ribosomal 62- and 66-kDa τ polypeptides coelectrophoresed with the most slowly moving polypeptides in SDS extracts of cortical homogenates from the same region. Controls were negative. In addition, all four antibodies decorated isolated ribosomes at the EM level. The purity of the preparations was verified by EM of the ribosomal pellet and negative staining with uranyl acetate of ribosomal solutions. These findings show that in AD τ is indeed associated with ribosomes and will further elucidate the etiopathogenesis of AD.

422.15

MICROTUBULE-ASSOCIATED PROTEIN TAU IS A COMPONENT OF NEUROFIBRILLARY TANGLES OF GERSTMANN-STRÄUSSLER-SCHEINKER DISEASE-INDIANA KINDRED. F. Tagliavini*, F. Prelli*, G. Giaccone, M. Porro*, J. Ghiso*, M.R. Farlow*, B. Ghetti, O. Bugiani* & B. Frangione. Istit. Neurol. Besta, 20133 Milan, Italy, Indiana Univ., Indianapolis, IN 46202 & NY Univ., NY, NY 10012.

In the Indiana kindred of Gerstmann-Sträussler-Scheinker disease (GSS-IK) amyloid deposits immunoreactive for prion protein coexist with neurofibrillary tangles (NFT). NFT are composed of paired helical filaments and are immunoreactive with antibodies to NFT isolated from Alzheimer's disease (AD) brain. Our aim was to immunochemically characterize proteins extracted from NFT isolated from cerebral cortex of two patients of GSS-IK. Amyloid-NFT enriched preparations were sonicated in formic acid and centrifuged. The supernatant was fractionated by gel filtration and the fractions were subjected to SDS-PAGE and immunoblot analysis using anti-tau antibodies, including Alz50. Protein bands of molecular weights of 68 kDa and lower were present, and were immunoreactive with anti-tau antibodies. Immunoreactivity was abolished by absorption of the antibodies with human fetal tau. These findings indicate that in GSS-IK, similarly to what has been shown in AD, tau protein or its fragments are a component of NFT, suggesting that comparable pathogenetic mechanisms of different origin may lead to cytoskeletal damage.

422.16

QUANTITATIVE SOLUBILIZATION AND ANALYSIS OF DETERGENT-INSOLUBLE PAIRED HELICAL FILAMENTS (PHF) OF ALZHEIMER DISEASE (AD). G. Perry, P. Mulvihill*, S.L. Siedlak*, and Peggy Richey*. Case Western Reserve University, Cleveland, OH 44106

Historically, detergent-insoluble PHF have been qualititively evaluated by morphological, immunochemical or amino acid sequencing methodologies. The limitation of these approaches has been that the dominant subunit of detergent-insoluble PHF has not been determined. In this study, we use protein release and specific volume decrease as *quantitative* measures of PHF solubilization. Detergent-insoluble PHF were isolated from AD cases by homogenization in 1% SDS followed by sucrose gradient centrifugation. Solubilization was sequentially performed for 10-50 min with the following agents 1) 1% SDS, 2) 1% SDS/1% βME, 3) 0.1M EDTA or 5M NaCl, 4) 8M urea, 6M guanidine-HCl, or 70% formic acid, 5) 0.2M NaOH-37°C, 6) 1M NaOH-90°C. Protein was quantitated by laser densitometry of SDS-PAGE stained with Coomassie blue or silver. Only SDS/βME, NaOH-37°C or NaOH-90°C were effective in protein extraction. Sequentially, the volume occupied by PHF was reduced *to* 96±1.9% by SDS/βME; 5.2±0.2% by NaOH-37°C; 0.27±0.28% by NaOH-90°. Immunoblots of these extracts showed τ, tubulin, P-component and ubiquitin in the SDS/βME extract, and only τ (60-64kDa) in the NaOH-37°C and NaOH-90°C extracts. Treating neurofilaments, τ, or β-protein with NaOH-37°C for 10-30 min had minimal effect on densitometry or epitopes. Therefore, τ is correlated with PHF dissolution for detergent-insoluble as well as has recently been reported for detergent-soluble PHF. Supported by NIH AG09287 and KO4-00415.

SPECTRIN (240/235E) AND DENDRITIC REORGANIZATION IN ALZHEIMER'S DISEASE. Angela Lee and Neil W. Kowall. Neurology Service, Massachusetts General Hospital, Boston MA 02114

Neuronal degeneration in Alzheimer's disease (AD) is associated with axonal and dendritic plasticity and reorganization. The axonal microtubule-associated protein tau is aberrantly located in the somatodendritic compartment of degenerating neurons in the form of neurofibrillary tangles (NFT) and dystrophic neurites. It is not known if a more generalized disruption of neuronal polarity occurs in AD. In normal neurons, subtypes of the major submembranous cytoskeletal protein spectrin are differentially distributed in axons and dendrites suggesting a possible role in the generation and maintenance of neuronal polarity. We examined the distribution of dendritic spectrin in normal and AD hippocampus using a polyclonal antibody that recognizes the dendritic isoform of spectrin (240/235E). We sought to determine whether specific alteration of the somatodendritic compartment occur in AD. In normal human hippocampus, red blood cells were prominently stained. A discrete band of immunoreactivity defined the dentate gyrus granule cells and the inner molecular layer. Neurons were prominent in CA1 with occasional intensely reactive granuolovacuolar degeneration (GVD). Rare astrocytes were immunoreactive. In AD, immunoreactivity in the dentate gyrus extended into the outer molecular layer and a band of decreased immunoreactivity was seen in the polymorphic layer. Occasional intensely reactive neurons containing NFT or GVD were found in CA1 and the subiculum. Spectrin (240/235E) retains its normal somatodendritic localization in the dentate gyrus in AD but its distribution shifts in conjunction with dendritic reorganization. GVD contain prominent dendritic spectrin immunoreactivity. A small subset of NFT-bearing neurons are intensely immunoreactive suggesting that the synthesis and/or proteolysis of dendritic spectrin may be altered in AD.

422.18

ABNORMAL PHOSPHORYLATION OF TAU IS ONE OF THE EARLIEST EVENTS IN ALZHEIMER NEUROFIBRILLARY PATHOLOGY. Köpke-Secundo, E., Grundke-Iqbal*,I and Iqbal, K. Institute for Basic Research in Developmental Disabilities, New York, NY 10314.

Previously it has been shown 1) that the major protein subunit of paired helical filaments (PHF) in Alzheimer disease (AD) is microtubule associated protein tau and 2) that tau in PHF is abnormally phosphorylated. In this study the cytosolic tau was isolated from the 27,000 x g to 200,000 x g pellet of AD cerebral cortex by extraction in 8 M urea, followed by acid precipitation, GFAP affinity and phosphocellulose (PC) chromatographies. The PC-chromatography revealed a wide range of abnormally phosphorylated tau species (AD P-tau) with different charges which were not detectable in control brains. AD P-tau species had no ubiquitin reactivity as determined with mAb 3-39 and 5-25. Furthermore, AD P-tau had increased immunoreactivity when treated with alkaline phosphatase prior to immunostaining with both mAb Tau-1 (amino acids 191-207 of tau) and antiserum 102c (amino acid 39-49 of tau). These studies suggest that tau in AD brain is abnormally phosphorylated at more than one site prior to its polymerization. (Supported in part by NIH fellowship 1 F32 AG0 5541-01 to Köpke-Secundo and grants NS 18105, AG0 4220, AG0 5892 and AG0 8076.

ALZHEIMER'S DISEASE: NEUROCHEMISTRY II

423.1

ALTERATIONS IN THE PHYSICAL PROPERTIES OF BRAIN MEMBRANES IN ALZHEIMER'S DISEASE. A. S. Bloom, P.G. Antuono and L. F. Vena*, Departments of Pharmacology and Neurology, Medical College of Wisconsin, Milwaukee, WI 53226.

Several studies have indicated that there are changes the fluidity of a variety of biological membranes during aging and in Alzheimer's Disease (AD). We have expanded upon these observations by examining differences between the fluidity of purified synaptic plasma membranes (SPM) prepared from the brains of persons dying with AD (n= 11)and aged-matched controls (n=6). Membrane fluidity was determined in 7 brain regions using fluorescence polarization. A temperature of 35° C was used. When diphenylhexatriene (DPH) was used as as a fluorescent probe, (It measures membrane phospholipid ordering.) decreases in polarization were observed in SPM prepared from temporal and parietal cortex of AD brains when compared to controls. Polarization values decreased from 0.2737 to 0.2638 in parietal cortex and from 0.2709 to 0.2620 in temporal cortex. Significant differences were not seen in the other regions studied. When TMA-DPH which localizes to the more superficial regions of the lipid bilayer was used as a probe, decreases in fluorescence polarization were observed in temporal cortex and hippocampus of AD brains. Polarization values decreased from 0.3487 to 0.3364 in the hippocampus and from 0.3441 to 0.3340 in temporal cortex. Again, significant changes were not seen in other regions. Lastly, the effects on the polarization of 12-anthroyloxystearic acid (12-AS) fluorescence, which reports on the mobility of phospholipid acyl chains, were examined. Significant differences were seen only in the cerebellum, where polarization was increased from 0.1308 to 0.1429 in AD brains. These data indicate that there are regionally specific changes in synaptic plasma membrane ordering in AD brains that correlate with areas where AD pathology is observed. It is yet to be determined if these alterations are due to changes in membrane lipid or protein composition.

423.2

INCREASED SATURATION OF FATTY ACIDS IN ALZHEIMER'S DISEASE. P. G. Antuono, G. D. Cherayil* and K. C. Ho*. Departments of Neurology and Pathology, Medical College of Wisconsin, Milwaukee, WI 53226.

Compositions of phosphatidylethanolamine (PE), lysophosphatidylethanolamine (lysoPE) and phosphatidylcholine (PC) fatty acids (FA) were determined in post-mortem brain tissue of 12 AD patients and 8 controls. The two groups were matched for several clinical and post-mortem variables. PC, lysoPE and PE were transmethylated and the resulting FA methylesters were analyzed by gas liquid chromatography. FA compositions from white and gray matter of the frontal and occipital lobes were similar in the two groups. The temporal cortex showed a trend towards a reduction in the ratio of monounsaturated to polyunsaturated FA, reaching a significant difference for arachidonic acid (20:4n6) in PC and lyso PE. Temporal lobe white matter showed a similar abnormality with a reduction of monounsaturated FA in PC and PE. Conversely polyunsaturated FA as decosahexaenoic acid (22:6n3) were significantly increased in PC, lysoPE and PE; arachidonic acid was increased in PC.

These results suggests a regional decrease in monounsaturated FA and increase in polyunsaturated FA in the temporal lobe of Alzheimer patients. Although this change may be secondary to the pathological changes of this disease, it may contribute to the alterations in membrane fluidity and neurotransmission reported in AD.

THE EFFECT OF MUSCLE INACTIVITY ON CALCIUM ACTIVATED NEUTRAL PROTEASES. F. Grynspan , R.A. Nixon, S. Bursztajn. McLean Hospital, Harvard Medical School, Belmont, MA 02178

Calcium activated neutral proteases (CANP) are non-lysosomal intracellular proteases which play a major role in turnover and in degradation of cytoskeletal and membrane proteins. A potent endogenous inhibitor protein named calpastatin coexists with calpain in tissues. In this investigation we measured the enzymatic activity of mCANP, (the form of the enzyme that is optimally activated in vitro by millimolar calcium levels) and the inhibitor in pre- and post-fusion, and in paralysed muscle cells. Cultured chick muscle were harvested 1, 3 and 7 days after plating, and the inhibitor and mCANP were separated by DEAE cellulose column chromatography. The CANP activity was measured using ^{14}C-azocasin as a substrate in the presence of 7 mM calcium. Activity of the heat stable inhibitor was measured after 100°C treatment of the active fraction for 10 min, and adding an external source of mCANP. No inhibitor activity was detected day 1 after plating. A significant increase in inhibitor activity occurred at day 3 (45%) and day 7 (87%) after plating. The mCANP activity was low in cells at all ages. Muscle cells treated with tetrodotoxin (10 mM) (TTX, a sodium channel blocker that paralyzes the muscle) and assayed 7 days after plating showed a 2-7 fold increase in mCANP activity as compared to untreated cells. Inhibitor activity was not altered by TTX treatment. On the other hand, TTX-treated cells show a 2-3 fold increase in the acetylcholine receptor (AChR) protein and mRNA levels but no change in secretory or intracellular acetylcholinesterase (AChE) activity or creatine phosphokinase (CPK) activities. If the CANP system is activated by TTX treatment, these results imply selective roles of CANP in protein modification and degradation. (Supported by NIH grants.)

MONITORING ACTIVITY OF THE MULTICATALYTIC PROTEASE IN LIVING NEURONS. R. Siman and S. Mistretta*, Cephalon, Inc., West Chester, PA. 19380.

The multicatalytic protease (proteasome) and the calpains are two cytoplasmic, non-lysosomal protein-degrading systems present in many cell types. We have begun to evaluate the involvement of these systems in protein turnover in neurons. Protease activity was monitored in cerebellar granule neurons grown in primary culture by use of membrane-permeable fluorogenic substrates, such as Suc-LLVY-AMC. Experiments with purified proteases confirmed that both calpain and the multicatalytic protease readily degrade the substrates. Granule neurons produced a time- and dose-dependent substrate hydrolysis. Protease activity occurred intraneuronally, and did not result from any enzymes secreted into the medium. Several observations argue that the activity is due to the multicatalytic protease. A protease with the size (700 kD) and properties of the multicatalytic protease could be extracted and purified from granule neuron cultures. Moreover, the purified enzyme degraded the same substrates that were degraded by the granule neurons, and was selectively inhibited by the same agents which blocked the activity within the living neurons. The substrates cannot be ubiquitinated, because of a blocked N-terminus, indicating that the multicatalytic protease of neurons can degrade substrates without prior ubiquitination. Activation of calpain, evoked by raising the intraneuronal calcium content, caused only a small increase in substrate hydrolysis. The results indicate that the multicatalytic protease is a major cytoplasmic proteolytic system within neurons. The ability to monitor the activity of this protease in living neurons should facilitate identification of the factors that regulate its activity.

"MULTICATALYTIC PROTEINASE COMPLEX, A NONLYSOSOMAL PROTEINASE, IS PRESENT IN SIGNIFICANT AMOUNTS IN A NEURONAL CELL LINE" M.E. Pereira[¶], K. Berg, S. Maayani and S. Wilk[¶], Departments of Pharmacology[¶] and Anesthesiology, Mount Sinai School of Medicine, C.U.N.Y., New York, N.Y. 10029

Recent findings suggest that Alzheimer's disease (AD) may result from abnormal processing of multiple proteins. The multicatalytic proteinase complex (MPC) constitutes a major nonlysosomal proteinase with unique catalytic properties, splitting peptide bonds on the carboxyl side of hydrophobic (chymotrypsinlike activity), basic (trypsinlike activity) and acidic (peptidyl glutamyl activity) amino acids. Furthermore, MPC has been suggested to be the "catalytic core" of the Ubiquitin/ATP-dependent protein degradation pathway. The neuropathological finding of ubiquitinated proteins in neurofibrillary tangles in AD and in other neuronal inclusion bodies may implicate MPC-malfunction in neurodegenerative disorders, resulting in abnormal accumulation of ubiquitin-protein conjugates. In addition, MPC has chymotrypsinlike activity, the proteolytic activity believed to produce β-protein, the most abundant insoluble protein of senile plaques in AD brains. It is thus important to find a model system to study the regulation of MPC-activity. We report that the cytosolic fraction of a neuronal cell line (HT_4) has chymotrypsinlike, trypsinlike and peptidyl glutamyl activities, as shown by hydrolysis of the chromogenic substrates Cbz-Gly-Gly-Leu-pNA, Cbz-D-Ala-Leu-Arg-2NA and Cbz-Leu-Leu-Glu-2NA respectively. Specific immunoprecipitation of MPC with polyclonal antibodies generated in our laboratory resulted in the inhibition of the above described peptidase activities, providing evidence for the involvement of MPC in these activities. Moreover we demonstrate that low concentrations of SDS (0.04%) stimulate the peptidyl glutamyl activity. The HT_4 cells have been shown to differentiate with neuronal morphology, express neuronal antigens, synthesize and secrete nerve growth factor (NGF), and have receptors for NGF. Thus HT_4 cells are an excellent tool for studying the regulation of MPC-activity. (Supported by the Alzheimer's Association/New York City Chapter Pilot Research Grant PRG-90-114 to M.E.P.; NIH grant NS-17392 and an ADAMHA Research Scientist Award MH-00350 to S.W.; USPHS grant GM-34852 to S.M. The HT_4 cells were kindly provided by R.D.G.McKay.)

SELECTIVE LOSSES OF SOMATOSTATIN SS1 BINDING SITES IN FRONTAL AND TEMPORAL CORTEX OF ALZHEIMER'S PATIENTS. S. Krantic, Y. Robitaille, and R. Quirion, Douglas Hospital Research Center, Dept. of Psychiatry, McGill University, Verdun, Quebec, Canada.

Somatostatin (SS) binding sites were found to be decreased in frontal and temporal cortices of Alzheimer's diseased (AD) patients (Beal et al. 85). However, the human brain cortex was shown to contain two sub-types of SS receptors, classified as SS1 and SS2 (Reubi et al. 87). Therefore we assessed if a sub-type is preferentially altered in AD. Direct saturations of the non-selective (^{125}I-Tyr^0,D-Trp^8-SS$_{14}$) and SS1-selective (^{125}I-SMS-204090) ligands were performed in homogenates of frontal and temporal cortices from AD (n=14) and control (n=8) patients. Apparent binding affinities (Kd) were not different between these two groups, neither in frontal nor in temporal cortices. However, maximal binding capacity of SS1 sites were significantly lower ($p<0.05$) in both regions of AD subjects vs. controls. In contrast, Bmax value of the non-selective radioligand (SS1+SS2) was decreased only in the temporal cortex in AD. These results indicated that cortical SS1 and SS2 binding sites are differentially affected in AD. Supported by the MRC.

PNMT mRNA LEVELS IN C-1 NEURONS IN ALZHEIMER'S DISEASE. W.J. Burke, C.A. Schmitt* and H.D. Chung*. St. Louis VAMC and St. Louis University Medical School, St. Louis, MO 63125

Phenylethanolamine N-methyltransferase (PNMT) activity and protein levels decrease in Alzheimer's disease (AD) brains without loss of C-1 neurons (Ann Neurol 22:278, 1987; 24:532, 1988). To determine whether the deficit is due to decreased levels of PNMT mRNA we measured PNMT mRNA using PCR amplification and densitometric quantitation of northern blots of PNMT mRNA extracted from human C-1 neurons. Ten AD cases (75.6 ± 26 yrs; PMI of 5.1 ± 1.3) were compared to 4 controls (71 ± 3.6 yrs; PMI of 5.7 ± 1.1). There was no difference in C-1 PNMT mRNA levels between the groups (AD:32.1 ± 8.8 units/ng RNA vs. controls: 40.6 ± 14.1). We conclude that decreased PNMT protein in AD is not due to decreased transcription of PNMT mRNA but may be due either to decreased translation of PNMT mRNA or increased degradation of PNMT protein.

OXYGEN-FREE RADICAL MEDIATED PROCESSES IN ALZHEIMER'S DISEASE. L.J. McIntosh, M.A. Trush* and J.C. Troncoso. Department of Environmental Health Sciences, The Johns Hopkins University School of Hygiene & Public Health, and Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Balto., MD 21205.

Free radical damage has been proposed as a factor in aging and in several neurodegenerative disorders, including Alzheimer's disease (AD). Changes of nucleic acids, proteins, and membranes may result from reactions with oxygen species, including superoxide and hydroxyl and peroxyl radicals. To assess the role of free radicals in AD, we used chemiluminescence (CL), which measures bond breakage as it occurs, and the thiobarbituric acid test, which measures malondialdehyde (MDA) formed during lipid peroxidation. Tissue samples were obtained from the temporal cortices of six pairs of cases of AD and controls matched for age, postmortem delay, and accession date. In AD tissues, we found significant increases in CL (28%) and MDA formation (42%), as compared to controls. These were differences in basal levels from tissue supernatants that were not stimulated by iron, ascorbate, or hydrogen peroxide. Studies with biochemical probes to determine the predominant radical species in these cases are in progress. Our results support the hypothesis that oxidative stress may contribute to the damage and degeneration of neurons at risk in AD.

DIFFERENTIAL SCREENING OF A MONKEY FRONTAL POLE cDNA LIBRARY: IDENTIFICATION AND CHARACTERIZATION OF mRNAs WITH REGIONAL DISTRIBUTION. K.Chandrasekaran, J.Stoll, T.Giordano, J.R.Atack*, M.F.Matocha*, S.P.Wise and S.I.Rapoport. Lab of Neurosci, NIA, Bethesda, MD 20892 and Lab of Neurophysiology, NIMH, Poolesville, MD 20837.

Alzheimer's disease afflicts selectively association as compared to primary sensory and motor neocortices. To understand the molecular basis of this selective vulnerability, we screened a frontal pole cDNA library from the rhesus monkey (Macaca mulata) brain to identify mRNAs that are expressed in frontal pole as compared to primary visual cortex. Six cDNA clones, whose differential expression was confirmed by Northern blot analysis were identified. These cDNA clones showed higher levels of mRNA in frontal pole and dorsal lateral prefrontal regions as compared to primary visual cortex. Sequencing and homology search with GenBank showed that 3 of the cDNA clones were homologus to the mitochondrial DNA encoded genes, cytochrome oxidase subunits I, II and III (COX I,II,III). Cytochrome oxidase histochemistry showed highest level of enzyme activity in dendritic rich neuropil areas of cortex. *In situ* hybridization with COX cDNA probes showed laminar distribution in visual and somatosensory cortices, but was not apparent in the prefrontal cortex. These results suggest differences in the distribution of neuropil as compared with cell bodies among the brain regions . Comparison of COX gene expression in motor and temporal regions of normal and Alzheimer brain samples showed 2-5 fold lower levels in temporal region of Alzheimer brain. Abnormal synaptic and dendritic metabolism in the dementia in Alzheimer's disease is suggested.

TRANSFERRIN AND ALUMINUM: EFFECTS ON RAT HIPPOCAMPAL CULTURES. R.K.Lartius and E. Uemura. Neuroscience Program, Department of Anatomy, Iowa State University, Ames, IA 50011.

Aluminum (AL) has been found associated with very specific brain regions in Alzheimer's disease (AD). Higher than normal levels of AL can be detected in the hippocampus, basal forebrain and cortical regions. This regional specificity might be explained by a receptor mediated mechanism, where AL is transported to these select areas. In the present study, we have examined the metal chelating protein, transferrin (Tr), and its ability to enhance AL uptake in primary rat hippocampal cultures. Further, we examined the effects of the transferrin-AL complex on the microtubule-associated-proteins, MAP-2 and TAU. AL was complexed to TR as previously described by Roskams and Connor (1990) and at 4 days post-plating, the hippocampal neurons were exposed to either solvent (10 mM sodium bicarbonate in Tris Saline), 1.5 uM Tr, 1.5 uM AL+Tr or 3.0 uM AL. Twenty-four hours later the cultures were fixed and MAP-2 and Tau-like immunoreactivities were detected using the HM-2 antibody to MAP-2 and the Tau-1 antibody to Tau. The intracellular AL accumulation was also detected using Morin Stain at low pH. We found that cultures exposed to AL+Tr were the only cultures that had detectable levels of intracellular AL. Further, these neurons displayed extensive neuritic retraction and decreased Tau and MAP-2 immunoreactivities compared to control. No other cultures were affected. These results support the theory that transferrin or a similar chelator may play an integral role in the AL accumulation seen in Alzheimer's Disease. While it appears unlikely that AL is responsible for initiating the pathology, the ultimate presence of this bioactive metal warrants further investigation.

ALZHEIMER'S ANTIGEN: A RE-EXPRESSED PROTEIN OF IMMATURE CNS

Klein, W.L., Enam, S.A., Miller, B.E., Ghanbari, H.A. Northwestern University Center for Biotechnology, Evanston, IL; Abbott Laboratories, Abbott Park, IL.

Anti-PHF-1 (CD1) is a novel monoclonal antibody that recognizes an epitope abundant in AD brain tissue but totally absent from age-matched controls. Species screening has detected the epitope in immature rat and chicken CNS; immunofluorescent studies have been done using chicken to compare CD1 antigen, tau and Alz-50 antigen. *Brain Distribution* Tau and CD1 antigen were both abundant, similarly occurring in immature axon tracts of the central nervous system, and in the cranial and peripheral nerves. Alz-50 immunoreactivity (IR) was present only in occasional cells of the developing neuroepithelium. *Retina Development* At embryonic day 6, tau occurred in the ganglion cell layer; post-hatch, it was detectable in perinuclear regions of most cells, but was abundant only in the optic fiber layer. CD1 antigen distribution resembled tau initially, but unlike tau, it underwent total down-regulation in optic nerve axons. Alz-50 was nearly negative throughout retina development. *Cell Culture* Tau in explant cultures maintained a normal distribution, but it was expressed aberrantly in dissociated cell culture, appearing in all neurites, not just axons. CD1 in dissociated cultures occurred less frequently than tau, with unlabeled neurites often observed. Alz-50 IR was absent from explant cultures, but in dissociated cell cultures, it was expressed in many neurites, particularly within cell clusters. Initially, Alz-50 IR was absent from all cells (tau was present), appearing only with time, suggesting its aberrant expression was induced by lack of proper cell-cell interactions. *Conclusion* Alzheimer's pathogenesis entails an aberrant re-expression of proteins from the immature CNS, evidenced by CD1 antigen, a growth-associated axonal protein. Possibly triggered by multiple stimuli, re-expression of developmentally-regulated proteins into an improper milieu may create dysfunctional complexes that disrupt and ultimately destroy the cell.

423.12

ELEVATED TEMPORAL CORTEX SUPEROXIDE DISMUTASE IN ALZHEIMER'S DISEASE.

S. S. Panter and M. D. Scott*, Letterman Army Institute of Research, Presidio of San Francisco, CA 94129 and Children's Hospital Oakland Research Institute, Oakland, CA 94609.

Recent analyses indicate that Alzheimer's disease (AD) is a heterogeneous disorder, certain types of which may involve a genetic component residing on chromosome 21. The gene encoding copper/zinc superoxide dismutase (Cu/ZnSOD; SOD-1) is also located on chromosome 21. To determine whether levels of Cu/ZnSOD might be altered in AD, SOD activity was measured in postmortem samples of temporal cortex from 12 patients with AD, 12 age- and sex-matched controls, and four patients with non-AD neuropathies (N-ADN). Cu/ZnSOD activity was significantly increased in samples from patients with AD; activity of Cu/ZnSOD was (mean $\pm$ SEM, in U SOD/mg protein): Controls, 56.2 $\pm$ 3.9; N-ADN, 52.1 $\pm$ 3.4; and AD, 67.5 $\pm$ 3.5 ($p < 0.05$ AD versus Controls and N-ADN). There were no differences between groups in mean postmortem time. The patients affected by AD were further subdivided by age into two groups, < 80 years of age (N = 9) and $\geq$ 80 years of age (N = 3) at autopsy. Cu/ZnSOD activity in samples from patients $\geq$ 80 years of age (33.5 $\pm$ 3.6) was not significantly different from levels detected in similarly age-stratified Control (33.3 $\pm$ 1.9, N = 4) or N-ADN (37.6, N = 1) groups. Cu/ZnSOD activity measured in samples from patients < 80 years of age at autopsy (47.4 $\pm$ 1.6, N = 9) was significantly greater ($p < 0.01$) than the activity in Control samples (32.2 $\pm$ 5.5, N = 8), N-ADN samples (30.8 $\pm$ 3.8, N = 3), and samples from patients $\geq$ 80 years of age (33.5 $\pm$ 3.6, N = 3). There were no differences between any of the groups, regardless of age stratification, in the activity of manganese SOD.

423.13

A PILOT CROSSOVER STUDY OF THE ANGIOTENSIN CONVERTING ENZYME INHIBITOR (ACEI) SQ29,852 IN ALZHEIMER'S DISEASE.

A. Sudilovsky, N.R. Cutler, S. Repetti, A. Veroff* and T. Wardle*. Bristol-Myers Squibb Pharm. Res. Inst., Princeton, NJ and California Clinical Trials, Beverly Hills, CA

Animal experiments as well as results from a study on the quality of life of hypertensive patients treated with captopril suggest that ACEI may possess cognitive enhancing properties. The present study was a 3-way crossover trial of two dose levels (5 mg and 40 mg b.i.d.) of the ACEI SQ29,852 and placebo b.i.d. in normotensive patients with Alzheimer's disease (n=30; mean age 67.5 years). Each patient participated in three consecutive periods of 5 weeks (1 week single blind placebo lead-in and 4 weeks double blind comparison treatment). Cognitive evaluation was performed using a computerized battery of tests examining attention, verbal learning, and short- and long-term memory. Analyses by chi square on the frequencies of "best score" on each drug condition for all tests showed no significant differences for individual tests. However, the visual memory tests approached significance (p=0.058) in favor of SQ29,852 and best scores were obtained by the greatest number of patients on 9 of the tests at the high-dose SQ29,852, on 7.5 at the low-dose, and only on 4.5 with placebo. Overall, patterns and relationships of results were consistent with a drug effect. A study of longer duration and/or higher dosages using a stratified design would be indicated to clarify these observations.

423.14

INTERLEUKIN-1 INCREASES THE EXPRESSION OF AMYLOID PRECURSOR PROTEIN mRNAs IN NEURONAL BUT NOT GLIAL CELLS.

G.L.Forloni, N. Angeretti* and F. Demicheli*.
Istituto di Ricerche Farmacologiche "Mario Negri", 20157 Milano, Italy.

Increased levels of interleukin-1 (IL-1) have been observed in brain of patients with Alzheimer's disease (AD) and it has been demonstrated that IL-1 enhanced the expression of amyloid precursor protein (APP) in human endothelial cells. We compared the effects of IL-1 treatment on APP mRNAs expression in neuronal, glial and endothelial cells.The gene encoding the precursor of the APP can be expressed as APP695 and/or APP563/751/770 depending on the presence of a Kunitz family protease inhibitor sequence. We investigated the expression of APP gene by using three different probes recognizing the total APP mRNA, the APP563/751/770 mRNA or the APP695 mRNA. Total RNA was extracted from human and mouse endothelial cells, from rat cortical neurons dissociated at E17 and from rat forebrain astrocytes. The Northern blot analysis was performed using the APP ^{32}P-cDNA probe to detect the general APP sequence and two ^{32}P-labelled oligonucleotides (40 mer) complementary to the sequence of the protease inhibitor or to the APP695. In endothelial cells, we observed similar increase of APP695 mRNA or APP563/751/770 mRNA after treatment with human recombinant IL-1β. In neuronal cells, IL-1 (50-200ng/ml) induced a significant increase of APP mRNAs, detected with all three probes. In glial cells, the expression of APP mRNAs did not appear altered by IL-1. The present results demonstrate the potential role of IL-1 in the mechanisms related to the β-amyloid protein deposition in AD.

COMPARISON OF THE EXPRESSION AND TOXICITY OF THE COOH TERMINAL 100 AMINO ACIDS OF APP CONTAINING A SIGNAL SEQUENCE.

T.L. Martin, K.M. Felsenstein and E.E. Baetge. Bristol-Myers Squibb Co., Cell and Molecular Neurobiology Dept., 5 Research Parkway, Wallingford, CT.

Previously we and others (Yankner et al., Science 245: 417-420, 1989) have demonstrated that the carboxyl terminal 100 amino acids of APP yields a product that is toxic to differentiated PC12 cells. Recently, Maruyama et al., (Nature 347: 566-569, 1990) have reported that the carboxyl terminal 100 amino acid sequence of APP when attached to a signal peptide results in secretion of the full length APP fragment into the media. We have constructed an analogous signal sequence containing carboxyl terminal APP construct and compared it to the unmodified construct in a variety of cell lines. Western blot analysis of transient and stable lines reveals an approximately 14 kilodalton band using a carboxyl terminal APP antibody; while the signal sequence construct containing line shows an additional band of 15-16 Kd. (R1, N. Robakis, Mt. Sinai School of Medicine). Medium conditioned by each cell line was tested for toxicity in NGF differentiated PC12 cells. Preliminary data indicates that medium conditioned by cells transfected with the non signal sequence containing construct was toxic whereas the medium conditioned by the signal sequence containing lines was not toxic. These data suggest that the signal sequence containing construct may be subject to normal processing thereby eliminating the toxic amyloid fragments while the unmodified carboxyl terminal APP fragment may be abnormally processed to yield a toxic species.

423.16

DEXAMETHASONE AND DIBUTYRYL CYCLIC AMP INDUCE THE EXPRESSION OF ALPHA-1-ANTICHYMOTRYPSIN IN RAT ASTROCYTES: IMPLICATIONS FOR ALZHEIMER'S DISEASE.

S. Das*, R.B. Nelson, and H. Potter. Department of Neurobiology, Harvard Medical School, Boston, MA.

The acute phase protein α_1-antichymotrypsin (ACT) is a primary component of the senile plaques characteristic of Alzheimer's disease (AD), where it is found bound to β-protein, a proteolytic fragment of the amyloid precursor protein (APP). Immunocytochemistry and *in situ* hybridization indicates that astrocytes are a source of the increased amounts of ACT in the AD brain. Thus it appears that an acute phase response occurs in the CNS that may be instrumental in the etiology of Alzheimer plaque formation.

In light of the fact that the mediators of the acute phase response, dexamethasone and interleukin-1, can induce the expression of ACT in rat hepatocytes *in vitro*, we asked whether these mediators can also induce the expression of ACT in astrocytes. Astrocyte cultures were prepared from newborn CD rats and grown to confluence. Cells were then switched to serum-free N2 medium for two hours and then treated with the appropriate agents for four hours. Total RNA was isolated and subjected to Northern blot analysis.

We found that dexamethasone induced the expression of ACT message synergistically with dibutyryl-cAMP. The effect of dexamethasone was blocked by treatment of the cells with cyclohexamide, indicating that protein synthesis is necessary for the induction. Thus, there are multiple regulators of ACT expression in astrocytes of which we have found one; the intracellular messenger of another is cAMP. These results, indicating an acute phase expression of ACT in astrocytes, joins a growing body of evidence that an inflammatory response is involved in β-protein amyloid deposition. However, since not every inflammatory event leads to plaque formation, there must be a second prerequisite event: the abnormal processing of APP. We posit that the pathology observed in AD arises from the presence of β-protein (or a fragment of APP containing intact β-protein) in the extracellular compartment of the CNS, coupled with an acute phase response.

423.17

IS ALZHEIMER'S DISEASE A LATE-ONSET, MOSAIC FORM OF DOWN SYNDROME? H. Potter and L.N. Geller. Dept. Neurobiology, Harvard Medical School, Boston, MA 02115.

Perhaps the most interesting clue to the cause of Alzheimer's disease is the fact that Down syndrome patients who live beyond the age of 30 or 40 develop dementia and neuropathology essentially indistinguishable from classic Alzheimer's disease. The implication of this finding is that trisomy for chromosome 21—the pathogenetic cause of Down syndrome—is also capable of causing Alzheimer's disease, possibly through the overexpression or duplication of a gene residing on chromosome 21. A hypothesis has been presented (Potter, Am. J. Hum. Genet., June 1991) that explains both the familial and sporadic forms of Alzheimer's disease as arising from the accumulation of chromosome 21 trisomy cells during the life of the individual. That is, trisomy 21 cells, developing over time by unequal chromosome segregation during mitosis, may ultimately lead to many cases of Alzheimer's disease through the same (as-yet unknown, and perhaps multistep) mechanism by which Down syndrome patients get the disease, but at a later age due to the modulating effect of the mosaicism. The propensity to develop trisomy 21 cells could be genetic in origin (either due to an aberrant chromosome 21 centromere or to a mutation occurring elsewhere in the genome and affecting all chromosome segregation), or it could be caused by environmental factors. *In situ* hybridization studies are being carried out to determine the extent of trisomy 21 mosaicism in the skin and central nervous system of familial and sporadic Alzheimer's disease cases.

423.18

IDENTIFICATION OF CANDIDATE ALZHEIMER β-PROTEIN-GENERATING PROTEASES FROM RAT BRAIN USING THE POLYMERASE CHAIN REACTION. R.B. Nelson, S. Das*, and H. Potter. Department of Neurobiology, Harvard Medical School, Boston, MA.

A chymotrypsin-like protease (CLIP) is predicted to be able to directly generate the N-terminus of β-protein from the β-amyloid precursor protein (APP). Moreover, an inhibitor specific for certain CLIPs, α_1-antichymotrypsin (ACT), shows increased expression by reactive astrocytes in affected areas of Alzheimer brain, and is co-deposited with β-protein as an integral component of Alzheimer amyloid. We have previously characterized and purified a CLIP from 7-day-old rat brain which selectively cleaves a synthetic substrate containing the APP amino acid sequence immediately "upstream" from the N-terminal cleavage site of β-protein. The amino acid sequence of this protease matches that of rat mast cell protease I (RMCP I) and its distribution and ontogeny in rat brain are consistent with a mast cell origin.

We are currently searching for other ACT-inhibited CLIP species in brain by using PCR. The amino acid sequences of the serine active site present in all serine proteases and of an N-terminal domain found in all ACT-inhibited CLIPs were used to construct degenerate primers spanning a ~560 base pair coding region for CLIPs. We first prepared poly A+ RNA from 7-day-old rat brain meninges (a tissue enriched in RMCP I activity), generated cDNA by reverse transcription, and amplified this cDNA. We have successfully used this approach to sub-clone and partially sequence an amplification product coding for RMCP I. Restriction enzyme mapping indicates the presence of at least one other cDNA species in this amplified band, probably corresponding to a second mast cell CLIP. We have also used this approach to examine cDNA from cultured astrocytes expressing ACT (see Das et al., this meeting) because cells expressing a protease inhibitor will also commonly express the target protease. We have amplified from astrocyte cDNA a single PCR product of appropriate size which we are sub-cloning and sequencing, and have identified a corresponding activity by gel enzymography.

EFFECT OF AGING ON NA^+/CA^{2+} EXCHANGE ACTIVITY IN HUMAN FRONTAL CORTEX. R.A. COLVIN*, L. WINCE, A. WU* and N. DAVIS*. **Zoological and Biomedical Sciences, Ohio University College of Osteopathic Medicine, Athens, OH 45701.**

Cerebral plasma membrane vesicles (PMV) were purified by sucrose density gradient centrifugation from either rat brain or frozen human post-mortem frontal cortex tissue slices. Human specimens were obtained from the National Neurological Research Bank, Los Angeles, CA. An animal model was tested for the effect of short term post-mortem delay on Na^+/Ca^{2+} exchange activity. Rats were decapitated and their skulls were incubated at 0-4°C for various times up to 4 hrs. The brains were then removed and processed into PMV. No significant effect of post-mortem delay was seen on the purification, as judged by the activity of plasma memebrane markers. Proteolysis of memebrane associated proteins, as judged by SDS-PAGE, was not evident even after 4 hr of preincubation. No significant effect of post-mortem delay was seen on estimates of Na^+/Ca^{2+} exchange V_{max} or K_m, or Ca^{2+} passive permeability. PMV from human frontal cortex samples (ranging in age from 20 to 90 yrs.) were assayed for Na^+/Ca^{2+} exchange V_{max} and K_m, and passive Ca^{2+} permeability, At present, no age related effects have been observed in these parameters of Na^+/Ca^{2+} countertransport in human tissues. Mean values obtained thus far are: V_{max}=2.13±.86 nmol/mg/sec;K_m=.143±.06mM; and the rate constant of Ca^{2+} release = .032±.03 min^{-1}. The results indicate that cerebral plasma membrane Na^+/Ca^{2+} countertransport is extremely stable with respect to post-mortem delay. Although more human tissues must be assayed before final conclusions are made, preliminary studies indicate few, if any age related effects on plasma membrane Na^+/Ca^{2+} countertransport.

PRESENCE OF ABERRANT PROTEINS IN DORSAL ROOT GANGLIA PRODUCES INTRANEURONAL INCLUSIONS CONTAINING CYTOSKELETAL COMPONENTS AND UBIQUITIN. P.L. Di Patre, N. Wicker*, Y. Chen*, L. Autilio-Gambetti, and P. Gambetti. Division of Neuropathology, Institute of Pathology, Case Western Reserve University, Cleveland, Ohio, 44106, USA.

Formation of intraneuronal inclusions containing both normal and altered cytoskeletal proteins as well as ubiquitin is a feature of age-related neurodegenerative disorders. These inclusions might result from the presence of aberrant proteins. To test this hypothesis, we studied the effect of canavanine (Can), an arginine analogue, on cultured rat dorsal root ganglia (DRGs). In DRGs kept for 5 days in medium in which Can replaced Arginine, most neurons contained rounded cytoplasmic inclusions that were silver positive and immunoreacted with antibodies to phosphorylated and non-phosphorylated neurofilaments, tau and ubiquitin. These findings indicate that a condition resulting in the presence of a large amount of aberrant proteins is associated with the formation of intracellular inclusions. The antigenic characteristics of these intraneuronal inclusions are similar to those of the inclusions present in neurodegenerative diseases. Thus, we suggest that the presence of aberrant proteins secondary to the disease process might play a role in the formation of neuronal inclusions of neurodegenerative diseases such as the neurofibrillary tangles of Alzheimer disease.

NEUROCHEMISTRY OF THE AMYGDALA IN ALZHEIMER'S DISEASE (AD), HYPERTENSION AND CRITICAL CORONARY ARTERY DISEASE (cCAD). D. Larry Sparks, John C. Hunsaker* & William R. Markesbery. Alzheimer's Disease Research Center/Sanders-Brown Center on Aging; U.K.M.C., Lexington, KY 40536

The importance of the amygdala in memory function has been established by lesion studies in animals. In man, bilateral lesions of the amygdala cause amnesia. Histologic investigation of the amygdala in Alzheimer's disease (AD) has revealed the presence of senile plaques (SP) and neurofibrillary tangles (NFT), as well as reduced volumn of most nuclei of the amygdala. Abundant SP are also found in the amygdala of non-demented individuals with cCAD and hypertension compared to non-demented non-hypertensive non-heart disease (non-HD) controls, often at levels diagnostic of AD, while NFT are rarely found in the amygdala of these individuals.

Utilizing established methods we have investigated markers of cholinergic, serotonergic and noradrenergic neurotransmission in whole amygdala from 19 age-matched individuals (5 AD, 3 hypertensive, 5 cCAD and 6 non-HD). Scatchard analysis of QMB and 5-HT binding, single point analysis of imipramine and DHA binding, monoamine oxidase A and B (MAO-A &B) and acetylcholinesterase (AChE), kinetics of choline acetyltransferase (ChAT), and HPLC quantification of NE, 5-HT and 5-HIAA were performed simultaneously. Postmortem interval and age at death was not significantly different among the groups.

The Vmax, but not the Km, of ChAT activity, AChE activity, NE and 5-HT levels, and Bmax, but not the Kd, of QMB binding were reduced ($p<0.05$) in AD compared to all three non-demented control groups. Binding of 5-HT and DHA were non-significantly decreased and increased, respectively, in AD compared to all three control groups. Imipramine binding and MAO-A activity were significantly ($p < 0.05$) increased in AD compared to non-HD and cCAD controls, only. The Vmax of ChAT activity was significantly ($p < 0.05$) increased in cCAD and non-significantly increased in hypertension compared to non-HD controls. The data indicate a possible over estimation of cholinergic decrements in AD by the inappropriate use of controls with cCAD and raise questions about the pathophysiologic importance of SP in AD.

DIFFERENTIAL CELLULAR EXPRESSION OF MAO-A AND MAO-B IN CONTROL VS. ALZHEIMER BRAINS. J. Saura*,[1] J.C. Shih, M. Da Prada*,[2] V. Chan Palay,[3] J. Ulrich*, G. Huber, J. Löffler* and J.G. Richards, Pharma Division, Preclinical Research, F.Hoffmann-La Roche Ltd, CH-4002 Basel, [1]John Stauffer Pharmaceutical Scl. Center, USC, Los Angeles CA; [2]Neurology Clinic, Kantonsspital, Zürich, and [3]Pathology Institute, Kantonsspital, Basel, Switzerland

Monoamine oxidases (MAO) oxidatively deaminate neurotransmitter and xenobiotic amines in the CNS and peripheral organs. Two forms (MAO-A and MAO-B) have been identified by substrate selectivity, inhibitor sensitivity and primary structure. Quantitative enzyme radioauto-graphy and in situ hybridization have now revealed the distribution, abundance and cellular localization of the isoenzymes and their mRNAs in human postmortem brainstem. Whereas MAO-A (protein and mRNA) is expressed by noradrenergic neurons of the locus coeruleus, MAO-B is expressed by serotoninergic neurons of the raphé nuclei. In the substantia nigra, MAO-A is restricted to the zona compacta whereas MAO-B was found mainly in the zona reticulata. To date, mRNA for neither MAO-A nor MAO-B could be detected in the substantia nigra or in glial cells of the brainstem. In cerebral cortex and hippocampus but not cerebellum from Alzheimer individuals, MAO-B was markedly increased in astrocytes surrounding senile plaques (identified by ß-amyloid- and GFAP-antigenicity); MAO-A was unchanged. MAO-B mRNA could not be detected in plaques. The functional implications of the differential compartmentalization and regulation of these isoenzymes will be discussed.

MAPPING THE DEFECT IN M1 MUSCARINIC RECEPTOR - G PROTEIN COUPLING IN ALZHEIMER'S DISEASE: AN AUTORADIOGRAPHIC STUDY. D. C. Mash, M. J. Basile and D.D. Flynn, Departments of Neurology and Pharmacology, University of Miami School of Medicine, Miami, FL., 33101.

Cortical M1 receptors are the current target for the development of potent and selective cholinomimetic drugs to improve memory and cognitive impairments associated with Alzheimer's disease (AD). We have demonstrated a defect in the ability of the M1 receptor subtype to form high affinity agonist receptor-G protein complexes in AD frontal cortex (Flynn et al., 1991). Since the high affinity agonist state mediates signal transduction by the M1 receptor, we have speculated that this 'altered state' of the cortical M1 receptor for agonists may account for the relative lack of effectiveness of cholinergic replacement therapies attempted thus far. In this study, quantitative autoradiographic methods were used to map the defect in M1 receptor coupling in AD. To visualize the density and distribution of M1 receptors, brain sections were labeled with 3 nM [^{3}H]-pirenzepine (33% occupancy of M1 receptor subtype). Competition curves were generated by increasing carbachol concentrations (10^{-8} to 10^{-2}) with 3 nM [^{3}H]-pirenzepine. The effect of guanine nucleotides on [^{3}H]-pirenzepine and carbachol binding was measured in the presence of 0.2 mM GppNHp. In aged control brain sections, the full agonist carbachol (10^{-5} M) displaced 40 - 55 % of the specific binding of [^{3}H]-pirenzepine to frontal, temporal and occipital cortices. Treatment with GppNHp abolished high affinity agonist binding in brain sections co-incubated with carbachol and [^{3}H]-pirenzepine. In AD cases with severe neocortical pathology, carbachol failed to displace [^{3}H]-pirenzepine binding in frontal (Brodmann 9) and temporal (Brodmann 28) cortices. However, high affinity agonist binding to M1 muscarinic receptors was spared in the motor and occipital cortices and in the putamen. These results demonstrate a regional specificity of the pathological defect in M1 receptor coupling in AD. (Supported by NS25785, NS19065 and the AHAF.)

DIFFERENTIAL EXPRESSION OF CORTICAL NICOTINIC AND MUSCARINIC CHOLINOCEPTORS IN ALZHEIMER'S DISEASE H. Schröders#, E. Giacobini‡, R.G. Struble+, K. Zilles#, P.G.M. Luiten‡, A.D. Strosberg^ and A. Maelicke°. Depts. Pharmacology‡ and Psychiatry+ Southern Illinois Univ. Sch. Med., Springfield, IL 62794, #Dept. Anatomy, Univ. Köln, F.R.G., ‡Dept. Animal Physiology, Univ. Groningen, The Netherlands, ^Institut Cochin, Paris, France and °Dept. Physiological Chemistry, Univ. Mainz, F.R.G.

The cellular expression of nicotinic cholinoceptors (nAChR) is significantly reduced in the frontal cortex in Alzheimer's disease (AD) (Schröder et al., *Soc. Neurosci. Abstr.*, 16:612, 1990) whereas no data are available on the expression of muscarinic AChRs (mAChR). Using the monoclonal mAChR-antibody M35 (André et al., *J. Recept. Res.*, 7:89, 1987) autopsy samples of human frontal cortex were studied immunohistochemically in: (1) middle-aged controls [n=3; 55±5yrs], (2) age-matched controls [n=3; 73±6yrs] and (3) AD cases [n=6; 74±5yrs]. Densities of M35-labeled [(1) 4673±1364 neurons/mm^3, (2) 2393±499, (3) 5070± 1008)] and of cresylvioletstained neurons did not show statistically significant differences ($p>0.05$). By contrast to nAChR protein, mAChR expression appears to be virtually not affected in AD. Since nAChRs and mAChRs are colocalized in about 30% of cholinoceptive cortical neurons (Schröder et al., *Synapse*, 4:319, 1989) in AD cholinergic cortical transmission might be mediated in great part exclusively by mAChRs. THE EFFECTS OF TETRAHYDROAMINOACRIDINE ON ATTENTION AND MEMORY IN ALZHEIMER'S DISEASE B.J. Sahakian, S.A. Eagger* and R. Levy* Section of Old Age Psychiatry, Dept. of Psychiatry, Institute of Psychiatry, London, U.K.,SE5 8AF.

The efficacy of tetrahydroaminoacridine (THA) plus lecithin in the treatment of cognitive impairment in patients with probable Alzheimer's disease (AD) was compared to that of placebo. Eighty-nine patients entered the study, 24 were withdrawn, 19 due to side effects and 5 for other reasons. Patients received the maximum tolerated dose of up to 150 mg per day of THA and 10.8 gm/day of lecithin. They were randomly assigned to double-blind treatment of either active or placebo drugs crossing over after 13 weeks treatment and 4 weeks washout. An analysis of the 65 patients who completed the trial showed a statistically significant beneficial effect of THA over placebo on the Minimental State Examination with 45% showing an improvement of 3 or more points compared to 11% in the placebo phase. Similar changes occurred in the Abbreviated Mental Test Score. There was however a considerable inter-subject variability in response. It is concluded that THA produced a demonstrable improvement in key outcome measures roughly equivalent to the deterioration which might have occurred over 6 - 12 months. Significant improvements were also seen on tests of attention but not memory as measured by the CANTAB batteries. Results are discussed in terms of the role of the cholinergic system in the control of attention and information processing.

423.26

LOW FRONTAL CHOLINE ACETYLTRANSFERASE ACTIVITY IS ASSOCIATED WITH SLOWING OF THE EEG AND WIDENING OF THE THIRD VENTRICLE IN ALZHEIMER'S DISEASE. H.Soininen, K.Reinikainen*, J.Partanen*, M. Puranen* and P.J.Riekkinen. Dept. of Neurology, Neurophysiology and Radiology, Univ. Kuopio, 70211 Kuopio, Finland.

Alzheimer's disease (AD) is characterized by marked loss of neocortical choline acetyltransferase (ChAT), slowing of the EEG, and ventricular widening. In 20 autopsy confirmed AD cases, we studied relationship between ChAT depletion of the frontal cortex, EEG slowing and enlargement of the third ventricle on the brain CT scan. The ChAT activity for patients with the dominant occipital rhythm of 5-6 Hz (n=7), 7 Hz (n=8) and 8-9 Hz (n=5) was 36.6±7.8, 42.5±7.8 and 49.6±12.6 (mean±SEM, pmol/mg protein/min), respectively, the control values being 94.5±6.5; the groups with highest and slowest rhythm differed significantly (p=.011). The width of the third ventricle correlated with the frontal ChAT activity (r=-.65, p=.005). The finding supports the contribution of the cholinergic deficit to EEG slowing in AD. The width of the third ventricle may partly reflect shrinkage of the basal forebrain and thus be related to the neocortical ChAT depletion.

423.27

ADENOSINE (A1) AND NMDA RECEPTORS IN THE HIPPOCAMPUS AND PARAHIPPOCAMPAL GYRUS OF ALZHEIMER'S DISEASE BRAINS. J. Ulas, L.C. Brunner and C.W. Cotman, *Department of Psychobiology, University of California, Irvine, CA 92717, USA.*

Adenosine acting *via* presynaptically located A1-receptors can inhibit the release of several neurotransmitters including the potentially neurotoxic excitatory amino acid glutamate which has been implicated in the pathology of Alzheimer's disease (AD). Our previous studies have demonstrated a significant decrease of binding to the NMDA receptor channel-associated sites in the CA1 hippocampal region of AD brain. This region is selectively vulnerable to AD pathology. In the present study, we compared the distribution of adenosine A1-receptors with that of NMDA receptors in the hippocampus and parahippocampal gyrus of six normal elderly controls and five AD patients in order to determine if a loss of A1-receptors in AD might play a role in CA1 vulnerability. The control and AD group were matched according to the age and postmortem delay. Autoradiography of A1-receptors was performed with the use of an antagonist ([3H]DPCPX) and an agonist ([3H]PIA), and binding to the NMDA receptor channel was studied with the use of [3H]MK-801. In control brains, adenosine A1 and NMDA receptors exhibited quite similar distributions with high density of both receptors in the CA1 hippocampal region and the dentate gyrus molecular layer. In AD brains, there was a significant decrease in binding to A1-receptors in the dentate gyrus molecular layer which was accompanied by a smaller drop in binding to NMDA receptors. This seems to reflect the pathology in the entorhinal cortex and loss of the perforant path input to the hippocampus. On the other hand, a significant loss of [3H]MK-801 binding in the CA1 strata pyramidale and radiatum was not paralleled by changes in binding to A1-receptors. Since some loss of neurons was observed in the CA1 area of AD hippocampi, the data suggest that adenosine A1 and NMDA receptors are not located on the same neuronal elements and/or are differentially regulated in AD.

HUMAN BRAIN FIXATION AND STORAGE CONDITIONS FOR CHOLINESTERASES HISTOCHEMISTRY. M.A. Morán and P. Gómez-Ramos. Dept.Morfología, Fac.Medicina, Univ.Autónoma,Madrid,Spain.

Collection of human brains must be preceded by the analysis of fixation and storage conditions.We searched for the optimum preservation of both acetylcholinesterase and butyrylcholinesterase, which accumulate in senile plaques and neurofibrillary tangles. Three fixatives (A,B and C) were analyzed: A) 4% paraformaldehyde in 0.1 M phosphate buffer. B) 10% formaline. C) 2% glutaraldehyde + 2% paraformaldehyde in 0.1 M phosphate buffer. The best fixative for both cholinesterases was A), and the optimum fixation-time was 48 hours. With B) both enzymes were reduced after short fixation-times (24-48 h), and completely inactivated after longer fixation-times (weeks or months), invalidating the use of old formaline collections. With C) very short fixation-times (less than 24 h) only slightly reduced the activity of both enzymes, but after 42 h the enzymatic preservation (mainly of butyrylcholinesterase) was very low. Still, glutaraldehyde can be used for a few hours to improve the E.M. ultrastructure.

Fixed blocks were stored at 4°C in 0.1 M phosphate buffer + 40% sucrose for 2-3 months before a reduction of butyrylcholinesterase was observed. For longer periods (a year or more)blocks were kept unfrozen at -17°C in a 30% glicerol + 30% etilen glycol buffered solution, without further decrease of enzymatic activity. Tissue already sectioned was successfully stored unfrozen at -17°C for up to 4 months in the glycol solution. Supported by FIS 88/0922 and 90/0259.

A CELL MODEL FOR THE STUDY OF PARKINSONISM.

W.L. Yang, F.F. Oldfield and A.Y. Sun. Department of Pharmacology, University of Missouri, Columbia, MO 65212.

A loss of dopamine (DA) containing neurons appears to be the primary pathological changes in Parkinson's disease. The cause of DA cell death remains unclear. Since paraquat is chemically similar to MPTP and was implicated in causing Parkinsonism's symptom in humans. We have studied the action of paraquat on catecholamine containing cells. We have demonstrated that the rat pheochromocytoma cell line (PC12) can actively take up both dopamine and paraquat. Incubation of cells with paraquat leads to some cell death in a dose- and time-dependent manner. We have also demonstrated that pretreatment of cells with paraquat at various time intervals have led to progressive decrease in dopamine uptake activity. Since oxygen radicals may be involved in the toxicity of paraquat as demonstrated (Yang *et al.*, Free Radical Biol. Med. 9 Suppl. 1, 165, 1990). Our results correlated well with synaptosomal DA uptake and lipid peroxidation activity after mice treated with paraquat. It appears that the neurotoxins, such as MPTP and paraquat may cause Parkinson's disease by free radical attack on dopaminergic neurons. The possible protective effect by free radical scavengers and endogenous agents which might cause Parkinson's disease through free radical mechanisms are under extensive investigation in our laboratory using the cell model.

DIHYDREXIDINE, A FULL DOPAMINE D1 AGONIST, REDUCES MPTP-INDUCED PARKINSONISM IN THE AFRICAN GREEN MONKEY.

J.R. Taylor, M.S. Lawrence*, D.E. Redmond, Jr., J.D. Elsworth, R.H. Roth, D.E. Nichols§, and R.B. Mailman†. Depts. of Psychiat. & Pharm., Yale Univ. Sch. of Med., New Haven, CT 06510, †Univ. of N. Carolina Sch. of Med., Chapel Hill, NC 27599, and §Dept. of Med. Chem., Purdue Univ., W. Lafayette, IN 47907

The antiparkinsonian effects of dopamine agonists have largely been attributed to activation of D2 dopamine receptors. Reports in human and non-human primates using SKF38393, the prototypical D1 agonist, have failed to demonstrate significant antiparkinsonian effects, suggesting that D1 receptors were not involved. Based on stimulation of cAMP synthesis, SKF38393 is only a partial agonist. Recently, dihydrexidine has been reported to be a full D1 agonist, bioavailable in brain, and to have a ten fold D1:D2 selectivity. We have therefore administered dihydrexidine to MPTP-treated non-human primates. MPTP produces a parkinsonian syndrome in humans and in non-human primates. In Parkinson's disease and the MPTP-treated primate, motor deficits are correlated with regional dopamine losses and decreased eye blink rates. Dihydrexidine (0.3-0.9 mg/kg, i.m.) significantly reversed parkinsonism and increased eye blink rates in five parkinsonian MPTP-treated African green monkeys in a "blind", pseudorandom sequence, saline-controlled study. Behavioral measures of parkinsonism were markedly reduced for 30-45 minutes after the drug, while eye blink rates and healthy behaviors increased. After 45 minutes, the monkeys returned to their prior level of disability. Antiparkinsonian effects were correlated with changes in blink rate. Our pharmacological studies show that blink rate can be independently regulated by D1 and D2 receptors. Dihydrexidine's dramatic antiparkinsonian effects indicate that it and other full efficacy D1 receptor agonists may be of particular utility in the treatment of Parkinson's disease.

BIOCHEMICAL AND PHARMACOLOGICAL STUDIES ON CABERGOLINE, A NEW PUTATIVE ANTIPARKINSONIAN DRUG.

N. Carfagna, C. Caccia*, M. Buonamici, M.A. Cervini*, S. Cavanus*, M.G. Fornaretto*, D. Damiani* and R.G. Fariello. R&D, Farmitalia Carlo Erba, Erbamont Group, CNS Dept, 20014 NERVIANO, Milan, Italy.

Cabergoline (CAB) is a new ergoline derivative. CAB in vitro showed high affinity binding for striatal dopamine (DA) receptors labeled by [^{3}H]-n-propylnorapomorphine (K_i=3nM) or [^{3}H]-spiroperidol (K_i=11nM) with lower affinity for other neuronal receptors such as D-1 dopamine, α-1, α-2 adrenoreceptors, S-1 and S-2 serotonin. CAB specificity for D-2 receptors was confirmed by its inhibiting effect on striatal DA-sensitive adenylate cyclase activity (IC_{50} in μM range). In vivo CAB (ED100=1 mg/kg s.c.) elicited contralateral rotation in 6-OHDA unilaterally lesioned rats in the nigra and completely reversed (0.5 and 1 mg/kg s.c.) the parkinsonism in MPTP-treated monkeys. These functional changes were blocked by sulpiride but not by SCH 23390 a D-1 receptor antagonist. CAB decreased DA turnover as indicated by the reduced DOPAC/DA and HVA/DA ratios in the striatum (-17% and -26% respectively) and n. accumbens (-26% and -34% respectively). The lowering effects on HVA and DOPAC peaked at about 9 hr after drug administration and vanished 24 hr later. The rate of the DA synthesis and utilization evaluated by GBL and α-MT was also significantly reduced in the striatum (-33% and -66% respectively) and n. accumbens (-21% and -70% respectively) suggesting an activation of both pre-and postsynaptic DA receptors. In contrast to other ergot derivatives e.g. bromocriptine, pergolide and lisuride, CAB had no significant effects on noradrenaline and serotonin turnover. The results indicate that CAB is a potent and selective DA D-2 receptor agonist with long duration of action.

424.4

BEHAVIORAL EFFECT OF CHRONIC TREATMENT WITH CY 208-243 A PARTIAL D-1 AGONIST IN DRUG NAIVE MPTP-TREATED MONKEYS.

B. Gomez-Mancilla and P.J. Bédard. Lab. of Neurobiology, Laval University, Fac. of Med., Ste-Foy, (Qc), CANADA G1K 7P4.

In order to study pharmacologically the action of CY 208-243 a partial D1 agonist we performed the following experiment. A group of 5 female cynomolgus monkeys (±3kg) was rendered parkinsonian by one or repeated doses of MPTP (0.3-10 mg/kg). At least two months after the last injections, a daily s.c. injection of CY 208-243 at 0.05, 0.1 and 0.5 mg/kg was started. All animal improved their parkinsonian symptoms, but 3 out 5 animals developed dyskinesias under treatment. After 36 days of treatment the daily dose of CY 208-243 was replaced by an experimental agent and the animal was monitored for dyskinesias and other effects. LY-171555 at 0.01 mg/kg reproduced the same dyskinesias produced by CY 208-243. The D1 antagonist SCH-23390 at 0.05 mg/kg as well as Sulpiride at 20 mg/kg were without effect by themselves. However dyskinesias induced by CY 208-243 could be antagonized by SCH-23390, partially antagonized by Sulpiride at 20 mg/kg, and prevented by previous treatment by alpha-methyl-paratyrosine. Our results show that chronic treatment with CY 208-243 can produce dyskinesias in MPTP-treated monkeys and D1 and D2 receptors activation appears necessary for their manifestation.

MOTOR AND NON-MOTOR ASPECTS OF HEMI-SPATIAL NEGLECT IN HEMI-PARKINSONIAN MONKEYS.

W.W. McLaughlin, J.S. Schneider and D.P. Roeltgen*, Dept. of Neurology, Hahnemann Univ., Phila., PA. 19102.

Monkeys with unilateral damage to the nigrostriatal dopamine system display a hemi-parkinsonism characterized by a flexed posture, rigidity and disuse of the limbs (particularly the arm) contralateral to the dopamine denervation. The present study was conducted to assess the degree to which lateralized non-motor deficits such as hemi-neglect might be present in the primate lesion model. Three male rhesus macaque monkeys were trained to perform motor tasks which measured bar press rate and reaction and movement times and tasks such as response to double simultaneous stimuli, response to lateralized moving stimuli, and lateralized reward retrieval, designed to assess neglect phenomena. Normal data were obtained over several weeks from the left arm with the right arm restrained and vice versa. All animals then received unilateral (right side) intracarotid infusion of MPTP (performed by K. Bankiewicz). All monkeys developed a stable left-sided hemi-parkinsonism characterized by lack of performance of motor tasks with the left arm and normal performance with the right arm. Post-lesion, all monkeys showed significant deficits in the use of the left arm in both hemispaces and in the use of the intact right arm in response to stimuli or performance of tasks in the left or impaired hemispace. When the left arm performed tasks, it did so on the right and not on the left. With the intact right arm, monkeys showed a clear response bias to the right and an inattention to the left in response to double simultaneous stimulation and lateralized reward retrieval. In response to lateralized moving stimuli, there were deficits in directing attention into the impaired hemispace. Deficits on these tasks could be overcome after administration of N-0923 (D2 agonist) but not after SKF-38393 (D1 agonist). The response deficits of the right arm cannot be explained by motor dysfunction since this arm performed normally on motor tasks and on tasks centered in the intact hemispace. Instead, these results show that hemi-parkinsonism in the monkey is a complex syndrome characterized by overt motor disturbances and less overtly apparent defects in sensorimotor integration.

DOPAMINE RECEPTORS IN THE GLOBUS PALLIDUS AND SUBSTANTIA NIGRA OF MPTP-MONKEYS TREATED CHRONICALLY WITH BROMOCRIPTINE OR BROMOCRIPTINE+CY 208-243,

C. Gagnon[1], B. Gomez-Mancilla[2], P.J. Bédard[2] and T. Di Paolo[1], [1]Sch. of Pharmacy, Laval Univ. and Dept of Mol. Endo., CHUL, Quebec, G1V 4G2; [2]Dept of Pharmacol., Fac. Med., Laval Univ., Quebec, G1K 7P4, Canada.

Dopamine (DA) receptor densities, as measured by the autoradiography of antagonist (^{3}H-SCH 23390 (D-1), ^{3}H-spiperone (D-2)) and agonist ligands (^{3}H-SKF 38393 (D-1) and ^{3}H-N-propylnorapomorphine (D-2)) binding, were compared in the globus pallidus (external (GPE) and internal (GPI) segments) and substantia nigra (SN) of MPTP-monkeys treated daily during one month with bromocriptine (BROMO) alone or in combination with CY 208-243 (CY). MPTP decreased by 67% or more DA levels in the GPE and GPI. Following MPTP, antagonist and agonist sites decreased in the GPE and GPI (except D-1 antagonist sites which remained unchanged in the GPI). Neither DA agonist treatments changed antagonist sites in the GPE and GPI compared to the untreated MPTP-animal. However, agonist sites increased after both dopaminergic treatments in GPI, whereas only agonist sites of D-2 receptors increased in the GPE after BROMO treatment. Antagonist sites of D-1 and D-2 receptors were, respectively, increased and not detectable in the SN of MPTP-monkeys, whereas agonist sites were, respectively, decreased and unchanged. Both dopaminergic treatments increased antagonist sites in the SN compared to the control animal. Agonist sites returned toward control values in the SN of BROMO+CY-treated monkeys, whereas agonist sites of D-2 receptors decreased in the BROMO-treated animals in this brain region. In summary, changes in DA receptors in the GP and SN may play a role in the changing response to DA agonists after chronic treatments.

Supported by the Parkinson Foundation of Canada.

INTRA-CEREBRO-VENTRICULAR APOMORPHINE INFUSION IN MPTP MONKEYS. A.L. Benabid, P. Pollak*, P. Limousin*, F. Serre-Debeauvais*, E. Seigneuret*, A. François-Joubert*, C. Feuerstein and M. Gavend*. Dept. of Clin. and Biol. Neurosciences and Lab. of Pharmacology, INSERM U-318, Joseph Fourier University of Grenoble, France.

Apomorphine, a dopaminergic agonist drug, administrated by continuous subcutaneous infusion is efficient in parkinsonian patients suffering from severe L-dopa-induced on-off effects. As the best temporal mode of infusion is not well established and external infusion methods are difficult to implement in such patients, a continuous intra-cerebro-ventricular (ICV) apomorphine administration was carried out in MPTP primates using an implanted programmable pump. A Medtronic DAD pump connected to an intra-ventricular catheter was placed intraperitoneally in 7 macaca fascicularis monkeys. An access system was implanted for cisternal CSF sampling. Permeability of catheters and pump system was checked by contrast radiography and ^{99m}Tc-DTPA scintigraphy. CSF and blood pharmacokinetic studies of apomorphine were carried out in 3 animals following ICV and intramuscular (IM) continuous infusions. MPTP was intravenously injected in 4 monkeys until a stable parkinsonian motor state was obtained.

The implanted system was well tolerated in all animals up to 12 months but recurrent surgery was sometimes needed to repermeate occluded catheters. Pharmacokinetic results have shown that ICV apomorphine infusion led to CSF apomorphine concentrations far higher than those obtained after IM infusion of the same apomorphine dose, whereas blood concentrations remained to low values compared to peripheral administration. ICV apomorphine infusion induced the recovery of a normal motricity in MPTP monkeys during the time of administration and 30 min after its arrest. Long term ICV apomorphine infusions are in progress to evaluate the motor response induced by temporal modalities of administration during the nycthemere and by various apomorphine flow rates.

424.8

THE ROLE OF DOPAMINERGIC NERVE TERMINALS IN THE TREATMENT OF PARKINSON'S DISEASE WITH L-DOPA. E.D. Abercrombie and S.R. Wachtel. *Center for Molecular & Behavioral Neuroscience, Rutgers University, Newark NJ, 07102 (USA).*

Previously, we reported that systemic doses of L-DOPA which increase tissue levels of dopamine (DA) in striatum produced either no significant change (50 mg/kg) or a relatively modest 54% increase (100 mg/kg) in extracellular (EC) DA level in that structure despite large increases in EC DOPAC at both doses (Abercrombie et al., 1990). In animals treated with 6-OHDA, sustaining virtually complete depletions of striatal DA, 100 mg/kg of L-DOPA produced a 4-fold greater absolute increase in EC DA relative to that observed in controls. A model is proposed in which DA terminals, by efficiently metabolizing DA formed from L-DOPA, may actually be a sink rather than a source of transmitter in L-DOPA therapy of Parkinson's disease. In order to examine more closely the role of DA terminals in L-DOPA-induced increases in EC DA, in vivo microdialysis was used to monitor the effect of pretreatment with 50 mg/kg L-DOPA on increases in EC DA produced by 0.5 mg/kg HAL (Ca^{++} dependent release) or by 0.5 mg/kg AMPH (Ca^{++} independent release). The vesicular release of DA produced by HAL was not affected by L-DOPA pretreatment whereas the translocation of cytoplasmic DA produced by AMPH was significantly enhanced. Furthermore, the increase in EC DA produced by 100 mg/kg L-DOPA was not abolished when 10^{-5}M TTX was infused via the dialysis probe, a manipulation that decreased basal EC DA to non-detectable levels. These results suggest that DA formed from exogenous L-DOPA in DA neurons is efficiently metabolized in the cytoplasm and that the efficacy of L-DOPA in the treatment of Parkinson's disease results from non-specific spillover of DA from non-DA striatal elements.

CONCURRENT DEVELOPMENT OF BEHAVIORAL SENSITIZATION AND BIOCHEMICAL TOLERANCE WITH CHRONIC L-DOPA TREATMENT. Robert J. Carey Brown University and VA Medical Center, Providence, RI 02908

In L-DOPA therapy for Parkinson's disease, overstimulation of the motor system often occurs with chronic treatment resulting in dyskinetic effects which are often followed by on-off and wearing-off effects. Unilateral 6-OHDA lesion animals were used to study this process in an animal model analogue. Following 30 L-DOPA treatments with subthreshold (10 mg/kg) and suprathreshold (20 mg/kg) doses, behavioral sensitization of contralateral rotation was observed in both groups. In conjunction with the behavioral sensitization, there was a substantial decline in dopamine metabolite levels from acute treatment levels, indicating a tolerance effect. Behavioral sensitization and biochemical tolerance effects with chronic L-DOPA treatment were interpreted by a two-factor model. Behavioral sensitization and overstimulation were assumed to reflect the combined effects of dopamine receptor priming and Pavlovian drug conditioning whereas the eventual wearing-off effect of L-DOPA could reflect the development of tolerance in the conversion of L-DOPA into dopamine.

NICOTINE METABOLITES ALTER DOPAMINE UPTAKE AND RELEASE IN RAT STRIATUM IN VITRO. L.L. Leibee, P.A. Crooks*, S.T. Buxton, A.L. Jewell and L.P. Dwoskin. College of Pharmacy, University of Kentucky, Lexington, K.Y. 40536-0082.

Although controversial, chronic nicotine and cigarette smoke exposure antagonize the MPTP-induced decrease in striatal DA stores and tyrosine hydroxylase activity (Janson et al., 1988; Carr and Rowell, 1990). Recently, nicotine has been reported to stereoselectively inhibit striatal dopamine (DA) uptake at lower concentrations (pM-nM) than induce DA release in vitro (Izenwasser et al., 1991). The aim of this study was to determine if metabolites of nicotine inhibit [3H]DA uptake or increase DA release from rat striatal slices in vitro. Significant inhibition (60%) of [3H]DA uptake occurred with S(-)N-methylpyridinium nicotine metabolites (10 uM), which are structurally similar to the neurotoxin MPP^+, while the S(-) N'-methylpyrrolidinium metabolites (10 uM) exhibited no inhibition of [3H]DA uptake. S(-)Nornicotine (100 uM) evoked a greater increase (3-fold) in the concentration of endogenous dihydroxyphenylacetic acid in superfusate than the same concentration of the parent compound, S(-) nicotine. Endogenous DA was not detected in striatal superfusate. Therefore, alterations in DA uptake and DA release by metabolites of nicotine may contribute to the neuropharmacology of nicotine. HUMAN AND RAT MESENCEPHALIC AND STRIATAL NEURONS STUDIED IN ORGANOTYPIC SLICE CULTURES. K. Østergaard, B.R. Finsen and J. Zimmer. PharmaBiotec, Institute of Neurobiology, University of Aarhus, DK-8000 Aarhus C, Denmark.

Tyrosine hydroxylase immunoreactive (TH-i), dopaminergic (DA) neurons and striatal neurons can survive and retain their in vivo morphological characteristics for 60 days in slice cultures of ventral mesencephalon (VM) and striatum prepared from newborn to seven day old rats. We now report long term survival for up to nine months of TH-i, DA neurons in slice cultures of rat VM.

We also report the presence of TH mRNA and cholecystokinin (CCK) mRNA in VM slice cultures prepared from newborn rat as visualized by *alkaline phosphatase labeled oligonucleotide probes. Likewise somatotatin* (SS) mRNA and enkephalin (ENK) mRNA were visualized in rat striatal neurons.

A second aim was to examine whether human, fetal mesencephalic and striatal neurons can survive and differentiate in slice cultures. Slices of VM and striatal tissue were obtained from two 7 week old (postconception), aborted fetuses according to the permission granted by the Regional and Central Ethical Committees. The VM and striatal slice cultures survived for 5 weeks before immunocytochemistry and in situ hybridization were performed. Human TH-i neurons were observed to have mature in vivo morphological characteristics. Further results of these studies will be presented.

Storage of human, fetal DA neurons in slice culture would allow treatment with trophic factors, pooling of neurons and examination for infectious agents before transplantation to patients with Parkinson's disease.

INTRACEREBRAL GRAFTING OF AADC-EXPRESSING PRIMARY FIBROBLASTS FOR SITE-SPECIFIC DELIVERY OF DOPAMINE. U.J. Kang, L.J. Fisher, H.A. Jinnah, M.B. Rosenberg, T.H. Joh, T. Friedmann, F.H. Gage. Departments of Neurosciences & Pediatrics, Univ. California San Diego, La Jolla, CA 92093 and Burke Medical Research Institute, Cornell University Medical College, White Plains, NY 10605.

Primary dermal fibroblasts from adult, female Fischer 344 rats have been infected with a retroviral vector containing the cDNA for bovine aromatic L-amino acid decarboxylase (AADC). This enzyme catalyzes the conversion of L-DOPA to dopamine. Transduced fibroblasts (FF2/AADC) showed positive immunoreactivity for AADC protein in vitro. The recombinant AADC in FF2/AADC cells has a Km of 29 μM for the substrate L-DOPA and Vmax of 26 nmoles dopamine/mg/20 mins with most optimal activity when the cofactor pyridoxal phosphate concentration ranges from 10 to 100 μM. The AADC activity remains stable in culture for up to at least 18 passages.

The FF2/AADC fibroblasts synthesize and release dopamine into the media (3.9 nmoles/mg/hour) when incubated in DMEM/10 % fetal calf serum with pyridoxal HCL and L-DOPA. FF2/AADC fibroblasts implanted in the striatum of Fischer 344 rats survived through 13 weeks post-implantation with relatively constant graft size from 3 weeks to 13 weeks. There appears to be a decrease in the number of fibroblasts within the graft during that period. Immunolabeling for AADC protein is strongly positive at 1 and 3 weeks, with decreased AADC-reactivity at later times. Further studies using these FF/AADC fibroblasts to reverse dopamine-deficient behaviors in a rat model of Parkinson's disease are in progress.

STRIATAL TRANSPLANTATION OF BOVINE CHROMAFFIN CELL-LOADED MICROCAPSULES REDUCES EXPERIMENTAL PARKINSONISM IN RATS S.R. Winn[1], S.A. Tan*[1], P.A. Tresco[1], J. Sagen[2], P. Aebischer[1]. Brown Univ., Providence, RI[1] and U. of IL, Chicago[2].

Striatal transplantation of catecholamine-releasing cells encapsulated within a selectively permeable membrane may provide a strategy for dopamine replacement in animal models of parkinsonism and prevent immune rejection in xenotransplants. Immobilizing adult bovine adrenal chromaffin (BAC) cells in a polyelectrolyte matrix prevents fusion of cellular aggregates which may develop necrotic centers due to inadequate nutrient support. Coseeding with an NGF-releasing cell line was attempted to transform BAC cells from an endocrine to a more neuronal phenotype. In vitro, cell-loaded microcapsules were characterized by analyzing basal, amphetamine and high K^+ evoked release of catecholamines and observing cell viability over time. Cells within the microcapsules continued to survive for at least 12 weeks in vitro. Short neurites were seen extending from the coseeded BAC cells after 4 weeks in vitro. This differentiation increased amphetamine and high K^+ stimulated dopamine output from 1 to 4 weeks that was maintained for up to 12 weeks in vitro. BAC-loaded microcapsules were implanted into 6-OHDA unilaterally lesioned striata of rats. From one to four weeks post-implantation, BAC cell-loaded recipients (n=6) showed a 50% reduction in rotation behavior under apomorphine challenge as compared to animals which received empty microcapsules (n=6). Intact microcapsules containing DBH and TH immunopositive BAC cells were observed after 4 weeks of implantation in animals exhibiting a reduction in turning behavior. Immobilization of discrete cell clusters in polyelectrolytes prevents reaggregation and may provide a method for enhancing long-term maintenance of chromaffin cells.

424.14

REVERSAL OF BEHAVIORAL RECOVERY FOLLOWING THE REMOVAL OF POLYMER ENCAPSULATED PC12 CELLS IMPLANTED IN THE LESIONED RAT STRIATUM. P. A. Tresco[1], S. R. Winn[1], B. Zielinski*[1], C. B. Jaeger[2], L. A. Greene[3], P. Aebischer[1]. Brown Univ.[1], Purdue Univ.[2], and Columbia Univ.[3]

The feasibility of delivering physiologically relevant concentrations of dopamine (DA) to the striatum with an implantable, selectively-permeable, polymer capsule containing DA-secreting cells was investigated. A significant reduction in the apomorphine-induced rotational response was observed when PC12 cell-containing capsules were implanted into the 6-OHDA lesioned striata of rats, whereas no reduction was observed following the implantation of empty polymer capsules. Polymer-encapsulated PC12 cells survived in the striatum, did not form tumors, and expressed tyrosine hydroxylase after 4 weeks in situ. Cellular viability was consistently better within implanted capsules when compared to those maintained in vitro. Microdialysis studies of denervated striata revealed the presence of DA near PC12 cell-loaded capsules which was comparable to extracellular DA levels of unlesioned controls. To further clarify if the observed reduction in rotation was mediated by chronic stimulation of DA receptors secondary to its diffuse release from the PC12 cell-containing capsules, a flushable PC12 cell-containing encapsulation system was implanted into the 6-OHDA lesioned striata of rats. Only cell-containing devices reduced the apomorphine-induced rotational response. Morever, one week after removing the PC12 cells by flushing the U-shaped encapsulation system the effect was reversed. Viable cells were confirmed by staining with a fluorescent vital dye. The reversibility suggests that release of a neurotransmitter, most likely DA, was responsible for the observed functional effect using this cell line.

EXPRESSION OF TYROSINE HYDROXYLASE IN STRIATAL CELLS WITH A HSV-1 VECTOR CAUSES STABLE PRODUCTION AND REGULATED RELEASE OF DOPA AND DOPAMINE: POTENTIAL GENE THERAPY FOR PARKINSON'S DISEASE. A. Freese, M.J. During, K. O'Malley, and A.I. Geller. Dept. of Neurosurg., Hosp. Univ. of PA., Phila. PA. 19104; Dept. Neurosurg., Yale Univ. Sch. of Med., New Haven CT. 06510; Dept. Anat. and Neurobiol., Washington Univ. Sch. of Med., St. Louis MO. 63110; Div. of Cell Growth and Regulation, Dana Farber Can. Inst., Boston MA. 02115.

We have developed defective Herpes Simplex Virus (HSV-1) vectors to deliver genes into neurons in culture and in the adult mammalian brain (Science 241, 1667, 1988, Proc. Natl. Acad. Sci, 87, 1149, 1990; Biochem. Pharm., 40, 2189, 1990). Thus, a new gene therapy approach to Parkinson's Disease is to use a HSV-1 vector expressing tyrosine hydroxylase (TH), the rate limiting enzyme in dopamine synthesis, to direct dopamine synthesis in striatal neurons and glia. Towards this goal we constructed a HSV-1 vector (pHSVth) which expresses the human TH gene from the HSV-1 IE 4/5 promoter, a constitutive promoter active in most neural cells. Fibroblasts infected with pHSVth contain TH DNA, TH RNA, and TH immunoreactivity (in approximately 10 % of the cells). pHSVth infected fibroblasts also contain a 90-fold increase in TH enzyme activity and a 10-fold increase in both L-dopa and dopamine levels. Cultured striatal cells were infected with pHSVth, one week later TH immunoreactivity was detected in approximately 70 % of the cells. Furthermore, both L-dopa and dopamine were released from these cells in a regulated fashion for at least one week after infection. The levels of TH enzyme and monoamines was comparable to cells which naturally synthesize monoamines, or to fibroblasts transfected with the TH gene; both of these cell types demonstrate behavioral improvement upon transplantation into the animal models of Parkinson's Disease. Therefore, pHSVth should be an effective therapeutic tool if it can be delivered into a sufficient number of cells in vivo; such studies are in progress.

QUANTIFYING IMPROVEMENT FOLLOWING CNS TRANSPLANTATION IN HEMIPARKINSONIAN MONKEYS USING AN OPERANT BEHAVIOR TASK. R.A.E. Bakay, L.D. Byrd* and J. Tigges. Yerkes Regional Primate Research Center, Emory Univ., Atlanta, GA 30322.

One of the most difficult problems in evaluating the success of CNS transplantation techniques is obtaining a quantitative measure of the disability produced by the parkinsonian model. Our experience with MPTP hemiparkinsonian monkeys suggests rotational behavior is not a satisfactory index of disability. In an attempt to obtain a more representative quantitative analysis, monkeys were trained to perform a discrete-trial operant task which required the simultaneous depression of two levers on a response panel. Once both levers were depressed, lights above the right or left lever were darkened to indicate which hand to use in touching an illuminated area on a touch-sensitive screen. Correct responses were rewarded with a food pellet. Highly stable and accurate performance with both hands was established prior to MPTP injection. Testing allowed the separation of hand functions into response time, movement time, precision and accuracy of the responses, and provided a quantitative behavioral measure of parkinsonism. Preliminary results with this technique suggest quantitative improvement after transplantation procedures which yielded viable grafts as opposed to those performed on a sham basis. The smaller the MPTP-induced deficit, the more likely the behavioral improvement. Supported by VAR&D, RO1 NS24340 and RR-00165.

QUANTIFYING BEHAVIORAL IMPROVEMENT IN HEMIPARKINSONIAN MONKEYS USING TWO DIFFERENT OPERANT TASKS. R.L. Watts, L.D. Byrd*, R.A.E. Bakay and A. Mandir*. Yerkes Regional Primate Research Center, Emory Univ., Atlanta, GA 30322.

One of the most difficult problems in evaluating the success of CNS transplantation techniques is obtaining a quantitative measure of the disability produced by the parkinsonian model. We have been investigating techniques for characterizing and quantifying behavioral performance related to parkinsonism in monkeys. One group of monkeys was trained to perform a discrete-trial operant task which required the simultaneous depression of two levers, release of the correct hand in response to a light cue, and touch-contact with a lighted CRT (see related presentation). Another group of monkeys was tested on a ballistic wrist flexion/extension task. A potentiometer connected to the manipulandum provided a signal of wrist angular position and velocity. Visual feedback of hand position and task performance was provided to the monkeys. Agonistic and antagonistic EMG potentials were recorded using surface electrodes. Highly stable and accurate baseline performances were established, and response time and movement time, as well as the precision and accuracy of the response, were measured. Subsequent manipulations with MPTP injection, surgery and drug therapy could be quantitated. Comparisons of the two techniques will be made to each other and to other behavioral measures. Supported by VAR&D, RO1 NS24340 and RR-00165.

GUANIDINOETHANE SULFATE ENHANCES THE SURVIVAL RATE OF MICE EXPOSED TO ANOXIA: BRAIN LACTIC ACIDOSIS PROTECTIVE AGENT? T. Nakada and I. L. Kwee. Neurochem Res Lab, VA Med Ctr, Martinez, CA 94553 and Dept of Neurology, Univ of California, Davis, CA 95616.

Several lines of evidence now support the concept that lactic acidosis plays a key role in determining the outcome of brain anoxia/ishemia. Our previous studies on brain of the fetus and the 1 and 10 day old neonate demonstrated that taurine increases the brain cytosol acid buffering ability and plays a fundamental role in the immature brain's high resistance against anoxia. In this study, we assessed the protective effects of guanidinoethane sulfate (GES), a taurine analogue, on brain lactic acidosis in adult mice. The data indicated that GES can serve to increase the brain acid buffering ability and effectively prevents severe acidosis from lactic acid generation in response to anoxia. GES greatly enhanced the survival rate of mice exposed to anoxia.

	Survival rate	
Duration of Anoxia	GES	Control
2.5 minutes	100%*	40-60%
2.75 minutes	80-90%	0%

*Each experiment consisted of 5 GES and 5 control animals and experiment was repeated three times.

DIETARY NONPROTEIN CALORIES AND CEREBRAL INFARCTION SIZE. C.S. Robertson,* J.C. Goodman, R.G. Grossman, Department of Neurosurgery, Baylor College of Medicine, Houston, TX 77030

The effect of reducing carbohydrates in the diet on cerebral infarction size was studied after a 45 minute reversible middle cerebral artery occlusion (MCAO). Rats were either fasted for 24 hours prior to MCAO or were fed a control diet containing 51.5% of the calories as carbohydrates, or one of 5 experimental diets in which 60% of the carbohydrate calories were replaced with one or more of the following substrates: 1,3-butanediol, triacetin, and tributyrin. The lowest plasma glucose concentration was achieved in the fasted group, 6.5±1.1 mmol/ml, and the highest was found in the control diet, 9.2±1.4 mmol/ml. The 1,3-butanediol diet resulted in a plasma glucose concentration of 7.8±1.3 mmol/ml. The smallest infarct volume was found in the fasted group, 53±43 mm^3, and the largest in the control diet group, 162±56 mm^3. Significantly smaller infarcts were found with the 1,3-butanediol diet, 98±41 mm^3, and with the triacetin/tributyrin diet, 105.4±52.6 mm^3. The size of the infarction was directly related to the preischemia blood glucose concentration (n=69, r=.47, p<.01). It may be possible to develop a diet using nonglycolytic calorie sources which would supply systemic caloric and protein requirements without the adverse effect of conventional diets.

425.3

INTRAVITREAL INJECTION OF GLUCOSE PROTECTS AGAINST ISCHEMIC DEGENERATION OF RETINAL NEURONS C.Romano, M.T.Price, H.Y.Bai, J.W.Olney, Depts. Ophthalmology and Psychiatry, Washington University School of Medicine, St. Louis, MO 63110.

We reported last year that Honghua, an extract of safflower used as an herbal medicine in China, has neuroprotective activity in experimental models of excitotoxicity. In the *in vivo* adult rat retina, ischemic damage induced by dye photothrombosis was greatly reduced by intravitreal injection of Honghua. In the isolated chick embryo retina (CER), Honghua protected against the excitotoxicity of glutamate receptor agonists, N-methyl-D-aspartate, kainic acid and quisqualic acid (QA), and against neuronal degeneration caused by simulated ischemia (30 min glucose/oxygen deprivation). Subsequently, we found that Honghua more potently protected against simulated ischemia than against the agonists. Biochemical fractionation procedures were used to purify an active component of Honghua. An approximately 100-fold purification of an active principle was acheived using ion-exchange, gel filtration, and reverse-phase chromatography. The purest fractions were determined to be rich in glucose, so the effects of glucose in the models of excitotoxicity were determined. Many of the neuroprotective effects of crude and highly purified Honghua were quantitatively mimicked by pure solutions of equivalent glucose concentration. Concentrations of glucose ≥ 3.2 mM in the CER-ischemia assay provided complete protection from neurotoxicity, despite the absence of oxygen. Intravitreal injection of 1.05 µmol of glucose provided highly significant neuroprotection (67% reduction in retinal damage determined histologically at 1 hr post ischemia; n=14, $p < 0.001$) in the adult rat retina dye-photothrombosis model. It should be noted that substances injected intravitreally diffuse freely into the ischemic retina. Thus, direct delivery of glucose to ischemic neurons in the immediate period following CNS vascular occlusion (stroke), delays progression of neuronal degeneration for at least 1 hr. These findings have relevance for the management of retinal vascular occlusion and possibly other neuro-ischemic disorders. This work was supported by grants from Fight-for-Sight (CR) and NIH (JWO).

PATHOPHYSIOLOGY OF ASPHYXIA-INDUCED LESION TO THE RAT NIGRO-STRIATAL DOPAMINE SYSTEM. EFFECTS OF NICOTINE TREATMENT. K.Andersson*, B.Bjelke, S.O. Ogren*, P.Bolme* and P.Bach-y-Rita. Karolinska Institutet, 104 01 Stockholm, Sweden.

Asphyxia to male Sprague-Dawley rat pups was induced by a delayed cesarean section (Bjelke et al.,1991). Immunohistochemical and functional analyses were carried out on the pups at an age of 3 weeks. It was demonstrated that asphyxia time-dependently produced an increase in the number of tyrosine hydroxylase immunoreactive (TH-IR) nerve cell bodies in the substantia nigra. Furthermore, asphyxia time-dependently reduced rearing behavior and increased locomotion (Bjelke et al.,1991). In the present study the pups received nicotine via the breast milk of dams implanted with an Alzet minipump (0.125 mg nicotine/kg/h for 3 weeks). It was found that nicotine treatment counteracted the asphyxia-induced increase in the number of TH-IR nerve cell bodies of the substantia nigra as well as the changes in rearing and locomotor behavior.

In conclusion, nicotine treatment of male rat pups can counteract asphyxia-induced changes in nerve cell body number in the substantia nigra, as well as changes in locomotor behavior.

BMY-14802 AND CLOZAPINE ARE NEUROPROTECTIVE IN A GERBIL MODEL OF ISCHEMIA. P. C. Contreras, D. M. Ragan*, N. M. Gray*, T. S. Rao and T. H. Lanthorn, CNSDR, G. D. Searle & Co., Skokie, IL 60077.

Recently, BMY-14802, a putative sigma antagonist and antipsychotic agent, and clozapine, an atypical antipsychotic agent, were shown to antagonize harmaline and D-serine induced increases in cGMP in the cerebellum, a well characterized second messenger response mediated by the NMDA receptor-channel complex. The purpose this study was to assess whether clozapine and BMY-14802, like NMDA antagonists, could also be neuroprotective in an *in vivo* model of ischemia. Using the gerbil model of ischemia, there was significant neuroprotection when gerbils were pretreated with 50, 30 or 10 mg/kg of BMY-14802 or 10 or 20 mg/kg of clozapine. Unlike many of the NMDA competitive and noncompetitive antagonists, BMY-14802 did not induce stereotyped behavior or ataxia. These results suggest that clozapine and BMY-14802 may be useful in attenuating ischemia-induced injury in the CNS.

425.6

THE EFFECTS OF FOSPHENYTOIN ON INFARCT SIZE AND BEHAVIORAL DEFICITS IN RAT MODELS OF FOCAL ISCHEMIA. J.J. Cordon, P.A. Boxer and F.W. Marcoux, Department of Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor, MI, 48105

Fosphenytoin is a water soluble prodrug of phenytoin that is rapidly converted to phenytoin by non-specific phosphatases in plasma. Previous experiments with phenytoin have indicated that it has neuroprotective effects in models of both global and focal ischemia. These experiments were conducted to determine if fosphenytoin would decrease the size of ischemic damage in a distal model of middle cerebral artery (MCA) occlusion and decrease the neurological deficits caused by a proximal MCA occlusion. In halothane anesthetized Fisher-344 rats the common carotid and ipsilateral MCA were occluded. Drug or vehicle was administered IV, 30 minutes and 24 hours post occlusion and the infarct was measured using TTC staining 48 hrs post surgery. In the distal MCA occlusion model fosphenytoin was tested at 17, 30, 56 and 100 mg/kg (n=12 per group) and significantly decreased the infarct volume at each dose by 22%, 35%, 39% and 26% respectively as compared to vehicle treated rats. In the proximal MCA occlusion model fosphenytoin was tested at 30 mg/kg and decreased the infarct volume by 37%. These animals were tested for neurological deficits by measuring the duration they remained on a 50° inclined plane. Fosphenytoin reduced the neurological deficits to sham levels as compared to vehicle treated rats. These experiments suggest that fosphenytoin reduces ischemic damage and may be useful in the treatment of human stroke.

CYCLOHEXIMIDE OFFERS PROTECTION AGAINST THE DELETERIOUS INFLUENCES OF ANOXIA IN THE RAT.

S. Papas, D. Hasboun*, V. Crépel*, P. Chinestra* and Y. Ben-Ari
INSERM Unit 29, 123 Bd. de Port-Royal, Paris, 75014, France

Forebrain ischemia in the rat results in decreased protein synthesis and delayed neuronal death (DND) in CA1 of the hippocampus. However, treatment of these rats with cycloheximide (CHX), a protein synthesis blocker, prevents DND in CA1 (Goto et al., 1990), implicating protein synthesis as a mediator of ischemic damage. We have now examined *in vivo* and *in vitro* effects of CHX on the influences of anoxia in the rat.

Adult male Wistar rats were subjected to forebrain ischemia (4-vessel occlusion model) for 30 min and monitored for 7 days. Rats were injected (i.p.) with saline or CHX (1.5 mg/kg) 1h before or after occlusion. CHX treatment prior to ischemia decreased ($p<0.05$, student' s t-test) weight loss (2.5 ± 11.0g vs. 28.5 ± 8.0g in controls, mean±SEM) and enhanced survival rate (73% vs. 48% in controls) of rats. Weight loss was similar to controls ($p>0.05$) and survival rate (25%) decreased in rats given CHX after occlusion. Hence, protein synthesis occurring during or within 1 h of insult may mediate *in vivo* effects of forebrain ischemia.

Effects of anoxia on CA1 field EPSPs in the presence of CHX were also examined. EPSPs in adult hippocampal slices incubated in Krebs (controls) or 60 uM CHX were subjected to various periods (3min 15s to 4min 30s) of anoxia (glucose-free Krebs,95%N_2/5%CO_2 perfusion) and their percent recuperation determined 20 min later. EPSP recuperation in control and CHX slices was similar for all ranges of anoxia, except 3min 45s. After this period, CHX treated slices exhibited a greater ($p<0.05$) recuperation ($57.5\pm17.0\%$) than controls ($11.0\pm11.0\%$). CHX may thus enhance CA1 resistance to anoxia, and some of its protective effects may occur in the hippocampus.

BMY 14802 IMPROVES BEHAVIORAL OUTCOME AFTER BILATERAL CAROTID OCCLUSION IN THE GERBIL.

S. L. Moon, K. E. Timko*, J. A. Stanley*, M.N. Duquette*. CNS Neuropharmacology, Bristol-Myers Squibb Co., Wallingford, CT 06492.

We have reported that BMY 14802 (Bristol-Myers Squibb) is effective in attenuating hippocampal histopathology when assessed by means of a rating scale to denote the severity of cell loss after a 15-min bilateral carotid occlusion followed by a 96hr survival period in the Mongolian gerbil. To determine whether significant histological protection translated into significant behavioral protection, preservation of function after occlusion was evaluated by a passive avoidance step-through task.

Animals received BMY 14802 (10, 25, 50, 100 mg/kg) or vehicle 1hr pre- and 1 hr postsurgery, and once/day for the next 3 days. On day 2 after surgery, animals were trained in the passive avoidance task: each animal was placed on a brightly lit runway leading into a darkbox containing an electrified floorgrid. Training consisted of two trials, 10min apart. Animals that failed to enter the box during training were disqualified. Behavioral performance was assessed 24hrs after training as the number of animals/dose group to reach a 2-min. latency criterion.

A statistically significant difference between sham-operated and occluded controls indicated that this test is a behaviorally sensitive measure of impairment induced by forebrain ischemia. The results with BMY 14802 yielded $r=-0.95$ for group mean hippocampal damage vs. group passive avoidance score. BMY 14802 showed histological protection at all doses tested (10-100 mg/kg); however, only the 50mg/kg group performed significantly better than occluded controls while also not differing statistically from sham-operated controls on the passive avoidance task. These results are compared to some other putative neuroprotective agents.

DIAZEPAM FOLLOWING CEREBRAL ISCHEMIA PRESERVES CA1 PYRAMIDAL CELLS AND $GABA_A$ RECEPTORS OF THE HIPPOCAMPUS.

Robin A. Huff* and Rochelle D. Schwartz, Dept. of Pharmacology, Duke University Medical Center, Durham, NC 27710.

Cerebral ischemia-induced neuronal injury in selectively vulnerable areas is associated with excessive excitatory neurotransmission. We investigated whether enhancement of inhibitory neurotransmission could protect hippocampal neurons from ischemic damage in gerbils subjected to bilateral carotid occlusion (BCO) for 5 minutes. Diazepam (DZ), a drug that enhances GABA neurotransmission, was injected into sham-operated and occluded gerbils during the reperfusion phase. Post-ischemic hyperactivity was measured as a predictor of CA1 hippocampal damage 1 day following the occlusion. Seven days after the occlusion, CA1 damage was assessed by histologic procedures, and the distribution of the $GABA_A$ receptor-gated chloride channel was assessed by [^{35}S]TBPS autoradiography. One day following BCO, gerbils showed a robust increase in locomotor activity, while BCO gerbils that received DZ failed to show this hyperactivity. Histologic analysis revealed that DZ treatment also significantly protected CA1 pyramidal neurons from ischemia-induced degeneration. Autoradiography studies showed that [^{35}S]TBPS binding in the CA1 stratum oriens was significantly decreased following ischemia. DZ completely protected BCO gerbils from this loss of [^{35}S]TBPS sites. These results indicate that 1) DZ given after an ischemic insult is neuroprotective of CA1 pyramidal neurons, and 2) the neuroprotective effect of DZ prevents the loss of $GABA_A$ receptors residing on CA1 pyramidal cell dendrites. We conclude that enhancement of GABA neurotransmission following an ischemic event may limit excitatory neurotransmission and thereby avert neuronal death. Supported by the American Heart Association (R.D.S.). RDS is an Established Investigator of the American Heart Association.

ω-CONOPEPTIDES PREVENT DAMAGE TO CA1 NEURONS CAUSED BY GLOBAL ISCHEMIA.

K.L. Valentino, T. Gadbois*, T. Singh*, S. Bowersox*, S. Bitner, A. Justice, L. Nadasdi*, G. Miljanich, and J. Ramachandran*. NEUREX Corporation, Menlo Park, CA 94025.

Synthetic ω-conopeptides (see abstract by Miljanich et al. for description) bind specifically to N-type calcium channels and block release of neurotransmitters. We have tested several peptides of this class, including some with novel structures, to determine if they are neuroprotective in the unanesthetized rat 4 VO model of global ischemia. Damage in the CA1 region of the hippocampus was determined semi-quantitatively in hematoxylin and eosin stained frozen sections 5 days following the 15 minute ischemic insult. Conopeptides were effective when administered into the lateral ventricle immediately following ischemia, by IV bolus injection up to 1 hour post ischemia, and via a 90 minute IV infusion post occlusion. Damage was decreased significantly from vehicle control values, and also compared to the non-competitive NMDA antagonist, MK-801. This work demonstrates the efficacy of the ω-conopeptides in global models of ischemia and suggests that presynaptic blockade of neurotransmitter release could be an important mechanism in preventing cell death.

425.11

DYNORPHIN A(1-13) IMPROVES OUTCOME FOLLOWING THREE VESSEL OCCLUSION IN THE CAT.

M.A. Widmayer*, J.L. Browning and D.S. Baskin*. Department of Neurosurgery, Baylor College of Medicine and Research Service Houston VAMC, Houston, Texas 77030.

Treatment of experimental stroke with opiate agonists has provided variable data. Previous models of focal ischemia involved occlusion of only the middle cerebral artery (MCA). In the current study, 20 cats underwent occlusion of 2mm of the right MCA, anterior cerebral and intracranial internal carotid arteries. Six hours post-occlusion half of the cats received an injection of 2mg/kg dynorphin A(1-13) (DYN) and a subcutaneous, 50ug/hr DYN osmotic pump, and half received saline (SAL). Cats were sacrificed on the eighth post-operative day and their brains stained with TTC.

Survival was 10% for SAL and 50% for DYN. Abnormally stained tissue was categorized into infarct (colorless) and ischemia (lightly stained). There was less infarcted tissue present in the DYN treated group. For example, at the level of the optic chiasm, the brain consisted of 67% infarct and 7% ischemia for SAL cats, and 43% infarct and 20% ischemia for DYN cats. Brainweight (edema) was higher in the SAL than in the DYN cats (20.8g vs 17.8g) The data suggests that tissue that would have been infarcted without treatment, recovered following DYN treatment. Our data is consistent with the theory that kappa opioid receptor agonists have a therapeutic anti-edema effect in cerebral ischemia. The three vessel occlusion model shows promise as a model for experimental stroke.

ANOXIC DEPRESSION OF NEOCORTICAL SYNAPTIC POTENTIALS.

A.S. Rosen and M.E. Morris. Department of Pharmacology, University of Ottawa, Ottawa, Canada K1H 8M5.

During the depolarization (AD) which brief anoxia (5 min) evokes in pyramidal neurons of layers II-III of rat neocortical slices (*Rosen & Morris 1991, Neurosci. Lett. 124:169*) both EPSPs and IPSPs are depressed. The early (*e*) EPSP is decreased by 50-75% at 5 min, while the late (*l*) EPSP is abolished within the first 2 min; persistence of these changes during temporary V_m restoration indicates a mechanism distinct from their post-synaptic occlusion by AD. EPSP amplitude fully recovers at 6-8 min of reoxygenation. Evoked IPSPs disappear even sooner than the *l* EPSP and their recovery is more delayed.

When temperature is changed from a control level of 33.5° C to 30° or 37° warming depolarizes the membrane slightly and reduces the amplitude of both EPSPs and IPSPs. Cooling reduces and delays anoxic-evoked depression of post-synaptic potentials and hastens recovery; warming has opposite effects. The peak amplitude of AD is not significantly altered, although the rising phase is slower at 30°. These findings show that in the neocortex anoxia produces a consistent depression of synaptic transmission, which can be opposed by hypothermia.

PROTECTIVE EFFECTS OF BRAIN HYPOTHERMIA ON BEHAVIOR FOLLOWING GLOBAL CEREBRAL ISCHEMIA IN RATS. F. vanDijk*, E. J. Green, W.D. Dietrich, R. Busto, P.M. McCabe, C. G. Markgraf, M. Y-T. Globus, O. Alonso, M. D. Ginsberg, and N. Schneiderman. Dept's of Psychology and Neurology, University of Miami, Coral Gables, FL 33124.

Histopathological studies indicate that mild brain hypothermia can attenuate the neuronal and microvascular injury following transient global ischemia in rodents (e.g., Busto et al.,1987). Although histopathological measures can provide a general index of the ultimate neurological status of an animal, they do not reveal the functional integrity of an affected brain region. The present study evaluated whether mild brain hypothermia can influence behavioral outcome following ischemia induced by transient 4 vessel occlusion (4VO).

Wistar rats were subjected to one of three surgical procedures: a) 4VO with hypotension (80 mm Hg) for 12 1/2 minutes at a brain temperature of 36° C (4VO-36); b) 4VO with hypotension for 12 1/2 minutes at 30° C (4VO-30); and c) SHAM surgical procedures. Reflexes and sensorimotor function were evaluated between post-operative weeks 2 and 4. Beginning in week 5, the rats were trained in two tasks using a water maze: the simple place task, in which the hidden platform was kept in a fixed location, and the "learning set" paradigm, in which the platform was moved daily (e.g., Auer et al., 1989).

Histopathological examination of the tissue 7-8 weeks post-surgery revealed that 4VO-36 rats had substantial pyramidal cell death in subfield CA1 of the septal 2/3 of the hippocampus, and sparse damage in the dorsolateral neostriatum and neocortex. 4VO-30 rats showed only minimal necrosis in CA1, neostriatum and cortex. There were no group differences in any of the sensorimotor measures or in performance on the simple place task. In contrast, during acquisition of the more complex learning set task, the performance of 4VO-36 rats was significantly impaired relative to either of the other groups. The performance of 4VO-30 rats did not differ significantly from the SHAM rats. These data confirm the finding that global cerebral ischemia impairs behavioral performance in the water maze, and suggest that mild brain hypothermia can provide protection from behavioral deficits induced by global ischemia. POSTISCHEMIC HYPOTHERMIA PRODUCED BY MK-801 ACCOUNTS FOR SOME, BUT NOT ALL, OF ITS NEUROPROTECTIVE ACTION. R.E. Minahan*, K.H. Neill*, B.J. Crain and J.V. Nadler. Depts. Pharmacology, Pathology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

The ability of the NMDA receptor antagonist MK-801 to protect brain neurons against ischemic damage has been attributed by some investigators to a reduction in postischemic brain temperature. We reported previously that MK-801 (10 mg/kg) initially reduces postischemic brain temperature and then usually causes brain temperature to oscillate between hypothermic and normothermic-to-hyperthermic. To determine the extent to which this postischemic temperature pattern accounts for the neuroprotection obtained with the drug, we utilized a novel system that permits brain temperature to be monitored and regulated in a conscious gerbil. We selected representative postischemic brain temperature patterns that were associated with either complete protection of CA1 hippocampal pyramidal cells by MK-801, average protection or no protection and simulated each pattern in the absence of drug. Intraischemic brain temperature was maintained at 35.8 °C and intraischemic rectal temperature at 36.5 °C. The postischemic temperature patterns associated with average or complete protection partially prevented the degeneration of CA1 pyramidal cells, but not to the extent that pretreatment with MK-801 did. In addition, when MK-801 was administered before simulating a temperature pattern associated with either complete or no protection, additional CA1 pyramidal cells were spared.

These results support the view that MK-801 protects neurons from ischemic damage partly through reducing postischemic brain temperature. However, the drug also exerts a robust neuroprotective action that appears to be independent of postischemic brain temperature. (Supported by NIH grant NS 06233.)

425.15

INTRAISCHEMIC BRAIN TEMPERATURE, POSTISCHEMIC BRAIN TEMPERATURE AND NEUROPROTECTION BY MK-801. K.H. Neill*, R.E. Minahan*, B.J. Crain and J.V. Nadler. Depts. Pharmacology, Pathology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Intraischemic and postischemic brain temperatures have been shown to influence the extent of ischemic brain damage and the neuroprotective action of MK-801. We have investigated this relationship in gerbils subjected to a 5-min bilateral carotid occlusion. MK-801 (10 mg/kg) or saline was administered either 1 h before or 30 min after ischemia. During the occlusion, rectal temperature was maintained at 36.5 °C and the brain was maintained at either 35.8 or 36.5 °C. When the intraischemic brain temperature was 36.5 °C, degeneration of CA1 hippocampal pyramidal cells correlated only with the difference between the preischemic baseline and the mean brain temperature for the first 30 min after ischemia. Lowering intraischemic brain temperature to 35.8 °C produced the following changes. (1) MK-801 more effectively protected CA1 and neocortical pyramidal cells. (2) The value of brain temperature 3-6 h after reperfusion became at least as important as brain temperature soon after reperfusion. (3) If the mean postischemic brain temperature was ≤ 36 °C, there was minimal CA1 damage. However, MK-801 achieved this degree of hypothermia in only a minority of animals. (4) Correlations between neocortical damage and postischemic brain temperature could also be demonstrated.

These results demonstrate that factors which influence ischemic brain damage - intraischemic brain temperature, postischemic brain temperature and treatment with MK-801 - are highly interactive. Maintaining intraischemic brain temperature at a nearly physiological value diminishes both the influence of postischemic brain temperature on ischemic damage and the neuroprotective action of MK-801. ISCHEMIA-INDUCED NEUROTRANSMITTER RELEASE: EFFECTS OF MILD INTRAISCHEMIC HYPERTHERMIA. L.L. Sternau, M.Y.-T. Globus, E. Martinez, W.D. Dietrich, R. Busto, and M.D. Ginsberg. Cerebrovascular Disease Research Center, Univ. of Miami School of Medicine, Miami, FL, 33101.

Elevated brain temperature may adversely influence the outcome of an ischemic insult. Using microdialysis, we examined neurotransmitter release in rats subjected to 20 min of forebrain ischemia by 2-vessel occlusion plus hypotension (45 mmHg). In Group 1 (n=5), intraischemic brain temperature (BT) was maintained at 37°C . In Group 2 rats (n=6), BT was raised to 39°C by a warming lamp over the head. Striatal extracellular fluid was sampled by microdialysis 30 min prior to and during ischemia, and for 4 hr following recirculation. Dialysate levels of GABA, glycine and glutamate were measured by HPLC. During ischemia, there was a 41-fold rise in GABA at 37°C and a 50-fold rise at 39°C . Glycine levels increased 3-fold in Group 1 and 7-fold in Group 2 during ischemia and remained high during recirculation. Glutamate levels rose 21-fold in Group 1, but in Group 2 there was a 37-fold rise over baseline. The excitotoxic index, reflecting the net influence of excitatory and inhibitory neurotransmitters (glycine x glutamate/GABA), was elevated only 2-fold during recirculation in Group 1, but in Group 2 there was a 20-fold increase over baseline. We conclude that mild cerebral hyperthermia imposed during transient cerebral ischemia increases extracellular levels of excitatory amino acids. This is consistent with the detrimental effect of hyperthermia on ischemic neuropathology and microvascular function.

425.17

ROLE OF HYPOTHERMIA IN MULTIPLE CEREBRAL ISCHEMIC INSULTS. B. Lin, W.D. Dietrich, M.Y.-T. Globus, R. Busto, and M.D. Ginsberg. Cerebral Vasc. Dis. Research Center, Univ. of Miami School of Medicine, Miami, FL, 33101.

To evaluate the cerebroprotective effect of hypothermia for repeated ischemic insults, we subjected male Wistar rats to three 5-min periods of global forebrain ischemia (by bilateral carotid artery occlusions plus hypotension to 50 mmHg), separated by 60-min periods of normotensive recirculation. Rectal temperature was held at 37.0-37.5°C . In Group A (n=5), *brain* temperature (BT), measured by a thermistor in frontal cortex, was thermostated at 36.5-37.0°C throughout. In Group B (n=6), BT was held at 36.5-37.0°C during ischemia but was reduced to 30°C for 30 min following the first insult, and for 60 min following the third insult. Ischemic cell change was graded blindly, on a 0-3 scale following 7-day survival. In area CA1 of hippocampus, Groups A and B showed moderate-to-severe ischemic changes in 4/5 and 5/6 brains, respectively. The range of injury-grades in somatosensory neocortex and thalamus was also similar for Groups A and B. In dorsolateral striatum, there was a trend toward lesser injury-grade in Group B rats (median 0.5-1) than in Group A (median 1.5). In 2 and 3 rats of Group B, respectively, the striatum and thalamus showed marked side-to-side differences in injury-grade. Although early postischemic cerebral hypothermia (30°C) reduces neuronal damage following a *single* 10-min period of ischemia (Busto et al, Neurosci Lett 101:299,1989), the present data suggest that multiple normothermic insults may be more resistant to protection.

PRE- BUT NOT POSTEXPOSURE MILD HYPOTHERMIA PROTECTS AGAINST HYPERGLYCEMIC ANOXIC BRAIN INJURY

K.R. Wagner, M. Kleinholz*, G.M. deCourten-Myers*, R.E. Myers. Research Serv., DVAMC; Depts. Neurol. & Pathol., U. Cinc. Coll. Med., Cincinnati, OH 45220.

Hyperglycemic animals with normal core (38°C) and brain (36°C) temperatures at systemic anoxia develop neurologic signs including seizures and show diffuse brain injury with marked neuronal loss and glial and capillary proliferation upon long-term survival. In contrast, identically exposed hyperglycemic animals which are mildly hypothermic (core and brain temperatures = 33 and 32°C, respectively) are remarkably brain protected, remaining neurologically and neuropathologically intact. The cerebral cortex in both groups shows similar marked elevations of lactic acid (>25 μmoles/g) and reductions in high energy phosphates at the end of anoxia. Rapid reduction of brain temperature to 32°C following normothermic hyperglycemic anoxia fails to prevent postanoxic neurologic signs and brain injury. In conclusion, mechanisms underlying the development of diffuse brain injury from hyperglycemic anoxia are activated at anoxic exposure and can be prevented by mild hypothermia prior to but not following exposure. HYPOTHERMIA PROTECTS SOMATOSTATIN NEURONS IN RAT DENTATE HILUS FROM ZINC ACCUMULATION AND FAST ISCHEMIC CELL DEATH. F.F. Johansen, N. Tønder[1], J. Zimmer[1], N.H. Diemer. PharmaBiotec Research Center: Institute of Neuropathology, University of Copenhagen, and [1]Institute of Neurobiology, University of Aarhus, Denmark.

We have previously shown that somatostatin containing neurons in the rat dentate hilus are highly susceptible to ischemic brain damage. Within 48 hours after ischemia they demonstrate fast ischemic cell death. Simultaneously, we have shown that necrotic cells in dentate hilus accumulate free zinc in their cytosol. We have now demonstrated directly that somatostatin containing cells in dentate hilus also accumulate zinc during maturation of fast ischemic cell death. Since it is known that hypothermia ameliorates ischemic brain damage, we studied whether hypothermia (29° Celsius) protected the highly susceptible somatostatin containing neurons in dentate hilus from ischemic cell death and zinc accumulation. It was demonstrated that hypothermia during cerebral ischemia prevented cell necrosis and neuronal zinc accumulation in dentate hilus. Hypothermia possibly prevents excitotoxic glutamate release and associated translocation of zinc from the glutamatergic mossy fiber terminals to the vulnerable somatostatin containing cells during ischemia. We find it less likely that zinc is released from intracellular binding sites during ischemic cell death, because neurons located outside the mossy fiber layer do not show zinc accumulation during necrosis.

LIMITS OF HYPOTHERMIC PROTECTION OF HIPPOCAMPAL NEURONS DURING CARDIAC ARREST IN THE NEONATAL PIG D.T. Ross,[1] L.N. Sutton,[1*] E. Woodford,[2*] C. Norwood,[2*] and W.I. Norwood,[2*] B.J. Clark[2*] [1]Division of Neurosurgery, University of Pennsylvania, and [2]Dept. of Cardiothoracic Surgery, Children's Hospital of Philadelphia, Philadelphia, PA 19104

Hypothermia has a profound neuroprotective effect on the prevention of neuronal loss following ischemia. Results from a rodent global ischemia model (Brain Res 512:169-174, 1990) suggest that this protection is only relative; once a critical threshold duration is exceeded, selectively vulnerable structures such as the hippocampal CA1 are no longer protected. Since prolonged periods of hypothermic cardiac arrest are integral parts of pediatric open heart surgery, we sought to establish whether these procedures result in neuronal loss from vulnerable brain structures.

Neonatal (21 day old) pigs were anesthetized with Nembutal, placed on cardiopulmonary bypass, cooled to body temperatures of 15-20°C, and the bypass pump then turned off. The pump was restarted 45 minutes to an hour later, the animal taken off bypass, and its incisions closed. Animals survived for 7 days prior to sacrifice by nembutal overdose and transcardial perfusion with 4% paraformaldehyde. Brain sections were cut at 40μm and stained with cresyl violet.

Extensive neuronal loss was seen in the CA1 region in 2/6 hippocampi from cases which sustained 45 minutes of cardiac arrest at 20°C. Longer durations of cardiac arrest (1 hour) at colder temperatures (15-18°C) produced scattered patches of selective neuronal loss in the CA3 region in 2/6 hippocampi. All cases had evidence of partial loss of neurons from the regions of CA4 proximal to the granule cell layer. A partial loss of neurons from the rostral portion of the thalamic reticular nucleus was also evident in some cases. These results suggest that hypothermic neuroprotection alone may not be sufficient to prevent the loss of neurons from selectively vulnerable structures during open heart surgery. Augmentation with the prophylactic administration of pharmacological agents may be necessary for insuring complete neuroprotection during intra-operative ischemia.

COGNITIVE DEFICIT AS A RESULT OF CEREBRAL ISCHAEMIA. S.Hogg*J.M.Barnes*,B.Costall*,P.L.Irving*,M.E.Kelly* and J.R.McCurrie*. (SPON: European Neuroscience Association) Studies in Pharmacology, School of Pharmacy, University of Bradford, Bradford, BD7 1DP, UK.

We have reported a cognitive deficit in a spatial learning task as the result of carotid occlusion (Barnes et al, 1990). Here we assess the effects of an ischaemic insult on brain biochemical and histological parameters.

Lister-hooded rats underwent 45 min bilateral common carotid artery occlusion under ketamine anaesthesia (100mg/kg). 7 days later they were either tested in a swim maze task or sacrificed for choline acetyltransferase (ChAT) analysis (Fonnum, 1975) or haematoxylin and eosin (H & E) staining.

Carotid occlusion resulted in a loss in learning ability (escape latencies for sham and occluded 14.5±2.18 and 54.2±4.3s respectively, P<0.001, one way ANOVA). ChAT activity (sham and occluded) was only reduced in striatum and tuberculum olfactorium (779.0±64.8 to 465.5±50.5 and 504.9±52.3 to 352.2±20.0 nmol/min/mg protein, P<0.05,t-test) whilst H&E staining showed no change in density of hippocampal neurones.

Therefore the loss of learning ability in the rat following an ischaemic insult is not necessarily correlated with changes in ChAT activity or cell loss.

IMPAIRED WATER MAZE ACQUISITION FOLLOWING CA1 ISCHEMIC DAMAGE IN THE GERBIL. D. Corbett, S. Nurse*, S. Evans* and D. W. McKay. Fac. of Medicine, Memorial Univ., St. John's, NF, CANADA A1B 3V6.

The Morris water maze is a sensitive test of spatial learning that has been used to document deficits in rats that have extensive loss of CA1 neurons induced by forebrain ischemia (Auer et al., 1989). Similarly, we have found this test to be effective in gerbils subjected to carotid artery occlusion.

Gerbils were given 5 days (4 trials / day) of swim training (to a visible platform) in a circular pool filled with warm water. The next day, the gerbils were exposed to 5 min carotid occlusions under Halothane anesthesia (N =12) ; sham surgery (N = 6) or left intact (N =6). Water maze acquisition took place 2 days later in a different testing room using a hidden platform and several conspicuous visual stimuli that were attached to the walls of the maze. Ischemic gerbils were slower to acquire the water maze task ($F = 6.00$, $p < .025$) than sham/normal gerbils although they eventually (7-10 days) learned to locate the platform. The Morris water maze has potential as a functional test in studies of cerebral ischemia in gerbils.

426.3

REMACEMIDE EFFECTS ON MEMORY AND HIPPOCAMPAL CA1 NEURONAL DAMAGE IN THE RAT FOUR-VESSEL OCCLUSION (4-VO) MODEL OF GLOBAL CEREBRAL ISCHEMIA. J.M. Ordy, G.J. Thomas, P. Bialobok*, T.M. Wengenack, R.J. Murray*, and W.P. Dunlap*. Fisons Pharmaceuticals, Rochester, NY 14623, Univ. of Rochester, Rochester, NY 14642, Tulane Univ., New Orleans, LA 70118.

Clinical studies have reported memory impairment and selective loss of hippocampal CA1 neurons after global ischemia. Significant memory impairment with selective CA1 cell damage have also been observed in the rat 4-VO model of global ischemia. The concordant pathophysiology of memory impairment and CA1 cell damage in man and in the rat 4-VO model have suggested that the 4-VO model could be useful for evaluation of "neuroprotective" efficacy of novel compounds after global ischemia. Remacemide, (±) 2-amino-N-(1-methyl-1,2-diphenylethyl)-acetamide, is an anticonvulsant currently in Phase II clinical trials. The desglycinated metabolite of remacemide is a non-competitive NMDA antagonist. The effects of remacemide were evaluated functionally in terms of neuroprotective effects on memory of 4-VO memory-impaired rats in a T-maze, and morphometrically, by evaluation of cell damage in stereotaxically comparable CA1 regions. Remacemide, at 20 mg/kg, or saline was administered i.p. at 1 hour post-4-VO, and then once daily for either 14 or 21 days, depending on the study design. Statistical comparisons of remacemide or saline-treated 4-VO rats indicated significant improvement of 4-VO memory impairment and reduction of CA1 cell loss in the remacemide-treated animals. Comparisons of remacemide with the non-competitive NMDA receptor antagonist, MK-801, were made on CNS safety profile studies in non-ischemic rats. Remacemide produced no significant effects on memory, psychotomimetic signs, sensory-motor functions, body temperature, blood glucose, or corticosterone levels. In contrast, MK-801 produced adverse effects on these same variables which would exacerbate ischemic CA1 neuronal damage.

426.4

GLOBAL ISCHAEMIA PRODUCES DEFICITS IN SPATIAL LEARNING AND MEMORY IN THE WATER MAZE BUT NOT IN THE RADIAL-MAZE. JA Nunn, E Le Peillet,* CA Netto,* P Sowinski,* H Hodges,* BS Meldrum and JA Gray*, Departments of Psychology and Neurology, Institute of Psychiatry, London SE5 8AF, UK

We have previously shown that both 15 and 30 min 4-vessel-occlusion ischaemia (4VO ISC) in the rat produce equivalent deficits in learning and memory in a water maze place task and are accompanied by >90% hippocampal CA1 cell loss. The present study compared the effects of 15 and 30 min 4VO ISC on water maze (WM) and radial-maze (RM) performance. The first test (WM: 7 wks post-op) confirmed that comparable spatial deficits are seen after both 15 and 30 min ISC. In ISC rats latency to find the platform was increased relative to controls during acquisition ($p<0.01$), whilst time spent in the quadrant containing the platform was reduced ($p<0.01$). Both ISC groups showed an equivalent deficit in retention of the platform location in a probe trial. All rats were tested on place and cue tasks in the radial-maze (10-25 wks post-op); no behavioural deficits were seen. Rats were retested on reversal learning in the WM (26 wks post-op). ISC spatial deficits were similar to those seen in the first WM test. These data indicate that ISC can impair WM performance but spare RM performance. The requirement for more accurate use of allocentric spatial cues and the higher motivational demands of the WM may explain the difference between the two tasks. Since WM learning was still impaired after RM testing, recovery as a function of time or training cannot explain the lack of RM deficits.(Supported by the Wellcome Trust and the British Heart Foundation)

426.5

4-VO INDUCED ISCHEMIA RESULTS IN CA1 CELL LOSS AND IMPAIRED 14-UNIT T-MAZE PERFORMANCE. E. Spangler[1], J. Ordy[2], P. Bialobok[2], G. Thomas[2], P. Garofalo[1], T. Wengenack[2], J. Hengemihle[1], M. Jucker[1], M. Talan[1], D. Ingram[1]. [1]Gerontol. Res. Ctr., NIA, NIH, Baltimore, MD 21224 and [2]Fisons Pharmaceut. Rochester, NY 14623

The four vessel occlusion (4-VO) model (Pulsinelli & Brierly, *Stroke*, 10: 267, 1979) of transient, global ischemia produces neuronal loss in hippocampus (HC), particularly CA1, and memory impairment in a variety of tasks. We used this model to assess the effect of CA1 damage in young rats on learning in a 14-unit T-maze that has provided robust evidence of age-related memory impairment (Ingram, *Neurobiol. Aging*, 9:475, 1988). Rats received either 15-min of 4VO ischemia, temperature maintained at 37.5°C during reperfusion, or were in an operated control (CON) group. Rats were trained 2 wk later in one-way active avoidance in a runway (0.8mA; criteria = 13/15 correct avoidances). Rats were given 15 trials in the complex maze the next day. With the maze divided into 5 segments, the rat had to move through each segment within 10 sec to avoid footshock (0.8 mA) while negotiating a series of 14 left-right turns enroute to the goal box. 4-VO rats had significantly higher scores than CON rats in 3 measures of maze performance: errors, alternation errors, and runtime (p's < 0.05) but were not markedly affected in shock frequency or duration measures. Six wk after maze training, rats were sacrificed to assess HC cell death. Estimation of relative cell density (thionin Nissl stain) measured by automated image analysis revealed significant cell loss in CA1 in 4-VO rats compared to CON, $p<0.05$. No difference in acetylcholinesterase staining density in CA1 between groups was observed, $p>0.05$. Mean error score/trial in 4-VO rats was correlated with relative CA1 cell density, $r=-0.62$. Subsequent ratings of CA1 neuropathology yielded a correlation of 0.67 with maze errors. The utility of this model in evaluating age-related impairments in tasks such as the 14-unit T-maze are suggested by the present findings.

CHANGES IN SYNAPTOPHYSIN LEVELS FOLLOWING ISCHEMIC INSULT. R.P. Stroemer, T.A. Kent and C.E. Hulsebosch. Depts. of Anat. and Neurosci., Marine Biomed. Inst., Neurol., Univ. of Texas Med. Br., Galveston, TX 77550.

Synaptophysin, a calcium binding protein, is present in presynaptic endings. Changes in the density of synaptic numbers and density are believed to be reflected in the amount of synaptophysin present. Using immunohistochemistry, The amount of synaptophysin is measured in the cortex in hypertensive and normotensive rats following ischemia. The insult is produced by permanent occlusion of the middle cerebral artery and the ipsilateral common carotid artery. Changes in synaptophysin are examined at time points of 3 days to 2 months following ischemia. We hypothesize that the differences in synaptophysin levels reflect the plasticity of the cortex following ischemia. SPATIAL RESOLUTION OF K^+o AND CBF DERANGEMENT DURING MCA OCCLUSION IN RAT NEOCORTEX. Z.-C. Feng, T.J. Sick and M. Rosenthal. Dept Neurology, University of Miami School of Medicine, Miami, Fl. 33010.

Focal cerebral ischemia may produce a penumbral area outside of the ischemic zone with suppressed electrical activity but preserved ion homeostasis. To better understand focal ischemia-induced pathophysiology of brain, present studies sought to spacially resolve extracellular potassium ion activity (K^+o) and cerebral blood flow (CBF) during middle cerebral artery occlusion (MCAo) in exposed neocortex of rats anesthetized with pentobarbital. K^+o and CBF were monitored at multiple sites along the cortical surface from the MCA clamp toward the midline of the brain by ion selective and polarographic (hydrogen clearance) microelectrodes implanted approx 500 μ within the cortical gray mantle. At 1-3 mm medial from the MCA clamp, blood flow was reduced approx 75% and K^+o was elevated to the 50-80 mM levels characteristic of anoxic depolarization (AD) This situation persisted for 3 hours after MCAo. Approx 7-8 mm medial from the clamp, blood flow and K^+o were unchanged by MCAo during this period. Between these zones, intermediate CBF and K^+o levels (the latter in the range of 20-35 mM) were recorded at 30 and 90 min following MCAo. At 180 minutes, however, these intermediate zones were less evident as K^+o often increased in areas closer to the ischemic core to levels characteristic of AD while K^+o sometimes decreased in loci adjacent to normal sites. The presence of intermediate K^+o levels is unusual since regenerative spreading depression-like like depolarization often accompanies elevation of K^+o beyond approximately 10-15 mM. Identifying factors limiting K^+o in intermediate zones during focal ischemia may provide new insights toward salvaging tissues after such insults.

Near-term foetal rats resist hypoxic neuronal injury. L. Kendall*, S.P. Butcher* & J.S. Kelly, (SPON: Brain Research Association), Department of Pharmacology, University of Edinburgh, U.K.

Hypoxic and ischaemic insults during the perinatal period are known to be a major cause of non-progressive neurological deficits in humans. We have developed a model of perinatal hypoxia in anaesthetized rats which involves occlusion of the uteroplacental vessels of one uterine horn. After an occlusion period of 10, 20 or 30 minutes, which may or may not be followed by a reperfusion period, the pups are delivered by Caesarian section. The pup brains are extracted at 0, 1, 60 or 180 minutes for analysis of metabolites. The remaining pups are resuscitated then cross-fostered onto lactating dams and perfusion fixed at a later date for histological analysis. Following the most severe insult, a 30 minute occlusion, brain tissue levels of lactate are elevated from 6.1 $\pm$ 0.5 nmols/mg to 22.2 $\pm$ 1.5 nmols/mg tissue, ATP and phosphocreatine levels are reduced from 2.4 $\pm$ 0.3 nmols/mg to 0.9 $\pm$ 0.3 nmols/mg and from 1.0 $\pm$ 0.2 nmols/mg to 0.3 $\pm$ 0.2 nmols/mg tissue respectively. Histological investigations showed little or no damage 4 hours after the hypoxic insult however four to seven days post-insult discrete damage can be identified in some areas in the hind brain region.

REPRODUCIBLE ISCHEMIC CORTICAL LESIONS IN RATS BY PHOTOTHROMBOSIS OF THE DISTAL MIDDLE CEREBRAL ARTERY. C.G. Markgraf, S. Kraydieh*, R. Prado*, B.D. Watson*, W.D. Dietrich and M.D. Ginsberg. Cerebral Vascular Disease Research Center, Univ. of Miami Sch. of Med., Miami, FL 33101.

To model accurately the clinical disorder of human thrombotic stroke, the present study used a photochemical reaction to induce focal thrombosis of the distal middle cerebral artery (dMCA) in two strains of rats. Male Wistar (n=9) and Sprague-Dawley(n=12) rats were anesthetized and prepared with arterial and venous catheters. The right dMCA was exposed above the rhinal fissure. After i.v. injection of rose bengal, a potent photosensitizing dye, thrombosis was induced by irradiating the vessel with 20 mW from an argon laser-activated dye laser tuned to 562 nm. The right common carotid artery (CCA) was then permanently occluded and the left CCA was temporarily occluded for 60 min. Animals were perfusion-fixed 3 days later and infarct volume was determined. Infarcts of the right cortex varied in size by strain. Sprague-Dawley rats had significantly larger cortical infarct volumes ($\bar{x}$ $\pm$S.E.=116.29 $\pm$ 17.35 mm^3) than did Wistars ($\bar{x}$ $\pm$ S.E.=47.88 $\pm$ 8.86 mm^3). Blood pressure (BP) and pCO_2 did not differ between groups either before dMCA occlusion, during or after CCA occlusion. BP and infarct volume were significantly correlated, and showed that differences in BP accounted for 15.4% of the variability in size of infarcts. Mortality was 9%, similar to other models of distal MCA occlusion. The advantages of the present model are the reproducibility and consistency of cortical infarcts, the relative ease of the surgical procedure, and that the photothrombosis is less invasive than mechanical occlusion while it more realistically simulates the pathophysiological events of a thrombotic stroke in humans. Supported by NS-05820, NS-22603 and NS-23244.

EARLY CHANGES IN HIPPOCAMPUS FOLLOWING TRANSIENT GLOBAL CEREBRAL ISCHEMIA IN MONGOLIAN GERBILS. E. Fadda, S. Romanello*, M. Santi, R. M.M. Zanellato*, R. Arban*, Dal Toso, and S. Mazzari. Fidia Research Labs, 35031 Abano Terme, Italy.

A selective neuronal death (SND) in the CA_1 hippocampal region occurs within 3-4 days after a transient episode of global cerebral ischemia. We monitored, in Mongolian gerbils, hippocampal MK-801 binding sites and GFAP mRNA following 1 and 5 min of bilateral carotid artery occlusion, at both 24 and 72 hr of reperfusion. MK-801 binding sites were significantly reduced (-30%) within 24hr after 5 min of ischemia. GFAP mRNA levels dramatically increased, reaching a plateau (10-fold increase) at 24hr of reperfusion following 5 min of ischemia. No significant modifications of these indexes were seen following 1 min of ischemia, nor were there any evident histopathological changes (i.e. Nissl staining) in the hippocampal CA_1 area. These findings indicate that SND is associated with relatively rapid biochemical changes in the hippocampus in both neurons and glial cells, thus facilitating SND detection and quantification.

NEUROPATHOLOGICAL CORRELATES OF MAGNETIC RESONANCE IMAGES OF ISCHEMIC DAMAGE IN A BABOON MODEL OF CEREBRAL ISCHEMIA. C.A. Pardo, L.H. Monsein*, V.P. Mathews*, P.B. Barker*, S.J. Blackband* and R.N. Bryan. Neuropathology Laboratory, Department of Pathology, and Division of Neuroradiology, The Johns Hopkins University School of Medicine, Baltimore, Maryland 21205

A baboon model of regional ischemia of the middle cerebral artery was developed to evaluate cerebral metabolism in the early postischemic period with magnetic resonance imaging (MRI), proton magnetic resonance spectroscopy (MRS), and neuropathology. Histological and immunocytochemical analysis (i.e., phosphorylated and nonphosphorylated neurofilaments, MAP2, calbindin, and parvalbumin) were used to evaluate morphological changes. Abnormal signal intensity was seen as early as 30 minutes with MRS, 3.12 hours with T2 weighted, 3.32 hours with T1 weighted, and 4.92 hours with spin density images. Neuropathological evaluation 18 hours after occlusion demonstrated regional dysruption of myelin and neuronal necrosis that correlated with MRI signal changes. However, additional neuronal changes, such as immunoreactivity for calbindin and phosphorylated neurofilaments, and loss of immunoreactivity for MAP2 were detected in a greater area than shown by MRI. In conclusion, MRI appeared to detect tissue necrosis but was less successful in detecting earlier changes of cell damage.

TEMPORAL RELATIONSHIP BETWEEN REACTIVE GLIOSIS AND NEURONAL NECROSIS IN POST-ISCHEMIC RAT HIPPOCAMPUS. C.K.Petito and I.A. Halaby. Dept. of Pathology and Neurology, Cornell University Medical College, New York, NY, 10021.

Since astrocytes may protect the brain from ischemia, this study tests the hypothesis that reactive astrocytosis develops prior to neuronal necrosis in CA1 neurons of post-ischemic hippocampus where cell death is characteristically delayed between 3 and 7 days. Cerebral ischemia for 2 or 10 min was produced by the 4-vessel occlusion rat model with reperfusion of 1 to 14 days, producing mild (2 min) or moderate-severe (10 min) CA1 necrosis. Astrocyte reactivity was evaluated by changes in glial fibrillary acidic protein (GFAP) and vimentin (Vim) and by incorporation of bromodeoxyuridine (BRDU) given 1 and 2 hours prior to sacrifice. Normal control(n=4) astrocytes were GFAP+, Vim-, and BRDU-. Increased GFAP preceded neuronal necrosis in 5 of 10 rats between 1 and 3 days after 10 min ischemia and in 5 of 6 rats between 3 and 7 days after 2 min ischemia. Vim+ astrocytes and BRDU + cells were present following 10 minutes of ischemia but rare after 2 minutes of ischemia. These results show that glial reactivity is proportional to the severity of neuronal necrosis. Furthermore, they indicate that reactive astrocytosis may precedes the development of neuronal necrosis in vulnerable CA1 neurons, especially when the ischemia is mild and the development of cell death is prolonged. Supported by NSO3346-30,NINCDS.

EARLY NEURONAL CHANGES IN THE GLOBAL CEREBRAL ISCHEMIA. K. Kawai, L. Nitecka, C. Ruetzler, J. Lohr, N. Saito, T.S. Nowak Jr. and I. Klatzo, Lab. of Neuropathology and Neuroanatomical Sciences, NIH, NINDS, Bethesda, MD 20892

In elucidation of the pathophysiology of global cerebal ischemia the early neuronal changes were studied in rats subjected to 10 minute cardiac arrest by compression of major cardiac vessels. The early neuronal changes were manifest in animals sacrificed 15 minutes after resuscitation and consisted in appearance of a clear peripheral zones in the cytoplasm of predominantly GABAergic neurons. After one hour these peripheral zones appeared to be compartmentalized into individual clear vacuoles and they were especially conspicuous in the n. reticularis thalami (NRT). The other neuronal populations showing similar changes were: n. dorsalis medialis thalami, n. centralis amygdalae, pars reticulata substantiae nigra, and hippocampal interneurons. Preliminary E.M. observations on the NRT neurons revealed peripheral vacuoles surrounded frequently by membranes, compatible with endoplasmic reticulum origin and the presence of well preserved mitochondria. The immunostaining for parvalbumin showed disappearance of specific staining of middle portion of the NRT in animals sacrificed 3 hours after resuscitation. Our observations suggest a possibility that early changes in GABAergic neurons may provide a period of disinhibition and thus contribute to an excitatory damage in regions connected by GABAergic circuitry.

426.14

Increased expression of mRNA encoding calbindin-D28K, the glucose-regulated proteins, or the 72 kDa heat-shock protein in three models of CNS injury. R.P. Gwinn*, M.S. Seren , R.P. Simon , T.K. McIntosh , M.J. Thomas*and D.H. Lowenstein , Epilepsy Res. Lab., Dept. of Neurology, UCSF, FIDIA Res.Labs, Italy, and Dept. of Surgery, U.CT. Health Ctr.

Changes at the level of gene expression are becoming an increasingly recognized component of the neuronal response to injury. We used Northern analysis and 3 *in vivo* models of CNS trauma in the rat to determine whether injury alters the expression of gene products potentially related to cellular homeostasis. The 3 models included: 1) seizures induced by 12 mg/kg IP kainic acid (KA), 2) 10 minutes of global ischemia following four vessel occlusion, and 3) focal fluid percussion injury to the cerebral cortex. Animals were sacrificed at various times after injury, and total RNA was isolated from specific CNS regions. Northern blots were hybridized with probes for calbindin-D28K, the 78 and 94 kDa glucose-regulated proteins (grp78 or grp94), the inducible 72 kDa heat-shock protein (hsp72), and a control probe for the 18S ribosomal subunit. Results show that mRNA for calbindin-D28K, grp78, grp94, and hsp72 increased in the hippocampus following seizures. Peak expression occurred 6-12hrs after administration of KA, and returned to baseline by 24hrs. Similar changes in all 4 transcripts were seen in the hippocampus and cortex following global ischemia, although the return to baseline tended to exceed 24hrs for the grps. In the focal trauma model, mRNA for hsp72 and grp78 was increased in the cortex and hippocampus ipsilateral to the impact 12 hours after injury.

These results expand the repertoire of known changes in mRNA expression following CNS injury. The increases in hsp72 and grps indicate the occurrence of a generalized stress response. Furthermore, given the evidence that grp78 and grp94 are induced by calcium ionophores *in vitro*, and the potential role of calbindin-D28K in buffering cytoplasmic calcium, the changes observed in this study may represent a cellular response to the perturbed calcium homeostasis that is common to all 3 forms of injury.

426.15

HEAT SHOCK AND TUBULIN mRNA IN POSTISCHEMIC BRAIN. K. Kumar, B.V. Madhukar. Departments of Pathology, and Pediatrics, Michigan State Univ, E. Lansing, MI 48824.

Recent evidence suggests that while total protein synthesis is reduced following brain ischemia, the expression of a family of heat shock proteins (HSP) may actually be enhanced in the postischemic (PI) brain during reperfusion. To examine the expression of HSP-70 in PI brain, and to compare it with that of tubulin, a protein abundant in neural tissue, ischemia was produced in gerbils by bilateral common carotid artery occlusion for 10 min and was followed by reperfusion for 6 and 24 h. The forebrains of PI and nonischemic controls (NIC) were processed for RNA extraction. The RNA from all 7 animals was analyzed for inducible HSP-70 sequences and for alpha-tubulin by Northern blot and hybridization by utilizing specific synthetic oligonuceotide probes. With the probe for HSP-70, no distinct hybridization bands were observed in the NIC, whereas a striking induction was evident in the 6 h PI group. Continued induction was present at 24 h. RNA for tubulin was expressed at high levels in the NIC as well as the 6 h and 24 h PI groups, with the trend of expression in PI brains toward an increase in comparison with the NIC. However, on quantitation, the difference was not statistically significant. This time course contrasts with the expression of inducible HSP-70 that is not detectable in the NIC but is significantly elevated in the PI brain.

426.16

HEAT-SHOCK PROTEIN (HSP70) EXPRESSION IN FOCAL BRAIN DAMAGE P.J.Lindsberg, T.S.Nowak, Jr.†, A.-L.Sirén, J.M.Hallenbeck*. Dept. of Neurol., USUHS and †NINDS, NIH, Bethesda, MD 20814.

Global ischemic or hyperthermic brain damage alters gene expression inducing production of mammalian heat shock proteins. We hypothesized that HSP70 expression indicates an area at risk in focal brain injury. Progressive cortical damage was produced by focal laser pulse in rats (n=14). Double-labelling fluorescence technique (Evans-Blue albumin, FITC-dextran, i.v.) was used to map and measure BBB-damage and microvascular perfusion from fresh-frozen brain sections. HSP70 mRNA was localized by in situ hybridization. While absent at 30 min after injury, striking HSP70 expression took place by 2 hrs in a ~300 μm wide rim surrounding an area of expanding BBB-damage. HSP70 mRNA was observed only in regions of preserved microcirculation. Subcortically migrated edema fluid apparently did not induce further HSP70 expression, which persisted at 8 hrs. We conclude that progressive focal brain damage rapidly induces localized HSP70 expression, which is dissociated from increasingly ischemic, edematous areas and may identify cells with the capacity to adapt to the metabolic challenge.

ZINC INDUCTION OF HSP72 AND CELL DEATH IN PRIMARY ASTROCYTE CULTURE. R.A. Swanson and F.R. Sharp Dept. of Neurology, Univ. of California San Francisco and Veterans Affairs Medical Center, San Francisco, CA 94121

Zinc is a potent inducer of the 72kD heat shock protein (HSP72), and extracellular zinc concentrations may be greatly elevated in brain during pathologic conditions. The present study examines the effect of zinc on HSP72 expression in primary rat cortical astrocyte culture. Astrocytes were grown to confluency and exposed to zinc chloride in Earle's buffered salt solution. HSP72 expression was induced by incubation with 40uM Zinc for 4 hours or 1mM for 15 minutes. Expression occurred in a patchy distribution with HSP72 positive astrocytes frequently forming the margin between dead and viable cells, similar to the pattern seen after cerebral ischemia in vivo. Exposure to zinc at higher levels, 100uM for 4 hours or 500uM for 1 hour, caused greater than 90% cell death. Elevated extracellular zinc concentrations may contribute to HSP72 induction and astrocyte death under pathologic conditions in brain.

426.18

RELATIONSHIP BETWEEN EXPRESSION OF HEAT SHOCK PROTEIN-70 mRNA AND HISTOLOGIC INJURY FOLLOWING FOCAL ISCHEMIA IN RAT BRAIN. F.A.Welsh, D.J.Moyer and V.A.Harris*. Div of Neurosurgery, Univ of Penn Sch Med, Philadelphia, PA 19104.

Cerebral ischemia induces the expression of stress proteins, which may limit the extent of cellular injury. The objective of this study was to compare the regional expression of heat shock protein-70 (HSP-70) mRNA with regional injury measured 4 hr and 24 hr after permanent occlusion of the distal middle cerebral artery in Wistar rats. HSP-70 mRNA was measured with a 30-mer oligonucleotide probe using in situ hybridization. Adjacent sections were stained with acid fuchsin and thionin to locate injured neurons. The regional relationship between HSP-70 mRNA and neuronal injury was similar at 4 hr and 24 hr. In all animals, the expression of HSP-70 mRNA encompassed a wider area of cortex than that undergoing infarction. Frequently, highest levels of HSP-70 mRNA occurred peripheral to the area of infarction. Further, the core of infarction occasionally showed background levels of HSP-70 mRNA. Thus, the expression of HSP-70 mRNA in regions bordering tissue injury is consistent with the hypothesis that induction of stress proteins may limit the regional extent of injury.

426.19

THRESHOLD DURATION OF FOCAL ISCHEMIA REQUIRED TO TRIGGER EXPRESSION OF HEAT SHOCK PROTEIN-70 mRNA IN RAT BRAIN. D.J.Moyer, F.A.Welsh, V.A.Harris.* Div of Neurosurg, Univ of Penn, Phila, PA 19104.

Reperfusion following 60 min of focal ischemia induces strong expression of heat shock protein-70 (HSP-70) mRNA in neocortex, striatum, and hippocampus (Neurosci Abstr 16:938, 1990). The objective of the present study was to determine regional expression of HSP-70 mRNA following focal ischemia of varying duration. Focal ischemia was produced in Wistar rats by transient occlusion the distal middle cerebral artery (MCA) and both carotid arteries for 5, 10, or 20 min, followed by reperfusion for 2 hr. Regional levels of HSP-70 mRNA were measured using in situ hybridization, employing a 30-mer oligonucleotide probe labeled with S-35. Following 5 min of focal ischemia, mild expression of HSP-70 mRNA was detectable in the outer layers of the MCA zone of neocortex. A 10-min insult triggered moderate expression in the outer and inner layers of the MCA neocortex. A 20-min insult produced stronger expression throughout the MCA neocortex and also in adjacent cortex and lateral striatum. Thus, lengthening the duration of focal ischemia not only increased the intensity of expression, but also increased the number of regions expressing HSP-70 mRNA.

426.20

72 KD HEAT SHOCK PROTEIN AND ISCHEMIC TOLERANCE I. Halaby, T. Mima*, C. Petito[1] and W. Pulsinelli. Dept. of Neurology and Neuroscience, Dept. of Pathology[1] Cornell University Medical College, New York, NY.

To test whether the 72kd heat-shock protein (HSP72) protects CA1 hippocampal neurons against severe ischemia, we induced HSP72 synthesis in rats with mild ischemia and later to ischemia that is normally lethal to most CA1 neurons. Adult rats were exposed to 2 min of 4-vessel occlusion (4-VO) ischemia (Pulsinelli and Duffy, J Neurochem, 40:1500, 1983) and then at 6 hr or 48 hr they were made ischemic for 10 min. Separate groups were exposed to 2 or 10 min of 4-VO alone. The animals were killed 5 days later by perfusion-fixation. Stained coronal (7 μm) sections were examined with the light microscope. CA1 damage was graded by a blinded observer on a scale of 0 (normal) to 3 (maximal). Separate rats were subjected to 2 min of 4-VO ischemia, killed by perfusion-fixation at 6 hr (n=3) or 48 hr (n=3), and HSP72 in the CA1 zone was identified with monoclonal antibody and the avidin-biotin-peroxidase method.

MEAN GRADE CA1 HIPPOCAMPAL DAMAGE

2 min Isch.	2 min + 10 min 10 min Isch.	2 min + 10 min Isch. (6 hr)	Isch. (48 hr)
0.6 ± 0.5 (n=9)	2.7 ± 0.5 (n=11)	2.5 ± 0.6 (n=9)	1.4 ± 0.8[a] (n=10)

[a]Kruskal-Wallis plus Mann Whitney U Test $0.025 < p < 0.05$

Immunoreactivity to HSP72 after 2 min of ischemia was barely detectable at 6 hr but prominent at 48 hr. Two min of ischemia followed by 10 min of ischemia at 48 hr, but not at 6 hr, significantly decreased CA1 damage compared to 10 min of ischemia alone. The ischemic tolerance induced by 2 min of sublethal ischemia may result from the induction of HSP72.

EXTRACELLULAR AMINO ACID(AA) AND PURINE METABOLITE LEVELS IN A CORTICAL ISCHEMIA-REPERFUSION MODEL IN THE RAT. T-N. Lin, Y.Y. He, G. Wu, W. Liu, K.E. Peek, J.C. Goodman, and C.Y. Hsu Div. Resto. Neurol. BCM, Houston, TX 77030.

Excessive release of glutamate contributes to ischemic brain injury. Adenosine is thought to be an endogenous neuroprotective modulator. The aim of this study is to measure the extracellular changes of glutamate and adenosine in cerebral cortex following ischemia-reperfusion using a stroke model with irreversible ischemic injury confined to the right MCA cortex. The extracellular amino acids and purine metabolites were recovered from the extracellular fluid before, during ischemia and after reperfusion using microdialysis technique and analyzed by high performance liquid chromatography. Ischemia caused a 30-40 fold (peak level:12.8±1.8uM, mean±SEM, n=16) increase in extracellular levels of glutamate in the right MCA cortex. Aspartate, taurine, gamma-aminobutyric acid, phosphoethanolamine and glycine also increased but to a lesser extent. No significant changes occurred with other AAs. There was no changes in the level of AAs in the left MCA cortex which sustained only mild ischemia (blood reduction of 20-40%). The increase in extracellular adenosine levels was moderate and transient (4-5 fold; peak level:0.6±0.3uM, n=6). Extracellular inosine (peak level:2.2±0.5uM) and hypoxanthine (peak level:3.7±0.8uM) levels rose markedly (8-10 fold) during ischemia and sustained during early reperfusion. The transient elevation in extracellular adenosine concentration followed by a more pronounced increase of its metabolites, inosine and hypoxanthine, suggests rapid turnover of extracellular adenosine. The moderate rise in extracellular adenosine level in comparison to the more substantial and delayed increase in glutamate level during ischemia raise the possibility that this model maybe suitable for studying adenosine modulation of ischemia-induced glutamate release.

427.2

REGULATION OF ENDOGENOUS ADENOSINE DURING HYPOXIA IN THE RAT HIPPOCAMPAL SLICE. J.C. Fowler. Dept. of Physiology, Texas Tech Hlth. Sci.Ctr., Lubbock, TX 79430.

Adenosine levels were measured, using absorbance HPLC, in aliquots taken at 30 min intervals from static chambers of 2 ml volume each containing 4 hippocampal slices. Slices were kept on a net at an interface between the physiologic medium and the humidified atmosphere at a temp of 33-34°C. After a recovery period of 1 hr, fresh medium was placed in the chambers. In 95%O_2/5%CO_2 basal adenosine levels remained around .25 μM for at least 2 1/2hours. Typical population spikes could be evoked. During hypoxic conditions (95%N_2) adenosine levels rose to a new steady-state value of 1.35 μM by 60 min. Removing glucose from the medium during normoxic or hypoxic conditions did not significantly change adenosine levels from their control over 2 1/2 hr.

The adenosine agonist CHA (10 μM) and the antagonist 8-CPT (10μM) both slightly but significantly increased adenosine levels at 60 min in hypoxia. The adenosine transport blocker, dipyridamole (200μM), had no effect on basal adenosine but doubled extracellular adenosine levels above hypoxia alone. Inclusion of the sugar transport inhibitor, phloretin (1 mM), increased adenosine six-fold compared to normoxia alone and quadrupled adenosine levels from hypoxia alone.

Experiments attempting to demonstrate a negative feedback exerted by adenosine on its own levels were equivocal. Glucose-free medium may be ineffective because of glucose remaining in the slice as phloretin greatly increased adenosine. Blocking adenosine transport appears to increase extracellular adenosine but dipyridamole, like phloretin, can reduce sugar transport.

427.3

ADENOSINE ANALOGS MODULATE TRANSMITTER AMINO ACID RELEASE FROM THE ISCHEMIC RAT CEREBRAL CORTEX. R.E. Simpson, M.H. O'Regan, L.M. Perkins and J.W. Phillis. Dept. Physiology, Wayne State Univ., Detroit, MI 48201.

Ischemia is a powerful stimulus for excitotoxic amino acid release from the brain. Adenosine levels are also elevated during cerebral ischemia and purines are cerebroprotective against ischemic and excitotoxic cellular damage. Since adenosine analogs are able to reduce glutamate and aspartate release from nerve terminals, we examined the ability of two such analogs, N^6-cyclopentyl adenosine (CPA) and N-ethylcarboxamido adenosine (NECA) to depress amino acid release from the ischemic rat cerebral cortex. Using the cortical cup technique and HPLC analysis, superfusates of artificial CSF were obtained prior to, during, and following a 20 min period of four vessel occlusion. CPA (10^{-8} to 10^{-12}M) and NECA (10^{-9}M) significantly reduced the release of aspartate, glutamate and GABA, especially during the reperfusion period, in comparison to no drug controls. CPA was most effective at 10^{-10}M. However, at higher doses CPA (10^{-4} to 10^{-6}M) and NECA (10^{-5}M) had no significant effect on release. The specific A_2 receptor antagonist CGS 15943A (0.1 mg/kg i.p.) also reduced ischemia-evoked release of these amino acids. Adenosine depresses transmitter amino acid release via high affinity A_1 receptors and coactivation of lower affinity A_2 receptors may block the A_1 response.

427.4

IN VIVO RECOVERY BY MICRODIALYSIS PROBE DETERMINED BY USE OF MANNITOL. A.J. Hansen, M.J. Sheardown, M.E. Judge, and A. Fink-Jensen. Novo Nordisk A/S, CNS Division, DK-2860 Soeborg, Denmark.

The microdialysis probe collects substances from the interstitial space, but the fraction removed is unknown precluding determination of the interstitial concentration. We have used the extracellular marker, mannitol, to assess the change in recovery between saline and the tissue. Firstly, we showed that recovery of mannitol is similar to loss from the probe in vitro. Secondly, ^{3}H-mannitol was added to the perfusion medium of the microdialysis probe and the loss determined when the probe was immersed in saline +1/2% agar at 37°C and in the rat brain. The loss was reduced by a factor of 3-3.5 in brain, demonstrating the increased diffusion resistance of the tissue. Thirdly, we measured the recovery of calcium in the same experimental set-up. (Calcium was chosen because the interstitial concentration can be accurately measured by ion-selective microelectrodes). In this case the difference between agar and brain was a factor of approx. 5. We suggest that in vivo recovery of most solutes may be assessed by incorporation of mannitol in the perfusion medium.

427.5

ISCHEMIA-INDUCED EXTRACELLULAR RELEASE OF SEROTONIN PLAYS A ROLE IN CA1 NEURONAL CELL DEATH. M.Y.-T. Globus, P. Wester*, R. Busto, E. Martinez*, I. Valdés*, W.D. Dietrich and M.D. Ginsberg. CVD Research Center, University of Miami, School of Medicine, Miami, FL, 33101.

Serotonin (5HT), via $5HT_2$ receptors, exerts an excitatory effect on CA1 neurons and may play a role in ischemia-induced excitotoxic damage. To evaluate the role of 5HT in ischemia, rats were subjected to 12.5 or 20 min of normothermic ischemia by 2-vessel occlusion plus hypotension and extracellular 5HT levels were measured in the hippocampus (12.5 min ischemia, n=5) or striatum (20 min ischemia, n=5) by microdialysis. 12.5 min of ischemia induced a 7-fold increase in 5HT in the hippocampus (mean±SD, baseline=2.11±1.07, ischemia=15.6±7.7 pmol/ml perfusate; $p<0.05$ by ANOVA). Twenty min of ischemia induced a 41-fold increase in 5HT in the dorsolateral striatum (0.76±0.19 and 31.2±9.12, respectively; $p<0.001$). The effects of ritanserin ($5HT_2$ antagonist, 8 mg/kg), administered continuously from 30 min prior to ischemia until 1h of recirculation, was evaluated in animals subjected to 10 min of ischemia (n=5). After 3 days, quantitation of normal-appearing neurons in the CA1 region was performed. Non-treated animals demonstrated severe ischemic damage in all CA1 regions (medial=34±16, middle=52.2±22.9, and lateral=56.6±21.8). Treatment with ritanserin significantly attenuated ischemic damage (117.6±6.5, 131.4±4.9, and 130±7.5, respectively; $p<0.01$). Results suggest that 5HT plays a detrimental role, mediated by $5HT_2$ receptors, in the development of hippocampal ischemic damage.

427.6

DOPAMINE RELEASE AND CYTOSOLIC FREE CALCIUM DURING HYPOXIA IN PC12 CELLS. G.E. Gibson, L. Toral-Barza* and B. Tofel-Grehl*. Burke Med. Res. Inst. Cornell Univ. Med. Coll. White Plains, NY 10605

Calcium and neurotransmitter release have been implicated in hypoxia/ischemia-induced damage. To define the molecular basis of hypoxia-induced alterations in a cellular system, viability, ATP, cytosolic free calcium ($[Ca^{2+}]_i$) and dopamine release were examined during early stages (5 minutes) of chemical hypoxia (i.e. KCN) in PC12 cells. High concentrations of KCN (0.5 mM) significantly altered these variables only when glucose was omitted from the media. The response of these same factors to a range of KCN concentrations (0.005, 0.05 or 0.5 mM) was then examined in the absence of glucose. ATP levels did not change with 0.005 mM-KCN, but declined by 57% and 84% of control at the two higher concentrations. K^+ depolarization did not alter ATP further in any group. Similarly, $[Ca^{2+}]_i$ was unchanged at the 0.005 mM-KCN, but increased 2- and 5-fold of the control at the two higher concentrations. Depolarization increased $[Ca^{2+}]_i$ and the values in the hypoxic cells after depolarization were elevated. The increasing KCN concentrations elevated dopamine in the media under resting conditions (43, 134 and 296% of control) and after K^+-stimulation (5, 52 and 81 % of the K^+ stimulated control). PC12 cells are a convenient cellular system in which to establish the mechanism by which hypoxia alters dopamine release.

427.7

PERSISTENT DECREASE IN HIPPOCAMPAL NOREPINEPHRINE RELEASE ASSOCIATED WITH TRANSIENT FOREBRAIN ISCHEMIA. K.U. Frerichs, L. Näveri*, K. Xu*, J.M. Hallenbeck*, G. Feuerstein, J.N. Davis, and A.L. Sirén. Dept. Neurology, USUHS, Bethesda; Neurology Res. Lab., Durham VA, Duke University, Durham; SK&B Labs., King of Prussia.

Central noradrenergic neurons may modulate neuronal death in cerebral ischemia. Others have shown an increased release of norepinephrine (NE) during ischemia, but little is known about chronic postischemic changes. We measured extracellular NE in the hippocampus using microdialysis and HPLC for up to 48hours after 20min of forebrain ischemia (FI). FI was induced by four vessel occlusion in halothane-anesthetized rats. Baseline NE was 3.6±1.7pg/20µl (flow rate 1µl/min;n=12). During ischemia, there was a massive release of NE (90.8±10.5pg/20µl; n=6,$p<0.01$) followed by a gradual decline of NE to preischemic levels over 40min of reperfusion. Thereafter (8,24, and 48hours), NE was undetectable in the dialysate (limit of detection 1.0pg/20µl). In sham-operated rats, dialysate-NE was detected at baseline concentrations at all time points (2.3±0.4pg/20µl;n=6). These findings indicate an early and long-lasting depression of the noradrenergic system in the hippocampus, which coincides with the development of delayed neuronal death in this brain region. Therapeutic interventions aimed at maintaining sufficient extracellular NE levels may constitute an approach to protection from delayed neuronal death following global cerebral ischemia.

427.8

AMELIORATION OF TEMPORARY FOCAL CEREBRAL ISCHEMIC BRAIN INJURY IN TRANSGENEC MICE OVEREXPRESSING HUMAN SUPEROXIDE DISMUTASE Yang GY*, Epstein CJ, Chen SF, Weinstein PR, Chan PH. Depts. of Neurosurgery, Neurology, and Pediatrics. UC San Francisco, CA 94143

Oxygen free radicals have been implicated in the pathogenesis of brain edema and neuronal cell death in cerebral ischemia. Our previous studies have demonstrated that liposome-entrapped SOD significantly reduced the infarct size after middle cerebral artery occlusion(MCAO) in rats. We have confirmed that infarction volume in transgenic mice, which are genetically modified to overexpress human CuZn-SOD (h-SOD-1), was significantly reduced following permanent MCAO($P<0.05$). The purpose of present study was to determine the effect of temporary MCAO and reperfusion on transgenic mice as compared to normal diploid mice. Transgenic mice carrying the h-SOD-1 gene were produced as described by Epstein et al(1987). SOD-1 activity was identified by native gel electrophoresis followed by staining with nitroblue tetrazolium. All mice weighing 30±5 grams were anesthetized with chloral hydrate (350 mg/kg IP). The MCA was occluded by introducing a 5-0 rounded tip nylon suture into the left internal carotid artery 11 mm past the site of the common carotid bifurcation. Reperfusion was performed by withdrawal of the suture. All mice received 3 hrs MCAO followed by 3 hrs reperfusion. Infarction area, measured by image analysis after 2,3,5-triphenyltetrazolium chloride staining, was smaller in transgenic mice: transgenic/nontransgenic, (mean% of whole brain area at 3, 5, 7, and 9 mm distal to the frontal pole) 13.8/21.9, 23.1/28.6, 19.0/23.4, and 6.9/17.4, respectively. The neurological deficit scale (0-4) in transgenic mice was lower than that in nontransgenic mice($p<0.05$). Our results suggest that superoxide radicals play an important role in the pathogenesis of ischemic infarction in temporary MCAO and reperfusion. NEUROPROTECTIVE EFFECTS OF GM1 TREATMENT FOLLOWING CNS ISCHEMIA INVOLVE RESTORATION OF CELLULAR MEMBRANE LIPID METABOLISM AND DEFENSE AGAINST OXY-RADICAL TOXICITY.

SP Mahadik, BL Hungund*, TK Makar*, V Gokhale, A Ortiz, and SE Karpiak. NYS Psychiatric Inst., Neuroscience & Analy. Psychopharmacology, Dept. Psychiatry, Columbia U (P&S) NY, NY 10032.

Several studies using both *in vivo* & *in vitro* models of CNS ischemia have shown that GM1 treatment reduces intracellular ionic imbalances & eventual cell death thereby indicating a protective & restorative effect on cellular plasma membrane structure and function (1,2). The precise mechanism of GM1's efficacy is unclear. Ischemia initiates membrane fatty acid release. Following reperfusion, the metabolism of released fatty acids together with increased cellular metabolism generate oxy-radicals which cause additional membrane damage by lipid peroxidation, inactivate vital cellular enzymes & the expression of certain vital genes. Using a model of focal cortical ischemia in rat (1) we find that *acute* GM1 ganglioside treatment (10 mg/kg, at 1,24&48hrs after ischemia) restored membrane lipid metabolism (increased fatty acid acylation) in peri-ischemic areas & partially restored metabolism in the primary ischemic area *at two weeks after the ischemic episode*. There was also an increase in the *capacity* of the oxy-radical defense system evidenced by an *additional* increase in the already elevated levels of superoxide dismutase, glutathione peroxidase & catalase. This increase by GM1 was sustained for up to 6wks. We hypothesize that the neuroprotective effects of GM1 are a result of its effect on those processes which restore and maintain plasma membrane fatty acid composition and distribution.

This work was supported in part by a grant from NINDS NS-25856 and a research grant from the FIDIA Research Foundation.

POST-ISCHEMIC DETECTION OF HYDROXYL RADICALS IN GERBIL BRAIN: ATTENUATION BY THE 21-AMINOSTEROID TIRILAZAD MESYLATE (U-74006F).

P.K.Andrus*, E.D.Hall, J.S.Althaus, C.M.Williams*, and P.F.VonVoigtlander. CNS Dis. Res., The Upjohn Co., Kalamazoo, MI 49001.

During ischemia and particularly upon reperfusion, oxygen free radicals are formed. An important free radical species is the hydroxyl radical OH•. Salicylate can be used as a marker for the production of OH• as salicylate reacts with it to form 2,3- and 2,5-dihydroxy benzoic acid (DHBA). To investigate whether pretreatment with the 21-aminosteroid antioxidant U-74006F can reduce brain post-ischemic formation of OH•, as measured by DHBA formation, gerbils were given i.p. doses of either vehicle or U-74006F (10 mg/kg) ten min prior to bilateral carotid occlusion (BCO). Following the 10 min BCO, gerbils were allowed reperfusion times of 1, 5 and 15 min. Salicylate was administered i.p. 10 min before sacrificing the animals. Brain hemisections, hippocampus or cortex were removed and immediately frozen. Tissues were homogenized in ethanol (1% ascorbate) and analyzed by HPLC. Data were expressed as the ratio of DHBA's to salicylate measured. Results indicated the 2,5-DHBA/salicylate ratio was indeed increased at 1 min reperfusion; pretreatment with U-74006F attenuated DHBA production at all time points.

CHANGES IN PROTEIN PHOSPHORYLATION INDUCED BY SPINAL CORD ISCHEMIA.

D.A. Shackelford* and J.A. Zivin. Dept. of Neurosciences, Univ. of Calif. at San Diego, La Jolla, CA 92093-0624.

Protein phosphorylation, an important ATP-dependent process that may be altered during ischemia, is a molecular mechanism by which extracellular signals regulate many intracellular functions. Previously the activities of protein kinase C and the Ca^{2+}/calmodulin-dependent kinase were demonstrated to be reduced in the rabbit spinal cord ischemia model (RSCIM). To expand these studies we have taken two approaches to assay changes in (1) protein tyrosine kinases or (2) serine/threonine kinases. For both studies, cytosolic and particultate fractions of spinal cord homogenates from animals subjected to 0-60 min of ischemic insult were separated by SDS-PAGE and transferred to Immobilon filters. To analyze changes in protein tyrosine phosphorylation , which is one of the earliest metabolic changes observed after perturbation of cells with various agents resulting in either cell growth or death, filters were immunoblotted with affinity-purified rabbit anti-phosphotyrosine antibodies. This type of analysis revealed changes in tyrosine phosphorylation of at least 6 proteins in the M_r range of 20-120K detectable after 10-60 min of ischemia. To assay total serine/threonine kinase activities, the proteins bound to filters were denatured with guanidine-HCl and then allowed to renature slowly. The filters were incubated with [^{32}P] gamma-ATP to reveal kinase activities. In the RSCIM, this type of analysis revealed two interesting changes. First, a kinase of M_r= 80K was transiently detected after 10 or 25 min of ischemia but was absent after 30-60 min of insult. Second, a kinase of M_r= 55K was detected in the 0-25 min samples, but was not detected at later times. The time course of these changes suggests that these kinases could play a role in the ischemic-induced cell death.

THE RELATIONSHIP BETWEEN EXTRACELLULAR GLUTAMATE AND GLUCOSE UTILIZATION IN FOCAL CEREBRAL ISCHEMIA.

SH Graham, J Chen*, and RA Swanson. Department of Neurology, University of California, San Francisco, 94121.

The phenomena of increased glucose utilization in the border zone of infarcts in rat focal cerebral ischemia has been attributed to the effects of tissue hypoxia. Anaerobic metabolism is less efficient than aerobic metabolism and thus requires more glucose to meet cellular energy requirements. An alternative mechanism is that the release of the excitatory amino acids may contribute to increased glucose utilization in focal cerebral ischemia. We first studied the effect of glutamate upon glucose metabolism *in vitro* using primary neuronal-glial cocultures. Glucose utilization was determined by 2-deoxy-glucose (2DG) method. Addition of glutamate to the medium significantly increased glucose utilization in a dose dependent fashion at 100 and 500μM. The relationship between glucose utilization and glutamate release was also studied *in vivo* in the rat. Glucose utilization in the parietal cortex was measured at 5 minutes, 1.5 hrs., and 4 hrs. after middle cerebral artery (MCA) occlusion. Extracellular glutamate changes in this border zone region were monitored by use of microdialysis. 2DG uptake and microdialysate glutamate both peaked at 1.5 hrs. after MCA occlusion. These results suggest that glutamate release may contribute to increased glucose utilization in focal cerebral ischemia.

FRUCTOSE-1,6-BISPHOSPHATE (FBP) INCREASES CO_2 PRODUCTION BY THE PENTOSE PHOSPHATE PATHWAY (PPP).

G A. Gregory*, J A. Kelleher, T.Y. Chan*, and P H. Chan. University of California, San Francisco, Departments of Anesthesia and Neurology, Box 0648, San Francisco, CA 94143

Fructose-1,6-bisphosphate (FBP) decreases CNS injury following ischemia/hypoxia. Similar protection occurs in cultured astrocytes. To determine whether this protection is the result of the metabolism of FBP itself or is the result of an FBP-induced increase in glucose (GLC) metabolism, CO_2 production was measured in normoxic, cultured astrocytes with and without 3.5 mM FBP in the culture medium. CO_2 production from [U-^{14}C]-FBP and from [6-^{14}C]-GLC (1.51±0.39 and 1.34±0.16 nmol/mg protein/hr, respectively) was small. However, CO_2 production from [1-^{14}C]-GLC increased from 30.12 ±3.4 to 48.26±5.11 nmol/mg protein/hr when FBP was present in the media. In separate studies, lactate production was shown not to be increase. These studies indicate that the protection afforded by FBP is not the result of FBP being utilized as a substrate. A small amount of FBP is taken up by the cells, which may be sufficient to increase metabolism of GLC through activation of one or more enzymes of the PPP. Alternatively, FBP may act as a Ca^{++} chelator which may protect hypoxic astrocytes from injury.

427.14

EARLY REDUCTIONS IN CYTOCHROME OXIDASE (CO) ACTIVITY PREDICT THE DISTRIBUTION OF ISCHEMIC INJURY IN PERINATAL RODENT BRAIN.

Carrie Nelson*, Faye S. Silverstein. Depts. of Pediatrics and Neurology, University of Michigan, Ann Arbor, MI.

In a model of perinatal stroke, induced by right carotid ligation and 8 % O_2 exposure (2.5-3 h) in 7 day old rats, diffuse hippocampal (HIP) injury, often including dentate gyrus (DG), evolves. We hypothesized that regionally selective disruption of energy metabolism might predispose HIP neurons to irreversible ischemic injury. CO histochemistry accurately estimates mitochondrial respiratory function and neuronal metabolic activity. Using computerized densitometry, we quantitated CO activity in frozen brain sections prepared from lesioned rats killed 1 (n=8) or 24 (n=6) h post-hypoxia. Adjacent sections were processed for CO and for Nissl substance to assess cellular integrity. At 1 h, Nissl staining was normal in 4/8 while 4/8 had very subtle reductions in HIP staining. In contrast, 6/8 showed prominent diffuse ipsilateral suppression of CO activity most marked in HIP (-9 % in striatum, -26 % in CA1, -23% in CA3, -18 % in CA4, -29 % in DG, p=0.0001, 2 way ANOVA). At 24 h, there was a close regional correspondence between loss of Nissl-staining in lesioned tissue and loss of CO activity. In perinatal rodent brain, after an acute hypoxic-ischemic insult, early disruption of CO activity predicts the distribution of irreversible injury. The prominent loss of CO activity in DG parallels the enhanced susceptibility to ischemic injury of this cell population at this developmental stage.

EXPRESSION OF MAP2 mRNAs IN RAT AND GERBIL BRAIN AFTER TRANSIENT ISCHEMIA. N. Saito*, K. Kawai*, I. Klatzo and T. S. Nowak, Jr. Lab. of Neuropathol. and Neuroanat. Sci., NINDS, NIH, Bethesda, MD 20892

Levels of mRNAs encoding microtubule-associated proteins MAP2b and MAP2c were evaluated in rat and gerbil brain by in situ hybridization with oligonucleotide probes based on known rat sequences. Rats were subjected to 10 min cardiac arrest produced by compression of major thoracic vessels, under anesthesia with 2% halothane in 70% N_20, 30% O_2. Gerbils were subjected to 5 min bilateral carotid artery occlusion under the same anesthesia. Hybridization was carried out on 15 μm frozen sections using ^{35}S-labeled probes, and detected by film autoradiography. In the gerbil, significant reductions in MAP2b hybridization were detected in hippocampal CA1 neurons by 12 h recirculation, falling by approximately 50% at 2 days. The fall in MAP2b mRNA thus preceeded both the fall in immunoreactive MAP2b and the eventual cell loss in this region. A similar depletion of MAP2b mRNA in CA1 neurons was observed in the rat model. Preliminary results demonstrate a reciprocal change in MAP2c hybridization in rat hippocampus, with a striking increase in CA1 neurons at 24 h. MAP2c hybridization was not detected in the gerbil with the available probe. Induction of mRNA encoding MAP2c, a truncated form of the protein normally expressed during periods of neuronal plasticity, thus appears to occur selectively in vulnerable neuron populations after ischemia. It remains to be determined whether this increase occurs in dying or surviving cells, and whether functional MAP2c protein can be expressed under conditions of translational impairment known to occur following ischemia.

427.16

ACTIVATION OF PROTEIN KINASE C BY H_20_2 IN UCIIMG ASTROCYTES. W.J. Chiou* and K.L. Leach. Cell Biology, The Upjohn Co., Kalamazoo, MI 49001

Oxidative damage, which involves free radical formation and subsequent lipid peroxidation, plays a significant role in the pathogenesis of tissue injury, including the brain injury induced by hypoxia or trauma, and cardiac injury arising from ischemia and reperfusion. However, the mechanism(s) by which oxidative insult eventually leads to cell death are still unknown. In these studies we have examined the role of the calcium and phospholipid-dependent protein kinase C (PKC), which plays a major role in cellular signal transduction pathways, in oxidative injury. Treatment of UC11MG cells, a human astrocyte cell line, with 0.5 mM H_2O_2 resulted in a 2-3 fold increase in malondialdehyde levels within 30 min. PKC activation following oxidative injury was assessed by examining the phosphorylation of an endogenous protein, the 80 kD protein, which is a specific substrate for PKC. Incubation of UC11MG cells with 0.5 mM H_2O_2 for 30 min resulted in a 4-6 fold increase in the phosphorylation of the 80 kD protein. The increase in phosphorylation was apparent within 10 min following treatment, and was maintained for up to 60 min. The H_2O_2-stimulated increase in 80 kD phosphorylation was inhibited by treatment of the cells with either 1 μM staurosporine or 100 μM H-7, two PKC inhibitors. In addition, in cells in which PKC was down-modulated by pretreatment with 200 nM phorbol 12-myristate 13-acetate for 48-72 hrs, H_2O_2-induced 80 kD phosphorylation was markedly reduced. These results suggest that protein kinase C may be one of the early events activated in the cellular response to oxidative injury.

427.17

TRANSLOCATION OF Ca^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II (CaM-KII) AFTER FOREBRAIN ISCHEMIA. J.ARONOWSKI*, J.C.GROTTA* AND N.WAXHAM. (SPON: N. WAXHAM). Depts.of Neurobiology and Anatomy and Neurology, Univ. of Texas Medical School, Houston, TX 77225

Transient forebrain ischemia induced by four vessel occlusion in rats, resulted in depressed activity of both CaM-KII and Ca^{2+}/phospholipid-dependent kinase while no changes were detected in the activity of cAMP-dependent kinase, as measured in both cerebral cortex and hippocampus. The decrease in CaM-KII activity, measured by phosphorylation of synthetic peptide substrate, coincided with translocation of the enzyme from the cytosol to the particulate fraction, determined using a CaM-KII specific monoclonal antibody followed by an ^{125}I-labeled secondary antibody. The inactivation and translocation of CaM-KII was fully reversible following 2 hr of reperfusion of animals exposed to 5 min of ischemia. In contrast, the translocation and inactivation of CaM-KII following 20 min of ischemia was not completely reversible with reperfusion. The mechanism(s) responsible for down regulation and/or translocation of CaM-KII is unknown. Phosphorylation due to increasing intracellular Ca^{2+} following ischemia is one possible step in this pathway. In preliminary experiments to test this hypothesis, we phosphorylated crude homogenates of rat cerebral cortex and examined changes in the distribution of CaM-KII between cytosolic and particulate fraction. A time dependent decrease occured in the amount of CaM-KII enzyme in the cytosol after the addition of Ca^{2+} and calmodulin. This process was partially blocked by specific inhibitors of CaM-KII and the phosphatase inhibitor okadaic acid.

427.18

DISAPPEARANCE OF BRAIN Ca^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II AFTER BRIEF ISCHEMIA.

H. Yamamoto*, K. Fukunaga, K. Lee and T. R. Soderling.

Vollum Institute, Oregon Health Sciences Univ., Portland, OR 97201,
Dept. Neurosurgery, Univ. Virginia, Charlottesville, VA 22908

Several studies have suggested that ischemia produces neuronal cell death by the elevation of intracellular calcium which activates calpain, resulting in extensive proteolysis. In this paper, we examined the effects of forebrain ischemia in gerbils in Ca^{2+}/calmodulin-dependent protein kinase II (CaM-kinase II) by both kinase activity assays and Western blot analysis. In cortex and hippocampus, cytosolic CaM-kinase II was completely lost within 2-5 min of ischemia. Particulate CaM-kinase II was more stable and decreased about 40% after 10 min of ischemia followed by 2 hrs reperfusion. CaM-kinase II in cerebellum, which does not become ischemic, was not affected. The rapid loss of forebrain CaM-kinase II was quite specific since hippocampal cytosolic cAMP-kinase and protein kinase C were not affected. These data strongly suggest that very brief ischemia causes immediate proteolysis of soluble CaM-kinase II which would be deleterious since CaM-kinase II modulates numerous neuronal cell functions.

427.19

The effect of nerve growth factor on the delayed neuronal death after ischemia. K. Tanaka, Y. Yonekawa, T. Tsukahara, N. Ogata, Y. Kaku, T. Kimiura[1], T. Taniguchi[1], O. Ohara[2]. Department of Neurosurgery, National Cardiovascular Center, Suita, Osaka, Japan. Department of Neurobiology, Kyoto Pharmaceutical University[1], Shionogi Research Laboratories[2].

Protective action of nerve growth factor (NGF) against delayed neuronal death (DND) and the involvement of neurofilament (NF) and microtubulin associated protein 2 (MAP2) in its protective mechanism of DND were investigated. Wister rats were divided into following three groups; Group 1; 8 min transient forebrain ischemia, Group 2; intraventricular administration of artificial cerebrospinal fluid (CSF) and the ischemia. Group 3; intraventricular administration of 2 μg of 2.5S NGF and the ischemia. Hippocampal neuronal death was examined on 1st and 7th day after the ischemia. The histology was confirmed by HE staining and by immunohistochemical staining with anti-NF200 and anti-MAP2 antibody. Quantitative measurement of NF and MAP2 in the hippocampus was also analyzed by western blotting method. Mean cell survive, NF and MAP2 content in the rat hippocampus were as follows.

	Cell survive		NF		MAP2	
	day 1	day7	day 1	day 7	day 1	day 7
Group 1	100%	15%	59%	47%	63%	55%
Group 2	100%	40%	63%	60%	78%	104%
Group 3	100%	67%	81%	63%	90%	110%

These results suggest that NGF has a protective effect on rat hippocampal DND and that its effect may be mediated by the restoration of the neuronal cytoskeletal proteins.

427.20

NEURONAL EDEMA MAY BE A CAUSE OF SPREADING DEPRESSION. M. Balestrino*, S. Mazzari**, A. Leon**
*Dept. of Neurology, University of Genoa and **Fidia Research Laboratories, Abano Terme PD (Italy)

In vitro rat hippocampal slices were equilibrated with artificial cerebrospinal fluid (ACSF) containing 100 mM mannitol. Ouabain (100 uM) was then added to the mannitol-containing ACSF to provoke a spreading-depression (SD) - like depolarization (Neurosci. Abs. 16:277, 1990). Ouabain was perfused for as long as 30 minutes, and no SD-like event was observed. Moreover, population spike (PS) in the CA1 region was still present at the end of this time. By contrast, in separate experiments neither APV (50 uM) nor kynurenic acid (100 uM) prevented ouabain-induced SD-like depolarization and the consequent disappearance of PS.

In other experiments, perfusion with ACSF that was made severely hyposmotic by decreasing NaCl concentration to either 50% or 25% of normal caused, by itself, an SD-like depolarization in 1 out of 3 (33%) and in 8 out of 11 (73%) slices, respectively. If the same, low-NaCl ACSF was made iso-osmotic with addition of the impermeant sugar saccarose, SD-like depolarization was prevented.

Thus, neuronal swelling may be a determinant of SD.

SYMPOSIUM: HUMAN EYE SACCADES - SENSORY AND CORTICAL FACTORS. P.E. Hallett, Univ. of Toronto (Chairperson); H. Deubel*, Max Plank Institut Fur Psych.; L.M. Optican, NIH; M.E. Goldberg, NIH; R.A. Andersen, MIT.

Humans explore their world with saccadic eye movements. Saccades are used in orienting, looking, searching, tracking, and perhaps dreaming. The processing for saccadic eye movements includes analysis of what is on the retina, where those targets are in space, the cognitive decisions of choosing when and where to make a saccade, and the motor programming to move the eyes effectively. The oculomotor system is accessible to psychophysical, physiological, and theoretical study, and we will discuss the concepts and controversies that these different approaches have yielded. This symposium will not provide answers, but it will illuminate the problems in appreciating the synergy and interactions of the neural mechanism of this, the best understood sensorimotor system in man. **Hallett** will give an introduction. **Deubel** will talk about "The sensory stimulus". **Optican** will discuss "The superior colliculus and sensorimotor transformation". **Goldberg** will speak about "Cortical mechanisms for spatial accuracy" **Andersen** will conclude with "Coordinate transformations in posterior parietal cortex".

430

SYMPOSIUM: ACTIVITY-DEPENDENT PLASTICITY; ANALYSIS AT THE CELL AND MOLECULAR LEVEL. P.G. Nelson, NICHD, NIH (Chairperson); U. Rutishauser, Case Western Reserve Univ.; R. Zigmond, Case Western Reserve Univ.; and M.E. Greenberg*, Harvard Medical School.

The nervous system can alter its biochemistry and architecture in response to levels and types of synaptic activity. This remarkable interplay between function and structure, often referred to as plasticity, has long been recognized as fundamental for neural development, physiology and repair. For the most part, plasticity has been appreciated at the tissue level, but in recent years the cellular and molecular basis of plasticity has become increasingly defined. It is now clear that activity can influence all levels of cellular function from the genome to the plasma membrane. This symposium, which features four very different manifestations of activity-dependent plasticity within or on the cell, is designed both to illustrate the rapid progress being made in the field and to make neural plasticity a more palpable concept to the cell and molecular biologist. The first speaker, Phillip Nelson, will describe the effects of electrical stimulation on neurite outgrowth and synaptic efficacy, using spinal and sensory ganglion neurons grown in culture. The theme of neurite behavior will be further explored by Urs Rutishauser, in studies showing that activity-dependent sprouting of motor axons *in vivo* involves regulation of adhesion molecules via enhanced expression of an unusual cell surface carbohydrate. Richard Zigmond will discuss the mechanism by which changes in nerve activity alter catecholamine biosynthesis and neuropeptide levels in adult sympathetic neurons. To close, Michael Greenberg will illustrate the ability of neurotransmitters and depolarization to influence the expression of immediate early genes such as *c-fos*.

VISUAL CORTEX: ARCHITECTURE AND INTERACTIONS

431.1

The Organization of Cytochrome-Oxidase Blobs in Cat Visual Cortex. K.M. Murphy[1], R.C. Van Sluyters[2] & D.G. Jones[3]*. Departments of Psychology[1] and Electrical Engineering[3], McGill University, Montreal PQ H3A 1B1, School of Optometry[2], University of California, Berkeley, CA 94720.

The primary visual cortex is parcellated into modules that have been defined using both physiological and anatomical techniques. Quite possibly the most striking demonstration of cortical modularity is that of the blobs of higher cytochrome-oxidase activity in the supragranular layers of the visual cortex. Previously, cytochrome blobs had only been demonstrated in primate visual cortex which led to the supposition that they were a unique feature of the organization of the visual system in this species. However, recently we demonstrated that cytochrome blobs are also present in the supragranular layers of cat primary visual cortex. Using the technique of unfolding and flattening the entire cat visual cortex, patterns arrayed tangential to the cortical surface, such as the cytochrome blobs, are most easily appreciated. Examination of such sections taken through supragranular layers of cat visual cortex and stained for cytochrome-oxidase reveals marked periodicity throughout the entire extent of area 17. The blobs of higher cytochrome-oxidase activity in cat visual cortex appear qualitatively similar to those observed in the primate.

Cytochrome blobs in primate cortex have been related to the organization of ocular dominance, and we have examined this relationship in cat primary visual cortex. As in the monkey, cytochrome blobs in cat visual cortex overlie both right- and left-eye ocular dominance columns. However, whereas cytochrome blobs in the monkey are aligned with the centers of ocular dominance columns, in the cat this relationship is less clear-cut. Analysis of the relationship between cytochrome blobs and ocular dominance columns is complicated by two factors in the cat. The ocular dominance columns in layer IV of the cat are not completely segregated, and their overall pattern consists of a series of irregularly branching, beaded bands. In an effort to overcome these problems, we have begun to study the arrangement of cytochrome blobs and transneuronally labelled ocular dominance columns in monocularly enucleated cats.

431.2

ROLE OF GABAergic ACTIVITY IN GENERATION OF UPPER LAYER OCULAR DOMINANCE COLUMNS IN MONKEY STRIATE CORTEX. Michael M. Haglund and Gary G. Blasdel, Dept. Neurobiology, Harvard Medical Sch., Boston, MA 02115

Using video imaging of voltage-sensitive dyes, we have shown previously that low doses of the $GABA_A$ blocker, bicuculline (BMI), disrupt images of ocular dominance columns in the upper layers (Neurosci. Abstr. 15:799, 1989). Even though the doses of BMI were below that which triggered seizure activity and the ocular dominance columns were clearly gone, independent confirmation that the cortex is still functional was lacking.

We have now shown that during video imaging of monkey striate cortex in low doses of BMI (10um) when ocular dominance columns are gone that retinotopic maps are still present. Using optical techniques (Blasdel and Salama, 1986), images of ocular dominance columns and retinotopic maps were obtained in 3 monkeys. BMI (10um) was then superfused onto the cortex and alternating ocular dominance columns and retinotopic maps were obtained. During the time when the ocular dominance columns were gone, the retinotopic maps were still present.

Microelectrode recordings were also performed in the presence of BMI to determine the single neuronal correlate of the ocular dominance column disruption. Vertical penetrations were made in the upper 500um of striate cortex. After identifying a region with primarily monocular cells, firing frequency histograms were obtained comparing the right and left eye. With low doses of BMI (10um), monocular cells consistently shifted toward binocular. In the presence of BMI, single IV boluses of thiopental (2.5-5.0 mg/kg) (potentiates GABA activity) shifted binocular cells back to monocular.

These findings suggest that $GABA_A$ activity is important in the generation of upper layer ocular dominance columns and that these inhibitory pathways are involved in sharpening individual cell ocular dominance preferences.

(Suppt. by Klingenstein, Grass, and McKnight Foundations).

431.3

ORIENTATION PREFERENCE, CONTINUITY AND DENSITY IN MONKEY STRIATE CORTEX. Gary G. Blasdel, Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

Previous work (Blasdel and Salama, 1986) has demonstrated the usefulness of differential video imaging in obtaining maps of ocular dominance and orientation in monkey striate cortex. It has also shown that orientation preferences change continuously and linearly in most areas of cortex, but only in patches 0.5-1.0 mm across that are bounded semi-periodically by *fractures* and *singularities* where preferences change discontinuously. Recent measurements show that these discontinuous changes are 55% more abundant in the centers of ocular dominance columns than they are at the edges, and 46% more abundant in regions of intense cytochrome oxidase activity.

Fractures, which occur one dimensionally (as lines), are themselves disrupted by Singularities, which occur zero dimensionally (as points). The latter arise in the centers of two dimensional vortices, where orientation preferences cycle continuously through ±180° in one revolution and thereby ensure two things: 1) that preferences for all orientations are represented compactly, within the smallest possible areas, and 2) that perpendicular orientations are always preferred on opposite sides. Since dendritic arborizations appear relatively constant, extending in most cases 250-350 μm across (Lund and Yoshioka, 1991), the radically different densities of orientation preference (in the continuous and discontinuous zones), suggest large variations in the range available to different cells. Those in the continuous zones should receive precise information about a few orientations while those near singularities should receive imprecise information about all orientations - differences that may underlie separate perceptual tasks.

(Supported by the Office of Naval Research, EY05403, as well as by grants from the Klingenstein and McKnight Foundations).

431.4

SPATIAL INTER-RELATIONSHIPS OF FUNCTIONAL DOMAINS IN PRIMARY VISUAL CORTEX. Eyal Bartfeld, Dov Malonek, D. T'so and Amiram Grinvald. Dept. of Neurobiology, Weizmann Institute, Rehovot Israel, and Laboratory of Neurobiology, The Rockefeller University.

Detailed mapping of the visual cortex has revealed that cells with similar receptive field properties are clustered together and arranged in columnar organization (Hubel and Wiesel). We investigated the spatial relationships of ocular dominance, orientation columns and blobs by optical imaging in monkey V1. The optically derived information was correlated with cytochrome oxidase histology of the same area.

Recent improvements in intrinsic signal imaging has facilitated high resolution functional mapping, providing additional details. We studied from the same portion of visual cortex, activity maps evoked by several different visual stimuli. First we computed ocular dominance map, and then orientation specif'city map. The most prominent feature was a precise radial pin-wheel like architecture of orientation selectivity (Swindle et al.). This arrangement closely resembled the organization of orientation selective regions, around orientation centers, in cat area 18 (Bonhoeffer & Grinvald) and 17. The orientation centers were often found in the middle of ocular dominance columns. We found that in a patch of 4.5 by 3 mm of cortex there were 72 orientation centers and 62 blobs.

We are currently investigating the relationship between the orientation centers and the blobs.

Supported by IBM and The Riklis Foundation.

431.5

LINKING SENSORIAL MAPS IN THE VISUAL CORTEX

F. Wörgötter Inst. Physiol. Univ. Bochum, Germany.

Orientation specificity in the visual cortex is organized in an ordered manner and changes gradually so that adjacent cells have (on average) similar preferred orientations. The preferred orientations form an interlaced and curved structure and at several points (singularities) all orientations meet. The *average* orientation tuning strength is low at such singularities. This local coupling suggests that preferred orientation and orientation tuning strength might also be linked globally both being a function of the cortical surface coordinates. We demonstrate that such a link actually exists and that it can be described by a simple analytical expression. In good approximation, the map of the orientation tuning strength is obtained from the map of the preferred orientations by Fourier transformation methods. We found good correspondence between these computed maps and experimentally measured maps obtained from optical imaging of intrinsic signals (Bonhoeffer & Grinvald, Neurosci. Abs., 1990 and unpubl. data). This supports the view that a common design principle underlies the maps for preferred orientations and orientation tuning strengths and we expect this result to facilitate progress towards a more unified theory of the development of visual cortex. We thank Drs. Grinvald & Bonhoeffer for sharing with us their unpublished data in digital form.

OPTICAL IMAGING REVEALS PREFERENTIAL LABELING OF CYTOCHROME OXIDASE-RICH REGIONS IN RESPONSE TO COLOR STIMULI IN AREAS V1 AND V2 OF MACAQUE MONKEY.

C.E. Landisman, A. Grinvald, D.Y. Ts'o. Laboratory of Neurobiology, The Rockefeller University, NY, NY, 10021 and The Weizmann Institute, Rehovot, Israel.

In vivo optical imaging of the cytochrome oxidase blobs using the intrinsic (no dye) optical signals has previously been performed by localizing the centers of monocularity, during stimulation with a moving luminance grating. We now report that optical imaging maps have demonstrated cortical regions that yield a notably stronger response to low spatial frequency isoluminant chromatic gratings than to the luminance gratings. These patches of strong response to chromatic gratings coincide with the cytochrome-oxidase blobs. Results suggest, however, that the segregation of responses is not complete. There are residual responses of the interblob regions to the chromatic stimuli and of the blobs to luminance stimuli. Indeed with very low spatial frequency stimuli, striate cortex in general was more responsive to chromatic than luminance stimuli. In V2, isoluminant color stimuli preferentially labeled color-selective subcompartments of the stripes.

Optical imaging during standing versus flashing visual stimuli has also shown preferential labeling in V1 and V2. Preliminary results suggest that interblob regions and the thick stripes are less responsive to standing stimuli than flashing stimuli. Using our ability to localize the blobs *in vivo* with optical imaging, we have begun to target specific blobs with electrical recordings to explore the relationship between the optical responses to color stimuli and the electrophysiological assessment of receptive field properties. (Supported by EY08240 and the Whitaker Foundation).

431.7

ORIENTATION SELECTIVITY OF AND INTERACTIONS BETWEEN COLOR AND DISPARITY SUBCOMPARTMENTS IN AREA V2 OF MACAQUE MONKEY.

D.Y. Ts'o, C.D. Gilbert, T.N. Wiesel. Laboratory of Neurobiology, The Rockefeller University, NY, NY 10021.

By combining optical imaging maps of V2 with electrophysiology, we have studied the relationship between the stripes that contain disparity sensitive cells and stripes that contain color selective cells. Both cytochrome oxidase histology and the optical imaging maps have suggested that disparity compartments at times lie directly adjacent to or merge with color compartments, all within a single histologically-defined "stripe". Systematic electrode penetrations across these regions reveal a gradual progression of receptive field properties, from cells with sharp disparity tuning and no color selectivity, to cells having both disparity tuning and color selectivity, to color selective cells with no disparity tuning. After injections of retrograde tracers in pure color or disparity compartments, label is found in border regions containing color disparity cells, up to 6mm away.

Within the disparity zones, cells tended to have vertical or near vertical orientation preference. This result was most pronounced among cells with the sharpest disparity tuning, which were also unresponsive to monocular stimulation. In general, we found two types of regions in V2 containing oriented cells: one in which orientation was organized in a columnar fashion, where the preferred orientation was very uniform and altered very little both for the length of a vertical penetration and for neighboring penetrations. A second type of region of oriented cells exhibited no columnar organization for orientation, but instead the preferred oriented changed rapidly not only for neighboring penetrations, but also for neighboring cells within a single vertical penetration. These two types of organization for orientation were reflected in the optical imaging orientation maps. (Supported by grants EY07968, EY05253, EY08240 and the Whitaker and Rita Allen Foundations).

431.8

CHARACTERIZATION OF DYNAMIC PATTERNS OF CORTICAL ACTIVITY BY A SMALL NUMBER OF PRINCIPAL COMPONENTS.

D. Shoham, S. Ullman and A. Grinvald. Weizmann Institute, Rockefeller University and MIT.

In previous years our group (Arieli et al 88, 90) has used real-time optical imaging to study the spatio-temporal organization of the activity of large neuronal populations in cat visual cortex. The activity of a 3x3*mm* patch of cortex was imaged by an array of 120 detectors. We have observed complex coherent patterns which scanned the cortex at several frequencies. The results were presented as 'brain wave movies'. While these movies appear quite irregular and complex, a closer inspection reveals several recurring spatial patterns.

Here we attempt to measure the level of complexity inherent in those cortical waves by using Principal Component Analysis. In this method the given set of patterns is used to define a base of orthogonal patterns (principal components), which under a specific mathematical criterion is optimal for representing all the data. Each of the original patterns is decomposed into a weighted sum of the principal components. While the complete base of principal components is needed to fully represent the data, a small subset may give a good approximation in some cases where the data exhibit high regularity.

We applied this method to the brain wave movies, using all the movie frames as the data set. Surprisingly, we found that as few as 3-10 principal components (out of 120) were sufficient to approximate an entire experimental movie with an accuracy of 80-90%. An examination of the weights of the different components as a function of time revealed that the weight of the first component is proportional to the temporal signal averaged over detectors. We compared the components obtained under different stimulus conditions and found a high degree of similarity. These results suggest that further analyses might be simplified by replacing the data by the first few components. More importantly, they seem to point to a basic low-dimensionality underlying cortical activity. [Supported by The Riklis Family Foundation.]

INTRACORTICAL INTERACTIONS IN CAT VISUAL CORTEX: EVIDENCE FROM POSTSYNAPTIC FIELD POTENTIALS.

T. Kasamatsu, M. Kitano, E.E. Sutter and A. M. Norcia*.
Smith-Kettlewell Eye Res. Inst., San Francisco, CA 94115.

The extensive lateral spread of the dendritic and axonal arborization of cortical neurons is not reflected in the functional organization of single-unit receptive fields which is retinotopic and columnar. We have found local postsynaptic potentials which reflect long-range lateral connectivity.

We compared extracellular single-unit responses and local field potentials in area 17 of the cat using a pair of microelectrodes (tip separation, ~300μm). Single-unit receptive fields were plotted with oriented light bars. Field potentials were elicited using grating reversal at 61 5-deg patches covering the visual field. The temporal modulation of the gratings was pseudorandom. In one experiment only one patch was stimulated at a time, while in another, all patches were stimulated simultaneously but independently.

The two modes of stimulation produced drastically different local responses.With single-patch stimulation two of postsynaptic components with different receptive-field properties were obtained: a fast retinotopic component and a slow non-retinotopic component with a very large receptive field (30 deg across). With all-patch stimulation only the fast component was present. This indicates that the slow component is subject to strong lateral inhibition. These findings suggest the presence of long-range lateral interactions of visual afferents at dendrites within visual cortex.

431.10

EXPERIENCE-DEPENDENT INTRACORTICAL INTERACTIONS IN CAT VISUAL CORTEX: EVIDENCE FROM POSTSYNAPTIC FIELD POTENTIALS.

M. Kitano, T. Kasamatsu, A. M. Norcia* and E.E. Sutter.
Smith-Kettlewell Eye Res. Inst., San Francisco, CA 94115.

Cortical neurons in area 17 receive intracortical lateral afferents from a large cortical area. Using bipolar microelectrodes, we have shown the presence of large "receptive fields" for postsynaptic potentials generated within a small cortical mass in response to contrast reversal of gratings (Kitano et al., Invest. Ophthal. Vis. Sci. Suppl., 1991). Using multi-input, non-linear systems analysis, the field potentials generated in normal visual cortex were divided into fast (retinotopic) and slow (non-retinotopic) postsynaptic potentials. The latter had a large "receptive field" and showed strong spatial interactions inside this field.

In cats which had one eye lid-sutured for 4 years from the age of one week, no single units were found in area 17 responding to stimulation of the lid-sutured eye, but field potentials were evoked. These field potentials had only one component whose waveform was similar to the non-retinotopic slow component obtained by stimulation of the normal eye. However, their receptive field was small, retinotopic and did not exhibit spatial interactions. In kittens which had received single-orientation visual experience binocularly, single units in area 17 showed normal receptive-field properties. In contrast, the characteristics of the field potentials were abnormal and essentially the same as those obtained for stimulation of lid-sutured eye. These findings suggest that normal development of extensive lateral interactions in visual cortex is essential for cortical function.

431.11

SHORT AND LONG TERM CHANGES IN RECEPTIVE FIELD SIZE AND POSITION FOLLOWING FOCAL RETINAL LESIONS.

Charles D. Gilbert and Torsten N. Wiesel. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

The classical view of cortical functional organization is that the receptive field properties of cells are fixed early in life. We have found quite to the contrary that in adult cats and monkeys rather profound shifts in receptive field size and position can be induced by sustained alterations in visual input. Focal retinal lesions at homologous retinotopic loci in the two eyes, destroying the photoreceptor layer but not the cells of the inner retina, were created with a diode laser. This effected a functional "deafferentation" of the cortex, leaving a region of cells that could not be activated by visual stimuli, which we refer to as the "cortical scotoma." The size of the retinal lesion, about 3 to 6° in diameter, was chosen to silence an area of primary visual cortex about 8mm in diameter. Within minutes after making the lesion, cells at the edge of the cortical scotoma had much larger receptive field diameters (by a factor of 2 to 4) than those recorded at the same cortical site before the lesion was made. Over a period of two months following the lesion, the cortical scotoma was entirely filled in, with cells that were originally silenced regaining visual input and shifting their visuotopic representation to retinal loci outside the lesion. For cells in the center of the cortical scotoma, this corresponded to 4mm shifts in the cortical visuotopic map. The shifted fields were orientation selective and remained enlarged relative to their prelesion state. Some cells had bipartite fields, with the subfields lying on either side of the lesion. At a time when the cortical scotoma had filled in, mapping of the LGN revealed a persistent region of unresponsive cells. This suggested that at least part of the topographical reorganization seen in the cortex was due to synaptic changes intrinsic to the cortex. Considering the extent of the alterations in the map, the long range horizontal connections may be responsible for bringing visual information into the scotoma. (Supported by NIH grants EY07968 and EY05253 and by the McKnight and Rita Allen Foundations).

431.12

CONTEXTUAL STIMULI INFLUENCE RECEPTIVE FIELD SIZE OF SINGLE NEURONS IN CAT PRIMARY VISUAL CORTEX.

Mark W. Pettet and Charles D. Gilbert.* Laboratory of Neurobiology, The Rockefeller University, NY, NY, 10021.

Cells in the visual cortex receive input from visual loci outside their receptive fields via intrinsic long range horizontal connections. These connections may mediate the modulation of receptive field properties by contextual stimuli. The effect of the horizontal inputs appears to be amplified by permanent alterations of sensory input, such as those induced by focal retinal lesions, which lead to lasting changes in cortical receptive field size and position. Surprisingly, large increases in receptive field sizes were observed at the edge of the cortical scotoma immediately after the placement of retinal lesions. This led us to test whether receptive field size could be influenced simply by incorporating artifical scotomata into the visual stimulus, and to determine the stimulus characteristics that are most effective for inducing the changes. We first measured the extent of the receptive fields of single cells in the superficial layers of cat primary visual cortex using the minimum response field technique. We then presented an array of moving bars covering a large area of visual field while the receptive field of each recorded cell was masked so that the stimulus would not activate the cell. This conditioning stimulus was interleaved with brief presentations of test stimuli to determine the positions of the receptive field borders. Our preliminary findings revealed that after a few minutes of conditioning, the receptive field diameters of some cells increased two- to three-fold. The effect was reversible: receptive fields could often be reduced to near their original size by presenting the stimulus pattern without the mask, and then expanded again after reintroducing the mask. These results give further evidence for dynamic changes in receptive field properties, depending on context. One may speculate that the balance between excitation and inhibition produced by the horizontal input may be altered by context, resulting in the observed changes. CATECHOLAMINE RECEPTORS: DOPAMINE V

432.1

MOLECULAR CLONING AND EXPRESSION OF A NOVEL D_1 DOPAMINE RECEPTOR WITH A UNIQUE DISTRIBUTION IN THE CENTRAL NERVOUS SYSTEM.

M. Tiberi, K.R. Jarvie, C. Silvia*, P. Falardeau, J.A. Gingrich*, T.L. Yang-Feng*, R.T. Fremeau Jr. and M.G. Caron. Dept. of Cell Biology, Duke University Medical Center, Durham, NC 27710.

Cloning techniques have now established that five different genes code for dopamine receptor subtypes in the central nervous system, two D_1 receptor subtypes and three D_2 related subtypes. Here we report the cloning of a rat gene coding for a novel D_1 receptor subtype. The rat gene has an intronless open reading frame of 1425 nucleotides which encodes a protein of 475 amino acids. This protein has structural features that are similar to G protein-coupled receptors. In COS-7 cells, the expressed protein binds dopaminergic ligands with a pharmacological profile similar to the previously cloned rat and human D_1 dopamine receptor. In 293 cells, D_1-selective agonists elicite a stimulation of adenylyl cyclase which is blocked by the D_1-selective antagonist SCH23390 but not by D_2- or β-antagonists. The human homologue of this novel gene is localized to the short arm of the chromosome 4 (4p16), the same region as the Huntington's disease gene. Northern analyses revealed that the mRNA for this gene (~3.0 kb) is essentially expressed in hippocampus and hypothalamus. In situ hybridization showed that high levels of mRNA are found in distinct layers of hippocampus, the mammillary nuclei and the anterior pretectal nuclei. In contrast to the previously cloned D_1 receptor, little or no mRNA for this novel receptor was observed in striatum, nucleus accumbens, olfactory tubercle and frontal cortex. The unique distribution of this receptor in restricted regions of the brain suggests a possible role for this receptor in visual and limbic functions. Based on its characteristics we suggest that this new dopamine receptor subtype be referred as the D_{1B}.

432.2

CLONING AND SEQUENCE OF A DOPAMINE RECEPTOR FROM OPOSSUM KIDNEY (OK) CELLS THAT IS EXPRESSED IN BOTH KIDNEY AND BRAIN.

S.R. Nash*, M.G. Fornaretto*, M.D. Bates*, J.R. Raymond*, & M.G. Caron. Dept. of Cell Biology, Duke Univ. Med. Ctr., Durham, NC 27710

In the kidney, dopamine increases renal blood flow through vascular effects and promotes natriuresis and diuresis through tubular effects. Dopamine receptors have been described in the renal cortex by autoradiographic, ligand binding, and second messenger studies; however, both pharmacological and molecular biological evidence suggests that previously cloned human and rat D_1, D_2, and D_3 receptors are not expressed in the kidney. In order to clone a kidney specific dopamine receptor message, we used a probe from the 5' end of the human D_{1a} receptor message coding block to screen a cDNA library made from opossum kidney (OK) cell mRNA. This established epithelial cell line, which expresses DA1 dopamine receptors, has been shown to have biochemical characteristics of proximal tubule cells. A partial cDNA clone containing an open reading frame homologous to the amino terminal half of G-protein coupled receptors was isolated from this library. Specific oligonucleotides were used to obtain the remaining portion by RACE-PCR. The deduced amino acid sequence from the open reading frame of this 1.8 kb message is 89% and 87% identical to the previously characterized human and rat D_1 receptors (D_{1a}) respectively (Dearry *et al. Nature* **347**:72-76 (1990); Zhou *et al. Nature* **347**:76-80 (1990)). The encoded receptor protein contains all the essential hallmarks of catecholamine receptors: glycosylation sites in the extracellular domains, conserved aspartate and serine residues in the 3rd and 5th transmembrane regions, and several consensus phosphorylation sites in intracellular regions. In situ hybridization using a probe derived from the 5' end of the cDNA yielded specific hybridization signals in opossum (*Didelphis virginiana*) renal cortex and various brain regions (e.g. corpus striatum, accumbens, and olfactory tubercle). It will be of interest to determine whether this receptor represents the synonymous D_{1a} sequence in a marsupial species or a new subtype highly homologous to the CNS specific D_{1a} receptor but expressed in both kidney and brain.

432.3

THE D1 DOPAMINE RECEPTOR AND ITS mRNA ARE MODULATED BY AGONIST.

C. Silvia, M. Caron and S. Collins*. Dept. of Cell Biology and Howard Hughes Institute, Duke Univ., Durham, N.C. 27710.

The recent cloning of the gene for the D1 dopamine receptor has provided a molecular probe for investigating the metabolism of D1 receptor and its mRNA in SK-N-MC human neuroblastoma cells. Northern blots of SK-N-MC cell mRNA probed for dopamine D1 receptor reveal a strongly hybridizing band at 4.2 kilobases. The identity of the mRNA was confirmed by RNAse protection assays using a fragment from the 5' untranslated region of the D1 receptor. Treatment of SK-N-MC cells with 10μM dopamine for varying lengths of time caused a 40% increase in D1 mRNA by one hour followed subsequently by a rapid decline to 70% of untreated levels by 3 hours and a slower decline to 50% by 12 hours. D1 receptor levels as measured by ^{125}I-SCH23982 binding show a slight rise over one hour followed by a decline to 37% of control by 12 hours. The observed increase in D1 mRNA is probably due to increased synthesis, since nuclear runoff experiments show a two-fold increase in D1 mRNA synthesis in nuclei from cells pretreated with dopamine for one hour. D1 mRNA half-life is unchanged in treated cells, further supporting this hypothesis. The responses of D1 receptor and mRNA to agonist are similar to those found for the β2 receptor and the LH/CG receptor, raising the possibility that this is a general phenomenon associated with G-protein coupled receptors that stimulate adenylyl cyclase.

432.4

SHORTER VARIANTS OF THE D_3 DOPAMINE RECEPTOR PRODUCED THROUGH VARIOUS PATTERNS OF ALTERNATIVE SPLICING.

B.Giros, M.P.Martres*, C. Pilon*, P. Sokoloff* and J.C. Schwartz*. Neurobiologie et Pharmacologie de l'INSERM, 2ter rue d'Alesia, 75014 Paris, France

Using Polymerase Chain Reaction (PCR) amplification of mRNAs from several areas of rat brain we have shown the occurrence of two shorter transcripts of the dopamine D_3 receptor gene, in addition to that corresponding to the D_3 receptor. Cloning and sequencing of these transcripts, together with the establishment of the exon-intron organization and structure of the D_3 receptor gene, shown these transcripts to result from different processes of alternative splicing. The first transcript encodes a 100 amino-acid protein produced by splicing of an exon whose absence deletes the third transmembrane domain and gives rise to a frameshift in the open reading frame. In the second transcript, an in frame 54 bp deletion is produced by splicing occurring at an internal acceptor site, suppressing half of the second extracellular loop and a part of the fifth transmembrane domain. This latter transcript was stably expressed in CHO cells which failed to reveal any dopaminergic ligand binding activity. The functionnal significance and possible role of these shorter variants of the dopamine D_3 receptor in cell signaling and aetiology of psychiatric diseases remains to be established.

432.5

STABLE TRANSFECTION OF CELL LINES WITH DOPAMINE RECEPTORS. T. M. Filtz, B. R. Monks* and P. B. Molinoff. Dept. of Pharmacology, Univ. of Penn. School. of Med., Philadelphia, PA 19104

Classically, dopamine receptors have been divided into two subtypes, D1 receptors linked to stimulation of adenylyl cyclase with high affinity for SCH-23390 and other benzazepines, and D2 receptors linked to inhibition of adenylyl cyclase with high affinity for butyrophenones and other neuroleptics. Six subtypes of dopamine receptors have thus far been cloned and sequenced. D1 and D5 receptor cDNA clones have similar coding sequences, and, when expressed in mammalian cells, have the pharmacological profile and second-messenger linkage expected of D1 receptors in striatal homogenates. $D2_S$, $D2_L$, D3, and D4 receptors are similar in coding sequence and possess the pharmacological properties associated with D2 receptors. Given the multiplicity of dopamine receptors and the complexity of the central nervous system, the pharmacological properties of these receptors are difficult to resolve *in vivo*. Selective expression of subtypes of dopamine receptors in mammalian cell lines permits unambiguous characterization of their properties. The rat D1 receptor, the human $D2_S$ and $D2_L$ receptors, and the rat D3 receptor coding sequences were excised with appropriate restriction enzymes from bacterial expression vectors and blunt-end ligated into a eukaryotic expression vector, pRC/CMV. This vector contains the cytomegalovirus promoter for high copy number in mammalian cells and a neomycin-resistance sequence for the selection of permanently transfected cell lines. COS-7, CHO, 293, and AtT-20 cells have been transiently transfected with D1, $D2_S$, $D2_L$, and D3 receptor sequences. Expression of receptors has been confirmed by radioligand binding studies using ^{125}I-SCH-23982, ^{125}I-IBZM, and ^{125}I-NCQ-298. Studies with the D2 receptor-selective antagonists ^{125}I-NCQ-298 and ^{125}I-IBZM show no differences between $D2_S$ and D3 receptors when expressed in COS-7 cells. Stable transfectants have been isolated and receptor expression confirmed by radioligand binding studies in COS-7 and CHO cells. (USPHS NS18591 and a PMA Foundation Fellowship)

432.6

Localization of D2 DA Receptor mRNA in Primary Olfactory Neurons. MICHAEL T. SHIPLEY, WILLIAM T. NICKELL, ANDREW B. NORMAN (University of Cincinnati) and CHARLES GERFEN (NIMH).

The glomeruli of the olfactory bulb are densely innervated by dopaminergic (DA) interneurons; the post-synaptic targets of these neurons are unknown. We recently showed that most DA receptors in the bulb are of the D2 subtype and are selectively localized in both the glomerular and the *olfactory nerve* layers. This suggested that DA neurons target D2 receptors on olfactory nerve terminals. Consistent with this idea, nerve lesions eliminate D2 binding in *both* the nerve and glomerular layers. If D2 receptors are present on olfactory nerve terminals, then these receptors should be synthesized in the cell bodies of primary olfactory neurons (PONs).

An ^{35}S-labelled oligonucleotide cDNA probe specific to the D2 receptor was used to localize D2 receptor sequences in rat olfactory epithelium using *in situ* hybridization.One olfactory bulb was removed from each rat 14 days prior to sacrifice. D2 mRNA labelling was present in all regions of the olfactory epithelium on the intact side; labelling was absent from the epithelium on the side of the ablated bulb. Since ablation of the olfactory bulb causes degeneration of the PONs, the present results demonstrate that the D2 mRNA is localized in the PONs and not in other cells in the epithelium.

Taken together, these findings support the hypothesis that juxtaglomerular DA neurons are presynaptic to olfactory nerve terminals. This implies that there is presynaptic DA regulation of olfactory nerve terminals. Synaptic targeting of olfactory nerve terminals by DA neurons might also explain the loss of DA and TOH in the bulb after peripheral deafferentation: Deafferentation would deprive juxtaglomerular DA neurons of their postsynaptic target. Target regulation of transmitter phenotype occurs in other neural systems. Supported by NIH-DC00347 and NS29218.

432.7

DIRECT VISUALISATION OF DIFFERENT DOPAMINE RECEPTOR CLASSES IN THE MAMMALIAN BRAIN: A CORRELATIVE STUDY USING IN SITU HYBRIDIZATION HISTOCHEMISTRY AND RECEPTOR LIGAND AUTORADIOGRAPHY.

J.M. Palacios[1,2], G.B. Landwehrmeyer*[3], G. Mengod[1,2]

[1] CID.CSIC Barcelona , Spain, [2] Sandoz Pharma Ltd, [3] Dep. Pathology Univ. Basel, Switzerland

The genes coding for several dopamine receptors have been recently characterized. The D2, D3 and D4 receptor classes are all recognized by ligands previously considered to be "D2" selective. In order to establish a differential labeling of these sites with the available "D2" ligands, we first identified the brain regions enriched for mRNA coding for a specific receptor form by in situ hybridization histochemistry using ^{35}P-labelled oligonucleotides. The pharmacological characteristics of the receptors in these regions were determined by direct labeling with [^{3}H]-spiperone, [^{3}H]-raclopride, [^{3}H]-CV 205 502, [^{125}I]-iodosulpride and [^{3}H]-YM 09151-2. Furthermore, displacement experiments using unlabeled compounds like domperidone, raclopride, clozapine and quinpirole, which present some selectivity for the different "D2" receptor classes, were carried out .The results obtained show that by combining selected radioligands with unlabeled compounds experimental conditions can be defined to visualise specifically the different dopamine "D2"-like receptor classes.

432.8

REGIONAL DIFFERENCES IN DOPAMINE D_1 AND D_2 AGONIST AFFINITIES IN THE RAT BRAIN G. von Euler and P. Hedlund* Dept. of Histology and Neurobiology, Karolinska Institutet., Box 60400, S-10401 Stockholm, Sweden

Competitive-inhibition curves with dopamine on [^{3}H]SCH 23390 (a D_1 antagonist) binding and on [^{125}I]sulpride (a D_2 antagonist) binding were analyzed by quantitative receptor autoradiography on cryostat sections in order to reveal possible regional differences in agonist affinities at D_1 and D_2 receptors in the rat brain. The IC_{50} value, probably corresponding to K_{Low}, of dopamine versus [^{3}H]SCH 23390 was lower in the nucl. accumbens (32%) but higher in the tub. olfactorium (217%) than in the striatum (100%=2.74 μM). No high affinity D_1 agonist binding was observed. The K_{High} value of dopamine versus [^{125}I]sulpride was lower in the nucl. accumbens (57%) and tub. olfactorium (45%) than in the striatum (100%=1.13 nM). In contrast, the K_{Low} was higher in the nucl. accumbens (146%) and tub. olfactorium (218%) than in the striatum (100%=12.7 μM). The percentage of binding sites in the high affinity state with regard to the total number of binding sites was higher in the nucl. accumbens (69%) and the tub. olfactorium (75%) than in the striatum (64%), indicating a higher degree of G-protein association in the former areas.

Taken together, the results indicate the presence of regional differences in the agonist affinities at central D_1 and D_2 receptors, which may underlie regional differences in the postsynaptic effects of dopamine neurotransmission. The affinity changes of the D_2 receptor may reflect regional differences in the phosphorylation state of the receptor, in the distribution of D_2 receptor subtypes, or in the association to modulatory receptors such as neurotensin receptors and adenosine A_{2a} receptors.

432.9

RECOVERY OF CENTRAL D_1 AND D_2 RECEPTORS FOLLOWING ALKYLATION IN YOUNG AND ADULT RAT BRAIN. R.J. Baldessarini, N. Kula*, T. George*, A. Campbell*, V. Bakthavachalam*, and J.L. Neumeyer. Departments of Psychiatry and Neuroscience Program, Harvard Medical School; Laboratories for Psychiatric Research, Mailman Research Center, McLean Division of Massaschusetts General Hospital, Belmont, MA 02178; and Research Biochemicals, Inc. (RBI), Natick, MA 01760.

Novel D_1 and D_2 receptor-selective alkylating agents are being developed and evaluated for their ability to bind irreversibly to central dopaminergic receptor proteins. Agents tested included several D_2-selective alkylating derivatives of *p*-aminophenethylspiperone (NAPS), such as the *p*-isothiocynate (NIPS) or its bromacetamino or ethylfumaramido congeners, and other nonalkylating N-substituted spiperone derivatives, which were compared with the nonselective alkylating agent 1-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ). Rates of recovery of dopaminergic receptors were assessed by increases in binding of selective ligands to D_1 (^{3}H-SCH-23390) or D_2 sites (^{3}H-YM-09151-2) in corpus striatum tissue, as well as of behavioral arousal induced by R(−)-apomorphine in the rat from 1 to 10 days after initial treatment with a test agent. We have found an orderly progression of recovery rates in adult rat following a series of N-alkyl-aryl derivatives of spiperone (methyl, phenethyl, NAPS and NIPS), with the slowest recoveries found with the alkylating compound NIPS ($t_{1/2}$ = 1–2 days). These rates were compared with those found after treatment with EEDQ. Recovery of both D_1 and D_2 sites in brain tissue (as B_{max} values) of 25–35-day old rats was more rapid than in adults. The latter observation corresponds with relatively high concentrations of these receptor proteins in brain tissue of similarly aged rats. Agents such as those tested show great promise for the study of synthesis rates of dopaminergic receptors. [Supported by USPHS-NIMH grants MH-34006, MH-45692, and MH-47370, and an award from the Bruce J. Anderson Foundation.]

432.10

EFFECT OF SELECTIVE D1 AND D2 DOPAMINE (DA) RECEPTOR INACTIVATION IN SUBSTANTIA NIGRA (SN) ON RESPONSES OF SN DA NEURONS TO I.V. R(-)NPA. R.F. Cox and B.L. Waszczak, Pharmacol. Sect., Northeastern Univ., Boston, MA 02115.

We have shown that SN but not striatal injections of the receptor inactivator N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) reduce the ability of of i.v. R(-)N-n-propylnorapomorphine (NPA) to inhibit SN DA cell firing (Soc. Neurosci. Abstr. 16:696, 1990). The effect was revealed as a rightward shift and depressed maximum of the NPA dose-response curve. We have now used selective receptor inactivation strategies to examine contributions of SN D1 or D2 DA receptors in this response. An hour before intranigral EEDQ injections (100 nmol/ul), rats were given s.c. "protection cocktail" (prazosin, idazoxan and ketanserin) containing either SCH 23390 (SCH, 4 mg/kg) to shield D1 sites, or eticlopride (ETIC, 2 mg/kg) to protect D2 sites. Controls received protection mixtures but no EEDQ. Single unit recording studies were done a day later, followed by quantitative autoradiography to assess the degree of SN D1 and D2 receptor loss. The ED50s for NPA were elevated after pretreatment with both SCH or ETIC, compared to control rats given only the basic cocktail (ED50s: 0.3 ug/kg, control; 1.5 ug/kg after SCH; 0.9 ug/kg after ETIC). Selective SN D2 receptor inactivation further increased the NPA ED50 to 2.3 ug/kg and reduced the maximum inhibitory response to 82%. SN D1 receptor inactivation, however, caused no decline in the maximum response and gave an NPA ED50 of 1.0 ug/kg, indicating no further change in the position of the curve relative to that for protection cocktail + ETIC. Autoradiography confirmed the selective loss of each receptor, i.e. SN D2 sites declined by 74% but D1 sites dropped by only 2% after SCH protection, whereas D2 sites declined by just 9% but D1 sites fell by 84% after ETIC. Overall, these results indicate a predominant role for SN D2 receptors in mediating the inhibition of DA cell firing by i.v. NPA. However, because SCH pretreatments also elevated the ED50 for NPA, a slight contribution from D1 receptors cannot be ruled out. (Support: NS 23541)

AMPHETAMINE-STIMULATED DOPAMINE RELEASE COMPETES IN VIVO FOR ^{123}I-IBZM BINDING TO THE D2 RECEPTOR IN PRIMATES. M. Al-Tikriti, R. Malison, S. Zoghbi*, P. Hoffer*, J. Seibyl, M. Laruelle, R. Baldwin*, E. Sybirska, E. Smith, D. Charney, J. Elsworth, R. Roth and R. B. Innis Depts. Psychiatry & Radiology, VA Med. Ctr. and Yale Univ., West Haven, CT 06516.

The reversibly binding D2 dopamine receptor radioligand ^{123}I-IBZM (iodobenzamide) was used to test whether the endogenous neurotransmitter dopamine competes *in vivo* for radiotracer binding measured with single photon emission computed tomography (SPECT).

In a series of non-human primate experiments (n=27), the effects of temperature, amphetamine, haloperidol, and reserpine on brain uptake of ^{123}I-IBZM were measured. After i.v injection of ^{123}I-IBZM (1.9-17.3 mCi), specific brain uptake reached a peak by 100 min and demonstrated a gradual, apparent "steady-state" washout over the next 2 hrs. Brain uptake was temperature dependent, with rates of washout of specifically-bound radioligand greater under normothermic conditions (26%/hr: core body temperature 35-37°C) than under controlled hypothermia (11%/hr; 32-34°C). Given the greater retention of radioactivity, low temperature conditions were used in all other experiments. Administration of haloperidol (0.02 mg/kg i.v.) during the period of apparent steady state resulted in a dramatic increase in washout (60%/hr) as did d-amphetamine (1.0 mg/kg i.v.; 34%/hr). Reserpine pretreatment (1.0 mg/kg i.v.) caused greater than 90% depletion of striatal dopamine levels, blocked amphetamine-enhanced washout (10%/hr), but did not block the effects of the direct-acting D2 receptor antagonist haloperidol. Postmortem analysis of the two animals pretreated with reserpine confirmed greater than 90% depletion of tissue dopamine levels.

These results are consistent with the hypothesis that endogenous dopamine effectively competes for radioligand binding in neuroreceptor imaging studies and suggest that receptor imaging may be developed to monitor transmitter turnover.

432.12

IN VIVO HUMAN DOPAMINE RECEPTOR QUANTIFICATION IN SELF-INJURIOUS BEHAVIOR SYNDROMES. DF Wong, J Harris, S Naidu,* E Shaya,* M Yaster,* RF Dannals,* AA Wilson,* H Ravert,* HN Wagner, Jr.,* W Nyhan,* H Moser,* Div. Nuclear Medicine, Kennedy Inst. and Div. Child Psychiatry, Johns Hopkins Univ., Balto. MD. 21205

The Lesch Nyhan (LN) and Rett syndromes are neurodenerative disorders with infantile onset associated with motor handicaps and a compulsive hand to mouth behavior leading to self injury (SIB). Post mortem studies and CSF dopamine metabolite measurements show both disorders have dopamine neurotransmitter abnormalities. Six LN males (aged 4 to 23) and 4 Rett females have been studied with a quantitative model which requires 2 PET scans to determine absolute D2 receptor density B_{max} using ^{11}C NMSP. Motor handicaps are so severe that general anesthesia (nitrous oxide with rectal methohexital induction) is necessary for immobilization for the 90 minute PET procedure. When compared to normal subjects aged 18-70 years the B_{max} showed a linear fall with age. Three adult Rett Syndrome cases showed borderline low B_{max}, while LN cases showed high normal or elevated B_{max} relative to 95% confidence limits on a linear regression. Animal models of self injury respond to D1 antagonists and suggest that in vivo D1 studies in LN and Rett syndrome need further study. Investigations of the D1/D2 interaction in vivo compared to post mortem values would assist in understanding the pathogenesis. Supported by NICHD 23042, 23540, 24061.

TIRILAZAD MESYLATE (U-74006F) ATTENUATES THE ACCUMULATION OF NEUTROPHILIC LEUKOCYTES (NLs) IN ISCHEMIC GERBIL BRAIN. J.A. Oostveen and L.R. Williams. CNS Diseases Res., The Upjohn Co., Kalamazoo, MI.

The involvement of NLs was examined in the gerbil unilateral carotid occlusion (UCO) model of transient focal cerebral ischemia (Hall et al., 1988). Frozen coronal sections were processed with cytochrome oxidase (CO), myeloperoxidase (MPO), and cresyl violet histochemistry. In control gerbils after 3 hr UCO, NLs are clumped within the cerebral vasculature, and are commonly observed crossing the capillaries into the brain parenchyma. After UCO and 24 hr of reperfusion, there is considerable necrosis within the ischemic hemisphere, and numerous CO- and MPO-positive, degranulated NLs are dispersed throughout the necrotic tissue. Computer-assisted image analysis of the lateral cortex indicated an average (± SEM) density of 194 ± 32 (CO) and 202 ± 41 (MPO) cells/mm^2 (n=7). In gerbils treated with U-74006F (10 mg/kg i.p.), the density of CO-positive cells was significantly reduced by 66% ($p \leq 0.05$). The density of MPO-positive cells was reduced 31%. Thus, one mechanism by which U-74006F provides cytoprotection to ischemic brain tissue may be to limit the accumulation of NLs in tissue at-risk, thus limiting consequent NL-mediated oxidative tissue destruction.

MK801 INCREASES CBF IN "MODERATELY" ISCHEMIC RAT CORTEX. M. Jacewicz, U. Dirnagl and W. Pulsinelli. Dept. Neurology and Neuroscience, Cornell Univ Medical Center, New York, NY 10021

The effect of MK801 (an NMDA antagonist) on cerebral blood flow (CBF) was studied in Spontaneously Hypertensive rats under conditions in which MK801 reduces cortical infarct volume (from 169 ± 34 mm^3 to 134 ± 58 mm^3, Dirnagl, 1990, Brain Res 527:62) following middle cerebral artery and common carotid artery occlusion (MCA/CCAO). Rats received MK801 5mg/kg i.p. (N=10) or saline (N=10) 30 min before undergoing MCA/CCAO under brief halothane anesthesia. A ^{14}C-iodoantipyrine CBF study was performed in conscious rats at 2.5 h after MCA/CCAO, when ischemic injury in this model becomes largely irreversible and enlargement of the ischemic tissue volume has nearly peaked (Jacewicz et al, submitted). The volumes of ischemic cortex with CBF <35 ml/100g/min (VIC_{35}) and CBF = 35-65 ml/100g/min (VIC_{35-65}) were quantified by ^{14}C-autoradiography and computerized image analysis. Body temperatures were maintained at 37.5 ± 0.5 °C, and physiologic variables remained comparable in MK801-treated animals and controls.

MK801 caused widespread increases in CBF except in the ischemic core of the middle cerebral artery (MCA) territory. MK801 shrank VIC_{35-65} from 82 ± 25 mm^3 (controls) to 50 ± 12 mm^3 ($p < 0.05$, Student's t-test) while having no effect on VIC_{35} (79 ± 41 mm^3 and 79 ± 61 mm^3 in MK801-treated rats and controls respectively). Recent work (Jacewicz et al, submitted) has determined that rat cortex with CBF = 35-50 ml/100g/min will infarct and oligemic regions (CBF = 50-65 ml/100g/min) will suffer ischemic injury if ischemia is prolonged. In this model, the modest protection MK801 offers against infarction may involve critical CBF increases in the moderately ischemic cortex of the MCA periphery.

HYPOTHERMIA IN PERMANENT FOCAL ISCHEMIA: EVOKED POTENTIALS, REGIONAL CEREBRAL BLOOD FLOW AND QUANTITATIVE MRI. E.H.Lo and G.K.Steinberg. Department of Neurosurgery, Stanford University School of Medicine, Stanford, CA94305.

A rabbit model of permanent focal ischemia was used to study the effects of hypothermia on somatosensory evoked potentials (SEP), regional cerebral blood flow (rCBF) and quantitative magnetic resonance imaging (MRI) parameters. Three temperature (temporal muscle) groups were used: 37°C, 33°C, and 30°C (n=4 per group). SEPs were measured before and after occlusion. After 4 hrs of permanent focal ischemia, rCBF was measured using radioactive microspheres. Brains were removed immediately afterwards for MRI measurements. Improved SEP recovery was found in the 30°C and 33°C groups compared to the normothermic group ($p<0.05$). T1 and T2 MRI values of the core ischemic regions were significantly increased in the normothermic group ($p<0.05$, left vs right hemisphere). In both hypothermic groups, left vs right T1 and T2 values were not significantly different. No significant differences in rCBF were found between any temperature groups. These results demonstrate that hypothermia protects against permanent focal ischemia without altering rCBF.

CHANGES IN EXTRACELLULAR OPIOID PEPTIDES AND DOPAMINE FOLLOWING FOCAL CEREBRAL ISCHEMIA

G.K. Steinberg, N.T. Maidment, E.H. Lo, and C.J. Evans
Dept. of Neurosurgery, Stanford University Medical School, Stanford, CA

Increases in extracellular excitatory amino acids and dopamine have been implicated in the pathophysiology of cerebral ischemic injury. However, it is not known whether ischemia-induced release is restricted to certain neurotransmitters or is more widespread. This study used microdialysis to measure extracellular opioid peptides and dopamine in the caudate nucleus of the rabbit using ischemic episodes of varying duration. Twelve rabbits underwent stereotactic placement of a dialysis probe in the caudate. Baseline samples were collected and rabbits underwent occlusion of the left internal carotid, anterior cerebral and middle cerebral arteries. The time from occlusion to sacrifice was 6 hours but the duration of occlusion was varied between 10 minutes and 6 hours. Opioid peptides were measured with RIA and dopamine with HPLC. Ischemic neuronal damage (IND) was assesed with histopathology. Extracellular content of opioid peptides and dopamine increased markedly between 15 - 234X within the first 10 minutes after occlusion. The rate of return to preocclusion levels was dependent on the length of the occlusion period, but dopamine levels remained elevated longer than opioid peptide levels. Histopathology revealed > 75% area severe IND in the striatum when the occlusion was ≥30 minutes. These results suggest that ischemia-induced increases in extracellular neurotransmitters are a general phenomenon. If either dopamine or opioid peptide are involved in ischemic neuronal damage, a sustained elevation in their extracellular content may be required to produce such injury.

POST-ISCHEMIC TREATMENT WITH FELBAMATE REDUCES DELAYED NEURONAL CELL DEATH. C.G. Wasterlain, L.M. Adams, and P.H. Schwartz. Epilepsy Res. Labs., VAMC, Sepulveda, CA 91343.

Rescuing neurons from delayed cell death should be one of the main goals of post-ischemic therapy. We previously reported that the anticonvulsant felbamate protects neurons from hypoxic and/or ischemic injury *in vitro* and *in vivo*. This study investigated the effectiveness of felbamate given after the hypoxic-ischemic insult in reducing delayed neuronal necrosis. We used 7-day-old rat pups subjected to bilateral carotid ligation, followed by a 1 hr exposure to 6% O_2, and sacrificed 72 hr later. 100-400 mg/kg ip injections or oral administration (300-500 mg/kg) raised serum felbamate to 100-150 μg/mL for several hours. Following bilateral carotid ligation and exposure to 6% O_2 for 1 hour (which had no effect on serum levels), felbamate (300 mg/kg ip) given immediately (0 hr), 1, 2, or 4 hr after the end of hypoxia significantly reduced the volume of neocortical infarcts by 55%, 30%, 44%, and 24%, respectively. In this model, dentate gyrus granule cells are intact at 4-24 hours after the insult but display delayed necrosis by 72 hours. Felbamate given immediately after hypoxia reduced granule cell necrosis by 92% ($p<0.001$). Single doses of 100 and 200 mg/kg were less effective given after the insult than 300 or 400 mg/kg. These data suggest that felbamate given after a hypoxic-ischemic insult is very effective in rescuing neurons from delayed post-ischemic death.

LIPOCORTIN-1 INHIBITS CEREBRAL ISCHAEMIA. J.K.Relton[*1], F.Carey[*2], D.C.U'Prichard[2] and N.J.Rothwell[*1]. [1]Dept. Physiol. Univ. of Manchester, UK. [2]ICI, Macclesfield, UK.

The objective of the experiment was to determine the effect of lipocortin-1 (annexin-1), an endogenous phospholipid and calcium binding protein, on neuronal damage following cerebral ischaemia (unilateral middle cerebral artery occlusion (MCAo)) in the rat. The extent of damage was determined using a stain for mitochondrial viability (tetrazolium blue), and results quantified using a Seescan image analysis system. Central injection (1.2μg icv) 30min prior to and 10min after MCAo, of an active fragment of lipocortin-1 (N-terminal 1-188aa) profoundly reduced (by 71.4 ± 8.5%) the extent of neuronal damage (infarct volume) assessed at 24h (81.2 ± 15.5 vs 23.2 ± 6.9mm^3, $n=8$, $p<0.01$). In a separate study, a single injection (4μl icv), 10min after MCAo, of neutralizing anti-lipocortin-1 fragment antiserum increased (by 53.2 ± 18.1%) the size of infarct assessed 2h later (22.6 ± 2.4 vs 34.6 ± 4.1mm^3, $n=10$, $p<0.05$). These findings indicate that lipocortin-1 is an endogenous inhibitor of cerebral ischaemia with considerable therapeutic potential.

Early neuronal membrane injury precedes very delayed histologic degeneration after "ischemia" in organotypic hippocampal culture. J. J. Vornov, R. C. Tasker and J. T. Coyle Depts. Neurology, Anesthesiology, Neuroscience and Psychiatry, The Johns Hopkins School of Medicine, Baltimore, MD 21205

To examine the time course of ischemic injury, we have used organotypic hippocampal culture which preserves synaptic circuitry and regional differentiation. Brief *in vitro* "ischemia" was achieved with 2-deoxyglucose (2-DG) and potassium cyanide (KCN) to inhibit glycolysis and oxidative metabolism. Propidium iodide fluorescence was used to observe early membrane injury as it occured in the living culture. Staining was most rapid following a 30 minute exposure at high concentration (5 mM 2-DG, 1 mM KCN), and only started after 2-4 hours of recovery. The staining began in CA1, then involved CA3 with sparing of the dentate gyrus. Histology after 24 hours of recovery demonstrated marked pyknosis of neuronal nuclei in the propidium stained regions. Exposures of either shorter durations (8-15 min) or lower concentrations of 2-DG and KCN produced a pattern of propidium staining which was further delayed (4-6 hours), less intense, and affected only CA1 and then CA4/CA3c, but spared CA3a,b and the dentate gyrus. Histology at 24 hours was largely normal. With longer recovery (3, 5, and 7 days), an increasing severity of pyknosis was noted in the areas showing early propidium staining. The time course and regional distribution of ischemic neuronal degeneration in organotypic culture appears to reproduce that observed in animal models. Membrane injury, as revealed by propidium staining, far precedes histologic degeneration. Furthermore, the pattern of injury is distinct from that produced by brief exposure to NMDA .

SEROTONIN MAY MEDIATE PLATELET NEUROTOXICITY. Rajiv Joseph, Chock Tsering, Saul Grunfeld and KMA Welch. Lab. of Experimental Hematology & Stroke, Henry Ford Hospital, Detroit, MI 48202.

Our earlier studies suggested that platelet secretory products have a toxic effect on acetylcholinesterase positive neurons in organotypic spinal cord cultures (Neurology 1991; 41 (Suppl.1):163). Further work was done with added refinements such as use of gel-filtered platelets, platelet membrane and red blood cells as additional controls, and using both rat and human platelets. The results indicate, as in our previous study, that platelet secretion has a morphologically demonstrable toxic effect on neurons ($p<0.0001$). In order to identify a toxic component from among the known platelet secretory products, experiments were carried out exposing the explants to 5HT, a major platelet product. Based on the concentration of 5HT in whole blood, before and after platelet activation, and the estimated content of platelets in an occlusive thrombus, we calculated that the concentration of 5HT around an acute thrombus could well reach 4000 times the concentration in whole blood with the platelets unactivated. We exposed the explant-cultures to varying concentrations of 5HT in order to obtain a dose-response curve. There was evidence of neurotoxicity at 5HT concentrations of 3.5 uM and higher. The number of surviving neurons in the treated group ([5HT] 350 uM) was 72% less than in the controls ($P<0.0001$). Considering that this effect was seen with a 5HT concentration (350 uM) that is about one-fourth the calculated concentration that could theoretically be present in the vicinity of an acute thrombus, it appears reasonable to postulate that 5HT could significantly contribute to ischemic neuronal injury.

433.9

SOMATOSTATIN AND DYNORPHIN A INDUCE INCOMPLETE FOCAL ISCHEMIC CORTICAL INJURY IN RATS. J.B. Long and F.C. Tortella, Neuropharm. Br., Dept. of Med. Neurosci., Walter Reed Army Inst. of Res., Washington, D.C. 20307.

Vasoactive peptides are evident in innervations of the cerebrovasculature and can pharmacologically alter microcirculatory function. After spinal subarachnoid injection in rats, dynorphin A (DYN) and somatostatin (SOM) cause dose-dependent reductions in blood flow that lead to neuronal loss and persistent hindlimb paralysis. We now describe parietal cortical responses to these peptides following their topical application in anesthetized rats. Videomicroscopy and laser doppler flowmetry revealed that application of 10 μl of artificial CSF containing 10-40 nmoles of these peptides caused immediate intense arteriolar vasoconstriction associated with dose-dependent 30-90% focal reductions in blood flow of 45-90 min duration. Cortical EEG monitored 1-2 mm from the site of application indicated that 70-80% reductions in blood flow induced by 40 nmoles of SOM were associated with 50-60% reduction in EEG amplitude coincident with induction of paroxysmal epileptiform activity. Evans Blue dye extravasation revealed appreciable localized breakdown of the blood-brain barrier by 2 hrs after peptide application. After 1 week, the site of peptide application was characterized by large hemorrhagic lesions, gliosis, and macrophage infiltration confined to the cortex. These results indicate that these peptides provide a novel pharmacological means to conveniently and reproducibly study the pathophysiology associated with focal incomplete ischemia/reperfusion injury to the neocortex.

433.10

REPERFUSION IN A RAT MODEL OF FOCAL ISCHEMIA. W.R. Selman*, A. Hopkins*, R.C. Crumrine, R.A. Ratcheson and W.D. Lust. Departments of Neurosurgery and Anatomy, Case Western Reserve University, Cleveland, OH 44106

Reperfusion following focal ischemia has been shown to be of little benefit in protecting tissue from injury if initiated after 2 h of occlusion. In this report, the metabolic recovery of the focal and perifocal regions was examined at 1 h of reflow either after 1 h [1,1] or 4 h [4,1] of middle cerebral artery (MCA) occlusion in spontaneously hypertensive rats. Diffusion-weighted MRIs were performed after reflow and the brains were frozen in situ at 1 h of reperfusion. Tissue sections were lyophilized and dissected based on the hyperintense areas on the MRI scans, which presumably indicate edematous changes at these early time periods.

The edematous regions corresponded with infarcted areas at 3 days post-occlusion. The area of edema in the [1,1] group was confined to the ventrolateral cortex, whereas in the [4,1] group the edema extended dorsally to include the entire ipsilateral cortex served by the MCA. Glucose levels were at or above control in all regions, suggesting that all tissues, including the ischemic core, were reperfused. ATP and P-creatine did not recover in either the ischemic core or the perifocal region in the [4,1] group. While ATP in the [1,1] group recovered to 60% of control, the P-creatine levels completely recovered in both the focal and perifocal region. Lactate remained significantly elevated in both regions of the [4,1] group and in the ischemic core of the [1,1] group. In the perifocal region of the [1,1] group, lactate levels were not significantly different from those of control.

The results indicate that metabolic recovery was severely compromised between 1 and 4 h of ischemia, supporting the histological evidence that the threshold for irreversible damage had been exceeded. The fact that the ischemic focus in the [1,1] group was destined to become infarcted despite evidence of metabolic recovery implicates a different postischemic type of cell damage.

433.11

HISTOLOGICAL ANALYSIS FOLLOWING TEMPORARY OCCLUSION OF THE MIDDLE CEREBRAL ARTERY (MCAO) IN HYPERTENSIVE RATS (SHR). R.K. Clark, E.V. Lee*, W.J. Price*, R.F. White*, C.J. Fish*, G.Z. Feuerstein and F.C. Barone. SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406

Permanent MCAO in SHR rats results in ischemic changes characterized by focal pan necrosis, inflammatory cell infiltrate, gliosis, and loss of the necrotic tissue by thirty days post occlusion. We have now characterized changes which occur after MCAO followed by reperfusion. Temporary MCAO results in infarcts which vary in size in an occlusion-time dependent manner. After one hour of reperfusion, ischemic changes were observed histologically, including microhemorrhages and the beginning of an inflammatory infiltrate in and around the vasculature. This infiltrate consisted primarily of neutrophils; however, monocytes were present. Infiltration occurred much more quickly and to a greater extent in reperfused tissues than in permanently occluded tissues, where it began approximately 12 hours post occlusion. Three days after surgery, in addition to the neutrophils, a heavy macrophage infiltrate was present in the reperfused tissues. Macrophages were a minor component of the permanently occluded lesions. Following five days of reperfusion, the necrotic tissue was largely replaced by macrophages, with numerous neutrophils distributed throughout the lesion. In contrast, in the permanently occluded tissues, macrophages were scattered through a loose extracellular matrix and remaining necrotic tissue, and neutrophils were located focally. The data indicate that duration of occlusion affected the size of the lesion, while reperfusion affected the timing, extent and composition of the response that leads to resolution of the necrotic tissue. Histologic and immunohistochemical evidence of these changes will be presented.

433.12

MIDDLE CEREBRAL ARTERY OCCLUSION (MCAO) IN THE MOUSE. FC Barone, DJ Knudsen*, AH Nelson*, GZ Feuerstein, MN Tzimas*, DB Schmidt*, EV Lee*, RK Clark and HM Sarau, SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406.

MCAO, alone or with ipsilateral common carotid artery ligation (CCAL), and sham surgeries were made in BDF and CFW mice. Histological and biochemical techniques were utilized to characterize the effects of focal ischemia 24 hr later. Hemispheric swelling (% SWELL), hemispheric infarction (% INFARCT) and infarct volume (mm^3 INFARCT) were (n=7-12, *=p<0.05 vs MCAO):

STRAIN	SURGERY	% SWELL	% INFARCT	mm^3 INFARCT
BDF	SHAM	1 ± 1	0 ± 0*	0 ± 0*
	MCAO	4 ± 2	7 ± 1	5 ± 1
	MCAO + CCAL	9 ± 2*	21 ± 5*	15 ± 3*
CFW	SHAM	2 ± 1*	0 ± 0*	0 ± 0*
	MCAO	7 ± 1	17 ± 2	15 ± 2
	MCAO + CCAL	13 ± 3*	46 ± 4*	38 ± 4*

Neutrophil adherence and infiltration was identified within meningeal and parenchymal vessels bordering infarctions at various stages of diapedesis into tissue. A Myeloperoxidase (MPO) activity assay was used to quantify increased neutrophil influx (mUnits per gram wet weight) for control (8.5±2.7) compared to ischemic (33.9±8.6, n=8, p<0.01) hemispheres of CFW mice following MCAO + CCAL. LTB_4 receptor density (fmol per mg protein) increased under the same conditions for control (3.7±0.3) compared to ischemic (5.4±0.3, p<0.01) hemispheres. Results indicate that MCAO damage in this mouse model is sensitive to strain differences and CCAL. Mouse focal ischemia is characterized by an inflammatory response with neutrophil infiltration that can be quantified by MPO activity. Increased LTB_4 receptor binding might be important in this process.

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: MOLECULAR STUDIES

434.1

CORTICOTROPIN RELEASING-FACTOR GENE EXPRESSION IS NOT INCREASED AFTER PHARMACOLOGICAL ADRENALECTOMY. Tallie Z. Baram MD, PhD and Linda Schultz* Dept. of Neurology, University of Southern California; Div. of Neurology, CHLA; Los Angeles, CA 90054

A regimen of twice daily metyrapone injections (100 mg/kg), resulted in pharmacological adrenalectomy of pregnant rats and fetuses in utero: i.e., depression of plasma corticosterone and elevation of plasma ACTH in pregnant and in fetal rats. Toxicity was minimal on days 14-17 of pregnancy, and increased with higher maternal weight and pregnancy progression.

Maternal Corticotropin releasing-factor (CRF) messenger RNA abundance increased significantly within 48 hours of metyrapone initiation. No change in CRF gene expression in the paraventricular nucleus of fetuses (days 17-19) was seen, even after 72 hours of the regimen. This is compatible with the independence of CRF gene expression of glucocorticoid feedback in the fetal rat.

434.2

HYPOTENSIVE HEMORRHAGE ELEVATES CRH mRNA, BUT NOT AVP mRNA IN RAT HYPOTHALAMUS. D.N.Darlington, C.A. Barraclough and D.S. Gann. Depts. of Surgery and Physiology, University of Maryland, Baltimore, MD 21201 USA.

To determine if acute hypotensive hemorrhage affects mRNA for corticotropin releasing hormone (CRH) and vasopressin (AVP) in the rat hypothalamic paraventricular nucleus (PVN), 300g Sprague-Dawley male rats were cannulated (femoral artery and vein) and subjected to 15ml/kgx3min hemorrhage 4days later. Time controls received no hemorrhage. Rats were killed at 1 or 4hr (n>6/group), the hypothalamus was removed, frozen and sectioned at 12 μm. In Situ hybridization was performed using an oligodeoxynucleotide probe for CRH mRNA and AVP mRNA. Hemorrhage led to a fall in arterial blood pressure and heart rate that recovered by 1hr. Plasma ACTH and corticosterone were elevated 20, 60, 90 and 120 min after hemorrhage, but returned to control by 4 hrs. CRH mRNA was significantly elevated 1 and 4hrs after hemorrhage in parvocellular PVN. AVP mRNA did not change after hemorrhage in parvocellular or magnocellular PVN, nor in the supraoptic nucleus. These data suggest that neural signals originating from cardiovascular receptors upregulate message for CRH, but not AVP, in the PVN. Supported by DK26831 ,GM27946 and HD02138.

DISTRIBUTION OF CRF-BINDING PROTEIN mRNA AND IMMUNOREACTIVITY IN THE RAT BRAIN. E. Potter*, D.P. Behan*, P.E. Sawchenko and W.W. Vale. The Salk Institute, La Jolla, CA 92037

Initial studies on the structure and tissue distribution of the rat CRF-binding protein (CRF-BP) gene indicated that CRF-BP mRNA was expressed in the brain. We have used cRNA probes generated from non-overlapping regions of a rat cDNA clone, along with antisera raised against human recombinant CRF-BP, to analyze by hybridization and immunohistochemical means the cellular localization of CRF-BP and protein, respectively. Results from both approaches converged to indicate that CRF-BP is expressed principally in the cerebral cortex. This includes cells in layers II, III, V and VI of all neocortical fields, the hippocampal formation, the olfactory bulb, anterior olfactory nucleus, and endopiriform nucleus. Other prominent sites of mRNA and protein expression include the inferior colliculus, raphe nuclei, nuclei of the trapezoid body and lateral lemniscus and the lateral reticular nucleus. In the hypothalamus, the most prominent site of expression is in the ventral premammillary nucleus; only scattered cells have been seen in the paraventricular and dorsomedial nuclei. Dual immunostaining for CRF and CRF-BP has thus far revealed a partial overlap in some of these regions. In addition, prominent CRF-BP-stained terminal fields have been identified in CRF-expressing cell groups, including the suprachiasmatic nucleus and the bed nucleus of the stria terminalis. In the anterior pituitary, CRF-BP mRNA has been colocalized with ACTH-immunoreactivity in a majority of corticotropes. Thus, CRF-BP which reversibly neutralizes the biological activity of CRF could serve to modify the actions of CRF by intra- and intercellular mechanisms in both the CNS and pituitary. CRF-BP interferes with the binding of most CRF antisera and its distribution may explain discrepancies in CNS cell groups where CRF mRNA is readily demonstrable in the face of little or no evidence for corresponding peptide expression.

434.4

TISSUE DISTRIBUTION OF CRF OVER-EXPRESSION IN TRANSGENIC MICE. A.V. Cameron*, M.P. Stenzel-Poore*, P.E. Sawchenko, E.R. Brown and W.W. Vale, The Salk Institute, La Jolla, CA 92037.

To produce an animal model of chronic over-expression of CRF, transgenic mice have been generated bearing a CRF transgene comprising the metallothionein promoter and the CRF structural gene. We have monitored a single lineage, which like the transgenic founders, shows significantly elevated plasma glucocorticoids, obesity, and bilateral hair loss, suggestive of a Cushing's-type syndrome (Stenzel-Poore et al., J. Cell Biochem. 15A:203, 1991). Using *in situ* hybridization with a cRNA probe for CRF, the brains of transgenic individuals of this lineage compared to nontransgenic littermate controls show elevated levels of CRF mRNA in many regions which normally express the CRF gene, especially in the lateral septum, medial preoptic area, amygdala, supraoptic, arcuate, parabrachial, and Barrington's nuclei, and the inferior olivary complex. However, CRF mRNA was also observed in the medial habenula, subfornical organ, dentate gyrus of the hippocampus (granule and hilar cells), deep nuclei of the cerebellum, and anterior pituitary, which are not normally prominent sites of CRF expression. The hypothalamic paraventricular nucleus showed only a modest elevation of CRF mRNA, possibly as a result of feedback by the high levels of glucocorticoids. By Northern blot and *in situ* hybridyzation studies, CRF expression was increased in the testes of transgenic compared to control mice, but was not detected in liver and kidney, which commonly express other metallothionein fusion genes. Thus, the greatly elevated levels of CRF gene expression in these Cushingoid mice is manifest in a tissue distribution which is similar, but not identical, to normals, and which does not appear to be a simple consequence of targeting conferred by the metallothionein promoter.

DIFFERENTIAL REGULATION OF THE HUMAN CORTICOTROPIN-RELEASING HORMONE GENE IN JEG-3 AND PC-12 CELLS. H.Guardiola-Diaz, C.Boswell*, B.Mesa*, A.F.Seasholtz. Department of Biological Chemistry and Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109

Hypothalamic neurons mediate the mammalian stress response by integrating multiple synaptic inputs from higher brain centers and producing and secreting factors such as corticortopin-releasing hormone (CRH). Such integration at the hypothalamic level involves various second messenger systems and steroids that act by regulating transcription of the CRH gene. We are using gene transfer and DNaseI footprinting methods to localize regulatory elements in the human CRH gene. Chimeric genes containing human CRH gene 5'flanking sequence and the bacterial chloramphenicol acetyl transferasc (CAT) coding sequence were transiently transfected into JEG-3 (human choriocarcinoma) and PC-12 (rat pheochromocytoma) cells. A cAMP responsive element (CRE) has previously been identified for the rat CRH gene (-238 to -182) and is highly conserved in the human CRH gene. Addition of 25uM forskolin results in a 7 fold increase in CAT activity in JEG-3 cells and 15 fold increase in CAT activity in PC-12 cells. Transfected PC-12 cells respond synergistically to forskolin and dexamethasone treatment resulting in 35 fold increase in CAT activity. In contrast, forskolin treated JEG-3 cells show a 35% inhibition of cAMP-induced CAT activity after addition of dexamethasone. DNase I protection analysis has revealed a protected region across the CRE consensus sequence in the human CRH gene. Chimeric constructs containing a mutation in the CRE result in loss of both forskolin responsivcness and protein binding. We are presently localizing the positive and negative glucocorticoid responsive elements as well as glucocorticoid receptor binding sites in the CRH gene. This will aid in understanding the molecular mechanisms involved in the "crosstalk" between cAMP and steroid pathways that result in changes in gene expression. This work was supported by a NARSAD Young Investigators Award, and NIH Grant DK42730 to A.F.S.

TRANSCRIPTIONAL REGULATION OF THE POMC GENE BY CRF AND DEX IN THE FETAL AND NEONATAL RAT PITUITARY. R.E.M. Scott and J.E. Pintar, Dept Anat. and Cell Biol., Columbia P&S, NY, NY 10032.

POMC synthesis in the anterior lobe (AL) is under positive regulation by CRF and is inhibited by glucocorticoids, while in the intermediate lobe (IL) glucocorticoids have little effect which is thought to result from the absence of functional glucocorticoid receptors (GR) in the IL. Previous studies have shown that at late fetal and early neonatal ages dexamethasone (DEX) inhibits both CRF stimulated secretion and cAMP stimulated increases in POMC mRNA levels in both the IL and AL. These effects of DEX on the IL disappear by p3 and indicate transient GR expression in the IL during development. We have now extended these studies to show that the effect of DEX on CRF stimulation is at the transcriptional level and that transcriptional regulation of fetal POMC cells by glucocorticoids and CRF begins soon after their first appearance.

A POMC splice junction probe was used in an RNA protection assay to measure POMC hnRNA and provide an indirect measure of transcriptional change. We measured changes in POMC hnRNA in response to CRF and DEX at fetal and postnatal ages in both the AL and NIL after 1 hour treatment in vitro. At e15, POMC hnRNA in whole fetal pituitaries increased in response to CRF (3-fold) and was inhibited by DEX. At p1, in both AL and NIL, the CRF-mediated 2-fold increase in POMC hnRNA was inhibited by pretreatment with DEX and remained at the control level. By p10, DEX had no effect on CRF stimulation in the NIL and POMC hnRNA increased ~1.6 fold with or without preincubation with DEX. In the AL, CRF stimulated POMC hnRNA levels by ~1.5 fold, but if preincubated with DEX these levels remained unchanged. These results demonstrate that POMC transcription can be regulated by CRF and DEX by as early as e15 and also show that glucocorticoids effect POMC transcription in the IL during development and that this effect disappears as the IL undergoes a maturation process closely linked to the arrival of dopaminergic fibres at ~p3.

EFFECTS OF CHRONIC DEXAMETHASONE ON MOUSE POMC GENE TRANSCRIPTION FROM UPSTREAM START SITES. M. Woloschak*, J. R. Lundblad*, N. Levin, J. L. Roberts. Fishberg Research Center for Neurobiology, Mt.. Sinai School of Medicine, N.Y., N.Y. 10029.

Glucocorticoids inhibit transcription of the POMC gene by a proposed mechanism involving inhibition of the binding of activating transcription factors, such as fos and jun, to the POMC promoter by the glucocorticoid receptor. The POMC gene is transcribed in the pituitary to a major mRNA species of 1100 bases with minor larger and smaller species being detected in the pituitary as well as in many non-pituitary tissues. Recently many ACTH-secreting tumors have been demonstrated to contain larger mRNA species that comprise a relatively large percentage of the total POMC mRNA level, and that originate from transcription initiated upstream from the usual pituitary start site. In the present study, RNase protection assays have been used to examine the regulation of upstream POMC gene transcription in AtT20 cells treated with or without 100nM dexamethasone for 4 weeks. From a mouse 5' genomic POMC clone, a 840-base 5' POMC riboprobe was constructed extending from 40 bases of intron A upstream through the entire first exon and including 700 bases of the 5' promoter region. Treatment with dexamethasone significantly reduced POMC gene transcription from the usual pituitary start site relative to control as expected. Transcription from upstream start sites, however, was diminished with dexamethasone to a much lesser extent than that seen from the usual start site. These results demonstrate decreased sensitivity of upstream POMC promoters to glucocorticoids in the mouse and suggest differences in the interactions of the glucocorticoid receptor and activating transcription factors to upstream elements relative to those downstream. Since fos and jun have been shown to induce POMC gene transcription (Loeffler, Boufflier, Lorang, and Roberts, unpublished), further studies will be directed at the effects of glucocorticoids on fos gene expression in these cells.

CORTICOTROPIN RELEASING HORMONE INDUCES PROOPIOMELANOCORTIN mRNA EXPRESSION IN AtT-20 CELLS BY A c-FOS DEPENDENT MECHANISM. Mirela O.Fagarasan*, Francesca Aiello*, Katherin Muegge*, S.K. Durum* and J. Axelrod. National of Mental Health, Bethesda, M.D. and National Cancer Institute, NIH, Frederick, MD.

Corticotropin releasing hormone (CRH) causes a time dependent increase in proopiomelanocortin (POMC) mRNA levels and in adrenocorticotropin releasing factor (ACTH) and β-endorphin synthesis in AtT-20 cells. After treatment of AtT-20 cells 24 hours with CRH the amount of POMC mRNA was about 3 fold higher than control. We found that CRH induces c-fos mRNA expression in a time and dose dependent manner. The effect appeared in 15 minutes, was maximum after 30 minutes and returned to basal levels after 1 hr. CRH had no effect on c-jun mRNA expression. When antisense oligonucleotides to c-fos mRNA were introduced into the cells, the induction of POMC mRNA by CRH was abolished. Desensitization of protein kinase C by long term treatment with phorbol ester (TPA) partly abolished the ability of CRH to induce c-fos as well as POMC m-RNA expression.Thus the transient induction of c-fos mRNA by CRH appears to be a critical step in CRH induced POMC mRNA expression in AtT-20 cells and appears to be partly mediated by protein kinase C.

BASAL HYPOTHALAMIC-PITUTARY-ADRENAL AXIS FUNCTION IN THE AGED RAT Morano M.I., Vázquez D.M., Caamaño C.A., Kwak S.P., Watson S.J., Akil H. Mental Health Research Institute. University of Michigan. Ann Arbor, MI 48109.

The aged rat shows a delayed recovery to basal corticosterone levels following some stressors. We have previously demonstrated that there is a decrease in the binding capacity and mRNA levels of both glucocorticoid (GR) and mineralocorticoid (MR) receptors in the hippocampus of aged Fisher-344 rats, although the basal plasma corticosterone levels are similar to those in young rats. In order to further investigate the consequences of this loss of GR and MR, we have examined the basal status of the HPA axis in young (6 mo.) and old (27 mo.) male rats. CRF mRNA content in the paraventricular nucleus (PVN) was quantitated by RNase protection assay. Corticosterone, ACTH, β-endorphin (βE) and Nacetyl βE were measured in plasma. ACTH, βE or NAc βE and POMC mRNA contents were also measured in the pituitary anterior and neurointermediate lobes (AL and IL). Quantitation of POMC peptide biosynthesis was determined by [3H]Leu pulse labeling and chase of AL and IL dipersed cells, followed by immunoprecipitation and SDS-PAGE. CRF mRNA content is similar in the PVN of young and old rats. In contrast, POMC mRNA levels are lower in the AL of old animals [Y= 100 ± 8% vs O= 59 ± 9%, $p < 0.005$]. However, the POMC peptide levels are not changed in the AL and plasma of aged rats with respect to young ones. After 15 min pulse, *de novo* AL POMC synthesis of aged animals is similar to that of young rats although there are lower levels of POMC mRNA, suggesting an increase in the POMC translation rate. POMC processing is similar in the AL of young and old rats. All the parameters studied in IL are unaltered in the aged animals. We conclude that: 1) although aged rats have lower hippocampal GR and MR binding capacities, the CRF mRNA content of the PVN is normal; 2) AL POMC mRNA levels are 40 % decreased in the older animals; 3) the increase in AL POMC biosynthetic efficiency in old rats may account for the maintenance of a basal HPA function similar to that observed in young ones. CRH, ACTH, AND CORTICOSTERONE INDUCE THE C-FOS PROTO-ONCOGENE IN RAT BRAIN. K. Nudelman*, F.R. Sharp, and S.M. Sagar. Dept. of Neurology, Univ. of California, San Francisco, CA 94121.

We have shown that adrenalectomy (Jacobson et al., Endocrinology, 1990) induces Fos in PVNp neurons containing CRF; and stress induces c-fos mRNA in cortex, septum, hypothalamus, and other regions (Sharp et al., J. Neurosci., 1991). The present experiments examine whether stress hormones induce c-fos. A catheter was inserted into the femoral veins of anesthetized rats. 1d later subjects had 0.9% NaCl, CRH, ACTH, corticosterone (CCX), or dexamethasone (DX) injected IV. 2h after injection subjects were anesthetized, perfused, and the brains processed for immunocytochemistry using a monoclonal antibody (MicoAss) specific for Fos. Midline thalamic nuclei and scattered cortical neurons were stained in NaCl injected rats. CRH (10-120 ug/kg) and ACTH (.1-1mg/kg) induced Fos in posterior cingulate & retrosplenial cortex; lateral septum; stria terminalis; caudal ventral striatum; the central, lateral, and basolateral nuclei of amygdala; PVNp, PVNm and SON in some rats, preoptic, anterior, and posterior hypothalamus; nucleus tractus solitarius; and locus coeruleus. DX and CCX tended to induce Fos in the same regions except for SON, PVNm, and central nucleus of amygdala. Release of ACTH and CCX could account for stress induction of c-fos in some neurons.

11ß-HYDROXYSTEROID DEHYDROGENASE (11ß-OHSD) mRNA EXPRESSION IN PARAVENTRICULAR NUCLEUS: ENZYME INHIBITION REDUCES PORTAL BLOOD CRF. J.R. Seckl, R.C. Dow*, S.C. Low*, C.R.W. Edwards* and G. Fink, Dept Medicine, Edinburgh Univ. and MRC Brain Metabolism Unit, Edinburgh, UK.

Corticosteroid feedback regulation of the hypothalamic-pituitary-adrenal axis is imperfectly understood with differences in the effects of physiological and synthetic glucocorticoids. 11ß-OHSD rapidly metabolizes physiological glucocorticoids to inactive products, thus acting as a tissue-specific regulator of glucocorticoid access to and activation of peripheral mineralocorticoid and glucocorticoid receptors. 11ß-OHSD bioactivity and mRNA are also present in the brain where 11ß-OHSD might alter corticosteroid-receptor interactions. Using *in situ* hybridization with cRNA probes we found high expression of 11ß-OHSD mRNA in magnocellular and parvicellular neurons in the paraventricular nucleus, where corticotrophin-releasing peptides are synthesized. Administration of glycyrrhetinic acid (GE; a potent inhibitor of peripheral and brain 11ß-OHSD) to anaesthetized male rats, significantly decreased CRF release into hypophysial portal blood over the next 90 min (260±36 pg/45 min in controls, n=15; 123±24 pg/45 min after GE, n=10). This occurred in the presence of unchanged circulating corticosterone levels, suggesting that inhibition of 11ß-OHSD activity increases the effective intracellular feedback signal of corticosterone within paraventricular CRF neurons. Adrenalectomy reversed the fall in CRF induced by GE (241±54 pg/45 min) confirming dependence of the GE effect on adrenal products. Paraventricular 11ß-OHSD represents a novel and important level of control of early-intermediate feedback of physiological glucocorticoids on hypothalamic CRF release *in vivo*.

CALMODULIN mRNAs' IN RAT BRAIN: DISTRIBUTION AND REGULATION BY GLUCOCORTICOIDS. M. N. Gannon and B. S. McEwen. Lab. of Neuroendocrinology, Rockefeller University, New York, NY 10021.

Manipulation of the hypothalamic-pituitary-adrenal axis selectively alters Ca^{2+}/calmodulin (CaM)-dependent adenylate cyclase (AC) activity in rat brain. Since many effects of glucocorticoids are mediated through a genomic mechanism, we have attempted to determine whether changes in AC activity are secondary to, or associated with, alterations in CaM mRNA levels. Selective oligonucleotide probes for CaM mRNAs' derived from 3 separate genes (I, II, and III) were developed. By northern analysis, the probes identified a heterogeneous tissue distribution of mRNAs' for CaMI, CaMII and CaMIII, with sizes consistent with those found using cDNAs. Interestingly, *in situ* hybridization analysis, at the level of the dorsal hippocampus, revealed that all species of CaM mRNA were high in both hippocampus and cortex, and (at the light microscope level) appeared to be colocalized. Preliminary evidence (n = 5) suggests that ADX attenuates CaMIII mRNA levels in both brain regions, and that this effect is prevented by daily administration of corticosterone (50 mg/Kg ip.). ADX effects on CaMI and CaMII, if any, are currently under investigation. These results support a growing body of evidence implicating a role for glucocorticoids in modulating Ca^{2+}-dependent signal transduction mechanisms in brain.

ION CHANNELS: MODULATION AND REGULATION III

435.1

POTENTIATION OF PRESYNAPTIC CALCIUM INFLUX BY ELEVATION OF CYCLIC AMP. Ruth Heidelberger and Gary Matthews, Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

Retinal bipolar cells are non-spiking interneurons that relay information from photoreceptors to amacrine and ganglion cells. Previously we have shown that depolarization induces Ca influx in synaptic terminals and somata of goldfish Mb1 bipolar neurons via L-type Ca channels (Heidelberger & Matthews, Invest. Ophth. Vis. Sci., 31, 389, 1990). Here, we present data on the modulation of this dihydropyridine-sensitive influx pathway by agents known to elevate cAMP. Goldfish bipolar cells were isolated after papain treatment, and incubated with fura-2AM for monitoring $[Ca]_i$. Cells were depolarized by elevated $[K]_o$. Depolarization-induced Ca influx following a 200 second exposure to a test compound was compared to the control response to high $[K]_o$. Peak increase in $[Ca]_i$ following incubation with 2-5 µM forskolin was 198 ± 23% of the control (mean ± s.e.m.,N=27). 1,9-Dideoxyforskolin, a forskolin analog that does not activate adenylate cyclase, had no effect on Ca-influx (93 ± 17% of control; mean ± s.e.m.,N=8). Peak Ca-influx in terminals after 1 mM CPT-cAMP, a membrane-permeant derivative of cAMP, was 227 ± 29% of control (mean ± s.e.m.,N=21). Dopamine (10 - 100 µM), which elevates cAMP levels in retina, increased depolarization induced Ca-influx in terminals to 194 ± 16% of control (mean ± s.e.m.,N=15). The potentiation of Ca influx after elevation of cAMP was seen in 81% of cells. Enhancement of influx was slowly reversible, often requiring more than 10 minutes. These results suggest that cAMP regulates the Ca channels in bipolar neurons, and therefore that transmitters such as dopamine may modulate release of neurotransmitter from bipolar-cell synaptic terminals. DUAL MODULATION OF A HYPERPOLARIZATION-ACTIVATED Cl^- CURRENT BY cAMP AND cGMP IN APLYSIA SENSORY NEURONS. B. Armitage, N. Buttner and S.A. Siegelbaum. Ctr. Neurobiol. and Behavior, Columbia U., New York, NY 10032

In Aplysia sensory neurons, the hyperpolarization-activated Cl^- current (Chesnoy-Marchais, Nature 1982) is increased by FMRFamide, 8-Br-cGMP, and 8-Br-cIMP in whole cell recordings (540 Cl^- inside, 600 Cl^- outside) (Buttner and Siegelbaum, Soc. Neurosci. Abstr., 1990). Here, we show the antagonistic modulation of this Cl^- current by dual second messengers.

While FMRFamide and cGMP/cIMP activate the Cl^- current, the neuropeptide SCP and 8-Br-cAMP inhibit the same Cl^- current. This inhibtion is probably mediated by cAMP-dependent protein kinase since the kinase inhibitor K252A (10 uM) decreases the response to SCP by 70% (n=4) and to 8-Br-cAMP by 60% (n=3). Activation of the Cl^- current is likely to result from activation of a cGMP-stimulated cAMP phosphodiesterase (PDE) which reduces cAMP since: 1. 8-Br-cIMP activates this PDE but not cGMP-dependent protein kinase, and 2. The PDE inhibitors IBMX and RO 20-1724 inhibit the response to FMRFamide, 8-Br-cGMP, and 8-Br-cIMP. To test whether the sensory neurons can synthesize cGMP, we applied zaprinast, a specific inhibitor of cGMP phosphodiesterase, and Na nitroprusside (1mM), which releases nitric oxide and activates guanylate cyclase in other systems. Both zaprinast and Na nitroprusside activate the Cl^- current. In addition, Na nitroprusside elevates cGMP levels in sensory neurons by 40%.

MODULATION OF ACETYLCHOLINE CHANNEL BY DBcAMP IN XENOPUS CELL CULTURE. W.M. Fu and M.M. Poo. Department of Pharmacology, College of Medicine, National Taiwan University, Taipei, Taiwan and Department of Biological Sciences, Columbia University, New York, N.Y. 10027.

Application of a membrane-permeable form of cAMP and agents that activates adenylate cyclase system to isolated embryonic Xenopus myocyte in culture markedly altered the ACh sensitivity of the muscle membrane, as assayed by focal extracellular iontophoresis of ACh: the ACh-response is elevated and accompanied by an increase rate of desensitization. Singel channel recordings showed that activation of adenylate cyclase system increases opening probability and the mean open time of ACh-channels, without affecting the single channel conductances. These effects on ACh channels disappeared in older isolated myocytes as well as at extrasynaptic regions of innervated myocytes, suggesting the confinement of susceptibility to the synaptic regions following innervation. Possible involvement of cAMP second messenger system in the physiological modulation of synaptic functions was further supported by the markedly enhancement of spontaneous activity at developing Xenopus neuromuscular synapses by agents that activates the adenylate cyclase system. Neuropeptides co-released with ACh, if acts through adenylate cyclase system, could thus help the synaptic maturation by elevating the efficacy of the synapse.

435.4

PHOSPHORYLATION MODULATES THE RATE OF VOLTAGE-DEPENDENT INACTIVATION OF THE BARIUM CURRENT IN DISSOCIATED HELIX NEURONS. J.L. Yakel, Laboratoire de Neurobiologie, Ecole Normale Superieure, 75005 Paris, France.

Whole-cell recording techniques were used to investigate how phosphorylation modulates the rate of voltage-dependent inactivation of the voltage-activated barium current in Helix neurons. The amplitude of the barium current rapidly ran down while the rate of inactivation greatly increased if either (1) neurons were not dialyzed with ATP, or (2) neurons were dialyzed with alkaline phosphatase. ATPγS dialysis partially reduced the rate of run-down in non ATP-dialyzed neurons, and dramatically reduced the rate of both activation and inactivation of the barium current. Dialysis with the protein phosphatase inhibitor okadaic acid enhanced the amplitude and decreased the rate of inactivation of the barium current, without significantly altering the rate of activation. Dialysis with either AMP-PNP, the catalytic subunit of protein kinase A, or synthetic peptide inhibitors of protein kinases A or C did not significantly alter the amplitude or kinetics of the barium current, whereas dialysis with a synthetic peptide inhibitor of the calcium/calmodulin-dependent protein kinase significantly reduced the rate of inactivation. Therefore, the rate of voltage-dependent inactivation of the barium current in Helix neurons is modulated by the state of phosphorylation of either the calcium channels themselves or an associated regulatory protein.

SYNERGISTIC ACTIVATION OF PROTEIN KINASE C BY ARACHIDONIC ACID AND OAG REDUCES *HERMISSENDA* POTASSIUM CURRENTS. R. Etcheberrigaray, C. Collin, D. S. Lester* and D. L. Alkon. *Neural Systems Section*, NINDS, National Institutes of Health, Bethesda, MD 20892.

It has been shown that protein kinase C (PKC) can be activated by either diacylglycerol (DG) or arachidonic acid (AA). The concentrations of these lipid activators commonly used to activate PKC are relatively high compared to physiologic levels. In vitro studies (Lester *et al.*, Society for Neuroscience 1991) have indicated that submaximal activating concentrations of AA and DG act synergistically to activate PKC. In the present study, we further test this hypothesis of synergistic PKC activation in a cellular system. For this purpose, we used the *Hermissenda* B photoreceptor known to have at least two PKC-regulated K^+ currents (I_A & I_C). Two-electrode voltage-clamp measured both I_A and I_C in the axotomized Hermissenda B cell. Bath application of the cell permeant diacylglycerol analog, 1-oleoyl-2-acetylglycerol (OAG 5 μgml^{-1}) did not have significant effects on the two K^+ currents after 15 min. incubation. At 30 min. OAG, a 25% increase of I_A amplitude was observed, I_C remained virtually unchanged. Staurosporine had no effect on the I_A enhancement, suggesting that this OAG effect may not be PKC mediated. Application of 5 μM AA had no effect on both I_A and I_C. Application of 5 OAG μgml^{-1} followed by 5 μM AA 15 min. later, caused a strong reduction of K^+ conductances. A 57% amplitude reduction was observed for I_A, and I_C amplitude decreased in 44%. Staurosporine blocked these effects, suggesting that these OAG-AA effects are PKC mediated. PKC regulation of these same K^+ currents has been shown to induce responses similar to those found for classical conditioning. This OAG-AA synergistic effect may, therefore be an important step in this process.

435.6

CANNABINOIDS INHIBIT A HIGH-THRESHOLD CALCIUM CURRENT. K. Mackie and B. Hille. Physiol. and Biophysics, Univ of WA, Seattle, WA 98195.

Medicinal properties of *Cannabis sativa* and its major biologically active constituent, Δ^9-tetrahydrocannabinol (THC), have been known for years. Recently a high-affinity THC receptor has been identified that has a CNS distribution consistent with the behavioral effects of THC. The cellular mechanisms of action of THC are uncertain. One action of THC is to inhibit adenylyl cyclase (AC). As neurotransmitters that inhibit AC often affect ionic channels by other pathways, we have investigated a link between cannabinoid receptors and calcium channels. In NG108-15 cells, the cannabinomimetic alkylaminoindole, WIN 55,212-2, potently, stereospecifically and reversibly inhibited a component of the high-threshold voltage-sensitive I_{Ca}. Maximal inhibition of I_{Ca} was 40% at 100 nM WIN 55,212-2. A similar decrease was found with the non-classical cannabinoid, CP 55,940 (100 nM). The inhibition is not likely to be due to a decrease in cAMP level as prior incubation with 8-(chlorophenylthio)cAMP (100 μM), dibutyryl cAMP (1 mM) and/or isobutylmethylxanthine (100 μM) did not prevent I_{Ca} inhibition by WIN 55,212-2. The components of I_{Ca} inhibited by cannabinoids are not entirely the same as the I_{Ca} inhibited by norepinephrine (NE) and adenosine (ADO) in these cells. WIN 55,212-2 inhibited a subset of the I_{Ca} inhibited by NE (1 μM) with a slower onset of inhibition. On the other hand, WIN 55,212-2 and ADO (50 μM) inhibited distinct I_{Ca}'s, however the onset of inhibition was similar for the two compounds.

Given the central role of calcium channels in neurotransmitter release and in patterned firing of action potentials, it is possible that inhibition of these channels contributes to the profound behavioral changes produced by THC.

Inhibition by LHRH of N-type Ca current in bullfrog sympathetic neurons: kinetics and state-dependence. L.M. Boland and B.P. Bean, Department of Neurobiology, Harvard Medical School, Boston, MA 02115

Inhibition by luteinizing hormone releasing hormone (LHRH) of Ca channel current was studied using whole-cell recordings from freshly dissociated bullfrog sympathetic ganglion neurons. LHRH acts through activation of G-proteins to inhibit N-type but not L-type channels. The rate of development of inhibition is faster at higher [LHRH], reaching $\tau \sim$ 2 sec at saturating [LHRH] of 0.3-3 uM. Recovery proceeds with $\tau \sim$ 19 sec and is not concentration-dependent. LHRH inhibition is strongly affected by the gating state of the channel: LHRH has little effect if applied during a long activating voltage pulse but strongly inhibits if applied when channels are mostly in the resting state. Inhibition can be partly overcome if channels are activated by short, large depolarizations or long, smaller depolarizations. The state-dependent properties are predicted by a model that assumes: 1) Inhibition results from activated G-proteins binding to the channel, 2) G-protein binding stabilizes closed gating states, and 3) activation of G-protein bound channels destabilizes G-protein binding.

SINGLE CHANNEL PROPERTIES OF SOMATOSTATIN- OR MET - ENKEPHALIN - ACTIVATED, GTP - DEPENDENT INWARDLY RECTIFYING K-CONDUCTANCE IN CULTURED RAT BRAIN NEURONS. J.J.Grigg, T.Kozasa*, S.Nakajima and Y.Nakajima, Dept. of Anat. & Cell Biol. and Dept. of Pharmacol., Univ. of Illinois, College of Medicine, Chicago, IL 60612.

Somatostatin (SOM) and μ opioid receptors are coupled to inwardly-rectifying K-channels through a pertussis toxin-sensitive G protein in locus coeruleus neurons (North et al. PNAS, 84:5487,'87; Inoue et al., J. Physiol. 407: 177,'88). We have investigated the single channel properties of these K-channels in cultured noradrenergic neurons from the locus coeruleus, using inside-out patches. When the solution bathing the cytoplasmic face was switched from a GDP-containing to a GTP-containing solution, there was an increase in channel activity if the pipette contained either SOM or met-enkephalin. This increase in activity did not occur in the absence of agonists. At potentials more depolarized than 0 mV, GTP did not produce an increase in channel activity, suggesting an inward rectification of the single channel current. Supported by AG06093 and DA05701.

K_i = 125 mM / K_o = 100 mM; 0.5 μM SOM

MODULATION OF G PROTEINS AND HETEROLOGOUS DESENSITIZATION FOLLOWING CHRONIC MUSCARINIC AND α_2-ADRENERGIC AGONIST TREATMENT. Z.Vogel, D. Saya*, B. Attali* and S.-Y. Nah*. Dept. of Neurobiology, Weizmann Institute of Science, Rehovot 76100, Israel.

Muscarinic and α_2-adrenergic agonists inhibit adenylate cyclase and the dihydropyridine-sensitive voltage-dependent Ca^{2+} channels in rat spinal cord-dorsal root ganglion cocultured cells. For example, oxotremorine and clonidine, at 100 μM, inhibited $^{45}Ca^{2+}$ influx through the channels by 35±6 and 42±2%, respectively. This inhibition was reversed by the respective antagonists, atropine and yohimbine, and by pretreatment with pertussis toxin. Chronic treatment (≥24h) with oxotremorine or clonidine desensitized the Ca^{2+} channel response to both muscarinic and α_2-adrenergic agonists (i.e., heterologous desensitization). In addition, it led to a marked reduction (≥40%) in the capacity of $G\alpha_i$ and $G\alpha_o$ subunits to undergo pertussis toxin-catalyzed ADP-ribosylation. No difference was found in cholera toxin-induced ADP-ribosylation of $G\alpha_s$. The reduction in pertussis toxin ADP-ribosylation was attenuated when the concentration of Lubrol PX in the reaction mixture was increased above 0.01%. We propose that prolonged agonist exposure leads to alterations in the receptor-G protein transduction system, which in turn accounts for the heterologous desensitization and reduction in ADP-ribosylation. *Supported by the Israel Anti-Drug Authority, Minerva Foundation, National Institutes of Health and the German-Israel Foundation for Scientific Research and Development.*

REGULATION OF Kv1 CHANNEL GENE EXPRESSION IN CLONAL AND NATIVE PITUITARY CELLS. E.S. Levitan, J. Miklos*, C. Severns*, and B. Attardi*. Depts. of Pharmacology and Medicine, Univ. of Pittsburgh, Pittsburgh, PA 15261

We have been exploring the hypothesis that transmitters and hormones produce long-term changes in cell excitability and secretion by regulating ion channel gene expression. Previously, we reported that dexamethasone (DEX), a glucocorticoid receptor (GR) agonist that **suppresses** secretion of many pituitary hormones, **increases** voltage-gated K^+ current and mRNA encoding the Kv1 K^+ channel subunit in GH3 rat pituitary tumor cells. We have now investigated the role of GR activation, and have identified a neuropeptide that may have an opposing effect. Kv1 RNA is increased with corticosterone (COR) and hydrocortisone (HC). This induction is inhibited by the GR receptor antagonist RU38486 and is not seen with estradiol or testosterone. To explore whether this gene regulation is physiological, native rat pituitary cells were dissociated, cultured for 3 days, and then treated with steroids. 6 hour treatments with DEX or COR increased Kv1 mRNA ~3-fold. This induction was blocked by RU38486 and was not mimicked by estradiol. Therefore, GR activation increases K^+ channel gene expression in clonal and native pituitary cells. In contrast to the glucocorticoids, the neuropeptide TRH, which **increases** secretion, **decreased** Kv1 mRNA in GH3 cells in a preliminary experiment. This suppression was also seen with BAYK 8644+40 mM K^+, suggesting that cytoplasmic calcium may inhibit expression of Kv1. Thus, glucocorticoids and TRH may have opposing effects on secretion and K^+ channel gene expression.

DEVELOPMENT OF TWO TRANSIENT POTASSIUM CURRENTS IN CULTURED MOUSE HIPPOCAMPAL NEURONS. R-L. Wu* and M.E. Barish, Division of Neurosciences, Beckman Research Institute, City of Hope, Duarte, CA 91010.

We studied the potassium currents present in mouse hippocampal pyramidal neurons in dissociated cell cultures derived from embryonic day 15 embryos. Potassium currents were isolated in whole-cell gigaohm seal recordings by using a KCl/KF-based internal solution to remove Ca currents, and TTX in external solutions to block Na currents. Control experiments confirmed that the remaining voltage-gated K currents were insensitive to removal of external Ca or addition of sufficient Cd to block Ca currents. Two transient outward currents were separated based on voltage-dependence and sensitivity to 4-aminopyridine (4-AP). A-current showed fast activation and inactivation, negatively-positioned steady state inactivation, and block by millimolar concentrations of 4-AP. D-current showed slower activation and inactivation, more positively-positioned steady state inactivation, and block by 100 μM 4-AP. An additional slowly inactivating delayed rectifier (K-current) was sensitive to TEA. All outward current was blocked by a combination of conditioning depolarization to -40 mV and addition of 100 μM 4-AP and 20 mM TEA to the bath, indicating that under our recording conditions outward current could be accounted for by the combination of A-, D- and K-currents.

We observed that during the three day period following day 0 (the day of dissociation), as total outward current amplitude and whole cell capacitance increased, inactivation of total potassium current slowed and the aggregate steady state inactivation curve shifted towards more positive voltages. Separation of the various potassium currents indicated that during this period the amplitude of A-current declined while that of D-current increased. These changes in potassium currents, in combination with maturation of Na and Ca currents, may underlie developmental changes in responses of hippocampal neurons to depolarizing stimuli. (Supported by NIH, AHA and BRI/CoH).

REGULATION OF AUTONOMIC FUNCTIONS

VIBRATORY STIMULATION (VS) AND RECTAL PROBE ELECTROSTIMULATION (RPE) OF SPINAL CORD INJURED (SCI) MEN. N.L. Brackett and C.M. Lynne*. The Miami Project to Cure Paralysis, University of Miami, Miami, FL 33136

Men with spinal cord injuries are often impotent and infertile due to erectile and ejaculatory dysfunction. The present study compared the quality of erections, ejaculations and semen using the methods of VS or RPE. These measures were correlated to the subjects' neurological level and completeness of injury as well as other variables.

Thirteen SCI men were stimulated a total of 35 times. Five subjects could ejaculate with either method, five with only RPE, one with only VS and two with neither method. The ability to ejaculate using the vibrator correlated more with completeness than with level of injury. In those subjects who ejaculated, both antegrade and retrograde samples were recovered in most cases. Antegrade ejaculations produced by VS tended to be forcefully expelled compared to those produced RPE which looked more like emissions. Occurrence of erections prior to stimulation did not predict occurrence or quality of erections during stimulation. Subjects reported pleasurable feelings associated with orgasm more often when VS rather than when RPE was used. Serum levels of follicle stimulating hormone, luteinizing hormone, prolactin and testosterone ranged from low-normal to normal with the exception of three subjects in which one or more of these hormones fell below normal ranges. Higher sperm counts tended to occur with RPE compared to VS. Sperm motility was low in almost all subjects and did not change with the type of stimulation used. The normative data collected in this study are intended as a basis from which to design future studies investigating the causes and treatments of male impotence and infertility following SCI.

REDUCED URINARY BLADDER AFFERENT CONDUCTION VELOCITIES IN STREPTOZOTOCIN DIABETIC RATS. I. Nadelhaft and P. Vera. VA Med. Ctr. & Univ. Pittsburgh Med. Sch. Depts. of Neurosurgery and Pharmacology, Pittsburgh, PA, 15240, USA.

Previous experiments in our laboratory have described the method used to measure the conduction velocity distribution of a selected group of fibers (Br.Res.520:83-89[1990]). We have applied this technique to the diabetic rat. Ten female Sprague-Dawley animals were made diabetic with streptozptocin (60 mg/kg iv). Six matched animals were used as controls. Two diabetics died shortly after their injections but the remaining animals survived to the completion of the experiment (approximately two months). Glycosylated hemoglobin values measured at the time of death were 17.19 +/- 4.74 % (diabetic, n = 8) and 4.07 +/- 0.74 % (controls, n = 6). Diabetic bladders were thicker and heavier. The wet weights were 0.50 +/- 0.11 gm (diabetic, n = 7) and 0.16 +/- 0.01 gm (controls, n = 6). The conduction velocities of a total of 151 and 86 single afferent fibers were measured in the diabetic and control animals respectively. The conduction velocity distribution of the diabetics showed a shift towards slower speeds when compared to controls. The mean conduction velocities were 1.70 m/s for diabetics and 2.84 m/s for controls. The percent of units with conduction velocities greater than 2.5 m/s was 11.3 for diabetics and 27.9 for controls. This experiment demonstrates, for the first time, that diabetes causes a significant reduction of afferent conduction velocities in a functionally well-defined system.

GALANIN IMMUNOREACTIVITY IS SEXUALLY DIMORPHIC IN AUTONOMIC REGIONS OF THE RAT LUMBOSACRAL SPINAL CORD. B.W. Newton. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

Galanin-like immunoreactive (GAL-LI) fibers have been demonstrated to surround preganglionic autonomic neurons; and a large group of GAL-LI neurons, which project to the thalamus, is found in lumbar laminae VII and X (Ju et al., Neuroscience, 20:439, '87). Additional characterization of the distribution of GAL-LI in the rat spinal cord reveals pronounced sexual dimorphism in the lumbosacral autonomic spinal cord. Ten male and ten female adult Sprague-Dawley rats were perfused for the PAP technique in order to reveal spinal GAL-LI (anti-GAL diluted 1:10,000; Peninsula Labs., Belmont, CA #RAS-7153-N). GAL-LI was not sexually dimorphic in the thoracic spinal cord. However, GAL-LI fibers in autonomic regions of the lumbosacral spinal cord were more abundant in males than females. The females showed a marked variation in the number of GAL-LI fibers: this variation was subjectively classified as either "average" or "heavy". The variation is probably due to fluctuations in estrogen levels during the estrous cycle. However, the number of GAL-LI fibers in any female never exceeded the number found in males. The number of previously described lumbar GAL-LI neurons was also sexually dimorphic: males have significantly ($P < 0.01$) more GAL-LI neurons (62%) than females. The number of GAL-LI neurons in females was not variable. The physiological significance of sexually dimorphic, autonomic, GAL-LI is presently unknown. Supported by BRSG RR05350 and the Arkansas Caduceus Club.

IN VITRO NEONATAL RAT: INTRACELLULAR RESPONSES OF BRAINSTEM NEURONS TO SUBDIAPHRAGMATIC VAGAL STIMULATION. C.S. Yuan* and W.D. Barber. Department of Anatomy, College of Medicine, University of Arizona, Tucson, AZ 85724.

We developed an *in vitro* neonatal rat preparation to investigate brainstem neuronal processing of subdiaphragmatic vagal input. (Barber et al., FASEB J. 5(5): A1063, 1991). Neonatal rats, 0 to 2 days of age, were anesthetized with halothane. Following a craniotomy, the brainstem was transected at the rostral medulla and the stomach with intact vagi and caudal brainstem was isolated. The preparation was superfused in a recording chamber with modified Krebs solution. The subdiaphragmatic vagal nerves were electrically stimulated by suction electrodes. Intracellular potentials, identified by orthodromic spikes resulting from supramaximal vagal stimulation, were recorded from neurons in the nucleus tractus solitarius (NTS). Electrical stimulation of the subdiaphragmatic vagal trunks produced EPSPs in some neurons but failed to produce an action potential. Some neurons discharged spontaneously, others were "silent". The background synaptic activity of some NTS neurons consisted of both EPSPs and IPSPs with amplitudes of more than 3.0 mV. The synaptic activity increased for a period of 100-300 msec following vagal stimulation. This *in vitro* neonatal preparation retains the functional circuitry to investigate brainstem neuronal responses to subdiaphragmatic vagal input without the effects of general anesthesia. (Supported by USPHS Grants NS 27972 and DK 36289).

ORGANIZATION OF MEDULLARY AUTONOMIC REFLEX ARCS. M. Anwar, D.J. Reis and D.A. Ruggiero. Div. Neurobiol., Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., NY, NY 10021.

Medullary autonomic reflex arcs are composed of 1° visceral afferents ending in nucleus tractus solitarii (NTS), relaying by direct and indirect pathways to autonomic preganglionic and respiratory lower motoneurons. Polysynaptic limbs of reflex arcs are thought to involve interneurons in the lateral tegmental field (LTF). We sought to define interneuronal networks in the medullary LTF and their relationships to the solitario-reticulospinal (transtegmental) tract bridging NTS and autonomic premotor pools in the ventrolateral medulla (VLM). In adult male anesthetized (0.5 mg/kg chloral hydrate, i.p.) rats, injections of two retrograde fluorescent tracers (rhodamine microbeads and FluoroGold) were centered on NTS and the rostral ventrolateral reticular nucleus (RVL); distributions of single and double-labeled neurons were mapped in the medulla. NTS and RVL afferent projection neurons were backfilled along elongate sheets concentrated in the intermediate reticular zone of LTF; most formed independent populations. Neurons colocalizing both tracers were detected in a dorsal reticular zone (LTFd) subjacent to NTS. PHA-L injections into LTFd confirmed divergent projections to NTS and VLM. Methods combining anterograde transport of PHA-L with retrograde tracers were developed to determine relationships between the solitario-reticular tract (SRT) and RVL afferents. RVL-fluorescent interneurons were distributed throughout LTF; and embedded within immunofluorescent fibers of SRT. An interstitial nucleus of the SRT extending from the NTS to VLM may be an anatomical substrate of multisynaptic autonomic reflex arcs.

436.6

EFFECT OF SOMATOSTATIN-28 (SS) ON VAGAL CARDIOMOTOR NEURON (VCN) FUNCTION M.M. Caverson, C.M. Willey* and E.T. Kiriakopoulos, Depts. of Anatomy & Physiology, Univ. of Western Ont., London, Canada N6A 5C1.

We have shown that SS-immunoreactive fibers are located around VCN in nucleus ambiguus (AMB). The present studies investigated the source of SS afferents to AMB and the effect of SS on VCN function. Experiments were done in adult male Sprague-Dawley rats. In the first series, rats were anesthetized with pentobarbital, the femoral artery was cannulated and heart rate (HR) was monitored. Double-barrel glass micropipettes were placed in AMB, cardiomotor regions were identified by the vagal bradycardia evoked by L-glutamate microinjections (10-30 nl;1M), and these sites received injections of the retrograde tracer Fluorogold (2%;10 nl). After 7-10 days animals were colchicinized, perfused 8-10 hrs later, and the forebrain and brain stem were processed using immunofluorescence to identify neurons containing FG and SS. Double-labeled neurons were found in the central amygdaloid nucleus, medial parvocellular divisions of the hypothalamic paraventricular nucleus and the central nucleus of the NTS. In the second study, animals (n=32) were anesthetized with alpha-chloralose, artificially ventilated and spinal cord transected at C_2-C_3. The femoral artery and vein were cannulated and arterial pressure (AP) and HR were monitored. Microinjections of L-glutamate were made to identify cardiomotor regions of AMB and these sites subsequently received injections of SS (20-100 nl;5-10mmol). SS consistently elicited a slow onset (6s-3.5min), long-duration (10-50min) increase in HR that was not accompanied by a change in AP. The HR response to SS was +22±12 bpm (5-60 bpm) from a control HR of 256±30 bpm. Control injections of 0.9% saline (n=8) did not alter HR. These data suggest that SS inhibits VCN function and that limbic, hypothalamic and/or medullary SS-containing cell groups projecting directly to cardiomotor regions of AMB may provide the anatomical pathways by which these SS effects are mediated. (Supported by the MRC).

EXCITATORY EFFECTS OF THYROTROPIN-RELEASING HORMONE (TRH) IN DORSAL MOTOR NUCLEUS OF THE VAGUS (DMV) MOTONEURONS. R.A. Travagli*, R.A.Gillis*, Y.M. Hernandez, and S.Vicini. Dept. of Pharmacology and FGIN, Georgetown Univ., Wash., DC 20007

The purpose of our studies was to characterize the excitatory effect of TRH in DMV motoneurons by using the patch-clamp technique in rat brainstem slices. In our initial studies we employed the cell-attached configuration using concentrations of TRH ranging from 3 to 30 μM. Exposure of DMV motoneurons to TRH resulted in dose-related increases in spontaneous occurring action potential firing rate (2- to 4-fold increase at the maximal TRH concentration tested). This was observed in all the DMV neurons tested (N=21) independently of their location rostral or caudal to the obex. Invariably, tachyphylaxis occurred to the excitatory effects of TRH. Subsequent experiments using current clamp confirmed the observation that TRH excites DMV neurons located rostral to the obex. However, excitation of DMV neurons located caudally to the obex was not always observed using this recording configuration. Finally, using voltage-clamp recordings from DMV neurons revealed the induction of an inward current of 7.8 ± 1.4 pA (N=5), by TRH. This current was associated with a 10% decrease in input resistance. This effect might be related to the activation of a cationic channel by TRH in DMV neurons. We also observed that TRH produced an increase in frequency of spontaneously occurring excitatory postsynaptic currents, and, in some cases, a decrease in spontaneous inhibitory postsynaptic currents in rostral and caudal DMV neurons.

EXPRESSION OF C-FOS IN NEURONS OF THE FETAL BRAINSTEM DURING HYPOXEMIA IN THE SHEEP. G.E. Hoffman, T.J. McDonald *, A. Syed, and P.W. Nathanielsz. Depts. Physiol. and Behav. Neurosci., Univ. Pittsburgh, Sch. Med., Pittsburgh, PA 15261 and Lab. for Preg. and Newborn Res., Dept. of Physiol. Cornell Univ., Ithaca, NY 14853.

The fetal pituitary adrenal axis is responsive to hypoxemia; fetal ACTH levels rise and c-fos expression in corticotrophin releasing hormone (CRH) neurons as well as other neurons in the paraventricular nucleus (PVN) of the hypothalamus is induced. Within the brainstem, the ventrolateral medulla and nucleus of the solitary tract (NTS), are sensitive to hypoxia and can influence the hypothalamus. Using c-fos as a marker for neuronal stimulation we examined the relationship between activation of these brainstem centers (including catecholamine neurons within them) and the PVN. Fetuses (123-125 days gestational age) were made hypoxemic by reducing the maternal oxygen to 60% of normal for 20-60 min and the brains were perfused and immunocytochemically stained for c-fos and CRH (hypothalamus)or DβH (brainstem). Following hypoxemia, the induction of c-fos in CRH and other PVN neurons neurons was accompanied by a marked activation of c-fos in the ventrolateral medulla and NTS; activation included catecholamine neurons in the A1/C1 and A2/C2 cell groups. The degree of c-fos activation of brainstem neurons was correlated with the magnitude of PVN activation.

These data support the hypothesis that fetal CRH neurons are stimulated during fetal stress, and suggest that catecholamine systems might mediate that stimulation.

PARAVENTRICULAR NUCLEUS (PVN) OXYTOCIN NEURONS ARE RESISTANT TO THE EXCITATORY NEUROTOXIN, IBOTENIC ACID. M.F. Callahan, M.J.A. Rocha*, G. Cai*, D.K. Sundberg*, and M. Morris. Dept. of Physiology and Pharmacology, Wake Forest University Medical Center, Winston Salem, NC, 27103.

Ibotenic acid lesions of parvocellular PVN neurons attenuate the tachycardia and plasma oxytocin (OXY) responses to stress. We examined the effects of this lesion on brain OXY mRNA and peptide levels in plasma, posterior pituitary (PP), brainstem (BS), olfactory tubercule (OLT) and spinal cord. Male rats received bilateral PVN injections of ibotenic acid (5.0 μg/0.5 μl) and were sacrificed at 7 days. The brains were fixed and processed for *in situ* hybridization using an oligonucleotide probe. Ibotenate produced moderate to extensive loss of cells and infiltration of glia into the parvocellular region of the PVN. There was heavy labeling for OXY mRNA in the magnocellular region and isolated labeling in parvocellular region for both groups with no apparent differences in the pattern or intensity of OXY mRNA. The lesion had no effect on OXY levels in BS (1.21±0.5 ng -v- 0.8±0.2 ng); PP (1.2±0.3 ug -v- 1.2±0.2 ug), or OLT (381±68 pg -v- 345±62 pg; control -v- lesion). Lesion had no effect on plasma OXY. OXY in the cervical-upper thoracic cord showed a 50% decrease. Although the neurotoxin destroys predominantly parvocellular PVN neurons, the current findings indicate that BS projecting OXY cells are not affected by the toxin. This indicates that a subpopulation of OXY cells, perhaps small magnocellular neurons, are resistant to the effects of ibotenic acid. (Supported by NIH HL-43178).

436.10

BARORECEPTOR NERVES INFLUENCE HYPOTHALAMIC PEPTIDE mRNA EXPRESSION. M.J.A. Rocha*, M.F.Callahan, D.K. Sundberg*, M. Morris. Department of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University. Winston-Salem, NC 27103

Neuroanatomical and physiological evidence indicates that baroreceptors influence hypothalamic vasopressin (VP) and oxytocin (OT) neurons. Experiments were conducted to evaluate the effect of sinoaortic denervation (SAD) on the expression of VP and OT mRNA under basal and stimulated conditions. Male control or SAD rats (10 days post oper) were given water or 2% salt to drink for 72 hrs. A second control group (salt intake limited) was included because the SAD rats consumed less salt solution. Two experiments were performed 1) *in situ* hybridization using oligonucleotide probes and 2) measurement of tissue peptide levels in the paraventricular (PVN) and supraoptic (SON) nuclear regions. Salt loading produced an increase in plasma osmolality, VP and OT with no differences observed between the groups. There was, however, a greater depletion of neurohypophyseal peptides in the denervated group. There was a 72% and a 71% depletion of VP and OT in the SAD rats as compared to 33% and 48% in the controls. Salt loading produced an increase in PVN and SON VP content in control animals (1.0+0.2 vs 2.8+0.5 ng/PVN and 1.6+0.2 vs 3.2+0.4 ng/SON; water vs salt loading). No changes were observed in SAD animals. There were no changes in central OT content with respect to the groups or treatment. Evaluation of message expression showed that there was increased expression under basal and stimulated conditions in the denervated animals. This suggests that denervation activates the hypothalamic neurosecretory neurons at the level of message expression and that activation is not reflected in the plasma peptide response. The fact that there is a greater salt-induced peptide depletion in the SAD rats indicates an inability to maintain peptide synthesis. (Supported by HL 43178.)

MAMMALIAN AUTONOMIC NEURONS EXPRESS APLYSIA BIO-ACTIVE NEUROPEPTIDES. D.A. Ruggiero[1], M. Anwar[1], A. Alevizos[2], D. Karagogeos[3] and K.R. Weiss[4]. Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., NY 10021; [2]Kaftatzoglou, Athens, Greece; [3]Dept. Med. Sci., Univ. Crete, Crete Greece; [4]Dept. Physiol., Mt. Sinai Med. Sch., NY 10029.

The R15 polyprotein gene in a marine mollusk Aplysia encodes a primary mRNA transcript, alternatively spliced in different neurons to generate overlapping sets of neuropeptides (Buck et al., *Cell* 51:127, 1987), including R15α_1 (38 a.a.) and R15α_2 (24 a.a.), which exert coordinated actions on invertebrate renovascular, digestive and reproductive systems. We sought to determine whether R15α_1 and R15α_2 are expressed in rodent brain and adrenal gland. Adult male anesthetized rats were perfused; tissues incubated in rabbit polyclonal R15α_1 (16 mer difference) or R15α_2 antisera and immunoprocessed. R15α_1-lir was restricted to locus ceruleus, ependymal and adrenal chromaffin cells; whereas R15α_2 was expressed by neurons in nucleus tractus solitarii, paraventricular and supraoptic (SO) hypothalamic neurosecretory nuclei, and processes in neurohypophysis. To determine whether R15α_2 is coexpressed in vasopressinergic cells, tissues were sequentially incubated in R15α_2 antiserum (24h; PAP) and arginine vasopressin (AVP) antiserum (24h; immunofluorescence). Neurons expressing R15α_2 and AVP were topographically segregated. Distributions of R15α_2-lir neurons in parvicellular divisions of PVN were skewed anteroventromedially to the AVP population. In the posterior magnocellular division, R15α_2-lir neurons formed a shell encircling an AVP-lir cell column. Striking parallels exist in localization of bioactive invertebrate neuropeptides to autonomic and neuroendocrine control sites in the mammal.

436.12

EFFECTS OF OVINE AND HUMAN CORTICOTROPIN-RELEASING HORMONE ON RESPIRATORY AND CARDIOVASCULAR FUNCTIONS IN HUMANS. M.Lehnert, M.Wink*, U.Krause*, E.Salomon*, J.Aldenhoff and J.Beyer*. Dept. of Internal Medicine - Endocrinology, Mainz University, 6500 Mainz and Central Institute of Psychiatry, 6800 Mannheim, FRG

It has convincingly been shown that corticotropin-releasing hormone (CRH) affects cardiovascular and respiratory parameters through extrahypothalamic pathways. Thus, in experimental animals, centrally applied CRH induces a specific stimulation of ventilation and an increase of arterial pressure and heart rate. In humans, we have previously demonstrated stimulatory effects on ventilation by exogenous CRH. In a group of 11 healthy subjects the cardiovascular and respiratory effects of 100 to 300 µg ovine (o) and human (h) CRH were now evaluated. During steady state ventilation was monitored pneumotachographically and by continuous registration of ventilatory gases. These parameters were determined following i.v. application (bolus over 30 sec vs. infusion over 30 min) and compared to placebo. Both hCRH and oCRH increased minute ventilation in all individuals by 60 to 90%. These effects lasted for 5 to 10 minutes following hCRH and for 10 to 15 minutes following oCRH after a single bolus injection. Another 100 µg of CRH infused over 30 minutes prolonged the effects on ventilation, in particular following oCRH. Heart rate were increased by 10 to 15% following hCRH, no major changes were detected in blood pressure. The mode of action of systemically applied CRH is still under investigation, but it appears possible that exogenous CRH may reach brain sites via circumventricular organs and thus alter autonomic outflow.

LEARNING AND MEMORY—PHYSIOLOGY V

437.1

THE NOVELTY-INDUCED INHIBITION IN BRAIN DNA SYNTHESIS IS MEDIATED BY THE DORSAL NORADRENERGIC BUNDLE. T.Menna*, A.Cerbone[2], A.G.Sadile[2], C.Lamberti-D'Mello[2]*, C.Buono*, F.Rafti* and A.Giuditta[3]*. (SPON: European Brain and Behaviour Society). IIGB, CNR, Naples; [2]Dip. Fisiol.Umana e Funz.Biol.Integr. "F.Bottazzi"; and [3]Dip. Fisiol. Generale ed Ambientale, Univ. Naples "Federico II", Naples, I.

The aim of this study was to investigate the role of the brain noradrenergic systems in modulating brain DNA synthesis (BDS) during nonassociative learning (Soc.Neurosci.Abstr., 16, 916, 1990). Adult male Sprague-Dawley rats were randomly assigned to one of six groups. Group A and B were bilaterally lesioned in the dorsal noradrenergic bundle (DNB) by injection of 6-OH-DA, group C and D were sham-lesioned, and group E and F were unoperated uninjected controls. All rats were given 50µCi ^{3}H-thymidine intraventricularly and sacrificed 0.5h later. The exposed rats were injected 15 min before test trial, Groups B, D and F were exposed for 10min to a a Làt-maze, and corner-crossings and rearings were monitored per 1min-blocks. BDS was measured in several brain regions by the incorporation of ^{3}H-thymidine into DNA. DNB-lesioned rats exposed to the Làt-maze did not show the marked inhibition in BDS observed under comparable conditions in control rats. The results support a role of noradrenergic systems in modulating brain DNA synthesis during learning. **(Supported by CNR and MURST 40% grants).**

Physical Activity Enhances Spatial Learning and Associated Hippocampal, not Parietal or Frontal Cortical, Cholinergic Function in F344 Rats. D.E. Fordyce[1,3] and R.P. Farrar[1,2,3]. [1]Institute for Neuroscience, [2]Department of Pharmacology and [3]Department of Kinesiology, The University of Texas at Austin, Austin, TX.

The effects of physical activity on spatial learning performance and associated cholinergic function were examined in F344 rats. Cholinergic analysis included resting and depolarization-induced activation of high affinity choline uptake (HACU) and muscarinic receptor binding in the hippocampus, parietal cortex and frontal cortex. Chronic-run rats demonstrated enhanced performance on the spatial learning task, indicated by second trial latencies and first and second trial proximity ratio scores ($p<.002$), and a reduction in hippocampal HACU, upregulation of muscarinic receptor density, and an increase in HACU 24 hours after spatial memory testing ($p<.05$). In addition, spatial memory tested rats demonstrated enhanced depolarization-induced activation of HACU compared to all other groups (62 vs 37 pmol/mg/4min, $p<.001$). Rats that were yoked for swim time to spatial memory tested rats did not show any spatial memory-induced alterations in HACU. Cholinergic alterations induced by chronic running were observed only in the hippocampus, not the parietal or frontal cortex. The data from this study, therefore, indicate that the chronic running-induced hippocampal alterations in HACU and upregulation of muscarinic receptor density, in combination with enhancement of HACU related to spatial memory testing, may contribute to the enhanced spatial learning performance in chronic-run rats.

437.3

[^{3}H]-CHOLINE UPTAKE IN THE FRONTAL CORTEX OF MATURE AND AGED RATS IS PROPORTIONAL TO THE ABSOLUTE ERROR IN THE CONTENT OF TEMPORAL MEMORY. W.H. Meck, Department of Psychology, Columbia University, New York, NY 10027.

The relationship between the magnitude of the error in the content of temporal memory and sodium-dependent high affinity choline uptake (SDHACU) in the hippocampus and frontal cortex was examined in mature (10-16 mo) and aged (24-30 mo) rats. The peak time of the response rate distribution that relates the probability of a response to signal duration in a 20-sec peak-interval (PI) timing procedure was used to index the remembered time of reinforcement. Discrepancies in temporal memory produce stable horizontal displacements of timing functions such that they can be centered at times that are either less than or greater than the actual time of reinforcement. Typically, the average remembered time of reinforcement for a group of mature rats would be very close to actual time of reinforcement,with a symmetrical distribution of individual peak times centered around that time. In contrast, as rats age they demonstrate a proportional rightward shift in their timing functions, indicating that remembered durations overestimate the actual time of reinforcement by a constant percentage. Regression analyses indicated that SDHACU in the frontal cortex, but not in the hippocampus, of both mature and aged rats is proportional to the absolute error in the content of temporal memory. Correlation coefficients averaged over both age groups were $r = .75$, $p < .001$ and $r = .06$, $p > .05$ for the frontal cortex and hippocampus, respectively.

437.4

EFFECTS OF ACIDIC FIBROBLAST GROWTH FACTOR ON MEMORY IN RODENTS. K. Sasaki[1], Y. Oomura[2,3], A. Li[2], K. Hanai[4], I. Tooyama[4], H. Kimura[4], and H. Yaqi[1] Fac. Engi., Toyama Univ[1]., Toyama Med. & Pharm. Univ., Toyama 930-01[2], Inst. Bio-Active Sci., Nippon Zoki Pharm. Co., Hyogo, 673-14[3], Inst. Molec. Neurobiol., Shiga Med. Univ., Shiga 520-01[4], JAPAN

Acidic fibroblast growth factor (aFGF) is produced in the ependymal cells of the cerebroventricular system and released into cerebrospinal fluid (CSF) by glucose. The aFGF in rat CSF increased 1000 times in a 2 hr period after intraperitoneal (IP) or intracerebroventricular (ICV) glucose infusion, and diffused into the brain parenchyma and was taken up into neurons in the hypothalamus, hippocampus and other parts of the brain. We investigated the effects of endogenous and exogenous aFGF on memory. IP glucose injection 2 hr before an acquisition trial of foot shock in a passive avoidance task significantly increased retention in mice when tested 24 hr later. In a Morris water maze task, IP glucose injection 2 hr before the first trial block reduced latency to escape onto a platform hidden just below the surface of the water. These glucose effects were abolished by ICV anti-aFGF antibody injection 30 min before the glucose injection. Continuous ICV infusion of aFGF into rats also significantly increased retention latency in passive avoidance task. Results suggest that aFGF facilitates memory in the central nervous system. Memory facilitation by aFGF was significantly attenuated by CA$_1$ neuron death in the hippocampus caused by 5 min ischemia of the brain.

BEHAVIORAL EVIDENCE FOR THE NAPLES HIGH AND LOW-EXCITABLE RATS AS A GENETIC MODEL TO STUDY HIPPOCAMPAL FUNCTIONS. A.G.Sadile, A.Cerbone, T.Sagvolden[2]*, H.Welzl[3], Dip.Fisiol.Umana "F.Bottazzi", Univ. Naples, I; [2]Inst.Neurophysiol., Univ. Oslo, N.; [3]Inst.Behav.Biol., ETH, Zurich, CH.

The behavioral evidence supporting the hypothesis that the Naples High (NHE) and Low-Excitable (NLE) rats may be a genetic model to study hippocampal functions (Adv.Biosci., 59:299, 1986) is presented. It comprises: (1) Differential activity in a spatial novelty situation (selection trait), proportional to the stimulus complexity rats are exposed to. NHE are hyper- and NLE- rats hypoactive; (2) Impaired acquisition rate of water motivated operant conditioning in both lines vs. controls; and (3) Impaired working memory in a non reinforced tunnel maze with 6 asymmetrical arms in both lines compared to random-bred controls (Adv.Biosci., 70:177, 1988). Thus, a defective hippocampus-dependent spatial processing is inferred. The behavioral evidence (qualitatively similar in both lines), along with histochemical (Behav.Brain Res., 24:111, 1987), electrophysiological and neurochemical one (Adv.Biosci., 59:299, 1986; Behav.Brain Res., 33:287, 1989), suggests that both NHE/NLE are disintegrated at the hippocampal interface. Moreover, far from fitting in current theories on hippocampal functions, they lend support to its modulatory role in the parallel processing of cognitive and non-cognitive (attentional, emotional) informational components. **(Supported by CNR and MURST 40% grants).**

COGNITIVE AND NEUROCHEMICAL CHANGES INDUCED BY EXPERIMENTAL AUDITORY DEFICIT IN AGED RATS. F. Drago, L. Nardo* and F. Spadaro* Department of Pharmacology, University of Catania Medical School, Catania, Italy.

In aging, auditory deficits occur frequently and have been involved in cognitive impairment. We studied the effects of an experimental acoustic deafferentation on learning and memory processes and on some neurochemical parameters of aged rats. Sprague-Dawley male rats, 18 months old, were used. A solution of fibrinogen, thrombine and Factor XIII was injected once in a week for three months in the middle ear of aged male rats. Learning and memory capacity, assessed with passive and active avoidance tasks, was reduced in rats with experimental auditory deficit as compared to control animals. In the despair test, a behavioral model for depression, animals with the auditory impairment showed a more serious depressive attitude than controls. After the behavioral tests were performed, an auditory recovery of a group of animals was allowed suspending the injections. A month later, the behavioral testing was repeated. The animals that recovered from the auditory deficit showed a normalization of the behavioral pattern. A neurochemical study showed a reduction in DA and DOPAC content and in CAT and AChE activity in various brain ares of animals with auditory deficit. These results show that prolonged acoustic deafferentation can induce reversible cognitive changes. This may be of clinical relevance in elderly people with an acoustic deficit without hearing aids.

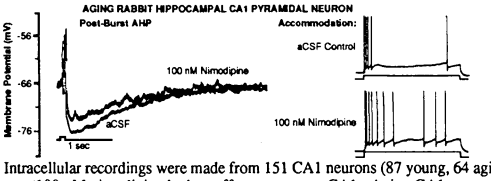
NIMODIPINE INCREASES EXCITABILITY OF CA1 NEURONS IN AGING RABBITS. J.R. Moyer, Jr., L.T. Thompson, J. Black', and J.F. Disterhoft. Department of CMS Biology, Northwestern Univ. Med. Sch., Chicago, IL 60611 and 'Dept. of Psychobiology, UC Irvine, Irvine, CA 92717.

Nimodipine, a dihydropyridine calcium channel antagonist, facilitates learning in aging rabbits (Deyo *et al.*, 1989) and increases spontaneous firing rates of CA1 pyramidal neurons *in vivo* (Thompson *et al.*, 1990). CA1 neurons from trace conditioned rabbits also exhibit learning-specific afterhyperpolarization (AHP) reductions (deJonge *et al.*, 1990). To investigate the mechanism by which nimodipine exerts its behavioral effects, we studied the AHP before and after application of nimodipine in both aging and young adult CA1 neurons *in vitro*.



Intracellular recordings were made from 151 CA1 neurons (87 young, 64 aging). Doses ≤100 nM nimodipine had no effects on young CA1. Aging CA1 neurons showed significantly reduced AHP amplitudes and areas, and decreased accommodation after 100 nM nimodipine (extracellular levels in behavioral studies). Aging CA1 neurons also showed significantly larger AHPs than young CA1 neurons. These data support the hypothesis that aging neurons have altered calcium regulation (perhaps via decreased calcium buffering capacities) resulting in larger AHPs, and that in aging CA1 neurons, nimodipine can decrease the AHP, thus increasing cellular excitability in a manner facilitating learning. ARE THERE PLACE CELLS IN THE PRIMATE HIPPOCAMPUS ? E.T.Rolls and S.M.O'Mara*. University of Oxford, Department of Experimental Psychology, Oxford OX1 3UD, England.

Previous work on the role of the primate hippocampus in spatial processing has shown that there are cells in the macaque hippocampus which respond when the monkey looks at particular positions in space, and that some of these cells respond in allocentric (world-based) rather than egocentric (body-centered) coordinates (J.D.Feigenbaum & E.T.Rolls, 1991, Psychobiology 19: 21-40). Such cells were named 'space' cells, to distinguish them from 'place' cells in the rat which respond when the rat is in a particular place in an environment. In the experiments described here, we investigated activity changes of cells when macaques (Macaca fascicularis) were moved in a small chair on wheels to different places in a cue-controlled testing environment (a 2m x 2m chamber). Many cells with spatial responses were recorded in the primate hippocampus and parahippocampal gyrus. For a number of cells, it was possible to show that firing rate depended on where in space the monkey looked, and not on the place in the environment, or on head direction. The responses of some cells were affected by the removal of cues in the environment. Other cells responded in relation to whole body movement of the monkey in the testing environment, with some specific for head-centred rotation, and others for linear translation. Cells which respond according to the place where the monkey is located and independently of local view and of head direction have not yet been found, but testing is continuing.

SINGLE NEURONS IN PRIMATE TEMPORAL CORTEX CODE BOTH OF PAIRED ASSOCIATES STORED IN VISUAL LONG-TERM MEMORY. K. Sakai* and Y. Miyashita. Dept. of Physiology, Sch. of Medicine, Univ. of Tokyo, Tokyo 113, JAPAN.

Human memory is assessed by the paired associate learning test, in which the subject is shown a series of paired figures and then asked to retrieve the associate of a cue figure. We prepared 24 computer-generated patterns and sorted geometrically distinct figures into pairs. Two monkeys (*Macaca fuscata*) were trained to memorize these pairs. In each trial, a cue stimulus was presented on a video monitor, and choice stimuli were shown after a delay period. Each monkey obtained a fruit-juice reward for correctly touching the paired associate. We found two types of neurons in the anteroventral temporal cortex. One type selectively responded to both of the paired patterns during the cue period. The other type, which responded to one pattern optimally, exhibited tonic activity during the delay period when the associate of that pattern was used as a cue. These results provide direct evidence that the single neurons acquired the response selectivity through associative learning, representing long-term memory of paired associates.

RAPID AND CONSOLIDATED ASSOCIATION OF CORTICAL MEMORY CIRCUITS BY THE HIPPOCAMPUS: "TRACING-CIRCUIT ASSOCIATION" MODEL FOR HUMAN MEMORY.

Yoichiro Kuroda Dept. of Neurochem., Tokyo Metropolitan Institute for Neurosciences, Fuchu-shi, Tokyo 183 Japan.

The hippocampus has long been considered important in the consolidation of memory. In 1989 , a "tracing circuit" model of human memory was proposed where in consolidation occurs by "impulse tracing" to stabilize connections by strengthening synapses in closed circuits in the cortex (*Neurochem.Intern.* 14,309). The existence of reciprocal cortico-hippocampal projections suggests that closed circuits between cortex and hippocampus can be formed and can further consolidate the tracing circuits in the cortex. Here, using recent compelling data on a longitudinal(septotemporal) axis of the hippocampus, I propose a "tracing circuits association" model, in which association of episodic memories of different modalities is formed in the hippocampus by intra-hippocampal connections of cortico-hippocampal closed circuits. When tracing impulses carrying simultaneously presented information of different modalities can form a new closed circuit through the hippocampus by reciprocal projections with the association cortex, the tracing circuits are further stabilized, with prolongation of firing in closed circuit. Since all CA3 neurons appear to project to CA1 neurons distributed along the long axis of the hippocampus (Ishizuka et.al., *J.Comp.Neurol.* 295, 580,1990), simultaneous excitation of closed circuits of different modalities can easily be connected by cross projection of CA3 neurons in one cortico-hippocampal closed circuit to CA1 neurons in a different circuit. Such inter-closed circuit CA3-CA1 synapses are repetitively stimulated during the prolonged firing, induced LTP and other facilitatory processes which stabilize these synaptic connections over long periods, enabling reactivation of the associative memory circuit.

A SPIKING NEURON NETWORK MODEL OF DYNAMIC SHORT-TERM MEMORY. B. Kehoe* and D. Zipser, Department of Physics, CSUF, Fresno, CA 93740 and Department of Cognitive Science, UCSD, La Jolla, CA 92093.

The firing patterns of cortical neurons in monkeys engaged in short-term memory tasks (see, e.g., Fuster, J.M., *J. of Neurophysiology*, **36**, 61-78, 1973) have been shown to be similar to the activity patterns of units in a recurrently connected, discretely updated, artificial neural network (ANN) trained as a gated sample and hold register (D. Zipser, *Neural Computation*, **3**, 178-192, 1991). This similarity suggests a dynamic storage mechanism for short-term memory utilizing a recurrent network. The discrete time model has been extended to an approximation of a continuous time ANN and also to a model of a spiking network based upon the continuous model, trained using the backpropagation through time algorithm subject to biologically based constraints. The characteristic features of the discrete network corresponding to the neurobiological data are preserved. Large networks have been trained with significant levels of noise to reflect the variability of average spiking rate of real neurons. The resulting trained network spontaneously learns to utilize all of its resources by creating clusters of similarly connected units that represent what were single units in smaller networks. These clusters presumably help to overcome the effects of noise by averaging. Networks made up of spiking units, with biologically based parameters and connections determined by the continuous network, are being studied. Their interspike interval distributions model those found in the data. The attractor dynamics of spiking networks, and the implications of those dynamics for purturbed neurons in such a network, are explored as a guide to further experimental testing of the recurrent model of dynamic short-term memory.

NMDA-BASED PATTERN DISCRIMINATION IN A MODELED CORTICAL NEURON. B. W. Mel, Computation and Neural Systems Program, Caltech, 216-76, Pasadena, CA, 91125.

Compartmental simulations of an anatomically characterized cortical pyramidal cell were carried out to study the integrative behavior of a complex dendritic tree (anatomical data from Rodney Douglas and Kevan Martin). Theoretical considerations had suggested a possible role for cooperative interactions among groups of neighboring synapses in the generation of cell responses (Mel, B.W., Soc. Neurosci. Abst., 208.5, 1989). In earlier compartmental modeling studies of a layer 2-3 pyramidal cell (Mel, B.W., Soc. Neurosci. Abst., 205.4, 1990) it was found that when dendritic spines contained a high proportion of voltage-dependent NMDA channels, the pyramidal cell responded selectively to spatially-clustered, rather than random, distributions of activated synapses. The cluster-sensitivity effect has now been replicated in a layer 5 pyramidal cell of very different morphology, where it is shown to persist under wide ranging biophysical parameter variations. In a demonstration of the possible biological utility of cluster sensitivity, the NMDA-rich neuron is shown to be capable of solving a complex image discrimination task within its dendritic tree. We conclude that a relatively simple statistical characterization of the input-output behavior of the cortical pyramidal cell may be both possible and appropriate.

CORTICAL ASSOCIATIVE MEMORY FUNCTION AND ACETYLCHOLINE: A COMPUTATIONAL MODEL.

M.E. Hasselmo, Dept. of Psychology, Harvard University, Cambridge, MA 02138.

Psychopharmacological evidence suggests a role for acetylcholine in memory function. Computational modeling of cortical associative memory function may help link this role in memory to the specific effects of acetylcholine on cortical neurons. Acetylcholine (100μM, presented with 1μM neostigmine) selectively suppresses intrinsic fiber synaptic transmission in slice preparations of piriform cortex, while leaving afferent fiber synaptic transmission unaffected (Hasselmo and Bower, J. Neurophysiol., in press). A model of piriform cortex shows that this selective suppression of excitatory feedback, applied during learning of new input patterns, can greatly enhance associative memory performance. Without this suppression, excitatory feedback generates previously stored patterns during the learning of new patterns which activate any of the same neurons. This leads to the strengthening of connections between all neurons activated by overlapping input patterns, resulting in considerable interference between stored patterns. Cholinergic suppression of excitatory feedback can prevent this problem by decreasing the activity of neurons not receiving direct afferent input during learning, thereby satisfying the following condition:

$$\mu, \Omega > a_i = \sum_{j=1}^{n} (1 - c)B_{i,j}\, g(a_j) - H_{i,j}\, g(a_j)$$

where μ = synaptic modification threshold, Ω = output function threshold, a = neuron activation, c = cholinergic suppression, B = excitatory feedback strength, H = inhibitory feedback strength, g(a) = neuron output function. This has an effect similar to clamping neuron activity to the input pattern during learning, a technique used in the modeling literature, but not previously justified by neurophysiological data. Memory deficits associated with presentation of cholinergic antagonists show some characteristics of the interference predicted by this model. This work suggests how the memory deficits associated with Alzheimer's disease could arise from a loss of cortical cholinergic innervation.

CHEMICAL SENSES: PERIPHERAL MECHANISMS III

438.1

ROLE OF cAMP PHOSPHODIESTERASE IN OLFACTORY SIGNAL TRANSDUCTION. F.F. Borisy-Rudin[1], G.V. Ronnett[1], A. Cunningham*[1], J. Beavo*[2], S.H. Snyder[1]. [1]Depts. of Neuroscience, Neurology, and Molecular Biology & Genetics and the Howard Hughes Institute, Johns Hopkins University School of Medicine, Baltimore, MD 21205. [2]Dept. of Pharmacology, SJ-30, University of Washington, Seattle, WA 98195.

To investigate the mechanisms by which the olfactory signal is terminated we have characterized the phosphodiesterase (PDE) activities present in cilia and homogenates of olfactory turbinates. At least two forms of PDE, Ca^{2+}/calmodulin PDE (CAM-PDE) and rolipram-sensitive cAMP selective PDE (RS-PDE), are present in olfactory turbinates as determined by biochemical and immunohistochemical methods. High affinity CAM-PDE appears to be the predominant form in washed preparations of olfactory cilia and is fivefold greater than in brain when assayed at low micromolar cAMP. By comparison, in turbinates about half the PDE activity is sensitive to rolipram. Following bulbectomy, CAM-PDE activity is significantly depleted in turbinates. Immunocytochemical staining of the rat olfactory mucosa reveals selective expression of CAM-PDE in mature olfactory receptor neurons with immunoreactivity most pronounced within the dendritic knob and cilia, as well as the axon bundles. Neither sustentacular cells nor basal cells display any immunoreactivity. Bulbectomy greatly depletes the population of CAM-PDE positive cells. We propose that Ca^{2+} activation of CAM-PDE may be involved in termination of olfactory signals.

438.2

OLFACTORY RECEPTOR NEURONS OF THE MALE MOTH MANDUCA SEXTA EXPRESS SECOND MESSENGER MODULATED ION CHANNELS IN VITRO. M. Stengl[1], R. B. Levine[2], J. G. Hildebrand[2]. [1]Fak. für Bio., Univ. Konstanz, Postfach 5560, 7750 Konstanz, BRD. [2]ARL, Neurobio., Univ. of Arizona, Tucson, AZ 85721

Primary cultures of identifiable olfactory receptor neurons (ORNs) from male Manduca sexta pupae facilitated studies of olfactory transduction mechanisms. About 30% of the 21 d cultured ORNs responded to puffer-pipette-applied DMSO extracts of female pheromone glands. In most cases pheromone-dependent cation channels with subconductance states opened, with reversal potential around 0 mV, non-linear I/V relationship, and no discrimination between K^+, Na^+ or Cs^+. Patch-excision opened channels which closely resembled the pheromone-dependent cation channels. These channels were blocked by TEA and cGMP+ATP. In the whole-cell configuration with other channels blocked via TTX and Cs^+, transient cation currents were elicited via perfusion of the cells with GTPγS+ATP, IP_3, or 10^{-6} M Ca^{++}. These currents resembled the pheromone-dependent cation currents in reversal potential and ion selectivity. At least a subpopulation of these currents were blocked by TEA or bromo-cGMP+ATP. These Ca^{++}-permeable channels opened only transiently with mM concentrations of Ca^{++} outside. Application of protein kinase C (PKC) activators to cultured ORNs opened Ni^+-blockable Ca^{++} channels and opened cation channels which resembled the pheromone-dependent cation channels. The Ni^+-blockable Ca^{++} channels also opened when internal Ca^{++} was buffered to less than 10^{-8} M. Future studies will examine our working hypothesis that pheromone leads to transient opening of second messenger-dependent Ca^{++} channels which then lead to opening of Ca^{++}-dependent cation channels, both of which change their sensitivity to Ca^{++} via PKC-dependent phosphorylation.

438.3

EXPRESSION OF 5'-ECTONUCLEOTIDASE AND PHOSPHATASE ACTIVITY FROM THE OLFACTORY ORGAN OF THE SPINY LOBSTER IN XENOPUS OOCYTES. H.G. Trapido-Rosenthal, M.A. Holman, R.M. Greenberg, R.A. Gleeson* and W.E.S. Carr.* Whitney Laboratory, University of Florida, St. Augustine, Florida 32086.

The olfactory organ of the spiny lobster, Panulirus argus, consists of a dense array of aesthetasc sensilla on the lateral filament of the antennule. Electrophysiological studies have shown that sensilla include populations of receptor cells that respond to the odorant adenosine 5'-monophosphate (AMP). Biochemical studies have shown that sensilla also contain a potent extracellular enzymatic activity that rapidly dephosphorylates this odorant. In this study, we report that messenger RNA (mRNA) isolated from lobster olfactory organ can induce the expression of ectonucleotidase/phosphatase activity in oocytes of the frog Xenopus laevis. Oocytes microinjected with mRNA from lobsters' lateral antennular filaments exhibited an increase in their ability to dephosphorylate exogenous AMP, relative to non-injected and water-injected control oocytes. The amount of ectoenzymatic activity expressed depended upon the amount of lobster mRNA injected. Injection with non-messenger RNA did not enhance the ability of oocytes to dephosphorylate AMP. Heterologous expression in Xenopus oocytes may be of general value for studying odorant-degrading enzymes, since the biochemical assays used to monitor expression are both simple and highly sensitive. This work was supported by grants from the National Science Foundation (BNS-8908340 and BNS-8805885) and the University of Florida (D-50-8990 and RDA-1-9).

438.4

STEREOSPECIFIC DETECTION OF AMINO ACIDS BY LOBSTER OLFACTORY RECEPTOR NEURONS. W.C. Michel[1], H.G. Trapido-Rosenthal[1], E.T. Chao[1,2*] and B.W. Ache[1,3]. [1]Whitney Lab. and [3]Depts. of Zool. and Neurosci., Univ. of Florida, St. Augustine, FL. 32086, [2]Dept. of Psychol., Berea College, Berea, KY, 40404.

Olfactory receptor cells of crustaceans detect many small, water-soluble organic compounds, including amino acids. Previous investigations of receptor cell specificity in crustaceans have focused on L-amino acids. Here we report that lobster olfactory receptor cells also detect D-isomers of amino acids and do so in a stereospecific manner. Specific binding for L- and D-alanine to an enriched olfactory ciliary membrane fraction was *ca.* 2241 and 792 fmoles/mg protein, respectively. The association of both isomers to the membrane fraction was rapid and saturable; disassociation was also rapid. Distinct receptor sites for the enantiomers were indicated by the preferential displacement of radiolabelled L- or D-alanine by the like isomer. Scatchard analysis identified two binding sites for each isomer. A higher affinity site (K_d *ca.* 5 μM) was interpreted as receptor binding while a lower affinity site (K_d *ca.* 150 μM) may reflect binding to a transport system. Alanine binding was not uniformly distributed across alanine-sensitive receptor cells. Electrophysiological recordings identified D-alanine (n=2) and L-alanine (n=1) specific neurons, as well as neurons with nearly equal sensitivity for the two isomers (n=4). Stereospecific neurons were also identified for 17 of 19 other amino acids tested. Of 89 amino acid-sensitive cells, 35 and 19 were stereospecific for L- and D-isomers, respectively. Collectively, our data suggest that lobster olfactory receptor cells express stereospecific receptor proteins. The non-uniform distribution of receptors across the olfactory receptor cell population presumably allows across fiber discrimination of amino acid isomers. (Funded by NSF Grants BNS 88-10261 & BNS 89-08340 and ONR Grant N00014-90-J-1566.)

438.5

MODEL FOR THE DISCRIMINATION OF ODORS BY 7-TM DOMAIN RECEPTORS AND BY A GROUP OF OLFACTORY NEURONS. P. Nef*, I. Hermans-Borgmeyer*, G. P. Gasic, S. Heinemann, V. Dionne*. Molecular Neurobiology Laboratory, The Salk Institute & UCSD, San Diego, CA 92037

Using PCR amplification, we recently cloned a novel multigene family of putative receptors characterized by 7 transmembrane (7-TM) domains and expressed only in olfactory epithelium. Experiments are in progress to determine wether the proteins encoded by these clones represent functional olfactory receptors which play a key role in the detection of odorants. These putative receptors probably constitute an integral part of the molecular mechanisms involved in discriminating among hundred or even thousand of different smells.

In situ hybridization analysis with some of these putative olfactory receptors revealed patterns of expression that correspond to groups of olfactory neurons topographically distributed within the olfactory epithelium. We have named these patterns "primary olfactory maps". We predict that the total number of primary olfactory maps is not infinite mainly because of the overlaping distribution of individual olfactory 7-TM receptors in the epithelium.

Currently, we propose a model for the discrimination of an odorant in which a given odor activates a group of olfactory receptors as well as a group of olfactory neurons. The combination of these two interactions produces "odorant finger-prints" consisting of a pattern of specific depolarizations that are sent to the CNS and further processed by the olfactory bulb.

438.6

THE CLUSTERING OF AN AXONAL SUBSET WITHIN THE PLANE-TO-POINT HOLOGRAPHIC OLFACTORY PROJECTIONS IN TROUT. B. Oakley and D. R. Riddle[1]. Dept. of Biology, Univ. of Michigan and [1]Dept. of Neurobiology, Duke Univ. School of Medicine.

In rainbow trout (*Oncorhyncus mykiss*) a given cluster of olfactory receptor neurons (ORNs), labeled by HRP, makes highly divergent projections to the glomerular layer. In corresponding retrograde tracing experiments, fluorescent latex beads were picked up and transported from small glomerular sites to ORNs scattered widely in all lamellae of the epithelial plane. Thus, instead of a point-to-point or regional topographic map, there is a plane-to-point or holographic projection, since every point in the glomerular layer receives information from the entire olfactory epithelial plane. Such iterated mapping of the rosette could arise if each of many intermingled sets of ORNs converged its axons into a glomerular subregion. To approach this issue we used the lectin, pokeweed agglutinin (PWA). PWA reacted with an ORN subset whose somata were highly dispersed in the olfactory epithelium and whose axons were widely scattered in the olfactory nerve. Yet, at the nerve-bulb interface the PWA positive axons converged into fascicles that terminated in two-thirds of the glomerular layer. The two glomerular fields lacking PWA positive axons received many other olfactory axons, perhaps from dispersed receptor cells having other molecular commonalities. Fourteen weeks after olfactory nerve transection, new axonal projections replicated the nine glomerular fields, including the two that were PWA positive. Evidently, the olfactory epithelium of rainbow trout makes a stable holographic projection, within which one or more subsets of scattered ORN axons may converge to glomerular subregions.

438.7

MULTIPLE NEURAL SOURCES OF VIP-LIKE IMMUNOREACTIVITY IN THE SALAMANDER OLFACTORY MUCOSA. M.L. Getchell[1,2] & T.V. Getchell[1,2,3]. [1], Div. Otolaryngol., Dept. Surgery; [2], Sanders-Brown Center on Aging; [3], Dept. Physiol. & Biophys., Univ. of Kentucky Coll. of Med., Lexington, KY 40536.

The olfactory mucosa may receive extrinsic innervation from 3 sources: terminal nerve, trigeminal nerve, and autonomic fibers accompanying the trigeminal nerve. Based on cell structure, staining pattern, and localization of immunoreactive elements, we have correlated VIP-immunoreactive innervation with its neural source. Immunofluorescence was used to identify and localize VIP innervation. Terminal nerve innervation was characterized by granular staining in occasional bipolar cells with thick, non-varicose processes localized within immature neuroepithelium, at the base of mature neuroepithelium, and in the olfactory nerve. Trigeminal innervation was associated with agranular staining in thin, varicose fibers within nerves, located at the base of the lamina propria, whose branches terminated within glands and blood vessel walls. Immunoreactivity for substance P, also present in fibers of these nerves, was not colocalized with VIP. Thus, VIP-immunoreactive innervation from different neural sources is associated with different structures and targets in the olfactory mucosa. Supported by NSF BNS-88-21074 (MLG) and NIH DC-00159 (TVG).

VOLTAGE-SENSITIVE DYES LOCALIZE TRANSDUCTION EVENTS WITHIN OLFACTORY RECEPTOR NEURONS. R.C. Gesteland, J. Brouwer* & P. Farmer*, Anatomy & Cell Biology, Univ. of Cincinnati Medical Center, OH 45267.

Voltage-sensitive dyes confirm whole-cell patch recording evidence that transduction processes differ in frog and in salamander olfactory receptor neurons. Patch-clamp studies show that in frogs the dendritic and somal membranes are inactivated at rest, with unusually low conductances. In salamanders sodium channels are available for excitation and respond to stimulation with increases in sodium conductance. Voltage dye measurements in slices of olfactory epithelium with the laser scanning confocal microscope discriminate voltage gradients within single neurons. They show that an effective stimulus depolarizes only receptor cilia and the knob on the apical end of the dendrite in the frog. The membrane potential of the dendrite and soma is unchanged, within the sensitivity limits of the technique. In salamander olfactory receptor neurons, stimulus-induced depolarization invades the dendrite and soma. It appears that receptor currents in the frog are funneled from the receptor cilia to the axon for action potential initiation through the cytoplasm without significant electrotonic energy loss. In the salamander, conventional electrotonic and active processes conduct the stimulus message from the cilia to the axon spike generator. In epithelium preparations viewed *en face* odor response properties of different neurons are easily compared to allow studies of stimulus selectivity among neuronal subpopulations. These are difficult with microelectrode methods. Some voltage-sensitive dyes preferentially light up supporting cells in the olfactory epithelium. These cells show stimulus-evoked hyperpolarization. This may be a measure of potassium uptake by these cells which are thought to regulate the epithelial extracellular ionic environment. Resolution of spatially separate events within cells of the olfactory epithelium is a unique property of high-resolution fluorescent voltage-sensitive dye microscopy.

CLONING OF GUSTATORY SPECIFIC G PROTEINS FROM RAT. Susan McLaughlin*, Zhou Hao*, Peter McKinnon*, Robert F. Margolskee. Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

The guanine nucleotide binding proteins (G proteins) mediate signal transduction in olfactory, visual, and hormonal systems. The G proteins comprise a family of proteins which transduce an extracellular signal into an intracellular second messenger (e.g. cAMP, cGMP, IP_3). In the vertebrate taste cell, electrophysiological, and biochemical evidence suggest that G proteins are involved in the transduction of both bitter and sweet tastants. The bitter compound denatonium raises the intracellular calcium concentration in rat taste cells, apparently via G protein induced IP_3. Sucrose causes a G protein-dependent generation of cAMP in rat taste cells which in turn depolarizes the cell. To identify and characterize those proteins involved in the taste transduction process, we have cloned G proteins from rat taste cells. Isolated rat circumvallate and foliate taste papillae were used to make polyA^+ RNA and a taste cell enriched cDNA library. Control RNA and cDNA was also made from regions of the lingual epithelium devoid of taste cells. Using degenerate primers corresponding to conserved regions of G proteins, the polymerase chain reaction (PCR) was used to amplify and clone taste cell G protein cDNAs. Hybridization with G protein cDNA probes was also used to screen this library for G protein clones. To date, seven distinct G protein cDNAs have been isolated, cloned and sequenced from the taste cell library. Four different G protein clones correspond to G_q and G_i subtypes. The G_q and G_i clones are more highly expressed in the RNA from taste cells vs. non-taste cells. Three other G protein clones are expressed in taste cell RNA but not in non-taste RNA, one of these clones ($G_{gustatory}$) is novel and only distantly related to other known G proteins. Presumably, G_{gust} is specifically involved in taste signal transduction.

438.10

POSTSYNAPTIC RESPONSES IN BASAL CELLS ARE ELICITED BY STIMULATING RECEPTOR CELLS IN *NECTURUS* TASTE BUDS. Douglas A. Ewald & Stephen D. Roper Dept of Anat & Neurobiol, Colo St U, Ft Collins CO 80523 & the Rocky Mtn Taste & Smell Cntr, Denver CO 80262

Receptor cells comprise the majority of cells (90%) in *Necturus* taste buds. Receptor cells extend apical processes into the taste pore. Basal cells, which comprise only 10% of the total population, lack apical processes yet are involved in the majority of the morphologically-identified synapses in the taste bud (Delay & Roper, J. Comp. Neurol. **277**: 268, 1988). In thin (150-300 μm) slices of lingual epithelium, chemical stimulation of receptor cells with focally applied KCl (140 mM) elicited receptor potentials in receptor cells and long-latency depolarizing responses in cells that were subsequently identified by dye injection as basal cells (Ewald & Roper, Neurosci. Abstr. **16**: 25, 1990). We have made simultaneous intracellular recordings from receptor cell-basal cell pairs to study the long-latency responses and test whether they represent synaptic coupling from receptor to basal cell. Varying the magnitude of the KCl-evoked receptor potentials revealed a threshold for basal cell responses of a membrane potential between -30 to -10 mV. In about 20% of the simultaneous impalements, electrical stimulation of the receptor cell elicited small depolarizing responses in the basal cells. The magnitude of basal cell responses evoked by electrical stimulation of a single receptor cell (mean = 0.53 ± 0.06 mV, N=10) was 14% of the responses elicited by KCl stimulation of the entire population of receptor cells. The threshold for electrically-evoked responses was in the same range as for those elicited by chemical stimulation. The lack of a long latency in responses elicited by electrical stimulation suggests that the long latency in response to KCl stimulation resulted from the time for the chemically-evoked receptor potential to reach threshold. The incidence (20%) of synaptic coupling between receptor cells and basal cells and the ratio of amplitudes of direct, electrically-evoked responses to KCl-evoked responses (14%) suggests extensive convergence of receptor cells to basal cells. The role of this type of synaptic connection in integrating or modulating the response to gustatory stimulation is under investigation. Supported by NIH grants DC00244, DC00374 and AG06557.

ALZHEIMER'S DISEASE: AMYLOID II

439.1

AGGREGATION AND AMYLOIDOGENICITY OF FRAGMENTS OF THE ß/A4 AMYLOID PROTEIN PRECURSOR IN EUCARYOTIC CELLS. A. Weidemann*, R. Prior*, T. Dyrks*, T. Hartmann*, C. L. Masters, H. Monyer and K. Beyreuther*. Center for Molecular Biology Heidelberg, 6900 Heidelberg, F.R.Germany.

In Alzheimer's disease the typical amyloid deposits are mainly composed of ß/A4 amyloid protein being synthesized as part of a larger precursor protein (APP) from which it is released by so far unknown proteolytic breakdown events. We have begun to examine the biochemical mechanisms by which ß/A4 bearing APP fragments are generated and deposited *in vitro*. Expressionplasmids coding for various C-terminal fragments of APP which include the ß/A4 region were introduced into mammalian cell lines. The corresponding gene products were analyzed with antibodies directed against the ß/A4 region and the cytoplasmic domain of APP. The C-terminal fragments of APP are proteolytically processed giving rise to a complex pattern of breakdown products. Fragments that react with á ß/A4 antibodies accumulate within the cells and form aggregates that are not soluble in SDS buffers. Immunostaining of transfected cells reveals the presence of dense aggregates in the cytoplasm. These structures are ß/A4 positive and can be stained with Thioflavin S, suggesting that the aggregates adopt the characteristic ß-pleated sheet conformation of brain ß/A4 amyloid. The accumulation of stable ß/A4 bearing APP fragments within cells offers the possibility to study the proteolytic processing events and aggregational properties of APP and its fragments in eucaryotic cells.

Effects of Alzheimer Amyloid in Rat Brain. G. M. Cole, S.A. Frautschy and A. Baird. Dept. of Neurosciences, UCSD, La Jolla, Ca. 92093 and Dept.of Cellular and Molecular Biology, Whittier Institute, 9894 Genesee, La Jolla, Ca.92037

Because they have not been directly induced in an animal model, the significance of beta-amyloid deposits in Alzheimer's disease has remained unclear. Although recent data suggest that injection of solublized beta protein and related peptides may have acute toxic or pharmacological effects, there is no data on the existence or levels of soluble beta protein or related peptides in either normal or Alzheimer brain making it difficult to assess their possible physiological or pathological significance. We have injected Alzheimer's amyloid cores into rat cortex and hippocampus and similarly isolated control lipofuscin fractions on the contralateral side. Rat brain sections were silver and immunohistochemically stained for Alz 50, ubiquitin, and beta protein at 2, 7, 30 and 60 days after injection. At 2 days prominent Alz 50 immunoreactivity was observed along the needle track on both the amyloid and lipofuscin sides and this effect was less by 7d. In contrast, at 30d, marked ubiquitin and Alz 50 immunoreactivity was present only on the amyloid injected side. Only the amyloid injected side displayed abberrant silver reactive profiles and marked neuronal loss and this was in close association with beta protein immunoreactive material. These results indicate that complex and fully developed human amyloid deposit fractions can be neurotoxic when injected into adult rat brain.

439.3

THE FAMILIAL ALZHEIMER'S DISEASE MUTATION DOES NOT PRODUCE GROSS ALTERATIONS IN APP SYNTHESIS OR PROCESSING. D.H. Gabuzda, J. Busciglio and B.A. Yankner. Dept. of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115. A point mutation resulting in a single amino acid substitution of isoleucine for valine at residue 717 in the amyloid precursor protein (APP) has recently been identified in some pedigrees with familial Alzheimer's disease (Nature 349: 704, 1991). To determine whether this mutation alters APP synthesis or processing, eukaryotic expressor plasmids containing cDNA's encoding the 695 and 751 isoforms of APP were constructed and site-directed mutagenesis was used to introduce the isoleucine for valine substitution. The wild-type and mutant APP expressor plasmids were transfected into COS cells. Cell lysates and supernatants were analyzed by radioimmunoprecipitation using antibodies which recognize the APP N-terminus, APP C-terminus and the amyloid β protein (AβP). In cell lysates, the N- and C-terminal antibodies both identified 3 APP bands at 100-125 kD (APP_{695}) and 110-135 kD (APP_{751}). In the supernatants, the N-terminal antibody identified 3 bands at 90-115 kD (APP_{695}) or 100-125 kD (APP_{751}). The AβP antibody identified the 3 APP bands in cell lysates and supernatants and, in addition, recognized a unique smaller species in supernatants. The same bands appeared at similar intensities in cells transfected with the wild-type or mutant APP cDNA's. These results suggest that this mutation in APP does not produce a gross alteration in APP synthesis or processing, but do not exclude the possibility that the mutant APP may be processed differently in other cell types or in vivo as a function of age.

FATE OF AMYLOID PRECURSOR PROTEIN IN THE NERVOUS SYSTEM. S.S. Sisodia*, E.H. Koo, P.N. Hoffman, V.E Koliatsos, G. Perry and D.L. Price. Neuropathol. Lab., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205; Dept. of Pathology, Case Western Reserve School of Medicine, Cleveland, Ohio 44106.

In Alzheimer's disease, amyloid plaques contain β/A4, a 4-kD peptide derived from an amyloid precursor protein (APP). *In vitro*, APP matures through a constitutive pathway and, following a membrane-associated cleavage, C-terminally truncated APP is secreted into the media. *In vivo*, truncated precursor is present in the spinal fluid, suggesting that similar maturational processes occur in the CNS. We have demonstrated that holo-APP is rapidly transported in the PNS, but little is known about the processing of APP by neurons in the CNS. The present study examined the biology of neuronal APP, detected by several specific polyclonal antisera. When retinal ganglion cells were labeled by injection of [^{35}S] methionine into the vitreous, full-length APP was transported to terminals in the geniculate. In separate experiments, synaptosomal preparations were shown to contain APP. This system should be useful for studying processing of neuronal APP in young animals, and the possible abnormalities of processing in aged animals.

A SERINE PROTEASE FROM MONKEY AND ALZHEIMER'S BRAIN AND A CYSTEINE PROTEASE FROM ALZHEIMER'S BRAIN DEGRADE THE AMYLOID PRECURSOR PROTEIN. C. R. Abraham, B. Razzaboni and G. Papastoitsis*. Arthritis Ctr, Boston Univ. Sch. of Med., Boston, MA 02118.

Alzheimer's disease (AD) brains exhibit abnormal deposits of amyloid ß-protein, a 4Kd fragment of the larger ß-protein precursor (ßPP). The finding of the abnormally processed ß-protein and a protease inhibitor (α1-antichymotrypsin) in the amyloid deposits prompted us to search for proteases which may generate the ß-protein. We here report the presence and partial purification of two such proteolytic activities from AD brain. AD brain homogenates were fractionated and proteases were detected by incubating the fractions with an iodinated peptide flanking the N-terminus of the ß-protein. The cleaved radio-labeled products were separated by thin layer chromatography and exposed to X-ray film. Two distinct active fractions were further purified and characterized by using a battery of protease inhibitors. One activity appears to be a calcium-activated serine protease which cleaves the peptide between the methionine and aspartic acid. A similar proteolytic activity was purified from saline-perfused, fresh-frozen monkey brain. The calcium-activated protease is also able to degrade the full length ß-PP (a gift from S. Sisodia, E. Koo and R. Siman). The second proteolytic activity seems to be a metal-dependent cysteine protease which prefers the met-asp bond as the cleavage site, thus also being able to cleave at the N-terminus of the ß-protein. Finding the protease(s) which generate the ß-protein can lead to the design of protease inhibitors aimed to arrest amyloid deposition which is believed to cause neuritic abnormalities, neuronal cell death and dementia. Supported by NIA, Alzheimer's Association and Cephalon, Inc.

CHARACTERIZATION OF NEURITE-STIMULATING ACTIVITY FROM CONDITIONED MEDIA OF TRANSFECTED PC12 CELLS THAT OVEREXPRESS ß/A4-AMYLOID. R.E. Majocha, B. Tate, M. Ventosa-Michelman and C.A. Marotta. Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

Conditioned media (CM) from transfected PC12 cell lines permanently expressing the A4 to C terminal portion of the amyloid precursor protein cause significant increases in the area of the cell and length of neurites of non-transfected PC12 cells. The CM factor(s) responsible for the effects have apparent MW above 5000. Both alkaline and acidic treatment reduce CM activity. The CM factor(s) are resistant to denaturation at 90° C for 60 minutes. The CM effects are significantly reduced by protease treatment. However, heparinase could not destroy the stimulatory activity. Absorption of CM with Sepharose conjugated heparin sulfate or dextran sulfate do not completely remove stimulatory activity. Antibodies to ß/A4-amyloid are only partially effective in removing activity. These results suggest that multiple stimulatory factors are released from PC12 cells overexpressing ß/A4 peptide. Supported by NIH AG02126 and the Metropolitan Life Foundation.

ß-AMYLOID PRECURSOR PROTEIN EXPRESSION IN RAT BRAIN. INCREASED LEVELS OF KUNITZ DOMAIN CONTAINING FORMS AFTER NEURONAL LESIONS. G. Mengod [1,2], C. Solà[1], F.J. Garcia-Ladona [3], M. Sarasa [4], P. Frey [3], A. Probst [3] and J.M. Palacios [1,2].
1 CID-CSIC Barcelona Spain, 2 Sandoz Pharma Ltd, 3 Dept. of Pathology Univ. Basel Switzerland, 4 Fac. of Veterinary Zaragoza Spain.

We have examined the effects of neuronal lesions in amyloid expression in the rat brain. Two types of neuronal lesions were induced in rats 1) icv injection of kainic acid and 2) axotomy of motor neurons of cranial nerves. The effect of these lesions on the expression of the different forms of the ß-amyloid precursor protein (ßAPP 695, 714, 751, 770) were examined using in situ hybridization histochemistry (ISHH) with oligonucleotide probes specific for each form and by immunohistochemistry with antibodies raised against different synthetic peptides of the ßAPP.
Kainic acid injections resulted in neuronal cell death and glial reaction in the hippocampus. As previously described (Siman et al, 1989) some of the glial cells display positive staining for ßAPP. The ISHH experiments revealed a loss of ßAPP concurrent with neuronal loss. In contrast, the Kunitz domain containing forms 751 and 770 were dramatically increased in correspondance with the glial reaction. Axotomy of the facial and hypoglossal motor nerves resulted in increased ßAPP immunoreactivity in these motor neurons shortly after axotomy. The mRNA coding for the different ßAPP forms were also increased. After regeneration, the level of ßAPP mRNA and protein returned to normal. These results suggest different modes of response of the ßAPP protein to neuronal injury that affect differentially the forms containing the protease-inhibitor domain.

MICROGLIAL CLUSTERS GENERALLY LACK AMYLOID PRECURSOR PROTEIN (APP) mRNA IN ALZHEIMER'S DISEASE (AD). S.A. Scott, S.A. Johnson, C.E. Finch, and L.S. Perlmutter. Dept Neurology and Andrus Gerontology Center, University of Southern California, Los Angeles CA 90033

The distribution of beta amyloid in the brains of AD patients is well-described, yet its origin remains unclear. Human studies using in situ hybridization and Nissl staining indicate that APP mRNA is synthesized primarily by neurons, but also several other cell types including microglia. This study combines in situ hybridization with immunocytochemistry to confirm the microglial localization of APP mRNA. Using 6 AD and 5 non-AD subjects, aldehyde-fixed hippocampal sections were processed immunocytochemically using the microglial antibody LN3, and then hybridized with sense or antisense APP cRNA probes.

For both AD and non-AD cases, our preliminary conclusion is that microglia generally lack APP mRNA signal, especially when compared to the strong neuronal pattern observed using this probe. Most microglial clusters in regions of high plaque density (with a few exceptions) did not contain APP mRNA. Microglia with specific signal were sporadically found in white matter tracts (e.g. alveus) as well as in the dentate molecular laminae. On the other hand, many signal aggregates resembling the shape of pyramidal neurons appeared to be surrounded by clusters of LN3+ microglia.

To summarize, these data suggest that plaque-associated microglia do not produce amyloid *de novo*, although microglial processing of exogenous APP cannot be ruled out.

ß/A4 AMYLOID PRECURSOR PROTEIN IN ALZHEIMER'S PAIRED HELICAL FILAMENTS. F.P. Zemlan, G.E. Dean and G.D. Vogelsang. Alzheimer's Research Center, University of Cincinnati College of Medicine, Cincinnati, OH 45267-0559.

Several laboratories have demonstrated that antibodies (Abs) against restricted regions of the ß/A4 amyloid precursor protein (APP) label neurofibrillary tangles in Alzheimer's brain. The present study examines whether APP is loosely associated with paired helical filaments (PHF) in tangles or is directly incorporated into PHF core protein. Alzheimer's PHF was purified and solubilized as previously reported by our laboratory, then examined on immunoblots with Abs raised against recombinantly expressed APP. Anti-$APP_{590-695}$ selectively labeled the monomeric 66 kD PHF core protein (AD66 protein) on immunoblots while anti-APP_{20-304}, anti-$APP_{444-592}$ and anti-KPI did not. As $APP_{590-695}$ includes the ß/A4 amyloid region, Abs directed against synthetic 42-mer ß/A4 amyloid and purified ß/A4 protein were examined. Both selectively labeled AD66 PHF protein on immunoblots. To confirm these results, immunocytochemical studies were performed on fresh, unfixed AD cortical tissue. Consistent with the above studies, Abs raised against synthetic ß/A4 protein labeled both intracellular and extracellular tangles in unfixed AD cortex. The present data are consistent with the hypothesis that a restricted region of the APP is directly incorporated into the 66 kD PHF core protein in AD brain. This incorporated region appears limited to the ß/A4 protein which suggests that about 4 kD of the 66 kD PHF core protein is comprised of ß/A4 amyloid with the bulk of the AD66 PHF core protein consisting of MAP tau which has been post-translationally modified.

BIOLOGICALLY ACTIVE SECRETED AMYLOID PRECURSOR PROTEINS EXPRESSED BY RECOMBINANT BACULOVIRUS INFECTED INSECT CELLS. **R.Bhasin, W.vanNostrand, T.Saitoh, M.A.Donets*, E.A.Barnes*, W.W.Quitschke and D.Goldgaber. Dept. of Psychiatry, SUNY, Stony Brook, NY 11794, Dept. Micro. and Mol. Gen., Univ. California, Irvine, CA 92717, Dept. Neurosc., Univ. California, San Diego, CA 92093.**

Three alternatively spliced forms of the amyloid precursor protein (APP), APP695, APP751 and APP770, were expressed in the baculovirus expression vector system. The recombinant proteins were secreted into the culture medium by infected insect cells and APP molecules were detected in insect cells and media two days after infection with the recombinant APP baculoviruses. A partial sequence of the amino terminus of the secreted protein revealed identity with the native secreted protein and showed that the signal peptide was recognized and properly cleaved in insect cells. Purified secreted recombinant APP751 co-migrated with protease nexin II (PN-2) purified from platelets and fibroblasts. A 15 Kda C-terminal fragment of APP was also detected in cells infected with the recombinant baculoviruses suggesting that the recombinant APP proteins were cleaved at the C-terminal end like the native APP protein. Recombinant APP751 and APP770 formed complexes with epidermal growth factor binding protein (EGF BP) whereas APP695 did not. In addition, recombinant APP751 and APP770 inhibited trypsin and chymotrypsin activity whereas APP695 did not. A human fibroblast cell line, A-1, that required APP for complete growth, had its growth restored upon addition of secreted recombinant APP695 or APP751. Thus the appropriately sized, secreted recombinant proteins produced in this expression system are biologically active.

MUTATIONAL ANALYSES OF *AMYLOID PRECURSOR PROTEIN-LIKE* GENE IN *DROSOPHILA*. L. Luo and K. White, Department of Biology, Brandeis University, Waltham, MA 02254.

The *Drosophila Amyloid precursor protein-like* gene encodes a protein with strong sequence homology, similar biochemical properties and tissue distribution compared with APP695, a neural-specific form of the amyloid precursor protein associated with Alzheimer disease (Rosen et al, PNAS **86**, 2478-2482; Luo et al. J. Neurosci. **12(10)**, 3849-3861). We are using a genetic approach in *Drosophila* to investigate the *in vivo* function of this class of molecules.

By deficiency duplication combination, we have generated null *Appl*$^-$ flies by the criteria of PCR, Southern and Western analyses. These *Appl*$^-$ flies are viable and morphologically normal, however, they exhibit behavioral deficits. A phototaxis behavior assayed by a counter current apparatus was chosen for further analysis because the quantitative difference could be partially rescued by transduced heat-shock promotor-*Appl* cDNA construct. This behavioral abnormality provides a potential *in vivo* assay for APPL protein function.

We have also generated by *in vitro* mutagenesis constructs expressing secretion-defective or constitutively secreted APPL proteins. These constructs are being introduced into flies through germ-line transformation. Such transduced genes, when introduced into *Appl*$^-$ background, may provide insight about which form is biological active by their ability to rescue the behavioral deficit. In addition, they could be used to study the cell biological properties of various forms of APPL protein in developing nervous system.

BINDING BY A HIGH MOLECULAR WEIGHT HEPARAN SULFATE PROTEOGLYCAN TO THE EXTRACELLULAR DOMAIN OF THE BETA-AMYLOID PROTEIN OF ALZHEIMER'S DISEASE. A.D. Snow*, M.G. Kinsella*, R.T. Sekiguchi*, D. Nochlin and T.N. Wight*. Dept. of Pathology, Univ. of Washington, Seattle, WA 98195.

Previous studies have shown the accumulation and co-localization of a basement membrane derived heparan sulfate proteoglycan (HSPG) to the amyloid deposits containing beta-amyloid protein (BAP) in neuritic plaques and amyloidotic blood vessels in Alzheimer's disease (AD) brain. In the present study the potential binding interaction between different PGs and the extracellular domain of the BAP was explored. In situ and affinity column chromatography experiments utilizing isolated ^{35}S-sulfate labelled PGs from medium or cell layer of bovine aortic endothelial cells or smooth muscle cells, demonstrated that a high MW HSPG (MW ~ 600 kd) binds relatively tightly, 2 smaller dermatan sulfate/chondroitin sulfate (DS/CS) PGs (MW ~100-250 kd) bind weakly, and a large chondroitin sulfate PG (of smooth muscle cells) did not bind to the BAP. Competitive inhibition studies using ^{125}I-labelled HSPGs in the presence of a variety of different unlabelled ligands suggest that both the core protein and GAG chains of the HSPG are involved in BAP binding. The specific binding of the high MW HSPG to the BAP may explain its constant co-localization to BAP amyloid deposits in AD brain, and further implies a possible role for this particular PG in BAP accumulation in AD.

RESPONSES TO CLICKS OF THE CHINCHILLA BASILAR MEMBRANE. M.A. Ruggero, N.C. Rich* and A. Recio*. Dept. of Otolaryngology, Univ. of Minnesota, Minneapolis, MN 55414.

Basilar membrane responses to clicks and tones were studied in chinchilla cochleae using a new application of laser velocimetry (Ruggero and Rich, Hearing Research, 51: 215-230, 1991). Basilar membrane velocity at a site located 3.5 mm from the round window [characteristic frequency (CF): 8-10 kHz] was determined from the Doppler frequency shift of laser light reflected from glass microbeads (10-30 μm) placed on the basilar membrane. Responses to clicks in healthy cochleae consisted of relatively undamped transient oscillations with periodicity close to 1/CF. Intense rarefaction clicks caused initial basilar membrane motion toward scala vestibuli after a latency of about 90 microseconds (measured from the onset of inward stapes displacement). The initial response oscillations grew linearly with stimulus intensity but later response cycles grew nonlinearly, at rates less than 1 dB/dB. Thus, with increases in stimulus level, the response envelopes became progressively more asymmetrical, with maxima shifting to earlier times. The frequency spectra of click responses were computed by Fourier transformation. As click level increased, sharpness of frequency tuning diminished and the maximal spectral response component shifted to lower frequencies. Spectral components immediately below CF phase lagged responses evoked by less-intense clicks, while those just above CF led lower-level responses. In spite of the CF-specific nonlinearities, the magnitude and phase frequency spectra of click responses resembled those for responses to tones. Upon cochlear damage or death of the chinchilla, all nonlinearities disappeared; the gain spectra became broadly tuned and insensitive and thus very similar to those of responses evoked by intense stimuli.

440.2

RESPONSES OF SPIRAL-GANGLION UNITS TO ELECTRICAL STIMULATION OF THE AUDITORY NERVE ROOT. M.C. Brown. Depts. of Physiol. and Otol. and Laryngol., Harvard Medical School, and Eaton-Peabody Lab., Mass. Eye & Ear Infirmary, Boston, MA 02114.

The mammalian auditory nerve is composed of thick, myelinated axons from type-I neurons and fine, unmyelinated axons from type-II neurons. Type-II axons number only 5-10% of all axons in the auditory nerve and their sound-evoked responses have not been documented. Since their fine axons should have long impulse conduction times, type-II units recorded peripherally in the spiral ganglion should have long antidromic latencies to shocks from a stimulating electrode placed centrally in the auditory nerve root. Single units were recorded with micropipettes from the basal-turn spiral ganglion of the anesthetised guinea pig. Most units (n=129) had short-latencies (0.3-1.0 msec) to shocks and sound-evoked activity typical of type-I units (Liberman, 1982, Science, 216:1239-1241). A second class (n=24 units) had sound-evoked activity typical of olivocochlear efferent fibers (Brown, 1989, Hearing Res. 40:93-110); and sometimes responded to high-level shocks with latencies of 1.5-2 msec. Presumably at high shock levels, the current spreads to the nearby vestibular nerve where olivocochlear fibers run. A rare class of units (n=5) had much longer latencies (5-8 msec), appropriate for the caliber of type-II axons (Brown, 1987, J. Comp. Neurol. 260:591-604). These units had moderate to high electrical thresholds. One long-latency unit (from a preparation with good type-I thresholds) responded to high-level noise bursts. It may be suggested that these long-latency units correspond to type-II neurons, although an unusual type of olivocochlear neuron cannot be entirely ruled out.

(Supported by NIH grants DC00351 and DC00119.)

440.3

GLUTAMATE RECEPTOR mRNA EXPRESSION IN THE RAT COCHLEA. A.F. Ryan, D. Brumm* and M. Kraft*. Division of Otolaryngology and Department of Neurosciences, UCSD Medical School and VA Medical Center, La Jolla, CA 92093.

Pharmacological evidence suggests that glutamate may be the transmitter between cochlear hair cells and afferent neurons. Recently, a gene family encoding subunits of non-NMDA glutamate receptors has been recognized, and several genes cloned (Hollmann et al., Nature 342:643, 1989; Boulter et al., Science 249:1033, 1990). To determine whether these receptors participate in cochlear neurotransmission, adult rat cochleas were screened for expression of the genes GluR1, GluR2, GluR3 and GluR4 by in situ mRNA hybridization. GluR1 riboprobes showed no hybridization with any cochlear cells. GluR2 and GluR3 riboprobes both showed intense hybridization with spiral ganglion neurons (SGNs), consistent with a major role for these receptors in SGN neurotransmission. GluR4 riboprobes showed positive but lower levels of hybridization to SGNs. The most likely site for GluR2, GluR3 and GluR4 receptor subunits is on SGN afferent dendrites beneath the cochlear hair cells, since presynaptic endings are relatively sparse on SGN axons in cochlear nucleus and there is no evidence that the olivocochlear efferents use glutamate as a neurotransmitter. These results support the hypothesis that non-NMDA glutamate receptors mediate neurotransmission between cochlear hair cells and SGNs.

Supported by DC00139 and the VA Research Service. Glutamate receptor cDNAs were provided by J. Boulter of the Salk Institute.

440.4

ANATOMICAL DISTRIBUTION OF CHOLERA TOXIN BINDING SITES IN THE COCHLEA. P.A. Santi and P. Mancini*. Dept.of Otolaryngology, Univ. of Minnesota Medical School, Minneapolis, MN 55455.

The B subunit of cholera toxin specifically binds to the carbohydrate residues of the GM1 ganglioside. A FITC-labelled B subunit of cholera toxin was applied to fixed, cryosections of the mammalian cochlea in an attempt to localize the GM1 ganglioside within cochlear tissues. The cholera toxin probe strongly reacted with cells of the organ of Corti, interdental cells, Boettcher cells, inner and external sulcus cells, spiral prominence cells, interosseous globuli, and cochlear nucleus cells that extend into the internal auditory canal. Less reactivity was observed in cells of the stria vascularis, spiral ganglion, modiolus, and Reissner's membrane. No reactivity was observed in the connective tissue cells of the spiral ligament, spiral limbus, basilar membrane or perilymphatic scalas. Controls consisted of probe binding to normal brain tissue, absorbing out the probe with bovine GM1, binding inhibition of the probe with unlabeled cholera toxin, and ethanol extraction of GM1 from cell membranes prior to probe exposure. The functional significance of cholera toxin binding sites and their relationship to the GM1 ganglioside in the cochlea will be discussed. (Research supported, in part, by NIDCD and DRF).

440.5

SENSITIVE PERIOD FOR α-DIFLUOROMETHYLORNITHINE (DFMO) OTOTOXICITY IN THE DEVELOPING PIGMENTED RAT. C. M. Henley*, G. K. Martin and B.L. Lonsbury-Martin, Dept. of Otorhinolaryngology, Baylor College of Med., Houston, TX 77030.

To determine the potential role of the ODC/polyamine system in the functional development of the rat cochlea we quantified ODC and polyamines in developing cochlear tissues and then determined the effects of postnatal DFMO treatment on both cochlear function and on cochlear polyamine metabolism. DFMO, an inhibitor of ODC, is a useful biochemical tool in studying polyamine-dependent processes. Rats (n=3 to 5) were terminated at postnatal ages ranging from 3-60 days and cochlear tissues were analyzed for ODC/ polyamines. Cochlear ODC increased rapidly during the first 10 days of life, peaked on days 9-10, then rapidly declined. ODC in the lateral wall-organ of Corti was greater than in the cochlear nerve in developing, but not in adult rats. Polyamines were elevated during the period of differentiation of various cell types comprising the lateral wall-organ of Corti. The spermidine/ spermine ratio was high in the cochlear nerve, even in adults, indicating the continued elevated level of protein and nucleic acid synthesis necessary for nerve function. This may explain the reversibility of DFMO ototoxicity in humans, since the drug is cytostatic and not cytotoxic. Rats treated with DFMO (500 mg/kg/day) during the period of increased polyamine biosynthetic activity demonstrated age and frequency-dependent deficits in outer hair cell function, as assessed by acoustic distortion-products. DFMO significantly inhibited ODC during this specific period. The developing rat appears to be hypersensitive to the effects of DFMO during the period when polyamine biosynthetic activity is increased. We are currently evaluating the effects of DFMO on cochlear polyamine levels to correlate biochemical effects with observed functional losses. These studies suggest that the polyamines are critical for the normal development of cochlear function.

440.6

SENSITIVITY OF AUDITORY NERVE FIBERS TO THE RELATIVE PHASE OF FREQUENCY COMPONENTS IN COMPLEX SOUNDS. D.A. Bodnar and R.R. Capranica, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

A complex sound is uniquely specified by the magnitude and phase spectra of its individual frequency components. Excitatory tuning curves of individual auditory nerve fibers only reflect the selectivity to single tone stimuli. Thus, tuning curves do not provide any information regarding the encoding of the relative phase spectrum in more complex signals.

To address the question of peripheral sensitivity to phase spectrum, we recorded from single units in the VIIIth nerve of the bullfrog (*R. catesbeiana*) using multi-tone stimuli. These stimuli consisted of the first 10 components of a harmonic series with a fundamental frequency of 200 Hz, and spanned most of the frequency range of the bullfrog's vocal repertoire. For all units the same standard reference stimulus was initially presented and then the relative phases of single harmonic components were varied systematically. Most of the cells exhibited pronounced changes in their spike rates when the relative phase of only a single component was varied, and were most sensitive to changes in phase of the component closest to their best excitatory frequency. Plots of spike rate vs. phase angle revealed a wide variety of patterns in spike rate changes. Most cells also showed significant changes in their coefficients of synchronization to the fundamental period of the stimulus. The shapes of cycle histograms, plotted on the fundamental period, changed with shifts in the relative phase of a single harmonic.

The phase relationships of individual frequency components affect the fine temporal structure of the acoustic signal waveform. The observed sensitivity of auditory nerve fibers to these relative phases suggests that complex waveform features of auditory stimuli are encoded by the peripheral auditory system.

This research is supported by NIH grant NS 09244.

440.7

DUALITY OF ENCODING WITHIN THE TUNING CURVES OF AUDITORY NERVE FIBERS IN THE TOKAY GECKO.

E. Dodd and R.R. Capranica, Section of Neurobiology & Behavior, Cornell University, Ithaca, NY 14853.

Excitatory tuning curves of auditory nerve fibers in the Tokay Gecko (*Gekko gecko*) have typical "V" shapes with a distinct best excitatory frequency (BEF) and a pronounced low-frequency tail that can encompass several octaves at moderate stimulus intensities. Since these remarkable lizards are highly vocal and produce several different types of loud calls whose waveform periodicities normally fall within the low-frequency tail regions, we explored to what extent different regions within a tuning curve preferentially dominate the fiber's spike pattern. This relative effectiveness was determined by first measuring spike rate and coefficient of synchronization intensity functions to a sequence of tonal triplets whose frequency components were the BEF and the two 30 dB cutoff frequencies on the opposing skirts of the tuning curve, while the relative amplitude of the BEF component was attenuated in 5 dB steps from 0 to -30 dB relative to the other two equal-amplitude components. Next, a set of harmonic series with fundamental frequencies of 100, 400 and 600 Hz were presented at 70 dB SPL in which the phases of the individual components were shifted systematically while cycle histograms were generated for each of the harmonic components in each series. The results clearly verify that each auditory nerve fiber selectively phaselocks to the lowest frequency component in a complex signal that falls within its excitatory tuning curve. The integrated energy contributed by the higher frequency components, especially weighted in the vicinity of the BEF, governs the corresponding spike-rate intensity function. These results therefore lead to a duality of spike train dependency: The low frequency tail below the BEF dominates the temporal phase-locked spike pattern whereas the absolute overall spike rate is governed by a complex summation of energy contributed by the higher frequency components in the stimulus. The spike response patterns to the Tokay's natural calls corroborates this interpretation. [Supported by NIH grant NS-09244, Danish Research Academy (F8900930) and the Carlsberg Foundation (88-0125)].

ENCODING OF AMPLITUDE-MODULATION (AM) RATE AND TEMPORAL-GAP IN FROG AUDITORY NERVE FIBERS. Albert S. Feng. Department of Physiology & Biophysics, University of Illinois, Urbana, IL 61801

Recordings were made from single auditory nerve fibers in the 8th nerve of northern leopard frogs to assess quantitatively their abilities to encode the AM rate and detect signal gaps, and how these abilities change with the duration of the AM signals. The goal was to test a hypothesis that signal gap is the factor that determines the upper limit of time-locked responses of these fibers to rapidly-fluctuating pulsed AM stimuli shown in an earlier study (J. Neurophysiol. 65: 424-445, 1991).

Acoustic stimuli comprised AM tone pulses of different durations presented as: (1) a pair in which the silent interval or gap was systematically varied from 0.1 to 100 ms, or (2) a train (which mimics frog's natural vocalizations) in which the AM rate was orderly varied whereby the gap between tone pulses covaried from 0 to > 100 ms. Responses of auditory nerve fibers to these two sets of stimuli were measured in terms of synchronization coefficient, mean spike count, and firing rate; these measures were plotted against the stimulus variable, e.g., gap or AM rate, to construct gap- or modulation-response-functions. These responses were compared to test the working hypothesis. Results to date indicate that the signal gap exerts a strong influence that determines the range of AM rate to which each fiber can faithfully respond. Moreover, the gap detection ability is dependent on signal duration, being superior when the signal duration is shorter. (Supported by NSF grant 88-09490)

KAPPA BUT NOT MU NOR SIGMA AGONISTS REDUCE AUDITORY THRESHOLDS AND INCREASE AUDITORY SENSITIVITY. TL Sahley, FE Musiek and DW Hoffman. (Spon. F Musiek) Dept. of Psychiatry, Pharmacology, Medicine and Surgery, Dartmouth Medical School, Hanover, NH 03756.

Little is known about how abused opioid drugs affect sensory systems. Opioid peptides and receptors are present in many nervous system structures mediating sensory function. This laboratory is studying the effects of intravenously administered opioid agonists and antagonists on auditory-evoked potentials. N1 and N2 amplitudes or latencies were not altered by the opioid receptor antagonist naloxone or the μ-receptor agonist fentanyl . The κ-receptor agonist, μ-receptor antagonist (-)-pentazocine or its racemate caused marked increases (up to 263% over baseline) in N1 and N2 amplitudes at and near threshold stimulus intensities, effectively increasing auditory sensitivity. Similar effects were seen with the κ-agonist U50488H. These actions were reduced by nor-binaltorphimine but not naloxone. (+)-Pentazocine had no effects. No changes were seen in the cochlear microphonic, supporting a site of action of these effects at the lateral olivocochlear efferent terminals on auditory nerve dendrites under inner hair cells, which contain enkephalins, dynorphins and acetylcholine. Similar results were obtained for far field auditory evoked responses. This action of κ-agonists on auditory-evoked potential amplitudes may represent a physiological role of the lateral olivocochlear efferent innervation. The different olivocochlear efferent neurotransmitters may have antagonistic or synergistic actions pre- and/or post-synaptically. [Supported by the Deafness Research Foundation.]

MINERALOCORTICOID (TYPE I) RECEPTORS IN THE INNER EAR. D.Z. Pitovski[1], M.J. Drescher[1,2*], and D.G. Drescher[1,2]. [1]Dept. of Otolaryngology, [2]Laboratory of Bio-otology, Wayne State University School of Medicine, Detroit, MI 48201.

The presence of mineralocorticoid (Type I) receptors in the mammalian inner ear was previously suggested by aldosterone modulation *in vivo* of ^{3}H-ouabain binding measured *in vitro* (Pitovski et al., Assoc. Res. Otolaryngol. Abstr. 13: 303, 1990). ^{3}H-Aldosterone binding has now been measured in the lateral wall of the basal turn of the cochlea and in the ampulla of the semicircular canal in male Hartley guinea pigs. Microdissected inner-ear tissues were incubated with 40 nM ^{3}H-aldosterone and binding determined. Specific binding was defined as total binding in the absence (experimental) minus binding in the presence (control opposite ear) of 2000-fold excess of unlabeled hormone. Binding values were also corrected for ^{3}H-aldosterone present intercellularly, monitored with ^{14}C-sucrose and normalized to tissue dry weight. Specific binding, thus measured, was 9.1 ± 1.5 (4) and 9.8 ± 1.5 (4) fmol per mg dry tissue [mean ± SEM (n)] in the lateral wall of the basal turn of the cochlea and in the ampulla of the semicircular canal, respectively.

These results demonstrate significant aldosterone binding and the presence of mineralocorticoid (Type I) receptor sites correlating with aldosterone-sensitive Na, K^{+}-ATPase activity and suggest that these inner ear tissues are a target site of mineralocorticoid action.

441.1

MAGNITUDE MEASUREMENT OF HINDLIMB WITHDRAWALS TO GRADED NOXIOUS HEAT IN CONSCIOUS RATS. R.L. Kitchell, D. Ansley* and E. Carstens. Depts. of Animal Physiology and Veterinary Anatomy, Univ. of California, Davis, CA 95616.

Most animal pain models measure the latency (ie., threshold) of nocifensive responses. However, measurement of response magnitude would be desirable in showing psychophysical stimulus-response relationships throughout the noxious range. We therefore measured the magnitude of the conscious rat's hindlimb flexion withdrawal reflex.

Sprague-Dawley rats were habituated to a restrainer through which the left hindlimb protruded. The ventral hindpaw was taped against a Peltier thermode. Hindlimb flexor EMGs during attempted withdrawals elicited by graded noxious heat pulses (40-52°C, 5 s) were monitored via teflon-coated microwires in biceps femoris. Responses were quantified (area beneath integrated EMG for 7 s after heat onset) and normalized to % maximum. Humans tolerated all stimuli and rats showed no signs of distress.

Integrated EMGs increased in a graded fashion from 42-52 °C (N=12); no rats withdrew at 40°. The slope of the stimulus-response function was reduced, with no threshold change, 20-40 min after systemic administration of morphine (3.5 mg/kg i.p.) in a naloxone-reversible manner.

This relatively simple method measures reflex magnitude from threshold to tolerance levels of noxious heat, is sensitive to the opiate analgesic morphine, and might therefore serve as a useful new quantitative pain model.

441.2

QUANTIFICATION OF THE RAT TAIL-FLICK REFLEX (TFR). E. Carstens and C.G. Wilson*. Dept. of Animal Physiology, Univ. of California, Davis, CA 95616.

The TFR is a widely used pain test measuring the latency for a rat's tail to be flicked away from an unregulated noxious heat source. However, it is unknown if TFR magnitude increases in a graded or ballistic way with stimulus intensity, clouding the interpretation of all-or-none increases (to cutoff) in TFR latency (threshold?) often seen following analgesics. We therefore developed a method to measure TFR force in conscious rats.

Radially arranged transducers measured the force of horizontal, dorsal and rostrally directed components of TFRs elicited by feedback-controlled noxious radiant heat pulses (40-58°C, 5 s) delivered unilaterally to the tail. Areas beneath force traces were integrated to calculate TFR force vectors. Stimuli evoked no signs of distress.

The rostral force components of TFRs were much larger than horizontal/dorsal components. Most rats showed a preferred horizontal direction of TFRs (left or right in approximately equal numbers) regardless of the side of tail stimulation. TFR force vectors increased linearly from 40-48°C and then levelled off (N=10). Responses to 44°C stimuli decreased over repeated trials (2 min interval) and recovered following a 15 min break. Responses to repeated 50°C stimuli did not decrement.

Thus, the TFR is graded over a narrow range of noxious heat intensities and may habituate at low temperatures.

441.3

ULTRASTRUCTURAL AND NEUROPHYSIOLOGICAL ANALYSIS OF THE INTERNAL ARCHITECTURE OF INTACT HUMAN NERVES **R.G. Hallin,* T.Carlstedt, R. Ekedahl* and Y.-X. Yu,* Dept Clin Neurophysiol, Huddinge Univ Hospital, 141 86 Huddinge, Sweden.**

Single units within the entire nerve fibre spectrum can be studied in man. Furthermore, thin concentric needle electrodes are useful as a tool for integrative analysis of both functional and structural aspects of human peripheral nerves.

In this study, we used concentric needle electrodes (O.D. 200-250 μm, inner core diameter 10-70 μm) for percutaneous median nerve exploration. The firing characteristics of A and C fibres and their relative localization with respect to each other were studied in adjacent recording sites in the nerve. Electrodes with thicker cores were used to screen intraneural fascicular organization. Individual cutaneous fascicles destined to the hand were mutually organized in a somatotopic manner at both wrist and elbow level. Electrodes with a thin core were used to study the detailed intrafascicular fibre organization. Many observations suggested the presence of an orderly organization also within the individual fascicle, which extended to even the single unit level.

The traditional view that the fibres are spread out in disarray proximally in limb nerves was not substantiated by these studies. Instead we feel tempted to suggest that our data reflect the existence of a pervading somatotopic organization which starts in the periphery of the neuraxis and then extends to central levels of the nervous system. Some clinical implications of the obtained data will be discussed.

441.4

THE FAILURE OF CONDUCTION OF IMPULSES IN LONG RANGE AFFERENTS RUNNING IN RAT SPINAL CORD. PD Wall* and SB McMahon. Dept Anatomy, University College London, UK and Dept Physiology, St Thomas' Hospital Medical School, London, UK.

When myelinated sensory afferents enter the spinal cord, they form a T branch running rostrally and caudally. The rostral branch may run as far as the dorsal column nuclei. However, the caudal branch may also run for many segments and extend with dorsal horn terminals far beyond the region in which such afferents have been shown to produce postsynaptic effects. 50% of lower thoracic afferents extend 3 segments caudally and 5% extend 8 segments (20mm) caudally (PD Wall & P Shortland (1991) Phil Trans Roy Soc, *in press*). For 70 myelinated fibres, we have tested the possibility that these long range caudal axons do not normally conduct orthodromic impulses by measuring their partial refractory period either following local microelectrode stimulation in the dorsal columns or following the injection of an orthodromic impulse from the dorsal root. This measure showed that orthodromic impulses may fail to penetrate the caudal branch at distant caudal sites in all fibres tested. In contrast, the rostral branch always appeared to conduct orthodromic impulses. Furthermore, this apparent orthodromic blockade is relieved 2-10 days after the neighbouring dorsal roots have been sectioned.

ACTIVITY OF NEURONS IN THE ROSTROVENTRAL MEDULLA WHICH RESPOND TO NOXIOUS HEAT ARE CORRELATED TO CHANGES IN ARTERIAL BLOOD PRESSURE. C.L. Thurston & A. Randich, Dept. of Psychology, Univ of Alabama at Birmingham, Birmingham, AL 35294

Extracellular recordings were made of neurons in the rostroventral medulla (RVM) in methohexital-anesthetized rats. The neurons were classified as ON, OFF, or NEUTRAL cells depending on their response to noxious heat applied to the tail. ON cells were excited just prior to the tail flick (TF) and OFF cells were inhibited just prior to the TF. Both ON and OFF cells showed spontaneous fluctuations in activity that were correlated with fluctuations in arterial blood pressure (ABP). When ON cells are active and OFF cells are inactive, ABP is lower than when OFF cells are active and ON cells are inactive. Further, changes in neuronal activity precede changes in ABP. In addition, electrical stimulation of the cervical vagus produces a depressor response at intensities which increase ON cell activity and decrease OFF cell activity. These data suggest that ON and OFF cells in the RVM are important in autonomic regulation.

COACTIVATION OF THE NUCLEUS RAPHE MAGNUS (NRM) BY LATERAL HYPOTHALAMUS (LH) AND THE PERIAQUEDUCTAL GRAY (PAG). M.M. Behbehani, M. Jiang* and S.D. Chandler. Depts. of Physiology and Biophysics and Anesthesia. U. of Cincinnati. Cincinnati, OH 45267-0576.

There is evidence that NRM receives input from both the LH and PAG. However, it has not been established whether a given cell in NRM responds to stimulation of both sites. We tested this possibility by extracellular and intracellular recording from NRM neurons and measurement of their response to electrical stimulation of LH and PAG. In addition, we examined the role of neurotensin (NT) in coactivation of NRM. Extracellular recording was made from 100 NRM neurons of adult male rats; in 10 cells intracellular recordings were made. Cells were identified according to their response to peripheral stimulation. Stimulation of both sites excited 15 cells and inhibited 23 cells; 29 cells responded in opposite direction to LH/PAG stimulation. The excitatory response to PAG and LH had an onset latency of 12.45±4.4 and 14.9±9.8 and duration of 22.6±15.5 and 33.9±31.5 respectively. The inhibitory response had an onset latency of 14.75±8.34 and 11.14±10.12 and duration of 91.5±31.6 and 62±29.54 respectively. In 2 cells recorded intracellularly, IPSPs produced by stimulation of LH had a larger magnitude and duration than IPSPs produced by stimulation of PAG. In 56 cells the effect of NT on NRM was tested, 31 cells were excited, 14 were inhibited and 11 were unresponsive to NT. Comparison of the response of NRM cells to LH, PAG and NT showed no significant interaction. It is concluded that 1) a significant number of NRM neurons are coactivated by PAG and LH, 2) the inhibitory response is more dominant and 3) NT is unlikely to be the mediator of the coactivation response.

NOCICEPTIVE RESPONSES OF RACCOON THALAMIC NEURONS. B. H. Pubols, D. A. Simone, N. A. Bernau, and M. E. Hanson. Good Samaritan Hospital & Med. Ctr., Portland, OR 97209.

Raccoon thalamic neurons with receptive fields (RFs) totally (N = 10) or partially (N = 10) on glabrous skin of the forepaw were examined for their responsiveness to noxious mechanical and thermal stimuli. Recording loci were in the core of the ventrobasal complex (VB; N = 8), the ventral periphery of VB (N = 4), or the medial division of the posterior nuclear group (POm; N = 8).

Eleven VB neurons were classed as multireceptive (MR) and one as nociceptive specific (NS); five POm neurons were classed as MR and three as NS. All MR neurons had larger high threshold RFs than low threshold RFs, and this difference was greater for POm neurons than for VB neurons. 85% of the total were rapidly adapting and 15% slowly adapting.

For 16 out of 19 neurons tested, the thermal threshold was greater than 53°C. Thermal thresholds were between 51°C and 53°C in three MR units. Sensitization following a mild burn (53°C for 30-90 sec) to the RF, persisting for up to one hour, occurred in four of eight units tested.

These data indicate that raccoon thalamic cells responsive to nociceptive input are not segregated within VB, but are located throughout this nucleus as well as in POm. Many of these cells may become sensitized following an injury, and thus contribute to hyperalgesia. [Support: NS-19486, USPHS.]

SOMATOSENSORY EVOKED MAGNETIC FIELDS STUDIED WITH A 19-CHANNEL FIRST-ORDER GRADIOMETER SYSTEM.

I. M. Tarkka, R. Laudahn* and B. Bromm*. Institute of Physiology, University Hospital Eppendorf, D-2000 Hamburg 20, F.R.G.

Novel 19-channel MEG equipment was used to record somatosensory evoked fields (SEF) in normal subjects. The channels were arranged in a hexagonal configuration with the distance between nearest neighbors being 2.5 cm. The SQUIDs were connected to axial first-order gradiometers with 2.0 cm diameter and 5.0 cm baseline. All channels were placed in parallel. The exact relationship between the subject's head and the recording sensors was monitored using three 3-D coils placed on the scalp (international 10-20 locations Fz, Cz and Pz). The coils served as a defined magnetic source giving the coordinates of each coil relative to the gradiometers. Somatosensory stimuli were electrical pulses of 0.2 ms duration given to the right median nerve at wrist. The stimulus intensity was adjusted above the individual motor threshold. 100 sweeps were averaged and a recording window of 250 ms was used. The bandpass was 0.5 - 250 Hz. The following components were identified: M20, M35, M80, M110 and M140. Phase reversal was observed for M20, M35, M80 and M110 components within one recording location posterior to C3. Addional locations were recorded for finding the maxima of the fields of interest. The current dipole estimations confirmed multiple generators in the somatosensory cortex. The estimated dipoles were superimposed on individual MR images of the subjects.

THREE DIMENSIONAL ANALYSIS OF CENTRAL TERMINATIONS OF TRIGEMINAL PRIMARY AFFERENTS IN CATS. K.Otani*, H.Ikeda*, O.Takahashi and T.Shimosato*, Dept.Oral and Max-Fac. Surg. II, Hiroshima Univ. Sch.of Dent., Hiroshima,Japan.

We have previously reported morphological feature of trigeminal primary afferent fibers which showed electrophysiological fast adapting (FA) and slowly adapting (SA) type of afferents. In the present paper, we would like to submit more detailed quantitative analysis of them with special reference to morphological features of FA and SA types of primary afferents. Under sodium pentobarbital anesthesia, trigeminal primary afferent fibers of FA and SA type were characterized electrophysiologically and they were stained with horseradish peroxidase (HRP) with intracellular technique. The terminal and en passant boutons of them were observed under a microscope, and then analysed three-dimensionally using computer. The densities of boutons in each trigeminal subnucleus were calculated by defining a volume of terminal arbor. The density of FA-type boutons showed no significant difference between that in the trigeminal principal nucleus (Vp) and that in the oral subnucleus of the spinal trigeminal nucleus (Vo). On the other hand, the density of SA type boutons in Vp were higher than that in Vo. These results suggested that FA- and SA-type primary afferents had characteristic features in terms of the density of boutons.

COMPUTER SIMULATIONS OF THALAMOCORTICAL RESPONSE TRANSFORMATIONS IN THE WHISKER/BARREL SYSTEM.

H.T.Kyriazi and D.J.Simons. Dept. of Physiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

A model of a somatosensory cortical neuronal network (Neurosci.Abstr.15:313,1989) has been tested for its ability to simulate barrel neurons' responses to different whisker stimuli. The model incorporates known anatomical and physiological features of a barrel in cortical layer IV and is activated by actual pre-recorded spike trains from thalamic barreloid neurons. Initially, responses of spiny and smooth neurons to deflection of the principal whisker (PW) alone were studied. Model parameters were adjusted to produce accurately the reductions, relative to thalamic input, in the sizes of spiny cell ON and OFF responses and the increases in these responses for smooth cells. Subsequently, the same model parameters correctly produced the disproportionately smaller ON responses evoked in spiny cells by adjacent whisker stimuli. Also in both cell types, movements of adjacent whiskers generated post-excitatory inhibition and realistic response suppression to subsequent deflections of the PW. Finally, when the duration of the PW alone stimulus was increased, the simulated OFF response increased appropriately. Thus, circuitry within a barrel is sufficient to produce significant changes in spatial and temporal characteristics of the thalamic input signal. Supported by NS19950 and the Pittsburgh Supercomputing Center.

SELECTIVE POST-DISCRIMINATION SIGNALS IN THE MOTOR AND PREMOTOR CORTICES. V. B. Mountcastle, P.P. Atluri, & M.A. Steinmetz, Bard Labs Dept Neurosci. Johns Hopkins Un Sch of Med,Baltimore, MD 21205

Earlier studies were made of cortical neural activity in waking M.mulatta discriminating between the frequencies of mechanical sinusoids delivered to the glabrous skin of one hand. They projected the other to one of two targets to indicate whether the comparison stimulus of a pair was higher/lower in frequency than that of the base stimulus; e.g., 30 vs 32 Hz. Such stimuli evoke periodic activity in postcentral neurons (areas 3b and 1) related to Meissner afferents innervating the hand. The harmonics of respon se trains reflect precisely stimulus frequencies; the neural discriminandum is the difference in the cycle lengths in the neural periodicities; it is a sequential order code.

Identical experiments have now been made in the motor and premotor cortical areas of the hemisphere opposite the projecting arm (5 hemispheres, 1191 neurons). A selective signal of the correct discrimination occurs during one or the other sets of comparison stimuli, often beginning about 200 msec after onset of the comparison stimuli and frequent ly continuing into the reaction time. The discharge is aperiodic. No similar responses were observed when simi lar stimuli were delivered to the hand of an alert but idling monkey. We interpret this to be a post-discrimination signal projected trans-callosally from the contralateral sensory hemisphere to the motor & premotor areas.

A COMPETITIVE DISTRIBUTION THEORY OF NEOCORTICAL DYNAMICS *J.Reggia, C.D'Autrechy*, G.Sutton*, & M.Weinrich**. Neurology & Comp.Sci. Depts., Univ. of Maryland, Baltimore MD 21201.

Peristimulus inhibition in sensory pathways is generally attributed to lateral inhibitory connections. While this is convincing in prethalamic pathways, the situation is less clear in the thalamus and neocortex. Thalamocortical circuitry is incompletely defined at present, and in some cases there is an apparent mismatch between observed inhibitory effects and intracortical inhibitory synaptic connections. This paper puts forth the hypothesis that a different mechanism, competitive distribution of activation, underlies some inhibitory effects observed in neocortex. Analysis of a mathematical model based on this hypothesis predicts that peristimulus inhibitory effects generally attributed to lateral inhibitory connections can alternatively be explained by competitive distribution of activation in the absence of such inhibitory connections. Computer simulations verify these predictions by demonstrating Mexican Hat patterns of lateral interactions, transformation of diffuse activity patterns into tightly focused "islands" of activity, and edge enhancement. Analysis and simulations also show that the amount of inhibition can be adjusted by varying the intensity of the underlying competitive process. The concept of competitive distribution of activation provides an important alternative perspective for interpreting neocortical and thalamocortical circuitry and can serve as a guide for further morphological and physiological studies. For example, it provides an explanation for the existance of cortex-to-thalamus connections, and predicts that analogous circuitry must exist in neocortex.

442.1

MOTION OF CERVICAL VERTEBRAE DURING DIFFERENT HEAD MOVEMENT TASKS IN HUMAN. D.H. Wang, W. Graf, C. de Waele, P.P. Vidal and B. Jaenisch. The Rockefeller University, N.Y., NY 10021; Lab. Physiologie Neurosensorielle, CNRS, 75270 Paris, France; Schildautal-Klinik, 3370 Seesen/Harz, FRG.

Our previous cineradiographic studies on human head movements in the sagittal plane indicated that head rotation results from simultaneous individual translations (slidings) of all cervical vertebrae. The present study investigated the distribution of vertebral motion at different cervical levels during different head movement tasks. Subjects were asked to perform swinging and nodding movements of the head in the sagittal plane. The orientation angle of the head and the translation angle of each cervical vertebra were measured from fluoroscopy images. During swinging movements, translational movements of the cervical vertebrae were uniformly distributed along all segments. Thus, a global center of head rotation could be calculated around C6. During the nodding task, however, the upper segments participated to a larger extent. In this case, the global center of head rotation could be approximated around C3. Furthermore, significant degrees of pure rotation at the upper joints (C0 to C1, and C1 to C2) contributed to head rotation when the head reached extreme flexion and extension. This result suggests that the biomechanical constraints within the cervical spine (i.e. passive or effected by intervertebral muscles) may be the main factor for different kinematics of the two types of head movements studied. (Supported by NIH grant EY-04613)

442.2

FORCE CONTROL IN PRECISION GRIP: EXISTENCE OF SYNERGIES ?
M.A. Maier*, M.-C. Hepp-Reymond and M. Meyer* Univ. of Zurich, Brain Research Institute, CH-8029 Zurich, and Dept. Neurology, CH-8091 Zurich

Isometric force generation in the precision grip requires the delicate interaction of many muscles in timing and activation levels. We have quantitatively examined the participation of each muscle in force control and the putative existence of muscular synergies.

Subjects produced force between index finger and thumb with visual feedback in a ramp-and-hold paradigm with 3 consecutive force steps up to 3.0 N. Full-wave rectified and averaged EMGs of 15 muscles were used for computing correlations between muscle activity and force, as well as correlations and cross-correlations (CC) between the activity of muscles recorded simultaneously. The results are, that the majority of the thumb and index finger muscles increased their activity monotonically as a function of force, though with considerable scatter. For some muscles, such as AdP and 1DI, an organized, non-random scatter and high correlations were found, suggesting a role as prime force generators. Correlations between the activity of two muscles showed muscular coupling in 50% of the pairs tested with some variability. Most prominent was coactivation (80%), and trade-off was rare (12%). Synergies between muscles of a single finger were almost twice as common as those between a thumb-and-index finger muscle pair. Temporal coactivation within muscle pairs was present in 20% of the cases, which all had clear CC peaks deviating no more than 8 ms from zero.

These data provide evidence, first for flexible muscle synergies that are not necessarily linked by biomechanical constraints, such as between flexor and extensor or between index and thumb muscles, and second for close synchronicity of a few muscle pairs, which in the majority are innervated by the same peripheral nerve.

442.3

SENSORY TRIGGERING OF A SEQUENCE OF POSTURAL RESPONSES
P.J. Cordo, Cent. Medico Riabil., Veruno,; Univ. Studi, Milano

Sudden destabilization of the body center of gravity with respect to the feet is known to trigger short latency postural responses in humans. In the present study, we show that this short latency response is only the first of a sequence of responses and that the sensory information used by the nervous system to trigger each response in the sequence is different.

Seven normal humans stood on a posture platform and were translated forward or backward from 3 initial postures, leaning forward or backward, or standing erect, to enhance or reduce the destabilizing effect of the platform movement. Subjects were instructed to take a step only if absolutely necessary.

When subjects reduced the effect of platform movement, they produced the well-known response in which the stretched ankle and knee muscles returned the center of gravity back over the feet ("torquing"). When subjects stood erect, they first produced the torquing response and then rose up on the heels or toes to shift the fulcrum point ("rising"). When subjects enhanced the effect of platform movement, they followed the first 2 responses with a step ("stepping").

The first 2 responses are most likely triggered by somatosensory input--for the torquing response, probably nonspecifically related to the movement, and for the rising response, specifically related to the change in ankle angle. The stepping response is related to the velocity of the center of gravity, and is more likely triggered by visual or vestibular input.

442.4

CHANGES IN TORQUE/EFFORT RATIO REVEAL CHANGES IN INVOLUNTARY MOTOR FUNCTION. P.R. Burgess and T.A. Cooper*, Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, UT 84108.

Standing subjects generated isometric tension by pulling upward on a bucket handle attached to one end of a cable with the elbow joint at 90° and the forearm horizontal and supinated. Other joints were braced to insure that the elbow flexors were the prime movers for the task. The moment arm of the isometric load was changed by anchoring the other end of the cable at different points so that the angle (θ) between the cable and the forearm varied between 90° and 150°. The subjects made the same effort at each anchor point in a given trial; low, medium and high efforts were made in different trials. The torque/effort ratio for the elbow flexors [torque = cable tension (sin θ)] was found to vary in a characteristic fashion, first increasing as the angle increased and then falling below the 90° value between 138° and 145°. Increases in torque/effort ratio were more pronounced when the effort was high and presumably reflect involuntary motor behavior designed to enhance cable tension until θ is sufficiently large (>140°) that the line of action is toward the body.

442.5

DIRECTIONAL INFORMATION DURING SLOW GOAL-DIRECTED ARM MOVEMENTS. J.B. de Graaf*(1), J.J. Denier van der Gon*(2), A.C. Sittig*(1) (SPON: European Neuroscience Association) (1) Product ergonomics, Delft University of Technology, Jaffalaan 9, NL-2628 BX Delft, The Netherlands, (2) Medical and Physiological Physics, University of Utrecht, Princetonplein 5, NL-3584 CC Utrecht, The Netherlands.

Recently we have shown that when subjects are asked to make slow arm movements to visual targets they start the movements to most targets in a direction that deviates consistently from the direction of the straight line between initial position and target position(de Graaf et al. 1991 Exp Brain Res 84: 434-438). To explore this phenomenon we did the following experiment with two congenitally blind subjects and two sighted blindfolded subjects. The subjects were seated at a table. They were asked to make slow arm movements to proprioceptive targets (the index-finger of the other hand) at a distance of 30 cm. We analysed the initial movement direction as well as the curvature of the movement trajectories. The results show that 1. the sighted subjects as well as the blind subjects started their movements to most targets in directions comparable to the directions we found in earlier experiments, and 2. the blind and sighted subjects showed more or less the same curvature in their movement trajectories. These results suggest that the movement trajectories we found in our earlier experiments do not originate from visual experience of the sighted subjects.

442.6

SENSITIVITY OF THE MANDIBULAR STRETCH REFLEX DURING CYCLIC JAW MOVEMENTS IN MAN.
A. van der Bilt*, F.A.M. Ottenhoff*, H.W. van der Glas and F. Bosman, Dept. of Oral Pathophysiology, University of Utrecht, Padualaan 14, 3584 CH, Utrecht, The Netherlands.

The reflex sensitivity was determined during various phases of rhythmic mandibular open-close movements. Subjects made such movements at their natural chewing rate controlled by a metronome. An external force, supplied by a solenoid in a magnetic field, acted on the mandible in a downward direction during the closing phase, simulating food resistance like in chewing. In addition to this force a downward directed force-pulse (10 ms; 5 N) was randomly given at various phases of the open-close cycle. The jaw movement and force as well as the activity of masseter, temporal and digastric muscles were recorded. Only weak or no reflexes were observed during the opening phase. A mono-synaptic reflex was observed in the elevator muscles if the force-pulse was given during the closing phase of the chewing cycle. The ratio of the reflex activity and the background muscle activity was largest at the beginning of the closing phase. It may be concluded that the fusi-motor system plays an important role in controlling muscle activity at the first engagement of the food between the teeth and that it is also involved in further load compensation during the closing phase.

442.7

SOLEUS H REFLEXES ARE INHIBITED DURING PEDALLING, BUT THIS IS NOT DEPENDENT ON SPEED OF MOVEMENT. J.D.Brooke, P.J.Whelan*, D.F.Collins and W.E. McIlroy, Lab. of Neurophysiol. School of Human Biology, University of Guelph, Canada, N1G 2W1.

Magnitudes of H reflexes are depressed during walking and running, compared to controls at a similar stimulation intensity and contraction level in the target muscle. We asked (a) is there such depression during pedalling and (b) if so, is the depression dependent on movement velocity? Specifically, as movement velocity increases from zero (sitting or standing), is the depression partly associated with the potential for the reflex latency to cause excitation out of phase in the cycle? For a range of pedal rates, the bursts of EMG in soleus and tibialis anterior did not systematically change their phase positions. During pedalling at 60 rpm, soleus H reflexes were significantly depressed when soleus activity was low [mean (n = 4) 0.09 mV, versus sitting mean 3.44 mV]. However, when the pedal rate was lowered to 30 rpm (perceived as very slow for rhythmic leg movement), reflexes were not significantly different from those evoked at 70 rpm. We conclude that soleus H reflexes are inhibited during pedalling compared to sitting, and that the inhibition is not due to the leg velocity being too high. Supported by NSERC (Canada) Grant #A0025.

BIPEDAL AND UNIPEDAL CYCLING BOTH DEPRESS H REFLEXES, COMPARED TO SITTING. D.F.Collins, J.D.Brooke, W.E.McIlroy, and P.J.Whelan* Lab. of Neurophysiol., School of Human Biology, University of Guelph, Ontario, Canada, N1G 2W1.

H reflex magnitude in the human soleus muscle is depressed during pedalling, compared to control reflexes when sitting (Brooke et al. Neurosci. Abs. 1991). We currently investigated whether this inhibition is dependent on the bipedality of the rhythmic task. H reflexes were recorded at four phases of the pedal cycle (90°, 180°, 270°, 360°) from five subjects while sitting, pedalling with both legs and pedalling with one leg. Soleus contraction magnitude and ankle angle were matched between conditions. Across all subjects, during one-legged pedalling reflex magnitude was significantly depressed ($p<0.05$) in the active leg at 180° and 270° compared to the stationary leg (to 21.9% and 8.8% of stationary, respectively) and compared to sitting (to 13.1% and 4.2% of sitting, respectively). Reflexes evoked in the single active leg were not significantly different from those when pedalling with both legs. Obviously, the observed reflex depression did not require bipedality. However, reflexes in the stationary leg were depressed when the contralateral leg was active. Thus, there was some bilateral interaction in reflex depression. Supported by NSERC (Canada) Grant #A0025.

CENTRAL MOTOR DRIVE AND ANKLE ROTATION DID NOT ACCOUNT FOR OBSERVED H REFLEX INHIBITION DURING PEDALLING. W.E.McIlroy, D.F.Collins, P.J.Whelan*, and J.D.Brooke. Human Biology, University of Guelph, Canada, N1G 2W1.

Human soleus H reflexes are depressed during walking, running and pedalling. What remains unclear are the sources of this inhibition. This study looked at two potential sources: 1) ankle rotation and 2) the central motor drive to move the limbs. These two factors were selected because in other paradigms they have been shown to strongly influence spinal reflex transmission, and they can be distinguished as peripheral and central influences, respectively.

Ankle Rotation: Subjects pedalled a cycle ergometer with and without a brace which prevented ankle rotation. H reflexes sampled in the recovery phase during pedalling with the brace were not significantly different from those during normal pedalling. (Mean H reflexes: Normal 5.3% SD 4.8, With brace 9.4% SD 6.0 - expressed as percent of control H reflexes). H reflexes from both pedalling trials were significantly lower than control H reflexes during sitting.

Central Drive: Subjects remained relaxed, seated on a tandem cycle ergometer, while the limbs were moved throughout the pedal cycle by a second cyclist. H reflexes sampled in the recovery of this passive movement were not different than those recorded during active pedalling. However they were both significantly lower than the control H reflexes (Mean H reflexes: Normal 6.9% SD 6.0, Passive 9.5% SD 11.0 - expressed as percent of control H reflexes).

The presence of substantial inhibition in the absence of that central motor drive may implicate peripheral inputs as an important source of inhibition. In spite of this we did not see a significant change in H reflex magnitude when ankle rotation was suppressed. It is possible that summed convergence from several peripheral sources is largely responsible for the inhibition of H reflexes during pedalling. (Supported by NSERC.)

SUPERPOSITION OF RHYTHMICAL AND DISCRETE MOVEMENT. A.G. Feldman, M.F. Levin and S.V. Adamovich*. Institute of Biomedical Engineering, University of Montreal, Rehabilitation Institute of Montreal, Canada H3S 2J4 and Institute of Information Transmission Problems, Moscow, USSR.

Control strategies underlying the simultaneous performance of rhythmical and discrete elbow movements were investigated. Two hypotheses regarding their combination were considered. Either movements are combined according to the principle of superposition (Feldman 1980) or they are integrated and therefore, interdependent. Subjects produced rhythmical flexion and extension movements about a target position which was shifted after a fixed period of time. After presentation of the second target, subjects made a fast movement to the new target while continuing the oscillation. EMG was recorded with surface electrodes from two elbow flexors and two elbow extensors. Position of the shoulder, elbow and wrist were recorded with light emitting diodes. Position and velocity traces were averaged to eliminate the rhythmical component of the movement and then compared to similar data from discrete movements to the same target positions. The results showed no difference in the discrete movement component produced in the two experimental conditions, a finding consistent with the hypothesis of superposition of control signals and movement patterns.

RECIPROCAL (R) AND COACTIVATION (C) COMMANDS FOR WRIST MOVEMENTS. M.F. Levin, A.G. Feldman, T.E. Milner and Y. Lamarre, Rehabilitation Institute of Montreal, Canada H3S 2J4; CRSN & Institute of Biomedical Engineering, University of Montreal, Canada. H3C 3J7

According to the equilibrium-point hypothesis, movements are produced by means of displacement of the invariant torque/angle characteristic (IC) of the joint and change in its slope. Displacement is produced via the central R command while the C command specifies the slope of the IC. These commands were investigated in single joint wrist movements by perturbation methods. Subjects made free flexion movements to a target at 30° or movements against randomly presented opposing or assisting loads. They were instructed not to correct the deflections arising in response to perturbations. Both peak velocity and EMG patterns were strongly affected by load conditions. Subjects undershot or overshot the target when flexion was perturbed by opposing or assisting loads respectively. However, after unloading (700 ms later), the target position was regained indicating that the IC was stable despite the perturbation. In two other experiments, subjects initially trained to reach the target with opposing or assisting loads, while the load was not presented in some trials. Depending on load conditions, the subject established different final IC positions. The slope of the IC was the same regardless of the magnitude of its shift. It is concluded that R and C commands can be specified independently. In addition, although kinematics and EMG are strongly dependent on peripheral conditions, the same does not appear to be so for basic central commands (R and C).

DETERMINANTS OF JAW MOVEMENT IN MASTICATION AND SPEECH. D.J. Ostry, A.G. Feldman, J.R. Flanagan, & K.G. Munhall. McGill University, Montreal, Canada, Institute of Biomedical Engineering, University of Montreal, Montreal, Canada, Queen's University, Kingston, Canada.

We report recent X-ray microbeam studies on human jaw movement kinematics in mastication and speech. Empirical findings are compared to simulations of jaw movement based on the equilibrium point hypothesis (λ model). In speech trials, subjects produced consonant-vowel-consonant sequences at either normal or loud speech volumes. In the mastication trials, subects chewed unilaterally on rubber tubing which varied in diameter and compliance. During mastication, we recorded the compression of the bolus. This was transformed into estimates of bite force using separately obtained functions relating applied force to tubing compression. Our previous work showed that jaw rotation and translation in speech can be separately controlled. For example, when rotation was plotted against translation, straight line paths were observed whose slopes depended on the consonant composition of the utterance. The present study extends this work by showing that rotation and translation are separately controlled in chewing. A version of the λ model for jaw motion which incorporates multiple jaw muscles, accounts well for the empirical bite-force pattern in mastication and for the kinematics of mastication and speech. The model permits separate central commands to be defined for jaw rotation, jaw translation and co-activation of muscles without motion. Superposition of commands can predict observed combinations of jaw rotation, translation and bite force.

OPTIMAL STIMULATION OF PARASAGITTAL MOTOR CORTEX USING THE MAGNETIC COIL. Joan B. Cracco*, Nasser F. Hassan*, Roger Q. Cracco, Paul J. Maccabee, Mahendra Somasundaram* and Vahe E. Amassian. SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203

We investigated the most effective method of exciting parasagittal motor cortex with a magnetic coil (MC) in 4 subjects. A round (9.4 cm diameter) MC which delivered an essentially monophasic pulse (1st phase 3X larger than 2nd) was moved over right parasagittal cortex from various directions; CMAPs were recorded from contralateral left leg and foot muscles. The threshold was determined before and after the direction of current in the MC was reversed by a switch.

The threshold for left foot and leg responses was always lowest when the MC approached parasagittal cortex from the front and the current was counter-clockwise in direction in the MC, i.e. the induced current flowed clockwise in the cerebral cortex from right to left parasagittal cortex and then from left to right more anteriorly. Therefore, this location, orientation and current direction are optimal for excitation of projection neurons in right parasagittal cortex.

Defining the optimal position and orientation of the MC in exciting parasagittal motor cortex is of particular importance in the study of patients with spinal cord disease and in intraoperative monitoring.

RAPID REVERSIBLE REORGANIZATION IN MAPS OF OUTPUTS OF HUMAN MOTOR CORTEX FOLLOWING TRANSIENT RESTRICTIVE DEAFFERENTATION . L. G. Cohen, J. Brasil-Neto*, A. Pascual-Leone, R.T. Wall*, F.K Jabir* and M. Hallett. Human Cortical Physiology Unit, Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892.

To evaluate timing of reorganization of motor outputs in human motor cortex, we studied motor evoked potentials (MEP) to transcranial magnetic stimulation (TCMS) in two normal volunteers immediately before, during and after unilateral anesthetic block of the distal arm below a pressure cuff inflated at the elbow. Anesthetic block was maintained for 70 and 45 minutes in the two cases. Electromyographic recordings were made from muscles immediately proximal (biceps, deltoid) and distal (abductor pollicis brevis) to the pressure cuff and, in one subject, contralateral muscles. With anesthesia, the MEP in abductor pollicis brevis became gradually smaller and eventually disappeared. Over the same time course the MEP became progressively larger in biceps ($p<0.0001$), but was unaffected in deltoid. In the subject studied, MEP amplitudes from muscles contralateral to the deafferented limb were unchanged. Reversal of the changes were observed within minutes of discontinuation of anesthesia. The rapid time course in reorganization of human motor outputs, by which a certain region of motor cortex can reversibly influence a new set of muscles, is compatible with unmasking of preexistent connections, perhaps due to disinhibition mechanisms.

THE ROLE OF THE SUPPLEMENTARY MOTOR AREA IN THE CONTROL OF SELF-PACED LIMB MOVEMENTS: A PET STUDY.

T.A. Zeffiro, C. Kertzman, C. Pelizzari and M. Hallett Medical Neurology Branch, 10-5N226, National Institutes of Health, Bethesda, MD, 20892.

In order to examine the hypothesis that different cortical motor areas are involved in the generation of either self-paced or externally-triggered limb movements, we used H_2O^{15} positron emission tomography to record regional cerebral blood flow (rCBF) in 10 subjects who performed unilateral finger flexion tasks while fixating a visual target. We studied three different tasks. In the self-paced (SP) condition, the subjects moved a joystick handle by finger flexion once every 2-3 seconds. Each movement caused the fixation target to briefly flash. In the visually-triggered (VT) condition, subjects were instructed to move in response to the target flash. In the control condition the target was flashed at the same rate; the subjects were instructed to maintain fixation but not respond. Movement onset times were recorded in the SP condition and then used to pace the subsequent two conditions. Difference images representing net rCBF changes were obtained by task pair subtraction. Response localization was determined by 3D registration of each subject's blood flow and MRI. A repeated measures ANOVA model was used for statistical analysis of rCBF changes.

We found equal rCBF increases in the SP and VT tasks in the precentral and lateral superior frontal gyri ($p<0.01$). Responses were more strongly lateralized in the precentral gyrus. In contrast, the contralateral medial superior frontal gyrus (corresponding to the supplementary motor area) was preferentially activated during the SP movements ($p<0.01$). These results provide further evidence for regional cortical specialization for control of kinematically similar limb movements that differ markedly in their behavioral context.

443.4

PRIMATE FRONTAL CORTEX: VISUOSPATIAL VS. VISUOMOTOR ACTIVITY S.P. Wise and G. di Pellegrino. Laboratory of Neurophysiology, NIMH, Poolesville, MD 20837

We examined neuronal activity in the premotor (PM) and prefrontal (PF) cortex while a rhesus monkey performed a visuomotor, spatial matching task. The monkey fixated and held a manipulandum beneath a central light emitting diode (LED), which had 8 LEDs arranged in a circle around it. On each trial, after 1 of the 8 LEDs illuminated for 0.5 s (the prime stimulus, PS), 0 to 4 of the other LEDs illuminated sequentially for 0.1 s at delays of 0.55 or 0.75 s each. At the end of this delay period, the PS illuminated again for 0.1 s whereupon the monkey had to execute a forelimb movement within 650 ms (and could break fixation). There were 2 response conditions: the monkey moved the manipulandum (1) to a predetermined target regardless of PS location (the *incompatible* condition) or (2) to the PS location (the *compatible* condition).

Because the visuospatial stimuli were physically and retinotopically identical in the two conditions, and because the monkey had to attend to (or remember) the PS location identically, the behavioral design allowed us to test the hypothesis that task-related activity simply reflects a sensory response. The alternative is that the motor instructional significance of the stimuli affects the cell activity. Second, because in the *incompatible* condition a single motor response followed a variety of visuospatial cues, we could examine whether the activity reflects simply motor aspects of the animal's behavior. The alternative is that some aspect of the visuospatial cue affects cell activity. Our results from 94 PM cells show that for many cells both hypotheses can be rejected. Accordingly, PM activity, regardless of any temporal correlation with either the sensory signals or the onset of movement, reflects integrative aspects of the visuomotor reaching behavior, i.e., aspects of behavior that cannot be simply characterized as either sensory or motor in nature. A sample of 55 PF cells suggests a higher proportion of cells there simply reflect the sensory, possibly visuospatial, aspects of the stimuli.

SPECIFIC EFFECT OF MOTOR LEARNING ON SET-RELATED CELLS OF THE PREMOTOR CORTEX IN PRIMATE. L. Germain, Y. Lamarre, M.T. Parent, Centre de recherche en sciences neurologiques. Université de Montréal, Québec, Canada H3C 3J7.

In order to assess the effect of learning on set-related cells in the precentral cortex and cerebellar nuclei we trained one primate to perform elbow flexion (F) or extension (X) according to a two choice instructed delay paradigm. During training (A) the presentation of the auditory instruction (400 Hz tone for X or 1000 Hz tone for F) was not randomized and the performance was at chance level (50%). After training (B) the presentation of the auditory instruction was randomized and the performance was (95%). Each trial started with a 500 msec control period followed by a 400 msec auditory instruction then by a randomized immobile waiting period of 500 to 1500 msec terminated by a small kinesthesic go-signal. A total of 386 movement - related cells were recorded and 267 set-related cells were found in this sample. A specific and significant increase of the proportion of set-related cells was observed in the premotor cortex from A) 22/45 (49%) to B) 65/68 (95%) ($\chi^2 = 33.5$, $p < 0.005$) furthermore the proportion of directional set-related cells increased in this area from A) 11/22 (50%) to B) 54/65 (83%) ($\chi^2 = 9.4$, $p < 0.005$). The mean coefficient of directionality (t value between F and X) of set-related cells increased specifically and significantly from A) 3.7 ± 1 to B) 7.6 ± 4 ($t = 3.19$, $n = 63$, $p < 0.005$) in the premotor cortex. The proportion of cells with auditory responses increased from A) 1/45 (0.02%) to B) 15/68 (22%) in the premotor cortex.and also from A) 7/30 (23%) to B) 13/30 (43%) in the dentate nucleus. These data suggest a predominant effect of learning an arbitrary association between an auditory instruction and the direction of an intended movement on set-related cells in the premotor cortex. INTRINSIC CONNECTIONS OF CAT MOTOR CORTEX: AXONAL PROJECTIONS OF SUPERFICIAL PYRAMIDS A. Keller and H. Asanuma. The Rockefeller University, New York, NY 10021

The functional organization of layer II-III pyramidal neurons in area 4γ of cat motor cortex were examined after intracellular injections of biocytin. All of the cells examined produced long-term potentiation (LTP) in response to tetanic stimulation of the somatosensory cortex. Their primary axon, originating from the soma or a basal dendrite, emitted intracortical axon collaterals before entering the subcortical white matter. The axon collaterals had both vertical and horizontal patterns of termination. Collateral branches formed a local terminal field in the immediate vicinity of their parent somata and dendrites. In addition, most neurons had axon collateral branches that projected horizontally for long distances. These long range, horizontal branches projected to and terminated within the same layer their parent soma was located, and ranged in length from 1 to 4 mm. Relatively shorter horizontal branches were emitted from the primary axon in deep layer V and in layer VI. Within the superficial layers, the long collaterals typically formed clusters of terminal fields, having a diameter in the order of 1 mm. The spatial arrangements of these intracortical connections indicate that these neurons are involved in 'clustered' networks of excitatory connections within the motor cortex. Specifically, these findings predict that the induction of LTP in neurons in the superficial layers of the motor cortex would affect the firing patterns of cells located in spatially segregated cortical columns. COULD THE CORPUS CALLOSUM PREVENT INTERHEMISPHERIC TRANSFER OF LEARNING TO ENABLE HEMISPHERIC SPECIALIZATION? INTERMANUAL TRANSFER OF SENSORY-MOTOR LEARNING IN NORMAL AND SPLIT-BRAIN RHESUS MONKEYS. B.Preilowski*, H.J.Engele*, M.Reger*, W.Pöll*, Weissenau-Field-Station, Tübingen University, Rasthalde 3, D-7980 Ravensburg, FRG.

In a series of experiments the development of distal and proximal sensory-motor skills and their intermanual transfer was studied in normal and callosotomized rhesus monkeys. When the monkeys had to learn to produce a specific force between the fingers of one hand, no transfer of learning to the opposite hand was observed in intact animals; in a comparable task involving force production by arm movements delayed transfer was observed. Delayed transfer was also found in a callosotomized animal postoperatively trained and tested for transfer in the finger force discrimination task. Furthermore, when animals were alternating between hands during training on the finger task, performance with both hands tended to become equalized after callosotomy.

The results, so far, suggest that the corpus callosum has variable functions in sensory-motor control. Among others, it may modulate bilateral sensory-motor processing taking place in both hemispheres, and, during prolonged unilateral training, it may inhibit interhemispheric transfer allowing for independent skill development and performance with either extremity. If confirmed, this would carry important implications for a possible theory of handedness and laterality as well as bilateral motor functions. (Supported by the German Research Foundation.)

EFFECTS OF MUSCIMOL INJECTION INTO THE DORSAL AND VENTRAL ASPECTS OF THE PREMOTOR CORTEX IN MONKEYS PERFORMING A CONDITIONAL MOTOR TASK. K. Kurata, D. S. Hoffman, and I. Kawamoto*. Department of Physiology, Tohoku University School of Medicine, Sendai, 980, Japan, and Research Service (151), VA Medical Center, Syracuse, NY 13210.

Muscimol (Sigma, 5μg/μl solution) was injected (1.0μl) into the dorsal and ventral aspects of the premotor cortex (PM) of two Japanese monkeys (*Macaca fuscata*), while they were performing a motor task that required wrist flexion or extension to a target. The correct movement was instructed by either: (1) conditional color cues (green or red LED) equidistant from the targets or (2) directional cues toward extension or flexion (right or left LED). When the green or right LED was illuminated, extension was to be done. When the red or left LED was illuminated, flexion was required. The movement was triggered by a visual stimulus either after a variable delay or simultaneously with the instruction stimulus. Before muscimol injection, single unit recordings were made to select injection sites (1) in the dorsal aspect of the PM (PMd) around the superior precentral sulcus where typical set-related activity was frequently recorded and (2) in the ventral aspect of the PM (PMv) immediately caudal to the genu of the arcuate sulcus where movement-related neurons were densely located. When muscimol was injected into the PMd, there was an increase in the number of direction errors primarily when the conditional cues were presented. The initiated movements were similar in amplitude and velocity to the preinjection behavior. In contrast, when muscimol was injected into the PMv, many of the initiated movements showed smaller amplitudes and slower velocities, but few direction errors were made. These results suggest that the PMd and PMv play differential roles in motor control.

443.9

DEFICITS OF VISUAL REACHING BEHAVIOR BY LOCAL INJECTIONS OF $GABA_B$ AGONIST AND ANTAGONIST (BACLOFEN AND PHACLOFEN) INTO THE PREMOTOR & MOTOR CORTEX OF THE RHESUS MONKEYS. K. KAWAHIRA* and K. KUBOTA, Dept. of Neurophysiology, Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, Japan

The role of intracortical $GABA_B$ergic inhibition in the performance of Visual Reaching was studied in two monkeys (Macaca mulatta). Baclofen (2.5 μg/μl) or Phaclofen (0.2-1 μg/μl) was injected locally into the hand motor area (MC) or the post-arcuate hand premotor area (PM), while monkeys were performing the task by hand. When Baclofen was injected into the MC (10 sites), neuronal bursts and convulsions of forearm muscles appeared gradually. Numbers of the task performance decreased gradually with decreased correct-performance. Monkeys released his hand slowly from hold key to reach target key and pressed the target key for longer periods. Number decrease was due to prolonged ITIs produced by that monkeys tended continuously to press the target key. Both reaction and movement time were prolonged. Similar effects, though weak, were produced when injected into the PM (6 sites). When Phaclofen was injected into the MC (6 sites) and the PM (5 sites), essentially similar changes as in Baclofen were induced in respective areas. Dual actions of $GABA_B$ agonist (autoreceptor presynaptic and postsynaptic) appear to be antagonized by dual actions of $GABA_B$ antagonist.

PERSISTENT DEFICITS OF EYE MOVEMENTS, GOAL-DIRECTED ARM MOVEMENTS AND VISUO-SPATIAL ORIENTATION FOLLOWING SMALL UNILATERAL POSTERIOR PARIETAL LESIONS. W. Heide*, B. Wild*, D. Petersen*. Depts. of Neurology and Neuroradiology, University of Tübingen, W-7400 Tübingen, FRG (SPON: European Brain and Behaviour Society).

Various visuo-spatial, visuo-vestibular and visuo-motor functions have been ascribed to the posterior parietal cortex. In a lesion study, we tried to correlate deficits of these functions with each other and with the cortical areas involved in 8 patients (5 left- and 3 right-hemispheric) with small chronic unilateral lesions around the intraparietal sulcus, according to MR imaging, compared to 10 normal controls. Besides DC-electrooculography of visually and vestibularly induced eye movements and psychophysical assessment of the subjective straight ahead (SSA), the subjective visual vertical (SVV) and the latencies of vection under optokinetic full-field stimulation, fast goal-directed arm movements were recorded by driving a pen to visual targets on a digitizing tableau.

Results showed that the patients' acute symptoms (visual hemineglect, spatial disorientation, optic ataxia, constructive apraxia, deviation of SSA) had almost disappeared. 3 of them, however, had a marked contralateral tilt of their SVV (>2°), associated with impaired circular vection, asymmetries of optokinetic and vestibular nystagmus (reduced gain of ipsilaterally directed slow phases) and an ipsilateral deviation in line bisection test. 3 others had a contralateral bias in this test, furthermore a spontaneous nystagmus (SPN, slow phases drifting ipsilaterally) and - only 1 of them -a direction-specific deviation of goal-directed hand movements (ipsilaterally) and of the SSA (contralaterally). We assume that the multimodal directional bias found in some of the cases might reflect a distorsion of egocentric spatial localization. Others have compensated this bias, maybe by means of an SPN.

443.11

DEPTH-TUNING IN AREA LIP BY DISPARITY AND ACCOMMODATIVE CUES. JW Gnadt and LE Mays. School of Optometry and Vision Science Research Center, University of Alabama at Birmingham, Birmingham AL 35294.

Area LIP in the intraparietal sulcus of rhesus monkeys contains many neurons that carry a presaccadic signal of motor error, representing the metrics of intended eye movements. Their functional properties are similar to those of the QV cells of the superior colliculus, a structure to which LIP projects. We have found that these LIP cells are tuned for depth with a sigmoid, broad-band preference for stimuli either near or far to the point of fixation. Two salient cues for depth, binocular disparity and accommodative demand (blur), were presented independently or in conjunction. Some neurons were found to prefer the combination of cues presented together. Others responded equally well or better to one stimulus alone. In most cases, linear combination of the two monocular response fields could not account for the tuning in depth. The midpoint of the tuning curve usually did not occur at zero disparity and the slopes near midpoint varied between cells. When disparity sensitivity was tested at various levels of vergence, the sensitivity either did not change or it increased in magnitude with no shift in the midpoint. Interestingly, cells identified as projecting to the superior colliculus also exhibited this property. Assuming collicular cells are not tuned for depth, this property may be averaged out at the tectum by convergent projections from near-tuned and far-tuned parietal cells. These data are consistent with the hypothesis that area LIP serves as an output element of convergent sensory inputs for a parietal 3-D visual-spatial system to other oculomotor structures. *These studies were supported by EY08217 to JWG and EY03463 to LEM.*

COMPARTMENT MODELS OF NEOCORTICAL INTRINSIC BURSTING AND REGULAR SPIKING PYRAMIDAL NEURONS

Paul A. Rhodes and Charles M. Gray
The Salk Institute for Biological Studies, La Jolla, CA

Neocortical pyramidal cells have non-linear input-output relationships which may be broadly classified as regular spiking and intrinsic bursting (Connors et al, 1982.) Their distinctive responses to current injection are thought to be due to the interaction of non-linear active conductances distributed in some presently unknown fashion in somatic and dendritic membranes. Any physiologically meaningful model of cortex will likely require model units incorporating physiological input-output characteristics. To explore the specification of such model neurons, a compartment model simulator was built. Dendritic geometry was simplified from filled layer V pyramidals from which intracellular recordings were obtained (Chagnac-Amitai et al, 1990.) Dendritic and somatic morphology was then fine tuned so that input resistance and time constant matched reported values. Ion channels (fast Na, persistant Na, K-DR, K-A, K-AHP, K-Ca, high threshold Ca, low threshold Ca) were modelled with Hodgkin-Huxley kinetics taken in most cases from studies done on cortical neurons. The parameters governing the kinetics of Ca accumulation and decay were preset based upon available data, but were subject to manipulation. Trial specifications of ion channel densities in the soma and in each compartment of the dendritic tree were interatively modified as suggested by comparison between simulated output and current injection results reported in the literature. In this manner, separate compartment models of layer V regular spiking and intrinsic bursting pyramidal neurons were developed which qualitatively matched current injection responses. These models generate detailed predictions which may be testable by techniques capable of applying channel blocker selectively to portions of the dendritic tree.

STIMULATION-EVOKED CHANGES IN INTRINSIC OPTICAL SIGNALS IN THE GUINEA-PIG ISOLATED WHOLE BRAIN. P. Federico, S.G. Borg*, and B.A. MacVicar. Neuroscience Research Group, The University of Calgary, Calgary, Alberta T2N 4N1 CANADA.

Neuronal activity has been shown to be associated with changes in the intrinsic optical properties of nervous tissue. We have used video imaging of reflectance changes to map patterns of evoked neuronal activity in the guinea-pig isolated whole brain preparation. The lateral entorhinal cortex (LEC) or lateral olfactory tract (LOT) was stimulated with concentric bipolar stimulating electrodes and evoked field potentials were recorded in surrounding cortical areas. Digitized images were averaged during stimulation and were subtracted from averages obtained during control periods. Stimulation of the LOT decreased tissue reflectance in the amygdala, pyriform cortex,intermediate entorhinal cortex, and LEC while stimulation of the LEC decreased tissue reflectance in the LEC, intermediate entorhinal cortex, and pyriform cortex. These intrinsic signals were repeatable, graded with stimulation frequency and intensity, consistently recovered and had an onset of approximately 3 sec. The pattern of the stimulus-evoked changes in optical properties was correlated with maps of the intensities of evoked field potentials in layers I - III of the various cortices. Intrinsic signals were recorded at wavelengths from 500 to 750 nm but the largest signals were observed at 550 and 600 nm which may be due to light adsorption by cytochrome oxidase a and c (550 nm: peak signal ΔR_r = 1.91 %; noise = 0.15%). LEC stimulation occasionally evoked seizure activity in the LEC. A large change in the intrinsic signal was found to spread across the medial entorhinal cortex/subiculum to the amygdala and pyriform cortex during the recorded seizure. Therefore, it is possible to image intrinsic optical signals in the guinea-pig isolated whole brain preparation. This technique may be useful for the examination of neuronal activity patterns and the spread of seizure activity. Supported by MRC (Canada).

POSTSYNAPTIC MECHANISMS IN NEUROTRANSMISSION

PHOTOLYTIC MANIPULATION OF $[Ca^{2+}]_i$ CONTROLS HYPERPOLARIZATIONS IN HIPPOCAMPAL PYRAMIDAL CELLS. B. Lancaster & R.S. Zucker, Molec. & Cell Biol., Univ. of Calif., Berkeley, CA 94720.

Experiments were performed to assess the reason for the slowness of the AHP in rat CA1 pyramidal cells. This Ca-dependent K current reaches a peak 500 ms following Ca^{2+} entry during spikes (28° C). In order to raise Ca^{2+} instantaneously throughout the cell, conventional intracellular recordings were made with electrodes containing DM-nitrophen loaded with 30% Ca^{2+}. UV light photolyses DM-nitrophen with an attendant reduction in Ca^{2+} affinity, thus releasing Ca^{2+}. For photolysis, a UV flashlamp (flash duration 1.6 ms) was focussed onto the slice surface. A single flash could evoke a 10 mV hyperpolarization from rest (-70 mV). The onset of 30 to 50 ms was limited by the membrane time constant. Durations of initial responses were 20-60 s. DM-nitrophen filled cells displayed small AHPs presumably as a result of Ca^{2+} buffering: these reduced AHPs showed the same slow kinetics as control responses. Flash responses and AHPs showed a common sensitivity to 1 uM isoproterenol, suggesting that both represent activation of the same current. When electrodes contained the caged BAPTA derivative Diazo-4, robust AHPs were observed. A flash (now to release Ca^{2+} buffer) at the peak of an AHP curtailed the response immediately. Subsequently, slow AHPs could not be evoked . These results show that rapid manipulations of $[Ca^{2+}]_i$ can cause similar rapid changes in AHP current. By contrast, this implies that spike induced Ca^{2+} entry causes slow $[Ca^{2+}]_i$ changes over the majority of AHP channels; possibly this is a consequence of spatial localisation.

HYPERPOLARIZING AND DEPOLARIZING $GABA_A$ RECEPTOR-MEDIATED DENDRITIC INHIBITION IN AREA CA1 OF RAT HIPPOCAMPUS N.A. Lambert, A.M. Borroni, L.M. Grover and T.J. Teyler Department of Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

$GABA_A$ receptor-mediated synaptic inhibition of pyramidal neuron dendrites was studied using intracellular and extracellular recording in the hippocampal slice preparation. In the presence of DNQX and APV stimulation in any layer evoked fast and late monosynaptic IPSPs and fast and late field potentials. Fast IPSPs and field potentials were reversibly blocked by bicuculline methiodide (BMI; 30μM); late IPSPs and field potentials were reversibly blocked by the $GABA_B$ receptor antagonist CGP 35348 (100μM). $GABA_A$ receptor-mediated field potentials (fast pIPSPs) were dependent on the extracellular chloride concentration, and use-dependent depression of fast pIPSPs was antagonized by CGP 35348 (0.8mM). Current source-density analysis of fast pIPSPs revealed current sources (outward current) horizontal to the stimulation site; BMI-sensitive sources could be evoked in all strata of area CA1. In the presence of DNQX, APV and 4-aminopyridine (50μM) BMI-sensitive long-lasting depolarizations (LLDs) could be evoked or occurred spontaneously. Current sinks mediating evoked LLDs and current sources mediating hyperpolarizing fast IPSPs were located in the same dendritic area. These results suggest that pyramidal neuron distal dendrites do not maintain a reversed electrochemical chloride gradient, and that depolarizing responses to dendritic application of GABA or orthodromic activation in area CA1 do not result from inward chloride current (Misgeld et al., *Science* 232:1413). Supported by NS28698.

SLOWER SPONTANEOUS EXCITATORY SYNAPTIC CURRENTS IN SPINY VS. ASPINY HIPPOCAMPAL HILAR NEURONS C.T. Livsey** and S. Vicini FGIN and *Dept. of Pharmacology, Georgetown Univ., Wash., DC 20007

Spontaneous excitatory postsynaptic currents (sEPSCs) from aspiny hilar interneurons (AHIs) and spiny "mossy cells" (SMCs) were examined using the whole-cell patch-clamp technique in young rat hippocampal slices. AHIs were identified electrophysiologically as neurons with action potentials (APs) followed by large afterhyperpolarizations, whereas SMCs were defined as those with APs followed by small, variably-directed afterpotentials. Confocal microscopy investigation after Lucifer Yellow injection revealed that most AHIs were aspiny, whereas SMCs were spiny and had thorny excrescences on their proximal dendrites. High frequency, large sEPSCs were not abolished by $GABA_A$ receptor antagonists, but were completely eliminated either with a non-NMDA receptor antagonist alone (most instances) or, in a few instances, in combination with an NMDA receptor antagonist. Peak amplitudes and decay time constants were increased by aniracetam (1 mM), a positive allosteric modulator of the non-NMDA receptor. TTX (1 μM) and Mn^{2+} (2 mM) did not abolish sEPSCs in most hilar neurons, suggesting spontaneous release of quanta from single synaptic boutons. The average amplitude of sEPSCs from 44 AHIs was 37 ± 23 pA, and from 34 SMCs was 29 ± 17 pA (mean ± SD). The amplitude distribution of sEPSCs could not be fit by single or multi-Gaussian distributions, reflecting spontaneous synaptic inputs originating from diverse neurons. Rise times of sEPSCs from 44 AHIs averaged 0.5 ± 0.2 ms and decay time constants averaged 3.6 ± 1.5 ms; in 34 SMCs, rise times averaged 1.0 ± 0.3 ms and decay time constants averaged 9.6 ± 4.8 ms (mean ± SD). Slower sEPSCs in spiny neurons result in increased synaptic strength. Spine structure modifications during neural activity may influence hippocampal circuitry and thus be operative in learning and memory. Supported by NIH grant PO1 NS 28130

Potentiation of Ca^{2+} changes in hippocampal CA3 pyramidal neurons by modulatory neurotransmitters. J.A. Connor, W. Müller and J.J. Petrozzino. Dept. of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110

Slow synaptic transmission, mediated by muscarinic, serotonergic, metabotropic quisqualate and β-adrenergic receptors appears to be important for learning in animals as well as for synaptic plasticity in single neurons which might underly learning. Most models of synaptic plasticity involve postsynaptic calcium (Ca^{2+}) changes as a trigger for subsequent processes. We imaged free Ca^{2+} accumulation in CA3 pyramidal neurons in the guinea pig hippocampal slice during synaptic train or direct stimulation and studied the effects of modulatory agonists on these transient Ca^{2+} accumulations. Carbachol, 5-HT, trans ACPD and isoproterenol all reduced a slow Ca^{2+} dependent afterhyperpolarization and were all effective in potentiating postsynaptic Ca^{2+} accumulations by 50 to 400 %. While all agonists enhanced proximal dendritic Ca^{2+} accumulations isoproterenol had a relative strong effect also on the soma. 5-HT could also reduce Ca^{2+} accumulations during an initial hyperpolarizing effect on the membrane. The effect of carbachol could be reproduced by firing cholinergic fibers in the slice. The response to repetitive stimulation of cholinergic fibers was enhanced by the acetylcholine-esterase blocker eserine and blocked by the muscarinic antagonist atropine. We surmise that modulation of postsynaptic Ca^{2+} changes by slow neurotransmission is an important pathway for the induction of synaptic plasticity.

GLUTAMATE RECEPTOR DESENSITIZATION GOVERNS THE STRENGTH OF EXCITATORY SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS. I.S. Isaacson and R. A. Nicoll, Depts. of Physiology and Pharmacology, University of California, San Francisco, CA 94143.

Rapid perfusion experiments with the non-NMDA type of glutamate receptor indicate that this receptor rapidly desensitizes in response to glutamate with a time course similar to that of synaptic responses (Trussell, L & Fishbach, G. *Neuron* 3:209, 1989). However, a physiological role for desensitization in synaptic transmission has not been established. In this study, we have found that aniracetam enhances the responses of neurons to glutamate (Ito, I. et al, *J. Phys.* 424:533, 1990) by reducing receptor desensitization and have examined its effects upon synaptic transmission in the hippocampus.

Outside-out membrane patches and synaptic currents were studied from CA1 and CA3 pyramidal neurons and dentate granule cells using "blind" patch clamp recording techniques in thick (500 μm) slices of adult guinea pig hippocampus. Outside-out patches were rapidly perfused with agonists via a segment of theta tubing attached to a piezoelectric switch. Excitatory post-synaptic currents (EPSCs) were evoked using conventional bipolar stimulating electrodes placed in s. radiatum or the perforant path.

The rapid application of glutamate or quisqualate to outside-out patches yielded responses which desensitized with time constants as short as 4.5 ms. In the presence of aniracetam the rate of desensitization of these responses was dramatically slowed and their amplitude increased, while the responses to kainate, which did not desensitize were unaffected. Aniracetam had two very consistent effects on non-NMDA receptor-mediated synaptic responses: it prolonged the time course and increased the amplitude of evoked EPSCs. To rule out a simple presynaptic site of action, we examined the effects of the drug on "miniature" EPSCs recorded in the presence of TTX. Aniracetam had essentially identical effects on these action potential-independent synaptic events.

The prolongation of synaptic currents by aniracetam provides a physiological role for glutamate receptor desensitization in governing the time course of excitatory synaptic transmission in the brain.

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL CHARACTERISTICS OF A GABA-MEDIATED SYNAPTIC DEPOLARIZATION IN THE RAT HIPPOCAMPUS. Avoli M; Tancredi V, Siniscalchi A and Zona C. McGill University, Canada H3A 2B4; Università di Roma Tor Vergata, Rome, Italy.

Intracellular recordings with K-acetate-filled electrodes were made in slices of the adult rat hippocampus to study the orthodromic inhibitory sequence generated by CA1 pyramidal cells. In 43 of 72 cells studied, stimuli that were delivered in the stratum radiatum induced: (i) an initial EPSP; (ii) an early hyperpolarizing IPSP (peak latency=approx. 20 ms); (iii) an intermediate depolarizing component (peak latency=60-120 ms; duration=60-150 ms) and (iv) a late, long-lasting hyperpolarizing IPSP (peak latency=120-160 ms; duration >400 ms). In the remaining cells this inhibitory response lacked the intermediate depolarizing component. The depolarizing component represented an active, GABA-mediated phenomenon since: (i) it was selectively blocked by local applications of bicuculline or picrotoxin on the apical dendrites (ii) it was enhanced by lowering the temperature or by the GABA-uptake blocker nipecotic acid. Application of the Cl^--pump blocker furosemide reduced and eventually blocked both early IPSP and depolarizing component. These data demonstrate that under physiological conditions rat hippocampal pyramidal cells generate a depolarizing component that is presumably caused by an outward-directed Cl^- movement due to the activation of $GABA_A$ receptors located on the apical dendrites. This novel mechanism might modulate hippocampal excitability under both physiological and pathophysiological conditions.

INTERACTION BETWEEN CHOLINERGIC AND HISTAMINERGIC CALCIUM SIGNALS IN MOUSE NEUROBLASTOMA CELLS. S. S.-H.Wang and S.Thompson*. Hopkins Marine Station of Stanford University, Pacific Grove, CA 93950.

Muscarinic and histaminergic receptors in N1E-115 cells activate phosphoinositide (PI) hydrolysis and calcium mobilization. Using fura-2 calcium imaging we find that carbachol (CBC) and histamine (HIS) elicit similar Ca "fingerprints" in the same cell, as defined by kinetics and spatial patterns of release from stores. The response to CBC is abolished by phorbol ester, implicating protein kinase C (PKC) in desensitization.

We examined the effects of long exposure to CBC and HIS. A Ca response was defined as ≥33% change in fluorescence at 380 nm after 30 seconds. Analysis was restricted to cells that respond to both agonists. A 5-minute exposure to 1 mM CBC desensitizes the cells by 37% to a second application of CBC, but this did not affect their responsiveness to HIS. Conversely, a 10-minute exposure to 10 μM HIS desensitizes the cells by 41% to a second application of HIS, while preserving the CBC response.

Desensitization is one way that receptor activation can alter synaptic efficacy. The lack of cross-desensitization here indicates that it may take place at a step prior to PI hydrolysis. This does not support a PKC-dependent mechanism.

SEROTONIN AND NORADRENALINE STRONGLY EXCITE GABAergic NEURONS OF THE THALAMIC RETICULAR NUCLEUS. David A. McCormick and Zhong Wang Section of Neurobiology, Yale Univ. Sch. Med.

The thalamic reticular nucleus (nRt) is a sheet-like formation of GABAergic neurons surrounding the thalamus, is important in the control of thalamocortical activity, and is innervated by noradrenergic and serotoninergic fibers of brainstem origin. Here we investigated the influence of 5-HT and NA on cat and guinea pig thalamic reticular neurons through the use of the *in vitro* slice technique. Application of either 5-HT or NA resulted in a pronounced depolarization of nRt neurons resulting from the reduction of a "leak" current which displayed a reversal potential of -105 mV (2.5 mM $[K^+]_O$), suggesting that it is mediated by K^+ ions. This K^+ current varied in a relatively linear manner with driving force on K^+ ($V-E_K$) and was not blocked by extracellular application of Ba^{++} or Cs^+, suggesting that it is distinct from I_M or I_h. The response to 5-HT was occluded by maximal application of NA, and vice versa, suggesting convergence of the two neurotransmitters onto the same effector mechanism. Application of ketanserin or ritanserin (1-5 μM) blocked the response to 5-HT but not to NA, while the application of prazosin (1 μM) blocked the response to NA but not to 5-HT. These data indicate that 5-HT and NA block a relatively linear K^+ current through activation of $5HT_2$ and α_1 receptors, receptively. Functionally, the slow depolarization of nRt neurons induced by 5-HT and NA resulted in a promotion followed by pronounced inhibition of rhythmic burst firing and the appearance of single spike activity. We suggest that in this manner the timing and prevalence of rhythmic burst firing in thalamocortical systems may be controlled by the ascending serotoninergic, noradrenergic and cholinergic transmitter systems. Supported by NIH and the Klingenstein Fund.

Excitatory Synaptic Currents Recorded *in-vitro* from Rat Superior Colliculus Neurons. Shaul Hestrin. Department of Physiology, U.C.S.F., S.F., CA. 94143.

The mammalian optical tectum plays an important role in controlling eye movements, integrating retinal and cortical inputs as well as brain stem inputs. The excitatory cortical and retinal inputs have been studied so far with extracellular recording. I have recorded using whole-cell techniques from the stratum griseum superficial (SGS) neurons in brain slices. Excitatory inputs were evoked by stimulating in the optical layer in the presence of picrotoxin.

At membrane potential of -80 mV the EPSC had a rapid decay time of about 2 ms. The fast component was blocked by CNQX was insensitive to APV, had a linear current-voltage relationship and its time course was voltage insensitive.

In the presence of CNQX membrane depolarization revealed a slow component which could be blocked by APV. The decay time of the NMDA component was voltage dependent: doubling by depolarization from -20 to +20 mV. The decay time constant of the NMDA component was quite variable; at -20 mV tau was between 17 ms and 70 ms. This variability could reflect differences in animal age or in cell types.

These results indicate that the EPSC in the SGS are mediated by an NMDA and non-NMDA glutamatergic receptors which are generally similar in their current-voltage relationship and pharmacological properties to those recorded at CA1 pyramidal neurons. The quantitative differences between the EPSCs recorded at SGS neurons compared to those recorded at CA1 may be explained by different receptor subtypes mediating synaptic currents in these two regions.

NMDA and non-NMDA receptors are not co-localized at excitatory synapses of on-off ganglion cells in salamander retina. W. R. Taylor*, E. P. Chen* and D. R. Copenhagen, Depts. Ophthalmology and Physiology, UCSF, San Francisco 94143-0730.

Previously it has been demonstrated that light evoked excitatory postsynaptic currents (EPSCs) in voltage-clamped salamander retinal ganglion cells are a result of concomitant activation of two types of glutamate receptor, the *N*-methyl-D-aspartate (NMDA) receptor and a non-NMDA receptor, presumably quisqualate or kainate receptors (Mittman, Taylor & Copenhagen, 1990). The non-NMDA input appears to be due to summation of numerous quantal like events. If non-NMDA and NMDA receptors were co-localized within the synapses of these ganglion cells, as supposed, then miniature excitatory postsynaptic currents (MEPCs) produced by spontaneous quantal release should also have a fast non-NMDA component and a slower NMDA component. In this study, analysis of MEPCs recorded during darkness and in light failed to reveal the presence of a slower NMDA component. The decays of MEPCs were well fitted by similar single exponential functionsat -90 mV, where the NMDA component of the light response was blocked, and at -45 mV where the NMDA component of the light response was comparable in magnitude to the non-NMDA component. At -90 and -45 mV MEPCs had average 10-90% rise-times of 1.2 and 1.6 ms respectively and exponential decay time constants of 3.6 and 4.3 ms respectively. CNQX (1μM), a non-NMDA antagonist, blocked the MEPCs and the non-NMDA component of light responses. AP7 (20μM), an NMDA antagonist, had no effect on the MEPCs but blocked the NMDA component of the light response. Furthermore, if co-localization were assumed then the magnitude and time course of the total light response at -45 mV could not be predicted from mathematical simulations of summed MEPC activity. These findings indicate that the non-NMDA and NMDA receptors mediating the light-evoked excitation are not co-localized within the synapses on the ganglion cells.

IDENTIFICATION OF A DISTINCT POPULATION OF NERVE GROWTH FACTOR LIKE-IMMUNOREACTIVE CELLS WITHIN THE DEVELOPING THYMUS. E.S. Purcell and V.H. Gattone, II. Department of Anatomy and Cell Biology, Univ. of Kansas Med. Center, Kansas City, KS 66103.

We previously described a developmentally increased monoaminergic innervation of thymus in the spontaneously hypertensive rat (SHR), an animal model with a T cell dysfunction (Soc. Neurosci. 16(2):1206). We hypothesized that trophic factors induced this hyperinnervation. To test this hypothesis, we examined NGF and NGF receptor immunoreactivity (-ir) using indirect immunofluorescence. A well defined population of cells with a rounded morphology and strong NGF-ir was identified in the interlobular septae of the developing thymus. These cells were loosely associated with the vasculature along which the innervation initially develops. The SHR thymus had an increased number of these cells which were more intensely labelled as compared to those seen in the Wistar Kyoto rat. Labeling for NGF receptor-ir was minimal, suggesting that the NGF-ir represents cellular production rather than receptor mediated uptake. More diffusely labeled cells were found in thymic cortex at older time points. In conclusion, a specific population of cells is immunoreactive for NGF in the developing thymus. Their location, number and temporal appearance correlate with the development of thymic hyperinnervation in the SHR. Supported by PHS grant MH46511.

CHARACTERIZATION OF NERVE GROWTH FACTOR RECEPTORS IN THE IMMUNE SYSTEM. C.E. Lomen-Hoerth and E.M. Shooter. Department of Neurobiology, Stanford University School of Medicine, Stanford, CA, 94305.

In addition to its neurotrophic effects, nerve growth factor (NGF) can affect the inflammatory and immune response. The specificity of these effects was investigated by determining NGF receptor expression in the immune system. In the rat spleen and thymus, NGF receptor mRNA is expressed in both the stroma and circulating cells based on northern analysis with the low affinity NGF receptor cDNA probe. To identify specific cell types, fluorescent activated cell sorting (FACS) was used with a low affinity NGF receptor antibody, MC192, and antibodies to cell type specific markers. In the mouse spleen, mature B cells express NGF receptor on their cell surface, while mature T cells, granulocytes, and macrophages do not. Using the same technique, CD4 and/or CD8 positive T cells in the thymus do not express NGF receptors on their cell surface. During development, the NGF receptor protein expression is highest in E18 thymus based on a western blot with MC192 and tapers off into adulthood based on northern analysis. The reverse is true in the spleen. Work in parallel with cell lines supports the above results. NGF binds to the mouse mast cell line BabY5 and the mouse B cell lymphoma CH27 and upregulates the NGF receptor in these cells based on FACS analysis. The adult mouse thymic epithelial line 3D.1 expresses NGF receptor mRNA based on northern analysis. Experiments in progress are aimed at further characterizing these cell lines as well as fetal thymic cell lines to compare the properties of the immune system NGF receptor with the neuronal receptor.

TRANSFECTION WITH THE *TRK* PROTO-ONCOGENE RESCUES NGF RESPONSIVENESS IN MUTANT NGF-NONRESPONSIVE PC12 CELL LINES. D. M. Loeb*, J. Maragos*, K. A. Phelan, M. V. Chao, L. F. Parada*, and L. A. Greene*. Columbia Univ. Dept. Path., New York, NY 10032, Dept. Cell Bio. and Anat., Cornell Univ. Med. Coll., New York, NY 10021, and Molec. Embryology Sect., ABL-Basic Res. Prog., NCI-Frederick Cancer Res. and Dev. Ctr., Frederick, MD 21701.

The *trk* proto-oncogene product ($p140^{prototrk}$) binds NGF and undergoes rapid autophosphorylation in response to this neurotrophic factor. EMS mutagenized PC12 cell lines deficient in high affinity NGF binding and unresponsive to NGF (PC12nnr; Green et al., J. Cell Biol. 102:830-843, 1986) were used to determine if $p140^{prototrk}$ is involved in transducing a functional NGF signal. Northern blot analysis using a *trk*-specific probe revealed that PC12nnr lines express significantly less *trk* mRNA than do wild type PC12 cells. Expression vectors encoding full length $p140^{prototrk}$ were transiently transfected into PC12nnr cells by the lipofectin method. After 4 days of exposure to NGF, approximately 10% of the cells displayed long neurites ending in growth cones; without NGF, no neurites were observed. Control cultures either mock transfected or transfected with a plasmid lacking $p140^{prototrk}$ did not grow neurites when exposed to NGF. Treatment of the cultures with 200 nM K252a, a drug that specifically blocks NGF responses, effectively suppressed NGF induction of neurite outgrowth. NGF is capable of promoting survival of PC12 cells, but not PC12nnr cells, in serum-free medium. PC12nnr cells transfected with *trk* cDNA were maintained in serum free medium, while untransfected and control transfected cells died. These results indicate that $p140^{prototrk}$ is necessary for PC12 cell responsiveness to NGF; they do not, however, address the issue of whether $p140^{prototrk}$ is sufficient for NGF responsiveness since PC12nnr cells also express the low affinity NGF receptor, p75. Generation of permanent PC12nnr-trk transfected cell lines will allow a more complete evaluation of the responses to NGF that are rescued by *trk* expression.

Two independent signaling pathways lead to the activation of the nerve growth factor gene. F. Jehan*, D. Wion*, I. Neveu*, Ph. Brachet. INSERM U.298, CHR, 49033 Angers cedex 01, France.

Increased expression of the nerve growth factor gene (NGF) may be obtained by treating L929 fibroblasts with serum or 1,25-dihydroxyvitamin D3. The action of serum is largely prevented by Pertussis toxin suggesting that it is mediated by GTP-binding protein(s). It requires protein synthesis and is associated with a transient activation of c-fos proto-oncogene. However, the expression of c-fos is not sufficient in itself to activate NGF gene, since cAMP also causes a transient increase of c-fos transcripts, which is not followed by an accumulation of NGF mRNAs. In contrast, 1,25-dihydroxyvitamin D3 promotes the synthesis of NGF in the presence of cycloheximide or Pertussis toxin, and does not induce c-fos gene. These data indicate that NGF gene may be controlled by two different signaling pathways.

445.5

THE SCHWANN CELL-DERIVED TRUNCATED FORM OF THE NGF RECEPTOR ARISES FROM POST-TRANSLATIONAL PROCESSING **P.A. Barker, F.D. Miller, T.H. Large, and R.A. Murphy Dept. of Anatomy and Cell Biology. Univ. of Alberta, Edmonton, Alberta, Canada T6G 2H7 and Dept. of Neurosci., Case Western researve Univ., Cleveland, Ohio 44106.**

Low affinity NGF receptors have been identified on neurons in the peripheral and central nervous system and on several non-neuronal cell types. The low affinity receptor is produced both in a membrane bound and soluble truncated form. We have undertaken to determine whether the truncated form is generated as a result of post translational proteolytic processing of intact membrane-bound receptor or from an alternatively spliced mRNA lacking a transmembrane domain.

Pulse chase analysis of primary rat Schwann cells coupled with immunoprecipitations using antibodies to the intracellular and extracellular domains of the receptor were used to monitor receptor production. Three forms of the NGF receptor (Mr 80, 82, 85kd) displaying a precursor-product relationship were detected over a two hour chase period in cell extracts with only the 85 kd species appearing on the cell surface. Truncated receptor (Mr 50 and 52 kd) was detected in conditioned medium five hours after labelling but not intracellularly. PCR and RNAse protection analyses detected no splice variants that could generate receptor and media conditioned by fibroblasts transfected with rat receptor cDNA, in which splicing cannot occur, produced truncated receptor as well. Therefore, the truncated form of the receptor arises from post translational processing of the intact receptor rather than as a distinct translation product.

NGF REGULATES NEURONAL GENE EXPRESSION IN A CONCENTRATION DEPENDENT FASHION. Y. Ma, R.B. Campenot, and F.D. Miller. Dept. of Anat. and Cell Biol., Univ. of Alberta, Edmonton, Alberta, CANADA.

Developing sympathetic neurons respond to systemic administration of NGF by alterations in gene expression (Mathew and Miller, Dev. Biol., 141, 84, 1990; Miller et al., JCB, 112, 303, 1991). To determine the direct effects of different concentrations of NGF on sympathetic neurons, we studied the regulation of mRNA's encoding the low-affinity NGF receptor (LNGFR), Tα1 α-tubulin (Tα1), and tyrosine hydroxylase (TH) in cultured rat sympathetic neurons from the postnatal day 1 SCG. Northern blot analysis of total cytoplasmic RNA isolated from sympathetic neurons cultured for 5 days in 2-200 ng/ml 2.5S NGF revealed that, as the NGF concentration increased, neurons expressed correspondingly increased levels of all three mRNAs. Both LNGFR and TH mRNAs were increased 7-fold, and Tα1 mRNA 4-fold in neurons cultured in 200 ng/ml versus 10 ng/ml NGF. Furthermore, when neurons were cultured in 10 ng/ml 2.5S NGF for 5 days, and the concentration was subsequently increased to 200 ng/ml, LNGFR, TH, and Tα1 mRNAs all increased within 12 hours. LNGFR and TH mRNA levels continued to increase for 48 hours following the NGF increase (latest timepoint examined) while Tα1 mRNA reached a plateau at 5 hours which was maintained. These experiments show that NGF directly modulates the expression of these neuronal genes in a concentration-dependent fashion. Since tubulin and tyrosine hydroxylase are important components of the axon and nerve terminal the NGF concentration dependency of their genes likely reflects a step in the regulation of neuronal growth by NGF. These data also raise the possibility that the effects of NGF on gene expression may be mediated through multiple signal transduction pathways that are activated at different concentrations.

445.7

A c-fos-NGF TRANSGENIC MICE. NEW PERSPECTIVES IN THE STUDY OF THE FACTOR. B. Onténiente[1], P. Horellou[2*], I. Makeh[3*], F. Lisovoski[1*], G. Grimber[3*], P. Briand[3*], J. Mallet[2*], M. Peschanski[1] 1)INSERM U161, Paris 2)CNRS UPR11, Gif 3)ICGM, Paris, France.

The lack of an appropriate way of delivery is an ongoing impediment to the *in vivo* study of NGF functions in the CNS. Transplantation studies suggest that embryonic neurons could be suitable vectors for the delivery of substances which do not cross the blood brain barrier, provided that the neurons develop and integrate with the host parenchyma definitively and without major damage.

To address this issue, the mouse prepro-NGF gene (gift from P. Brachet, INSERM U298) was inserted within a plasmid containing the *c-fos* promoter and the transcription termination and polyadenylation signals of the *ß-globin* gene (NAR 17:6,1989, gift from P. Fort). The vector-free construct was introduced into C57Bl6xDBA mice genome by micro-injection into fertilized eggs. Southern blot analysis of the offspring of three transgenic founder mice has revealed a stable transmission of the gene over several generations. *c-fos* was chosen as a promoter because of its sensitivity to several *in vitro* and *in vivo* stimuli which unable it to be used as a modulator of the production of NGF in transgenic cells. *In vitro* stimulation by 24h serum deprivation of fibroblasts transfected with the construct induced a clear differentiation of PC12 incubated with the supernatant. Preliminary *in vivo* attempts to modulate the production of NGF by external stimuli revealed an increase in the content of NGF-RNA in sub-maxillary glands of animals treated with pentylenetetrazole, a potent seizure-inducing agent.

445.8

INDUCTION OF NGF OCCURS BY MULTIPLE MECHANISMS. E.K. Hoffman*, M.E. Lewis, K. Clopton*, and S. Carswell. Cephalon, Inc., 145 Brandywine Parkway, West Chester, PA 19380.

NGF has been shown to be induced in various systems by seemingly unrelated compounds, among which are catecholamines, catechol derivatives, agonists of beta adrenergic receptors, serum, retinoic acid, IL-1 beta and prostaglandin E1. We are performing comparative studies to examine the molecular events involved in induction of NGF by various compounds. It was found that NGF, as measured by ELISA, could be induced, although to varying extents, in mouse L cells using each of the above types of compounds. Further, serum and the catechol derivative, 4-methyl catechol (4-MC), appeared to induce NGF synergistically. Northern blot analyses of NGF mRNA suggest that the inductions of NGF by both 4-MC and serum, as well as their synergistic induction, are reflected at the transcriptional level. 4-MC and the beta receptor agonist, isoproterenol, also appear to induce NGF by different means: the beta receptor agonist propranolol blocked induction by isoproterenol, but not by 4-MC. The molecular basis of these findings is now being investigated, including studies to analyze the DNA sequence elements within the NGF promoter and the proteins that bind to these elements that are required for both basal and induced levels of transcription.

445.9

NGF-REGULATORY REGIONS WITHIN THE TRANSIN/ STROMELYSIN GENE IN PC12 CELLS: INVOLVEMENT OF AN AP1 SITE AND OTHER CIS-ACTING ELEMENTS. G. Ciment, C.Machida*, J.Lochner*, L.Matrisian*,†. Dept. Cell Biology & Anatomy, Oregon Health Sciences Univ., Portland, OR 97223; †Dept. Cell Biology & Anatomy, Vanderbilt Univ., Nashville, TN.

In previous work, we found that NGF induced the mRNA encoding the metalloproteinase transin/stromelysin ("transin") in PC12 rat pheochromocytoma cells. Transin was found to be a late gene, requiring expression of transcriptional activator proteins. Transient transfection studies using the p750TRCAT plasmid, which contains a 750 base pair region of the transin promoter just 5' to the transcription start site, were found to confer NGF-responsive reporter gene activity to PC12 cells, indicating that NGF-regulatory sequences are present in this 750 base pair region.

In this study, we show that an AP1 element located at position -70 to the transcription start site is required for both basal and NGF-induced levels of expression. These studies involved transient transfection assays with a mutated version of the p750TRCAT plasmid in which the AP1 site was altered. Deletion studies, in which the transin promoter was truncated in various ways, were also performed. These studies found that additional NGF-responsive regulatory sequences were also present within this 750 base base region.

445.10

COMPARISON OF NGF RECEPTOR DISTRIBUTION ON PC12 AND SCHWANN CELLS USING ANTIBODIES 217c AND 192-IgG. G. Ferrari, M. Fabris*, A. Bruni*[1], L. Petrelli* and P.E. Spoerri. Fidia Research Labs., Abano T. (PD), Italy, [1] Dept. of Pharmacology, Univ. of Padova, Italy

Recently, we reported that the antibody 217c recognizes a different epitope on the NGF receptor (NGFR) than does 192-IgG (Ferrari et al. Exp. Neurol., 1991). These studies were extended by showing that 217c and 192-IgG recognize epitopes located on the extracellular domain of only the low-affinity NGF receptor (LNGFR) as both immunoprecipitated the LNGFR but not the high-affinity (HNGFR) cross-linked complex (Meakin S.O. and Shooter E.M., Neuron 6: 153, 1991). We have employed immunoelectron microscopy to examine the topographical distribution of antigens recognized by 217c and 192-IgG on NGF-primed PC12 cells (which have both LNGFR and HNGFR) and Schwann cells (which have only LNGFR). The two antibodies exhibited similar immunogold reactivity. However, in NGF-primed PC12 cells, colloidal gold was observed at regular intervals along perikaryal and neuritic surfaces. Prominent immunoreactivity was frequently localized in coated endocytotic vesicles, on SER and in secondary multivesicular lysosomes. In contrast, immunoreactivity in Schwann cells was only present along the plasma membrane. We conclude that these antibodies may be useful to follow the fate of the two forms of NGFR.

E1A domains binding p105Rb and p300 are required to block NGF-induced differentiation of PC12 cells. D. Kalman, K. Whittaker and P.H. O'Lague. UCLA Dept. of Biology. Los Angeles CA 90024.

Nerve Growth Factor (NGF) causes PC12 cells to cease division and undergo neuron-like differentiation including neurite outgrowth. We are testing whether differentiation and division share overlapping control mechanisms in these cells. To do this we are perturbing the activity of proteins known to participate in cell cycle regulation by introducing the E1A oncogene or its mutant forms via microinjection. E1A acts in part through specific binding domains to titrate putative cell cycle control proteins including, for example, p105Rb (retinoblastoma) and p60 Cyclin A, as well as others of unknown function such as p107 and p300 (Whyte et al. 1989; Cell 56:67). Similar to previous results (Maruyama et al. 1986; Oncogene 1:361), we find that wild type E1A detected immunohistochemically blocks NGF-induced neurite extension. In addition, NGF's effects do occur in mutants known to have greatly reduced binding to either p105Rb or p300. Wild type E1A's block can be partially relieved by an exogenous human Rb gene product concurrently expressed at high levels. Our results suggest that cell cycle regulatory proteins such as p105Rb and p300 might play an overlapping role in the NGF signal transduction pathway.

NGF ACTIVATES A PROTEIN KINASE WHICH PHOSPHORYLATES THE PROTO-ONCOGENE c-FOS. L.K. TAYLOR AND G.E.LANDRETH. Departments of Neurology and Neurosciences, Case Western Reserve University, Cleveland, OH 44106.

NGF rapidly induces the transcription of the c-fos gene in PC12 cells. The resulting Fos protein is highly phosphorylated. C-fos transcription is also induced by a number of other agents including depolarization, yet the Fos protein is not highly phosphorylated. This observation suggested the existence of an NGF-regulated Fos kinase. A peptide corresponding to the C-terminal region (residues 359-370) containing putative phosphorylation sites was synthe-sized and used to detect an NGF-regulated protein kinase.

NGF treatment of PC12 cells resulted in the rapid activation of a protein kinase which phosphorylated the peptide. Fos kinase was activated 3-5 fold in response to NGF or EGF, while bFGF, cAMP, TPA, or depolarization were without effect. Fos kinase activity was maximal after 5 min of NGF treatment, and remained elevated 2-fold after 1 hr. Fos kinase phosphory-lated authenic c-Fos protein and this phosphorylation was inhibited by the peptide substrate. Moreover, a Fos C-terminal deletion mutant was not phosphorylated. Fos kinase is distinct from other previously characterized protein kinases.

The phosphorylation of c-Fos at these C-terminal sites is likely to be responsible for the transrepressive activity of c-Fos. The identification of Fos kinase provides another element in the NGF signal transduction cascade which may mediate communication between the cytoplasm and nucleus.

PARTIAL CHARACTERIZATION OF NERVE GROWTH FACTOR-RESPONSIVE PHOSPHORYLATED NUCLEAR PROTEIN IN PC12 CELLS. M.Ikegame*,K.Fujita, H.Sakamoto*,H.Kuzuya and K.Titani*‖. Div. Mol. Biol.,‖Div. Biomed. Polymer Sci., Fujita Health University, Toyoake, Aichi 470-11, Japan.

A nuclear protein designated as SMP(slow migrating protein)** with a MW of approx. 30kDa in PC12 cells is known to be increased in its phosphorylation by NGF. In this study, NH_2-terminal amino acid sequence, production of monoclonal antibody, and immunocyto- and histochemistry of the nuclear protein were investigated. Proteins were extracted with 0.5M HCl from nuclei, precipitated with 25% TCA, and then electrophoresed on acid/urea PAGE (15%). Proteins were transferred to PVDF membrane, stained with CBB, and sequenced dierectly. NH_2-terminal sequence,GRVIRGGAGSVHRAHVKHRKGAARL, has considerable homology with those of ribosomal proteins L2 and KD4 of slime mold(Dictyostelium discoideum) and yeast(Schizosaccharomyces pombe), respectively, ICR mice were immunized against the nuclear protein; the gels on which the protein was separated were homogenized with Freund's adjuvant and injected. After the antibody was generated, spleen cells were fused with NS-1 myeloma cells. The monoclonal antibody stained PC12 cells differently among cells. Some cells were stained on nuclei and others on cytoplasms. Rat tissues such as adrenal medulla, superior cervical ganglia, and dorsal root ganglia were also stained. **M-Y.W.Yu,et al.,J.Biol.Chem.,255,10481(1980).

ACTIVATION OF THE CATALYTIC SUBUNIT OF cAMP-DEPENDENT PROTEIN KINASE BY PROTEIN KINASE N (PKN).

C. Volonté and L.A. Greene*. *Department of Pathology, Columbia University, College of Physicians and Surgeons, New York, N.Y., 10032.*

Protein kinase N (PKN), a serine protein kinase that is rapidly activated by NGF and other agents in PC12 cells and other cell lines, increases the phosphorylating activity of the catalytic subunit of cAMP-dependent protein kinase (PKA). Preincubation of the two kinases in the presence of ATP leads to potentiated phosphorylation of histone HF1, Kemptide (a specific substrate for PKA, but not for PKN) and several additional substrates. The potentiated activity is insensitive to 6-thioguanine (an apparently specific inhibitor of PKN) but is suppressed by the Walsh PKA inhibitor and by the regulatory subunit of PKA. PKN-activated PKA shows a 30-fold decrease in Km for Kemptide and a substantial increase in Vmax. The presence of 6-TG during preincubation of the two kinases prevents the potentiation of substrate phosphorylation, indicating that the catalytic activity of PKN is required for the activation. This is supported by the observation that the catalytic subunit appears to be a substrate for PKN. PKN-pretreated PKA is more stable to freeze/thawing and PKN can reactivate freeze/thawed PKA that has lost activity. This suggests that PKN may activate PKA by promoting a conformation that is more enzymatically active. PKN and PKA appear to be widely expressed, and past studies have shown that PKN can be activated in cells via a PKA-dependent pathway. The occurrence of PKN-PKA interactions within cells thus would have interesting biological implications for signal transduction.

Supported by grants from the NIH and March of Dimes.

DISSOCIATION OF CHANGES IN GTP CYCLOHYDROLASE, TETRAHYDROBIOPTERIN AND TYROSINE HYDROXYLASE INDUCED BY NGF IN SUPERIOR CERVICAL GANGLIA. K. Hirayama and G. Kapatos. Dept. of Psychiatry, Wayne State Univ., Detroit, MI 48235

GTP cyclohydrolase (GTPCH) is the first and rate-limiting enzyme in the tetrahydrobiopterin (BH4) biosynthetic pathway. BH4 is known to serve as a specific cofactor for tyrosine hydroxylase (TH), the rate-limiting enzyme in norepinephrine (NE) biosynthesis. To investigate the regulation of BH4 biosynthesis by NGF in NE-contalning neurons, we have used monolayer cultures of sympathetic neurons derived from the neonatal rat superior cervical ganglia (SCG). SCG maintained in the presence of 100 ng/ml NGF (7S) for 4 or 11 days in vitro (DIV) were treated with different concentrations of NGF (50 ng/ml to 1 μg/ml) for 7 days. When NGF treatment was begun at 4 DIV, GTPCH activity, BH4 levels and TH activity were increased in accordance with the concentration of NGF. In contrast, when treatment was begun at 11 DIV, GTPCH activity and BH4 levels were unchanged while TH activity was increased. These data suggest that in 4 DIV cultures the NGF-induced increase in BH4 is due to an induction of GTPCH and that the regulation of GTPCH and TH may be coordinated regulated. However, in 11 DIV cultures this coordinate regulation was no longer apparent. It is suggested that under certain conditions the induction of TH and of its BH4 cofactor can be dissociated and that changes in cell-free TH activity do not necessarily equate with an alteration in the capacity of the intact neuron to synthesis NE. (Supported by NIH NS26081).

445.16

PHOSPHORYLATION AND ACTIVATION OF SER/THR KINASE OF B-RAF BY NERVE GROWTH FACTOR IN PC12 CELLS. M. Oshima*, U. R. Rapp*, and G. Guroff. Section on Growth Factors, National Institute of Child Health and Human Development, Bethesda, MD 20892 and Laboratory of Viral Carcinogenesis, National Cancer Institute, Frederick Cancer Center, Frederick, MD 21701

The raf family oncogene, B-raf, is expressed in neuronal and urogenital tissues, which suggests a functional role for the product of this gene in these tissues. Treatment of PC12 cells with nerve growth factor (NGF), which causes these cells to differentiate into a neuron-like phenotype, does not alter B-raf mRNA (3.8 kb and 10 kb), but does induce rapid phosphorylation of 67 kD and 95 kD B-raf proteins. Phosphorylation was observed after 1.5 min and reached a maximum by 10-15 min. Phosphorylation was seen mostly on serine, but not on tyrosine. NGF-induced phosphorylation was not affected by the depletion of protein kinase C nor by the removal of extracellular calcium, but was inhibited by K-252a. NGF treatment also activated the ser/thr kinase activity of B-raf within 1-2 min. Preliminary data suggest that B-raf plays a role in sending the NGF signal to the nucleus.

445.17

THE CHARACTERISTICS OF THE NERVE GROWTH FACTOR (NGF)-INDUCED PHOSPHORYLATION OF PHOSPHOLIPASE C-γ (PLC-γ) IN PC12 CELLS. D. W. Fink, Jr.*, U-H. Kim, H. S. Kim, S. G. Rhee, and G. Guroff*. Section on Growth Factors, NICHD, NIH and Signal Transduction Section, NHLBI, NIH Bethesda, MD 20892.

Increased hydrolysis of phosphatidylinositol (PI) occurs within seconds of the addition of NGF to PC12 cells in culture. Receptor-mediated, NGF-stimulated PI turnover is presumed to be the consequence of a calcium-dependent activation of PLC. Treatment of PC12 cells for 5 min with NGF leads to a 2-3-fold increase in the phosphorylation of PLC-γ. Removal of extracellular Ca^{2+} blocks the action of NGF. Phosphoamino acid analysis indicates an increase in both phosphoserine and phosphotyrosine. Time-course studies show that the phosphorylation of tyrosine (30 sec) precedes that of serine (2.5-5 min). Pretreatment with the tyrosine kinase inhibitor genistein (150 uM) blocks both NGF-induced PI turnover and NGF-stimulated tyrosine phosphorylation. These data suggest that NGF-stimulated PI hydrolysis results from increased tyrosine phosphorylation of PLC-mediated by a receptor-linked tyrosine kinase.

445.18

NERVE GROWTH FACTOR (NGF)-STIMULATED RELEASE OF ADRENERGIC NEUROTRANSMITTERS AND UPTAKE OF CALCIUM BY PC12 CELLS B. Nikodijevic, C. R. Creveling*, and G. Guroff*. Section on Growth Factors, NICHD and Laboratory of Bioorganic Chemistry, NIDDKD, NIH, Bethesda, MD 20892.

It has been shown that NGF stimulates a calcium-dependent release of catecholamines from PC12 cells. NGF also stimulates $^{45}Ca^{2+}$ uptake into cells attached to collagen-polylysine coated plates by 60-80% within 3 min, but this effect is transient, being much lower or absent after 15 min of NGF treatment. The effect of NGF was blocked or significantly reduced by EGTA, K-252b, staurosporin, calmidazolium, fluphenazine, or suramine. The effect of NGF was not blocked by inhibitors of N- or T-type calcium channels, nor by calcineurin, nickel, or inhibitors of protein kinases C, A, or N, and only partially by high concentrations of inhibitors of L-type channels. The NGF effect on $^{45}Ca^{2+}$ uptake was much less in cell suspension, in very dense cultures, or in cells pretreated with calcium ionophores. The data indicate that the NGF-stimulated increase in calcium uptake relies on channels different than the well-known voltage- or receptor-operated calcium channels.

445.19

ACTIVATION AND DISTRIBUTION OF PROTEIN KINASE C (PKC) ISOZYMES IN PC12 CELLS AFTER TREATMENT WITH PKC STIMULATORS. J. I. Morris*, R. K. Singh*, A. P. Fields*, and K.E. Neet. Depts. of Biochemistry and Pharmacology, Case Western Reserve University, Cleveland, OH, and Dept. of Biological Chemistry, The Chicago Medical School, N. Chicago, IL.

PKC is activated by nerve growth factor (NGF), phorbol esters (PMA), and the macrocylic lactone bryostatin (BRY) but is not required for the generation of neurites in PC12 cells. We have characterized the response of PKC isozymes to various agents using isotype specific antibodies directed against peptide determinants of PKC α, β_{II}, and γ. Western blots have shown that all three isozymes are present in significant amounts in the cytosol of control cells with α the most abundunt. After acute treatment with NGF, PKC α and β_{II} levels remain unchanged but immunoreactive PKC γ rapidly disappears from all cellular fractions and then recovers by 1-2 h. We are currently investigating the mechanism of this loss. Chronic down regulation by PMA or BRY leads to rapid loss of PKC α and β_{II}, but PKC γ persists even at 24 h. Activity measurements have shown that the cytosolic PKC activity increases after NGF treatment and that PMA or BRY shift PKC activity toward the membrane fraction. The activities for individual PKC isozymes are being measured. We conclude that isozymes of PKC respond quite differently to NGF and that modulation of PKC γ may be important in regulating cellular response to extracellular stimulation. A basis for the differential effect of PMA and BRY on NGF-induced neuritogenesis has not yet been established. (Supported by NIH grants NS24380, GM43186, and AM07319)

445.20

REGULATION OF NERVE GROWTH FACTOR BY ENDOGENOUS OPIOID PEPTIDES. J.P.Schwartz and K.Mitsuo*. Clin.Neurosci.Br., NINDS, NIH, Bethesda MD 20892.

Daily treatment of newborn rats with 50 mg/kg naltrexone (NLT) for 21 days results in increased brain weight and numbers of neurons, neuronal processes, and glia in cortex, cerebellum(CB) and hippocampus(HC) [Zagon & McLaughlin, Science 221: 1179(1983), Dev.Br.Res. 28:233(1986)]. Astrocytes express the proenkephalin gene with processing of the precursor to free enkephalins high from embryonic day 20 to postnatal day 3 and then decreasing significantly, suggesting the possibility that astrocyte-derived enkephalins might play a trophic role early in CNS development. We have used the NLT model as a way to manipulate the effects of endogenous opioids on CNS development in vivo. Since nerve growth factor (NGF) is involved in CNS development, NGF was assayed in 3 brain regions after 1 or 2 wks of NLT. NLT led to a decrease of NGF content, measured by a 2-site ELISA, in striatum(ST) and HC, with no effect on CB NGF. In contrast, astrocyte cultures from CB or ST of NLT-treated rats contained increased levels of NGF, while HC astrocytes were unchanged. Opiate receptor binding assays are underway to determine whether NLT acts directly on astrocytes or indirectly via another mediator.

RETROGRADE TRANSPORT OF BDNF AND NT-3 BY SPINAL MOTONEURONS Q.Yan, K.Gray*, J.Sun*, C.Farrell, D.Patel*, R.Rosenfeld*, J.Talvenheimo*, G.Pierce*, J.Miller* Amgen, Inc., Amgen Center, Thousand Oaks, CA 91320

It has been shown that spinal motoneurons express NGF receptors, which can bind, internalize and retrogradely transport NGF (Yan et al., Neuron 1:335-343). Here we examined whether these spinal motoneurons could also specifically retrograde transport BDNF and NT-3, two new members of NGF family.

Recombinant BDNF, NT-3 and cytochrome c were iodinated by lactoperoxidase. ^{125}I-BDNF and ^{125}I-NT-3 retained their full biological activities on the chick DRG explant assay. Foot pads of postnatal day-3 rats were injected with 2.2 x 10^6 cpm in 2-3 μl PBS (n=4) and animals were perfusion fixed after 14 hrs. The lumbosacral spinal vertebral columns were dissected out, processed for either cross or horizontal paraffin sections and emulsion autoradiography. Heavy labeling was found in ipsilateral but not contralateral L4-6 DRG neurons and L4-6 spinal ventrolateral motoneurons of animals injected with either ^{125}I-BDNF or ^{125}I-NT-3. The labeling was on neuronal cell bodies and could be completely blocked with co-injection of excess unlabeled homologous ligand. ^{125}I-cytochrome c with same amount radioactivity was not transported. It is clear that the spinal motoneurons express BDNF and NT-3 receptors which are capable of mediating the retrograde transport of the ligands. These results suggest that BDNF and NT-3 should be evaluated for their potential neurotrophic activities on spinal motoneurons.

446.2

CILIARY NEURONOTROPHIC FACTOR (CNTF) EFFECTS ON RAT SPINAL CORD NEURONS IN VITRO: SURVIVAL AND EXPRESSION OF CHOLINE ACETYLTRANSFERASE AND LOW-AFFINITY NGF RECEPTORS. E. Magal, P. Burnham, S. Varon. Dept. Biol., Univ. Calif. San Diego, La Jolla, CA 92093.

CNTF promotes the survival of a variety of neuronal cell types, induces cholinergic properties in sympathetic neurons and differentiation of O-2A progenitor cells into type-2 astrocytes. We have studied the effects of CNTF and NGF on E14 rat spinal cord cultures. After 7 days of treatments with CNTF (human recombinant or purified from rat sciatic nerve; 100 TU/ml) an increase was seen in: i) the number of neurons not stained with choline acetyltransferase (ChAT) or low affinity nerve growth factor receptor (LNGFR) antibodies (identified by immunostaining for neurofilament and neuron-specific enolase); ii) the number of α-motoneurons (0.5% of the total neuronal population), identified by their size (>25 μm), morphology and ChAT and LNGFR-immunoreactivity, and iii) a population of small- to medium- sized (< 25 μm), ChAT- and LNGFR-positive neurons, representing 5-10% of the total neuronal population. Delayed administration of CNTF revealed that the ChAT/LNGFR-negative neurons and α-motoneurons were dependent on CNTF for their survival. In contrast, the small ChAT/LNGFR-positive neurons were not dependent on CNTF for survival, but were induced by CNTF to express these two markers. These observations suggest that CNTF is a neuronotrophic factor for α-motoneurons and a large unidentified population of spinal cord neurons, as well as a regulator of ChAT and LNGFR expression for some neurons of the fetal spinal cord. This latter regulatory role was also observed for a small number of neurons cultured from various other brain areas. Supported by NINCDS grants NS16349 and NS27047.

446.3

EFFECTS OF CNTF ON RAT SENSORY AND MOTOR NEURONS IN-VIVO. S. C. Apfel, J. C. Arezzo, M. Litwak, M. E. Moran*, and J. A. Kessler, Albert Einstein College of Medicine, Bronx, N.Y. 10461

We investigated the effects of daily administration of human recombinant ciliary neuronotrophic factor (CNTF) on rat motor and sensory neurons. CNTF has previously been shown to promote survival and physiological differentiation of a variety of neuronal populations in-vitro. We administered CNTF subcutaneously to adult Sprague Dawley rats in doses of 0.25 μg/g and 0.12 μg/g daily for two consecutive weeks and the buffer vehicle to control animals using the same schedule. We obtained baseline recordings from the caudal nerve of motor and sensory action potential amplitudes and conduction velocities in all our groups prior to initiating treatment with CNTF or placebo. After the fourteenth day of treatment, we repeated the electrophysiological measurements in all three groups. There were no significant changes of any electrophysiological measurements in the control group from baseline measurements. Administration of low dose CNTF significantly increased sensory conduction velocity ($p < 0.0001$), sensory amplitude ($p < 0.0001$), and motor conduction velocity ($p = 0.001$) as compared to baseline values. It did not significantly effect motor amplitudes. High dose CNTF significantly increased sensory conduction velocity ($p = 0.0001$) and sensory amplitude ($p = 0.01$). High dose CNTF did not significantly effect motor conduction velocity of amplitude. We also examined levels of endogenous neuropeptides in the dorsal root ganglia after the animals were sacrificed. Administration of CNTF at both high and low doses significantly increased levels of substance P ($p = 0.002$ and $p = 0.02$ respectively). Levels of calcitonin gene related peptide and met enkephalin were not changed significantly from control values. This data suggests that CNTF might improve peripheral nerve function in adult rats.

446.4

DOWN-REGULATION OF CNTF mRNA DURING PERIPHERAL NERVE DEGENERATION. N. Seniuk, M. Altares, R.J. Dunn, and P.M. Richardson. McGill University & Montreal General Hospital, Montreal, Canada.

The mRNA encoding CNTF (ciliary neurotrophic factor) has been assayed in rat sciatic nerves by an RNase protection assay at various time intervals after nerve transection or crush. Within one week of sciatic nerve transection, the concentration of CNTF mRNA in the distal nerve stump has fallen at least eightfold. Four weeks after injury, the concentration of CNTF mRNA remains low in cut nerves, but has recovered towards normal in crushed nerves. These results are compatible with earlier observations of a decrease in ciliary neurotrophic bioactivity during Wallerian degeneration (Brain Res 246, 57, 1982). CNTF mRNA has been localized by in situ hybridization to non-neuronal cells in the peripheral nerve. Expression of the gene for CNTF, like those of several myelin proteins, is regulated directly or indirectly by axonal signals.

446.5

DEVELOPMENTAL REGULATION OF KAINIC ACID-INDUCED ELEVATIONS OF BDNF mRNA LEVELS. M. Dugich-Djordjevic, P.A. Lapchak, G. Tocco, I. Najm, M. Baudry, R.F. Thompson, and F. Hefti. Andrus Gerontology Center and Dept. of Biological Sciences, U.S.C., Los Angeles, CA.

Recent studies have shown that hippocampal and cortical BDNF mRNA levels are increased in response to electrolytically induced limbic seizures and kainic acid (KA)-induced seizures in adult rats. We examined the regional and cellular distributions and the time course of BDNF mRNA expression in the hippocampus during postnatal development after KA-induced seizure activity using quantitative in situ hybridization techniques with a 460bp rat BDNF cDNA. KA-induced seizures resulted in large increases in BDNF mRNA levels in all hippocampal layers and in the cortex only in 21d, 25d old and adult rats. No increases were evident at P8, despite massive behavioral seizures of these rats. At P13, a modest elevation occurred only in the dentate gyrus and the CA3 field, whereas the other hippocampal fields and the cortical areas remained unchanged. There were pronounced variations in the time course and extent of BDNF mRNA elevations among the hippocampal and cortical areas at various developmental stages. Furthermore, labeling patterns visualized with emulsion autoradiography differed among regions and developmental stages. In particular, while KA induced a uniform elevation of grain density in the dentate gyrus at P13, a subset of cells within the granular layer showed a much higher grain density than adjacent cells in this layer at P21 to P60. These findings indicate that the regulation of BDNF mRNA expression in the hippocampus after KA-induced seizures is dependent upon developmental stage and cell type. Furthermore, the absence of BDNF mRNA induction during early postnatal development despite massive seizures indicates that elevation of neuronal activity is not sufficient for BDNF mRNA induction.

446.6

MOLECULAR CLONING OF NERVE GROWTH FACTORS FROM THE CHICKEN EMBRYO. A. Bäckström*, F. Hallböök, A. Kylberg*, C. Bark , D. Larhammar (§), H. Persson (#) and T.Ebendal. Department of Developmental Biology, and Department of Medical Genetics (§), Uppsala University, Biomedical Center, S-751 23 Uppsala, and Department of Medical Chemistry, Laboratory of Molecular Neurobiology (#), Karolinska Institute, Stockholm, Sweden.

The chicken embryo offers an accessible system for examining early developmental effects by neurotrophic factors. Hitherto, only the βNGF gene has been cloned from the chicken (Ebendal et al., 1986, EMBO J. 5: 1483-1487) and its appearance described during development. We now present approaches for molecular characterization also of chicken NT-3, BDNF and CNTF in the chicken.

Representative cDNA libraries from different stages and organs of the chicken embryo were prepared. DNA fragments corresponding to part of the chicken BDNF and NT-3 obtained by the PCR technique using genomic chicken DNA as template and degenerate primers covering highly conserved regions of the NGF family, were used to isolate cDNA from the λZAPII libraries. A clone encoding chicken NT-3 was obtained from an E3 embryo library and is presently sequenced in order to extend the sequence outside the PCR fragment used for screening. Specific antisense oligonucleotides were also used for *in situ* hybridization of NT-3 and BDNF in the chicken embryo.

In order to isolate the chicken CNTF we have synthesized both PCR primers and long oligonucleotides suggested by the available sequence data from mammalian CNTFs. A cDNA library prepared from the E18 chicken choroid, a rich source for the CNTF, was screened. Positive clones are now being sequenced in order to verify their identity.

446.7

REGULATION OF CNTF mRNA LEVELS IN RAT BRAIN CULTURES. P. Carroll*, M. Sendtner and H. Thoenen. Dept. Neurochemistry, Max Planck Inst. for Psychiatry, Am Klopferspitz 18a, 8033 Planegg, Germany.

CNTF (ciliary neurotrophic factor) is a 22 kDa molecule which has been shown to have survival and differentiation activities for specific populations of nerve cells in vitro as well as being involved in the in vitro differentiation of O-2A glial precursors to type 2 astrocytes in the rat optic nerve. Application of purified CNTF to axotomised newborn rat facial nerve rescues neurons which would normally die under these conditions. CNTF mRNA and protein are found post-natally in the developing rat optic and sciatic nerves where the protein is found in a sub-population of type I astrocytes and in Schwann cells, respectively. In order to identify factors which may be involved in the regulation of CNTF expression in vivo we have examined CNTF mRNA expression in 2-3 week-old cultures of newborn rat brain cells which contained predominantly astrocytes.

Northern blots were performed on total RNA isolated form primary cultures of rat brain cells. CNTF mRNA is found in relatively high amounts (1 pg/μg total RNA) in these cultures. Variations in culture conditions and treatment with a variety of cytokines and growth factors were used in attempts to alter CNTF mRNA levels. Rat IFN-gamma caused a 2-3 fold increase after 24 hrs. The adenylate cyclase agonist forskolin (10 μM) and the beta-adrenergic agonist isoproterenol (10 μM) down-regulated CNTF mRNA to almost undetectable levels after 24 hours suggesting an involvement of the cAMP second messenger system in the regulation of the CNTF gene. bFGF (20ng/ml) also down-regulated CNTF mRNA over the same time-scale. The effect of bFGF on CNTF mRNA levels is interesting in view of the proliferative and anti-differentiating effects of bFGF on O-2A precursor cells in optic nerve cultures.

446.8

CILIARY NEURONOTROPHIC FACTOR (CNTF) PREVENTS NEURONAL DEGENERATION AND INDUCES NGF RECEPTORS IN THE INJURED ADULT RAT BRAIN; COMPARISON WITH NGF. T. Hagg and S. Varon Dept. of Biology 0601, University of California San Diego, La Jolla, CA 92093

Recombinant human CNTF or purified mouse nerve growth factor (NGF) were infused intraventricularly for 2 weeks in unilaterally fimbria-fornix transected adult rats. NGF prevented the axotomy-induced disappearance of ipsilateral medial septum neurons immunoreactive for choline acetyltransferase (ChAT) and low affinity NGF receptor (LNGFR) and induced their sprouting, maintained their cell body size but had no effect on the substantial loss of the more numerous non-cholinergic neurons. CNTF prevented the lesion-induced disappearance of almost all (cholinergic and non-cholinergic) medial septum neurons. CNTF prevented the reductions of LNGFR and size of cholinergic medial septum neurons, but not the reductions of ChAT. CNTF also induced the appearance or increase of LNGFR-staining in cholinergic neostriatum neurons, lateral septum neurons and non-neuronal cells of the lesioned corpus callosum. In contrast to NGF, CNTF did not cause hypertrophy of septal or neostriatal cholinergic neurons or sprouting of LNGFR-positive fibers in the septum. Thus, CNTF: i) has a general trophic action, i.e. can prevent degeneration of several types of injured adult medial septum neurons, ii) is involved in regulation of LNGFR expression in several (but not all) types of neurons and at least one type of non-neuronal cell, iii) does not stimulate ChAT in the neurons (suggesting also different mechanisms for the regulation of ChAT and NGFR), and iv) does not appear to have neurite-promoting activities. Support: NINCDS grant NS-16349 and 27047.

TROPHIC ACTIONS OF BDNF ON DOPAMINERGIC NEURONS IN VITRO: EXPRESSION OF CELL-SPECIFIC PROTEINS AND ACCELERATED RECOVERY FROM MPP^+ TOXICITY. Klaus D. Beck, Beat Knüsel and Franz Hefti. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089-0191.

Trophic effects of BDNF on nigral dopaminergic neurons in vitro were reported recently (Knüsel et al. 1991, PNAS 88:961; Hyman et al. 1991, Nature 350:230). To further characterize these effects we used our cell culture system of fetal rat ventral mesencephalic cells. Exposure to 100ng/ml BDNF for 7 days in vitro increased the number of tyrosine hydroxylase (TH)-positive cells by 35%. Dopamine (DA) uptake was increased by 100%, whereas TH activity showed only a slight increase, indicating differential responses of parameters reflecting dopaminergic functions. Further experiments will determine whether BDNF stimulates TH mRNA expression.

The highly specific toxin for dopaminergic neurons, MPP^+ (Michel et al. 1989, J. Pharmacol. Exp. Ther. 248:842) was used to study possible protective effects of BDNF. Immediately after termination of the MPP+ treatment, DA uptake in BDNF-treated cultures was reduced to the same level as in MPP+-treated cultures not exposed to BDNF. However, after a recovery period of 3 additional days without growth factors or toxin, DA uptake was higher in cultures pretreated with BDNF. This protection was maximal at MPP^+ concentrations which led to a 30-50% decrease of DA uptake under control conditions. These findings suggest that BDNF accelerates the recovery of dopaminergic neurons from MPP^+ toxicity.

446.10

EXPRESSION OF BDNF AND TYPE II CALCIUM-CALMODULIN DEPENDENT PROTEIN KINASE mRNA IN THE HIPPOCAMPUS OF POSTMORTEM ALZHEIMER'S AND CONTROL TISSUE. K.D. Murray*, C.M. Gall, E.G. Jones and P.J. Isackson. Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

We have used in situ hybridization with ^{35}S-labeled cRNA probes to examine the expression of mRNAs for brain derived neurotrophic factor (BDNF) and type II calcium-calmodulin dependent protein kinase (CAM II kinase) in the hippocampus of control human and Alzheimer's disease tissue. Like nerve growth factor, BDNF, has been shown to be expressed in the hippocampus and neocortex and may provide trophic support for projecting cholinergic neurons of the basal forebrain which degenerate in Alzheimer's disease. In hippocampus, BDNF mRNA was predominantly localized in the dentate gyrus granule cell layer and the pyramidal cell layer of region CA3. In a comparison of tissue sections from 4 Alzheimer's and 4 age-matched control cases, there were no differences in the localization or level of expression of BDNF mRNA in hippocampus. CAM II kinase mRNA is normally present in the same cell layers as BDNF mRNA but at much higher levels. CAM II kinase mRNA was reproducibly increased in the pyramidal cell layer of region CA3 in Alzheimer's disease tissue. In view of previous results demonstrating increased CAM II kinase mRNA expression in monocularly deprived columns of adult monkey visual cortex (Benson et al., *J. Neurosci.* 11,31), these results suggest that the CA3 pyramidal cells receive reduced afferent input or decreased trophic support in Alzheimer's disease. (Supported by NIH grants AG00538 and MH 44188)

AUTORADIOGRAPHIC ANALYSIS OF NEUROTROPHIN-3 (NT-3) RECEPTOR BINDING IN ADULT RAT BRAIN Ai Shih*, E. Escandon, L E. Burton, H.S. Phillips, J. W. Winslow Departments of Developmental Biology and Process Development, Genentech, Inc., S.S.F., CA 94080.

Neurotrophin-3 (NT-3) is a structural homolog of NGF which displays a restricted pattern of mRNA expression in adult rat brain, confined mainly to hippocampus. To reveal possible targets of NT-3 trophic activity within mammalian brain, receptor binding autoradiography was performed with purified, recombinant human ^{125}I NT-3 labelled by the lactoperoxidase method. Approximately 2 moles of ^{125}I was incorporated per mole NT-3 homodimer, and ^{125}I NT-3 retained full biological activity as measured by chick embryonic nodose ganglion and sympathetic ganglion neuron survival assays. The pattern of specific binding of ^{125}I NT-3 was compared with that of ^{125}I NGF and displayed a broader distribution within one month old rat brain. Specific binding of 30 pM ^{125}I NT-3 was observed in cerebellum and telencephalic sites, particularly hippocampus. Binding was blocked by increasing concentrations of unlabelled NT-3 but not by equivalent concentrations of NGF. These results suggest possible targets of NT-3 trophic activity within mammalian brain.

AXONAL TRANSPORT OF [^{125}I]-LABELED NEUROTROPHINS IN THE CENTRAL NERVOUS SYSTEM. S.J. Wiegand, C. Alexander*, R.M. Lindsay and P.S. DiStefano. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

The mRNA's for the three known neurotrophins (NGF, BDNF and NT-3) are differentially distributed within the mammalian CNS. Therefore, it is expected that at least some neuronal populations responsive to BDNF and NT-3 will be found to be distinct from those which respond to NGF. The prototypic neurotrophin, NGF, is a survival factor for the cholinergic neurons of the basal forebrain and it is retrogradely transported by these cells. This suggests that studies of axonal transport of BDNF and NT-3 might prove useful in identifying neuronal populations potentially responsive to these related trophic molecules. [^{125}I]-BDNF, -NGF and -NT-3 (~0.6-1.5 μCi in 0.2-0.5 μl) were injected into the hippocampus or striatum of adult, male rats. Sections processed for autoradiography showed robust transport of NGF from the hippocampus to the medial septum and the diagonal band; transport of BDNF and NT-3 to these cholinergic nuclei was also evident, though less marked. All 3 neurotrophins were transported to the ventral mesecephalon from the striatum. However, the distribution for BDNF and NT-3 was distinct from that seen for NGF. Furthermore, BDNF and, to a lesser extent, NT-3 were transported within several additional telencephalic and diencephalic cell groups which did not transport NGF. Neuronal populations which selectively transport BDNF and/or NT-3 may respond specifically to these members of the neurotrophin family under normal or pathological conditions.

446.13

RETROGRADE AXONAL TRANSPORT OF [^{125}I]-LABELED NEUROTROPHINS IN PERIPHERAL NEURONS. P.S. DiStefano, B. Friedman, S.J. Wiegand and R.M. Lindsay. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

NGF is the prototype of target-derived neurotrophic factors. Endogenous, or exogenously administered NGF is internalized by responsive neurons and is retrogradely transported to the cell body where it exerts its actions by unknown mechanisms. Two recently described members of the neurotrophin family, BDNF and NT-3, were examined for their ability to be retrogradely transported in sensory, sympathetic and motor neurons. ^{125}I-NGF, -BDNF and -NT-3 used in transport studies exhibited activities in chick DRG bioassays that were equivalent to those of unlabeled neurotrophins. When injected into the crushed sciatic nerve in adult rats, ^{125}I-BDNF, -NT-3 and -NGF were specifically transported to the ipsilateral L4 and L5 DRG. Transport was blocked by the addition of excess, unlabeled homologous neurotrophin; however, transport was not completely blocked by the co-injection of heterologous neurotrophin. When injected into the anterior chamber of the eye, ^{125}I-NGF transport was evident in sympathetic neurons which supply the iris muscle, but negligible transport to sympathetic neurons was seen with radioiodinated BDNF or NT-3. These experiments provide a framework for further studies of subsets of peripheral neurons which may respond to various neurotrophins by selectively transporting these factors in a retrograde fashion.

446.14

DISTRIBUTION OF CNTF AND ITS RECEPTOR IN THE CNS AND PNS. N.Y. Ip, B. Friedman, J. McClain*, P. Masiakowski, S. Davis, M.E. Furth, S. Wiegand and G.D. Yancopoulos. Regeneron Pharmaceuticals, 777 Old Saw Mill River Road, Tarrytown, New York, 10591.

Initially identified as a neurotrophic activity that supports survival of parasympathetic neurons *in vitro*, ciliary neurotrophic factor (CNTF) has recently been shown to promote survival of motor neurons *in vivo* (Sendtner et al., 1990. Nature 345: 440-441; Oppenheim et al., 1991. Science 251:1616-1618). We have examined the distribution of CNTF message and protein *in vivo* in adult rats. The abundant CNTF message found in sciatic nerve by northern analysis was localized to Schwann cells by *in situ* hybridization. Immunocytochemical staining of CNTF with a polyclonal antibody showed that the CNTF protein was also restricted to Schwann cells in the peripheral nerve. In the CNS, northern analysis has demonstrated significant CNTF message in spinal cord, midbrain, hindbrain, brainstem and olfactory bulb. Preliminary immunocytochemical studies showed that CNTF can be localized to neuronal elements, as subsets of olfactory receptor axons are densely stained. We have recently cloned the rat CNTF receptor (CNTFR) by screening the rat brain cDNA library with a human CNTFR probe (Davis et al., in preparation). The rat CNTFR is extremely well conserved compared to its human counterpart. Studies with northern analysis showed that CNTFR mRNA is widely distributed throughout the brain. This result is corroborated by *in situ* analysis which has revealed that significant levels of CNTFR mRNA are found in cerebellum, olfactory bulb, and thalamus.

446.15

INJURY-INDUCED REGULATION OF NEUROTROPHIC FACTOR mRNA IN ADULT RAT BRAIN. J. S. Rudge, J. K. Morse, S. J. Wiegand and N. Y. Ip Regeneron Pharmaceuticals, 777 Old Saw Mill River Road, Tarrytown, New York 10591.

Mechanical injury to the adult rat brain results in the accumulation of neurotrophic activity for cultured parasympathetic, sympathetic and sensory neurons at the lesion site (Nieto-Sampedro et al, 1983. J. Neurosci. 3: 2219-2229). In order to determine which neurotrophic factors are responsible for this activity, we have measured changes in the levels of mRNA by northern analysis for Ciliary Neurotrophic Factor - CNTF, Brain Derived Neurotrophic Factor - BDNF and Neurotrophin 3 - NT3 in tissue samples taken from brain areas both adjacent and distant to the site of an aspirative lesion of the dorsal hippocampus and overlying cortex. We find that in the normal adult rat hippocampus and cortex, CNTF mRNA levels are relatively low but this increases dramatically after lesion by as much as 7 fold compared to sham operated controls. Areas distant from the lesion site show no increase in CNTF mRNA unless they are directly interconnected to the ablated areas, such as the regions of the contralateral cortex and hippocampus where mRNA levels are as high as at the wound site. In contrast, mRNA levels for the neurotrophins BDNF and NT3 were relatively high in normal adult hippocampus but fell by 2-3 fold after lesion both contralaterally and adjacent to the wound.

446.16

CHARACTERIZATION OF RECEPTORS FOR CILIARY NEUROTROPHIC FACTOR ON CULTURED RAT HIPPOCAMPAL ASTROCYTES. R. F. Alderson, Y. You*, E. Pasnikowski*, S. Davis, N. Panayotatos, G. D. Yancopoulos, J. Rudge and R. M. Lindsay. Regeneron Pharmaceuticals Inc., Tarrytown, NY 10591.

Rat ciliary neurotrophic factor (CNTF) has recently been molecularly cloned, purified to homogeneity and biologically characterized (Panayotatos et al,1991). Binding studies with [^{125} I]-CNTF on monolayer cultures of purified rat hippocampal astrocytes demonstrates equilibrium binding to be reached following a 60 min incubation period at room temperature and to remain stable up to at least 120 min. Scatchard analysis suggest that the [^{125} I]-CNTF binding is conferred through two sites. Experiments to biochemically characterize the ligand binding component of the CNTF receptor demonstrate a loss of specific [^{125} I]-CNTF binding following exposure (60 min at 37°C) to purified preparations of phospholipase C suggesting that a glycosyl-phosphatidylinositol anchor is involved in the attachment of the CNTF binding component to the plasma membrane. In addition to investigating potential second messenger mechanisms which may be activated as a consequence of the interaction of CNTF with its receptor, we have observed the induction of the messenger RNA for the immediate early gene c-fos. Time course studies demonstrate that a maximal increase in the c-fos mRNA occurs approximately 1 hour following a challenge with 50 ng/ml CNTF.

446.17

REDUCTION OF CNTF LEVELS IN SCHWANN CELLS IN DEGENERATING SCIATIC NERVE. B. Friedman, N.Y. Ip, M.E. Helgren, J. Rudge, T. Rakowski, L. Fu, D. Morissey, S.J. Wiegand, R.M. Lindsay. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

The adult rat sciatic nerve is a rich source of CNTF (ciliary neurotrophic factor). Immunocytochemical staining indicates that most of the CNTF is present in Schwann cells. To determine if the integrity of Schwann cell-axon contact is a prerequisite for high levels of CNTF expression, we have examined CNTF levels in degenerating and regenerating peripheral nerve. In adult rats, the sciatic nerve was transected and then examined histologically at a series of survival times from 1 day to two weeks. A second series of rats were prepared where the sciatic was crushed and examined after two week survival times. CNTF levels were assessed immunocytochemically with a polyclonal antibody generated against recombinant rat CNTF. CNTF mRNA was identified with in situ hybridization. Schwann cells in the **proximal stump** of a transected sciatic nerve remain densely stained by anti-CNTF antibody and continue to express message for CNTF. However, by one week post-transection, the Schwann cells in the degenerating **distal stump** lose most of their CNTF immunoreactivity and CNTF message is barely detectable. When axons are allowed to regenerate distal to a nerve crush then Schwann cells re-express CNTF protein. These results suggest that Schwann cell expression of CNTF is maintained by signal(s) from related axons and/or by the maturational state of the Schwann cell.

446.18

MOLECULAR CLONING OF THE RECEPTOR FOR CILIARY NEUROTROPHIC FACTOR. S. Davis, T. H. Aldrich, D. Valenzuela, M. E. Furth, V. Wong, S. P. Squinto, and G. D. Yancopoulos. Regeneron Pharmaceuticals, Inc., 777 Old Saw Mill River Road, Tarrytown, New York 10591.

Although neurotrophic factors were originally discovered based on their ability to support neuronal survival, these molecules are thought to be important in a variety of processes involved in the development and maintenance of the nervous system. Defining the receptors for neurotrophic factors should aid in identifying the cells on which they act, as well as in understanding the mechanisms of their actions. We developed a novel "tagged ligand panning" procedure to clone a receptor for ciliary neurotrophic factor (CNTF). Cross-linking studies reveal that CNTF-responsive neurons and neuronal cell lines express a CNTF-binding protein with the same molecular weight as the cloned receptor expressed in heterologous cells. In vivo, this receptor is expressed almost exclusively within the nervous system. This receptor has a structure unrelated to the receptors utilized by the NGF-family of neurotrophic molecules, but instead displays intriguing analogies with the receptor for a cytokine, interleukin-6 (IL-6). Structural as well as other similarities suggest that the CNTF receptor, like the IL-6 receptor, requires a second, signal transducing component. In contrast with the IL-6 receptor, the CNTF receptor is anchored to cell membranes via a glycosyl-phosphatidylinositol (GPI) linkage, raising important questions concerning the regulation and release of the membrane bound form of this receptor.

EXPRESSION OF NEUROTROPHIC FACTORS IN THE AXOTOMIZED FACIAL NERVE SYSTEM. W. Tetzlaff and K. C. Harrington*, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada, T2N 4N1.

Following axotomy CNS neurons undergo significant cellular atrophy and cell death, whereas PNS neurons usually survive disconnection from their targets and do not show atrophy until later stages post lesion. It is generally believed that this is due to differences in the availability of trophic factors. For motoneurons trophic support may come from the peripheral nerve and/or from the neuronal microenvironment with its reactive glial cells. We have tested these possibilities by using Reverse Transcription followed by Polymerase Chain Reaction amplification to study the expression of CNTF, bFGF and several other trophic factors in i) the normal facial nerve ii) the distal nerve stump after transection iii) the normal and iv) axotomized facial nucleus. Our preliminary results indicate increased expression of CNTF mRNA in the axotomized facial nucleus while the expression is reduced in the distal nerve stump (compared to normal nerve). bFGF mRNA was increased in the axotomized facial nucleus, but not detected in the peripheral nerve (both normal and distal stump).

These data suggest that the neuronal microenvironment may provide trophic support to the axotomized facial motoneurons. *In situ* hybridization analysis is under way to determine the cellular source within the facial nucleus.

A NEUROBLASTOMA CELL LINE REGULATES VIP GENE EXPRESSION IN RESPONSE TO CNTF Aviva J. Symes, Steven E. Hyman and J. Stephen Fink *Molecular Neurobiology Laboratory, Massachusetts General Hospital, Harvard Medical School, Charlestown, MA 02129.*

Ciliary neurotrophic factor (CNTF) was originally identified as a survival factor for embryonic neurons of the chick ciliary ganglion. CNTF has also been shown to promote the differentiation of cultured sympathetic neurons towards the cholinergic phenotype, inducing choline acetyltransferase activity and peptides including vasoactive intestinal peptide (VIP). We sought to determine whether CNTF would regulate expression of VIP in a neuronal cell line. CNTF treatment of the VIPergic human neuroblastoma cell line NBFL increased VIP mRNA levels 30-fold at 3 days. CNTF induction of VIP mRNA was detectable after 1 day of treatment and was sustained for at least 11 days. NGF treatment has no independent effect on VIP mRNA in NBFL cells but may enhance the effect of CNTF. Using VIP promoter-luciferase fusion genes we demonstrated that the effect of CNTF on VIP mRNA in NBFL cells is at least partially transcriptional. Two kb of 5' flanking region of the human VIP gene was sufficient to confer CNTF responsiveness to these fusion genes, increasing luciferase activity 20-fold in CNTF-treated, transfected NBFL cells. However, a deletion which yielded a still active promoter was unresponsive to CNTF. The CNTF-responsive NBFL cell line will enable further investigation of the molecular mechanisms by which CNTF, through alterations in gene expression, promotes neuronal differentiation.

CLONING AND EXPRESSION OF GROWTH-PROMOTING ACTIVITY (GPA), A CILIARY NEUROTROPHIC FACTOR ISOLATED FROM FROM ADULT CHICK SCIATIC NERVES AND EMBRYONIC CHICK EYES. Parent, A.S., Cachianes, G.*, Lee, A.*, Leung, D.W.*, Nikolics, K., Eckenstein, F. P., and Nishi, R., Dept. of Cell Biol. & Anat., Oregon Health Sciences University, Portland, OR 97210 and Dept. of Mol. Biol., Genentech, Inc., 460 Point San Bruno, So. San Francisco, CA 94080

Neurons in the chick ciliary ganglion (CG) undergo a defined period of cell death, and it has been postulated that the survival and development of CG neurons is regulated by a target-derived trophic factor. We have previously purified and characterized the biological activity of growth promoting activity (GPA) from adult chicken sciatic nerves. We have also found that a similar protein can be purified from embryonic chick eyes, the source of all target tissues for CG neurons. Based upon partial amino acid sequence obtained from 3 peptide fragments of the purified protein we designed three oligonucleotide probes. We used these probes to screen a cDNA library derived from embryonic day 15 chick eyes. A 1453 bp GPA cDNA clone was isolated which shows approximately 45% homology with mammalian sciatic nerve ciliary neurotrophic factor (CNTF). This relatively low degree of homology for a potent neurotrophic factor (ED50= 50pg/ml) suggests that GPA may be a homologue of CNTF, and not merely the chicken version of CNTF. GPA, like CNTF, does not seem to contain a signal sequence; however, evidence from our laboratory indicates that GPA is secreted by cells in culture derived from the choroid layer of the eye, which is one of the targets of CG neurons *in vivo*(see Coulombe et al, this meeting). In order to test whether GPA is a neurotrophic factor *in vivo* for CG neurons, and to determine the relationship between GPA and CNTF, we are examining the developmental- and cell-specific gene expression of the GPA gene, using northern analysis and *in situ* hybridization. We are also expressing a recombinant GPA to examine the *in vitro* and the *in vivo* activity of the protein. **Supported by NS25767 (RN) and AG07424 (FPE).**

Evidence for Target Cell Secretion of Survival and Differentiation Factors for Ciliary Ganglion Neurons.
James N. Coulombe, Rae Nishi, and Felix P. Eckenstein
Department of Cell Biology and Anatomy
Oregon Health Sciences University, Portland OR 97201

The recent purification and cloning of several factors which influence the survival and differentiation of embryonic neurons in culture has provided the curious observation that some of these factors lack the signal sequence normally associated with secretion. This observation has initiated controversy over the potential roles of these factors in vivo. We have established long-term cultures of cells from the choroid layer, a target tissue innervated by chick ciliary ganglion neurons. Conditioned medium (CM) from these cultures contains at least two biochemically separable factors: one which supports the survival and growth of ciliary ganglion neurons in culture (Growth Promoting Activity, GPA), and another which supports expression of the neuropeptide somatostatin (Somatostatin Stimulating Activity, SSA). To examine whether these factors are secreted into the culture medium or are instead released by cell lysis, we allowed choroid cells to condition medium for 24 hours before removing the CM and lysing the choroid cells. We then compared the amounts of GPA and SSA present in CM and cell lysate. As a measure of cell lysis we compared the amounts of activity of a ubiquitous cytoplasmic enzyme lactate dehydrogenase (LDH) present in CM versus cell lysate. CM contained less than 5% of the LDH activity present in the cell lysate indicating that little lysis occurred during the conditioning period. GPA was distributed about equally between the CM and cell lysate, suggesting that it is a secreted factor. The GPA present in CM was not due to a fibroblast growth factor since very little heparin-binding mitogenic activity was present in the CM. SSA in contrast was only found in CM and was not detectable in the cell lysate, suggesting that it is a secreted factor which may require activation upon release. These observations suggest that both GPA and SSA are secreted from target cells and therefore may serve as neurotrophic factors during development. *Supported by EY06178 (JNC), NS25767 (RN), AG07424 (FE).*

STRUCTURE-ACTIVITY STUDIES OF HUMAN CILIARY NEURONOTROPHIC FACTOR (CNTF) USING MUTAGENESIS. L. Callegaro*, V. Corsa*, G. Corona*, S.D. Skaper# and A. Negro. Advanced Technology Division and #Fidia Research Laboratories - FIDIA S.p.A., 35031 Abano Terme, Italy.

CNTF promotes the survival and/or differentiation of a variety of neuronal cell populations in vitro, and reportedly prevents lesion-induced degeneration of motoneurons within the facial nucleus of the neonatal rat. We have recently described the production and purification of recombinant human CNTF (Negro et al., 1991). A structural analysis of the CNTF molecule is critical to an understanding of its mode of action. Here we have utilized the Bal31 system and polymerase chain reaction to obtain mutant human CNTFs. Mutant CNTF DNA constructs were expressed in E.coli. The resultant CNTF proteins were isolated by SDS-PAGE, eluted and assayed for trophic activity on CNTF responsive ganglionic neurons. Several mutations directed at the hydrophobic core region of the protein yielded marked losses in biological activity. These findings are consistent with the observed alpha-helical nature of CNTF, and indicate that retention of this conformation is necessary for activity. Purification of these mutant human CNTFs now in progress will provide the material needed to accurately determine the 3-D structure of this trophic factor.

NUTRITIONAL CONTROL OF THE EXPRESSION OF EXERCISE-INDUCED GROWTH IN MATURE HAMSTERS. K.T.Borer, J.-O.Jansson*, C.A. CONN, and O.P.G.ISAKSSON.* Dept.of Movement Sci.,Univ. of Michigan,Ann Arbor,MI 48109 and Dept.of Physiology,Univ.of Göteborg,Göteborg,Sweden.

Voluntary running accelerates somatic growth in mature hamsters. When food restricted,exercising hamsters fail to grow but retain the capacity for delayed growth.To assess how food restriction affects the expression of growth, we measured the transcription of insulin-like growth factor-I (IGF-I) gene in liver and muscle and the concentration of circulating IGF-I in hamsters that were either exercising or sedentary and fed ad libitum or restricted to 70% of ad libitum food for 40 days. Expression of IGF-I gene was measured by solution hybridization of a radiolabeled mouse cRNA antisense probe with RNA from the hamster liver and quadriceps, IGF-I concentration,by RIA in acid-ethanol extracted and cryoprecipitated sera. Exercise accelerated ponderal growth by 8.5% and food restriction reduced it by 41%. There was a significant ($p<0.05$): (1)46% stimulatory effect of exercise and a 45% inhibitory effect of food restriction on hepatic IGF-I mRNA concentration; (2) 37% inhibitory effect of food restriction on the concentration of circulating IGF-I ,and (3)22% inhibitory effect of food restriction on muscle IGF-I mRNA. Hepatic IGF-I gene transcription constitutes the primary growth response to exercise, and a 50% reduction in this response in deprivation is accompanied by lesser reductions in circulating IGF-I and transcription of IGF-I gene in muscle. Support:NSF.

FACTORS AFFECTING SURVIVAL OF MOTONEURONS PURIFIED BY PANNING. C.E.Henderson, E. Bloch-Gallego*, W. Camu*, A. Charnet*, C. Mettling*, H. El M'hamdi*, F. Rassendren*, and F.K. Xie*. CNRS-INSERM, 34033 Montpellier, France.

Existing methods for enrichment of motoneurons (MN) from embryonic spinal cord have provided useful results but are often costly or insufficiently selective. This has hindered the molecular characterization of motoneuron growth factors. Recently, we showed (Bloch-Gallego *et al.*, Development (1991) **111**, 221) that monoclonal antibody SC1 could be used to identify chick MN in mixed cultures, and to purify them by "panning" on SC1-coated Petri dishes. MNs thus obtained are >98% pure by immunological criteria; more than 10^6 may be produced in 3 hrs and cultured on laminin in Terasaki wells (80 cells in 10 µl). We are developing an analogous method for rat MN. In serum-free conditions, chicken MN survival is considerably enhanced by muscle extract, but not by other factors tested, including NGF, TGFβ, human bFGF and chicken CNTF (gift of K.Wewetzer & K.Unsicker). However, in the presence of 10% horse serum, bFGF (100 ng/ml) was as effective as muscle extract in supporting MN survival; bFGF action may therefore require a cofactor.

Xenopus oocytes injected with poly-A^+ RNA from denervated chick muscle secreted a survival-promoting activity for MN. Only low levels of activity were seen using oocytes injected with RNA from control innervated muscle, or sham-injected. Levels of mRNA for such neurotrophic factors may therefore be regulated in muscle or nerve by the motoneuron itself.

BRAIN EXTRACT AND GLIAL-DERIVED TROPHIC AGENTS PREVENT DEAFFERENTATION-INDUCED MOTONEURON DEATH IN THE CHICK EMBRYO. Y. Qin-Wei, D. Prevette*, R.W. Oppenheim, and L.J. Van Eldik[1]. Dept. of Neurobiology & Anatomy, Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27103 and [1]Dept. of Pharmacology, Vanderbilt Univ., Nashville, TN 37232.

Removal of spinal and supraspinal descending input to the lumbar spinal cord by a thoracic spinal transection performed on embryonic day (E) 2 (deafferentation) results in a significant loss of lumbar motoneurons (MN) between E10 and E16. A small amount of naturally occurring MN loss (1500-2000 cells) also occurs between E10-E12. To examine whether these losses reflect the deprivation of CNS-derived trophic agents, brain extract (BEX), astrocyte conditioned medium (ACM), and several purified proteins (bFGF, CNTF & S100) were administrated daily to embryos in ovo between E10 and E15. MN numbers were assayed histologically on E16. Crude and partially purified BEX, ACM and S100 prevented both the late naturally occurring (E10-12), as well as the additional deafferentation-induced MN death. By contrast, bFGF and CNTF prevented the deafferentation-induced MN death, but were without effect on naturally occurring MN death between E10-E12. Surprisingly, partially purified muscle extract also prevented both types of cell death between E10 and E16. Although these data demonstrate that deafferentation-induced MN death can be prevented by CNS-derived proteins, the specific agents involved, their mode of regulation by afferents and their relation to muscle-derived trophic factors remain to be clarified.

NEURONAL DEATH II

447.1

A THEORETICAL MODEL OF NATURALLY OCCURRING NEURONAL DEATH IN DEVELOPMENT. Lucia Galli-Resta and Giovanni Resta*, Istituto di Neurofisiologia, CNR 56127, Pisa, Italy and *Istituto di Elaborazione dell'Informazione, CNR 56100 Pisa, Italy.

Throughout the animal kingdom, the formation of the nervous system involves the elimination of many cells. This naturally occurring cell death is observed in the majority of nervous structures and causes the loss of 30-75% of the neurones initially generated.

Elimination of erroneous projections, as well as proper size matching between connecting structures can be achieved through cell death. However many more cells die than it would seem necessary to eliminate erroneous projections and conflicting data exist as to the issue of size matching between target and input structures. It is believed therefore that no unitary model can be presented to account for the phenomenon of neuronal death in the different cases.

We have developed a simple theoretical model which accounts for naturally occurring neuronal death in development. The model quantitatively predicts the outcome of many of the experiments tried to investigate cell death and it finally reconciles in a single framework experiments until now viewed as contrasting.

INTENSE SOUND RELEASES AN AMINE PRESENT IN PERILYMPH AND CSF. R.P. Bobbin and M. Fallon*, Kresge Hearing Research Laboratory, LSU Medical Center, New Orleans, LA 70112.

Unk 2.5 is an amine released by 50 mM K^+ into effluent from the perilymph compartment of the cochlea (Bobbin et al., Hear. Res. 46: 83, 1990). We examined the effect of sound on levels of Unk 2.5 in cochlear effluent. Using anesthetized guinea pigs, the perilymph compartment of the cochlea was perfused with an artificial perilymph containing low [Na^+]. Effluent was collected before, during and after exposure of the ear to intense sound. Amines in the effluent were measured utilizing precolumn derivatization with o-phthalaldehyde/2-mercaptoethanol and HPLC. Broad band sound (10 min at 118, 124 and 130 dB SPL) increased the levels of Unk 2.5 without affecting the levels of glutamate and 15 other amines in the effluent. We call Unk 2.5 "noise induced release amine," or "niramine". Niramine eluted almost at the same time as carboxyglutamate, but before Asp, phosphoserine, cysteic acid, cysteine sulfinate, homocysteine sulphinate, and homocysteic acid. In CSF, niramine was found in higher concentrations than in plasma (5:1) and at about the same relative fluorescence as Asp. The chemical identity and role of niramine are unknown. (Supported by NIH grant DC-00379).

PC12 AND SYMPATHETIC NEURONAL APOPTOSIS DO NOT INVOLVE DNA FRAGMENTATION. P.W. Messner*, T.R. Winters* and S.H. Green. Dept. of Biology, Univ. of Iowa, Iowa City, IA 52242

A common feature of apoptosis is the cleavage of cellular DNA into fragments with sizes that are integral multiples of 180 bp (nucleosome repeat). DNA fragmentation is believed to be causal to apoptosis because apoptosis is inhibited by aurintricarboxylic acid (AT) — a drug that, among its many other effects, also inhibits nucleases. We have directly assayed DNA fragmentation during cell death in rat sympathetic neurons, in neuronal PC12 (nPC12) cells, and in chromaffin-like PC12 (cPC12) cells by observation of purified cellular DNA on agarose gels. The DNA was visualized by ethidium bromide staining or, if greater sensitivity was required, by transfer to nylon filters which were probed with [^{32}P]-labeled rat genomic DNA. Cell death was initiated by transfer of PC12 cells to serum-free, NGF-free medium or transfer of sympathetic neurons to NGF-free medium. No evidence of DNA fragmentation could be observed in these cells at any time up to 72 h after initiation of cell death (by 72 h most of the cells are dead). Electrophoresis of the DNA on denaturing gels also showed no detectable increase in single-stranded breaks. Similar assays performed using glucocorticoid-treated rat thymocytes showed typical DNA fragmentation, indicating that our assay system is capable of detecting neuronal DNA fragmentation were it to be present. Nevertheless, AT strongly inhibited cPC12 cell death and had a similar, albeit weaker, effect in nPC12 cells and neurons. Another difference between nPC12 and cPC12 cells is that cell death in the former, but not in the latter, was partially inhibited by protein synthesis inhibitors. We conclude that DNA fragmentation, whatever its role in nonneuronal cells, is not required for neuronal apoptosis. Furthermore, inhibition of apoptosis by AT, a very general inhibitor of protein-nucleic acid interactions, can't be taken to imply that nuclease activity is necessary for apoptosis. Finally, we suggest that apoptosis in nPC12 cells and cPC12 cells does not proceed by identical mechanisms, with a transcription-dependent process playing a role in nPC12 cell death as one does in neuronal death.

ABLATION OF THE THORCULUMBAR NEURAL TUBE IN CHICK EMBRYOS PROMOTES SURVIVAL OF CERVICAL PREGANGLIONIC NEURONS. P. Cauwenbergs. Anat.Dept., CMCC,Toronto,Ont. M4G 3E6.

In chick embryos two distinct columns of preganglionic neurons develop from a common primordium and establish structural contact with sympathetic trunk ganglia (STG);(1) a thoracolumbar column of Terni (CT) normally forms permanent synaptic connections with STG cells and (2) a primitive cervical column (CC) develops initial contact with STG early in development but degenerates and disappears by day 4.5E. The inability of CC neurons to form permanent contacts with STG neurons during normal development appears to be a characteristic intrinsic to CC cells alone, since neurons of the thoracolumbar CT transplanted into the cervical neural tube region do survive, contact the STG and maintain contact to at least day 16E (Soc. Neurosci. Absts. 14(2):867).

To test the possibility that CC neurons have the potential to establish stable structural contacts with STG the thoracolumbar neural tube was removed surgically at day 2.5E prior to neurite outgrowth. In these experimental (TL-Rem) embryos the cervical neural tube was left intact, while postganglionic STG neurons developed in the absence of their normal innervation. Analysis of urea silver nitrate stained serial cross-sections of day 8E experimental (TL-Rem) embryos revealed that after neural tube removal STG develop normally and primitive CC neurons now survive and maintain contact with STG. Thus, CC neurons have the potential to form stable contacts with STG neurons.Current analysis will determine if these connections are maintained beyond day 8E and define the pattern of neurite outgrowth into STG in experimental (TL-Rem) embryos.

DECREASE IN THALAMIC AND NEOCORTICAL VOLUMES AFTER A SMALL PRENATAL CORTEX LESION IN THE CAT. L. D. Loopuijt, J. R. Villablanca, R. Gayek* and D.A. Hovda, Mental Retardation Research Center and Division Lab Animal Medicine, UCLA, Los Angeles, CA 90024.

In monkeys, prenatal frontal cortex lesions have little effect on behavior or neuronal cell packing density (CPD) in thalamic mediodorsal nucleus [Brain Res. 152(1978)451]. In cats, lesion-induced degeneration is less in neonatal- than in adult-lesioned animals. Thus, degeneration in fetally lesioned cats might be minimal; yet, our pilot data indicated the opposite [Soc. Neurosci. Abstr. 13 (1987) 1116]. In the current study, 6 fetal cats (E43-48) received a small unilateral frontal or parietal cortex lesion and 6 controls were intact. After reaching adulthood, brain neocortical and thalamic volumes were determined. In thalamic ventrolateral (VL), principal ventromedial (VMP), external ventrobasal (VBX) and basal ventromedial (VMB) nuclei neuronal and glial CPD and neuronal soma size were measured. Thalamic and neocortical mean volumes were decreased compared to intact animals (thalamus: ipsil. 238.4, intacts 359.8 mm3; cortex: ipsil. 1,861.9, int. 2,175.3 mm3, $P<0.05$). Thalamic mean neuronal CPD did not differ between lesioned and intact (VL ipsil. 2.3, int. 2.2; VM ipsil. 2.1, int. 3.0, VBX ipsil. 2.2, int. 2.9, VMB ipsil. 2.9, int. 3.0 neurons/0.0003 mm3), while glial CPD tended to be lower ($P<0.05$ for VL, VMP). Preliminary analysis of neuron size did not reveal marked differences between lesioned and intact cats. Decreases in volume indicate atrophy in cortex and thalamus. Thalamic shrinkage without increase in CPD is probably due to increased developmental cell death. These findings fit well with behavioral impairments in fetal lesioned cats (Villablanca et al., this meeting). Grants USPHS R01 NS- 25780; P01 HD-05958.

RETROGRADE RESPONSE IN THE DORSAL LATERAL GENICULATE NUCLEUS (LGN) OF THE RAT TO DAMAGE OF VISUAL CORTEX. D.R. Diaz and R.E. Kalil. Neuroscience Training Program and Dept of Ophthalmology, Univ of Wisconsin, Madison WI 53706.

While varying in swiftness, severity, and extent among different species, the retrograde reaction of neurons in the LGN to a lesion of visual cortex is usually pronounced. In general, the reaction begins with the simple pallor of affected cell somas and leads subsequently to atrophy and often cell death. Retrograde degeneration in the LGN has been well-studied in some animals, but surprising there is little systematic information available in the rat.

To clarify the retrograde reaction of the LGN in the adult rat, we made a unilateral lesion of visual cortex in a series of animals, and studied the LGN after post-operative survivals that ranged from 24 hours to 6 weeks. At 24 hours, LGN neurons ipsilateral to the cortical lesion display a noticeable pallor, which becomes prominent by 3 days. By 7 days survival, affected LGN cells are atrophied and some are degenerating. At longer survivals, LGN cell atrophy and loss increase in magnitude, and thus after 6 weeks the LGN ipsilateral to the cortical lesion is markedly shrunken in comparison to the normal nucleus.

We also have studied the early stages of the astroglial response in the LGN that accompanies the retrograde neuronal reaction by staining for glial fibrillary acidic protein (GFAP) with a monoclonal antibody. An increase in GFAP immunoreactivity is detectable at 3 days survival, prominent at 7 days, and intense at 2 weeks and thereafter.

DEVELOPMENTAL CHANGES IN THE ARRANGEMENT OF MOTOR POOLS IN THE CHICK SPINAL CORD MAPPED USING FLUORESCENT BEADS R.V.Stirling and D.Summerbell. Department of Biology, Open University, Milton Keynes MK7 6AA, UK and National Institute for Medical Research, Mill Hill, London NW7 1AA, UK.

Each muscle of the vertebrate limb is innervated by a cluster of motor neurons in the spinal cord, its motor pool. These are usually mapped using retrograde filling techniques in which single muscles are injected with tracers, but such methods do not reveal the overlap between adjacent pools.

In the present experiments fluorescent latex microspheres (Lumafluor Inc) were used to retrogradely fill motor neurons. The position of filled motor neurons within the cord was plotted in three-dimensions using a computer-aided drawing system (InterActions Company). The advantages of using these beads is that they are available in several colours, do not fade, and all colours are transported in an identical manner. The advantages of the computer-aided system is that the position of the filled cells can be mapped in the intact spinal cord, thus avoiding problems related to sectioning.

Initially the pools are diffuse and overlapping but gradually become more discrete. We suggest that selective cell death is responsible for this change. This could not have been detected using single tracers. The method of filling also offers the opportunity of injecting motor neurons with dyes to study the relationship between morphology and position within the motor pool.

Expression of Ubiquitin in the Chick Embryo Spinal Cord. **S.E.McKay, L.M.Schwartz+ & R.W.Oppenheim, Dept.of Neurobiology & Anatomy, Wake Forest Univ.,Winston-Salem, NC & +Dept.of Zoology, Univ. of Mass.,Amherst, MA.**

We have been examining the expression of ubiquitin, a protein associated with cell death in insects,during the death of motoneurons and neural crest derived neurons in the developing chick embryo. Northern analysis has demonstrated that polyubiquitin transcripts increase in the spinal cord coincident with neuronal death. In situ hybridization is being used to determine the source of this mRNA. Western blotting experiments showed that ubiquitin-protein conjugates comprise a greater percentage of total spinal cord protein at early vs. later stages of cell death. Immunohistochemistry has revealed possible sites of expression: increased ubiquitin immunoreactivity (IR) was present over the entire lumbar lateral motor column at early stages of motoneuron death followed by more punctate staining at later stages. IR was also present in peripheral ganglia and nerves mainly associated with nerve fibers in the dorsal and ventral roots and in the marginal zone of the neural tube. These data suggest that polyubiquitin may play a role in developmental cell death in the vertebrate nervous system.

447.9

MOTONEURON CELL DEATH IN THE NUCLEUS AMBIGUUS AND HYPOGLOSSAL NUCLEUS OF RATS: CRITICAL PERIODS IN THE DEVELOPMENT OF UPPER RESPIRATORY TRACT CONTROL.
D.R. Friedland*, P.J. Gannon, A.R. Eden, J.T. Laitman*, Depts. Otolaryngol. & Cell Biology/Anatomy. Mt. Sinai Sch. Med., NY 10029.

Early neuromuscular development is characterized by a dramatic decrease in neuronal populations during the process of motoneuron cell death (MCD). Parameters of MCD in brainstem nuclei subserving upper respiratory tract (URT) function may, therefore, indicate critical periods in the development of URT motor control.

The nucleus ambiguus (NA) and hypoglossal nucleus (XII) of fetal rats at embryonic days 14 (E14), E15, E16, E17, E19 and adults (for NA) were examined (n=2/age). Fetal rats were removed from the mother, brainstems dissected out, processed for wax embedding, sectioned at 8μm, and stained with hematoxylin and eosin. Counts were made of large neuroblasts (>10μm) exhibiting distinct nucleoli.

Results show little organization of NA and XII at E14 and E15. At E16 NA is not yet discernible, however, XII is distinct and contains clusters of immature neuroblasts. By E17 motoneurons are clearly seen within both NA and XII. E19 brainstems are similarly organized with a more distinct appearance of motor nuclei. Counts were made of motoneurons in NA at E17, E19 and adult. There was a 53% decline in motoneuron numbers between E17 and adult, with 66% of this loss occurring prior to E19. Counts of motoneurons in XII showed an 18% loss between E17 and E19. The observed disparity in degree of cell death between NA and XII may reflect earlier maturation of XII, with a significant portion of cell death occurring prior to E17. Further investigation will clarify these observations.

These results establish late gestation as a period of intense modification of brainstem nuclei subserving URT function. As such, insults occurring during this period may interfere with the normal development of URT neuromuscular control and underlie neonatal pathologies such as SIDS.

447.10

NEURONAL BIRTH AND LOSS IN DEVELOPING RABBIT RETINAE.
S.R. Robinson[1*], F.C. Dangerfield[2*], B. Dreher[2*] and D.H. Rapaport[2]
[1]Vision, Touch and Hearing Research Centre, Department of Physiology, University of Queensland, St. Lucia, QLD, Australia. 4072.
[2]Department of Anatomy, University of Sydney, Sydney, NSW, Australia. 2006.

We have investigated the spatio-temporal patterns of cell birth and loss in the retinae of developing albino rabbits. Under Halothane and nitrous oxide anaesthesia, ^{3}H-thymidine was injected into foetuses on either the 13th post-conceptional day (13PCD), 18PCD or 22PCD. The mother and babies were sacrificed with an overdose of barbituate between 20PCD and 34PCD. The young retinae were embedded as wholemounts in plastic and cut into 3μm sections passing from superior retina through the optic disc to inferior retina. The sections were processed for autoradiography and the distributions of well labelled (i.e. born on the day of ^{3}H-thymidine administration) amacrine and horizontal cells mapped.

Cells born on 13PCD were concentrated in the visual streak and mid-superior retina, while those born on 18PCD or 22PCD tended to be uniformly distributed or more frequent towards the retinal periphery. These findings are consistent with the idea that the visual streak is developmentally advanced.

Three of our findings challenge accepted views of cell death in the developing retina. First, in all cohorts, the main period of cell loss (indicated by a reduction in the number of labelled cells and an increase in the number of pyknotic profiles) occurred between 30PCD and 34PCD. Thus, contrary to the predictions of the "Temporal Matching Hypothesis" *(Dreher and Robinson, 1988, Brain, Behav. Evol., 31: 369-390)*, cell birth arfd death are not temporally correlated. Second, much of the loss is unlikely to be target related, since most horizontal cells die before synaptogenesis begins in the outer plexiform layer. Third, the magnitude of cell loss varied substantially between cohorts: the proportions of labelled amacrine and horizontal cells lost from the 18PCD cohort (24% and 38%, respectively) were considerably less than the proportions lost from the 13PCD (73% and 88%) and 22PCD (64% and 55%) cohorts. Thus, a neurons' chances of survival are very much dependent on a timely birth.

MOLECULAR AND PHARMACOLOGICAL CORRELATES OF DEVELOPMENT: PEPTIDES

448.1

EXPRESSION OF PEPTIDE mRNA IN THE CAUDAL RAPHE COMPLEX DURING EARLY POSTNATAL DEVELOPMENT IN RAT.
R.K. Kanter, J.T. Erickson, C.L. Szymeczek and D.E. Millhorn.
University of North Carolina at Chapel Hill

Neurons of medullary caudal raphe complex (n. raphe obscurus and pallidus) contain substance P (SP), thyrotropin releasing hormone (TRH), and 5-hydroxy-tryptamine in the adult rat. We recently reported that TRH mRNA was not present in these neurons at birth but appeared during the first postnatal month (FASEB J. 4: A1109, 1990). In the present study we analyzed preprotachykinin A (PPT_A) mRNA (which encodes SP and neurokinin A) in 0-28 day old rats to determine if its expression is also developmentally regulated in raphe neurons. *In situ* hybridization showed very low levels of PPT_A mRNA in the raphe complex at 0d, rising to a maximum at 21d and 28d. Results from immunohistochemical studies revealed that fibers originating in the raphe complex demonstrated increasing levels of SP and TRH from 0-28 days consistent with the hypothesis that developmental regulation of these peptides occurs at the level of their mRNA. Maturation of the chemical phenotype of caudal raphe cells involves the parallel regulation of expression of coexisting neuropeptides SP and TRH which both increase progressively during the first postnatal month. The raphe neurons of the medulla provide an excellent model for studying regulation of peptide gene expression in the nervous system. (HL33831, HL34919, AHA, ALA)

PROENKEPHALIN TRANSGENIC MICE — INTEGRATION DEPENDENT PATTERNS OF TRANSGENE EXPRESSION IN EMBRYONIC CNS.
H. Dressler*, K. Herrup, & S. Hyman. E.K. Shriver Center, Waltham, MA. and Mass. General Hospital, Boston, MA

To study the regulation of proenkephalin (PE) gene expression, we joined 3.0 kb of human PE 5' flanking sequences to *E. Coli lacZ*, followed by 1.0 kb of human 3' PE sequences including the poly-adenylation signal. Three lines of transgenic mice (ENKL/1, 2, and 3) have been produced from this construct. In the adult CNS, a variable pattern of expression is found. To describe the developmental onset of this expression, X-gal-stained embryos were examined. In ENKL/1, two broad bands of staining appear in the prosencephalon as early as E10. By E12, cells in the nasal placode area are stained as is a broad patch of cells in the diencephalon. At E15, cells in the nasal area remain and a group of migratory cells (reminiscent of LHRH neurons) also appear; the CNS cells coalesce in the developing hypothalamic anlage. In ENKL/2, the staining of nasal placode cells is similar to ENKL/1, but neither migratory cells nor CNS cells are stained. Embryos of the ENKL/3 line exhibit the highest levels of adult transgene staining, but at midgestation only the trigeminal ganglion is X-gal positive. Our findings suggest that the PE sequences included in the transgene contain only part of the information needed for correct embryonic PE expression. The spatial variability of expression is thus likely to be a function of both the included PE sequences plus position effects conferred by the site of chromosomal integration.

448.3

EXPRESSION OF PRE-PROENKEPHALIN MESSENGER RNA IN DEVELOPING RAT SUPERIOR CERVICAL GANGLION.
K.F. Greif[1] and A.J. Tobin[2]. [1]Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010, [2]Dept. of Biology, UCLA, Los Angeles, CA 90024.

Previous studies on enkephalin expression in sympathetic ganglia have reported that only a limited number of neurons express either leu- or met-enkephalin, using immunohistochemical staining methods. We have examined the expression of pre-proenkephalin (PPENK) mRNA in developing rat superior cervical ganglion (SCG) by in situ hybridization histochemistry, using RNA probes. In adult ganglia, 55% of large principal neurons express PPENK mRNA. The amount of labeling varied between individual neurons; 14% were heavily labeled. PPENK mRNA can first be detected in developing SCG by in situ hybridization on postnatal day 4 (P4), when a few sparsely labeled cells are seen. At P7, 11% of principal neurons are labeled, increasing to 30% by P21. A greater percentage of cells fall into the heavily-labeled category in young SCG; the percentage decreases with age as the total number of labeled cells increases.

Our results suggest that expression of PPENK mRNA is more widespread than expression of peptides derived from it. The enhanced sensitivity of in situ hybridization reveals that different subpopulations of neurons express different amounts of mRNA.

448.4

PROENKEPHALIN AND PREPROTACHYKININ mRNA EXPRESSION IN THE DEVELOPING CHICK BRAIN.
T.L. Overbeck*J.L. Bradley*M.S. Randolph,*M.S. Kindy, K.M. Albers* and B.M. Davis. Dept. of Anatomy & Neurobiology, Univ. of Kentucky, Med. Ctr., Lexington, KY 40536.

Our lab is interested in the relationship between the mechanisms underlying regeneration and development. Enkephalin-like immunoreactivity is seen in the accessory occulomotor nucleus (AON) by stage 25, shortly after cell division ceases. Substance P (SP) coexists with enkephalin, but does not appear until late in development. We have initiated experiments to test whether the expression of proenkephalin mRNA (PRNA) is correlated with synaptogenesis during both phenomena. We have screened a chick E13 cDNA library (in λgt10, generously provided by L. Baizer) using rat random primed cDNAs. One of four positive clones for PRNA has been isolated and sequenced. This clone contains a sequence for Met-Enk and has 100% amino acid identity for the rat sequence (Rosen et al. JBC 259:14309) for amino acids # 121-143 and from 150-163. We have also isolated two positive clones for the preprotachykinin mRNA, which codes for SP. This clone is homologous for the non-tachykinin portion of the mRNA and contains a string of 45 nucleotides that has a 75% identity for the rat sequence. These clones have been inserted into pGEM and will be use to make cRNA probes to examine regeneration and development of the chick AON-ciliary ganglion system. Supported by NS25617 to BMD.

448.5

THE DEVELOPMENT OF VIP mRNA EXPRESSION AND VIP RECEPTOR BINDING IN THE RAT CNS. J.M. Hill, A.C. Tanner*, D. V. Agoston and S.K. McCune. Laboratory of Developmental Neurobiology. NICHD, NIH, Bethesda, MD 20892.

VIP has neurotrophic properties (PNAS:83:1159,1986) and a role in neurobehavioral development (Peptides 12:187,1991). The present work traces the development of VIP with in situ hybridization and receptor binding to both GTP-sensitive and insensitive sites with in vitro autoradiography in rat embryos from E14 to P14 and adult CNS.

The mRNA for VIP was expressed at very low levels until P8, however, by E14 it was seen in the cortex. By P8, message increased and was additionally found in the thalamus, superchiasmatic nucleus (SCN), striatum, superior colliculus and dorsal raphe. By P14, message was greater in the cortex than the thalamus, but in the adult, the SCN and thalamus had the greatest levels.

VIP binding was uniform and dense in the brain stem and spinal cord by E14, but localized to specific cortical and hippocampal layers. By E16, VIP binding was also seen in the SCN, thalamus, pineal and dorsal raphe. By E19, VIP binding was seen in the diagonal band, septum, cerebellar peduncles and hypothalamus. In D8-D14 VIP binding remained uniform and dense in the brain stem and basal forebrain and midbrain structures but in the cortex and hippocampus was limited to specific layers. In the adult, VIP binding was localized to specific cytoarchitectural sites throughout the brain. As in the adult, most VIP binding sites were sensitive to displacement by GTP, however, as early as E19 GTP-insensitive binding sites were observed in the spinal cord and thalamus.

VIP receptor binding develops earlier and is more widespread than VIP mRNA. Although changes in relative abundance occur in both throughout development, by P8 VIP and its receptors are colocalized in several brain regions and remain so in the adult.

448.6

REGULATION OF IGF-II GENE EXPRESSION DURING NEUROBLASTOMA PROLIFERATION AND DIFFERENTIATION. D.M. Martin, R.O. Carlson* and E.L. Feldman, Department of Neurology and Mental Health Research Institute*, University of Michigan Medical School, Ann Arbor, MI 48109.

Insulin-like growth factor-II (IGF-II) belongs to the insulin family of polypeptides and has been implicated in neuronal mitogenesis. Both primary neuroblastomas and some cell lines have been shown to produce large amounts of IGF-II, which can act as an autocrine growth factor (El-Badry, O. et al., J Clin Invest 84:829-839, 1989). Similarly, reduction of IGF-II production may be a means for inhibiting cellular growth. We speculated that IGF-II gene expression is regulated during neuronal proliferation and differentiation. In this study, we report decreased IGF-II gene expression in differentiated neuroblastoma cells.

We have found by Northern analysis that the clonal neuroblastoma line SH-SY5Y expresses high amounts of IGF-II mRNA. Neuroblastoma cells can differentiate in response to interferon-γ (IFN-γ) (Watanabe, H. et al., Jpn J Cancer Res 80:1072-1076, 1989). We observed growth arrest and gross morphological changes in SH-SY5Y following addition of IFN-γ. We analyzed IGF-II mRNA levels in SH-SY5Y cells maintained in the presence or absence of IFN-γ. Under these conditions, IGF-II mRNA levels decreased over a period of 3 or 6 days. These data suggest that decreased IGF-II gene expression is correlated with neuronal differentiation.

NMDA ACCELERATES AND AMPLIFIES THE ONTOGENY OF SOMATOSTATIN IN MONOLAYER CULTURES OF FETAL RAT TELENCEPHALON. R.J. Robbins, and S. Welsh*. Neuroendocrinology Program, Departments of Medicine and OB/GYN, Yale Univ. School of Medicine, New Haven, CT 06510.

The survival and differentiation of mammalian neurons depends in part on the stimulation which they receive during a critical developmental period. We have previously reported that telencephalic SS interneurons *in vitro* display enhanced susceptibility to excitatory amino acids (EAA) only after they become mature. For the first 11 days in vitro cortical SS neurons obtained from 16 day old embryos are not killed by NMDA. We hypothesized that EAAs would still bind to immature SS neurons and alter their in vitro development. Fetal rat telencephalic cultures were grown for 20 days in the presence of various concentrations of EAAs. The SS content of the cells was measured by RIA. NMDA (100 μM) added at the time of plating increased cellular SS content by 130% at day 5, by 180% at day 10, and by 50% on day 20. Equimolar doses of Quisqualic acid resulted in a greater than 80% decrease in SS at all time points. AMPA (10-100 μM) significantly increased SS content at days 10,15, and 20. The NMDA blocker APV, retards early SS development but results in increased SS content by days 20 and 27. In summary, EAAs can exert dramatic effects on the development of somatostatinergic neurons in vitro. We conclude: (1) that the normal development of SS interneurons in vivo may depend in part on their exposure to glutamate and, (2) that functional EAA receptors exist on neurons prior to their full maturation.

DEVELOPMENT OF SENSORY SYSTEMS II

449.1

NEUROMAGNETIC ASSESSMENT OF SOMATOSENSORY CORTICAL ORGANIZATION FOLLOWING PERIPHERAL NERVE INJURY AND RECONSTRUCTION A. Mogilner, L. Lopez, U. Ribary, F. Lado, J.A.I. Grossman*, and R. R. Llinás Department of Physiology and Biophysics, NYU School of Medicine, NY, NY 10016.

A 14-channel neuromagnetic recording system is being used to evaluate changes in cortical organization following peripheral nerve injury and surgical repair in a number of subjects. Studies in primates (Wall et al, J Neurosci 1986 6(1)218-233) have shown that following peripheral nerve transection and repair, the somatosensory cortical maps reorganize over a period of time during the repair process. The high spatial resolution of the MEG, on the order of a few millimeters, supports the idea that cortical plasticity in human subjects may be detected via recording and source localization of neuromagnetic evoked potentials. Two groups of patients are being studied: 1)Patients who have undergone traumatic nerve section of the upper extremity followed by surgical reconstruction of the nerve, 2)Patients who have undergone skin grafts with intact innervation ("neurovascular island transplant") from one region of skin to another. Both groups of patients are studied before the surgery, and after the surgery at regular intervals. Magnetic responses to vibratory stimulation of the digits are recorded at each session, and a single dipole model is used to localize the cortical sources of the evoked activity, resulting in a map of the hand area of somatosensory cortex SI. The MEG studies are accompanied by a neurological examination which delineates the area and the nature of the sensory pathology, and which will be used to correlate the MEG findings with the subjective sensory state of the subject during the process of recovery. For example, patients in the second group being studied who have undergone skin/nerve relocation initially cannot distinguish between tactile stimulation of the graft and stimulation of the finger which supplied the graft skin, but over time they become able to discriminate between the different fingers. MEG studies have confirmed that immediately following graft surgery, the dipole locations of the graft source and the graft are nearly identical. Further MEG studies during the process of sensory reeducation might elucidate the cortical processes associated with recovery following peripheral nerve injury and reconstruction.

A PERIPHERY-RELATED PATTERN IS EVIDENT IN RAT SOMATOSENSORY CORTEX AT BIRTH. B.L. Schlaggar and D.D.M. O'Leary Molecular Neurobiology Laboratory, The Salk Institute, La Jolla CA 92037.

The "barrels" of rat somatosensory cortex (SI) are arranged in a pattern isomorphic to the distribution of vibrissae on the body surface. A host of techniques have shown that barrels emerge postnatally and are distinct by the end of the first postnatal week. The timing and sequence of events that lead to the differentiation of barrels are crucial to defining the agents that instruct their formation. Ventrobasal thalamocortical (VB) afferents are hypothesized to control barrel differentiation and the somatotopic patterning characteristic of SI. Here, we investigate the emergence of barrel patterning of VB afferents in SI in rats at ages E16 to P4. (E0 is the day of insemination. P0 is the first 24 hrs after birth). We assayed for AChE, an early marker of VB afferents (Kristt JCN '79; Neurosci '89), and directly labeled VB afferents with DiI in fixed brains. AChE histochemistry reveals a periphery-related pattern in SI as early as 1 hr postnatal, 3 days earlier than previously shown with this method and 2 days earlier than with any other marker, including DiI labeling (Erzurumlu & Jhaveri Dev Br Res '90). The trigeminal (face) representation develops several hours earlier than that of the medial lemniscus (body) - the latter is apparent by late P0. At birth, AChE-positive rows are apparent from which the barrels of the PMBSF later emerge; the complete barrel pattern can be discerned by 24 hrs postnatal. DiI labeling renders a similar sequence of barrel emergence, but delayed by roughly a day. AChE histochemistry is a more precise indicator of developing barrels than DiI because it is specifically expressed by VB afferents, resulting in a higher "signal to noise" than DiI which backfills cortical neurons and their intracortical processes, masking the early differentiation of a barrel-related patterning. These findings provide the earliest evidence for the emergence of barrels and support the hypothesis that VB afferents govern the development of somatotopic patterning in SI. (Support: NIH NS17763.)

449.3

DEVELOPMENT OF THALAMOCORTICAL TERMINAL ARBORS IN LAYER IV OF MOUSE BARREL CORTEX. A. Agmon and E.G. Jones. Dept. of Anatomy and Neurobiology, College of Medicine, Irvine, CA 92717.

Thalamocortical axon terminals in the adult mouse somatosensory cortex are highly ordered. Radially they are segregated into a diffuse tier in the deep layers and a dense tier spanning layers IV and lower III. Tangentially the upper tier is parcellated into discrete patches, each at the core of a cluster of cells or "barrel". In the newborn mouse layers II-IV are still undifferentiated and thalamocortical terminals are restricted to layers V/VI. The formation (around postnatal days 3-4) of the barrels with their associated thalamocortical arbors is a complex morphogenetic event that is not yet fully understood. Of particular interest is whether the axonal clusters in layer IV arise from an initially diffuse projection by elimination of surplus branches or whether they are formed *ab initio* as discrete entities. We studied this question by placing several particles of Di-I in the thalamus in fixed 400 μm thick thalamocortical slices (Agmon and Connors, Neurosc. 41, 365-379, 1991) prepared from animals at different ages during the first two postnatal weeks. The dye was allowed to diffuse for 1-4 weeks at 37° and the slices imaged as whole mounts using a laser confocal microscope. At postnatal day 2 (P2) almost all labeled branches were in layers VI and lower V, with an occasional unbranched axon coursing up through the cortical plate (presumptive layers II-IV). By P4 individual axons were seen to course radially upwards through upper layer V without branching and upon entering lower layer IV abruptly fanned out into several branches; arbors of several axons overlapped to form a cluster, and adjacent clusters were clearly separated. The number of layer IV branches per axon increased dramatically over the next 10 days but the clusters remained well-defined. Our data are consistent with the hypothesis that the terminal arbors in layer IV are segregated from their very beginning and that new branches are added within their "correct" cluster.

449.4

THE CRITICAL PERIOD FOR SENSORY DEPRIVATION IN RAT VIBRISSA CORTEX. By K. Fox, and F.F. Ebner Center for Neural Science, Brown University, R.I. 02912.

Rats were raised with just the D1 vibrissa intact and the other vibrissae carefully pulled out. Deprivation was started at P0, P2 or P4 and continued until recording at 30-60 days. The latency and magnitude of responses to the D1 vibrissa were measured at histologically recovered locations within the cytochrome oxidase "barrel map". Small enlargements of the cytochrome oxidase D1-barrel were noted in 1/3rd of P0-onset animals but never in P2 or P4 animals. Short latency responses (5-10ms) to D1 stimulation were found in 30% of cells in barrels neighboring D1 in layer IV (22/73) compared with none in controls (0/82). Short latency responses fell to 18% at P2 and 13% at P4. Layer IV cells responding with greater numbers of spikes per stimulus to D1 than to the vibrissa anatomically related to their barrel location (shifted cells) fell from 37% at P0, to 23% at P2, to 8% at P4 (0% for controls). Urethane anesthesia was controlled by maintaining layer V burst rate between 0.7 and 2Hz. As a further control for anesthetic effects, responses to the deprived D2 vibrissa were tested in the same animals, but no enlargement of the D2 domain occurred, unlike for D1. Plasticity was greater in layers II/III than in IV at all ages, and showed a minor decline from 62% shifted cells at P0 to 49% at P4. Deprivation induced plasticity appears to end within the first post-natal week subcortically and/or in layer IV, but continues for an, as yet, undetermined period in supragranular layers. (supported by NIH grant #27759).

AGE-RELATED DIFFERENCES IN SI CORTEX RESPONSE LATENCIES AFTER SOMATIC STIMULATION OF THE FACE, FOREPAW, AND HINDPAW IN POSTNATAL DAY 1 THROUGH POSTNATAL DAY 14 NEONATAL RATS. C.A. McCandlish, C.X. Li*, and R.S. Waters. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, Col. of Medicine, Memphis, TN 38163.

Using natural somatic and electrical stimulation, we reported that evoked responses could be elicited from SI cortex of newborn rats prior to PND-7 and that the functional development of the barrel field map follows a lateral to medial gradient. We extend those findings to include a description of the latencies of evoked responses over the first 14 postnatal days.

Neonatal rats, ranging in age from PND-1 through PND-14, were anesthetized with Nembutal (40 mg/kg ip) and placed on a heating pad. A midsagittal incision was made overlying the skull, the skin retracted, and the cisterna magna opened. The animal's head was held rigid by a custom designed head holder. The area of skull overlying SI was removed and the dura opened. Carbon-fiber electrodes (1-2 MΩ) were used to record mechanically and/or electrically evoked responses from SI after stimulation of regions of the contralateral face, forepaw, and hindpaw. At the end of the experiment, electrolytic lesions (3 μA/5 sec) were made at selected sites, and animals sacrificed. Hemispheres were removed, sectioned coronally (40 μm), and processed using cresyl violet stain.

Beginning on PND-1, response latencies were measured and compared between each SI cortical subfield area showed that latency periods are shortest after stimulation of face, followed by forepaw, and then hindpaw region. Furthermore, latencies measured from each subfield region decreased over each successive postnatal day. (Supported by NSF Grant BNS 88-02766)

LECTIN BINDING PATTERNS IN WHISKER PATHWAYS OF PERINATAL RATS AFTER LESIONS TO SOMATOSENSORY THALAMUS OR CORTEX. J.J.Christensen, N.L. Chiaia, C.A. Bennett-Clarke, R.W.Rhoades and T.A. Woolsey. Dept. Neurosurgery, Washington University, St. Louis MO 63110 and Dept. Anatomy, Medical College of Ohio, Toledo, OH 43699

The plant lectin peanut agglutinin (PNA) transiently reveals patterns in the rat trigeminal (V) pathway that are isomorphic to the vibrissae on the face. It is not known whether the spatial distribution of PNA binding is determined primarily by afferents, neurons, glia, or some combination of these elements. Neonatal destruction of either the somatosensory cortex or VB results in a smaller principal nucleus of V (PrV) and an absence of the normal, vibrissa-related pattern of V-thalamic projection neurons, but does not qualitatively change the distribution of V primary afferents in this nucleus. We made lesions of either somatosensory cortex or thalamus on P0 and assessed patterns of PNA binding in the V neuraxis on P6. The vibrissa-related pattern of PNA binding was absent in PrV contralateral to the damaged cortex or thalamus. The pattern of PNA binding in PrV ipsilateral to the lesion and in spinal subnucleus interpolaris and spinal subnucleus caudalis on both sides of the brainstem was normal. Neonatal cortical lesions led to substantial retrograde degeneration and an absence of any vibrissa-related pattern in ipsilateral ventrobasal thalamus. Thalamic lesions resulted in the absence of a vibrissa-related pattern of PNA binding in the somatosensory cortex on the same side. These results indicate that segregated afferents are necessary, but not sufficient, for whisker-like PNA binding patterns to develop in PrV. Specifically, the patterned distribution of PNA requires rather than directs the organization of the neuropil resulting from the interactions between afferent axons and their target neurons.

VIBRISSECTOMY-INDUCED EXPRESSION OF GAP-43 mRNA IN ADULT RAT TRIGEMINAL NUCLEUS AND BARREL CORTEX. B.E. Levin, R.L. Neve and A. Dunn-Meynell. Neurol. Serv., DVA Med. Ctr., E.Orange, NJ 07019 and Dept. of Neurosci., NJ Med. Sch., Newark, NJ 07103.

Vibrissectomy induces plastic change in adult rat barrel cortex associated with a persistent increase in GAP-43 immunoreactive protein beginning 1wk post-surgery. Here we examined GAP-43 mRNA expression in barrel system relays from 1-7d after total unilateral vibrissectomy with sparing of C3. Autoradiograms were generated from brain sections hybridized with labeled mRNA transcribed from a cDNA clone for human GAP-43 which cross-reacts with rat GAP-43 mRNA. As compared to analagous areas in the control side of each section, densities representing GAP-43 mRNA transiently increased by 15% from 1-3d in the ipsilateral principal trigeminal n. (P=0.01), followed at 6-7d by a 12% increase (P=0.025) in layer IV of the contralateral barrel cortex. Levels were unchanged elsewhere. Thus, there is a sequential, vibrissectomy-induced, transsynaptic induction of GAP-43 mRNA in specific barrel system neural relays associated with plastic change in lamina IV of the barrel cortex.

POST CRITICAL PERIOD PHENOMENA IN CORTICAL BARREL FIELDS IN ORGANOTYPIC SLICE CULTURES FROM RAT SOMATOSENSORY CORTEX. M. Behan[1], A. Kroker, and J. Bolz; Friedrich-Miescher Labor der Max-Planck Gesellschaft, 7400 Tübingen, Germany. [1]Present address: Department of Comparative Biosciences, University of Wisconsin, Madison, WI 53706, USA.

During early postnatal development of the barrel field in rodent somatosensory cortex there is a critical period when alterations of the sensory periphery disturb barrel formation. However, peripheral manipulations after the critical period appear not to affect the barrel architecture. The mechanisms by which barrels are formed and maintained are, as yet, unknown. Although there is evidence that thalamocortical afferents play a role in shaping barrel fields, inputs from other subcortical and cortical sources may be equally important. We have begun to study barrel fields in slice cultures, where all of these inputs can be eliminated. First, we determined whether barrels could be maintained in the absence of afferent input, and secondly, in the absence of input from other cortical layers. Slice cultures of the somatosensory cortex were prepared from 5-8 day-old rats, by which time barrels are formed. Cytochrome oxidase histochemistry and Nissl staining were used to identify the presence of barrels in slice cultures. In sagittally cut slices, barrels were observed in cortical layer 4 after up to 10 days *in vitro* (DIV), the longest period examined. In tangentially cut cortical slices, after 1 DIV, barrels could usually be identified. However, after 2-4 DIV cells in the barrels reorganized, and cells from the barrel wall moved into the barrel hollow. After another 1-2 DIV, the remaining barrel septa disappeared and the cells were homogeneously distributed in the slice culture. Thus, intact connections within cortical columns appear to be necessary to sustain the functional architecture of barrel cortex *in vitro*. These results suggest that interactions between cortical layers may play a role in the termination of the critical period.

THE PRODUCTION OF CRYPTOTIA IN OPOSSUM PUPS FOLLOWING LESIONS OF THE TRIGEMINAL GANGLION. D.M. Feinberg* and B.L. Munger, Dept. of Neuroscience & Anatomy, Penn. State Univ., M.S. Hershey Med. Ctr., Hershey, PA 17033

During the course of studies on the impact of lesions of the trigeminal ganglion in opossum pups, we observed that the auricles on the side of the lesion were small and misshapen, i.e. evidence cryptotia. The auricle develops as a condensation of mesenchyme separated from the skull by a plate of stratified epithelium that is directly continuous with the meatal plug. This auricular plate is present at birth, progressively enlarges & undergoes keratinization in the center dividing the posterior surface of the auricle from the skin overlying the temporal bone. The separation of the auricular plate typically begins at 12-15 days of age. We created lesions of the trigeminal ganglion using a microcautery on pups attached to their mother at 1 day of age with halothane anesthesia. The condensing mesenchyme of the auricle and the auricular plate were consistently smaller and keratinization delayed on the side of the trigeminal lesions. By 21 days, grossly smaller auricles could be recognized in all experimental cases. We conclude that afferent nerves have a critical role in the differentiation of the auricular plate as other cutaneous appendages, and trigeminal lesions produce cryptotia that resembles its human counterpart. THALAMIC LESIONS AT BIRTH ALTER DENDRITIC MORPHOLOGY IN TRIGEMINAL NUCLEUS PRINCIPALIS (PrV). I.Z. Rana*, N.H. Hobart*, M.H. Cooper, N.L. Chiaia, R.W. Rhoades, & M.F. Jacquin. Dept. Anat. & Neurobiol., St. Louis University School of Med., St. Louis, MO 63104; Dept. of Anat., Medical College of Ohio, Toledo, OH 43699.

PrV cells undergo a dramatic postnatal regressive process (Hobart et al., Neurosci. Abstr. 15, '89). Dendritic #, length, area of influence, branching, and appendages are reduced to produce a simple, truncated, and polarized tree that is restricted to one "barrelette". We asked whether target destruction alters this process. Four newborn rats received electrocautery lesions of the right thalamus, therein "depopulating" PrV of 59±7% (mean ± SD) of its cells (Jacquin et al., Neurosci. Abstr. 16, '90), yet sparing primary afferent projection patterns (Chiaia et al., JCN 303, '91). In adulthood, standard Golgi staining and computer-assisted neuron tracing/morphometric methods were used to compare dendritic trees of 50 experimental (E, contralateral to lesion) and 50 control (C, ipsilateral) cells. Soma diameters did not differ (E: 15.5±3.9, C: 16.9±5.3 um), indicating that the E sample was not biased towards the small % of normally large PrV cells with widespread and heavily branched trees. Main effects (t-tests, $p < .05$) were significant increases in total dendritic length (E: 988±649, C: 774±599 um), # of dendritic branch points (E: 16.1±12.9, C: 9.8±7.6), and # of spines or swellings (E: 23.1± 35.6, C: 13.1±17.6). Important measures that did not differ were transverse area of influence (E: 22,498, C: 20,805 um2) and # of primary dendrites (E: 4.5, C: 4.4). These data suggest that near-normal patterning of afferent inputs is insufficient for normal dendritic development of PrV cells. Other factors, such as interactions among dendrites and retrograde signals from the target, may also play important roles. DE07662, DE07734, DE08941,

MECHANISMS UNDERLYING RAPID ENLARGEMENT OF SPARED-WHISKER PROJECTIONS AFTER NEONATAL INFRAORBITAL NERVE SECTION. N.H. Hobart*, T.A. Henderson, W.E. Renehan, N.A. Connors, & M.F. Jacquin. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104; Dept. Med., Henry Ford Hospital, Detroit, MI 48202.

Waite & de Permentier (in press) have shown that the central projections of non-infraorbital whiskers occupy supranormal transverse areas in the rat brainstem after infraorbital injury at birth. We (Neurosci. Abstr. 16, '90) reported that such plasticity is not due to peripheral sprouting, regeneration errors, or preservation of an immature projection pattern. Anatomical and physiological tools were used to study the time course and mechanisms underlying this phenomenon. Cytochrome oxidase patches representing the 2 **supraorbital** whiskers in trigeminal subnucleus interpolaris were reliably larger than normal by postnatal day (P) 1.5 (1.15 ± .11 X control), but had not achieved adult-like disparity by P3 (1.81 ± .36 X control). To determine whether patch enlargement is due to relative changes in impulse activity produced by nerve section, tetrodotoxin (N=3) or bupivicaine (N=4) were applied from birth to block infraorbital nerve impulses during the first 5-7 Ps. As previously reported, infraorbital maps developed normally. Supraorbital patch areas were also unaffected (1.05 ± .28 X control). Thus, injury-induced patch enlargement does not reflect an activity-based competitive advantage conferred upon spared collaterals. To determine whether patch enlargement reflects collateral reorganization, intra-axonal recording and HRP staining methods were used to compare 10 control and 10 experimental spared-whisker primary afferents. Bouton or collateral numbers did not differ in interpolaris; however, experimental arbor areas were reliably larger ($p < .05$). Thus, patch enlargement reflects arbor expansion, but not collateral or terminal sprouting, in spared whisker collaterals. DE077734,DE07662.

DAILY WHISKER TRIMMING FROM BIRTH MIMICS NERVE INJURY-INDUCED RESPONSE ALTERATIONS IN TRIGEMINAL SECOND-ORDER CELLS. M.F. Jacquin & N.H. Hobart*. Anatomy & Neurobiology, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

To assess experiential contributions to developing response profiles in subnucleus interpolaris, 343 single units were studied in 10 rats after 6-9 weeks of left mystacial whisker trimming. Data were compared to 385 control cells. Encounter rates and whisker maps were normal. However, receptive field (RF) size, character and higher-order inputs were abnormal (neonatal infraorbital nerve cut data also shown, N=478; from JCN 282:63, '89):

Significant Effects	Control	Nerve Cut	Deprived
% local circuit with > 1 whisker RF	3.4	41.0	35.3
% with split RF	0	14.2	4.9
% interdivisional RF: local circuit	0.5	5.1	4.0
" thalamic-project	18.0	45.1	33.3
" cerebellar-project	3.7	13.1	7.3
% unresponsive to mechanical stimuli	2.8	7.2	7.6
% with intermodality convergence	1.4	23.1	12.6
% with directional sensitivity	3.9	9.8	13.2
% with high velocity sensitivity	13.9	24.9	27.1
% responsive to cortical shocks	8.7	14.5	23.9

These data indicate that deprivation alters development of response profiles in some trigeminal brainstem cells. These changes mimic those induced by nerve section. Thus, deprivation may underly nerve injury-induced effects on trigeminal brainstem RF size and character. Inasmuch as deprived primary afferents had normal RFs (N=59) and maps, second-order RF changes likely reflect subtle alterations in brainstem circuits. Support: DE07734, DE07662.

THE MATURATION OF THE LATERAL SPINOTHALAMIC AND TRIGEMINOTHALAMIC TRACTS IN RATS. D.Y.Miya & G.A. Barr. Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and Dept. Developmental Psychobiology, New York State Psychiatric Institute, NY, NY 10032.

In order to identify the neurons of origin and to study the ontogeny of both the lateral spinothalamic tract (LSTT) and the trigeminothalamic tract, two retrograde labels, WGA-HRP (5%) or green fluorescent latex microspheres were used. Rat fetuses of 17, 18, 19 (FD-17, FD-18, FD-19) days of gestation were injected with either tracer into the ventral posterior lateral nucleus (VPL) or the ventrobasal complex of the thalamus unilaterally. All injections were made through the use of the suture landmarks of the skull and penetrated the uterine and amniotic membranes. After a 24 hour survival period, a caesarian section was performed and all animals were perfused intracardially. Last year at this meeting it was reported that spinal cord cells were labeled in the contralateral dorsal horn of postnatal day 1 and day 10 rat pups. In the FD-19 rat, both methods yielded labeled cells in the same pattern as postnatal rats with the exception that the neurons of the lateral superficial lamina (lamina III) were absent and only neurons of the contralateral ventromedial dorsal horn were labeled. The ipsilateral medial lemniscus and most lateral aspects of the contralateral principal sensory trigeminal nucleus were also labeled following VPL injections. Results in the younger animals so far demonstrate that both sensory systems, the trigeminothalamic and LSTT are early developing tracts that are present prenatally in the rat.

STEREOLOGICAL ANALYSIS OF SYNAPSE NUMBER IN MEDULLARY DORSAL HORN LAYERS I AND II AFTER INFRAORBITAL NERVE SECTION AT BIRTH. I. Golden, D.S. Zahm, & M.F. Jacquin. Dept. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis MO 63104.

A large # of trigeminal (V) ganglion and brainstem cells die after neonatal infraorbital (IO) injury, producing shrinkage and permanant deafferentation of the V brainstem complex. Yet, the cytoarchitecture of layers I and II of the medullary dorsal horn is selectively preserved. As a first step in characterizing the anatomical reorganization subserving such "plasticity" in the dorsal horn, random systematic sampling and EM stereological methods were applied to layers I and II 90 days after cutting the left IO nerve at birth in 2 rats. To count synapses and terminals, as well as to compute a terminal areal fraction, the double dissector, profile counting, and point counting methods were used, respectively. In each case the # of IO nerve axons proximal to the point of neonatal injury were also determined.

	LEFT	RIGHT
	Case 1 2	Case 1 2
# of infraorbital axons (2 cases listed)	8,281, 9,737	36,236, -
# of synapses/100 um3	27.5, 28.9	22.6, 25.2
# of terminals/100 um2	36.0, 37.5	32.9, 28.3
# of terminals with dense core vesicles/100 um2	14.8, 15.4	13.5, 15.6
# of terminals with round vesicles/100 um2	18.1, 18.8	13.8, 10.8
# of terminals with flat vesicles/100 um2	2.6, 3.3	5.4, 1.5
terminal areal fraction (%)	14.9, 17.1	16.7. 14.9

These data suggest that at least normal #s of terminals and synapses exist in layers I and II, despite the fact that only 25% of IO axons survive axotomy at birth. The selective preservation of inputs to layers I and II may reflect a higher % survival of ganglion cells that normally project here, maintenance of immature projections, or sprouting. DE07734, DE07662, NS23805.

NF-L AND PERIPHERIN IMMUNOREACTIVITIES DEFINE DISTINCT CLASSES OF RAT SENSORY GANGLION CELLS. M.E.Goldstein, S.B. House* and H. Gainer. Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

We have used double immunofluorescence techniques with antibodies against NF-L and peripherin to identify peripherin positive, NF-L positive, and peripherin/NF-L coexistent subpopulations in adult and neonatal (PN2) DRG *in vivo*. In addition, we have determined which of the subpopulations contain the neuropeptides, substance P and calcitonin gene-related peptide (CGRP). Finally, we have determined which of these subpopulations are stably maintained in tissue culture. These studies have revealed three distinct subpopulations of neurons in rat dorsal root ganglia (DRG). In the adult rat, 46% of the DRG neurons were small and peripherin positive (NF-L negative), and 48% were large and NF-L positive (peripherin negative). About 6% were both peripherin and NF-L positive. All of the DRG neurons reacted with antibodies to NF-M and nonphosphorylation-dependent or phosphorylation-independent antibodies to NF-H. The neuropeptides were predominantly found in the small peripherin positive cell population. Eighty-seven percent of the peripherin positive small cell population contained substance P immunoreactivity, while 43% of this cell population contained CGRP. In contrast, only 18-24% of the NF-L positive, large cell population contained neuropeptides and these were primarily in a smaller sized subpopulation. Similar patterns of antigen representation were observed in neonatal (PN2) DRG cell populations. Tissue cultures of sensory ganglion cells from PN2 DRG, in serum free medium, stably maintained exclusively peripherin positive neurons, with about five percent of these containing coexistent NF-L immunoreactivity. Very high levels of neuropeptide gene expression were exhibited by these postnatal neurons in culture. In future experiments we hope to confirm these results using *in situ* hybridization histochemistry and to examine the effect of growth factors on the phenotypes of DRG neurons in culture.

THE STRUCTURAL, FUNCTIONAL AND NEUROCHEMICAL DEVELOPMENT OF SOME OF THE CUTANEOUS RECEPTORS AND THEIR AFFERENT FIBRES IN FETAL SHEEP. S.Rees, I.Nitsos* and J. Rawson*. Dept. of Physiology, Monash Univ., Clayton, Victoria, 3168, Australia.

The age at which a fetus is capable of receiving and experiencing sensations delivered by noxious or tactile stimuli remains uncertain. In this study we have used electrophysiological and anatomical techniques to examine the development of some of the cutaneous receptors and their afferent fibres in fetal sheep (n=28) from 83 to 143 days of gestation (term=146). At each age, recordings were made in the dorsal root ganglia to assess the response properties of these afferents to brushing, touching and pinching the skin of the hindlimb. At the conclusion of the experiment, the fetuses were perfused and the tissue taken from the skin, dorsal root ganglia and spinal cord and stained for immunoreactivity for substance P (SP) and calcitonin-gene related peptide (CGRP). Samples of skin were also processed for silver staining to demonstrate nerve fibres. The earliest responses, recorded at 87 days resulted from activation of high threshold, rapidly adapting mechanoreceptor afferents. By 97 days, afferents responded to all of the above stimuli and had well defined peripheral receptive fields. Immunoreactivity for SP and CGRP was detected in the dorsal horn as early as 83 days. Wool follicle innervation and free nerve endings in the skin were present in silver-stained sections at 87 days. With increasing gestational age, cutaneous innervation increased in density and complexity and the responses to stimulation were more readily elicited. These results suggest that cutaneous receptors are functional and afferent input is reaching the spinal cord as early as sixty percent of the way through gestation in the sheep.

449.17

Fos-Protein-Like-Immunoreactivity in the Suprachiasmatic Nucleus of Developing Rats. Myra P. Joyce and Gordon A. Barr. Dept. of Psychology, Hunter College-CUNY, New York, NY 10021.

Visual system projections from the retina (RHT) and the lateral geniculate nucleus terminate in the ventrolateral portion of the suprachiasmatic nucleus (SCN) and entrain the circadian activity of SCN neurons. In the 3 day old rat pup synapses arising from the RHT are not observed in the SCN, but by 4 days of age, RHT synaptic contacts are present. By 10 days of age, the number of SCN synapses is similar to that of the adult. In the present study we examined the appearance of Fos in the SCN of rats, 3 to 35 days of age. The avidin-biotin-HRP method was used with the primary antibody, rabbit-anti-Fos (Oncogene Sciences) diluted 1:10,000. In the ventrolateral SCN, developmental changes in activity, as indicated by the presence of Fos-LI, were observed that coincide with the synaptogenesis of the visual system projections. Three day old pups showed essentially no Fos-positive nuclei in the ventrolateral SCN. By 4 days of age, a few Fos-positive nuclei were observed and the number of labeled nuclei increased as the animal matured. At all ages, large numbers of Fos-positive nuclei were present in the dorsomedial SCN and this number also increased as the animal matured. Neither naturally occurring eye opening at 14 days of age nor surgical eye opening at eight days of age changed the activity of SCN neurons significantly. The results suggest that Fos appearance coincides with synaptogenesis in this system.

PARALLEL DEVELOPMENTAL CHANGES IN HIPPOCAMPAL PKC AND ELECTROPHYSIOLOGICAL PROPERTIES OF CA1 PYRAMIDAL CELLS. J.V. Sanchez-Andres, D.L. Alkon, J.L. Olds. Neural Systems Section, NINDS, NIH, Bethesda MD 20892.

Electrophysiological and autoradiographic experiments were performed on rabbit littermates in order to elucidate the effect of activated protein kinase C (PKC) on hippocampal physiology in ontogeny. Brains were rapidly removed from littermates (Day 0 to Day 15 post partum) and bisected. Half of the brain was used for electrophysiology. The other half of the brain was processed for quantitative 3H-PDBU autoradiography.

CA1 impulse patterns recorded from littermates prior to the day when neonates opened the eyes (NEO) showed marked adaptation and few impulses (1-3) in response to a depolarizing pulse. After NEO, all cells showed an adult firing pattern, i.e. with much less adaptation, as has been extensively characterized (Disterhoft et al., 1986).

The pattern of PKC distribution seen before NEO was qualitatively different from that seen either after that point in development or in adults. This was manifested by extremely dense bands of 3H-PDBU binding on either side of the stratum pyramidale both in CA1 and in CA3. These bands dramatically delineated the cell body layer and were localized to the most proximate apical and basilar dendritic zones. After NEO, this pattern shifted to one reminiscent of that seen in an adult classically conditioned animal 24 h into retention (i.e. stratum oriens and pyramidale showing together the greatest binding).

Taken together, the above data support the hypothesis that PKC plays an important role in controlling the excitability of CA1 pyramidal cells both in development and in learning. Thus, this enzyme may control functional connectivity both intrinsic and extrinsic to the hippocampus during and after behavioral and developmental modification.

CALCIUM CURRENTS IN FETAL HIPPOCAMPAL NEURONS IN PRIMARY CULTURE FROM THE TRISOMY 16 MOUSE, A MODEL FOR DOWN SYNDROME. **Z.Galdzicki, E.J.Coan & S.I.Rapoport. LNS,NIA,NIH,Bethesda, MD 20892**

The entry of calcium through voltage-gated membrane channels plays a crucial role in a variety of hippocampal neuronal activity. The trisomy 16 mouse is considered to be a model of human trisomy 21 (Down Syndrome). It has been reported that both low voltage activated (LVA) and high voltage activated (HVA) calcium currents can be detected in embryonic hippocampal neurons in primary culture. Hippocampal neurons were cultured from fetal trisomy 16 and normal mice at gestation day 14-16 using standard techniques. Whole cell inward currents were recorded from the somatic region of 10-21 day old cells, with 120 mM choline chloride, 20 mM 4AP, 10 mM $CaCl_2$, and 10 mM TEA in the bath solution and 130mM CsCl, 10 mM BAPTA, and 20 mM TEA in the pipette solution. Currents were evoked with 10 mV, 150 ms steps, from holding potentials of -90, -40, and -60 mV. Both HVA and LVA calcium currents were identified. In trisomy neurons the peak amplitude of the inward current reached a maximum at a membrane potential (Vm) of 6.7 mV (n = 12) for currents evoked from a holding potential of -40 mV and at 0.4 mV (n = 19) for currents evoked from a holding potential of -90 mV. The latter currents showed a statistically significant hyperpolarizing shift for Vm of 7.5 mV compared to control neurons. During the recording time the I-V response of the trisomy 16 cells showed a significant shift of 7.1 mV (n = 15) in a depolarizing direction which was not observed in control neurons. These observations suggest that calcium currents are abnormal in trisomy 16 fetal hippocampal neurons.

450.3

ACTION POTENTIALS IN CULTURED FETAL HIPPOCAMPAL NEURONS FROM MOUSE TRISOMY 16, A MODEL OF DOWN SYNDROME. E.J.Coan, Z.Galdzicki & S.I. Rapoport. LNS, NIA, NIH, Bethesda, MD 20892.

The trisomy 16 (Ts16) mouse is considered to be a model of human trisomy 21 (Ts21) (Down syndrome). This laboratory has reported that action potentials in Ts16 and Ts21 cultured dorsal root ganglion (DRG) neurons are different from those in control neurons. The aim of these experiments was to investigate action potentials in Ts16 hippocampal neurons. Primary cultures of hippocampal neurons were prepared from Ts16 embryos and littermate controls at gestation day 14-16, whole cell patch clamp recordings were made from 2-4 week old neurons. Extracellular medium included 140 mM NaCl and 5 mM KCl, intracellular solution 5 mM NaCl and 130 mM KCl. 5 mV 10 ms or 50 pA 1 s pulses were used to measure passive membrane properties. Action potentials were evoked by 0.1 to 0.8 nA, 5 ms depolarizing pulses. All measurements were done at -60 mV. Data were taken from 10 control and 14 Ts16 cells. Resting membrane potentials were -49 mV and -42 mV for control and Ts16 neurons respectively. In control cells the mean action potential amplitude ranged from 87 mV (0.1 nA pulse) to 114 mV (0.8 nA pulse), the mean time to peak amplitude from 5.3 to 3.9 ms, the mean width from 3.5 to 3.6 ms, the mean depolarization rate from 100 to 117 V/s and the mean repolarization rate from -31 to -54 V/s. None of the mean passive or active membrane properties measured in Ts16 neurons was significantly different from control values. This result is different to that reported in Ts16 and Ts21 DRG neurons, and might be explained by differences in maturation and/or the presence of growth factors.

MORPHOLOGICAL AND PHYSIOLOGICAL DEVELOPMENT OF NEURONS AND AFFERENTS IN ORGANOTYPIC SLICE CULTURES OF PARIETAL CORTEX. C.M. Annis, R.T. Robertson, A. Agmon, and D.K. O'Dowd Depts. of Anatomy and Neurobiology & Developmental and Cell Biology UC Irvine, Irvine, CA 92717

Previous studies have demonstrated extensive changes in the rodent neocortex at both the anatomical and electrophysiological levels during early postnatal development. We are utilizing an organotypic slice culture system (Gähwiler, 1981) to facilitate examination of cellular mechanisms that underlie postnatal development of cortical neurons and their afferent connections. Transverse slices of rat parietal cortex or oblique thalamocortical slices from mouse brain (Agmon and Connors, 1991) were taken from P0 animals and maintained in defined medium (Annis et al., 1990). The whole cell recording technique was used to examine cortical neurons between 1 day and 3 weeks in culture. Inclusion of Lucifer Yellow in the recording electrode permitted correlation of electrophysiological and morphological properties of individual cells.

Electrophysiological recordings were obtained from three morphologically distinct classes of neurons in cultures from rat parietal cortex: pyramidal, multipolar and bipolar. During the first five days in culture the majority of intracellularly labeled neurons exhibited cell bodies with short unbranched processes. By 8-14 days most of the cells encountered had much longer processes with the pyramidal cells exhibiting basal dendrites, elongated apical dendrites and axons with several collaterals. Physiological experiments revealed an increase in the action potential amplitude, decrease in the duration and an increase in the probability of eliciting multiple spikes in response to depolarizing current pulse, as a function of age in culture. The role of afferents in cortical neuron development is being studied in mouse thalamocortical slices. Morphological data, using DiI, demonstrate growth of thalamocortical projections in culture. These two slice preparations and the baseline information on their development in culture provide a unique system for identifying the factors that may influence cortical development. This work was supported by grants from Alzheimers Fnd. 90-082, NS25674 (RTR) and NS27501 (DOD).

CHOLINERGIC RESPONSES OF DEVELOPING RAT NEOCORTICAL CELLS IN TISSUE SLICES, A LAMINAR STUDY. Finlayson, P.G. and Cynader, M.S., Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, B.C. Canada, V5Z-3N9

Enhanced plasticity of neonatal systems are paralleled by developmental changes in the cortical laminar distribution of many receptors, as observed in autoradiographic studies. Muscarinic cholinergic receptors, M1 and M2, redistribute in the developing kitten cortex, and are transiently high in layer IV at young ages but predominantly concentrated in layers I, II and III in adult cats. Nicotine receptors exhibit a transient density in layer IV of rat pup visual and auditory cortices during the second postnatal week. In this study, physiological correlates of receptor redistributions during development were examined. Responses of neurons in layers 2/3, 4, and 5 in the visual areas of rat neocortex tissue slices from P9 to P25 day rat pups were evaluated. Membrane properties, spike properties, afterhyperpolarizations and responses to electrical stimulation of either supra or infragranular layers were recorded. One or two cells per slice were also labelled with Lucifer yellow and imaged using a confocal microscope to determine the type, size and location of neurons recorded. Responses to carbachol and acetylcholine, applied by pressure ejection, were depolarizations, decreases in after-hyperpolarizations, and changes in input resistance and evoked psp's. Developmental changes in the laminar distribution of these response were compared to changes in binding distributions of pirenzipine, oxotremorine, and nicotine in developing rat neocortex.

DEVELOPMENT OF CHOLINERGIC AND SEROTONERGIC RECEPTORS IN THE SOMATOSENSORY CORTEX OF THE RAT. M.I. Davila-Garcia, A.K. Chan*, P. Tran* and F.M. Leslie. Dept. of Pharmacology, University of California, Irvine, College of Medicine, Irvine, CA 92717.

There is now considerable evidence that neurotransmitters may regulate many developmental processes. In particular, cholinergic and serotonergic systems have been found to appear early in the development of somatosensory cortex, and have been implicated in control of morphogenesis. The receptors through which these neurotransmitters may act are currently unknown. In the present study we have used radioligand binding and autoradiography to examine the distribution of both cholinergic and serotonergic binding sites at postnatal day 10 (P10), and have compared this with the adult binding pattern. Radioligands used to label muscarinic receptors included [^{3}H]pirenzipine for M1 sites, [^{3}H]AFDX-384 for M2 sites and [^{3}H]NMS for non-M1/non-M2 sites, while [^{125}]α-BTX was used to label a subpopulation of nicotinic binding sites. For the serotonergic system, we have examined the distribution of [^{3}H]8-OH-DPAT-labeled S1A binding sites. While muscarinic M1 and non-M1/non-M2 binding sites were found to exhibit a distribution in the neonate that is similar to that in the adult, with the highest density of sites concentrated in superficial layers, M2 sites at P10 are patchy, bilaminar and arrayed in dense columns. [^{125}I]α-BTX sites in neonatal somatosensory cortex are distributed in radially oriented columns that have various thin, dense bands in the developing laminae, in contrast to the distribution in the adult which is mostly concentrated in lower layers. Similarly, the distribution of S1A binding sites at P10 is found to be patchy in this area and exhibits a columnar arrangement which is distinct from that of the adult. These data suggest that cholinergic and serotonergic receptor ontogeny within somatosensory cortex is complex, and that some receptor types exhibit developmental changes consistent with a role in the modulation of cortical architecture and function. *Supported by USPHS grant DC 00450.*

DEVELOPMENT OF ACHE-POSITIVE FIBER CONNECTIONS BETWEEN BASAL FOREBRAIN AND CEREBRAL CORTEX IN ORGANOTYPIC TISSUE SLICE CULTURES P.G. Distler* & R.T. Robertson. Dept. of Anatomy and Neurobiology, Univ. of Calif., Irvine, CA 92717

Projections of the cholinergic basal forebrain nuclei into the cerebral cortex are part of a complex neuronal network of the brain especially involved in learning and memory. To study the development of these projections *in vitro*, slices of basal forebrain and lateral cortex tissue from early postnatal rats were co-cultured for up to 4 weeks using the roller tube technique (Gähwiler, 1981). During this time period the development of the cholinergic innervation of the cortex by basal forebrain neurons was studied by means of AChE-histochemistry and ChAT-immunostaining. Tissue cultures were maintained either with serum-based medium or with chemically defined medium (Annis et al., 1990), in some cases supplemented with nerve growth factor (NGF).

Basal forebrain explants show numerous outgrowing AChE-positive neurites. Although AChE-positive neurons are observed in cerebral cortex, these neurons never gave rise to AChE-positive axons. ChAT-immunostaining reveals positively labelled neurons only in the basal forebrain tissue. Within one week of culturing, AChE-stained fiber processes are visible growing into the adjacent cortex slice. Many labeled axons travel tangentially beneath the cerebral cortex and then turn to grow into the cortex, in some cases extending to the pial surface. Ramifications are visible in the subplate region as well as in the more superficial cortical layers. Cortex slices placed with the pial surface to the basal forebrain reveal a slightly different innervation pattern; AChE-positive axons enter the cortical tissue through the pial surface and show dense ramifications within the superficial layers. Co-cultures with the different culture media exhibit similar innervation patterns of the cortex. Control experiments with co-cultures of basal forebrain and cerebellum slices show no AChE-positive fiber ingrowth into the cerebellum tissue and provide evidence for the specificity of the basal forebrain-cortical connections *in vitro*.

DEVELOPMENTAL ANATOMY OF BASAL FOREBRAIN CHOLINERGIC PROJECTIONS IN THE RAT. G.R. Stewart and B. Stanfield, Lab. of Neurophysiology, NIMH, NIH Animal Center, Poolesville, MD 20837.

The basal forebrain cholinergic (BFC) system provides the major source of cholinergic innervation to the neocortex, hippocampus, and amygdala. In the present study, the postnatal development of these projections was examined following injections of the retrograde tracers fast blue and diamidino yellow into various cortical and subcortical regions in the rat (Sprague-Dawley). By postnatal day 5 (P5), the distribution and proportion of labeled neurons within the various subsectors of the basal forebrain (medial septum, diagonal band, etc) that project to a given target are similar to that seen in adult rats. Non-overlapping cortical injections of both tracers into the same hemisphere or bilaterally results in a low incidence (0-5%) of double labeled cells as has also been noted in adults. These observations suggest that BFC projections are established with the appropriate target early in postnatal development, and display even at this stage, an adult-like degree of topographic specificity.

The development of cholinergic innervation within BFC targets was studied quantitatively using densitometric measurement of acetylcholinesterase (AChE) histochemistry and qualitatively with cholineacetyltransferase (ChAT) immunohistochemistry. Within most cholinoceptive regions, there is a rapid increase in staining for both enzymes between P2 and P20 with adult levels present by P40. One notable exception is the delayed development of staining within the nucleus of the lateral olfactory tract (NLOT). In adults, the NLOT has one of the highest concentrations of ChAT and AChE activity in the forebrain, but through P9 there is virtually no staining of the nucleus even though neighboring regions are well-stained. In addition, placement of the carbocyanine dye, DiI, into the basal forebrain prior to P9, fails to label fibers within the NLOT, but between P10 and P20 there is a rapid invasion of DiI-positive fibers in conjunction with increased staining for ChAT and AChE. It is unclear why the cholinergic innervation of such a prominent, and proximal, target of the BFC system lags behind all other regions during this critical phase of development.

EARLY FETAL DEVELOPMENT OF CALCIUM-BINDING PROTEINS, PEPTIDES, DARPP-32 AND MONOAMINERGIC INNERVATION IN THE HIPPOCAMPAL REGION OF THE RHESUS MONKEY.

B.Berger, D.Pouhé*, C.Alvarez*, P.S.Goldman-Rakic. INSERM U106, Hôpital Salpêtrière, Paris, France and Section of Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510.

Immunocytochemical detection of calbindin (CaBP), parvalbumin, neurotensin (NT), somatostatin (SST), DARPP-32 as well as tyrosine hydroxylase (TH), dopamine- -hydroxylase (DBH) and serotonin (5-HT) was carried out in 5 rhesus monkey fetuses from E64 to birth (gestation 165 days). At E64, the already well defined entorhinal cortex displayed all aforementioned types of innervation but in different density and laminar and topographical distribution: CaBP-immunoreactive (IR) plexus in layer I and numerous IR cells in all layers and subplate (SP) contrasted with the few parvalbumin-IR neurons in layer 6 and DARPP-32-IR perikarya in layers 2-3; a dense SST-IR plexus was present in layers 1 and 5-6 as well as IR-neurons in layer 6 and SP. NT innervation mainly developed from E83 on, in layers 1 and 5-6. Aminergic afferents predominated in the lateral entorhinal cortex, 5-HT afferents being denser than TH-IR ones. At E64, the hippocampal formation was much less differentiated; the relatively low density of aminergic afferents contrasted with an area-specific expression of the other markers: DARPP-32 -IR neurons, NT-IR neurons and terminals in both the ventral and dorsal subiculum and cingulate cortex; CaBP-IR neurons and terminals in Ammon's horn, dentate g., dorsal sub. and cingulate cx; dense SST innervation restricted to the ventral hippocampal formation. The density of neuroactive substances in the main association and output areas of the hippocampal region (subiculum and entorhinal cortex) in early fetal life in primates, is of special interest in view of the hypothesis that some forms of schizophrenia could be related to developmental abnormalities of this region.

DOPAMINE BETA-HYDROXYLASE (DBH) AND TYROSINE HYDROXYLASE (TH) IMMUNOREACTIVITY IN HIPPOCAMPUS-LOCUS COERULEUS CO-CULTURES.

A.M. Moudy, D.D. Kunkel, C.A. Robbins*, M.E. Gross* and P.A. Schwartzkroin. Dept. of Neurological Surgery, Univ. of Washington, Seattle, WA 98195.

Co-cultures of hippocampus (HC) and locus coeruleus (LC) were studied immunocytochemically to examine noradrenergic innervation of hippocampus. Vibratome slices (350 μm) of P4 rat HC and E17-P1 LC were co-cultured on glass coverslips for 2-6 weeks. TH and DBH positivities were then evaluated in fibers and cells. Large, multipolar cells were labelled in LC, and an occasional cell appeared near or within HC and in fiber tracts. DBH-positive cells tended to concentrate near the edges of LC tissue, apparently having migrated out from more central regions. LC slices cultured alone showed little sign of fiber outgrowth in any direction. TH- and DBH-positive fiber tracts were traced from LC to HC. Cresyl violet counterstaining, used to distinguish hippocampal cell layers, revealed that immunopositive fibers entered the HC at the hilus and near CA3. Beaded fibers formed extensive collateral branches upon reaching the HC. Light microscopy suggests that DBH-positive fiber growth is densest at or near the pyramidal cell layer in CA3b and CA3c and the infragranular region of the dentate hilus. Electron microscopic studies are currently underway to determine the postsynaptic targets of these fibers.

IMMUNOCYTOCHEMICAL CHARACTERIZATION OF PUTATIVE NEUROTRANSMITTERS IN RAT HIPPOCAMPAL SLICE CULTURES.

D.D. Kunkel, D.L. Schmiege, A.T. Malouf and P.A. Schwartzkroin. Dept. of Neurological Surgery, Univ. of Washington, Seattle, WA 98195.

Hippocampal slice cultures retain their basic structural organization when "grown" by the roller-tube technique. Typical neuronal morphology and much of the intrinsic connectivity is maintained. However, since extrinsic afferents are lost in cultured slices, one would expect at least subtle re-organization of local circuitry. We have been particularly interested in local inhibitory function and structure, and therefore initiated a morphological study of two major putative inhibitory neurotransmitter systems - gamma-aminobutyric acid (GABA) and somatostatin (SRIF) - using immunocytochemical staining techniques and electron microscopy. GABA immunoreactivity was seen in numerous somata distributed throughout different strata of the slice cultures. GABA-positive cells were often clustered near major pyramidal and granule cell layers. A very extensive GABA immunoreactive axonal plexus was seen; a dense positive fiber arborization surrounded principal cell somata, and numerous positive terminals were found making synaptic contacts with pyramidal and granule cells. SRIF immunoreactivity was observed mainly in cell populations localized in stratum oriens and within the hilar region. Numerous SRIF-positive axonal fibers extended throughout all regions of the culture, with synaptic connections found on principal cell somata and dendrites. These characteristics of the GABA and SRIF systems in culture were grossly similar to GABA and SRIF patterns previously defined in rat brain, but differed in a number of important aspects which require further elucidation.

Supported by grants from NIH (NS15317, NS18895), and the Epilepsy Foundation of America.

INTRACELLULAR INJECTION OF TWO DYES INTO DIFFERENT NEURONS IN THE RAT HIPPOCAMPAL SLICE PREPARATION: DUAL RECOGNITION FOR LIGHT AND ELECTRON MICROSCOPY.

D.L. Schmiege, D.D. Kunkel, H.E. Scharfman and P.A. Schwartzkroin. Dept. of Neurological Surgery, Univ. of Washington, Seattle, WA 98195.

Intracellular recordings and labeling techniques have become extremely important in the physiological and morphological identification of neurons in the central nervous system. Intracellular dyes, such as biocytin/Neurobiotin (BC/NB) and Lucifer Yellow (LY) have proven useful for morphological analysis of neurons at the light (LM) and electron microscopic (EM) levels. We now report the physiological and morphological identification of two different hippocampal neurons in the same slice with electrodes containing two different intracellular markers - LY in one pipette and biocytin (or neurobiotin) in the other. BC/NB was injected with positive current, and the filled neuron was recognized using avidin-HRP; LY was injected with hyperpolarizing current and the labeled cell identified with a LY antibody (a generous gift from Molecular Probes), followed by a secondary IgG-HRP. HRP histochemical processing then proceeded with different chromagens (e.g., diaminobenzedine (DAB), DAB/nickel, benzenedihydrochloride (BDHC), chloronapthol, or carbazole) associated with the LY and BC/NB label. Cells could be easily distinguished, and processes clearly visualized by the different colored chromagens. We have also successfully differentiated labeled neurons at the EM level, using different electron-dense markers (e.g., DAB, BDHC, ferritin, and gold) associated with the LY and biocytin labels. Simultaneous use of these intracellular dyes and recognition markers allows for a more detailed examination of cell-to-cell circuitry in the hippocampus.

Supported by NIH grants NS18895 and NS20482.

ANATOMICAL STUDIES OF CA3 HIPPOCAMPAL NEURONS AND NETWORKS DURING POSTNATAL DEVELOPMENT.

J.W.Swann[1], C.M.Gómez[2], F.L.Rice[2], K.L.Smith*[1], J.N.Turner[1]. [1]Wadsworth Center for Laboratories and Research, NYS Dept. of Health, Albany, N.Y. 12201 and [2]Dept. of Anatomy, Cell Biology & Neurobiology, Albany Medical College, Albany, N.Y. 12208.

Age-dependent alterations in local circuit collaterals from individual CA3 hippocampal pyramidal cells were examined. These results were related to CA3 neuronal density at each age.

Individual CA3 hippocampal neurons from postnatal day (PND) 4 to 70 rats were characterized physiologically in slice preparations. After labelling with biocytin, the morphology of the cells was quantified by a computer-assisted neuron reconstruction system. The perikaryon number was also assessed in Schiff stained sections by confocal microscopy.

An extensive pyramidal cell axonal arborization occurs during the second postnatal week, concomitant with a transient period of hippocampal hyperexcitability. Total arbors were about three times longer than those observed in mature neurons and about thirty times longer than those observed from rats under one week of age. Density of varicosities along the axons was similar between week two and adulthood.

Qualitatively, CA3 cell number per 500um slice decreases significantly from PND 5 to PND 50. Quantitative estimations are in progress.

Clearly, individual cells from week two make many more synapses per 500um slice than their adult counterparts. Whether the overabundance in total varicosity number translates to a potential excess of synapses onto neighboring neurons is currently under study.

STAINING FOR ZINC REVEALS COLUMNAR PATCHES IN THE HIPPOCAMPUS OF THE NEWBORN RAT.

C.J. Frederickson, G.Danscher, K.J. Cravens, L. Slomianka, and L.B. Sylvan, Laboratory for Neurobiology, UT-Dallas, Box 688 Richardson TX 75083

In the striatum of the newborn rat, staining for zinc-containing axonal boutons is an early marker that distinguishes the patches from the matrix. (Dev. Brain Res., 45 (1989) 155). We now report that staining for zinc-containing axonal boutons also reveals a patchy, "columnar" pattern of organization in the hippocampus of the newborn rat.

Pup brains were stained for zinc-containing boutons by the selenium method. Na2SeO3 was injected i.p. 1 hr before sacrifice, then brains were removed, cut frozen, and developed by silver-enhancement.

In newborns (P0), the staining in hippocampal zone s. oriens was organized into distinct bands or patches, each about 50 - 75 um wide, alternating with unstained patches of comparable width. Often the patches continued from s. oriens through s. pyramidale and into the proximal half of s. radiatum, producing radially-oriented bands, or columns, of stain oriented perpendicular to s. pyramidale. So far, the patches have been observed only in CA1 of the mid-body of the hippocampus. In development, they become indistinct by day P2 - P3, and virtually invisible by P5, when uniform staining of zinc-containing boutons fills the neuropil.

The possibility that columnar units endure in some form within the internal circuitry of the adult hippocampus is raised. Supported by MH42798 to CJF.

DEVELOPMENT OF DIAPHORASE CONTAINING NEURONS IN THE AMYGDALA, HIPPOCAMPUS AND ENTORHINAL CORTEX IN HUMANS. S.B. Schueler, H.K. Le*, E.J. Mufson, and J.H. Kordower, Dept of Anatomy and Cell Biology, Univ. Illinois Sch. Med. Department of Neurological Sciences, Rush Presbyterian Medical Center, Chicago Ill. 60612 USA.

As part of our continuing comparison between normal human developmental patterns and changes seen in neurodegenerative disease, we examined the distribution of diaphorase (NADPH-D)-containing neurons within the medial temporal lobe of the embryonic human brains at gestational (E) points 10-26 weeks. No NADPH-D-containing profiles appeared in the medial temporal lobe prior to week E19. At E19, faint NADPH-D staining was seen within the central nucleus of the amygdala. Staining for Nissl substance and acetylcholinesterase (AChE) at E19 revealed an immature, but existing, cytoarchitecture suggesting that neurons which normally synthesize NADPH-D are present but are not expressing the enzyme. At E21, the accessory basal and lateral basal amygdaloid nuclei contained numerous NADPH-D-positive neurons and a dense neuropil. The lateral amygdaloid nucleus was moderately labeled. The entorhinal cortex displayed a trilaminar pattern with darkly labeled cell islands in layers I-II, a dense neuropil in II-III and V-VI. In the hippocampus, a continuous band of NADPH-D was seen from CA1-CA3. CA4 contained only light NADPH-D staining. NADPH-D-stained profiles were also seen in the dentate granule cell layer. Clouds of NADPH-D stained neuropil were seen in layer II of the subiculum. At E24-26, NADPH staining within the medial temporal lobe resembled the adult. These data will be compared to potential morphological changes seen in normal aging and disease.

450.16

AXONAL STRATA AND FIBRE SYSTEMS IN THE FRONTAL LOBE OF THE HUMAN FETAL AND INFANT BRAIN. I. Kostović, H.B.M. Uylings, C.G. Van Eden and M. Judaš. Croatian Institute for Brain Research, Zagreb, Yugoslavia and The Netherlands Institute for Brain Research, Amsterdam, The Netherlands.

We have analyzed arrangement and sequence of growth of fibre systems in the frontal lobe of postmortem human fetuses and infants (10 weeks of gestation - 1 year) using Di-I, acetylcholinesterase (AChE) and silver techniques. The correlated analysis of Di-I, AChE and silver staining of the fetal brains revealed the stratified, discrete distribution of axons within the cerebral wall. The earliest fiber system demonstrable occupies the outermost position within the white matter and forms external capsule radiation. Thalamocortical radiation and efferent cortical fibres occupy intermediate stratum, while the deepest, subventricular stratum contains growing callosal fibres (in fetuses older than 11 weeks). Cortico-cortical association fibres (including U-fibres) grow in the superficial stratum situated between the subplate zone and external capsule during the perinatal and early postnatal period. The growing axons from all strata penetrate the subplate zone forming a transient plexiform compartment. In conclusion, afferent fibres form axonal strata as a result of the laminar sequential growth. The development of cortico-cortical fibres correlates with the perinatal development of cerebral convolutions.

NOVEL **ANTENNAPEDIA**-CLASS HOMEOBOX GENES ISOLATED FROM HUMAN 11 WK FETAL BRAIN LIBRARY. J.F. Leckman, X. Lin*, A. Swaroop*, M.T. Murtha*, F.H. Ruddle*. Child Study Ctr., Depart. of Biol., Psychiatry, and Pediatrics, Yale University, New Haven, CT 06510 and W.K. Kellogg Eye Ctr., Depart. Ophthalmol. and Human Genetics, Univ. Michigan, Ann Arbor, MI 48105.

Three novel **Antp.**-class homeobox genes have been isolated from a human 11 wk. fetal brain cDNA library. PCR with two sets of oligonucleotide primers (specific for highly conserved regions of the **Antp.**-class homeobox) was used to amplify portions of homeobox genes present in the fetal brain library. The products were cloned into a modified **pGem** vector and transformed into DH5a cells. Sequencing 100 clones (spanning 77 to 81 bases between primers) identified 11 unique **Antp.**-class genes. The base sequence of one of the novel HOX genes, HOXBA, showed 65% homology with HOX1.1, 89% homology with the CHOX7 gene (isolated from fetal chicken), and 95% homology with the MMOXA gene (isolated from fetal mouse telencephalon). Based on the origin of MMOXA, it appears that HOXBA is among the first **Antp.**-class homeobox genes identified in the developing human telencephalon.

VISUAL SYSTEM: SUBCORTICAL PATHWAYS

451.1

MOLECULAR CLONING OF A TYPE I KERATIN FROM GOLDFISH OPTIC NERVE:INCREASED KERATIN EXPRESSION DURING REGENERATION. R. Druger*, E. Levine*, P. Jones*, N. Schechter and J. McCaughran. Depts. of Biochemistry and Psychiatry, SUNY Stony Brook, Stony Brook, NY 11794.

The goldfish visual pathway displays continuous growth, development, and plasticity throughout life. Furthermore, a remarkable capacity for functional regeneration occurs after optic nerve injury. This laboratory is interested in intermediate filament (IF) proteins and their structural relationship to cellular growth and development.

Glial cells in this pathway express a type II keratin, not the expected GFAP. The presence of a type II keratin predicts the expression of a type I keratin partner. Using a PCR protocol, core regions from type I keratins were amplified from a goldfish optic nerve cDNA library. DNA fragments from this core region were then used to rescreen the cDNA library to isolate larger clones. The largest cDNA clone was translated, compared to known IFs, and classified as a type I keratin. Northern analysis revealed an mRNA of 1.6 kb that is abundantly expressed in the optic nerve. In situ hybridization on regenerating optic nerve shows that both the type I and type II keratins have increased mRNA levels throughout the optic nerve 10 days after nerve crush.

Keratins are known to be expressed in mammalian CNS only in early development. Thus, these IF proteins may have structural attributes which support the growth characteristics of this pathway and therefore may be linked to the capacity for growth in this system. (supported by NIH grant EY05212 to NS)

451.2

FIBER RE-ORGANIZATION IN THE MAMMALIAN OPTIC CHIASM: *DE NOVO* ESTABLISHMENT OF THE DORSO-VENTRAL RETINAL AXIS. B.E. Reese, G.E.Baker*, G. Tassinari* and C.A. Marzi*. Neuroscience Research Institute, University of California at Santa Barbara, U.S.A., Department of Human Anatomy, University of Oxford, U.K. and Istituto di Fisiologia Umana, Università di Verona, Italy.

Optic axons undergo a transformation in their fiber ordering within the chiasmatic region to become segregated by type within the optic tracts. In the tract, these segregated axon classes are themselves roughly retinotopically ordered, particularly with respect to the dorso-ventral retinal axis. The present study has examined the emergence of this retinotopy within the chiasmatic region of adult ferrets and cats. Ferrets were given discrete retinal lesions and were then examined for the distribution of degenerating myelin in semi-thin sections along the course of the fiber pathway. Cats were given implants of Horseradish peroxidase via a transbuccal approach to label the chiasmatic path and retinal origin of the superficially placed axon classes coursing through the lateral or medial halves of the optic tract.

The retinotopic ordering of individual axon classes observed in the tract must be established afresh within the chiasmatic region, since 1) axonal degeneration induced by dorsal vs. ventral retinal lesions is relatively well-segregated in the post-orbital nerve and tract but is widely dispersed along the intracranial and pre-chiasmatic segments of the nerve in adult ferrets, and 2) retrogradely labelled fibers of a given ganglion cell class, labelled from the lateral vs. medial optic tract, are intermingled in the pre-chiasmatic optic nerve of adult cats despite arising from the ventral vs. dorsal retina. Dorsal retinal axons decussate caudal to ventral retinal axons for any axon class, yet prior to crossing the midline they are intermingled.

The degree of retinotopic precision becomes too degraded along the nerve to account for the order found in the optic tracts. An active re-organization must occur within the chiasmatic region, and for the decussating fibers this occurs in the region of the midline.

451.3

THE ARRANGEMENT OF AXONS BY SIZE AND LATERALITY OF PROJECTION IN THE OPOSSUM'S OPTIC TRACT.

L.A. Cavalcante, S. Allodi# and §B.E. Reese, Instituto de Biofisica C. Chagas Filho, UFRJ, 21941 Rio de Janeiro, Brazil and §Dept. of Human Anatomy, University of Oxford, OX1 3QX, U.K.

We have examined the relative positions and size spectra of crossed and uncrossed optic axons in the opossum's optic tract (OT) to compare its regional organization with both the patterns of ganglion cell genesis and the disposition of axonal terminations in target nuclei. Regional histograms of axon size show that (1) the deep parts of the OT contain medium and fine fibers with uncrossed axons displaced towards the tract's pial margin, (2) the intermediate parts contain axons of all diameter classes with coarse crossed elements deeper than uncrossed counterparts, (3) the superficial parts contain primarily crossed, fine fibers and mostly uncrossed, medium and coarse axons. Thus, as in eutherians, the fiber order in the opossum's OT arises from the sequences of genesis of ganglion cells and presages the (partial) segregation of axonal terminations in the thalamus and midbrain. (CNPq, FAPERJ, FINEP, CEPG/UFRJ)

451.4

RETINAL DECUSSATION PATTERN IN THE RHESUS MONKEY EMBRYO. B. Lia. Dept. Psychol., & Calif. Regional Primate Res. Ctr., Univ. Calif., Davis CA 95616-8686

Using DiI in fixed embryos of the rhesus macaque (*Macaca mulatta*), the first optic axons are seen to enter the optic tracts by embryonic stage 20 (E40±2). At stage 21 (E42±2), retrograde labeling from the optic tract reveals that the most advanced axons arise from ganglion cells within a discrete area just dorsal to the optic nerve head and far from the prospective fovea. Given the exceptional hemiretinal specificity evident at later fetal ages (Chalupa & Lia, 1991), it is remarkable that the first ipsilateral projections arise from this portion of the presumptive nasal hemiretina, similar to the case in the mouse (Colello & Guillery, 1990). By the end of the embryonic period (E48±2), the most advanced projections arise from scattered ganglion cells distributed in relatively low density across the entire retina, some with well-developed dendrites. This early projection cohort exhibits the inherent primate decussation pattern, lacking the crossed temporal projection present among nonprimate mammals.

These observations suggest that retinal positional information is present for the decussation of the early projection cohort, but that expression of this information is dependent upon interaction of nasal and temporal axons at the chiasm. Nasal axons alone may not be endowed with explicit instruction to cross the chiasm. Temporal axons seem to avoid a sector of the midline chiasm and grow along crossed fibers from the other eye (Godement, Salaün & Mason, 1990). Additionally, prior to their crossing of the chiasm, nasal axons may avoid growing along the temporal axons filling the ipsilateral optic tract. Such a guidance mechanism for crossed projection from the nasal retina would not be operative until the arrival of temporal axons at the chiasm. (Supported by NIH RR00169)

TRANSCELLULAR DIFFUSION EVENTS OF THE CARBOCYANINE DYE, DiA, IN THE EMBRYONIC FERRET VISUAL SYSTEM. I. Kelly Johnson[1] & Vivien A. Casagrande.[1,2] Depts. of Cell Biology[1] & Psychology[2], Vanderbilt Univ., Nashville, TN 37232-2175.

Optic axons appear to make a choice at the optic chiasm. It is unclear what mechanisms may signal such a choice. We inoculated DiA into embryonic eyecups between E21-E30 to examine interactions between cross/uncrossed labeled retinal axons at the optic chiasm. Embryos were delivered via cesarean section from anesthetized ferrets and immersion fixed in 4% paraformaldehyde in phosphate buffer. DiA crystals [4-(4-dihexadecylaminostyryl)-N-methylpyridinium iodide; Molecular Probes] were then put into the eyecup. Following incubation at 37°C for 1-2 months, brains were vibratome sectioned and mounted on subbed slides.

Optic axons reach the chiasm by E25 (Guillery & Walsh, 1987, JCN, 265:203-217; Johnson & Casagrande, 1991, IOVS Suppl., 32(4):1035). The chiasm, and optic nerve and retina contralateral to the inoculated eye, become stikingly labeled beginning at this age. Ganglion cells and radial glial cells, putative Müeller cells, also become labeled. Transcellular labeling of thalamic radial glia bordering labeled optic tracts was routinely observed. Transneuronal diffusion into cortex was not observed.

These results suggest that the dye communicates between cells (neuron-neuron, neuron-glia) at and near the optic chiasm, and within the retina, via specialized cell-cell contacts. Alternatively, the strongly labeled projection to the contralateral retina may reflect an interretinal pathway present early in development. Johnson, et al. (1990, Soc. Neurosci. Abst., 16:53) reported similar transcellular diffusion events of carbocyanine dyes in fixed tissues of the horseshoe crab.

ALTERATION OF AXON ARBOR COMPENSATES FOR NUMERICALLY MISMATCHED POPULATIONS IN THE HAMSTER RETINOTECTAL SYSTEM. M. Xiong (1), S.L. Pallas (2), and B.L. Finlay (1). (1) Dept. of Psych., Cornell Univ., Ithaca, NY 14853 and (2) Dept. of Brain and Cog. Sci., M.I.T., Cambridge, MA 02139.

After early partial tectal lesions in the hamster, the spatial convergence from the retina to the tectum increases at the population level but is unchanged at the single neuron level, i.e., the visual receptive fields of single neurons are the same size as normal (Pallas and Finlay, 1989). Thus, how developing connections are adjusted in order to meet both functional needs is of interest. In this study, we used an *in vitro* bulk fill technique to visualize individual axon arbors in both normal and early partial lesioned tecta. After a bead of HRP was placed into the brachium, the brain was incubated in a culture media for the transport of HRP (3 or 4 hours) and then processed with DAB histochemistry. Axon arbors were traced and branching pattern and bouton number were quantified for *en fâce* sections.

Axon arbors (n=8) from lesioned tecta were qualitatively less complex: covered a smaller area, had fewer branches, and had significantly decreased bouton numbers compared to normal (n=7) (Normal=113±17, Lesion=63±9; $t=4.995$, $p<.001$). These findings indicate that each retinal axon makes fewer contacts in the lesioned tectum than normal to compensate for the numerical disparity between number of retinal axons and tectal space.

Since prior research has shown that cell death is little changed and synaptic density is unchanged in this preparation, present data indicates the principal means of adjustment of numerically disparate populations is alteration of axonal arborizations. A more extensive morphological examination is under way to describe in more detail the structural changes in axonal arborizations.

CORRELATION BETWEEN CELL PROLIFERATION IN EYE FRAGMENTS AND DUPLICATED RETINOTECTAL PROJECTIONS: INDICATION FOR AN EPIMORPHIC REGULATION OF POSITIONAL MARKERS IN THE RETINA OF XENOPUS LAEVIS. J.Häse*, N.Degen and K.Brändle*, Zool.Inst., Univ.Frankfurt, Siesmayerstr.70, D-6000 Frankfurt 11, FRG

In Xenopus embryos fragmentation of the early eye anlage often results in pattern - duplicated retinotectal projections: i.e. two retinal ganglion cell groups, located at different sites in the retina, project to the same tectal area. Such experiments indicate that these cells carry identical positional markers. Thus, in eye fragments a respecification of retinal ganglion cells seems to occur in relation to their positional information.

We tried to find out whether effects, such as mitosis, caused by eye fragmentation in the retinal tissue could be involved in positional respecification. For this purpose the temporal half of the eye anlage was removed in Xenopus embryos at tail bud stages (St.33/34). The remaining nasal half - eye rounded up within 3 to 5 days. Computer reconstructions of serial sections show that the cut edges enclosed the lens and fused together in the temporal region of the orbit, forming an eye of normal shape. We determined histologically the distribution of mitosis in the eye fragments during the rounding - up process. The results indicate that in most cases mitotic cells outside the normal germinative growth zones appeared during the fusion of the cut edges. These additional mitotic cells were always in the fusion area of the eye fragment, i.e. in the temporal part of the retina. We also examined the optic projection of the nasal half - eyes in Xenopus tadpoles at metamorphosis (St.60) by means of electrophysiological recordings in the tectum. In most cases double projections occured, which originated from a restricted sector of the visual field. Quantitative measurements showed that this area corresponded to the fused area of the retina, where extra mitosis had been found.

Therefore we suggest that the duplication of positional markers in eye fragments is correlated with cell proliferation, which indicates an epimorphic regulation of positional information following partial extirpation of the eye anlage.

ANTIBODIES AGAINST NEURITE GROWTH INHIBITORS FROM OLIGODENDROCYTES CHANGE THE COLLICULAR TERMINATION PATTERN OF POSTNATALLY SPROUTING RETINAL FIBERS. Josef P. Kapfhammer,[1,2] Gerald E. Schneider[1] and Martin E. Schwab[2]. Dept. Brain & Cogn. Sci., M.I.T., Cambridge, MA 02139[1] and Brain Res. Inst., Univ. of Zürich, August-Forel-Str. 1, CH-8029 Zürich, Switzerland[2].

After early postnatal unilateral ablation of the superior colliculus (SC) together with the ipsilateral eye in Syrian hamsters, retinal fibers abnormally cross the tectal midline and innervate the remaining SC (Schneider, 1973). The recrossing retinal fibers are mainly confined to the stratum griseum superficiale (SGS), with little ingrowth or termination in the deeper stratum opticum (SO); laterally, most termination is in the superficial part of SGS. Establishment of this pattern, observed at postnatal day 12, is temporally correlated with the appearance of oligodendrocytes in the SO during growth of recrossing fibers (Schneider et al., SN Abstr.,'90; Carman et al., SN Abstr.,'87).

We now show that application of the IN-1 antibody directed against neurite growth inhibitors from oligodendrocytes (Caroni and Schwab, 1988) changes this termination pattern. In the presence of this neutralizing antibody, but not with a control antibody, recrossing retinofugal fibers traverse the SO as well as the SGS, with greater depth of termination in SGS and SO. This pattern resembles that of the normal contralateral retinotectal projection.

The results indicate that neurite growth inhibitors expressed by oligodendrocytes are responsible for restricting the innervation of a target area in postnatal plasticity.

VIP- AND SEROTONIN -LIKE IMMUNOREACTIVITY IN THE VISUAL SYSTEM OF *RANA PIPIENS*. Q. Liu and E.A. Debski. Sch. of Bio. Sciences, University of Kentucky, Lexington, KY 40506.

NMDA receptors mediate the topographic mapping of retinal ganglion cell terminals onto the optic tectum of the frog (Cline & Constantine-Paton, Neuron, 3:413-426, 1989). In other systems, serotonin and VIP have been shown to modulate the activity of NMDA receptors (Reynolds et al., Brain Res. 456: 28-292, 1988; Sah, Biophys. J. 53:356a, 1988). We wish to determine if serotonin and VIP modulate topographic map formation by interacting with the NMDA receptor. As a first step we have investigated the distribution of these two substances in the frog visual system using immunocytochemical techniques. VIP-like immunoreactivity was detected in both the cellular and plexiform layers of the optic tectum. VIP-like immunoreactive (VIP-IR) cell bodies constituted 19, 26 and 29% of the cells in layers II, IV and VI, respectively. In addition to being located in layers V and VII, VIP-IR fibers were also found in layer IX where retinal ganglion cells terminate. The nucleus isthmi (NI), a structure reciprocally connected to the optic tectum, also contained a high proportion of VIP-IR cells in the posterior nonrim cortex (53%) and the rim cortex (42%). There were very few VIP-IR cell bodies in the anterior nonrim cortex. The thalamus, which has several projections to the optic tectum, also contained many VIP-IR cells. Serotonin-like immunoreactivity in visual areas was limited to a subset of cells in tectal layer VI and a ventral thalamic region. This project was supported in part by BRSG SO7 RRO7114-22.

NON-UNIFORM DISTRIBUTION OF SOMATOSTATIN-LIKE IMMUNOREACTIVITY IN THE FROG OPTIC TECTUM. E.A. Debski. Sch. of Biol. Sci., Univ. of Kentucky, Lexington, KY 40506.

Retinal ganglion cell terminals create a topographic map of visual space at the optic tectum, their primary target. The formation of this map is dependent on 1) differences in cell properties that cause the rough alignment of the retinal projection onto the tectum and 2) an activity-dependent process that stabilizes the terminals from neighboring retinal ganglion cells at neighboring synaptic sites.

Staining of the optic tectum in adult *Rana pipiens* with an antibody directed against somatostatin suggests that different regions of the tectum are composed of functionally non-equivalent cells. Somatostatin-like immunoreactive cell bodies were distributed non-uniformly along the rostral to caudal extent of the tectum: 0.6% of the immunoreactive cells were found in the rostral third of the tectum, 8.8% of the cells were present in the middle third of the tectum and 90.6% were found in the caudal third of the tectum. However, these same cells were distributed uniformly in the medial to lateral dimension being present in approximately the same numbers in lateral and medial sagittal sections of the tectum. In the radial dimension, the immunoreactive cells were divided equally between tectal layer IV (36.5%) and layer VI (42.4%). An additional 6.8% of the cells were found in layer II. The remainder of the cells (14.3%) occupied positions where the laminar identities of layers IV and VI began to break down. This project was supported in part by BRSG SO7 RRO7114-22.

QUANTITATIVE ANALYSIS OF AGONIST-EVOKED CURRENTS IN IDENTIFIED TECTAL NEURONS OF *RANA PIPIENS*. P.W. Hickmott and M. Constantine-Paton, Dept. of Biology, Yale Univ., New Haven, CT 06511

Previous work in our lab has implicated the N-methyl-D-aspartate (NMDA) receptor in the activity-dependent refinement the retinotectal map in *Rana pipiens*. For example, chronic NMDA treatment of the optic tectum of *Rana* tadpoles causes both a sharpening of the retinotopic map, and a decrease in the sensitivity of the tectum to acutely-applied NMDA (E. Debski and M. Constantine-Paton, in preparation) However, since this decrease has only been examined at the level of the electrically-evoked field potential, the precise mechanism responsible for the decrease is unknown. To address this question, we have developed a tectal slice preparation in which we can record from single tectal neurons, using whole-cell voltage clamp. Previously, we have examined postsynaptic currents (PSC) evoked by electical stimulation in the optic tract, and the effects of bath application of various drugs on these PSCs (P. Hickmott and M. Constantine-Paton, Soc. Neurosci Abstr., 16:985 1990).

Instead of using electrical stimulation to evoke the PSC, we have now developed techniques for using iontophoresis of neurotransmitter agonists to evoke PSCs. We have determined that tectal neurons can respond to iontophoresed glutamate, NMDA, AMPA, and GABA; in some cases neurons respond to all these agonists. By using multibarrel iontophoresis we will examine the quantitative relationships between these currents in various morphologically-identified cells in the tectum. Thus, we will be able to examine the question of whether certain tectal cell types respond preferentially to one agonist over another, which will give us further insight into the tectal circuitry. We will also compare these data from normal tadpoles to similar data obtained from tadpoles that have had their tecta chronically treated with NMDA, to determine if the decrease in NMDA effectiveness seen at the level of the field potential is reflected in a selective change in any of the single-cell currents.

EM ANALYSIS OF SINGLE RETINAL GANGLION CELL TERMINALS IN NMDA-TREATED TECTA OF *RANA PIPIENS*. Lai-Hsing Yen and Martha Constantine-Paton, Dept. of Biology, Yale University, New Haven, CT 06511

Previous work in this lab has shown that chronic NMDA application to the striped tecta of three-eyed frogs causes a dramatic decrease in branching within retinal ganglion cell (RGC) terminals (Cline & Constantine-Paton. 1990. J. Neurosci. 10:1197). To determine whether these alternations are accompanied by changes in retinotectal synaptic contact we have examined the distribution of synapses within single, HRP-filled, RGC terminal in NMDA-treated striped tecta. The tecta of young post-metamorphic frogs were treated with a low dose of NMDA for 4 to 5 weeks and then processed for EM. The morphology of isolated, HRP-labled Type IV RGC terminals were then reconstructed at the light microscope level (LM). Using the centripetal Strahler scheme we labeled all the branches in the reconstructed RGC terminals in a hierarchy of order 1 to 5. Order 1 refers to the most distal branches and order 5 to the major axon cylinder. The ratio of synaptic contact to axon membrane of HRP-filled profiles was sampled at the EM level, and multiplied by the total axonal length measured at the LM level to estimate total synaptic contact for each branch order. These values were normalized to give the percentage of total synaptic contact contributed by each branch order within the arbor.

The analyses showed that, in the NMDA-treated arbor, the distal order 1, 2, 3 branches contained almost all the synaptic contact, 42%, 35%, 17% respectively. This synaptic distribution is similar to that of Type IV arbors in normal tecta even though NMDA-treated arbor are less branched. The decrease in branching and the maintenance of the same proportion of total synaptic contact contributed by each branch order suggests a proximal shift of synaptic distribution toward the main axon in NMDA-treated arbors. In addition, these analyses suggest that total synaptic contact of NMDA-treated arbors decrease relative to that of the arbors in normal tecta. However, this may not indicate a decrease in total synaptic efficacy: Earlier analyses (Yen & Constantine-Paton. 1990 Proc. Soc. Neurosci 16: 532.4) showed an increased synaptic convergence and thickened pre- and post-synaptic density following NMDA treatment of striped tecta. (Supported by NIH grant EY08760).

RESPONSES OF CULTURED FROG RETINAL AXONS AND DISSOCIATED TECTAL CELLS TO GLUTAMINERGIC AND CHOLINERGIC AGENTS. M. Constantine-Paton and Glen Prusky, Department of Biology, Yale University.

We have examined the cellular sites of action and the immediate structural effects of receptor activity in *Rana pipiens* retinal and tectal cells in culture to identify the mechanisms responsible for intraocular competition and retinotopic map refinement during development. Retinal explants, elaborating immunocytochemically-identified ganglion cell axons, were monitored with timelapse video microscopy. Focal application of nicotine (100 μM) to isolated growth cones rapidly inhibited filapodial growth and movement, and initiated the collapse of the growth cone and retraction of the axon. The noncompetative ganglionic nicotinic receptor antagonist, mecamylamine, blocked this effect. Similar application of glutamate did not produce the same effect. The complete range of neuronal cell types found in the intact tectum appeared to be represented in dissociated tectal cultures; the cultures contained both large and small pyramidal and pear-shaped bipolar and multipolar neurons. We observed the level of intracellular-free Ca^{++} (Ca^{++}) in these cells after loading them with either Fluo-3 or Fura-2. These neurons exhibited considerable heterogeneity in basal somatic Ca^{++} concentration, however, there was no clear correlation between cell morphology and this basal level. Non-uniform subcellular distributions of Ca^{++} were common among these neurons with varicosities along their processes frequently showing elevated levels. Focal application of glutamate to these cells often resulted in a dramatic increase in Ca^{++} in the neurites, possibly indicating a loci for glutamate/Ca^{++} interactions. We are currently investigating the morphological responses of tectal neurons and their processes to a range of applied glutamate concentrations to determine if cell type or cell process-specific differences are present. In addition, we have recently developed reliable methods for co-culturing retinal explants and dissociated tectal cells. We are now in a position to examine possible differences in the responsiveness of retinal axons and tectal cells to applied glutaminergic and cholinergic agents when their processes, which are normal synaptic partners *in vivo*, have an opportunity to recreate these contacts *in vitro*. NMDA RECEPTOR BLOCKADE INTERFERES WITH THE DEVELOPMENT OF RETINOTOPIC MAPS IN MAMMALS. G. Prusky[1], D.K. Simon[2], M. Constantine-Paton[1] and D.D.M. O'Leary[2], Dept of Biology, Yale Univ, New Haven, CT 06511[1] and Molecular Neurobiology Lab, The Salk Institute, La Jolla, CA 92037[2].

NMDA receptor activation is critical for maintenance of orderly retinal connections in frog tectum (Cline & Constantine-Paton, Neuron '89), establishment of order in the regenerating fish retintotectal projection (Schmidt, JNS '90), segregation of on-off afferents in ferret LGN (Hahnet al ARVO '90) and deprivation-induced plasticity in the cat geniculocortical projection (Kleinschmidt et al, Science '87). Here, we report a role for NMDA receptors in the development of topographically ordered retinal projections to the rat superior colliculus (SC). In neonatal rats, retinal axons project diffusely throughout the SC; many form arbors in topographically incorrect positions. By P12, virtually all mispositioned axons are eliminated; none arborize outside of topographically correct locations (Simon & O'Leary, Dev Bio '90). To determine if the remodeling of the initially diffuse rat retinocollicular projection depends on NMDA receptor activation, we used a technique effective in disrupting NMDA receptor function in the frog retinotectal system. A slow-release polymer (Elvax) containing the NMDA receptor antagonist AP5 or MK801, or MK801 + NMDA, or buffer alone (control), was implanted over the SC on P0. Axons arising from temporal retina (topographically matched with rostral SC) were labeled with focal DiI injections at P9 and examined at P12. By P12, in control rats, the axons develop a normal retinotopic projection. However, in rats treated with AP5, MK801, or MK801 + NMDA, many aberrant axons remain and even arborize at topographically incorrect sites, including far caudal SC. In these same animals, though, a focus of arbors forms at the topographically correct position in rostral SC, suggesting an NMDA-independent component to map formation or incomplete receptor blockade. Nevertheless, the abnormal persistance of diffusely projecting axons following NMDA receptor blockade shows that NMDA receptor function is crucial for the development of retinotopic maps in mammals. NORMAL DEVELOPMENT AND EFFECTS OF DEAFFERENTATION UPON THE MORPHOLOGY OF SUPERIOR COLLICULAR (SC) NEURONS PROJECTING TO THE LATERAL POSTERIOR NUCLEUS IN HAMSTER. S.V. Savage, T.D. King*, S.C. Hobler*, R.D. Mooney and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Neurons in the superficial layers of the hamster's SC can be divided into distinct morphological classes. Neonatal enucleation has only slight effects upon the morphology of cells within a given class, but significantly reduces numbers of neurons (narrow and widefield vertical cells) with dorsally directed dendrites. Does this change reflect differential transneuronal degeneration or alterations in the dendritic arbors of surviving cells? In this study, we restricted our analysis to a specific and relatively homogeneous subpopulation of superficial layer neurons, those that project to the lateral posterior nucleus (LP). The combination of retrograde tracing and intracellular injection with Lucifer yellow demonstrated that over 75% of tecto-LP cells in normal hamsters are widefield vertical cells. Most tecto-LP cells in the neonatally enucleated adult hamsters were either horizontal cells (17.7%), giant stellate cells (25.3%), or had dendrites that were directed only toward the deep SC laminae (10.1%); less than 25% were widefield vertical cells. Differential enucleation-induced cell death could not account for all of these changes. Tecto-LP neurons were retrogradely labelled with Di-I in hamsters on postnatal day (P-) 0 through P-10. As early as P-0, most retrogradely labelled neurons could be identified as either widefield (44.6%) or narrow field (18.9%) vertical cells. These results support the conclusion that neonatal eye removal results in a reorganization of dendritic arbors that have already undergone considerable development at the time of the lesion. EFFECTS OF FETAL AND NEONATAL DEAFFERENTATION UPON ADENOSINE DEAMINASE IMMUNOREACTIVE NEURONS IN THE RAT SUPERIOR COLLICULUS. R.D. Lane*, C.A. Bennett-Clarke, N.L. Chiaia, S.V. Savage, D. Allan*, J.A. Brown, R.D. Mooney and R.W. Rhoades. Depts of Anatomy and Neurosurgery, Medical College of Ohio, Toledo, OH 43699.

It has been well-documented that neonatal enucleation causes major changes in the number and function of cells located in the superficial layers of the superior colliculus (Findlay et al., Dev. Brain Res. 28: 1, '86, Rhoades, J. Physiol., (London) 301:383, '80; Tokunaga et al., Dev. Brain Res. 23:131, '85). How this deafferentation effects specific populations of neurons in these layers has not been well defined. Adenosine deaminase immunoreactivity (ADA-IR) can be used as a marker for a population of neurons located primarily in the stratum opticum (SO). A subpopulation of these ADA-IR neurons project to the lateral posterior nucleus (LPN) of the thalamus (Miguel-Hidalgo et al., Brain Res. 476:189, '89). We undertook this study to examine the effects of fetal and neonatal deafferentation on the ADA-IR population of SO cells. Unilateral and bilateral enucleations were performed on rats at embryonic day 17 or at birth. All animals received injections of fluorescein labeled beads into the LPN. In normal animals, there was an average of 2189 ± 562 S.D. ADA-IR SO neurons per colliculus of which 498 ± 228 ADA-IR cells projected to the LPN. Surprisingly, neither the fetal enucleations or the neonatal enucleations had an effect upon the total number of ADA-IR SO neurons per deafferented colliculus (1927 ± 600 and 2086 ± 70, respectively) or the number that projected to LPN (577 ± 326 and 576 ± 28, respectively). These results indicate that a specific population of neurons in the superior colliculus are refractory to neonatal or fetal deafferentation. Support: EY04170, EY08015, HL36573.

SYNAPSES ARE LOST DURING THE NORMAL DEVELOPMENT OF THE SEROTONINERGIC INNERVATION OF THE SUPERIOR COLLICULUS (SC) IN HAMSTER. E. Arce*, C.A. Bennett-Clarke, R.D. Mooney and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

We have employed immunocytochemistry in conjunction with both light and electron microscopy to describe the normal development of the serotoninergic innervation of the hamster's SC. Serotonin-immunoreactive fibers in adult hamsters are present in all SC laminae and are most dense in the lower part of the stratum griseum superficiale (SGS) and stratum opticum (SO). Serotonin immunoreactive fibers were visible in the SC by embryonic day 14 (two days prior to birth). By the day of birth, some immunoreactive fibers were present just below the pial surface and others were generally oriented either parallel or orthogonal to the SC laminae. Over the next two weeks, the serotoninergic innervation of the SC increased in density and assumed the laminar distribution observed in adult animals. Electron microscopic examination of 113 5-HT-positive varicosities in single thin sections taken from the SGS and SO of adult hamsters revealed only 5 conventional synaptic contacts while similar analysis of 250 varicosities from hamsters killed on postnatal day 3 revealed 103 conventional synaptic contacts, most of which were axodendritic. Serial section analysis of additional 5-HT-positive swellings from adult hamsters provided further support for the conclusion that very few serotoninergic axons make synapses in the SC of these animals. These results indicate a substantial synaptic reorganization of the serotoninergic input to the SC in developing hamster. The role that these transient synapses might play in collicular function or development is currently unknown. EY 04170, EY 08015

CORTICAL FEEDBACK TO LGN MAY PLAY A MAJOR ROLE IN OCULAR DOMINANCE COLUMN DEVELOPMENT K.P. Unnikrishnan and Harmon S. Nine*, GM Research Labs, Warren, MI 48090 and University of Michigan, Ann Arbor, MI 48109

A model is presented to investigate the role of feedback in the development of ocular dominance columns in the primary visual cortex. In our model, summed responses of groups of cortical neurons are fed back to the LGN neurons to modify their activities and consequently their connection strengths to the cortex. The synaptic modification rule uses temporal correlations between changes in local LGN activities and the cortical feedback signals and can easily be carried out by neuronal circuitry containing NMDA-type receptors.[1]

It has been observed that during development, the subplate neurons, situated just below the cortex, project axons to the thalamus and dendrites to the deep cortical layers.[2] This provides a mechanism for sending summed cortical responses to the geniculate neurons. Recent evidence suggesting that the death of the subplate neurons[2] and inactivation of the NMDA receptors[3] coincide with the termination of ocular dominance column development also supports our model.

LGN laminae representing each eye and the cortex are modelled using 32x32 arrays. Locally correlated spontaneous retinal activity drives the LGN neurons. Summed cortical responses computed over cell aggregates are fed back to the LGN. Intracortical interaction is implemented using mexican hat type functions. Simulations of the model show robust formation of ocular dominance columns. Experimentally verifiable predictions from the model will also be presented.

NEURONAL HYPERTROPHY IN THE NOVEL BILATERAL CORTICOTECTAL PATHWAY FOLLOWING NEONATAL CEREBRAL HEMISPHERECTOMY IN THE CAT. PD Adelson*, DA Hovda, JR Villablanca, K Tatsukawa, and YG Comair. Div. of Neurosurgery and Mental Retardation Research Cntr., UCLA Sch. of Medicine, Los Angeles, CA 90024.

To further define the anatomical reorganization associated with the cortical-tectal pathway following neonatal cerebral hemispherectomy, the left (ipsilateral to the lesion) superior colliculus (SC) of 3 intact adult cats (IN), 3 neonatal-hemispherectomized (NH), 5-15 days old, and 3 adult-hemispherectomized (AH) cats were injected (1 mm deep) with WGA-HRP (.3-.5 µl). The brains were processed for combined TMB/DAB histochemistry and the primary visual cortex (VC; areas 17 & 18) was examined (light microscopy, 1,500X). For each group, labelled neurons, which were restricted to layers IV and V, were counted and their soma was measured. For IN cats, the left (ipsilateral) VC had 1,268.7 cells (mean per cat, MPC), with a mean soma size (MSS) of 366.7 μm^2 (SD=±185.5), with the greatest percentage of cells within the 300-700 μm^2 range. There were no cells detected in the right VC of IN animals. For NH, the remaining contralateral VC, with a MPC=474.6, had a MSS=436.1 μm^2 (SD=±186.0), with a peak distribution of 400-800 μm^2. For AH, the contralateral VC had a MPC=93.6, and a MSS=486.6 μm^2, (SD=±202.5) with a peak distribution of 500-800 μm^2. In conclusion, following hemispherectomy, the cortical-tectal pathway becomes bilateral in both NH and AH, with this being more pronounced in NH; in addition, the cells of origin of this reorganized pathway become larger, perhaps in response to greater axonal arborization. USPHS R01 NS-25780, P01 HD-05958.

TEMPORAL-FREQUENCY SENSITIVITY OF LATERAL GENICULATE NEURONS IN AGING RHESUS MONKEYS. Charlene B. Y. Kim*, Rodney J. Moore, Peter D. Spear, Nina Tumosa, and Jin-Tang Xue*. Department of Psychology and Center for Neuroscience, Univ. of Wisconsin, Madison, WI and School of Optometry, Univ. of Missouri, St. Louis, MO.

Human psychophysical studies have demonstrated decrements in temporal-frequency sensitivity as a function of aging, even after pre-retinal ocular media differences have been controlled for experimentally. These studies have suggested either retinal and/or post-retinal (central visual pathways) sources for the differences in performance. In an effort to understand the nature and origin of the modifications of the visual pathways during aging, we recorded extracellularly from single neurons in the parvocellular (PCL) and magnocellular (MCL) layers of the lateral geniculate nucleus (LGN) of young (5-16 yr) and old (25-28 yr) rhesus (Macaca mulatta) monkeys. Each neuron was stimulated with gratings drifted at 10 different temporal frequencies (1-30 Hz) at its optimal spatial frequency and a sub-saturation contrast level.

Optimal temporal frequency, bandwidth, and high and low temporal-frequency cutoff values were determined for each cell. Neuronal receptive fields were matched for eccentricity (0-15 deg). Our preliminary results indicate that aging has no significant effect on temporal-frequency sensitivity of PCL or MCL neurons in the monkey LGN. This suggests that age-related neural deficits in temporal visual function may reside in more central visual structures, such as striate cortex. (Supported by EY01916, EY02545, and F32 AG05526.)

DECREASED AB5-IMMUNOREACTIVITY OF NEURONS IN LGN OF MONOCULARLY DEPRIVED CATS. S.B. Tieman and K.R. Fry. Neurobiology Research Ctr, SUNY, Albany NY 12222 and Ctr for Biotechnology, Baylor College of Medicine, The Woodlands TX 77381.

The monoclonal antibody AB5, which is specific for ganglion cells in the retina of cat and rabbit, also stains a limited subset of neurons in central nervous system. In lateral geniculate nucleus (LGN), it stains some of the larger neurons. We here report, that in monocularly deprived cats, AB5 immunoreactivity is decreased in the deprived laminae. Three long-term monocularly deprived cats were deeply anesthetized with i.v. Nembutal and perfused through the heart with buffered saline followed by 4% carbodiimide, 4% paraformaldehyde and 4% sucrose in 0.1 M phosphate buffer. Thalamus was frozen and sectioned coronally at 30 μm into 0.1 M phosphate with 0.02% azide. Sections were then immunoreacted for the presence of AB5 using standard ABC protocols. Although the staining of the retinal terminals did not appear to be affected by the monocular deprivation, staining of cell bodies was reduced in the deprived layers. These findings are reminiscent of those obtained with the monoclonal antibody CAT-301 (Sur et al. J. Neurosci., 8:874, 1988), and suggest that the AB5 staining is associated with cells that are particularly vulnerable to abnormal early experience, perhaps Y-cells. NGF PREVENTS THE SHRINKAGE OF NEURONS IN LATERAL GENICULATE NUCLEUS (LGN) OF MONOCULARLY DEPRIVED RATS. L. Domenici , A. Cellerino * and L. Maffei *. Istituto di Neurofisiologia (CNR) and Scuola Normale Superiore, Pisa, 56100, Italy.

In cats and monkeys monocular deprivation (MD) causes the shrinkage of neuronal perykaria in the deprived laminae of LGN, in correspondence with the binocular visual field. Here we report that the NGF supply prevents this shrinkage in the rat. To identify the ipsilateral LGN laminae which project to the binocular portion of the rat visual cortex, a HRP-solution (10 ul, 30% HRP plus 2% DMSO in saline) was injected into the deprived eye and after a 24-36 hours survival time the brain was fixed, processed by standard HRP histochemistry and Nissl method. One month of MD causes a shrinkage in the LGN deprived lamina with respect to the undeprived lamina (mean difference in soma size = 22 %). By contrast, the soma size distributions for the deprived and undeprived LGN laminae extensively overlap in MD rats treated with NGF.

We conclude that NGF treatment rescues from atrophy the neurons in the LGN deprived laminae projecting to the binocular portion of the visual cortex.

DEVELOPMENT OF MEMBRANE AND SYNAPTIC PROPERTIES IN NEURONS OF THE FERRET LGN. C.A. White and M. Sur. Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

During development, orderly projections from the retina to the lateral geniculate nucleus (LGN) are established through remodeling of a more diffuse set of immature projections. Neuronal activity is thought to play an important role in the remodeling process (Shatz and Stryker, '88; Hahm et al., '91). We have begun to examine ferret LGN neurons in slices to determine the degree of maturation of membrane and synaptic properties during a period that retinogeniculate afferents undergo considerable change. In the ferret, segregation of retinogeniculate afferents into eye-specific layers is essentially complete by postnatal day 14 (P14) and into On and Off sublayers by P21 (Linden et al., '81; Hahm et al., '91). In vitro intracellular recordings were carried out in animals from P1 to P33. Resting membrane potentials (range 51-67 mV), input resistances (26-118 Mohms) and time constants (5-11 msec) of the LGN cells showed no clear changes with age. At all ages, depolarizing current injection could elicit action potentials. The first low-threshold spikes, common in the adult LGN, were observed at P9 and were encountered routinely thereafter. Also at P9, the first postsynaptic potentials evoked by stimulation of the optic tract were recorded. In one neuron at P9, optic tract stimulation evoked an ipsp with a reversal potential of -56mV. At later ages epsps were more commonly observed. Our data indicate that at least some cells within the LGN are electrically excitable and make functional contacts with retinal ganglion cell axons during the period of segregation of retinogeniculate afferents. NMDA ANTAGONIST INFUSION DURING ON/OFF SUBLAMINAR SEGREGATION ALTERS DENDRITIC MORPHOLOGY OF CELLS IN FERRET LGN. M. Rocha*, A. Ramoa, J. Hahm and M. Sur. Department of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139; and Biophysical Institute, Federal University of Rio de Janeiro, 21941, Brazil.

The NMDA subtype of glutamate receptor may contribute to the establishment of specific connections in the developing central nervous system. Recently, chronic infusion of the NMDA antagonist, D-APV, has been shown to affect sublaminar segregation in the ferret LGN by altering the morphology of retinogeniculate afferents (Hahm et al., 1991). Here, we examine whether NMDA receptor blockade also affects the morphology of the postsynaptic target cells in the LGN.

The specific NMDA antagonist D-APV (0.8 mM) was chronically infused via an osmotic minipump into the thalamus of ferrets for one week from P14 to P21 (n=5) when retinogeniculate afferents normally segregate into On and Off sublaminae. Rhodamine-labeled latex microspheres were injected into visual cortex (area 17) to backfill and identify LGN relay cells. Immediately after treatment, these cells were intracellularly injected with Lucifer Yellow in living 300 μm horizontal slices.

D-APV treatment led to an increase in dendritic complexity of LGN cells, shown by an increased number of branch points (from 23±11 in normal animals at P21 to 60±28 in treated animals, p=.0001). Dendritic arbor area also increased from 26826±16626 μm^2 in the normal group (26 cells, 3 animals) to 48831±43867 μm^2 in the treated animals (19 cells, 5 animals, p=.01). These effects were particularly marked in the A laminae. Soma sizes were unaffected by NMDA receptor blockade.

These results indicate that the dendritic development of LGN cells is markedly affected by NMDA receptor blockade, and suggest that synaptic transmission through NMDA receptors may play a significant role in the concurrent maturation of presynaptic afferents and postsynaptic target cells.

AN NMDA ANTAGONIST DOES NOT DISRUPT NORMAL EYE-SPECIFIC LAMINAR SEGREGATION OF FERRET RETINOGENICULATE AXONS. D.K. Smetters, J. Hahm and M. Sur. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

In the ferret LGN, retinogeniculate arbors undergo two major periods of segregation; the afferents first segregate into eye-specific laminae between birth and postnatal day 7, and then into ON and OFF sublaminae between P14 and P21 (Linden et al., '81; Hahm et al., '91). Neuronal activity, and NMDA receptors in particular, play a crucial role in this second segregation, which is blocked by infusion of NMDA receptor antagonists (Hahm et al., '91).

We examined the role of NMDA receptors in the formation of eye-specific laminae by chronically applying a specific antagonist, CPP, during the initial period of segregation. Ferret kits (n=9) were systemically infused with CPP (0.05mM-5mM) from P1 to P8 via a subcutaneous osmotic minipump (0.5 ul/hr). Control animals received infusion of saline (0.9%). Dosage was chosen to be in the range effective for preventing ON/OFF sublaminar segregation, allowing for the difference in weight in these much younger animals.

Intraocular injections of WGA-HRP (20%/2%) at P7 revealed robust segregation of afferents into eye-specific laminae, even at the highest dose tested (n=2). Labeling of single axons *in vitro* in treated animals (n=2) showed no significant differences from controls in arbor area, width, or height. We saw no obvious changes in LGN size or cortical thickness in treated animals, but immaturity in the sulcal pattern and behavioral changes indicated that the drug concentrations used were effective.

These results suggest that eye-specific and ON/OFF segregation differ in their degree of dependence on NMDA receptors, and may occur through different mechanisms.

452.1

THE EFFECT OF CYCLOSPORINE-A ON EYE REMOVAL-INDUCED REJECTION OF MESENCEPHALIC RETINAL XENOGRAFTS T.Subramanian, I.F.Pollack and R.D.Lund. Depts of Neurobiol., Anat. & Cell Sc.and Neurosurg., Univ.of Pittsburgh, Pittsburgh, PA 15261.

Previous studies have shown that eye removal leads to the rejection of previously well integrated mouse retinal xenografts in the rat mesencephalon that are located close to degenerating optic axonal terminals (Lund et al.,Transpl. 46:216, 1988). In this response, lymphocytic infiltration is preceded by class I and class II major histocompatibility (MHC) antigen expression in the vicinity of the degenerating optic fibers in the superior colliculus and subsequently in and around the graft. In this study we examined the effect of the immunosuppressant Cyclosporine-A (CyA), which is known to prevent T cell activation, on this rejection response.

Fifty one postnatal day 1 (P1) Sprague-Dawley rats received embryonic day 13 CD-1 mouse retinal transplants into their mesencephalon. On P21, both the host eyes were removed and all animals began receiving systemic CyA at a dose of 10 mg/kg/day. On P36 the animals were divided into four groups. Group I animals (N=4) were sacrificed immediately and group II (N=10), were sacrificed on P51. CyA was discontinued on P51 in group III (N=17), while group IV (N=20) continued to get CyA until P81, at which point animals in both groups were sacrificed. The brain was cut in 30μm coronal sections and adjacent sections stained with cresyl violet and antibodies against MHC class I (OX18), class II (OX6) antigens, microglia (OX42), astrocytes (GFAP) and lymphocytes (anti-lym).

Although group I animals had MHC class I and II antigen expressing cells within the superior colliculus, the grafts showed no signs of rejection. All the group II animals (N=8), and 13 out of the 15 group IV animals, that had successfully engrafted had healthy appearing transplants with no evidence of rejection. In contrast all eleven group III animals with detectable grafts, showed obvious signs of rejection. These results indicate that while CyA protects mesencephalic retinal xenografts from eye removal- induced rejection, it does not eliminate the MHC antigen expression induced by this lesion. Moreover, immunoprotection is lost when CyA is withdrawn suggesting that it prevents T lymphocytes from activating the rejection response.

452.2

INTRARETINAL XENOGRAFTS OF MITOTICALLY ARRESTED HUMAN RETINOBLASTOMA CELLS. E. S. Lazar, M. del Cerro, M. F. Notter, G. Seigel, and C. del Cerro. Department of Neurobiology and Anatomy, University of Rochester Medical School, Rochester, New York, 14642, USA.

Retinoblastoma is the most common ophthalmic malignancy in childhood. Cell lines obtained from these tumors have been the topic of numerous studies at both the cellular and molecular levels. We report on the use of one of these cell lines (Y 79) for intraretinal xenografts into adult mammalian eyes. We wished to determine the survival, integration, and differentiation characteristics of these cells after they had been returned to the intraocular milieu from which the progenitor cells originated. Furthermore, we hoped to test the hypothesis that these cells could be used for cell replacement therapy in the adult mammalian retina in lieu of fetal retinal cells. 3H-thymidine labeled Y 79 cells were exposed to retinoic acid/butyrate to induce differentiation, and then were suspended in human plasma at a concentration of 4,000 cells/ μl. Using the method of Lazar and del Cerro (1989) for multisite retinal grafting, the cells were transplanted into the subretinal space of Fisher 344 rats. The host rats received daily injections of Cyclosporine A, and were sacrificed 30-60 days following transplantation. Histological examination showed that transplants survived as multiple clusters of rosette-forming cells. These cells differentiated into clearly recognizable photoreceptors. There were no signs of continued cell division or any indications of a host reaction against the grafted cells. The results indicate that appropriately treated Y 79 cells may serve as a substitute for fetal cells in retinal transplantation. 452.3

SURVIVAL OF INTRAOCULAR NEURAL RETINA GRAFTS IS INFLUENCED BY MICROENVIRONMENTAL FACTORS AS WELL AS IMMUNOGENETIC DISPARITY L.Q. Jiang and J.W. Streilein, Dept. of Microbiology & Immunology, Univ. of Miami, Sch. of Med., Miami, FL 33101

In order to achieve our ultimate goal of restoring vision to blinded eyes by use of transplantation of functioning retinal tissue, we have examined the effects of alloantigenicity on the long term survival of intraocular retinal grafts. Neural retina from neonatal BALB/c mouse eyes was implanted into the anterior chamber (AC) of syngeneic or allogeneic (C57BL/6) adult mice. The grafts were evaluated clinically and histologically at 5, 12, 17, 35, 70 and 105 days after transplantation. In this privileged site, both syngeneic and allogeneic grafts successfully implanted, reaching their maximum size at 17 days at which time all grafts displayed recognizable retinal structures, including typical rosettes (differentiated photoreceptor cells). Syngeneic grafts maintained a healthy appearance beyond 35 days, and then began to shrink, reaching a size approximately 30% of maximum at 105 days. Despite the reduction in size, these grafts still retained numerous rosettes (40% of maximum). Allogeneic grafts shrank more rapidly, being 75% of maximum at 35 days, and only 20% at 105 days. When examined histologically, few rosettes were observed in allografts at 35 days (16% of maximum), and none were found subsequently. Neither the slow deterioration of syngeneic grafts nor the much more rapid deterioration of allogeneic grafts was accompanied by clinically or histologically detectable inflammation. These results indicate that privilege can be extended briefly to allogeneic developing neural retina grafts placed in the AC. However, these implants eventually succumb to an atypical immune rejection that is nonetheless complete. In addition, the microenvironment of the AC appears to be only partially hospitable to retinal implants, presumably because the eventual success of these grafts requires appropriate growth and differentiation factors and opportunities for relevant neural connections. Thus, successful engraftment of developing retinal tissue into the eye can be expected to depend upon (a) immunogenetic disparity between graft donor and host, and (b) implantation into a site with an appropriate microenvironment. INTRARETINAL GRAFTS OF Y 79 CELLS INTO RATS. AN IN VIVO MODEL OF A HUMAN RETINOBLASTOMA. D. Hodari Brooks*, M. F. Notter, G. Seigel, E. S. Lazar, C. del Cerro, and M. del Cerro. Department of Neurobiology and Anatomy, University of Rochester Medical School, Rochester, New York, 14642, USA.

Retinoblastoma is the most common eye malignancy in childhood. This study reports on the use of a human retinoblastoma cell line (Y 79) for intraretinal xenografting into adult mammalian eyes. We hoped to develop an in vivo model to study the differentiation and invasive characteristics of these cells after they have been returned to the intraocular milieu from which the progenitor cells originated. Using the method of Lazar and del Cerro (1989) for multisite retinal grafting, 3H-thymidine labeled Y 79 cells were suspended in human plasma and injected under direct visualization into the subretinal space of Fisher 344 rats. The host received daily injections of Cyclosporine A, and were sacrificed 30 to 60 days following transplantation. Biomicroscopical observations showed vitreal invasion by masses of floculent material. Histologically these formations were found to be vitreal outgrowths of grafted cells lodged in subretinal and intraretinal locations. Multiple clusters of highly anaplastic cells were seen in the transplanted eyes. There were signs of continued and intense cell division within the grafts but there was no indication of cell-mediated host reaction against the transplant. These results reveal that following intraretinal xenografting, human Y 79 retinoblastoma cells survive, actively grow, and express a high degree of malignancy within the host eye. This is an attractive model for the in vivo study of human retinoblastomas and of retinal cytogenesis. (Supported by EY 05262, the Rochester Eye Bank, and private donations)

452.5

HOST PUPILLOCONSTRICTION IS LOST WITH INDUCED REJECTION OF RETINAL TRANSPLANTS R. Banerjee, J.D. Radel and R.D. Lund, Dept. Neurobiology, Anatomy & Cell Science, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261.

Embryonic retinae transplanted to the the dorsal midbrain surface of newborn rats can, at maturity, mediate host pupilloconstriction in response to transplant illumination. Selective immunological destruction of retinal transplants can be achieved by peripheral sensitization of the host immune system. The functional consequences of immunological lesioning of cross-strain transplants are reported here.

Newborn Long-Evans (L-E) rats were used as hosts, and embryonic (E14) Sprague-Dawley (S-D) rats supplied retinae for transplantation. Immune rejection of transplants was initiated when skin from adult S-D rats was grafted to the flank of mature L-E hosts. Transplant-mediated pupilloconstriction was measured over a range of stimulus intensities 5 to 25 days after skin grafting. Hosts were killed and the brains processed for histology at selected intervals to determine the extent and pattern of lymphocytic infiltration of the transplant.

Transplant-mediated pupilloconstriction was relatively unchanged during the first week after skin grafting, and was lost by the end of the second week. Perivascular cuffing was initially seen in transplants 8 days after skin grafting, while lymphocytic infiltration was first observed along the external surface of transplants 10 days after skin grafting and throughout the transplant by 15 days. This approach permits a quantitative assessment of the loss of transplant-mediated pupillary responses and how it relates to progressive destruction of the transplant.

Supported by NIH grant EY 05283.

452.6

ORGANIZATION OF EMBRYONIC RABBIT RETINAL TRANSPLANTS OF AGGREGATED DONOR TISSUE. [1]M. Seiler, [1]R. Aramant, [2]A. Bergström*, [2]B. Ehinger, [1]A.R. Adolph and [3]K.R. Fry. [1]Eye Research Institute, Boston, MA 02114; [2]Dept. of Ophthalmology, Univ. of Lund, Sweden; [3]Baylor Coll. of Med., Houston, TX 77030.

Immunohistochemistry was used to characterize the development of ganglion, horizontal and rod bipolar cells in retinal transplants. Cell aggregates of pigmented (Dutch-Belted) rabbit E 16 (=embryonic day 16) retinas were transplanted with and without RPE to lesioned retinas of adult rabbit hosts. Host animals were sacrificed 8 weeks after surgery and perfused with 4% paraformaldehyde. Frozen sections were stained with the monoclonal antibody **AB5** and antibodies against **PKC** (Protein Kinase C; Amersham), **MAP 1A** (microtubule-associated protein 1A; Amersham).

The **AB5**-antibody stained retinal ganglion cells and their processes in the host retina. Sometimes, small AB5-immunoreactive cells were seen in the transplants which did not resemble retinal ganglion cells. The **MAP 1A**-antibody labelled horizontal cells and ganglion cell bodies and dendrites in the host retina. In the transplants, MAP 1A-stained horizontal cells were frequently seen in the outer plexiform layers. Cells with the morphology and location of ganglion cells were rarely observed, but some inner plexiform areas showed MAP 1A-positive fibers. **PKC**-immunoreactivity in the host retina was most prominent on bipolar terminals at the border between inner plexiform and ganglion cell layer. Bipolar cell processes, somata, and terminals in the outer plexiform layer were more faintly stained. In the transplants, PKC-immunoreactive cells were frequently observed. The distribution of stained terminals in the inner plexiform areas was irregular; terminals in outer plexiform areas were more often seen. Occasionally, graft bipolar cells appeared to terminate on host cells.

In conclusion, retinal transplants derived from cell aggregates contain horizontal and bipolar cells with disturbed organization, but very few, if any, ganglion cells. *Supported by NIH-grant R01-EY8519 to R. A.*

KINETICS OF REFLEX INHIBITION IN NORMAL AND LIGHT-DAMAGED RATS. G.P. Bowen*, J.R. Ison, and M. del Cerro, Departments of Psychology, and Neurobiology, and the Center for Visual Science, University of Rochester, Rochester, NY 14627

In normal rats, as in humans, a light flash inhibits an acoustic startle reflex elicited briefly afterwards, with the degree of inhibition determined by the intensity of the light as well as by its lead time. We will demonstrate that the initial effect of light damage to the retina in the albino rat slows the rate at which peak inhibition develops (the standard 30 ft-c. flash has its peak at about 70 ms, which shifts by about 100 ms with 48 hour exposure to 300 ft-c). Decrements in the strength of inhibition are seen only with longer exposure times. The same temporal shift precedes the loss of inhibition in RCS rats, in which photoreceptor damage occurs because of a degenerative disease. We show further that the isolated temporal shift in peak inhibition seen with early retinal damage cannot be simulated in normal rats by varying the stimulus intensity, the stimulus duration, or the degree of light-adaptation. This data reveals that these early disease states cannot be modeled solely by decrements in sensitivity or integration time, or dark-adapting mechanisms. We can conclude from this study that early retinal damage directly retards the speed of sensory processing. (Supported by NEI-05262, EY-01319, EY-08243, and generous private donations.)

452.8

RETINAL TRANSPLANTS PRODUCE VISUAL IMPROVEMENT IN LIGHT-BLINDED RATS. M. del Cerro, G. P. Bowen, J. R. Ison, D. A. Gr, E.S. Lazar, and C. del Cerro. Depts. of Psychology, Neurobiology, and Ophthalmology, University of Rochester, Rochester, New York.

Light flashes inhibit subsequent acoustic startle responses. This inhibition is abolished by retinal damage. We sought to determine if retinal grafts would restore it. Fischer 344 rats were exposed to continuous fluorescent light at 300 ft-c or 1 ft-c for 4 weeks. Following this, fetal rat retinal cells were grafted intraretinally into one eye of each of the rats exposed to 300 ft-c. Reflex inhibition was measured before, during, and after continuous light exposure, and again following transplantation. Light flashes were presented from 20 to 500 ms before a sound burst. Prior to continuous light exposure, reflex inhibition was maximal at 40 to 70 ms. Inhibition was progressively delayed during the first two days of 300 ft-c exposure, and then disappeared. During the post-exposure period, inhibition was replaced by an anomalous peak of excitation. Grafted animals showed a reduction of this anomalous facilitation, and a partial recovery of inhibition. Comparison between the "peak post-exposure performance" of grafted rats (N=9) with the "peak post-exposure performance" of non-grafted rats (N=9) showed statistically significant differences: $p < .05$ overall; $p < .05$ for the reappearance of inhibition; $p < .02$ for the loss of anomalous excitation. Neither variations in flash intensity nor dark adaptation mimic the effects of light damage on inhibition or the anomalous appearance of reflex facilitation. The control rats subsequently received retinal grafts and similar results were observed. We conclude that retinal grafts in one eye partially repair the defects caused by the blinding action of continuous light. (Supported by EY 05262, EY-01319, the Rochester Eye Bank, and private donations).

452.9

RETINAL PIGMENT EPITHELIUM (RPE) TRANSPLANTATION DELAYS AGE RELATED RETINAL CELL DEATH IN THE FISCHER RAT. Keiko Yamaguchi*, Suzanne V. Stovall**, Vinod. P. Gaur**, James E. Turner**. Department of Ophthalmology, Tohoku University School of Medicine, Sendai Japan*. Department of Neurobiology and Anatomy**, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC. USA.

Age related retinal cell death in macular degenerations may in part be due to an aging RPE which loses its capacity to support photoreceptor cells. We wished to test the hypothesis of delaying photoreceptor cell death in the aging, normal retina by introducing young RPE into older eyes of an appropriate model. We have used the Fischer-344 rat where age related death of photo-receptor cell in the peripheral retina has been demonstrated. Peripheral retinas of 3-month-old rats were transplanted with pigmented and/or nonpigmented 6-8 day-old RPE. Morphometric analyses at 3, 6, and 9 months after transplantation indicated a significant delay in the age related cell death in the outer and inner nuclear layers and the two plexiform layers. Upto 9 months after transplantation, the grafted eyes showed significant neuronal rescue in the various layers. RPE transplantation appears to have benefical effects on the aging eye.

452.10

OPTIC INPUTS TO THE OLIVARY PRETECTAL NUCLEUS FROM HOST AND TRANSPLANTED RETINAE: SEGREGATION, CONVERGENCE AND IMPLICATIONS FOR BEHAVIOR
J.D. Radel, D. Kustra* and R.D. Lund, Dept. Neurobiology, Anatomy & Cell Science, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261.

Embryonic rodent retinae transplanted over the midbrain of newborn host rats establish connections with the host's olivary pretectal nucleus (OPN), an obligatory nucleus in the neural circuit subserving the pupillary light reflex. Pupilloconstriction can be elicited in the host by direct illumination of the transplant, and transplant-mediated responses are enhanced when host optic input is eliminated. No such change is observed in the pupillary reflex of control rats in response to illumination of the contralateral eye after intracranial sectioning of the ipsilateral optic nerve.

Anatomical studies after labelling the retinal projections of the transplant and host eye (in experimental rats) or both eyes (in normal rats) with different markers shows that the transplant and host inputs converge in the host OPN, while inputs from the eyes of normal rats are segregated to different regions of the nucleus. The convergence of transplant and host inputs may be reflected in the interaction of transplant and host inputs to determine host pupil diameter, and provides an anatomical basis for the rapid enhancement of transplant-mediated pupilloconstriction when host optic input is eliminated. Segregation of the left and right retinal inputs in normal rats, on the other hand, may serve to limit the functional interaction of inputs from the two eyes.

Supported by NIH grant EY 05283.

452.11

TECTAL GRAFTS PROMOTE RECOVERY FROM BEHAVIORAL DEFICITS AFTER INFERIOR COLLICULUS LESIONS. M.C. Zrull, J.R. Coleman and C. Bennett*. Dept. of Psychology, Univ. of South Carolina, Columbia, SC 29208.

Fetal tectal tissue grafted to inferior colliculus (IC) lesion sites has certain neuronal and cytoarchitectonic features similar to adult rat IC. Cell populations of tectal grafts exhibit sound-evoked activity and could play a functional role in the damaged auditory pathway. Neurons of the IC provide a substrate across which the spatial loci of sound sources may be encoded from convergent binaural afferent information. We examined deficits in spatial audition after bilateral lesions of adult rat IC and recovery from deficits following tectal grafts into the lesion sites.

In a lick suppression paradigm, hooded rats ($N=13$) were trained to stop licking when noise bursts (30 to 45 dB SPL) were presented at random loci in the horizontal plane. Responses were quantified as a detection ratio (DR) which reduced correct detection by the proportion of incorrect guesses (hits-hits*[false alarms]). Rats perform the spatial detection task well across intensity levels, DR=0.70±.02 (*M±SEM*). Under anesthesia (ketamine:xylazine, 50:10 mg/kg, ip), 5 rats received IC lesions (LO; 1.2 mA DC), 5 rats received grafts of E18 tectal tissue 1 week after lesions (LG), and 3 rats were sham operated. At 21 days post-surgery LO rats exhibited behavioral deficits, DR=0.49±.04, and LG rats had less behavioral loss, DR=0.62±.02. Both groups improved (LO, 0.54±.03; LG, 0.67±.04) by test sessions 35 days post-operative. Comparison of grafted and sham rats (DR=0.78±.02) to LO animals accounted for 65% of the recovery effect, $F'(1,2.5)=20.5$, $p<.025$. Analysis of brain sections shows similar lesion sites in LO and LG rats, and cell loss in the dorsal nuclei of lateral lemniscus (DNLL), a source of IC afferents, in LO animals. Sparing of DNLL neurons is observed in brains of grafted rats. In hooded rats, tectal grafts ameliorate, but do not completely reverse, deficits in spatial audition.

452.12

DIFFERENTIAL SURVIVAL OF SENSORY ELEMENTS IN INTRACRANIAL OTIC TRANSPLANTS. S.E. Hughes and M.S. Silverman. Sensory Neuroscience Lab, Central Institute for the Deaf, St. Louis, MO 63110.

We have previously shown that isolated embryonic rat inner ear can be transplanted to the anterior chamber of the eye of an adult. Initially, E15 inner ears were transplanted in isolation. While a considerable degree of organotypic development occurred in the transplants, the sensory structures present were limited to those found in the vestibular division: cristae and macular surfaces (Silverman and Hughes, 1987, ARO Abstr. 10: 219). When the E15 inner ear is cotransplanted with a portion of E15 brainstem, a considerably different outcome is obtained. With cotransplanted brain present in the anterior chamber, the cochlear duct develops recognizable sensory elements, including spiral ganglion cells and an organ of Corti (Hughes and Silverman, 1989, ARO Abstr. 12: 296).

In order to investigate the possibility that more mature brain might exert a similar supporting role on cochlear development, we transplanted E15 inner ears to either the cortex or the brainstem of a newborn rat. After survival times ranging from 3 to 5 weeks, we found that more than half the transplants survived and developed sensory structures. Transplants made to the cortex only showed evidence of the cristae and macular surfaces of the vestibular division. However, those transplants placed within the brainstem demonstrated organotypic development of the cochlear duct, with an organ of Corti apparent on the basilar membrane.

Other workers have shown that long-term survival of intracranial transplants of embryonic retinae depends on the presence of target cues to guide innervation (Sefton et al., 1987, Dev. Brain Res. 33: 145). While we as yet have no evidence of innervation of the brain by the transplanted inner ear, the improved cochlear development seen in the intraocular cotransplants and brainstem transplants suggests that the proximity of appropriate target cues also may be an important factor for the development of cochlear sensory elements.

453.1

EFFECTS OF TRANSPLANTS OF FETAL HIPPOCAMPAL TISSUE INTO HIPPOCAMPAL LESION CAVITIES ON ACQUISITION OF CUE OR PLACE TASKS BY RATS. R. L. Cannon, R. H. Baisden and M. L. Woodruff. Dept. of Anatomy, J. H. Quillen College of Medicine, East Tennessee State University, Johnson City, TN 37614.

Kimble et al. (Brain Res. 363: 356-363, 1986) found that transplants of fetal hippocampus reduced hippocampal lesion-induced deficits in the Rabinovitch-Rosvold mazes. Woodruff et al. (Prog. Brain Res., 82:367376, 1990) found that rats with hippocampal transplants were more impaired than hippocampal lesioned rats in acquisition of the Morris water maze. These contradictory results may be due to difference in use of internal vs. external cues. The present study tested the hypothesis that hippocampal transplants would effect performance in a radial arm maze with internal discriminative cues differently than performance in the same maze without the cues (i.e. a "spatial" maze). The results indicated that rats with transplants exhibited more working memory errors in both mazes than rats with just hippocampal lesions. These results are compatible with those of Woodruff et al. (Supported by NIH Grant ES 04070-05 to MLW.)

NORADRENALINE RELEASE FROM GRAFTS OF SUPERIOR CERVICAL GANGLIA OR FETAL LOCUS COERULEUS TRANSPLANTED TO THE HIPPOCAMPUS AS STUDIED BY IN VIVO MICRODIALYSIS M.A. Cenci*, O.G. Nilsson*, P. Kalén* and A. Björklund, Dept. of Medical Cell Research, University of Lund, Sweden.

Extracellular noradrenaline (NA) was monitored in the hippocampus (HPC) after a lesion of the normal NA innervation followed by grafting of either fetal locus coeruleus (LC) or superior cervical ganglia (SCG) tissue. Rats received a bilateral intraventricular injection of 6-hydroxydopamine. Two weeks later, the fornix-fimbria was unilaterally removed by aspiration. Solid grafts of either autologous SCG or fetal LC (E14) were transplanted in the resulting cavity. One year later, a microdialysis probe was implanted in the HPC. Samples were collected in 30 min fractions and analysed for NA by a radioenzymatic assay. At the end of the experiment, the brains were processed for dopamine-ß-hydroxylase (DBH) immunohistochemistry. Basal extracellular levels of NA were higher than normal in LC-grafted rats (47 vs 23 fmol/30 µl), and much lower than normal in SGC-grafted rats (4 fmol/30 µl). The addition of 100 mM KCl to the perfusion fluid for 30 min enhanced NA levels by 7-8-fold in normal, LC- and SCG-grafted animals, and the addition of 5 µM desipramine (DMI), a NA uptake blocker, induced a 4-5-fold increase in NA levels. The subsequent infusion of 1 µM tetrodotoxin (TTX) significantly reduced NA overflow in all three groups. In lesioned controls, infusion of KCl, DMI, and TTX did not modify NA levels, which were close to, or below the limit of detection of the assay (1 fmol) throughout the experiment. Morphological analysis revealed that both LC- and SCG-grafts had developed an extensive DBH-immunoreactive reinnervation in the whole HPC. Thus, although both LC- and SCG-grafts produced rich fiber outgrowth, spontaneous release of NA appeared to occur at a higher rate from central NA neurons. However, pharmacological manipulations modulated NA release from both types of grafts in a similar fashion.

SURVIVAL AND CONNECTIVITY OF NEURAL GRAFTS IN NORMAL AND DAMAGED HIPPOCAMPAL TISSUE VISUALIZED WITH VOLTAGE-SENSITIVE PROBES. D.M. Senseman[1], J. Fitzgerald*[2], B. Cobb[3], L.J. Ferguson*[4], J.P. Amaya*[1], J. Gonzalez*[1], and G.A. Mickley[3]. [1]Center for Information Visualization, Univ. of Texas at San Antonio, San Antonio, TX 78285; [2]Dept. of Biological Sciences, Rutgers Univ., Newark, NJ 07102; [3]USAF School of Aerospace Medicine, Brooks AFB, TX 78235; [4]AFFRI, Bethesda, MD 20814

The ability of neural grafts to attenuate behavioral effects of radiation-induced hypoplysia of dentata granule cells depends, in part, on the source and final location of the donor neural tissue (Mickley *et al.*, Brain Res. 509: 280, 1990). In this study the long-term survival (>2 yrs) and functional connectivity of fetal neural grafts were directly visualized using optical recording techniques (Senseman *et al.*, NATO ASI, H 39: 330-347, 1990). Both homolgous grafts (hippocampal neurons) and non-homologous grafts (cerebral cortical cells) were investigated. Evoked neural activity was recorded optically from "thick" hippocampal slices (400 um) stained with the voltage-sensitive dye RH155 following either focal and/or field stimulation. Focal stimulation of both homolgous and non-homolgous grafts produced relatively large optical signals that propagated radially from the site of stimulation. In the three non-homologous grafts studied, we failed to find evidence of functional connections between grafted cells and surrounding host neurons. However the spatial/temporal spread of activity from the point of stimulation suggests that ectopically grafted cortical neurons were capable of supporting regenerative electrical activity and may have developed a neural plexus within the graft. By comparision, in the two homologous grafts studied, focal stimulation of the graft evoked propagated responses that transversed the graft boundary and invaded surrounding host tissue. These results support the view that homologous grafts are more likely to form functional connections with surrounding host neurons than non-homolgous grafts. *Support by: AFSOR-89-0118, ARP 2227, BNS-0794 & AFRRI B4163*

INTRAHIPPOCAMPAL GRAFTS FROM FETAL STRIATUM AMELIORATE SPATIAL MEMORY DEFICITS IN RATS WITH FIMBRIA-FORNIX LESIONS. Y.J. Li[1], J.R. Simon[2], W.C. Low[1], [1]Dept. of Neurosurgery, Univ. of Minnesota Medical School, Minneapolis, MN 55455, and [2]Dept. of Psychiatry, Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Previous studies have shown that intrahippocampal grafts of cholinergic septal neurons are capable of ameliorating spatial memory deficits in rats with bilateral fornix lesions. In the present study, we have examined the behavioral and biochemical effects of transplanting cholinergic neurons derived from the striatum of fetal rats. Embryonic striatal neurons were transplanted into the hippocampal formation of adult rats with fimbria-fornix lesions. Spatial reference memory and spatial navigation performance were evaluated using a Morris water maze, and spatial working memory performance was evaluated using a T-maze. Animals with striatal grafts exhibited significant improvements in performance on all three spatial tasks in comparison to animals with lesions alone. Atropine administration dramatically disrupted spatial navigation performance in animals with grafts and sham controls. Regression analysis indicated that improvements in spatial memory function were significantly correlated with increases in high affinity choline uptake. We thus conclude that intrahippocampal grafts of striatal tissue produce similar effects as grafts derived from the medial septal nucleus.

FETAL HIPPOCAMPAL TRANSPLANT PROMOTES RECOVERY OF WIN-SHIFT BEHAVIOR AFTER HIPPOCAMPAL LESIONS. J.D. Chudik* and A.G. Gittis. Psychology Department. Westminster College, New Wilmington, PA 16172.

The extent to which fetal hippocampal tissue, extracted from embryos (17-19 gestation days) could ameliorate the alternation deficit seen in rats after hippocampal lesions was investigated. Prior to a hippocampal lesion, subjects were trained on a win-shift alternation task to a criterion of 18/20 correct responses over two days. In the first surgical procedure, the dorsal hippocampus and overlying cortex was removed via aspiration and win-shift behavior was reassessed. Only animals which demonstrated a marked win-shift deficit (less than 50% accuracy over two sessions) were continued in the study. A second surgical procedure was performed. Half received fetal transplants, the others underwent a sham surgery. Win-shift behavior was reassessed at 2 weeks and 3 months after the second surgery. Experimenters who conducted the behavioral testing were unaware of an animal's group assignment. Hippocampal animals, throughout testing, were severely impaired in win-shift performance demonstrating characteristic response perseveration, alternating less than 10% of the time. Transplant animals tended to alternate slightly more at 2 weeks post-surgery (38%) and improved even more at 3 months (59%). Histological analysis of cresyl violet and Kluver-Barrera stained sections revealed that dorsal hippocampal tissue was absent between 1.8 and 4.8 mm posterior to bregma in both the transplant and non-transplant subjects. The brains of fetal tissue recipients had anomalous cellular aggregations adhering to and incorporated within thalamic tissue in the evacuated hippocampal cavity. Thus it appears that transplanted fetal hippocampal tissue can reduce the response perseverative tendencies in hippocampal subjects in a win-shift task.

DENTATE GRANULE CELL TRANSPLANTS RESCUE MOLECULAR LAYER INPUTS. J. Wells and B.P. Vietje. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

When dentate granule cells were axotomized by fluid injections into the infragranular cleavage plane, the molecular layer (ML) shrank, due to the loss of both the inputs to the ML and their targets, the granule cell dendrites. If the fluid which created the axotomy also contained immature neurons, the same injection which made the lesion could replace the adult granule cells with potential target neurons. When immature granule cells replaced the adult granule cells, the ML was not as thin as the lesioned ML without transplants and cytochrome oxidase staining was restored in the ML. AChE-positive fibers also increased and were redistributed without distinct laminae. When immature septal cells replaced the adult granule cells, the lesioned ML continued to shrink and there was no cytochrome oxidase staining in the lesioned ML. Granule cell transplants rescued the lesioned ML and could have restored the normal circuit. Septal cell transplants were not adequate targets for ML inputs but grew into the intact molecular layer and perhaps established new circuits. Supported by PHS NS23266

TERMINAL FIELD SPECIFIC MONOCLONAL ANTIBODIES THAT DEMONSTRATE REINNERVATION OF ADULT RAT DENTATE GYRUS BY EMBRYONIC ENTORHINAL GRAFTS. P.L. Woodhams,* H. Kawano,[1] G. Raisman. (SPON: Brain Research Association). Norman & Sadie Lee Research Centre, Nat. Inst. for Medical Research, London NW7 1AA, U.K. [1]Dept. Anatomy, University of Tokushima, Japan.

We have derived monoclonal antibodies which give complementary staining patterns in the dentate molecular layer: OM-1 to OM-4 selectively recognise the outer two-thirds (the entorhinal terminal field), and IM-1 the inner one-third (the commissural-associational zone). OM-1 recognises a 93 kDa glycoprotein antigen, OM-2 to OM-4 a second glycoprotein of 36 kDa, and IM-1 multiple antigens of 120-260 kDa.

After unilateral entorhinal lesions, OM immunostaining was abolished in the ipsilateral entorhinal afferent zone of the dentate gyrus. At the same time the IM-imunoreactive inner zone acquired OM-1 staining and expanded by 10 μm in width, while the distal zone shrank by 80 μm. When grafts of embryonic entorhinal cortex were placed in the entorhinally deafferented distal zone of adult hosts, 14 out of 26 cases showed restoration of OM-1 immunoreactivity which was restricted to a band in the middle third of the molecular layer. However, staining for the antigen recognised by antibodies OM-2 to OM-4 was restored throughout the entire outer two-thirds of the dentate molecular layer.

Our results suggest that the membrane-associated glycoprotein antigens detected by the OM monoclonals may be part of an intrinsic signalling system used in normal development and in reinnervation of the adult by embryonic entorhinal transplants to direct and restrict the distribution of entorhinal axons to the appropriate part of the dentate molecular layer, the distal two-thirds. This hypothesis is currently being tested in vitro, using roller tube cultures of hippocampal slices.

DENDRITIC GROWTH FROM FETAL HIPPOCAMPAL CELLS TRANSPLANTED AFTER TRANSIENT FOREBRAIN ISCHEMIA IN RATS AS DEMONSTRATED BY MICROTUBULE-ASSOCIATED PROTEIN 2 (MAP2) IMMUNOHISTOCHEMISTRY. Morimichi Koshinaga*, Yoichi Katayama, Shuhei Miyazaki*, Takashi Tsubokawa* . *Department of Neurological Surgery , Nihon University School of Medicine, Tokyo 173, Japan*

Cell suspensions prepared from 17-18 gestational hippocampi were transplanted into the area just above the hippocampus of male Wistar rats (300-350g) following transient forebrain ischemia, and the dendritic growth patterns of the transplanted cells were examined by microtubule-associated protein 2 (MAP2) immunohistochemistry. The ischemic insult was carried out by hemorrhagic hypotension and bilateral occlusion of the carotid arteries at 7 days before transplantation. Four weeks after transplantation, the animals were perfused transcardially and fixed in 2% paraformaldehyde, and the brains were removed and embedded in paraffin. Consecutive paraffin sections of 5μm in thickness were stained by the ABC method, employing the anti-serrum rabbit anti-pig MAP2 polyclonal antibody (Penninsula Laboratories Europe) and anti-calbindin D monoclonal antibody (Sigma). It was found that far more transplanted cells survived and extensive dendritic growth occurred when complete death of CA1 pyramidal cells had been induced by the ischemic insult. The dendrites demonstrated two growth patterns: the cells located in the dorsal part gave off dendrites towords the dorsal direction, and the dendrites of the cells located in the ventral part oriented themselves towards the ventral direction, much like the parallel arrangements of apical dendrites of normal CA1 pyramidal cells. These findings suggest that dendritic growth from transplanted hippocampal cells is dependent on the absence of host hippocampal cells and is guided by the presence of remaining free terminals of afferent fibers.

453.9

REARRANGEMENT OF THE SEROTONERGIC AND DOPAMINERGIC FIBERS IN THE HIPPOCAMPAL FORMATION OF THE RAT. INTRAVENTRICULAR FETAL RAPHE TRANSPLANT AND INTRAOCULAR DOUBLE-GRAFT OF FETAL RAPHE AND HIPPOCAMPUS. S. Ueda' and M. Kawata. Dept. of Anatomy, Kyoto Pref. Univ. of Med., Kyoto 602, Japan.

Pieces of fetal midbrain raphe tissue were transplanted into the third ventricle near the dentate gyrus of adult host rats that had previously been denervated by treatment with 5,6-dihydroxytryptamine. In another experiment, the fetal midbrain raphe tissue was co-grafted with the fetal hippocampus including the dentate gyrus in the anterior chamber of the eye of adult rats. One and three months after transplantation, the extent of axonal outgrowth of raphe tissue into the hippocampus was studied using serotonin and tyrosine hydroxylase (TH) immunohistochemistry. Serotonin fibers were densely distributed throughout the raphe graft tissue, while TH fibers were restricted to an area near the somata of TH positive neurons. A large number of serotonin fibers were distributed in the hippocampus, especially in the molecular layer of dentate gyrus, while only a few TH fibers were observed in the hippocampus. These observations suggest that the serotonergic and dopaminergic neurons located in transplants of midbrain raphe have different reinnervation patterns in the hippocampal tissue.

AGING PROCESSES IV

AGE DIFFERENCES IN RABBITS IN THE DELAY CLASSICAL CONDITIONING PARADIGM USING 400 AND 750 MSEC CS-US INTERVALS. D.K. Sasse, J.M. Coffin, & D.S. Woodruff-Pak. Dept. of Psych., Temple Univ., Phila., PA 19122.

To explore aspects of eyeblink conditioning which are most impaired by processes of aging, we compared the performance of young (Y) and older (O; minimum of 24 months old) rabbits in the 400 and 750 msec CS-US interval delay paradigms. For all rabbits a 1 KHz, 85 dB tone was the CS, and a 3 psi, 100 msec corneal airpuff was the US. Twenty-four Y and 18 O rabbits were run for 90 trials/day until they attained a learning criterion of 8/9 CRs and then were overtrained a minimum of one day. Both O and Y rabbits required significantly more trials to reach criterion with a CS-US interval of 750 msec ($F=14.88$, $p<.01$). In the 400 msec paradigm O rabbits required 300 trials to criterion, while they required 713 trials to criterion in the 750 msec paradigm. Y rabbits required 171 and 343 trials to criterion with a 400 and 750 msec paradigms, respectively. These age differences were highly significant ($F=20.52$, $p<.01$). The age by paradigm interaction was significant at the .1 level ($F=3.47$), suggesting that O rabbits are more impaired at the longer 750 msec CS-US interval. Longer CS-US intervals impair acquisition in rabbits, and processes of aging exacerbate the difficulty at longer intervals. *Supported by a Research Incentive Fund Grant from Temple University.*

MULTIVARIATE ANALYSIS OF BEHAVIORAL AGING HIGHLIGHTS SOME UNEXPECTED FEATURES OF COMPLEX SYSTEMS ORGANIZATION. A. Giuliani *, O. Ghirardi *, A. Caprioli *, S. Di Serio *, G. Taglialatela, M.T. Ramacci , L. Angelucci [1]. Sigma Tau, Institute for Research on Senescence, Pomezia, Rome; [1]Institute of Pharmacology II, La Sapienza University, Rome, Italy

Male Fischer 344 rats aged 5 and 24 months were subjected to 10 behavioral tests for a total of 22 variables, including spontaneous activities, memory, and learning measures.

The behavioral performances of the two age groups were significantly different in most tests, indicating a clear factorial structure of the whole data set. Principal components analysis has evidenced a first factor describing some 40% of the information concerning the 22 variables with a 100% discriminating efficiency between the two groups. This first component may be taken as a comprehensive measure of the animals' "behavioral age". On the contrary, the same analysis performed separately on the two groups revealed a relationship pattern between variables, which was different for the two ages, thereby indicating different meanings for the same parameters and their different behavioral utilization in the two classes. With the aid of the spin glasses physical model, these results lead to the definition of the difference between causal linking and correlations driven by an external parameter.

454.3

TREATMENT OF d-AMPHETAMINE REDUCE AGE-RELATED MEMORY DEFICITS IN RATS. G.L. Dunbar, G.A. Smith, L.S. Janis, B.J. Snyder, and L.A. Mead. Dept. of Psychology, Central Michigan University, Mt. Pleasant, MI. 48858.

Since previous studies have indicated that some age-related memory deficits may be a result of reduced levels of catecholamines, we have attempted to counteract these behavioral deficits by treating rats 6, 12, or 24 months of age with either 0.5, 1.0, or 2.0 mg/kg d-amphetamine or saline (control). All rats were tested for 8 days on a Morris water maze task. Daily IP injections were given 20 minutes prior to testing. Rats were perfused 24 hours following the final testing day and their brains were processed using cytochrome-oxidase (CYO) histochemistry. Both the 12 and 24 month-old control rats took more time and swam further searching for the platform than did the 6 month old controls. These deficits were reduced by treatments of 1 mg/kg d-amphetamine in the 24 month old rats, while the 2 mg/kg dose caused further impairments in these aged rats. Age-related deficits in CYO activity were observed in the dorsalmedial thalamus, nucleus basalis, and caudate nucleus of the 24 month old rats and in the dorsalmedial thalamus of the 12 month old rats, irrespective of treatment. However, these histochemical deficits did not correlate significantly with either of the behavioral measures used, suggesting that amphetamine is affecting behavior in other ways.

454.4

PRINCIPAL COMPONENT ANALYSIS HELPS TO CLARIFY THE STRUCTURE OF A DATA SET: A CASE STUDY ON FOUR BEHAVIORAL PARAMETERS. S. Algeri*, A. Giuliani*, N. Pitsikas[1]*, Sigma Tau Institute for Research on Senescence, Pomezia, Rome; [1]Institute Pharmacol. Res., M. Negri, Milano, Italy.

Sprague Dawley rats (N. = 86) of different ages, fed standard or hypocaloric diet, were subject to a radial water maze test in order to assess the effect of age and diet on their performances. Four performance indeces were singled out from the test: 1) Spatial reference memory 2) Spatial working memory, 3) Non spatial reference memory 4) Non spatial working memory. These parameters, measure over 10 subsequent sessions, were globally analyzed with the aid of the principal component analysis (PCA), which highlighted a first factor explaining 65% of total variability. This factor was highly correlated with time course as measured by the successive sessions (R=0.9). Such a relation individuated the factor as "learning": all the parameters had a significant factor loading on this component.

When PCA was performed separately at each session, thus eliminating the "learning effect", the 4 kinds of memory resulted to be completely uncorrelated, thence pointing out to the role of "order parameter" exerted by learning with respect to the measured parameters.

Aging was demonstrated to decouple learning and working memory performances and this decoupling was antagonized by an hypocaloric diet.

454.5

HIPPOCAMPAL MOSSY FIBER ZINC AND SPATIAL MEMORY IN AGED RATS. D. Guidolin*, P. Polato*, A. Zanotti*, E. Mocchegiani*[1], N. Fabris*[1] and M.G. Nunzi. Fidia Research Laboratories, 35031 Abano Terme (PD) and [1]Center of Immunology, Dept. of Gerontologic Research, INRCA, 60121 Ancona, Italy.

Zinc is known to play a key role in synaptic function of the mossy fiber system, a pathway deeply involved in the modulation of processes related to spatial learning and memory. We evaluated the amount of histochemically detectable zinc in the mossy fibers from young adult (5 mo) and aged (25 mo) rats tested for spatial performance. Computer-assisted microdensitometry and x-ray microanalysis showed a significant difference (40%) on the neo-Timm's staining between memory-impaired and non-impaired aged rats, thereby suggesting a correlation between age-associated memory deficits and localized changes in hippocampal zinc levels.

Furthermore chronic oral administration of phosphatidylserine has been reported to significantly improve spatial memory in aged rats with a severe place-navigation deficit (Zanotti et al., 1989, Psychopharmacol., 99:316). Since phosphatidylserine restores plasma zinc levels in aged rats, we are currently evaluating the effects of this phospholipid on hippocampal zinc levels in aged memory-impaired rats.

A NEW TEST DESIGNED TO ASSESS MOTOR IMPAIRMENT IN AGED RATS. F. García-Hernández and R. Drucker-Colín. Instituto de Fisiología Celular, UNAM. Apdo. Postal 70-600, México. D. F.

Neurodegenerative disorders which involve motor impairment is characteristic of old age. Although there are a few tests which attempt to assess motor incapacities, many have utilized scales which have either a great deal of subjective evaluations or are subject to learning-performance complexities. This study describes a method able to measure motor impairment of aging rats which is subject to dopaminergic influences and has negligible practice effects. The test is designed so that rats have to traverse 2 meter beams of 15° inclination whose widths 3,6,12,18 and 24 mm are changed on each test session using a table of random numbers. The time ceiling allowed for traversing the 2 m beams was established at 120 sec. 3 month old rats (N=20) and aged rats (N=20) with a mean age of 26.5 ± 3.8 months ranging from 23 to 34 months were utilized in this study. All young rats traversed the beams, independently of beam width, while virtually none of the old rats traversed the 3 and 6 mm beams. However, as the beam width increased more and more aged rats ascended the beam. Nevertheless, there were always a few old rats who were unable to cross even on widest beam. When young rats were fitted with a lead belt which increased their body weight by approximately 40%, they still traversed all beam widths. On the other hand, Haloperidol (.1 and .2 mg/kg) severly impaired the performance of young rats. Conversely administration of amphetamine (1.0 mg/kg) or L-dopa (50 mg/kg) to old rats substantially improved their performance. The results suggest that beam taxis appears to be an effective and efficient test for screening motor dysfunction in aged rats and can be amenable to studies on changes of motor capabilities as a result of drugs and/or brain damage.

AGE DEPENDENT ALTERATION OF NERVE TERMINAL ACTIVITY AT THE NEUROMUSCULAR JUNCTION (NMJ) OF RAT; A MICROELECTRODE STUDY. M.D. Sokoll, B. Bhattacharyya,* and K. Tsen*. Department of Anesthesiology, University of Iowa College of Medicine, Iowa City, Iowa 52242

Rat NMJ has been chosen by several workers to study synaptic aging. Using the two microelectrode voltage-clamp technique, we studied age induced alterations of ACh release in phrenic nerve-diaphragm preparation of young (3 month old) and old (30 month old) Sprague-Dawley rats. Results of this study indicate that spontaneous release of ACH measured by recording miniature end-plate current (MEPC frequency) was significantly higher in old rats. Quantum content calculated by the direct method (recording MEPC and end-plate current (EPC evoked at 0.4 Hz from same cell)) indicate a larger quantum content in old muscle compared to the young. The EPC quantum content was also studied by recording MEPC's immediately before the in trains of EPC's elicited at 40 Hz. In these studies, quantum content of first EPC as well as the EPC in the plateau phase in a train is greater in old muscle than in young. A significant increase in neurotransmitter mobilization is also observed in old muscle. These results suggest altered capabilities for sustaining synaptic transmission by increasing nerve terminal activity in a continuously active muscle of senescent rats.

This study was supported by American Federation for Aging Research and Department of Anesthesia Trust Fund.

ACETYL-L-CARNITINE RELEAVES AGE- AND TRAUMA-INDUCED NEUROPATHIES IN RATS. C. De Angelis*, C. Scarfò*, M. Falcinelli*, A. Bellucci*, L. Pacifici*, E. Reda*, M.T. Ramacci, L. Angelucci[1] Sigma Tau Institute for Research on Senescence, Pomezia, Rome; [1] Institute of Pharmacology II, La Sapienza University, Rome, Italy

The neuronal trophic effects of Acetyl-L-Carnitine (ALCAR) prompted investigation on the substance favorably affecting peripheral neuropathies, both age-related (reduced neuromuscular conduction velocity (NMCV)); and trauma-induced (distal axonal degeneration, denervation of the soleus and extensor digitorum longus (EDL), and changed morphology of regenerated motor end-plate). NMCV was evaluated in the sciatic nerve soleus muscle preparation in anesthetized 3 - and 24 - month - old Fischer 344 rats, following acute (50-100 mg/kg i.v.), or 6 - month long-term treatment (150 mg/kg/day in drinking water) with ALCAR, and resulted to be increased. Anesthetized 3-month-old Sprague Dawley rats were subjected to sciatic nerve crush and morphological and morphometric evaluations were carried out on sections of muscle (combined silver-cholinesterase stain) and on tibial nerve sections (toluidine blue and antineurofilaments antibodies). Treatment with ALCAR (15-60 days, 150 mg/kg/day in drinking water) increased number, area and diameter of regenerating axons; decreased the number of degenerating elements; and maintained the ratio of axon/ myelinated fiber diameter within the range of the optimal values for conduction velocity. The number of branching points of nerve terminals x end-plate length rose significantly, and morphology of the end-plate was similar to that of unlesioned animals. Besides possessing a neurotrophic effect, ALCAR favors the activity of sprouting factors released from the denervated muscle, thereby enhancing synaptical transmission.

FURTHER ANALYSIS OF SENSORIMOTOR DYSFUNCTIONS IN AGED RATS: ADHESIVE PAPER TEST. T. Schuurman* and M. de Jonge. Troponwerke, Inst. for Neurobiology, Dept. of Geronto-pharmacology, Berliner Str. 156, 5000 Köln 80, FRG

Until now little research has been directed to the study of age-related sensorimotor dysfunctions compared with the number of studies on age-dependent cognitive deficits. Our previous studies showed an impairment of motor coordination of old rats subjected to balance rod and pole climbing tests. An analysis of the footprints of aged rats showed a disturbance of the coordination of the movements of the hindlegs during walking. In two experiments we assessed differences between young and old rats in stimulus-directed movements of the forepaws. In the first experiment, small pieces of adhesive paper were placed on various parts of the rat's snout or forepaws. The time needed to remove the sticky paper was measured. 25-month-old rats needed 2-4 times longer than 3-month-old rats to remove the stimulus. In the second experiment young and old rats were repeatedly subjected to the adhesive paper test. Latencies to remove the sticky paper decreased significantly in 3-month-old rats. In contrast, 25 month-old rats showed no improvement of their sensorimotor skills.

454.10

QUANTITATIVE ASSESSMENT OF CROSSED PHRENIC NERVE ACTIVITY AT VARIOUS TIME INTERVALS AFTER SPINAL CORD HEMISECTION IN OLD RATS. H. G. Goshgarian and X.-J. Yu*. Department of Anatomy, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

A recent quantitative electrophysiological study from our lab has shown that there is a significant augmentation of crossed phrenic reflex nerve activity that can be induced as early as 2 hours after spinal hemisection in 3-4 month old young adult rats (Exp. Neurol 111:224-250, 1991). The present study utilized the same techniques on older rats (9-10 months old) to determine if the time course for the augmentation of the reflex between the two age groups was similar. Mean integrated areas under phrenic nerve compound action potentials during the crossed phrenic reflex at 4 hours (26.60 ± 8.62 mm^2) and 12 hours (35.56 ± 14.91 mm^2) were not significantly greater than the mean area under the initial recordings taken at 30 minutes post hemisection (29.29 ± 9.67 mm^2). The first significant ($P<0.01$) increase of mean integrated area occurred 24 hours after hemisection (86.29 ± 26.12 mm^2). Activity measured at 7 days (86.66 ± 23.54 mm^2) and 30 days (99.48 ± 27.65 mm^2) was not significantly different from the enhanced activity measured at 24 hours. From these data, we conclude that crossed phrenic nerve activity increases significantly in older rats after spinal cord injury, but the augmentation of the reflex occurs more slowly than it does in young adult rats.

454.11

THE LONG-TERM EFFECTS OF MUSCLE USAGE ON AXONAL SPROUTING FOLLOWING PARTIAL DENERVATION IN RAT. B.R.Pachter and A.Eberstein*. Dept. of Rehab. Med., N.Y.U. Med. Ctr., New York, NY 10016.

The present study examined the effects of long-term muscle usage on axonal sprouting (intranodal, preterminal, and intraterminal) as well as terminal branch number and endplate area following 1,3,6,9, and 12 months of partial denervation induced by radicular nerve L4 transection in rat. We found that in the partially denervated (PD) plantaris muscles, there was a progressive increase in all types of axonal sprouting up to 9 months post-surgery as compared to sham-operated controls. The number of terminal branches per endplate in the PD muscles remained constant and less than controls from 1 to 6 months post-surgery; at 9 months post-surgery, it approximately doubled from previous values and was about 1.5 times greater than in controls. The endplate area in PD muscles at 3 to 12 months post-surgery was greater than in controls. At 12 months, axonal sprouting and number of terminal branches were decreased when compared to sham controls; denervated endplates and endplates exhibiting degenerative changes were also seen in PD muscles. It would appear that there is an earlier onset of aging-like changes in the PD muscles possibly induced by enhanced stress on the remaining motoneurons which are hyperfunctioning due to a greatly enlarged peripheral field of muscle fibers. Supported by NIH grant NS25624.

454.12

THE EFFECTS OF DIFFERENT LIGHT CYCLES ON LIFESPAN IN CARDIOMYOPATHIC HAMSTERS. S.D. Drastal*, B.H. Natelson, W.N. Tapp, and J.E. Ottenweller*. Dept of Neurosci., N.J. Medical School and VA Medical Center, East Orange, NJ 07019.

Our earlier work showed that hamsters with heart disease lived significantly longer in an environment devoid of time cues than in light/dark (LD) 12:12. To evaluate these results, male cardiomyopathic hamsters (CMHs) were housed two/cage in four lighting conditions: LD 12:12, LD 6:18, LD 6:30, and LL (constant light). In addition, CMHs were housed in LD 12:12, five/cage, but in larger cages. The LD 12:12 and LL groups were chosen to replicate our original finding while the other groups were chosen to evaluate the effects of a short photoperiod (LD 6:18) and an entrained non-24 hour LD schedule (LD 6:30) on lifespan. Survival curves were generated and tested for statistical significance compared to the LD 12:12 two/cage group. Compared to that control group, LL extended life over the entire survival curve, LD 6:18 did so over the first half of the survival curve, and LD 12:12 five/cage group did so over the second half of the curve. These data confirm our earlier work on the life-extending effects of constant light and suggest that other environmental factors related to either cage size or animal density also are important. SIBERIAN HAMSTERS AGE AT DIFFERENT RATES IN LONG AND SHORT PHOTOPERIODS. C.M. Finley, and I. Zucker, Dept. of Psychology, Univ. of California, Berkeley, CA 94720. In small mammals dry eye lens weight is a reliable marker of chronological age. Lens weights continue to increase throughout the life span even when body weight remains stable. In Siberian hamsters maintained in either long (LD 16:8) or short (LD 8:16) photoperiods after weaning on day 18, eye lenses increase in weight at comparable rates until day 35. Lens weights sampled at 15 weeks of age, however, were significantly greater in short than long-day animals (19.1 ± 0.2 vs 17.3 ± 0.2 mg, $p< 0.001$), though body, testes and uterine weights were significantly greater in long-day than short-day hamsters. Because older animals had heavier lenses than younger ones, these results indicate that Siberian hamsters age at a more rapid rate in short than long photoperiods. This may reflect seasonal differences in aging of free living hamsters.

NOCICEPTION INCREASES AND THE EFFECTIVENESS OF ANALGESICS DECREASE IN AGING. E.E. Quinton.Lab of Psychobio.,Univ. Louisville, Louisville,ky.40292.

The present study was undertaken to further characterize the age-nociception interaction in the mouse. Two age groups of C57BL/6j mice were used; old (27-30 mo) and adult (8-12 mo). In exp. 1 mice from both groups were inj with saline, morphine (15 mg/k), or CCK (400 µg/k) and tested on a hot plate (55° C) 8 times from 10 min to 120 min after inj. The old-sal group was more responsive through 30 min after inj but did not differ from the adult-sal group thereafter. CCK was analgesic in both groups through 45 min, but the old and adult groups did not differ. Mor. was more analgesic in the adults through 45 min, but less analgesic thereafter. In exp. 2 the formalin test for chronic pain was used and paw-lick was monitored for 60 min after inj of the formalin. Mor. (2 mg/k), CCK (400 µg/k), or sal was inj 5 min before the formalin. The old-sal group had a higher rate of paw-lick from 25min to 60min after formalin than the adult-sal group. Mor. was less effective in the old. CCK produced a short term analgesia followed by hyperalgesia in the adult, and had a stronger effect than mor. in the old group over the duration of the test interval. In exp. 3 & 4 stress-induced analgesia and tolerance to mor. was less in the old mice.

454.15

VENTROMEDIAL HYPOTHALAMIC IMPAIRMENTS DURING AGING? C.V. Mobbs. Rockefeller Univ., New York, NY 10021.

Rats with VMH impairments evince an increased adiposity setpoint which is defended by increased conversion of calories into fat and increased eating, especially during che light phase. To examine if the age-related increase in adiposity is similarly defended, 6-, 12-, and 18-month-old male Sprague-Dawley rats (n=12/age) were fasted for 72 hours. For 1 week after fasting, rats were restricted to consuming only as much food as before the fast. From 1 to 2 weeks after fasting, rats were allowed to eat *ad lib*. Rats weighed more with increasing age; older rats lost the same weight during fasting as younger rats. Rats of all ages gained weight even when restricted to pre-fast consumption, ate more during the *ad lib* period, and by two weeks most rats had regained initial body weights. At all times, the ratio of food eaten during the light to food eaten in the dark (L:D) was greater in older than younger rats.

Food eaten (L:D X 100):	6 Mo.	12 Mo.	18 Mo.
Before fast	10±2	18±2	34±10
After fast (restricted)	0.1±0.1	4±2	13±4
After fast (*ad lib*)	14±2	26±3	29±5

Thus older rats will defend the age-related increase in adiposity in a manner similar to VMH-lesioned rats. We will next examine if the age-related changes in body weight set-point correlates with changes in VMH gene expression. Supported by the Glenn Foundation.

ENHANCED ACQUISITION OF A SPATIAL MEMORY TASK BY AGED RATS RECEIVING CHRONIC NOREPINEPHRINE (NE) INFUSION OUTLASTS NE TREATMENT. T.J. Collier and P.D. Danielson*. Department of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, N.Y. 14642.

Studies of aged rodents (Leslie et al., Brain Res. 359:292, 1985; Collier et al., N.Y. Acad Sci. 495:396, 1987) and non-human primates (Arnsten and Goldman-Rakic, Science 230:1273, 1985) suggest that age-related declines in the locus coeruleus NE system contribute to age-related declines in learning and memory function. As part of our ongoing studies on aging, the NE system and memory function in rats, we examined the effects of chronic intraventricular NE infusion on acquisition and retention of a spatial task in the Morris swim maze. Male F344 rats, 22 months of age, were screened for baseline performance of the spatial task, then implanted with an osmotic mini-pump that delivered 5ug NE/hour into the lateral ventricle over 14 days. During the last eight days of NE infusion, rats were tested for acquistion and retention of a new spatial location in the swim maze. Seven days after termination of NE infusion, rats were tested for learning and memory of a third spatial location in the maze. Acquisition of the spatial task was improved during NE infusion in aged rats that were initially classified as "impaired" at the spatial task (n=4), as well as those aged animals that were relatively "unimpaired" (n=4). One week after termination of NE infusion, improved acquisition performance was maintained, and indeed, was slightly improved over performance during NE infusion. In contrast, 24 hour retention of the spatial location, as measured by distribution of swim-search on a no-platform probe trial, was not improved during or after NE treatment. These findings are consistent with the view that chronic NE replacement in aged rats enhances acquisition of a spatial location in the swim maze, and that NE replacement can influence the system to yield behavioral improvement that outlasts the presence of exogenous NE. In contrast, NE replacement appears to have a minimal influence on retrieval of spatial memory. Supported by R29 AG08133.

TUMOR NECROSIS FACTOR-α AND INTERLEUKIN-1β INCREASE THE PHOSPHORYLATION OF TWO 30,000 M_R (HEAT SHOCK) PROTEINS IN ASTROCYTES. P.L. Mobley* and D.L. Combs. Dept. Pharmacology, Univ. Texas Hlth. Sci. Cntr., San Antonio, TX 78284.

Cytokines affect various aspects of astrocyte function but little is known about the action of these agents on protein phosphorylation. Cultures of rat astrocytes were labeled with ^{32}P-orthophosphate for 2 hrs and then treated with 1 ng/ml interleukin-1β (IL-1β), 100 U/ml interferon-γ (IF-γ), or 100 ng/ml tumor necrosis factor-α (TNF-α) for 10 min. Treatment with IL-1β and TNF-α increased ^{32}P-incorporation into two 30,000 M_R proteins with pI values of 5.7 and 5.5; however, no effect was observed with IF-γ. Based on the apparent molecular weight, pI values, and phosphorylation response to other agents, these 30,000 M_R proteins are likely the low molecular weight heat shock proteins. Treatment with protein kinase C (PK-C) activators also increased ^{32}P-incorporation into these proteins, however, the effects of IL-1β and TNF-α are observed in PK-C-depleted astrocytes suggesting that their action is not mediated by PK-C. The 30,000 M_R proteins can also be phosphorylated in response to agents which mimic or increase cyclic AMP along with a number of other proteins including glial fibrillary acidic protein (GFAP) and vimentin. However, GFAP and vimentin are not phosphorylated in response to TNF-α and IL-1β suggesting that their action is not mediated by cyclic AMP-dependent protein kinase (PK-A). These studies suggest that protein phosphorylation, mediated by a signal transduction pathway independent of PK-C and PK-A, may play an important role in the action of TNF-α and IL-1β in astrocytes.

455.2

IMMUNOLOCALIZATION OF CALPAIN II IN RAT PERIPHERAL NERVE. M.Mata and D.J.Fink. Dept. Neurology, University of Michigan, and GRECC VAMC, Ann Arbor, MI 48105

Calpain II is a thiol protease which is activated by millimolar Ca^{++}. The protein is a dimer composed of an 80K catalytic subunit and a 30K regulatory subunit. We have used a rabbit polyclonal antibody raised against rat platelet Calpain II (a gift of J. Elce) which recognizes only the 80K subunit in Western blot of homogenate of rat peripheral nerve.

Light microscopic immunocytochemistry of 1 micron cryo-semithin sections of adult rat sciatic nerve using biotin streptavidin peroxidase detection revealed prominent staining of the Schwann cell cytoplasm which extended to the plasmalemma of the Schwann cell. No immunoreactivity was seen in the myelin, or in the axon using this method.

Electron microscopic immunocytochemistry of cryo-ultrathin sections using secondary antibodies bound to colloidal gold confirmed diffuse staining of Schwann cell cytoplasm. There was prominent staining of the plasma membrane and along the external surface of the Schwann cell.

These results suggest that calpain II in nerve may be exposed to the millimolar Ca^{++} concentration required for activation in the extracellular space, and may therefore play a role either at the Schwann cell membrane or in modulation of the extracellular matrix.

DISTRIBUTION OF mCALPAIN IN RAT BRAIN AND SPINAL CORD. Z.Li*, J.Xu, N.L.Banik and E.L.Hogan. Dept. of Neurology, Med.Univ.of SC, Charleston, SC 29425.

The calcium-activated proteinase calpains are involved in the pathological process in spinal cord injury. By using immunocytochemical ABC technique, we observed the morphological distribution of mcalpain in CNS. mCalpain immunoreactivity (IR) is widely distributed in adult rat CNS.

In spinal cord, mcalpain-containing structures include neurons, fibers, glia. The IR neurons with weak staining appear in laminae III, IV, V, VII, IX and X but the cell membrane and nuclear membrane of motoneurons are distinct. Sparse numbers of IR fibers appear in gray and white matter and dorsal root. Glia in particular fibrous astrocytes with the strongest staining were seen in both gray and white matter and were most dense at the surface of the spinal cord just beneath the pia mater.

In the brain, a few weak-staining IR neurons and sparse fibers appear in hypoglossal and vestibular nuclei, nuclei of trigeminal spinal tract and solitary tract, reticular formation, substantia nigra, hypothalamus, purkinje cells, dentate nucleus and layer V,VI of neocortex. Glia, ependyma and endothelium stained most prominently. Supported by NS-11066 and MS Soc.Grant-2130.

SEQUENCE ANALYSIS OF J1-160/180 cDNA. B.Fuss* and M.Schachner. Dept. Neurobiology, Swiss Federal Institute of Technology, Honggerberg, 8093 Zurich, Switzerland.

The J1 glycoproteins are glia-derived components of the extracellular matrix which are involved in cell recognition processes. The higher molecular weight J1 forms (200-240 kD) are designated J1/tenascin because they are structurally related to chicken tenascin. The lower molecular weight J1 forms (160 and 180 kD) are expressed by oligodendrocytes and in CNS myelin. Functional studies demonstrate their adhesive substrate properties for astrocytes and their repulsive substrate properties for neurons (Morganti et al.,Exp Neurol 109:98,1990; Pesheva et al.,J Cell Biol 109:1765,1989). Recent findings implicate the neuronal adhesion molecule F3 in the initial recognition process (Pesheva et al., submitted for publication). To characterize structure-function relationships we have isolated a J1-160/180 cDNA clone from a rat oligodendrocyte library (Fuss et al., J Neurosci Res,in press). The cDNA sequence coding for at least one of the lower molecular weight forms shows highest homology to tenascin from mouse fibroblasts. Sequence analysis reveals 4.5 EGF-like domains, 9 fibronectin type III repeats and a C-terminal region homologous to fibrinogen. Members of the J1 family thus appear to be composed of structurally closely related, yet functionally distinct glycoproteins.

455.5

DISTRIBUTION OF ASTROCYTES ALONG THE FREQUENCY AXIS OF THE GERBIL LSO. A. Hafidi*, D. H. Sanes, and W. Cammer. Dept. Otolaryngol and Physiol & Biophys, NYU Med Ctr, NYC, NY 10016

We are interested in the extrinsic signals that may lead to specific neuronal shape along the frequency axis of a central auditory nucleus, the lateral superior olive (LSO; Sanes et al., J Comp Neurol 294: 443, 1990). Since glial cells have been implicated in many aspects of neural development, the purpose of the present study was to determine the distribution of astrocytes along the tonotopic axis of the LSO. Antibodies directed against glial fibrillary acidic protein (GFAP) and glutamine synthetase (GS) were employed on sections of paraffin embedded tissue from adult gerbils (*Meriones unguiculatus*), and visualized with an avidin-biotin-peroxidase amplification system (Vector). In addition, the density of astrocytes was determined from toluidine blue stained semi-thin sections through the LSO.

GS immunoreactivity was restricted to the cytoplasm of small non-neuronal cells. The number of GS-positive cell bodies appeared greater in the low frequency region of the LSO. GFAP immunoreactivity was more prominent in astrocytic processes than their cell bodies, and some of these processes terminated on the blood vessel endothelium within the LSO. The GFAP immunoreactivity was much greater in the low frequency region of the LSO: Preliminary counts of GFAP-positive cells showed a threefold difference between the low frequency and high frequency regions. Preliminary counts of all astrocytes in toluidine blue stained material also showed a heterogeneous distribution. The present results suggest that glial cell distribution along the tonotopic axis of the LSO is correlated with a known difference in dendritic form.

AXONAL ALTERATION OF ACTION POTENTIAL CODING IN DEMYELINATED FIBERS. Peter Shrager, Dept. of Physiology, Univ. of Rochester Medical Center, Rochester, NY 14642-8642.

Demyelination may result in propagation delays, failure to transmit impulses at high frequencies, and total conduction block. However, there may also be mechanisms conferring hyperexcitability. Myelinated axons have, in addition to the usual refractory period, a supernormal phase, lasting typically from 10-100 msec after the termination of an impulse. During this time, the threshold for a subsequent action potential is reduced. While this phenomenon may not be apparent in firing patterns in normal fibers, it may play a significant role at sites of reduced safety factor. It has, for example, been shown that threshold changes are accentuated at demyelinated regions (Bostock and Grafe, J. Physiol. 365, 239, 1985). We have used optical techniques to follow conduction along single, identified axons that have been focally demyelinated by an intraneural injection of lysolecithin. Short bursts (1-8 impulses) are repeated 64 times at 10 Hz for signal averaging. By increasing the temperature the safety factor is gradually decreased until bursts consisting of just one stimulus fail to propagate. If the burst is now changed so that it contains 3 stimuli with an intraburst interval of 10 msec an unusual pattern may develop in which one or more of the initial spikes are missing. If the burst was elicited with, for example, 8 stimuli, then the final one or more impulses may also be deleted in demyelinated axons, so that only the middle few action potentials are transmitted. This pattern has been seen in demyelinated internodes, and also in presumptive new nodes of Ranvier forming during early stages of remyelination. We present evidence for the site of integration responsible for these events, and also for possible mechanisms, including the role of paranodal and internodal ionic channels.

RELEASE OF CALCIUM FROM INTRACELLULAR STORES OF ISOLATED RETINAL GLIAL (MULLER) CELLS. S.A. Keirstead and R.F. Miller. Dept. of Physiology and Neuroscience Graduate Program, University of Minnesota, Minneapolis, MN 55455.

Previous studies in our laboratory have shown that dissociated Muller cells from the tiger salamander respond to an elevation in extracellular potassium ($[K^+]_o$) with an increase in intracellular calcium ($[Ca^{++}]_i$), even in the absence of Ca^{++} in the extracellular medium. This suggests that the K^+-evoked depolarization causes a release of Ca^{++} from intracellular stores. In the present experiments, we have used Fura-2 imaging techniques to study the calcium release mechanism in single dissociated Muller cells from the tiger salamander retina.

Muller cells responded to bath application of caffeine (10 mM) in Ca-free Ringer (2 mM EGTA) with an increase in $[Ca^{++}]_i$. Ryanodine (10-50 µM; Ca-free Ringer) also evoked an increase in intracellular Ca concentration, and reduced or blocked the Muller cell response to caffeine (10 mM). The changes in $[Ca^{++}]_i$ evoked by ryanodine and caffeine were more prominent in the apical region and soma of the Muller cell and less evident or delayed in the specialized endfoot region. This same spatial pattern was often observed in response to an elevation in $[K^+]_o$ in the absence of $[Ca^{++}]_o$. These findings suggest the presence of a ryanodine-sensitive mechanism in Muller cells which may be involved in the K^+-evoked increase in $[Ca^{++}]_i$ that we report here. This type of mechanism could serve to mediate long term interactions between neuronally mediated changes in external K^+ and alterations in Muller cell homeostatic mechanisms. Supported by NEI grant EY03014.

455.8

EFFECTS OF VASOPRESSIN (VP) AND ATRIOPEPTIN (AP) ON THE WATER CONTENT OF CULTURED RAT ASTROGLIAL CELLS. H.F.Cserr, L.Latzkovits, C.S. Patlak, K.D. Pettigrew, and A.Rimanoczy. Section of Physiology, Brown University, Providence RI 02912.

VP and AP are synthesized and released within the brain. This study evaluates the hypothesis that VP increases brain cell water content (DePasquale et al., Am. J. Physiol. 256:F1059-F1066, 1989) and examines interactions between this peptide and AP in cultured astroglial cells. Cultures were derived from newborn rats with minor modification of the method of Rudge et al. (Dev. Brain Res. 19:161-172, 1985). Cell water was estimated in defined medium as the 3-O-methyl[^{14}C]-D-glucose space (Kimelberg & Frangakis, Brain Res. 361:125-134, 1985) in control cells and in cells treated for 30 minutes with VP (10^{-5} to 10^{-7} M) and/or AP (10^{-6} M). VP increased glial cell water content (mean±SD, µl/mg protein) by an average of 19% (P<0.001), from 4.22±0.19 (n=30) in control cells to 5.01±0.32 (n= 54). In contrast, cell water did not differ from control (P>0.5) in the presence of AP alone, 4.21±0.23 (n=18), or AP plus VP, 4.23±0.28 (n=18), indicating that AP blocks the VP-dependent increase in glial water content. Results support a role for centrally-released VP and AP in the homeostasis of brain water content. Supported by NS-11050.

455.9

GLIONEXIN, A GLIAL GLYCOPROTEIN, IS SELECTIVELY EXPRESSED IN INSECT MECHANORECEPTORS. L.H.Field*, M.R. Meyer*, and J.S.Edwards. Dept. of Zoology, NJ-15, Univ. of Washington, Seattle, WA 98195.

Glionexin (GX), a high molecular weight extracellular matrix (ECM) glycoprotein recognized by the 5B12 antibody [(Meyer et al., J. Neurosci 7:512 ('87); Dev. Biol.130:374 ('88)], is associated with discrete types of glia in the CNS of embryonic and adult cricket (*Acheta domesticus*). We now show that GX is also expressed selectively in the peripheral nervous system.

GX is found in: (a) mechanoreceptor hairs (cercal filiform and clavate sensilla) and (b) chordotonal organs (subgenual, tympanal, femoral, Johnston's) in legs and antennae. GX is excluded from fine trichoid mechano/chemoreceptors on cerci, antennae, legs, and palps, as well as from retinal photoreceptors. Therefore, GX expression in the periphery is sensory modality selective.

GX is transiently expressed on basal lamina of embryonic ectoderm and is present within the mechanoreceptor organs in developing limbs and cerci; mechanoreceptor labelling persists throughout development. Peripheral GX immunoreactivity appears to be non-neuronal, confined to the ECM investing sense organs. Highest levels of GX expression are usually associated with either ECM regions surrounding sensory neuron somata or with sheath cells which wrap sensory axons. Moreover, various types of mechanoreceptor organs show differential patterns of GX labelling. Thus, peripheral GX expression may be both receptor class- and non-neural cell type-selective. Supported by NS-07778.

455.10

SECRETION OF PEPTIDES BY CHOROID PLEXUS AND EPENDYMAL CELLS IN CULTURE. R.H. Angeletti, P. Gee* and C.H. Rhodes. Albert Einstein College of Medicine, Bronx NY 10461 & Dartmouth Medical School, Hanover NH 03756

Immunohistochemical studies with sequence-specific antibodies to the peptidylglycine alpha-amidation enzyme (PAM) have shown that this enzyme is found in glial cells: Schwann cells, astrocytes, ependyma, choroid plexus, subependymal and subpial glia [J Histochem Cytochem 38:1301 (1990)]. These data are consistent with recent reports that the mRNA for the endocrine carboxypeptidase (CPE), another neuropeptide processing enzyme, is also present in glia [Birch *et al.*, Mol Brain Res 7:53 (1990); MacCumber *et al.*, J Neurosci 10:2850 (1990). In order to study their secretion, we have set up primary cultures of rat ependyma and choroid plexus, as well as cultures of a choroid plexus cell line. Pulse-chase experiments with ^{35}S-methionine, ^{3}H-glutamic acid, ^{3}H-leucine, and other labeled amino acids show that a discrete set of polypeptides is secreted, ranging in molecular weight from >200,000 daltons to less than 10,000 daltons. These peptides are being isolated, so that their identity can be determined. Neuropeptide processing enzymes are also being measured by activity, cDNA and immunoaffinity probes. Further studies have demonstrated the presence of PAM immunoreactivity in human ependymomas. (supported by NIH grant NS-22697)

455.11

Peptidylglycine amidating monooxygenase (PAM), an enzyme involved in neuropeptide biosynthesis, is present in normal glia and glial tumors. C. H. Rhodes, C. Honsinger, R. H. Angeletti, and F. A. McMorris, Dartmouth Medical School, Hanover, NH; Albert Einstein College of Medicine, Bronx, NY; Wistar Institute, Philadelphia, PA

The enzyme peptidylglycine amidating mono-oxygenase (PAM) is required for the biosynthesis of about half of the known neuroendocrine peptides. PAM-like immunoreactivity has been demonstrated not only in neurons, but also in Schwann cells, normal ependyma and some glia (J Histochem. Cytochem., 38:1301-1311 (1990)). The presence of PAM in primary glial cultures was demonstrated by experiments which showed the production of PAM enzymatic activity, PAM immunoreactivity, and PAM message by those cultures. These results suggest that some glia may be producing an amidated peptide of as yet unknown function. The modulation of this system during neoplastic transformation is examined by studies of PAM expression in human glioma tissue.

ORGANIZATION AND STRUCTURE OF ASTROCYTES IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS. Lucas D. Pozzo Miller* and Dennis M.D. Landis. Depts. of Neurology and Neurosciences, School of Medicine, Case Western Reserve University, Cleveland, OH 44106-4901.

In organotypic cultures, the initial cellular relationships at the time of plating are essentially those of the tissue from which slices were made. We have prepared organotypic cultures of hippocampal slices obtained from 6-7 days old rats and maintained for 14-21 days in vitro. Astrocytes in such slices phagocytose large amounts of cellular debris, and appear to form a glial limitans. Among the neuronal elements, however, the patterns of astrocytic investments resemble those present in developing hippocampus.

In cultures prepared by aldehyde fixation and freeze fracture techniques, astrocytic processes in the superficial 15-20μm of the slice are characterized by very large gap junctions, and numerous "assemblies". These arrays of orthogonally-packed intramembrane particles are normally found in astrocytic processes investing blood vessels or forming the glial limitans in situ. Astrocytes in secondary cultures also express assemblies, but with lower densities than those observed in tissue or in organotypic cultures. Cytoplasmic organization in astrocytes appears similar in cultures prepared by aldehyde fixation and in cultures prepared by rapid freezing and freeze substitution fixation.

We find that selective neuronal death occurs in particular regions and at particular times in the cultured slices. These cultures provide an opportunity to examine the response of astrocytes to both the initial damage of making the slice, and to subsequent neuronal death, in the relative or complete absence of blood-borne macrophages.

455.13

PHENOTYPIC AND FREEZE-FRACTURE ANALYSIS OF TRANSFORMED ASTROCYTES. J.R. Fredieu*, J.W. Jacobergert, S. Collins, and D.M.D. Landis. Depts. of Neurology and Neuroscience, †Dept. of Genetics, Case Western Reserve University, Cleveland, OH 44106.

SV40 T-antigen transformed astrocytic cell lines offer several potential advantages for study with biochemical and molecular biological techniques. However, the transformed cell lines may differ from primary astrocyte cultures in significant aspects of differentiation. We compare two cell lines derived from aged murine astrocyte cultures with primary rat astrocyte cultures derived from neonatal rats.

Primary rat astrocytes express GFAP, vimentin, and Mab 8C10 immunoreactivity as assessed by immunocytochemical methods. Mouse astrocyte cell lines (Mastr) #6 and #11, however, express less GFAP, and did not express vimentin, galactocerebroside-C (a marker of oligodendroglia), and Mab 8C10 immunoreactivity.

Freeze fracture electron microscopic methods reveal characteristic, orthogonally-packed arrays of intramembrane particles (assemblies) associated with the cytoplasmic half of fractured astrocyte membranes; the density of these assemblies is increased in confluent primary astrocyte cultures by treatment with dexamethasone (dex). Mastr #6 expressed assemblies without dex, but no assemblies were found when dex was added to the culture media. Mastr #11, on the other hand, did not express assemblies in the presence or absence of dex.

Thus, clonal astrocytic cells lines may resemble astrocytes as visualized with phase contrast optics, but have significant differences in the expression of several epitopes and in membrane structure regulation. Assessing the utility of such cell lines for isolation of cell-type specific cDNAs requires careful characterization of specific cell lines and culture conditions.

455.14

IN SITU AND IN VITRO EXPRESSION OF TENASCIN BY SUPRAOPTIC NUCLEUS ASTROCYTES. A. K. Salm and P. S. Klinkhachorn. Department of Anatomy, West Virginia University, Morgantown, WV 26506.

The dendritic arbors of hypothalamic supraoptic nucleus (SON) neurons of adult rats undergo activity-related remodelling to form bundles. Tenascin is an extracellular matrix glycoprotein that is expressed by astrocytes, primarily during development. Appearing in restricted neural regions, it is believed to play a role in histological patterning by serving as a "boundary molecule" to outgrowing neurites. The morphological plasticity of the adult SON suggested the hypothesis that astrocytes in the adult SON express this morphogenetic molecule. Twelve adult rats were anesthetized, perfused with fixatives and histologically processed. Double-label immunocytochemistry with primary antibodies against tenascin and glial fibrillary acidic protein (GFAP) was used to assess 5-10 μm thick sections through the SON. We observed a consistent, generally overlapping, staining for tenascin and GFAP of those SON astrocytes with cell bodies in the subjacent glial limitans and processes extending into the nucleus. Staining was usually confined to fibers of the glial limitans and dendritic zone, but in four animals was seen to encircle neuronal cell bodies. Primary cultures prepared from the SON produced both flat and stellate GFAP+ astroglia. When immunostained for tenascin without permeabilization, a subpopulation of these cells clearly expressed a surface patchwork of the molecule. With permeabilization however, nearly all GFAP+ cells displayed tenascin+ perinuclear "granules", the distribution of which closely paralleled that of the glial filaments. These results indicate that some astrocytes whose processes distribute in the adult SON synthesize and express tenascin. The in vitro results suggest that synthesis and surface expression of this glycoprotein may be differentially regulated. Whether and how the presence of tenascin in the SON is related to structural remodelling, and the possibility of tenascin expression by other SON cell types, remains to be determined.

AGE AND SPECIES DETERMINANTS OF PROLIFERATION OF ASTROCYTES TO RECOMBINANT GAMMA-INTERFERON. T. Tejada-Bergés, F.P. Yong and V.W. Yong, Montreal Neurological Institute, Montreal, Quebec, Canada H3A 2B4

Determining the signals involved in regulating the proliferation of astrocytes is important to an understanding of normal brain development as well as pathological processes such as reactive gliosis. Our laboratory has previously reported that recombinant human gamma interferon (rhIFN; 10-1000 u/ml) is mitogenic (7-fold) for adult human astrocytes in vitro as assessed by GFAP/BrdU double immunofluorescence. Recombinant murine gamma interferon (rmIFN) inhibits the proliferation of cultured neonatal mouse astrocytes as measured by ^{3}H-Thymidine incorporation (50% reduction at 100 u/ml). The results from the immunofluorescence method of BrdU incorporation correspond well with measurements of ^{3}H-Thymidine. In order to determine whether the differential response was age- or species-dependent, human fetal astrocytes were examined for their response to rhIFN. RhIFN (10-1000 u/ml) induced a 2-fold increase in the proliferation of human fetal astrocytes in vitro as evaluated by both BrdU and ^{3}H-Thymidine incorporation. We are currently testing the mitogenic capacity of rm IFN on cultured adult murine astrocytes. The current data suggest that the differential effects of gamma-IFN on human and murine astrocytes reflect species-specific differences.

EXPRESSION OF A CARBOHYDRATE BINDING PROTEIN ON A SUBSET OF ASTROCYTES DURING DEVELOPMENT. M.J. Carson*, Y. Aizenman, F.-T Liu*, and R. J. Milner. Research. Institute of Scripps Clinic, La Jolla, CA 92037.

Increased attention has been focused on carbohydrate binding proteins (CBP's) for their potential contribution to the development of both neuronal and nonneuronal tissue as well as their potential role in cellular proliferation. One such CBP was defined in rat as an IgE binding protein (EBP). EBP is also known as RL-29 and is homologous to the mouse protein, CBP-35, which is identical to the Mac-2 antigen. Because EBP has been detected in rat brain, we examined EBP expression in rat brains and cell culture using an antibody against EBP. Interestingly, the antibody labeled all cells in two cell lines which express glial markers: C6 glioma cells and 36C.21 cells. In contrast, in primary astrocyte cultures, the antibody labeled only a subset of astrocytes (GFAP+ cells) and a few unidentified (GFAP-) cells. Similarly, in brain sections from 4 different ages (P1, P8, P15, and adult) two cellular populations were labeled with the EBP antibody: a subset of astrocytes (GFAP+ cells) and a set of unidentified cells (GFAP-). In sections from 1-day old rat pups, the labeled cells were located primarily around the ventricles, and few of these cells were also GFAP+. In sections from 8-day old rats, labeling was concentrated primarily in the cerebellum and around the ventricles and many of the EBP labeled cells were also GFAP +. This same pattern of labeling was visible, with greater intensity in sections from 15-day old rats. In sections from adult rats, labeling with the antibody against EBP was no longer concentrated in the cerebellum but was weak throughout the brain and slightly concentrated around the ventricles. Thus, the expression of EBP appears to be developmentally regulated on a subset of astrocytes in the rat brain. This work was supported by a fellowship from the National Multiple Sclerosis Society (MJC) and grants NS 22347 and MH47680.

INFLUENCE OF GRAFTED PURKINJE CELLS ON BERGMANN GLIAL ENZYME EXPRESSION. M. Fisher and P. Trimmer. Dept's. of Anatomy & Cell Biology and Neuroscience, University of Virginia, Charlottesville, VA 22908

Following the postnatal loss of Purkinje cells (Pcs), Bergmann glia (Bg) in the Lurcher (Lc) mouse cerebellum show a striking metabolic response that includes decreased expression of the enzyme glycerol-3-phosphate dehydrogenase (GPDH). Analysis of Lc chimeric mice showed that Lc Bg were competent to maintain normal GPDH levels as long as they were situated within the domain of at least one surviving wild-type Pc (Fisher, M. 1990, J. Neurogenet. 6:183.). Grafts of wild-type fetal Pcs into Lc mutant cerebella have been used to determine whether already down-regulated Bg can be reinduced to express a high level of GPDH. Grafts were made into hosts 3-8 weeks old and analyzed 6-8 weeks after surgery. Only grafts into very young hosts result in significant observable glial GPDH immunoreactivity. The host age restriction and the distribution pattern of GPDH-positive Bg suggest that grafted Pcs can sustain GPDH expression in Bg that have not completely shut down, but they can not reinduce expression in those cells that have already shut down. EM analysis shows a significant reduction in the extent to which Bg ensheath dendrites of grafted Pcs relative to that seen in normal cerebellum. The results are consistent with the idea that Bg require continuous extensive interaction with Pcs to maintain normal adult levels of GPDH. Supported by NS25350 from NINDS.

ENZYME EXPRESSION IN BERGMANN GLIA OF ADULT MICE REMAINS SENSITIVE TO PURKINJE CELL PRESENCE. G.Ruthel and M.Fisher. Department of Anatomy and Cell Biology, University of Virginia, Charlottesville, VA 22908.

Bergmann glia (Bg) in certain mutant mice respond to the early loss of Purkinje cells (Pcs) with metabolic changes that include a reduction in glycerol-3-phosphate dehydrogenase (GPDH) levels. Studies with mutants suggested that normal glial enzyme expression requires the presence of Pcs at least through the first postnatal month (Fisher, J. Neurogenet., 6:183, 1990). To determine whether glial GPDH expression requires the presence of Pcs in adults, intracerebellar injection of kainic acid (1 µL, 0.5 mg/mL) was used to produce areas of selective Pc loss in mice at 7, 10, and 13 weeks of age. By 3 to 4 weeks post injection, there was a noticeable decrease in GPDH immunoreactivity in Bg in areas devoid of Pcs. By 8 weeks post injection, GPDH immunoreactivity was almost entirely absent from glial cell bodies and reduced in the glial processes. The presence and normal appearance of radial Bergmann fibers in the affected areas was confirmed in sections stained with antibody to glial fibrillary acidic protein. In some cases, isolated Bg of high GPDH immunoreactivity were observed within an affected area. Visualization of Pcs in adjacent sections with antibody to calbindin showed such Bg to be within the dendritic field of a similarly isolated Purkinje cell. These results suggest that normal glial GPDH expression in adults depends on the continued presence of Purkinje cells.

QUANTIFICATION OF THE CELLULAR GROWTH BALANCE OF GLIOMA CELLS USING MULTIPARAMETER FLOW CYTOMETRY. Herbert H. Engelhard, Division of Neurological Surgery, Department of Surgery, Northwestern University, Chicago, IL 60611

Proliferating cells in the process of balanced cellular growth double their protein content before entering mitosis. Alterations in cellular growth balance produce changes in the ratio of total cellular protein (TCP):DNA, and the expression of specific proliferation-associated proteins. In this study, a new three-color, dual-laser flow cytometric technique was used to measure cellular DNA, TCP and c-myc protein content using cell staining with the fluorescent dyes DAPI, SR101 and FITC. Modulations in the cellular growth balance of A-172, U118MG and U138MG (human glioma) cells were produced using growth-inhibitory conditions including serum deprivation, stationary phase growth and treatment with DMSO and sodium butyrate (SB). Flow cytometric data were confirmed using immunoblot analysis and the Lowry method.

Growth-inhibited cells exhibited changes in DNA, TCP and c-myc protein content which could be quantified using the new technique. SB-treated and stationary phase A-172 cells exhibited the most pronounced derangement in cellular growth balance. In these cells, the ratio of protein content in G2/M:G0/G1 cells increased from 1.45 to 1.70 (±0.05), while c-myc protein:TCP dropped from 1.00 to 0.31 (±0.02). The new dual-laser flow cytometric method should be useful for understanding other complex cell processes.

CHARACTERIZATION OF PERIPHERAL-TYPE GFAP. D.L. Feinstein, G. Weinmaster*, R.J. Milner and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021; Research Institute of Scripps Clinic & The Salk Institute, San Diego, CA 92037.

Immunological studies have shown that an antigenically-distinct form of glial fibrillary acidic protein (GFAP) is expressed in various peripheral tissues. In these studies, we have investigated the structure and expression of PNS-type GFA mRNA and protein. Tryptic mapping of GFAP isolated from primary cultures of rat Schwann cells revealed differences between the CNS and PNS GFA proteins. Screening of a cultured rat Schwann cell library with rat brain GFAP cDNA resulted in the isolation of clone rGFA15, whose sequence differed from the rat brain mRNA (GFAP-α) by the presence of an extended 5'UTR. A polymerase chain reaction assay was developed to allow detection of the longer GFAP mRNA (GFAP-β) in tissue and cell samples. GFAP-β mRNA is expressed in various Schwann cell lines which express exclusively the PNS-GFA protein. GFAP-β mRNA is also expressed at low levels in cultured rat astrocytes, and its expression could be influenced by prior treatment of the cells with dbcAMP. In the CNS, GFAP-β mRNA was detected in RNA isolated from postnatal day 5 whole brain, and at lower levels in samples from postnatal day 25. These results suggest that in the CNS, GFAP-β mRNA may represent a developmentally regulated form of GFAP.

456.2

REGIONAL VARIATION OF ASTROCYTIC GAP JUNCTIONS D.K. Batter, D.C. Spray, E.L. Hertzberg and J.A. Kessler, Albert Einstein College of Medicine, Bronx, NY 10461.

The predominant protein comprising astrocyte gap junctions is connexin 43. Here we show that astrocytes derived from two brain regions express different levels of connexin 43 and of the resulting functional gap junctions. In this study, confluent cultures containing >90% astrocytes were prepared from neonatal rat striatum or hypothalmus. Cell homogenates were subjected to western blot analysis probing with specific antisera that recognize both phosphorylated and unphosphorylated forms of connexin 43. Densitometric analysis of the resulting signals revealed that hypothalamic astrocytes contained 5-fold more connexin 43 per mg protein than striatal astrocytes. Cell cultures from both regions were processed for connexin 43 immunocytochemistry. Consistent with the western blot results, hypothalamic astrocytes displayed a significantly higher level of connexin 43 immunofluorescence than those from the striatum. Interestingly, in cultures from both brain areas the immunostaining was much stronger for some cells than for others, suggesting the existence of astrocyte heterogeneity even within a particular brain region. To determine if these differences were reflected in functional gap junctions, astrocytes from both brain regions were injected with Lucifer yellow and the dye spread was monitored. These experiments showed that while coupling of striatal astrocytes was generally restricted to cells adjacent to the injected one, dye spread following injection of hypothalamic astrocytes often extended to fourth order cells and occasionally beyond. Taken together, our data indicate region-specific expression of connexin 43 levels in astrocytes resulting in a quantitative difference in coupling of these cells in different brain areas. If these data reflect the situation *in vivo*, differential coupling of astrocytes may have important implications for regional brain function.

TEMPERATURE EFFECTS ON GROWTH OF GRADIENT PURIFIED MURINE CNS CELLS IN VITRO: RAPIDLY PROLIFERATING GFAP EXPRESSING ASTROCYTES AT 34°C DIFFER IN DENSITY FROM SLOWLY PROLIFERATING CELLS WITH LOWER GFAP CONTENT

Benjamin Brooks, Wendy Neary,* Renée Madden,* and Scott Bjornstad.*
Neurology Svc, Wm S Middleton Mem VA Hosp and Univer of Wisconsin-Madison Sch of Med, Neurol & Med Microbiol Dept, Madison, WI 53705

Temperature sensitive retroviruses provide a means to study of the pathogenesis of the CNS neurodegenerative diseases produced by murine neurotropic retroviruses [Neurol 41(Suppl 1):143, 1991]. In order to study the specific vulnerability of CNS cells to these retroviruses in vitro, purified CNS cells were obtained from 5-10 day old FVB mice. Cerebral cortex [CTX] subcortex [SCTX] and cerebellum [CBL] were dissected, enzyme dissociated and separated by Dextran step gradient sedimentation into microvessels and other CNS tissue elements [Ann Neurol 28:291,1990]. The Dextran supernatant cells were separated by sedimentation through 30% Percoll into three bands at the following densities: [1] 1.018, [2] 1.033 and [3] 1.098 gm/cm^3. Because rapidly proliferating cells may permit more virus replication, proliferation rates of murine CNS cells from CTX, SCTX and CBL were measured at 34, 37 and 39°C. Cells from band 1 grew poorly at all temperatures. Cells in band 2 from all three regions grew significantly [$p<0.03$] better at 34°C [4.7 $\pm$ 0.6 (standard deviation) x 10^5 cells/cm^2 at 15 days in vitro (DIV)] compared to 39°C [2.6 $\pm$ 0.9]. Cells in band 3 from all CNS regions did not grow differently at 34°C [2.0 $\pm$ 1.4] from 39°C [2.8 $\pm$ 1.1]. CNS cells from different regions were characterized in vitro by immunocytochemistry and immunoblotting with cytoskeletal antibodies, fluorescent activated cell sorting with lectins and acetylated low density lipoprotein binding. Rapidly proliferating astrocytes in band 2 had a higher GFAP content than cells from band 3.

DISTRIBUTION AND MORPHOLOGY OF HIPPOCAMPAL MICROGLIA FOLLOWING CHRONIC EXPOSURE TO ETHANOL.

A.N. Kalehua, S.D. Hurley*, W.J. Streit, D.W. Walker, B.E. Hunter.
Department of Neuroscience, Univ. of Florida, Gainesville, FL 32610.

Microglial cells are potential immunoeffector cells which respond to neuronal injury and death by morphologic and phenotypic transformations. Chronic ethanol treatment (CET) has been shown to produce a loss of neurons in the rodent hippocampal formation. This study examined the effects of CET on microglial distribution and morphology in the rodent hippocampus. Animals in the ethanol (E) and control (S) groups were fed liquid diets containing either ethanol or sucrose for 28 weeks followed by an 8 week period of abstinence. Microglia were visualized in vibratome sections from the dorsal, central and ventral hippocampus using lectin histochemistry with the B_4-isolectin from *Griffonia simplicifolia*.

Resting microglia from S-group animals possessed extensive process staining and were scattered throughout all subfields and laminae, being most prominent in the dentate hilus and entorhinal cortex. Microglia were differentially distributed in various subfields and regions within the dorsal-ventral extent of the hippocampus. On the other hand, microglia from the hippocampi of E-group animals appeared reduced in number with a greater reduction in the dorsal as compared to ventral hippocampus, particularly in area CA1. In addition, animals possessed fewer and more truncated processes than observed in S-group animals. These results suggest that abnormal microglial cell function may be related to the reduction in reactive synaptogenesis following chronic exposure to ethanol.

ATTENUATION OF NEURITE OUTGROWTH PROMOTION AND NCAM AND HNK-1 EXPRESSION DURING IN VITRO MATURATION OF CNS ASTROCYTES. P. S. Frisa* and J. Jacobberger. Case Western Reserve University, Dept. of Genetics, Cleveland, OH 44106.

The attenuation of neuronal regeneration capacity during CNS maturation has been correlated with a decrease in the neurite outgrowth promoting properties of astrocytes and, in vitro, the ability of neonatal astrocytes to promote neurite outgrowth is dependent on the length of time in culture (Smith, G. M. et al., 1990. Dev. Biol. 138:377). Neurite outgrowth on astrocytes has been linked to the expression of cell surface molecules such as NCAM, laminin and N-cadherin. Changes in the neurite outgrowth-promoting ability of astrocytes can be expected to occur in step with changes in levels of these cell surface molecules. We have compared neurite outgrowth promotion and expression of NCAM and HNK-1 in astrocytes as they mature during culture in vitro.

A time course study of neurite outgrowth from embryonic chick retinal ganglion cells on neonatal and in vitro-aged astrocytes showed that a 12h outgrowth period was optimal for detecting differences between them. 12h neurite outgrowth on mouse cortical astrocytes was maximal at 2 days of culture and progressively declined, generally beginning to level off on astrocytes cultured for 6 days in vitro. NCAM and HNK-1 expression of the astrocytes was measured by flow cytometry. HNK-1 expression was maximal at 2 days of culture while NCAM reached peak levels at 4 days. Both HNK-1 and NCAM declined to low levels by 14 days.

These time dependent changes in vitro in neurite outgrowth promotion and expression of NCAM and HNK-1 by astrocytes correlate with the critical period for regeneration during development in vivo (Smith, G. M. et al., 1986. J. Comp. Neurol. 251:23).

CALCIUM WAVES PROPAGATE VIA GAP JUNCTIONS IN GLIOMA CELLS TRANSFECTED WITH CONNEXIN43 A. Charles, C. Naus+, D. Zhu+, E. Dirksen* and M. Sanderson*. Depts. of Neurology and Anatomy and Cell Biology, UCLA School of Medicine, Los Angeles CA 90024 and + Dept. of Anatomy, Univ. of Western Ontario, London Ontario, Canada N6A 5C1

C6 glioma cells in culture express low levels of connexin43 and have correspondingly weak gap junctional communication as evidenced by dye-coupling. These cells have been transfected with the cDNA encoding connexin43, resulting in clones which exhibit different levels of connexin43 expression and dye coupling, and decreased proliferation. We have previously reported that mechanical stimulation of a single cell in mixed glial or purified astrocyte culture induces a wave of increased $[Ca^{2+}]_i$ that is communicated from the stimulated cell to surrounding cells. In C6 glioma cells, mechanical stimulation induced a Ca^{2+} wave that was either not communicated or spread only to 1 or 2 adjacent cells. By contrast, C6 cells transfected with connexin43 cDNA showed extensive intercellular propagation of Ca^{2+} waves, with the distance and rate of intercellular propagation in different clones correlating directly with the level of connexin expression. A clone showing moderate expression of connexin showed propagation of Ca^{2+} waves to 5-10 adjacent cells, whereas a clone showing greater expression of connexin showed propagation of Ca^{2+} waves to 10-40 adjacent cells. These results provide direct evidence that Ca^{2+} waves are propagated intercellularly via gap junctions. Since transfection with connexin43 has been shown to reduce proliferation of C6 cells, intercellular Ca^{2+} signalling may participate in the regulation of cell proliferation.

PROTEIN PHOSPHORYLATION IN HYPOOSMOTIC-TREATED ASTROCYTES. JT Neary, AS Bender, J Blicharska* and MD Norenberg. Lab. Neuropathology, VA Med. Ctr. & Dept. Pathology, Univ. Miami Sch. of Med., Miami, FL 33101.

Calcium appears to play an important role in hypoosmotically-induced swelling and regulatory volume decrease (RVD). Previous studies from our laboratory using inhibitors of calcium-dependent protein kinases (Bender et al, 1990) suggested that the volume-related effects of calcium may be mediated by protein phosphorylation systems. To test this possibility, we studied ^{32}P incorporation in intact astrocytes during hypoosmotically-induced swelling and RVD. After a 1 min exposure to a hypoosmotic (105 mOsm) salt solution (maximum time for swelling), there was a reduction in ^{32}P incorporation in 24 and 21 kDa proteins (ca. 90% and 50%, respectively). After a 5 min exposure to the hypoosmotic solution (when volume regulation has begun), ^{32}P incorporation in these two proteins returned to nearly normal levels. The dephosphorylation of these proteins appears to be regulated by calcium because (a) treatment with ionomycin, a calcium ionophore, for 1 min leads to similar decreases in ^{32}P incorporation in the 24 and 21 kDa proteins and (b) application of extracellular ATP (100 uM, 1 min), which also increases intracellular calcium in astrocytes, causes a marked dephosphorylation of these proteins. We also found that dephosphorylation of 24 and 21 kDa proteins did not occur in a swelling model which does not undergo volume regulation (exposure to 80 mM external potassium). Taken together, our studies indicate that calcium-dependent protein phosphorylation/dephosphorylation systems play a role in hypoosmotically-induced swelling and volume regulation.

ASTROGLIOSIS IN SUBCORTICAL WHITE MATTER OF AMYOTROPHIC LATERAL SCLEROSIS (ALS).

D. Munoz O'Regan*, D. T. Stephenson, S. Wright and P.D. Kushner.
ALS Research Foundation, Pacific Presbyterian Medical Center, San Francisco, CA 94115

Histopathological features of ALS are commonly described as the isolated degeneration of upper and lower motor neurons and a pronounced demyelination in the primary motor tracts. We have discovered astrogliosis in ALS uniquely within the subcortical white matter. In all cases of ALS examined: 1) the GFAP-immunoreactive astrocytes have the morphological parameters of an on-going, "reactive" process and 2) the astrogliosis is widespread, as it is observed in multiple cortical areas, the midfrontal, inferior parietal, temporal, cingulate, and occipital cortices, as well as the motor cortex. To address the issue of neuronal degeneration and astrogliosis directly, we developed Marchi staining on cryosections and compared Marchi degeneration products in parallel with GFAP immunoreactivity. The amount of astrogliosis did not correlate with Marchi products. ALS was compared to eight different neurological diseases; the gliosis was similar to that in other diseases with gliosis ($p < .001$). Cytologically ALS astrogliosis resembles that present in cases of cerebral infarction, both focal and multiple microinfarction. Preliminary studies of Guam ALS have reiterated the findings of astrogliosis in the subcortical white matter. These data indicate a pathophysiological process in ALS beyond the motor system and implicate the subcortical white matter and its astrocytes as a special region of involvement.

FETAL GLIAL CONDITIONED MEDIUM STIMULATES THE PROLIFERATION AND DIFFERENTIATION IN VITRO OF TYPE I AND TYPE II ASTROCYTES ISOLATED FROM ADULT SPINAL CORD. L. Webster,* A. Tessler, P. Levitt. Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129

We are currently investigating the processes involved in the growth and differentiation of astrocytes derived from adult spinal cord in an effort to determine ways of modifying the environment to enhance axon growth after injury. Our previous study demonstrated that adult astrocytes do not survive well when grown alone in vitro, but survive well when they are grown in co-culture with E18 astrocytes and allowed to share medium but prohibited from direct contact. In order to determine the effects of fetal glial cells on adult glial cells, we examined the proliferation capabilities of adult cells grown in co-culture using bromodeoxyuridine (BrdU) as an indicator of proliferation. Preliminary data show that adult cells, grown in co-culture with E18 astrocytes, are capable of dividing and differentiating to produce GFAP+ cells with distinct type I and type II morphologies. Cells of connective tissue origin and PDGF do not have a similar capability to stimulate adult glial growth. It is likely that the E18 astrocytes are secreting a factor(s) that is capable of promoting the division of both quiescent type I astrocytes and O-2A progenitor cells in vitro. Other factors known to stimulate glial growth are currently being tested for proliferation-stimulating activity. Supported by VA Medical Research Service, USAMRDC grant 5193002, and NIH grant NS24707.

RESPONSES OF ASTROCYTES, MICROGLIA, AND MACROPHAGES TO PSEUDORABIES VIRUS (PRV) TRANSPORTED THROUGH CENTRAL VAGAL CIRCUITS. L. Rinaman[1], L.W. Enquist*[2], and J.P. Card[2]. *Department of Anatomy & Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129[1] and Viral Diseases Group, duPont-Merck Pharmaceutical Co., Wilmington, DE 19898[2].*

The responses of astrocytes, microglia, and other phagocytic cells of monocyte origin were examined in the rat CNS following the peripheral uptake and subsequent central transneuronal passage of PRV (a swine α-herpes virus). PRV was injected into the ventral stomach wall or pancreas, and rats were perfused 48-100 hrs later. PRV-positive cells were identified with Rb134 antibody, astrocytes were identified with GFAP antibody, and microglia and macrophages were identified with OX42 antibody (anti-C3bi complement receptor). ED1 antibody (anti-monocyte/macrophage cytoplasmic antigen) was also used to identify phagocytic cells of monocyte origin. Rb134 immunoreactivity was first seen in motoneurons in the dorsal motor nucleus of the vagus and was subsequently observed in neurons in synaptically-associated nuclei, consistent with transsynaptic passage of the virus. A time-course dependent proliferation of GFAP-, OX42-, and ED1-positive cells was observed in virus-infected areas. In nuclei containing severely infected neurons, some of the GFAP-, OX42-, and ED1-positive cells were also Rb134-positive. We suggest that the non-neuronal cells that proliferate following PRV infection sequester virus released from severely infected neurons, thereby reducing non-specific virus spread and contributing to the specific transneuronal transport of PRV that has been demonstrated in central neural circuits.

ELECTRICAL PROPERTIES OF CULTURED MOUSE ASTROCYTES AFTER BARIUM EXPOSURE RESEMBLE PROPERTIES OF RAT ASTROCYTES. N.S. Magoski* and W. Walz. Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, S7N 0W0, Canada.

The issue of cultured mouse astrocytes having a 20-fold or higher channel-mediated ^{42}K turnover than cultured rat astrocytes (Brain Res 340:333, 1985) has yet to be addressed. Electrophysiological studies to date have used rat astrocytes almost exclusively, with many authors being unaware of this difference and ignoring its importance in interpretating results. The membrane potential and input resistance of type-1-like cortical astrocytes, cultured from newborn mice, were recorded with and without barium (1 mM) exposure. Barium decreased the membrane response to 0 and 35mM K^+. It also revealed a Na^+/K^+ATPase mediated electrogenic component, as evident by a biphasic depolarization to ouabain (1mM), which was monophasic without barium. GABA or glutamate elicited small, monophasic depolarizations in untreated astrocytes. Barium-treated astrocytyes showed further transient responses to either transmitter, similar to rat astrocyte responses as reported in the literature. Uptake blockers for either amino acid did not change the responses. This electrophysiological study confirms that mouse derived astrocytes short-circuit electrogenic components and transmitter responses. The low channel-mediated K^+ flux in cultured rat astrocytes must be considered when using this preparation as a model of astrocyte function.

456.12

WITHDRAWAL OF EXOGENOUS GANGLIOSIDE GM1 ALTERS THE PATTERN OF B-CHOLERA TOXIN BINDING TO THE ASTROCYTE MEMBRANE. Ad J. Dekker and Mike S. Manley, Dept. Neurosciences, UCSD, CA92037.

Cultures of rat cerebral astrocytes were treated with ganglioside GM1 (30 μM) for 22 h, followed by ganglioside-free medium (2 h) or GM1 (30 μM, 2 h). The distribution of GM1 in the astrocyte membrane was then evaluated by indirect immunofluorescence using the B-subunit of cholera toxin (BCT). Approximately 60% of the astrocytes showed BCT-binding, with considerable variability across cells. After treatment with GM1, 70% of the astrocytes showed BCT-binding. In cultures where exogenous GM1 was previously withdrawn, BCT bound predominantly to the outer portions of the cells. These results suggest that the conformation or distribution of GM1 in the astrocyte membrane changes upon withdrawal of exogenous GM1.

456.13

MODULATION OF EPIDERMAL GROWTH FACTOR BINDING IN ASTROCYTES BY HORMONE AND PHOSPHORYLATION INFLUENCES. K.Huff and H.Tang*. Harbor/UCLA Med Ctr & Childrens Hospital, Los Angeles, CA, 90509.

The regulation of EGF binding including transmodulation of the receptor is multifactorial in many systems but not well understood in astrocytes where the majority of the CNS binding sites reside. We have studied 125-I labelled ligand binding in cultured neonatal rat astrocytes after 48 hr stabilization in serum free media. Increase in binding was a rapid response to elevators of intracellular cAMP, inhibitors of protein Kinase A, and to insulin, which have cell membrane sites of action. Protein kinase C inhibitors partially reversed Fibroblast Growth Factor down regulation. Decrease in binding was seen as a slower response to dexamethasone, and no response in binding changes was seen to thyroid hormone, although this hormone produced other effects. Regulation of receptor ligand effects may occur through a number of receptor related pathways in addition to transmodulation by other growth factors.

In Vitro Differentiation Inhibits the Migration of Cultured Neonatal Rat Cortical Astrocytes Transplanted to Neonatal Rat Cerebrum. JD Hatton and HS U*, Div. of Neurosurgery UCSD and VAMC, La Jolla, CA

Transplanted neonatal rat astrocytes have been shown to migrate throughout much of the rat host brain. In the present study, cortical astrocytes were collected from the brains of rats 1 to 3 days postpartum and purified by culturing them in DME medium supplemented with 10% calf serum. After 14 to 21 days, astrocytes were labelled with fluorescein-tagged latex microspheres. After 16 hours, the label was removed and replaced with either fresh medium or fresh serum-free medium plus 1mm dbcAMP. After 24 hours, cells were harvested and then transplanted into the right frontal cerebrum of neonatal rats at 3 days postpartum by injection with a hand-held Hamilton syringe. Animals were sacrificed at 3, 6, 9, 15, 21 and 28 days after inoculation. Brains were fixed by immersion in aldehydes, sectioned on a cryostat and examined with fluorescence microscopy. Undifferentiated astrocytes migrated along the corpus callosum, internal capsule, glial limitans, ventricular linings and the hippocampal structure. They also appeared to migrate in a radial fashion toward the periphery from the ventricular lining. Differentiated astrocytes did not appear to migrate into the neonatal parenchyma, remaining confined to the injection site or to the ventricular spaces. Thus neonatal cortical astrocytes migrate outward in a pattern similar to that defined by the radial glia. Differentiated glia, however, do not appear to migrate to any large degree in this environment, suggesting that differentiation may represent an end-point to glial migration in the neonatal host brain.

456.15

DELAYED RECTIFIER CURRENT EXPRESSED BY CULTURED RAT MICROGLIA. A. R. Korotzer and C. W. Cotman. Department of Psychobiology, University of California, Irvine CA 92717.

Microglia are thought to be the resident macrophages of the brain. Because many functions of immune system cells, such as interleukin 1 production by macrophages, appear to require K^+ channel expression, we have recorded from cultured rat microglia using the whole-cell patch clamp technique. Two types of voltage-gated K^+ currents were expressed: a previously described inward rectifier current (J Neurosci Res 26:278) and a delayed rectifier current (Ik). Ik activates at potentials positive to -40 mV, and the rates of activation and deactivation are voltage-dependent. The tail currents for Ik reverse close to the expected E_K in both 4.5 mM and 100 mM extracellular K^+. TEA (10 mM) reduces the magnitude of Ik. The rate of inactivation of Ik during a sustained depolarizing pulse varies from cell to cell. Many cells displayed slow recovery from inactivation, as reflected by the amount of use dependence of Ik. Ik is therefore similar to delayed rectifier currents described in many preparations.

456.16

TRANSPLANTATION OF PURIFIED GLIAL CELL POPULATIONS INTO THE MYELIN DEFICIENT RAT. I.D. Duncan, C. Paino*, P.M. Wood*, D.R. Archer*, and R.Hoffman*, School of Veterinary Medicine, University of Wisconsin, Madison, WI and The Miami Project, University of Miami, Miami, FL

Previous studies on glial cell transplantations into the CNS of the myelin deficient (md) rat have shown that transplanted dissociated CNS cell suspensions from neonatal or fetal rats can myelinate many axons in the area of the injection site. Whether the myelin produced by the grafted cells was derived from oligodendrocytes that were mature at the time of transplantation or from progenitors was not critically evaluated. The present study was designed to compare the capacity of mature oligodendrocytes and progenitors to produce myelin in the md rat. Progenitor cells from normal, neonatal littermates labelled with antibody to A2B5, or mature oligodendrocytes from normal adults labeled with antibody to O1 were purified by fluorescence activated cell sorting. The final purity of sorted cells was 95% or greater. Following sorting, 75,000 - 100,000 cells were injected into the spinal cord of 2-7 day old md rats and the rats perfused 14-20 days later. A number of rats were injected with freshly dissociated, non-sorted glial cell suspensions from adult rats. Patches of myelin were seen after injection of either progenitor or adult oligodendrocytes; however, the greatest amount of myelin was consistently seen in the rats injected with unsorted cells. These results show that: 1) transplanted A2B5 positive progenitor cells, purified by cell sorting, are capable of generating myelinating oligodendrocytes, and 2) mature oligodendrocytes from adult animals are also capable of myelinating md rat axons. (Supported by NMSS grants, RG-2219-A-1 and RG-1990-A-2.)

MYELINATION IN THE MYELIN DEFICIENT RAT BY TRANSPLANTED CANINE GLIAL CELLS. D.R. Archer*, R. Hoffman*, V. Miletic, and I.D. Duncan, School of Veterinary Medicine, University of Wisconsin, Madison, WI 53706.

Studies of allografts of mixed glial cell suspensions injected into the CNS of the myelin deficient (md) rat have shown that transplanted glial cells are capable of creating focal areas of myelination. In this study we examined the capacity of canine glial cells to myelinate host axons following transplantation into the md rat CNS. Mixed glial cell suspensions were dissociated from the spinal cord of a seven week old dog. After 24 hours in culture approximately 100,000 cells were injected into the T13/L1 region of the md rat spinal cord. Fifteen days later the animals were euthanized by perfusion fixation and the transplant site examined by light and electron microscopy. Patches of myelination attributable to transplanted oligodendrocytes were found in the dorsal columns of the graft recipients. In order to test the effect of cryostorage on the myelinating capacity of oligodendrocytes, a similar cell preparation from a four week old dog was frozen under liquid nitrogen and then thawed prior to transplantation. Again, approximately 100,000 cells were injected into the spinal cords of md rat hosts. The tissue was removed and examined thirteen days after transplantation. Patches of myelination were also found in the dorsal columns of the md rat spinal cord.

Two conclusions may be drawn from this work: 1) xenografts of canine glial cells are capable of myelinating md rat axons and 2) cryo-preserved canine glial cells retain their capacity to myelinate following transplantation into the md rat. (supported by NIH grant NS 23124 and the Myelin Project)

ADULT OLIGODENDROCYTES FAIL TO FORM MYELIN AFTER TRANSPLANTATION INTO CYCLOSPORINE-TREATED MYELIN-DEFICIENT RATS (MDR). J. Rosenbluth, Z. Liu, D. Guo & R. Schiff. Depts. Physiology and Rehab. Med., NYU School of Med., New York, N.Y. 10016.

Oligodendrocytes (OL) from adult rats do not form myelin within two weeks after transplantation into juvenile mdr spinal cord, while fetal glial cells do (J. Neurocytol. 19:718). One possible cause is a host immune response directed against donor OL antigens not expressed by precursor cells. To test this, we cultured adult (P32-55) or fetal (E15-16) rat OL, labeled them with fast blue and transplanted them into spinal cords of P8-9 rats treated with cyclosporine (10mg/kg/day). 11-14 days later, mdr that had received adult transplants showed fast blue and macrophages within the dorsal columns, but still no significant myelin formation. In contrast, fetal donor cells, lacking mature (GC+) OL at the time of transplantation, formed large islands of myelin that exhibited normal periodicity and formed normal axo-glial junctions. The results do not support an immune-mediated mechanism for the failure of transplanted adult OL to form myelin and are consistent with the view that immature rather than mature cells are needed for initiation of myelination. Supp. by NIH & NMSS.

A DIFFERENTIAL SCREENING APPROACH TO ISOLATE NEW OLIGODENDROCYTE-SPECIFIC cDNA CLONES. N.Schaeren-Wiemers, C. Schaefer*, G. Yancopoulos[1] and M.E. Schwab. Brain Research Institute, University of Zurich, August-Forel-Strasse 1, CH-8029 Zurich/Switzerland. [1]Regeneron Pharmaceuticals, Tarrytown, N.Y.

Oligodendrocytes are a very special and important cell type, both, from a functional and from a cell biological point of view. In addition to forming myelin they also express specific proteins inhibiting neurite growth. To identify and characterize new oligodendrocyte-specific gene products a postnatal P16 rat spinal cord cDNA library was differentially screened with either probes from first strand cDNA synthesis of P16 spinal cord (plus probe) or probes from X-irradiated (at P0) P16 spinal cord in which oligodendrocytes are absent (minus probe). From both probes "house keeping genes" were subtracted by hybridization against liver mRNA. Clones coding for the known myelin proteins MBP, PLP, MAG, and CNPase were identified by S-blots and discarded. By Northern analysis two groups of interesting clones emerged: 1.) Clones whose corresponding mRNAs are CNS-specific, most highly expressed around P16, lower in the adult, and absent in E17 spinal cord qualify as possibly oligodendrocyte-specific. 3 of these clones (mRNA sizes of 1.5-3.5 kb) were partially sequenced and found to represent unknown proteins. The coding strands were identified by defined riboprobes in N-blots and corresponded to those found by in vitro transcription-translation experiments. - 2.) Clones with a similar CNS expression pattern but additional expression in sciatic nerve probably correspond to oligodendrocyte-Schwann cell clones. 12 of these clones were analysed and showed mRNA sizes of 1.7 to 4.0 kb; some of them show 2 mRNAs probably resulting from differential splicing.

456.20

CHARACTERIZATION OF ANGIOTENSIN II RECEPTOR SUBTYPES IN RAT ASTROGLIAL CULTURES DERIVED FROM DIFFERENT BRAIN REGIONS. S.P. Bottari*, N. Obermuller*, K.L. Zahs[1] and C.F. Deschepper[1], Cardiovascular Research, Ciba-Geigy, 4002 Basel, Switzerland and [1]Dept of Physiology, U.C. San Francisco, CA 94143-0444

Recent studies with new, selective angiotensin II (AII) antagonists have revealed two main AII receptor subtypes, referred to as AT_1 and AT_2. To determine which subtypes were present on astrocytes, we have tested the effect of the selective antagonists Dup 753 (AT_1) and CGP 42112A (AT_2) on the binding of [^{125}I]-Sar^{1}Ile^8-AII. Membranes prepared fom cultured astrocytes were incubated for 90 min with 0.2 nM [^{125}]-Sar^{1}Ile^8-AII, and the bound tracer was separated from the free by filtration. Non-specific binding was measured in the presence of 1μM AII. The tracer bound to high (Ki = 54 $\pm$ 12 pM) and low affinity (Ki = 11 $\pm$ 3 nM) sites. The Ki of competition for tracer binding with Dup 753 was 24 $\pm$ 7 nM, while the Ki of competition with CGP 42112A was greater than 1μM. These values are characteristic of AT_1 sites, and indicate the absence of AT_2 receptors. The B_{max} of tracer binding on the membranes astrocytes from pons or diencephalon ranged from 1 to 4 pM/mg protein. On the other hand, much lower levels of AII-binding sites were detected on the membranes of astrocytes from frontal cortex. We conclude that (1) no AT_2 receptors are detectable on astrocytes; (2) high capacity AT1 receptors are present on astrocytes from subcortical regions; (3) astrocytes derived from cortex had less AII receptors than astrocytes from subcortical regions. Supported in part by HL29714 and HL38774.

457.1

VACCINIA VIRUS-MEDIATED EXPRESSION OF PLASMA MEMBRANE TRANSPORTERS: FUNCTIONAL ANALYSIS OF THE CLONED HUMAN L-NOREPINEPHRINE TRANSPORTER.

R.D. Blakely[1], T. Pacholczyk[2]*, J.A. Clark[2], and S.G. Amara[2] Dept. of Anatomy and Cell Biology, Emory University School of Medicine[1], Atlanta, GA 30322 and HHMI Section of Molecular Neurobiology, Yale School of Medicine[2], New Haven, CT 06510.

We have characterized a novel vaccinia-virus based transient expression method suitable for the rapid functional characterization of neurotransmitter transporters and applied this system to an analysis of the activity of the cloned human Na+/L-norepinephrine carrier. The expression system utilizes a vaccinia-virus encoded T7 RNA polymerase to synthesize, in infected cells, cytoplasmic transcripts from transfected plasmids bearing T7 RNA promoters. To characterize and optimize the expression methodology, we transfected separately the intestinal Na+/glucose and brain Na+/GABA transporters into vaccinia-T7 infected fibroblasts and demonstrated rapid (4-12hr) appearance of [^{14}C]α-methyl D-glucopyranoside and [^{3}H]GABA uptake, respectively, bearing pharmacological sensitivities previously documented in *Xenopus laevis* oocytes. Upon identification of a candidate cDNA encoding the human Na+/L-norepinephrine transporter (NET), we applied this system to document the functional properties of the expressed transporter in HeLa fibroblasts. Following transfection with NET, vaccinia-T7 infected cells expressed saturable (K_t=457 nM), sodium-dependent uptake of [^{3}H]L-norepinephrine which is antagonized by antidepressants (desipramine> nortryptyline> imipramine), D-amphetamine (K_i=56 nM) and cocaine (K_i=140 nM). GBR 12909 and paroxetine exhibited weak potency (K_i>100 nM) relative to their actions on brain dopamine and serotonin transporters, respectively. Anatogonists of adrenergic receptors, other plasma membrane transporters, and vesicular amine transport failed to block NET activity. Further studies are underway to characterize and localize the direct binding of radiolabeled antagonists to the cloned carrier. These results demonstrate that a single cDNA encodes many if not all of the readily observable properties of the high affinity, human norepinephrine reuptake system.

HUMAN MONOAMINE OXIDASE A AND B GENES EXHIBIT IDENTICAL EXON-INTRON ORGANIZATION.

J. Grimsby, K. Chen*, L-J Wang*, N.C. Lan and J.C. Shih. Dept. of Mol. Pharm. & Tox., Sch. of Pharm., Univ. of South. Calif., L.A., Ca. 90033

Monoamine oxidase (MAO) A and B oxidize a number of neuroactive amines and they are coded by separate genes (PNAS:85,4934,1988). Recently, we have isolated genes encoding human MAOA and B by screening four bacteriophage libraries with human liver MAOA and B cDNA subfragments. Twenty-one MAOA positive clones and forty-three MAOB positive clones were isolated. Southern blot analysis of phage DNA isolated from these bacteriophage clones identified 6 MAOA and 7 MAOB positive clones. By extensive mapping and sequencing the exons of MAOA and B were aligned based on the nucleotide sequences of MAOA and B cDNAs. Our results show that human MAOA and B genes span at least 60 kb, consist of 15 exons, and exhibit identical exon-intron organization. Exon 12 codes for the covalent FAD-binding site and is the most conserved exon; the amino acid sequences deduced from these exons share 93.9% identity between MAOA and B. These results suggest that MAOA and B are derived from duplication of a common ancestral gene and provide insight on the structural/functional relation of the enzyme. (Supported by NIMH grants R37 MH39085 (merit award), K05 MHH00796, R01MH37020, and Welin professorship).

457.3

THE ROLE OF SPLICE SITE-ENCODED AMINO ACIDS ON THE SUBSTRATE AND INHIBITOR SENSITIVITIES OF MAOB.

H.F. Wu, K. Chen* and J.C. Shih., Dept. of Mol. Pharm. & Tox., Sch. of Pharm., Univ. of South. Calif., L.A. Ca. 90033

We have recently isolated human MAOA and B genes and showed that they both consist of 15 exons and exhibit identical exon-intron organization. When the splice site-encoded amino acids in MAOA are compared with those in MAOB, 11 of 14 amino acids encoded at the 5'boundary and 9 of 14 encoded at the 3'boundary of the introns are identical. Among the different ones only 5 amino acids are not conserved. Thus, we made five MAOB mutants in which the splice-site coded amino acid was mutated to corresponding amino acid in MAOA. These MAOB mutants were prepared by oligonucleotide-directed mutagenesis. Each mutagenic clone was sequenced then cloned into an expression vector, pECE. High efficiency CaPO4 precipitation transient transfection was performed. The amount of MAOB mutants transfected was determined by Western blotting. The substrate specificities were determined by using ^{3}H-serotonin or ^{14}C-phenylethlyamine radioassay. The sensitivities to clorgyline or deprenyl was also determined. The role of each of these amino acids on the catalytic properties of MAOB will be discussed. (Supported by NIMH grants R37 MH39085 (Merit Award), K05 MH00796, R01 MH37020 and Welin professorship).

457.4

MOLECULAR ANALYSIS OF THE CATECHOL-O-METHYLTRANSFERASE GENE IN FISCHER AND WISTAR-FURTH STRAINS OF RAT.

M.H. Grossman J. Littrell* and R. Weinstein*. Department of Pediatrics, Temple University School of Medicine, St. Christopher's Hospital for Children, Phila., PA 19134

In mammals, catechol-O-methyltransferase (COMT) is a physiologically important enzyme for the metabolism of catecholamine neurotransmitters and catechol drugs. Soluble and membrane-bound forms of the enzyme exist, which differ in their substrate affinity, and apparent MW and pI. Breeding of Fischer-344 (F-344) and Wistar-Furth (W-F) rat strains has demonstrated monogenic inheritance of hepatic as well as renal COMT activities. The recent cloning of the gene for rat liver soluble COMT has enabled us to examine the molecular basis of these inherited variations. For this study, full-length DNA fragments were generated by PCR amplification of total poly+A mRNA, from both F-344 and W-4 strains, using synthetic oligonucleotide primers complementary to both ends of the coding region. Multiple clones from each strain were completely sequenced by the dideoxy method. Sequence analysis using the DNAStar program Lasergene indicates several nucleotide differences between the strains. A change exists from an A to G at nucleotide #192 which does not change the amino acid coded for by that triplet. Also, a possible deletion of a cytosine at nucleotide #33 alon with an insertion of an extra guanine at #42 is found in both strains compared to published sequence. Restriction fragment length polymorphism (RFLP) analysis has been performed on DNA from parents (F-344 and W-F), F1, F2, and backcross animals after digestion with a variety of restriction enzymes. A potential polymorphism (RFLP) is seen with the enzyme HhaI (recognition site GCGC), which agrees with the sequence variations seen around either #33 or #42 nucleotide. There also appears to be an RFLP that is identified by the PstI enzyme. Verification of this finding and complete analysis of flanking sequence is presently underway. (Supported by NIH grant NS24066 to MHG).

457.5

NITRIC OXIDE SYNTHASE: MOLECULAR CLONING OF THE MACROPHAGE GENE.

S. Snyder, D. Bredt, and C. Lowenstein*, Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD

Nitric oxide (NO) is a novel messenger molecule, acting as an endothelial-derived relaxing factor, and as a neurotransmitter released by discrete neuronal populations in the brain and periphery. Macrophages generate NO to elicit their bactericidal and tumoricidal effects via an NO synthase (NOS) which is distinct from the form found in brain. These macrophages probably include the microglial cells of the central nervous system. The goal of this work is to sequence the gene encoding the macrophage NOS.

Cerebellar NOS has been purified (P.N.A.S. 87:682, 1990) and molecularly cloned (TIPS 12:125, 1991). With this sequence data, various hybridization techniques were used to isolate the macrophage NOS. Using a probe of the cerebellar NOS gene, low stringency screening of a phage library of activated macrophage cDNA clones failed to isolate any homologous plaques. Using degenerate oligonucleotides that are homologous to various portions of the cerebellar NOS gene, the polymerase chain reaction of reverse transcribed mRNA templates from activated macrophages produced 300 bp and 500 bp fragments which are approximately 30% homologous to the cerebellar nitric oxide synthase sequence. A Northern blot of activated macrophage RNA shows that this message size is 4.5 kb.

These fragments have been used to screen a phage library of activated macrophage cDNA clones. When the entire gene is sequenced, the localization in the brain and other tissues will be studied, and the enzyme will be expressed and characterized.

457.6

CHARACTERIZATION AND CHROMOSOMAL MAPPING OF A CANDIDATE GENE FOR 3-HYDROXYANTHRANILATE OXYGENASE.

C. Ambrose*, B. Navia*, A. McClatchey*, E. Okuno*, R. Schwarcz, J. Gusella and M. MacDonald*. Neurogen. Lab, Mass. Gen. Hosp., Charlestown, MA 02129 and Maryland Psych. Ctr. Baltimore, MD 21228.

3-hydroxyanthranilate oxygenase (3-HAO) is the enzyme responsible for the synthesis of quinolinic acid (Quin) in the mammalian brain. An endogenous excitotoxin, Quin, has been postulated to be involved in several neurodegenerative disorders including Huntington's disease (HD). A candidate cDNA for 3-HAO, isolated from a rat liver library using a polyclonal antibody, has been previously reported (Neurosci. Abs., 1988). Here we report the further characterization of this clone and others obtained from cDNA and genomic libraries. Northern blot analysis has revealed that the 3-HAO mRNA is approx. 2.2 kb in rat and mouse and about 1.7 kb in baboon. 3-HAO mRNA is easily detected in kidney and liver total RNA, but not in whole brain RNA. However, 3-HAO cDNA fragments can be amplified from total brain RNA using PCR. The rat cDNA clone contains an inverted repeat at its 5' end which has the potential to form a 100 bp stem and a 155 bp loop. This 355 bp sequence has been shown to exist on 4 exons in a mouse cosmid. Sequence analysis of the genomic fragment containing the most 5' exon has identified a potential initiator methionine and TATA sequence. Cross-species hybridization on somatic cell hybrids, has localized the candidate 3-HAO gene to human chromosome 17q. A Spretus mouse cross allowed us to map the gene to mouse chromosome 11 and determine that it is tightly linked to the murine thymidine kinase gene. The location of the this gene eliminates it as a candidate gene for HD since the disease gene maps to chromosome 4p.

457.7

EXPRESSION, ORGANIZATION AND LOCALIZATION OF THE HUMAN N-CHIMAERIN GENE.

P. Smith[2] C. Hall[1*], J. Dong[2*], N. Spurr[3], & L. Lim[1*]
[1]Neurochemistry Dept., Institute of Neurology, 1 Wakefield Street, London WC1N1PJ
[2]Institute of Molecular and Cell Biology, National University of Singapore, Kent Ridge, Singapore 0511
[3]Imperial Cancer Research Fund, Clare Hall Laboratories, South Mimms, Potters Bar, Hertfordshire EN6 3LD

The novel brain-specific cDNA, *n-chimaerin*, encodes a predicted product with significant similarities to both the C1b cysteine-rich motif $CX_2CX_{13}CX_2CX_2CX_7C$ of protein kinase C and to BCR, the product of the *breakpoint cluster region* gene involved in Philadelphia chromosome translocation. The N-terminal half of n-chimaerin shares almost 50% identity with corresponding sequences in the regulatory domain of PKC. The C-terminal half of n-chimaerin has 42% identity with residues 1050 to 1225 of BCR. *n-chimaerin* RNA is specifically expressed in the brain with highest abundance in the hippocampus and the cerebral cortex. The RNA expression pattern is neuronal. The human *n-chimaerin* gene was localised to a specific chromosome by analysis of somatic cell hybrid DNA and a *n-chimaerin* related locus was detected on a different specific chromosome. Genomic clones containing the *n-chimaerin* gene show that three exon boundaries in the *n-chimaerin* gene precisely corresponded to those in the human *BCR* gene. A further exon boundary corresponded to a (drosophila) *protein kinase C* splice junction, in the region encoding the cysteine-rich zinc finger motif. The opposite end of the same *n-chimaerin* exon contains a region of sequence similarity to BCR.

457.8

MOLECULAR BIOLOGY OF THE D1 AND D5 DOPAMINE RECEPTOR GENES. D.K. Grandy, Q.-Y. Zhou*, Y. Zhang*, C. Bouvier*, L. Allen*, R.A. Johnson*, O. Civelli. Vollum Institute for Advanced Biomedical Research, Oregon Health Sciences University, Portland, OR 97201.

The complex pharmacological and physiological effects of dopamine are mediated by several different G protein-coupled receptors. In an effort to clone and characterize these molecules we have combined PCR with homology screening. Using degenerate primers directed against conserved regions of the catecholamine receptors we cloned both the rat and human D_1 receptor genes (Zhou et al., 1990). A search for regulatory elements that control D_1 gene expression has resulted in the identification of consensus sequences for AP1, AP2, CRE, and SP1. In experiments designed to identify other D_1-like genes we performed Southern blotting analyses of human DNA. Under condiditions of lowered stringency the D_1 gene hybridizes to a 5kb EcoRI fragment. Contained within this fragment is an open reading frame whose deduced amino acid sequence is 49% identical to D_1. This gene encodes a new dopamine receptor, D_5, which has a 10 fold higher affinity for dopamine than the D_1 receptor. Furthermore, D_5 is able to stimulate adenylyl cyclase in response to dopamine at concentrations 30 times lower than needed to activate D_1 receptors. This gene is also interesting because in contrast to rats, there are three copies in the human genome and at least one is a pseudogene. Therefore, at present only humans have been shown to contain a D_5 pseudogene. This is the first reported case of a pseudogene in the G protein-coupled receptor family which raises some interesting evolutionary questions.

457.9

A VERSATILE CLONING AND EXPRESSION SYSTEM TO ANALYZE FUNCTIONAL PROPERTIES OF HUMAN D2 RECEPTOR ALLELES. G.M. Lawless[1,2], C.H.J. Ruppert[1], T. Ritchie[2], E.P. Noble[2,3], and A.J. Tobin[1,3,4]. [1]Department ofBiology, [2]Alcohol Research Center, [3]Brain Research Institute, and [4]Molecular Biology Institute, University of California, Los Angeles, CA, 90024.

Dopamine receptors are widely studied because of their role in many neuropsychiatric disorders. A RFLP in the D2 receptor gene has been found to be associated with patients suffering from severe alcoholism (JAMA, 263:2055-2060). To analyze the functional properties of D2 receptors of different alleles we have developed a PCR-based method to clone and express specific cDNAs. Total RNA is purified from limited amounts of postmortem brain samples, and D2 receptor mRNA is transcribed into cDNA utilizing human D2 receptor specific primers. Two sets of primers allow us to clone the complete open reading frame of receptor sequence after amplification in a thermal cycler. Expression of the cloned sequence in a cell culture system will enable us to analyze and compare the biochemical and pharmacological properties of D2 receptor derived from the two human alleles A1 and A2 for its possible involvement in the appearance of severe alcoholism. (Supported in part by The Seaver Foundation.)

GENE STRUCTURES OF $GABA_A$ RECEPTOR β SUBUNITS.

E.F. Kirkness, G.A. Hastings*, A.L. Buller* and C.M. Fraser. Section on Molecular Neurobiology, LPPS, NIAAA, Rockville, MD 20852.

Subtypes of $GABA_A$ receptor subunits (eg. β1, β2, β3), are highly homologous but exhibit distinct temporal and regional patterns of expression in brain. As an initial step to study how expression of these genes is regulated, genomic DNA encoding β subunit subtypes has been cloned and characterized. Over 5kb of human genomic DNA, upstream of the β1 initiation ATG was cloned and mapped. Analysis of reverse-transcribed RNA by PCR, indicates that the exon containing the start of coding sequence extends only 70-140bp upstream of the initiation ATG. However, primer extension studies, and PCR analysis of human brain cDNA libraries, has uncovered cDNAs that contain exonic sequences 200-350bp upstream of the initiation ATG. These upstream sequences are not contiguous with the cloned genomic DNA and indicate the existence of one or more upstream introns.

The gene encoding the β3 subunit was found to be deleted from patients with Angelman syndrome and Prader-Willi syndrome, and its absence may play a role in the pathogenesis of one or both of these conditions (Am. J. Hum. Genet., in press). Genomic DNA, extending over 10kb upstream of the β3 initiation ATG was cloned from rat and human libraries. These genomic fragments, containing the first three coding exons, exhibit conservation of intron/exon junctions with the β1 gene. Gene fragments have been linked to a CAT reporter gene and used to transfect several cell lines, in order to define important regulatory features of the genes.

457.11

CLONING AND EXPRESSION OF THE PHOSPHATE ACTIVATED GLUTAMINASE GENE FROM RAT BRAIN. R.G. King*, H. Haleem-Smith*, H.J. Purohit*, V.P. Kedar*, and J.F. Mill. Lab. of Molecular Biology, NINDS, NIH, Bethesda, MD 20892.

L-glutamate (Glu) is the principal excitatory neurotransmitter in the vertebrate CNS. One of the primary enzymes involved in the metabolism of Glu is phosphate activated glutaminase (PAG).

Using a previously cloned partial cDNA to PAG (PGA1, Banner et al., 1988) as a probe, we isolated a PAG cDNA clone 4 Kb in length (OGA4K). This clone contains all of the sequence previously described in PGA1 as well as an additional 57 bases of coding sequence on the 5′ end and 2.7 Kb of 3′ untranslated region which includes the polyadenylation signal.

Antisense riboprobes generated from this clone were used in S1 nuclease protection assays to study the expression of PAG mRNA in rat cardiac and skeletal muscle, lung, kidney, intestine, liver and brain. PAG expression was also invetigated in several cell lines as well as primary astrocytes and granule cells.

A genomic clone for the rat PAG gene was isolated through homology to the OGA4K cDNA clone. Partial characterization of this clone has demonstrated that it extends to the 3′ terminus of the gene, and in two exons extends into the coding region of the gene. The two exons terminate in consensus sequences for splice sites.

457.12

GENES FOR RAT GLUTAMIC ACID DECARBOXYLASES.

C.S.Pinal*, N.J.K. Tillakaratne, M.G. Erlander, and A.J. Tobin. Department of Biology, Brain Research Institute, and Molecular Biology Institute, University of California, Los Angeles, CA 90024.

The brains of rats and humans contain at least two forms of glutamate decarboxylase (GAD_{65} and GAD_{67}), which differ in sequence and size, and which derive from different genes. The human GAD_{67} gene contains two promoters whose usage differs between adult and embryonic brain. We have isolated rat genomic DNAs for GAD_{65} and GAD_{67}. The restriction maps of these cloned DNAs suggest that the rat GAD_{65} gene spans a length of approximately 34 kb and the rat GAD_{67} approximately 32 kb. The two rat GADs derive from different genes: GAD_{65} cDNA hybridizes to genomic restriction fragments distinct from those that hybridize to GAD_{67} cDNA, and it does not hybridize to GAD_{67} genomic clones. The sequence of the putative promoter region of the rat GAD_{65} gene resembles, in several respects, that of the corresponding region of the human GAD_{67} gene. Functional analyses are now under way to determine the molecular basis of the coexpression and the independent regulation of the two GADs. (Supported by NIH grants NS 20356 and NS 22256)

457.13

HUMAN GLUTAMATE DECARBOXYLASES: cDNA CLONING, SEQUENCING, BACTERIAL EXPRESSION AND LOCALIZATION ON TWO CHROMOSOMES. D.F. Bu[1], M.G. Erlander[1], B.C. Hitz[1,*], N.J.K. Tillakaratne[1], C. Wagner[2,*], G.A. Evans[2,*] and A.J. Tobin[1,3,4]. [1]Department of Biology, [3]Brain Research Institute, and [4]Molecular Biology Institute, University of California, Los Angeles, CA 90024; [2]Molecular Genetics Laboratory, The Salk Institute, San Diego, CA 92186.

Using previously described feline and rat cDNAs, we isolated human GAD_{67} and GAD_{65} cDNAs that contain complete open reading frames. GAD_{65} cDNA encodes a polypeptide of 585 amino acids, while GAD_{67} cDNA a polypeptide of 596 amino acid residues. Northern blots reveal a single RNA species for each GAD using extracts of both fetal and adult human brain, with GAD_{65} mRNA 5.7 kb long, and GAD_{67} 3.7 kb long. Sequence analysis shows high conservation of each coding sequence between rats and humans, about 90% at the nucleotide level and 96% at the amino acid level. To obtain human GAD_{67} and GAD_{65} protein from recombinant DNA, we cloned the coding region of human GAD_{67} and GAD_{65} cDNA into bacterial expression vectors and expressed enzymatically active protein in E. coli. Using human GAD_{67} and GAD_{65} genomic clones, we determined the chromosomal localization of the two GAD genes by in situ hybridization. (Supported by NIH grants NS20356 & NS 22256)

457.14

GENE AND mRNA STRUCTURE OF HUMAN B-50 (GAP-43)
H.B. Nielander*, P.C. de Groen*, E.B.J. Ueffing*, B.J.L. Eggen*, L.H. Schrama, W.H. Gispen* and P. Schotman. Div. Mol. Neurobiol., Rudolf Magnus Inst., Lab. Physiol. Chem., Inst. Molec. Biol. & Med. Biotechnol., Univ. of Utrecht, Padualaan 8, 3584 CH Utrecht, The Netherlands.

The phosphoprotein B-50 (GAP-43) has been implicated in neuronal development, axonal regeneration and signal transduction. We previously identified the protein encoding part of the human gene, contained in 3 exons (Schrama et al. 1990, *Soc. Neurosci. Abstr.* 16:154.11).

We now report on the 3' and 5' regions of the human B-50 gene. Two polyadenylation signals are present in exon 3; they start respectively 506 and 580 bp downstream from the stop codon. Analysis of the 5' region of the gene revealed two purine-rich areas in the 358 bp upstream of the startcodon; sequences analogous to known transcriptional regulatory elements are not present however. Primer extension on adult human poly(A)$^+$ RNA using a primer in exon 2 showed multiple transcription starts. The extension products found thus far suggest two major transcription starts located approximately 130 bp and 340 bp upstream from the translation start. In addition, PCR analysis of the cDNA showed an uninterrupted extension product up to 200 bp upstream from the translation start. Both the length and the sequence of the untranslated regions of the human mRNA, as shown by primer extension, PCR and sequence analysis show a high degree of homology with the rat B-50 messenger. The combined results regarding the 3' and 5' regions suggest the existence of mRNA of at least 1.6 kb, not including the poly(A)-tail. Interestingly, this is the length reported by others (Kosik et al. 1988, *Neuron* 1:127) for the polyadenylated mRNA.

457.15

Identification of a mouse secretogranin III.

H.P. Ottiger, F. DePrincipe, and J.G. Sutcliffe. Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland and Research Institute of Scripps Clinic, La Jolla, CA 92037, USA.

Chromogranins/Secretogranins are family of acidic secretory vesicle proteins that are found in a variety of endocrine cells and neurons. Recently, the elucidation of the primary structure of a novel rat secretogranin, termed secretogranin III (SgIII), has been accomplished (Ottiger et al., J. Neurosci. 10, 3135 (1990). We have now extended this analysis to the mouse. (i) The generation of null mutants, where the gene for SgIII has been completely abolished should allow us to gain insights into the function of the proteins in normal physiology (Kingsley et al., EMBO J. 9, 395 1990). (ii) We report here the identification and determination of the primary structure of a mouse secretogranin III cDNA. Northern blot analysis confirmed the neuro-endocrine specific expression of SgIII. The deduced protein encodes for a 57-KDa protein and sequence specific antibodies detect a target of the same size in SDS-extracts of brain, but not liver or kidney. These data demonstrate that the SgIII genes are highly conserved between species.

CLONING OF THE THYMOSIN BETA-10 GENE: CHARACTERIZATION OF ITS STRUCTURE AND NUCLEOTIDE SEQUENCE.

M.R. Condon*, T.W. Lysz and A.K. Hall*. Department of Surgery UMDNJ - NJ Medical School, Newark, N.J. 07103 - U.S.A.

Elevated levels of thymosin B10 gene expression have been shown to be associated with the early phases of embryonic/fetal human brain development. How thymosin B10 transcription is regulated is currently not understood.

In order to elucidate the regulation of thymosin B10 transcription we have isolated the human thymosin B10 gene, and determined its exon/intron structure. The gene is composed of three exons and two introns. Exon two encodes amino acids 1-32 and contains the first nucleotide for amino acid 33, exon three encodes the remainder of the protein and the entire 3' untranslated portion of the gene. Currently we are sequencing the 5' untranslated region in an attempt to define the start of exon one as well as the promoter region. Preliminary primer extension studies map the start of transcription approximately 80 nucleotides upstream of the translational start site. The presumptive promoter region contains a putative CAT box consensus sequence also a Spl binding sequence. Future studies are aimed at determining promoter activity in vitro using CAT as the reporter gene.

Supported by NIH/NCI grant CA 49422-01 to A.K. Hall.

SYNAPTIC STRUCTURE AND FUNCTION I

458.1

PROTEIN METHYLATION IN SYNAPTOSOMES. L.S. Wright* and F.L. Siegel, Depts. of Pediatrics and Physiological Chemistry, Univ. of Wisconsin, Madison, WI 53706.

Synaptosomes from five regions of adult rat brain (cortex, cerebellum, hippocampus, brain stem and striatum) and three regions of 2 day old rat brain (cerebellum, brain stem and remaining brain) were isolated and used in studies of protein methylation. Synaptosomes were incubated with [methyl-^{3}H]-S-adenosyl-L-methionine at pH 6.5 and at pH 8, and methylated proteins visualized by SDS-PAGE and fluorography. For adult brain, methylated profiles in synaptosomes were compared with those in P_1, P_2, P_3 and cytosolic fractions. At pH 8, a protein of 68kDa was methylated synaptosomes from all brain regions to a greater extent than in other subcellular fractions, and in cerebellar synaptosomes a protein of 56kDa was a major methyl acceptor protein. Neither of these proteins was methylated at pH 6.5, indicating that this is not aspartate carboxylmethylation. In synaptosomes from the two day old rat, methylation of 68kDa and 48kDa (all brain regions), but not 56kDa was found. A methyl acceptor protein of 35kDa was found in all fractions and a family of 22kDa-26kDa methylated proteins was present in all membrane fractions. These results indicate an age-dependent, region specific methylation of synaptosomal proteins. (Supported by NIH grants NS24969, GM38497 and HD03352.)

458.2

AUTOPHOSPHORYLATION OF CEREBELLAR AND FOREBRAIN FORMS OF CAM-KINASE-Gr. Q.B. McDonald* and N. Sanyoun Wellcome Research Laboratories, 3030 Cornwallis Road, RTP, NC 27709.

A neuronal Ca^{2+}/calmodulin-dependent protein kinase, CaM Kinase-Gr, occurs as M_r 65,000 and 67,000 polypeptides in the rat cerebellum and as a M_r 65,000 polypeptide in the rat forebrain. Both enzyme forms were purified and were found to undergo stoichiometric autophosphorylation on a serine residue. Autophosphorylation caused a characteristic decrease in the electrophoretic mobility of both polypeptides. This altered migration on denaturing gels could be reversed by the action of an endogenous brain Mg^{2+}-dependent phosphoprotein phosphatase, or by the addition of an acid phosphatase. The shifts in gel mobility were confirmed by silver staining, autoradiography and immunoblotting with a CaM Kinase-Gr antiserum. Autophosphorylation of the cerebellar and forebrain enzymes acquired an autonomous, Ca^{2+}/calmodulin-independent activity,and displayed greatly increased sensitivity to subsequent exposure to Ca^{2+}/calmodulin.

458.3

Ca^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II IS ASSOCIATED WITH PURIFIED SMALL SYNAPTIC VESICLES. J. L. Rubenstein*, A. J. Czernik and P. Greengard. Laboratory of Molecular and Cellular Neuroscience, The Rockefeller University, New York, NY 10021.

Ca^{2+}/calmodulin-dependent protein kinase II (CaM kinase II) appears to play an important role in the regulation of neurotransmitter release. CaM kinase II-dependent phosphorylation of synapsin I, a major synaptic vesicle-associated substrate, is thought to regulate the availability of vesicles for fusion at the presynaptic active zone. We now provide evidence that CaM kinase II is associated with a highly purified preparation of small synaptic vesicles from rat cerebral cortex and characterize this interaction.

When purified vesicles were incubated in the presence of 1mM $CaCl_2$, 10mM $MgCl_2$ and 50 μM [γ-^{32}P]ATP, little phosphorylation of endogenous vesicle proteins was evident. Addition of calmodulin (10 μg/ml) markedly stimulated the phosphorylation of a number of vesicle proteins, which were resolved by SDS/PAGE. Synapsin I, specifically phosphorylated at sites 2 and 3, was a prominent ^{32}P-labeled protein, as were proteins migrating at 48 kD and 58-60 kD, respectively, corresponding to the autophosphorylated subunits of CaM kinase II. Addition of the CaM kinase II inhibitory peptide [281-302]Ala286 reduced all calmodulin-dependent phosphorylation in a dose-dependent manner. The peptide inhibited the phosphorylation of synapsin I with an IC_{50}=10 μM.

Immunoblots of synaptic vesicle proteins with affinity-purified antibodies against CaM kinase II demonstrated that both the α and β/β' subunits are associated with purified synaptic vesicles. Quantitative immunoblotting indicated that CaM kinase II was a major vesicle protein, representing 4.4% of total vesicle protein by weight (α subunit=2.8%; β/β' subunit=1.6%). Moreover, the molar ratio of CaM kinase II:synapsin I per vesicle approached 1. Extraction trials of vesicle proteins using low and high salt, EDTA, EGTA and Triton X-100 indicated that the kinase was tightly associated with the vesicle membrane. These results raise the possibility that CaM kinase II and synapsin I form a functional complex on the synaptic vesicle membrane (see Benfenati *et al.*, this meeting).

GROUPS OF STRUCTURAL COMPONENTS CO-LOCALIZED IN BRAIN SUBCELLULAR FRACTIONS ARE DIFFERENTIALLY AFFECTED BY A CALCIUM ACTIVATED PROTEASE. B.L. Bakus*, B.A. Bahr, E.T. Esteban*, A.C. Godshall*, J. Black & G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, California 92717

Integrins act as transmembrane linkages between components of the extracellular matrix and the intracellular cytoskeleton and play an important role in forming and maintaining contacts between cells. The present study used immunochemical methods to test the hypothesis that integrin-like proteins and their ligands found in synaptic membranes differ in important ways from those found in extra-synaptic regions. Antibodies against three integrins labeled proteins with much larger molecular weights in crude synaptosomes than in synaptosomal membrane fractions (SPMs). The high M_r (175 to 225 kDa) antigens which correspond to conventional integrin subunits co-migrated with synaptosomes and low density myelin in equilibrium buoyant density sucrose gradients, whereas the antigens of low M_r (27 to 65 kDa) that are concentrated 20 to 40-fold in SPMs migrated to higher density fractions including those containing synaptosomes and/or mitochondria. A similar pattern was evident for high and low M_r antigens recognized by antibodies against the integrin ligands fibronectin and laminin. Note, proteins of 43 and 40 kDa labeled respectively by anti-laminin and anti-fibrinogen were shown not to be the same, but were both concentrated 10 to 15-fold in SPMs compared to homogenates for all brain regions tested. A striking difference between the groups of antigens is that those in crude synaptosomes increased in concentration during early postnatal development while those in SPMs did not. Moreover, the synaptosomal polypeptides containing integrin epitopes were reduced in concentration by a typical amount of 81 ± 8% ($x \pm$ s.d., n = 8) following incubation with a calcium-activated protease (calpain), while those antigens in SPMs were unaffected by the enzyme. These results suggest that adhesion in synaptic zones differs from that in extra-synaptic regions, both in terms of the species of proteins involved and in the factors which regulate them. TWO LOCI WITH EXTENSIVE POLYMORPHISM ENCODE SNAP-25 IN GOLDFISH. C. Risinger and D. Larhammar. Dept of Medical Genetics, Box 589, Uppsala University, S-751 23 Uppsala, Sweden.

SNAP-25 (synaptosome-associated protein) is a 25-kDa protein which is expressed exclusively by neurons. It is localized to presynaptic nerve terminals and is associated with synaptosomal membranes. Its expression starts at the time of synaptogenesis.

We have previously shown that SNAP-25 is an extremely well-conserved protein which implies important functions. The chicken and mouse SNAP-25 proteins are identical throughout the 206 amino acids (S. Catsicas et al., PNAS 88, 785-789, 1991), and SNAP of goldfish, ray *(Torpedo marmorata)*, river lamprey, and *Drosophila melanogaster* show extensive similarity to the mouse protein (Abstract 154.14, Neuroscience Meeting 1990).

Surprisingly, all six clones that we have isolated from a goldfish retina cDNA library are distinct at the nucleotide level. They can be sorted into two groups according to degree of sequence identity. Within each group, the clones are virtually identical at the amino acid level. Between the two groups there is only 90% amino acid sequence identity. Furthermore, some clones contain mutations which preclude synthesis of a functional SNAP protein. Our results suggest that there are two loci for SNAP in goldfish in agreement with chromosome analyses which have shown that goldfish are tetraploid. The gene duplication has presumably allowed the redundant gene copy to accumulate deleterious mutations.

Our findings of SNAP gene duplication and polymorphism suggest that also other cloning results in goldfish should be regarded with caution until multiple clones have been analysed.

458.6

GENE ORGANIZATION OF SYNAPTIC PROTEIN SNAP-25 IN *DROSOPHILA*. I. Lundell*, C. Risinger, A. G. Blomqvist, C. Bark#, and D. Larhammar. Department of Medical Genetics, #) Department of Developmental Biology, Uppsala University, S-751 23 Uppsala, Sweden.

SNAP-25 is a 25-kDa protein which is expressed exclusively by neurons. It is associated with the inner side of the cell membrane in presynaptic nerve terminals. The expression of SNAP-25 starts concomitantly with synaptogenesis, indicating a role in this process or in the functions of the mature synapse.

We have previously shown that the chicken and mouse SNAP-25 proteins are identical throughout the 206 amino acids (S. Catsicas et al., PNAS 88, 785-789, 1991) and that SNAP of goldfish and *Torpedo* show approximately 90% similarity with the mouse sequence (see abstract by C. R. and D. L.).

Using low-stringency hybridizations, we have isolated SNAP-25 cDNA clones from a *Drosophila melanogaster* library. *Drosophila* SNAP-25 displays 60% sequence identity to the mouse protein, and a segment of 60 amino acids shows 85% sequence identity. We have also isolated several genomic SNAP-25 clones from a phage library. Determination of the exon organization will reveal whether the *Drosophila* SNAP-25 gene structure is as complex as that of the chicken SNAP-25 gene which consists of eight exons spanning more than 65 kbp.

These studies show that SNAP-25 is one of the most highly conserved synaptic proteins known which suggests a crucial role for SNAP-25 in synapse function.

458.7

TUBULIN IS IN A LARGE, HYDROPHOBIC COMPLEX ON SYNAPTIC VESICLES FROM RAT BRAIN. H. Qi* and E. Floor, Dept of Physiology & Cell Biology, University of Kansas, Lawrence, KS 66045.

Tubulin is present on a subpopulation (~30%) of synaptic vesicles purified from rat brain. We are analyzing the mode of association of tubulin with synaptic vesicles to gain insight into its possible function in these organelles. Both α- and β-tubulins are present, apparently externally, since all tubulin is removed from vesicle suspensions by mild protease digestion or by immunoprecipitation of vesicles with tubulin antibodies. Tubulin is not likely bound by association with MAPs, since it is not removed in 1M NaCl, although it does dissociate from synaptic vesicles in 50mM NaOH and is therefore not an integral membrane protein. Extraction of synaptic vesicles with Triton X-114 suggests that vesicular tubulin is hydrophobic; it partitions into the detergent-rich phase in contrast to whole brain tubulin, which acts like typical soluble proteins and is recovered in the detergent-poor (aqueous) phase. Vesicular tubulin may be hydrophobic because it is post-translationally modified, e.g. by acylation, or because it binds to a hydrophobic protein. To look for the latter, synaptic vesicles were treated with the covalent cross-linking reagent, DTSSP (Pierce). A discrete, large complex (~5,000K) was observed by chromatography on Sephacryl S-500HR in 0.1% SDS. Analysis by a two-dimensional gel electrophoresis method in which the crosslinker is cleaved by thiol reagent did not reveal any other proteins besides tubulin in this complex. These results indicate that a distinctive form of tubulin associates with synaptic vesicle membranes.

IDENTIFICATION OF AN ALTERNATIVELY SPLICED MEMBER OF THE SYNAPTOPHYSIN GENE FAMILY. J. L. Bixby. Dept. of Molec. & Cell. Pharmacology, Univ. of Miami, Miami, FL 33136.

Synaptic vesicle-associated membrane proteins are important in the regulation of transmitter release, and as markers for nerve terminal differentiation. One such protein, synaptophysin, has been shown (in mammals) to be part of a gene family with at least one other member, synaptoporin. In a search for related proteins, we screened a chick brain cDNA library at low stringency with a rat synaptophysin probe. Two classes of clones were isolated, with sizes of 2.3 and 2.5 kB, which differ in their use of alternative polyadenylation signals. DNA sequencing revealed that each class contained cDNAs that also differ in the N-terminal protein coding region. One such cDNA (psyn2A) has a deduced aa sequence 83% identical with rat synaptoporin. The other (psyn1B) is identical to psyn2A starting at aa 29, and continuing through the coding region and 1.6 kB of 3' untranslated DNA. The N-terminal 28 aa deduced from psyn1B are 60% identical with rat synaptophysin, and the C-terminal aa sequence shared by psyn1B and psyn2A is equally similar to synaptoporin and synaptophysin. Southern blotting with chick genomic DNA suggested that psyn1B and psyn2A are encoded by a single gene. Northern blots suggested that the corresponding mRNAs are moderately abundant in a variety of CNS tissues. Experiments are underway to determine whether the two forms are differentially expressed in different brain regions and at different developmental stages. The results suggest that the synaptophysin gene family is more complex than had been appreciated. Supported by grants from the NIH and the PMAF.

458.9

ISOLATION AND PRELIMINARY CHARACTERIZATION OF SYNAPTIC VESICLE-PLASMA MEMBRANE COMPLEXES ("ACTIVE ZONES"). C. Walch-Solimena* and R. Jahn. Max-Planck-Institute for Psychiatry, Dept. of Neurochemistry, Am Klopferspitz 18A, D-8033 Planegg-Martinsried, Germany.

At present, little is known about the molecular constituents of the contact sites between synaptic vesicles and the plasma membrane ("active zones") in nerve terminals. Here, we report the isolation and preliminary characterization of such complexes from rat brain. The isolation involves purification and lysis of nerve terminals, followed by separation of membrane-bound from free synaptic vesicles and finally immunoadsorption of membrane-bound material to a bead matrix coated with monoclonal antibodies against synaptic vesicle proteins. Electron microscopic analysis revealed that the adsorbed material contains synaptic vesicles attached to membrane fragments, resembling complexes of pre- and postsynaptic membranes. Using immunoblotting, a coenrichment of synaptophysin and synaptotagmin, two membrane proteins of synaptic vesicles, with the immunoisolated material was found. Separation of the protein constituents by SDS-polyacrylamide electrophoresis revealed the presence of membrane proteins different from those found in purified synaptic vesicles. A comprehensive analysis of the protein content is currently in progress.

458.10

THE ISOLATION AND PURIFICATION OF A PROTEIN ASSOCIATED WITH THE RIBBON SYNAPTIC STRUCTURE. Grant W. Balkema, S. Burt, M. Hatton, A. Duffy, and K. Bachman, Department of Biology, Boston College, MA 02167.

A monoclonal antibody, B16 (sub-type IgM), has been produced that recognizes a protein determinant associated with synapses throughout the brain and retina. Within the retina the antigen is concentrated at the ribbon synaptic structure in the photoreceptor terminal. We have found this antigen in every species that we have examined (fish, frog, lizard, mouse, rat, rabbit, cat, cow, monkey).

We are presently purifying the antigen with two aims in mind: 1) the purified protein will used as antigen to produce a panel of IgG monoclonal antibodies to the orginal protein. 2) the purified protein can be partially sequenced with the intent of producing primers for PCR. We have purified the protein using differential centrifugation, IEF column chromatagraphy, and SDS-PAGE. The protein is fairly soluble, requiring 70% salt to precipitate. Thus, with differential centrifugation we have been able to purify the B16 protein by 30-40 fold. This semi-purified fraction was then applied to an Iso-Electric-Focusing column (LKB) and focused for 48 hours. The fraction containing the B16 protein eluted at roughly pH 7.3 +/- 0.2 and resulted in a 3,600 fold purification. The 7.3 pH fraction was then applied to a 5-15% gradient SDS-PAGE and Western blotted. The B16 88kDa band was cut out of the blot and the protein eluted via 1%SDS-1%Triton. The purity is 100% as determined by initial amino acid analysis. From 100 grams of brain we have recovered 50 µg of purified protein. 458.11

DETECTION OF DYSTROPHIN IN A POSTSYNAPTIC DENSITY (PSD) FRACTION ISOLATED FROM ADULT RAT BRAIN. Kim, T.W.[1,2*], Wu, K.[2], Byers, T.J.[3], Sherwood, A.C.[2*], Xu, J.L.[2*] and Black, I.B.[2]. [1]Graduate program in Physiol. and Neurobiol., Rutgers-The State Univ. of NJ and UMDNJ/Robert Wood Johnson Medical School,[2]Dept. of Neurosci. and Cell Biol., UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ and [3]Children's Hospital and Howard Hughes Medical Institute, Harvard Medical School, Boston, MA.

Moderate non-progressive cognitive impairment is a consistent feature of Duchenne muscular dystrophy (DMD); underlying mechanisms remain unknown. Only recently, dystrophin was found to be present in brain. Preliminary immunocytochemical analysis has shown that the dystrophin is localized in the PSD. In the present study, we directly demonstrate the presence of dystrophin in the PSD isolated from cerebral cortex (CTX), cerebellum (CBL) and olfactory bulb (OB) of adult rat brains. The amount of dystrophin present in the structure was determined by western blot analysis using the antibody, anti 6-10. In all PSD fractions examined, the antibody detected multiple proteins with apparent molecular weight higher than 110 kDa under denaturing and reducing conditions. The relative proportion of proteins differed in CTX, OB and CBL, suggesting differential regional expression. Moreover, in CTX, there was 10-fold greater dystrophin in PSD than in synaptic membrane or total homogenate, confirming previous immunocytochemical localization. We are presently characterizing dystrophin in PSD from developing and DMD brains. Our results indicate that dystrophin is a component of the PSD, potentially suggesting abnormalities of dystrophin function at the synapse that underly cognitive deficits. (Supported by grants from NINDS, NICHD and McKnight Foundation)

458.12

NEUROCHEMICAL CHARACTERISTICS OF A POSTSYNAPTIC DENSITY (PSD) FRACTION ISOLATED FROM OLFACTORY BULB (OB) OF ADULT RATS. Huang, Y.[1*], Wu, K.[2], Stanley, M.[1], Xu, J.L.[2*], Cherry, J.A.[1], Wu, K.M.[3], Kim, T.W.[1*] and Black, I.B.[2] [1]Div. of Neurosci., [3]Div. of Neuropathal., NYSPI, New York, N.Y. and [2]Dept. of Neurosci. and Cell Biol., UMDNJ/RWJMS, Piscataway, N.J.

Abundant evidence suggests that the PSD, a proteinaceous disc-shaped structure attached to the postsynaptic membrane, is central to the function of the synapse. We have previously shown that environmental input regulates a specific novel major PSD protein (mPSDp). Moreover, we found that the molecular characteristics of the PSD differ in the cerebral cortex (CTX), cerebellum (CBL) and hippocampus (HI). To further examine regional differences in PSD characteristics throughout the brain, we chose to study the OB, a forebrain structure richly innervated by both peripheral and central afferents. Highly purified PSD was obtained from synaptosomal fractions after treatment with 0.5% Triton X-100. The yield was 21.7 mg PSD per 7.5 gm of OB, at least a 10-fold greater yield per unit tissue than CTX, HI or CBL. Morphologically, the OB-PSD exhibited a typically distinct disc-like structure. SDS-gel profile revealed that the proteins in the OB-PSD were qualitatively similar to but quantitatively different from the PSD in the aforementioned brain regions. Further, the mPSDp found in CTX and HI represented only a minor portion of the total OB-PSD protein, similar to that found for the CBL. The OB-PSD exhibited Ca^{2+}/calmodulin- and cAMP-dependent protein kinase activities. There were 5 proteins that bound calmodulin in a Ca^{2+}-dependent manner. Presently, we are examining the binding characteristics of the neurotransmitters GABA and dopamine in the OB-PSD. This is the first demonstration of a PSD fraction isolated from the OB. The high yield of the PSD, the presence of protein kinases and neurotransmitter receptors, as well as the characteristic calmodulin binding suggest that the OB-PSD may constitute a useful model to study the regulation of synaptic molecular architecture by environmental factors.

458.13

A PROTEOGLYCAN-LIKE HEPARIN BINDING PROTEIN OF HIGH MOLECULAR WEIGHT FOUND CONCENTRATED IN SYNAPTOSOMAL MEMBRANES. D. Capaldi*, B.A. Bahr, H. Lim*, K. Norenberg[1] & G. Lynch. Center for the Neurobiology of Learning and Memory, Univ. of Calif., Irvine, CA 92717 and [1]Dept. of Chem., Univ. of Calif., Santa Barbara, CA 93106

Structural molecules such as proteoglycans have been suggested to be involved in nerve terminal adhesion. It is conceivable that due to their adhesive nature proteoglycans contribute to the stable synaptic morphology which survives most subcellular fractionations. In an attempt to identify candidate proteoglycans positioned appropriately in synapses, synaptic plasma membranes (SPMs) were isolated and probed with antibodies against structural elements and [^{3}H]heparin using immunoblotting and gel overlay techniques. Anti-keratin strongly recognized a high M_r (400-600 kDa) species of heterogeneous electrophoretic mobility which is characteristic of a proteoglycan whose protein core is modified by the addition of many glycosaminoglycan side chains. This species was 20 to 50-fold concentrated in SPMs compared to homogenized tissue for all brain regions tested, and was sensitive to trifluoromethanesulfonic acid treatment. An antigen recognized by anti-keratan sulfate was shown to be very similar in locale and molecular weight to the species labeled by anti-keratin. Keratanase appeared to reduce the antigenicity of this species. The two antibodies, however, failed to recognize a similar species in other subcellular fractions such as myelin, mitochondria, or synaptic vesicles, nor in tissues throughout the body. SPMs but not brain homogenate exhibited a proteoglycan-like species in polyacrylamide gels stained with alcian blue or overlaid with [^{3}H]heparin which strongly resembled that labeled by anti-keratin. Hippocampal SPMs bound [^{3}H]heparin with a K_D of 0.5 µM and a B_{max} of 109 pmol/mg protein, whereas the homogenate expressed a similar K_D but a lower B_{max} of 38 pmol/mg. Both binding activities were inhibited by most glycosaminoglycans. A proteoglycan-like species was purified from solubilized SPMs on fibronectin-agarose eluted with GRGDSP. It has similar properties as that recognized by anti-keratin and may represent a class of proteoglycan involved in matrix organization in synapses. Supported by AFOSR#890383.

458.14

HIGH YIELD PURIFICATION OF GLYCOPROTEINS FROM SYNAPTIC MEMBRANES OF RAT CNS. D.E. Hurlbut and E. Weber. University of California, Irvine, CA 92717.

The postsynaptic density (PSD) is a structure associated with the postsynaptic membrane (PSM) found in the majority of chemical synapses and is comprised of various proteins including four glycoproteins which have been characterized by their affinity for concanavalin A (Con A; Mena, 1984). Of the four, the 110,000 kD glycoprotein (type III) is the major component (Mena and Cotamn, 1982,Science 216:422-424.). We decided to purify the type III glycoprotein and attempt to sequence it.

An alternative method from the described approach to isolate CON-A glycoproteins was devised. Briefly, rat CNS P2 pellets pretreated with Triton X-100 were solubilized with an SDS/beta-mercaptoethanol solution, centrifuged, and the supernatant was subjected to affinity chromatography on Sepharose 4B beads coupled to Con-A. Bound proteins were eluted from the column with 0.2 M alpha-D-methyl-glucoside. The eluted glycoproteins were dialyzed against water, lyophilyzed and analyzed by SDS electrophoresis.

The 110kD glycoprotein appeared as a doublet on 8.5% SDS-PAGE. This doublet was further resolved by running the Con-A eluted proteins on 5% SDS-PAGE. Of the doublet, the upper band was selected to be further purified and undergo amino-acid analysis. In order to reassure us that the 110kD doublet was a product of PSDs, CON A glycoproteins were also generated by the method of Mena and Cotman, 1982,Science 216:422-424). Once again a 110kD doublet was observed on 8.5% and 5% SDS-PAGE. This suggests that either method produces the same results with the notable exception that our method yields a greater amount of 110kD protein. *Supported by NIDA fellowship DA05393 to DEH and partially by NIDA grant DA06726 EW.*

SYNAPTOGLYCAN: A KERATAN SULFATE MEMBRANE PROTEOGLYCAN OF SYNAPTIC VESICLES. T.W. Scranton*, M. Iwata, and S.S. Carlson. Dept. of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195.

Previously a membrane proteoglycan was identified as a specific component of synaptic vesicles from elasmobranch electric organ. This molecule is recognized by two mAbs, Tor 70 and anti-SV1, which bind to the same luminal epitope (SV1). The SV1 epitope is found in high concentrations in the neurons which innervate the electric organ; very little is found elsewhere in the fish nervous system. This proteoglycan was thought to be either a member of the heparin/heparan sulfate or keratan sulfate family. Also shown to be present in synaptic vesicles is a 100kD glycoprotein identified with another mAb, anti-SV2, which recognizes a cytoplasmic epitope. We have now shown that the synaptic vesicle proteoglycan contains both the SV1 and SV2 epitopes. On SDS-PAGE two forms of the SV2 molecule exist in vesicles, a 100kd form with few glycosaminoglycan side chains and a higher molecular weight form (>200kd) with large glycosaminoglycan side chains. These glycosaminoglycan side chains contain keratan sulfate in electric organ vesicles, in fish brain, and in rat brain. In electric organ vesicles these side-chains vary greatly in size. The SV1 epitope is present on the largest keratan sulfate side chains of the electric organ proteoglycan. When chromatographed on Sephacryl S-500 under denaturing and reducing conditions the electric organ proteoglycan behaves like a protein of 250kd; the rat brain proteoglycan behaves like a 200kd protein. When solubilized with non-denaturing detergents, the electric organ proteoglycan exists in a complex with 4 small proteins. We propose the name synaptoglycan for this molecule.

SYNAPTIC STRUCTURE AND FUNCTION: HIPPOCAMPUS

459.1

ANATOMY OF ELECTROPHYSIOLOGICALLY CHARACTERIZED INTERNEURONS IN IMMATURE HIPPOCAMPUS. C.M.Gómez[1], K.L.Smith*[2], J.W.Swann[2]. [1]Dept. of Anatomy, Cell Biology & Neurobiology, Albany Medical College, Albany, N.Y. 12208 and [2]Wadsworth Center for Laboratories and Research, NYS Dept. of Health, Albany, N.Y. 12201.

The morphology of subpopulations of CA3 hippocampal interneurons were examined. Neurons were impaled in Stratum pyramidale (S. pyramidale) of minislices taken from area CA3 of 1 to 2 week old rat hippocampus. Cells were identified as interneurons when they displayed brief action potentials with prominent afterhyperpolarization and high firing rates in response to depolarizing steps of intracellularly injected current. Biocytin was injected via the recording electrode. Approximately 35% of such fills yielded single cells, 65% were dye-coupled with the number of cells filled ranging from 2 to 6. Thus far three classes of interneurons have been identified all of which possess dense basket-like terminal arbors. These include 1) pyramidal basket cells and 2) stellate cells, both with terminal arbors primarily in S. pyramidale; and 3) stellate cells with projections primarily outside S. pyramidale. Of the dye coupled cells, 100% were coupled to at least one other interneuron. In one instance, 6 interneurons were dye coupled. 38% of cells were coupled to spiny pyramidal cells which characteristically have intrinsic burst properties. The density of terminal arbors and attendent fiber swellings and breadth of projection within the CA3 subfield suggest that these immature hippocampal interneurons have many of the morphological features commonly ascribed to interneurons in mature hippocampus.

459.2

DUALISTIC PROPERTIES OF INTERNEURONS IN THE IMMATURE HIPPOCAMPUS. K.L.Smith*, C.M.Gómez and J.W.Swann, Wadsworth Center for Labs & Research, NY State Department of Health, and Albany Medical College, Albany, NY 12208.

Intracellular recordings were obtained from fast spiking cells in the CA3 cell body layer of mini-slices taken from rats 10-16 days of age. Characteristically, these cells have brief action potentials with prominent spike afterhyperpolarizations. They fire repetitively at frequencies of up to 200Hz and show little or no spike accommodation during prolonged depolarizing current steps. In experiments reported here, penicillin was bath applied and spontaneous synchronized population discharges were recorded. Previous studies have shown single bursting cells can initiate population discharges via recurrent excitatory synapses. Our results suggest fast spiking neurons also have the ability to trigger synchronized population discharges. Moreover, dual intracellular recordings reveal fast spiking cells can produce polysynaptic EPSPs in bursting cells. In order to anatomically identify these neurons they were injected with biocytin via an intracellular micropipette. Surprisingly, these cells have features of inhibitory interneurons. (Gómez et. al. this meeting) In order to determine if these interneurons produce IPSPs in bursting cells, penicillin was washed from the bath and CNQX was added to abolish residual synchronized discharges. Thusfar, one interneuron has shown both the ability to initiate the population discharge and to produce monosynaptic IPSPs in a pyramidal cell. The physiological processes underlying the excitatory actions of these interneurons are currently under investigation. (Supported by NIH Grant NS18309)

GLYCOLYSIS IS NECESSARY FOR NORMAL SYNAPTIC TRANSMISSION IN GUINEA-PIG HIPPOCAMPAL SLICES. Peter Lipton. Dept. of Physiology, Univ. of Wisconsin, Madison, WI 53706.

Synaptic transmission in dentate gyrus (DG) and CA1 of guinea-pig hippocampal slices is measured as the evoked extracellular field epsp and population spike following low frequency (.125Hz.) stimulation of the perforant path and Schaffer collateral/commissural pathway respectively.

The population spike decays rapidly in both regions following removal of glucose from the extracellular medium (9' in CA1; 15' in DG) and is rapidly restored to near normal levels by 5mM lactate. There are no changes in local ATP levels associated with these effects. The mechanism of the failure of transmission is presently unknown. However, there is no associated depletion of the releasable glutamate pool and there is no inhibition of the antidromically evoked population spike in DG.

Treatment of the "lactate-fortified" slices with 2 inhibitors of glycolysis, .2mM iodoacetate and 20mM 2-deoxyglucose, completely abolishes the population-spike in both regions, with no local changes in ATP. Transmission in these slices is also abolished by sodium pyruvate (2.5mM) and by higher concentrations of lactate. These data show that some aspect(s) of the glycolytic pathway is necessary for normal synaptic transmission even when there is adequate mitochondrial substrate; inhibition by pyruvate and elevated lactate is considered due to block of glycolysis by high citrate levels.

It is concluded that the glycolytic pathway is directly and obligatorily coupled to an aspect of synaptic transmission in guinea-pig hippocampus; this may explain the high ratio of local glucose metabolism to oxygen metabolism seen during physiological stimuli (Fox et al. Science 241:462).

459.4

PROPERTIES OF INHIBITORY AND EXCITATORY MINIATURE CURRENTS IN HIPPOCAMPAL NEURONS MAINTAINED IN LOW DENSITY CULTURE. K.S. Wilcox and M.A. Dichter. Depts. Physiology & Neurology, Univ. of Pennsylvania & Graduate Hospital, Phila., PA 19104

Electrophysiological properties of inhibitory and excitatory neurotransmission were studied using the whole cell patch clamp technique in hippocampal neurons maintained at an extremely low density in dissociated cell culture. Neurons were prepared as described (Buchhalter & Dichter, 1991), plated at 3.5-10x10^4 cells/ ml, and media was supplemented at 1-5 days with 20 mM [K^+] (Mattson & Kater,1989). Inhibitory and excitatory spontaneous miniature currents were recorded in the presence of TTX in neurons 2-3 weeks old. Miniature inhibitory currents occurred at lower frequencies than excitatory currents (0.01-3.3 Hz vs 0.75-16.0Hz), had lower rates of decay (>10 msec vs <4 msec) that were prolonged with depolarization, were blocked by $GABA_A$ receptor antagonists and prolonged with pentobarbital. Excitatory currents were blocked by glutamate receptor antagonists and showed NMDA and non-NMDA components. The frequency of currents increased with application of hyperosmotic bath solution. Amplitude distributions exhibited a large degree of variance for both currents. These results provide evidence that neurotransmission at both types of synapse is quantal. This evidence is essential before quantal analysis can be used to study short term changes in synaptic efficacy. Recordings from isolated pairs of neurons have demonstrated that frequency dependent changes in synaptic strength occur at inhibitory and excitatory synapses in this low density culture system. Supported by NS24260 to M.A.D.

COMPARISON OF TWO ANATOMICALLY DISTINCT EXCITATORY SYNAPTIC INPUTS TO CA3 PYRAMIDAL NEURONS.
S.H. Williams & D. Johnston, Division of Neuroscience, Baylor College of Medicine, Houston, Tx 77030.

The two major excitatory synaptic inputs to area CA3 of the hippocampus, the mossy fibers (MF) and the commissural/associational fibers (C/A), exhibit different forms of long term potentiation. This may in part reflect a differential distribution of NMDA receptors on the CA3 neuron's dendritic tree. These synapses also are likely to terminate at different electrotonic locations. We have investigated the kinetic properties of these two synaptic inputs. Rat hippocampal slices were maintained at 32-34°C. Inhibition was blocked by 10 μM picrotoxin and 10 μM bicuculine, and Ca^{2+} and Mg^{2+} ions were raised to 5 mM to prevent epileptiform activity. Single electrode current- and voltage-clamp recordings were made. The more distal C/A synapses had a slower 10-90% rise time and a slower decay time constant(τ_D) than the MF synapses. The τ_D of the MF EPSC was not voltage dependent. The C/A synapse did show a voltage-dependent prolongation of synaptic current at depolarized potentials (-20 mV or more). This was blocked by APV. The rise time of the EPSP for the two inputs were similarly different. The τ_D of the EPSP was also measured. If the dendritic tree is purely passive one would expect the EPSP to decay with the membrane time constant. We observed that both the MF and C/A EPSPs decayed more slowly than the membrane time constant. This effect was most marked for C/A EPSPs, which decayed with a time constant 1.8 times slower than the membrane time constant (MF decay was 1.3 times slower). This prolongation was voltage-dependent but not affected by APV. These data suggest that the kinetics of these synaptic inputs are affected both by electrotonic location of the synapses and by gated channels in the dendrites.

QUANTITATIVE ULTRASTRUCTURAL CHANGES ASSOCIATED WITH REACTIVE SYNAPTOGENESIS IN THE CA1 REGION OF THE HIPPOCAMPUS.
H.V. WHEAL, S. PHELPS* and J. MITCHELL*. (SPON: Brain Research Association). Depts of Physiology & Pharmacology & Human Morphology, Southampton University, SO9 3TU. UK.

Following the unilateral kainic acid lesion of the rat hippocampus, the effects of the dennervation on the distribution of asymmetric synapses in the CA1 pyramidals cell area were quantified. Ultrastructural examination of the proximal, mid and distal sublayers of the s. radiatum of the hippocampus ipsilateral to the lesion revealed a substantial loss of synapses from these sublayers, which peaked at between 3 to 7 days post lesion. This was followed by rapid reactive synaptogenesis that was differentially distributed, with the largest number of new synapses concentrated in the sublayer proximal to the CA1 pyramidal cell layer. An interim enhancement of multisynaptic boutons, dendritic shaft and complex synapses was also found in this sublayer.

Measurement of spine parameters revealed significant increases in neck length and width over the same time period. These morphological changes might underlie the apparent recruitment of NMDA receptor involvement in epileptiform activity in this model(Turner & Wheal, Neuroscience in press).

AFFERENT INNERVATION REGULATES SYNAPTIC MOLECULAR ARCHITECTURE IN THE HIPPOCAMPUS OF ADULT RATS.
Wu, K. and Black, I.B. Dept. of Neuroscience and Cell Biology, University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School, Piscataway, N.J. 08854.

The synapse plays a pivatol role in neuronal communication and information storage. Nonetheless, little is known about the factors that regulate synaptic structure. Our previous work indicated that synapses in developing and mature superior cervical sympathetic ganglion of rats were regulated by presynaptic innervation. In the present study, we investigated whether presynaptic innervation plays a similar regulatory role in hippocampus to define the regulation of synaptic molecular structure in the brain. Lesion of entorhinal cortex, a major souce of synaptic input to hippocampus, resulted in a dramatic 31% decrease in calmodulin binding to the novel major postsynaptic density protein, mPSDp, one day postoperatively. The maximum effect, a 55% decrease in mPSDp, was obtained 3-5 days after denervation. The lesions did not alter total synaptic membrane protein, suggesting that the denervation specifically affected the mPSDp. Combined lesions of fimbria-fornix and the entorhinal cortex resulted in a 66% decrease in the mPSDp one week after the surgery. The present findings suggest that afferent innervation plays an important role in regulating synaptic molecular architecture in the hippocampus, reproducing the findings obtained in the peripheral nervous system.

MULTIPLE CONTACTS BETWEEN HIPPOCAMPAL CA3 AXONS AND APICAL DENDRITES OF CA1 PYRAMIDAL CELLS.
K.E. Sorra and K.M. Harris. Program in Neuroscience, Harvard Medical School, & Neurology Research, Children's Hospital, Boston, MA 02115

Recent findings from quantal analyses of paired recordings between hippocampal CA3 and CA1 pyramidal cells have prompted this study to determine the frequency of contacts occurring between these cells (Malinow and Tsien, 1990; Bekkers and Stevens, 1990; Friedlander et al., 1990; Foster and McNaughton, 1991). In earlier work (Harris et al., 1980), the rapid Golgi method was used on hippocampal slices from adult rats (50-60 days old) that were maintained *in vitro*. In the present study, these slices were used to visualize the CA3 axons and the CA1 pyramidal cells. Eighty-five well-impregnated axons were located in s. radiatum between 19 and 370 microns from the apical edge of the CA1 pyramidal cell bodies; 42 of these were within 190 and 310 microns. All of these CA3 axons traversed the entire width of at least one dendritic arbor from a single CA1 pyramidal cell. A *contact* was defined as a point where an axon crossing a dendrite touched the dendrite or a dendritic spine in the same focal plane at 1260x magnification. Three classes of contacts were observed: i) single contacts (76%), ii) multiple contacts onto 2 dendrites (17%), 3 dendrites (2%), or 4 dendrites (1%) of a single arbor, and iii) two contacts onto a single dendrite (4%). These results are in accordance with earlier estimates of 1.3 contacts by each CA3 axon (Andersen, 1990, Prog. Brain Res. 83:215-222). Thus, at least 24% of the CA3 axons make multiple contacts with dendrites of a single CA1 pyramidal cell, a rate of occurrence that will need to be considered for a complete interpretation of quantal analyses from paired recordings of these cells.

PRESYNAPTIC MECHANISMS: PHOSPHORYLATION

460.1

EVIDENCE THAT CYCLIC AMP (A-KINASE) REGULATES HIGH AFFINITY SEROTONIN TRANSPORT BY AN INDIRECT MECHANISM.
Steven C. King*, Anita Tiller*, Albert S. Cheng*, Charles Densmore, and Dominic Man-Kit Lee. Baylor College of Medicine, Center for Biotechnology, The Woodlands, TX 77381.

We find that cAMP affects serotonin uptake in 1)PC12, a rat pheochromocytoma; JAR, a human placental choriocarcinoma; and L-14, a transgenic mouse fibroblast line. Transport in all cases was inhibited in medium lacking either Na^+ or Cl^-, and imipramine was a potent inhibitor (IC50<1 μM).

Agents elevating the cellular cAMP (e.g., isobutylmethylxanthine, forskolin, cholera toxin) either stimulated (JAR cells), inhibited (PC12), or had no effect (L-14) on serotonin uptake.

Toxin-mediated inhibition of serotonin transport in PC12 was caused by a two-fold decrease of Vmax with no significant effect on K_m. Stimulation of serotonin transport in JAR was due primarily to a two-fold increase in Vmax in toxin-treated cells. A significant increase in the JAR affinity for serotonin which contributed to the stimulatory effects of cholera toxin with subsaturating serotonin concentrations (i.e., 0.1 μM).

Although cholera toxin acts rapidly to raise the cellular concentration of cAMP, the maximum effect on serotonin transport in either JAR or PC12 occurs at 15 to 20 hours. These results, together with the fundamental observation that JAR, PC12, and L-14 behave differently under the influence of cAMP, suggest that these regulatory phenomena cannot be entirely explained by direct phosphorylation of the serotonin carrier by the A-kinase. The possibility that cAMP regulation of high-affinity serotonin transport occurs at the level of transcription or translation deserves further consideration.

460.2

GLIAL-DERIVED S-100 PROTEIN SELECTIVELY INHIBITS THE NEURON-SPECIFIC PROTEIN F1/GAP-43 PHOSPHORYLATION BY BETA I RECOMBINANT PROTEIN KINASE C: IMPLICATIONS FOR A GLIAL-NEURONAL INTERACTION.
F.-S. Sheu[1], E.C. Azmitia[2,3], D.R. Marshak*[3], P.J. Parker*[4], and A. Routtenberg[1] 1. Northwestern Univ., Evanston, IL 60208. 2. New York Univ., New York, NY 10003. 3. Cold Spring Harbor Lab., CSH, NY 11724. 4. Imperial Cancer Res. Fund, London, WC2A 3PX.

S-100 protein from brain glia exists as an alpha-beta heterodimer (S-100a), or a beta-beta homodimer (S-100b) (Cell Calcium 7:123, 1986). S-100b is elevated in Alzheimer disease and Down syndrome (DS) brain (PNAS 86:7611, 1989) and the S-100b gene is on chromosome 21 (Science 239:1311, 1988) which is trisomic in DS. The overexpressed S-100b suggests a role for S-100 in regulating learning and memory functions. Neuron-specific protein F1/GAP-43 may play a role in neuronal growth (Annu. Rev. Neurosci. 12:127, 1989) and its phosphorylation is increased after long-term potentiation, a physiological model of memory (Brain Res. 399:205, 1986). Since S-100b in cultured serotonergic neurons enhances neurite outgrowth (Brain Res. 516:354, 1990), perhaps it does so by regulating the phosphorylation of protein F1/GAP-43.

Four recombinant PKC subtypes from baculovirus promoter were maximally stimulated to phosphorylate purified rat protein F1/GAP-43. Using a mixture of S-100a and S-100b, a dose-dependent inhibition of phosphorylation occurred. The IC_{50} (uM) values of S-100 were 16, 2, 16, 2 for the alpha, beta I, beta II and the gamma PKC subtype, respectively. When pure S100 beta was used, a subtype-specific inhibition of beta I PKC subtype was observed. 8 uM of S-100 beta inhibited F1/GAP-43 phosphorylation by 5, 60, 5 and 17% for alpha, beta I, beta II and gamma PKC. The inhibitory effect of S-100 on protein F1/GAP-43 phosphorylation may arise from a direct kinase inhibition as indicated by decreased PKC autophosphorylation or binding to substrate (JBC 264:1824, 1989). These data suggest glial-neuronal communication and that S-100 protein may be important for trophic functions by regulating phosphorylation of protein F1/GAP-43. 460.3

INTERACTIONS BETWEEN ARACHIDONIC ACID AND Ca^{2+} IN THE PHOSPHORYLATION OF GAP-43 (F1, B-50)

J.D. Schaechter and L. I. Benowitz, Dept. Neurosurgery, Children's Hospital, Harvard Med. School, Boston, MA 02115

The presynaptic PKC substrate GAP-43 has been implicated in neuronal outgrowth, regeneration, and plasticity[1]. LTP in the mature hippocampus is characterized by correlated increases in GAP-43 phosphorylation[2] and transmitter release[3]. These presynaptic changes may depend on the post-synaptic generation of arachidonic acid[4] (AA; 20:4) and its subsequent stimulation of AA-sensitive isoforms of PKC[5,6]. In the present study, synaptosomal membranes from rat cerebral cortex were used to examine whether AA affects GAP-43 phosphorylation and if it interacts with changes in Ca^{2+} levels. Low concentrations of AA (50 μM) stimulated GAP-43 phosphorylation, and this effect was potentiated by Ca^{2+} (10^{-6} M). High AA concentrations (500 μM) decreased GAP-43 phosphorylation to less than that exhibited in the absence of the fatty acid. This bimodal effect was mimicked by another *cis*-unsaturated fatty acid (18:1*c*), but not by the *trans* stereoisomer (18:1*t*), nor by the saturated isomer of AA (20:0). These results demonstrate that the phosphorylation of GAP-43 is regulated synergistically by free AA and Ca^{2+}. This presynaptic regulation may be important in modifying mature synapses and may also play a role in the initial development of neuronal circuitry.

460.4

DEPOLARIZATION-DEPENDENT TYROSINE PHOSPHORYLATION IN SYNAPTOSOMES.

S.I. Woodrow*, N. Bissoon* and J.W. Gurd, Dept. of Biochemistry, Scarborough Campus, University of Toronto, West Hill, Ont. M1C 1A4.

Protein phosphorylation is involved in the regulation of synaptic activity. Although protein tyrosine kinases are present at the synapse [eg. Ellis and Gurd (1988) J. Neurochem. 51 611-620] their relationship to synaptic function is unknown. We therefore assessed the effect of depolarization on synaptosomal phosphotyrosine-containing proteins (ptyr-proteins) by immunoblotting with anti-ptyr antibodies. Freshly prepared synaptosomes from rat forebrain contained several ptyr-proteins and these remained essentially unchanged during incubation in vitro. Incubation for 45 min. in the presence of 0.1 mM Ca^{2+} followed by depolarization with high K^+ (41 mM) led to an increase in the amount of immunodetectable ptyr associated with a protein of Mr 117,000 (ptp117). This increase was apparent within 1 min. of the start of depolarization, reached a maximum between 3 and 5 min. and then decreased during the next 20 min.. Omission of Ca^{2+} from the incubation buffer, or the addition of EGTA 5 min. prior to depolarization prevented the increase in tyrosine phosphorylation of ptp117. The results suggest that the phosphorylation of ptp117 on tyrosine may be involved in the regulation or modulation of synaptic activity.

460.5

DEPHOSPHORYLATION OF B-50 (GAP-43) BY TYPE 1 AND 2A PHOSPHATASES IN SYNAPTIC PLASMA MEMBRANES.

Y.F. Han and L.A. Dokas. Departments of Biochemistry and Molecular Biology and Neurology, Medical College of Ohio, Toledo, OH 43699.

The neuronal protein kinase C substrate B-50 (GAP-43) is dephosphorylated in rat cortical synaptic plasma membranes (SPM) by phosphatase type 1 and 2A (PP-1 and PP-2A)-like activities. The present studies further demonstrate that B-50 is dephosphorylated not only by the active PP-1-like enzyme, but also by a latent form following pretreatment of SPM with 0.2 mM cobalt/20 μg/ml of trypsin in an inhibitor [1 μM okadaic-acid (OA) and 2.6 μg/ml of inhibitor-2 (I-2)]-sensitive manner. In the presence of an excess of I-2, histone H1 (16-64 μg/ml) and spermine (2 mM) increased B-50 dephosphorylation, an effect which was prevented by 2 nM OA. PP-1 and PP-2A-like activities from SPM were further displayed by using exogenous phosphorylase a and histone H1 as substrates. OA-induced inhibition of B-50 dephosphorylation was also demonstrated in rat cortical synaptosomes by use of an immunoprecipitation assay with affinity-purified anti-B-50 IgG. These results provide further evidence that SPM-bound PP-1 and PP-2A-like enzymes that share considerable similarities with their cytosolic counterparts may act as physiologically important phosphatases for B-50. [Supported by the Ohio Department of Aging and NIH (NS23598)].

460.6

HISTAMINE AND NICOTINE, VIA DISTINCT MECHANISMS, STIMULATE PARALLEL INCREASES IN SYNAPSIN II PHOSPHORYLATION AND NOREPINEPHRINE RELEASE

J.A. Firestone and M.D. Browning, *Dept. of Pharmacology, Univ. of Colorado Health Sciences Center, Denver, CO 80262.*

Protein phosphorylation is widely recognized as the primary molecular mechanism for regulation of protein function, and a family of phosphoproteins known as the synapsins are thought to be involved in neurosecretion. Indeed, a recent report demonstrated that synapsin II may play a role in production of synaptic vesicles and in synapse formation. (Han et al., *Nature, 349*, 697-700.) We have been examining synapsin II phosphorylation and its relationship to norepinephrine (NE) release from bovine adrenal medullary chromaffin cells (BACC). This is a complex phenomenon modulated by cholinergic and non-cholinergic transmitters. Primary cultures of BACC can be stimulated to release NE by nicotine, mimicking the cholinergic stimulus from the splanchnic nerve. Histamine also stimulates NE release from these cells in a time- and dose-dependent manner. We have previously shown that these two transmitters increase $^{32}PO_4$ incorporation into synapsin II. We report here that maximal doses of nicotine (100 μM) and histamine (100 μM), when combined, produce additive increases in both NE release and synapsin II phosphorylation. These data suggest different mechanisms of activation. We also find that nicotine-stimulated release is abolished in the absence of extracellular calcium, whereas histamine-stimulated release remains significantly elevated in calcium-free media. Nicotine is known to act through nicotinic receptors, stimulating a depolarization-dependent influx of extracellular calcium. Histamine acts through H_1-receptors, stimulating a release of intracellular calcium via IP_3 production. Thus, calcium arising from two separate pools can stimulate additive increases in NE release and synapsin II phosphorylation in BACC. In addition, these data provide evidence for the hypothesis that synapsin II phosphorylation plays a role in NE release from these cells. Supported by PHS grant DK40486 to MDB.

460.7

OPTICAL MEASUREMENT OF SYNAPTIC VESICLE RECYCLING

W.J. Betz & G.S. Bewick*; Dept. of Physiology, Univ. of Colorado Med. Sch., Denver, CO 80262

We have studied the pattern of dye loading and unloading in frog cutaneous pectoris motor nerve terminals using FM1-43, a derivative of RH414 (Molecular Probes, Inc). FM1-43 stains synaptic vesicle membranes, producing bright spots along the length of nerve terminals, each spot consisting of a cluster of hundreds of stained vesicles. We tested the hypothesis that recycled vesicles mix randomly within a vesicle cluster. Results from 3 experiments support the hypothesis.

1. Partial dye loading gives spots the same size as full dye loading, only dimmer.

2. Stained terminals destain with nerve stimulation. If a terminal is partly destained, and then stimulation is halted for 10 minutes and then resumed, the second destaining rate is slower than the first.

3. As independent measures of transmitter release, summed end plate potentials (epps) were compared with fractional dye release during destaining. The two curves deviated after 1-2 minutes, with dye release falling below summed epps.

These results quantitatively support the hypothesis that recycled vesicles distribute randomly throughout the vesicle cluster.

Supported by NS10207 and NS23466 (to WJB).

460.8

SYNAPTIC VESICLE-ASSOCIATED CaM KINASE II BINDS THE C-TERMINAL REGION OF SYNAPSIN I.

F. Benfenati, F. Valtorta*, A.J. Czernik and P. Greengard. Inst. Human Physiology, Univ. Modena, Italy; Ceccarelli Center, Dept. Pharmacology, Univ. Milano, Italy; The Rockefeller University, New York.

Synapsin I is a major neuron-specific phosphoprotein which associates with small synaptic vesicles at multiple sites in a phosphorylation-dependent fashion. In an attempt to identify vesicle protein(s) which interact with the C-terminal "tail" region of synapsin I, purified NTCB-cleaved tail fragment was conjugated to the heterobifunctional cleavable reagent SASD and subsequently iodinated in the dark. The ^{125}I-ASD-tail was then incubated with synapsin I-depleted synaptic vesicles, photolyzed and cleaved. Proteins in the mixture were then resolved by SDS-PAGE. A major vesicle protein of 47 kDa was labeled with ^{125}I. The protein was extracted from preparative gels and digested with endoproteinase Asp-N. Three peptides were purified by reverse phase HPLC and sequenced. The amino acid sequences were identical to regions of the α-subunit of CaM kinase II, which is associated with synaptic vesicles (see Rubenstein J. *et al.*, this meeting). We tested whether the binding of the tail fragment is competed by peptides corresponding to the sequences surrounding phosphorylation sites 2 and 3 of synapsin I or by CaM kinase II inhibitory peptides based on the sequence of the autoregulatory domain of the kinase. We found that, under basal conditions, the CaM kinase II peptides [273-302]Ala^{286} and [281-302]Ala^{286} were both effective in displacing the tail fragment from synaptic vesicles (IC_{50} = 10 and 35 μM, respectively), the site 3 peptide was less potent (IC_{50} = 450 μM) and the site 2 peptide was ineffective. The results indicate that CaM kinase II associated with synaptic vesicles is involved in binding the tail region of synapsin I. If synapsin I is present on the vesicles in close association with CaM kinase II, its phosphorylation, stimulated by an increased intraterminal Ca^{2+} concentration, could be an extremely fast process, conceivably involved in mediating exocytosis.

460.9

LABELING OF SYNAPTIC VESICLES IN LIVING NEURONS WITH ANTIBODIES TO THE LUMENAL DOMAIN OF SYNAPTOTAGMIN/P65
M.Matteoli*, K. Takei*, M.Perin*#, T. Südhof*# and P. De Camilli. Dept. Cell Biol., Yale Univ. Sch. Med., New Haven, CT 06510; #Howard Hughes Med. Inst. and Dept. Mol. Gen. , Univ. of Texas SMC, Dallas, TX 75325

We used polyclonal antibodies (p65-Abs) directed against the intravesicular domain of the intrinsic protein of synaptic vesicles (SVs) synaptotagmin (protein p65) to monitor SV exocytosis and recycling in living hippocampal neurons in culture. Cultures were first incubated with p65-Abs under different experimental conditions and subsequently without the antibodies for various times. Cells were then fixed, permeabilized and stained with rhodamine-conjugated secondary antibodies. Only very weak staining was observed when neurons were incubated with p65-Abs at 0°C, suggesting that the pool of SV proteins present in the plasmalemma at any given time is very low. When cultures rich in synaptic contacts were incubated for 1 hr in the presence of p65-Abs followed by a short wash (15 min) a specific staining of synapses was observed. This indicates a specific uptake of p65-Abs in synaptic terminals. When similar experiments were performed on neurons grown in isolation, intense SV staining was observed throughout the axonal arbour, indicating that SVs undergo exo-endocytosis even in absence of synaptic contacts. The staining pattern for internalized p65-Abs and for synaptic vesicle antigens was found to be identical even when the 1hr incubation with p65-Abs was followed by 2-5 days incubation without antibodies. If during this time synapses were formed, p65-Abs became clustered at synaptic sites in parallel with SVs. These observations indicate that binding of p65-Abs to the lumenal domain of p65 does not significantly affect the localization and traffic of the protein. Our results suggest that p65-Abs may be a powerful marker for SVs and nerve terminals in living neurons.

460.10

LOW pH PREVENTS SYNAPTIC VESICLE RECYCLING IN SNAKE MOTOR NERVE TERMINALS.
I.G. Marshall*, C. Prior*, K. Pemberton* and S.M. Parsons. Department of Physiology and Pharmacology, University of Strathclyde, Glasgow, U.K. and Department of Chemistry, UCSB, Santa Barbara, CA.

We have previously shown (Searl, T., *et al., Neuroscience*, **35**, 145-156, 1990) that prolonged motor nerve stimulation induces the appearance of two populations of miniature end-plate currents (MEPCs) at the snake neuromuscular junction. The so called "small-mode" MEPCs have been attributed to the release of recycling quanta. It is not clear why these recycling quanta are smaller than the normally released pre-formed quanta. Two possibile explanations are: (i) that the cytoplasmic supply of acetylcholine (ACh) for these recycling quanta is limited or (ii) that the synaptic vesicle proton gradient, required for the translocation of ACh into the synaptic vesicles, is in some way impaired. To determine which of these two possibilities is more likely we have examined the effects of 5 minutes of 10 Hz nerve stimulation on MEPC amplitude distributions in the presence of a reduced pH (5.0). In unstimulated preparations MEPC amplitude distributions were very similar in pH 7.0 (normal) and 5.0. However, in contrast to the effects of stimulation at pH 7.0, stimulation immediately following a switch to pH 5.0 did not lead to the appearance of a bi-modal distribution of MEPC amplitudes, the MEPC amplitude distributions being essentially identical to those seen pre-stimualtion. The inability to detect small-mode MEPCs following stimulation in the presence of a low pH suggests that, in the snake, the ACh content of recycling synaptic vesicles is more critically dependent on the synaptic vesicle proton gradient than the nerve terminal ACh content.

CALCIUM CHANNELS: MULTIPLE TYPES

461.1

PREFERENTIAL RECRUITMENT OF THE DIHYDROPYRIDINE-SENSITIVE COMPONENT OF ACTION-POTENTIAL-INDUCED Ca^{2+} INFLUX.
T. M. Piser, and S. A. Thayer. Department of Pharmacology, University of Minnesota Medical School, Minneapolis MN, 55455.

Intracellular free calcium concentration $[Ca^{2+}]_i$ transients were elicited by electrical field stimulation and measured by indo-1 based microfluorimetry in single rat hippocampal neurons grown in primary culture. The $[Ca^{2+}]_i$ transients were mediated by action potentials as indicated by a response threshold sharply dependent on stimulus amplitude, and complete block by tetrodotoxin (1 uM). $[Ca^{2+}]_i$ transients elicited by 10 pulses at 10 Hz (peak 546 ± 42 nM from basal 159 ± 16 nM, n=7) were only slightly sensitive to inhibition (11 ± 4%) by nitrendipine (NIT, 1 uM). Application of tetraethylammonium (TEA, 2mM) increased the amplitude of the response by 290 ± 60%. The TEA-recruited response was blocked by NIT (94 ± 9%, n=4). Stimulation at 50 Hz for 30 pulses increased the amplitude of the $[Ca^{2+}]_i$ transient by 199 ± 21% relative to that observed at 2 Hz. NIT did not effect the low-frequency response, but showed a marked inhibition of the high-frequency-recruited response (50 ± 7%, n=3). Previous results have shown that TEA (1) and high-frequency electrical stimulation (2) slow action potential repolarization by decreasing K^+ current. Preferential recruitment of dihydropyridine-sensitive Ca^{2+} influx by increased action potential duration may depend on the slow activation and inactivation kinetics of the dihydropyridine-sensitive, voltage-activated Ca^{2+} channel.

POTENTIATION OF THE LOW-VOLTAGE-ACTIVATED (LVA) CA++ CURRENT BY ALBUMIN.
S. Huck, M. Freissmuth,* S. Boehm* and S. Heiss.* Departments of Neuropharmacology and Pharmacology, University of Vienna, A-1090 Vienna, Austria.

Bovine serum albumin (BSA) has been reported to enhance LVA Ca and Na currents in chick and rat dorsal root ganglion neurons. In the present study, we have purified BSA with FPLC techniques, cleaved the molecule enzymatically with trypsin and tested the fragments for biological activity on the LVA Ca current.

Patch clamp recordings (whole cell configuration) were performed on acutely dissociated E_{13} chick dorsal root ganglion (DRG) neurons with 20mM Ca in the external solution. While not affecting HVA Ca currents, BSA enhanced peak amplitudes of the LVA Ca component with little effect on activation or inactivation kinetics. Half maximal enhancement occurred at approximately 1mg/ml BSA.

Upon chromatography on a MonoQ anion exchange column, the biological activity comigrated with the 67kDa protein. Enzymatic cleavage with trypsin yielded prevalent fragments with apparent molecular weights between 20 and 50kDa. On the MonoQ column, the trypsinized products eluted as three major protein peaks. Based on its protein contents, the first peak (primarily containing 7, 10 and 26kDa components) was about 15 times as active as the peaks two and three (containing fragments around 40kDa and albumin, respectively).

Our experiments indicate that the LVA potentiating activity is an integral part of albumin and that low molecular weight fragments retain this biological effect.

HIGH- AND LOW-THRESHOLD CALCIUM CURRENTS IN ACUTELY ISOLATED STRIATAL NEURONS
K. Hoehn, T.W.J. Watson and B.A. MacVicar, Neuroscience Research Group, University of Calgary, Alberta, Canada, T2N4N1

The neostriatum is intimately involved in the control of locomotion. Ca^{2+} channels are important in determining the firing patterns of a variety of neurons. The nature and possible modulation of voltage-dependent Ca^{2+} channels has not to date been described in mature striatal neurons. The ionic currents in acutely isolated neurons from rat (21 to 28 day postnatal) striatum were investigated using whole-cell voltage clamp. Striatal neurons, isolated in trypsin-hyaluronidase, could be divided morphologically into a population of small neurons with a whole cell capacitance of less than 10pF and a population of large neurons with greater than 12 pF capacitance. A TTX-sensitive Na^+ current as well as K^+ currents with properties similar to the A-current and delayed rectifier current were seen in both types of neurons. To isolate Ca^{2+} currents, the pipette solution contained (in mM): trizma phosphate 70, trizma base 28, TEACl 40, EGTA 11, MgATP 2, NaGTP 0.3 and the extracellular solution contained (in mM): NaCl 90, TEACl 40, HEPES 10, 4-AP 4, TTX 0.0012 and either Ba^{2+} 2.5 or Ca^{2+} 5. In 2.5mM Ba^{2+}, both types of neurons exhibited high-threshold, sustained inward currents. In 5mM Ca^{2+}, distinct high- and low-threshold inward currents were seen in both populations of neurons. At a holding potential of -100 mV, threshold for activation of the low threshold, rapidly inactivating current was about -60 mV and this current reached maximum at -40 to -30 mV. At holding potentials positive to -80mV this current was inactivated. A sustained, high-threshold inward current activated at -40 to -30 mV and reached maximum at -10 to 0 mV. Because dopamine is a major neurotransmitter in the striatum, we examined the possibility that it might modulate Ca^{2+} currents in these neurons. A reduction in high threshold Ca^{2+} current by either dopamine (10μM) or the D_2 agonist, quinpirole (10μM), was seen in only 3 out of 20 neurons. (Supported by the MRC of Canada and AHFMR).

461.4

MULTIPLE CALCIUM CURRENTS RECORDED IN RAT SUBSTANTIA NIGRA ZONA COMPACTA NEURONS *IN VITRO*.
M.S. Washburn and L.T. Meltzer Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI. 48105.

Numerous studies using intracellular voltage recordings have suggested that dopamine (DA) neurons in the rat substantia nigra zona compacta (SNZC) possess at least 2 distinct calcium currents (I_{Ca}s). To further examine the properties of I_{Ca}s in these cells, whole-cell recordings were obtained from DA neurons in horizontal slices of rat midbrain. Such cells were identified electrophysiologically by their broad action potentials, regular pacemaker firing and strong anomalous rectification.

I_{Ca}s were isolated from other voltage-dependent membrane currents by using cesium chloride (140 mM) in the recording pipette and by superfusion of medium containing TEA (10-20 mM), 4-aminopyridine (2 mM) and TTX (1 μM). When recording in the voltage-clamp mode under these conditions, 3 distinct I_{Ca}s could be elicited . The first, a transient inward current analagous to the T-type current recorded in many other neurons, was activated by relatively small (20-40 mV) depolarizations from a holding potential (V_h) of -80 to -90 mV and peaked between -20 and -30 mV. This low voltage-activated (LVA) current rapidly inactivated during a maintained (250 ms-1 s) voltage step and could not be elicited from a V_h more positive than -60 mV. In some cells, large voltage steps from a V_h of -80 mV activated an I_{Ca} which substantially inactivated during a 250 ms step and may correspond to the N-type I_{Ca} reported elsewhere. Finally, step depolarizations from a V_h of -40 mV activated a large, high voltage-activated (HVA) current which only partially inactivated during a prolonged (1 s) depolarizing step. This current peaked between 0 and -10 mV and its current-voltage relationship resembled that of the previously described L-type current.

Both the LVA and HVA I_{Ca}s were reduced or blocked by cadmium (30 μM- 1 mM) and the dihydropyridine nifedipine (100 nM- 3 μM), although the LVA current was relatively more resistant to these treatments.

461.5

"N"- AND "L"-LIKE CALCIUM CURRENTS IN LUNG CANCER CELLS ARE BLOCKED BY LAMBERT-EATON IgG.

S.C. Hulsizer, S.D. Meriney, A.D. Grinnell and V.A. Lennon,† Jerry Lewis Neuromuscular Res. Ctr., UCLA School of Medicine, Los Angeles, CA 90024 and †Mayo Clinic, Rochester, MN.

Lambert-Eaton syndrome (LES), an autoantibody-mediated disorder of presynaptic calcium channels at the neuromuscular junction (NMJ), is often associated with small cell lung cancer (SCLC). We are therefore studying the calcium currents in human SCLC cell lines that express both "N"- and "L"-like calcium currents in an attempt to characterize the type(s) of calcium channels that may exist at the NMJ. Whole-cell and cell-attached patch clamp recordings from the NCI-H345 cell line reveal two types of high-threshold calcium current (carried by barium). The "L"-like current is non-inactivating, 50% steady-state inactivated at -10 mV, sensitive to dihydropyridines, with a single channel conductance of about 21 pS. The "N"-like current significantly inactivates during a 100 ms pulse, is 50% steady-state inactivated at -50 mV, insensitive to dihydropyridines, and has a single channel conductance of about 16 pS. This is the first demonstration of an "N"-like channel in a non-neuronal cell. Both currents are significantly reduced following 72-hour incubation in LES IgG and unaffected by IgG from myasthenia gravis patients. Supported by grants from the MDA, NIH (CA37343†, NS06232) and NSF (BNS8919841).

461.6

A NEURONAL CELL LINE WITH ONLY T-TYPE CALCIUM CHANNELS.

R.T. McCarthy and P.E. TanPiengco. Miles Inst. Preclin. Pharm., West Haven, CT 06514.

Calcium channel currents have been studied using whole-cell and cell-attached patch recording in a cell line derived from N1E-115 (passages 20-40). After 2-5 days in culture these cells have only low threshold current (n=30). Culturing with DMSO (2-10% ;2 days-3 wks.) in an attempt to differentiate these cells failed to enhance neurite formation or induce high threshold currents. Elicitable currents activated near -55 mV, peaked near -15 mV and reversed positive to +40mV (20 Ca++/130 Cs+). Substitution of barium for calcium as the charge carrier did not enhance inward current or alter the voltage dependence of channel inactivation. The midpoint of the steady-state availability curve was -58.0 mV (n=5) with no elicitable current from depolarized holding potentials (Vh = -30 mV) even with strongly depolarizing test potentials (Vt = +20 mV). Tail currents with slow T-type kinetics (V_B=-65; τ=6 msec) were well fit by single exponentials. Cell-attached patch recording (n=6) characterized the underlying conductance as a 7.5 pS channel (110 Ba^{++}). This preparation provides an opportunity to study neuronal T-type calcium channels in isolation from N- or L-type.

461.7

PHARMACOLOGY OF T - TYPE CALCIUM CHANNELS IN A NEURONAL CELL LINE.

P.E. TanPiengco and R.T. McCarthy. Miles Inst. Preclin. Pharm., West Haven, CT 06514

The pharmacology of T-type calcium channel current was studied in a neuronal cell line derived from N1E-115 that expressed only T-type channels. These low threshold currents (activation as negative as -55 mV) could be inhibited by nickel (150 μM) and completely inhibited by cadmium (500 μM). Omega-conotoxin (5 and 10 μM) had no effect on currents. Neither whole-cell peak current nor tail current were enhanced by BAY K 8644 and, instead, appeared to be slightly inhibited by this drug. The agonist enantiomer of BAY K 8644 [BAY R 5417 (100 nM)] had no effect on this low threshold current. Studies with cell-attached patch recording (110 Ba^{++}) in the presence of calcium channel agonist failed to demonstrate large conductance openings or a switch in the mode of gating of the 7.5 pS conductance. Activity of the 7.5 pS channel was retained in excised patches. This calcium channel current shares the pharmacological characterization of T-type channels, providing an opportunity to study the modulation of T-type channel current isolated from other neuronal calcium channel types.

461.8

DIPHENYLBUTYLPIPERIDINE (DPBP) ANTIPSYCHOTICS PREFERENTIALLY BLOCK T-TYPE CALCIUM CHANNELS IN NEURAL CREST DERIVED THYROID C CELLS.

J.J. Enyeart*, B.A. Biagi#, and B. Mlinar. Depts. of Pharmacology and Physiology#, The Ohio State University, Columbus, OH 43210-1239.

The inhibition of Ca^{2+} channels by the DPBP penfluridol was studied with whole cell patch clamp in thyroid C-cell lines. Three separate components of Ca^{2+} current, corresponding to T, L, and N channels were identified in rat rMTC 6-23 (clone 6) cells. The low voltage-activated, rapidly inactivating T current was potently blocked by penfluridol. At a concentration of 500 nM, penfluridol inhibited 78.0 $\pm$ 2.3% (n=28) of T current. The slowly inactivating component of Ca^{2+} current, primarily N- and L-type, was less potently inhibited (25.6 $\pm$ 3.5%, n=29). Block of T current by penfluridol was use-dependent and promoted by channel activation. T-type Ca^{2+} channels were also effectively blocked by penfluridol in the human TT C-cell line. Among organic Ca^{2+} antagonists DPBPs are distinctive in their ability to preferentially block T-type Ca^{2+} channels at low concentrations. DPBPs will be useful in determining the function of this Ca^{2+} channel subtype in excitable cells.

461.9

LOW THRESHOLD CALCIUM CURRENT OF RAT LATERODORSAL TEGMENTAL NEURONS STUDIED WITH WHOLE-CELL PATCH CLAMP IN SLICES.

Anita Kamondi and Peter B. Reiner, Kinsmen Laboratory of Neurological Research, Department of Psychiatry, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3

As an integral part of the ascending reticular activating system, the laterodorsal tegmental (LDT) nucleus plays an important role in the regulation of thalamocortical function. Intracellular recordings have shown that there exist at least three electrophysiologically different classes of neurons in the LDT area. We have used the whole-cell patch clamp technique as applied to the *in vitro* slice preparation to study the characteristics of the transient calcium current, I_T, exhibited by a subpopulation of LDT neurons. The average current amplitude was 300 pA, which became larger in solutions containing elevated [Ca^{2+}], smaller in the presence of 2 mM Co^{2+} , and was unaffected by substitution of choline for sodium. I_T could be evoked by depolarizing voltage steps to -50 mV from a holding potential of -65 mV. Activation of I_T showed extremely steep voltage dependence in the voltage range from -55 mV to -45 mV. The time-to-peak latency became shorter at more depolarized voltages. The decay phase of the current followed a single exponential time course, with an average tau of 70 ms, and did not show strong voltage dependence. Removal of inactivation was both time and voltage dependent, with 300 ms needed for total removal at a membrane potential of -80 mV. The biophysical properties of I_T are largely responsible for the bursting behaviour of this subpopulation of LDT neurons.

Supported by the MRC.

461.10

T-TYPE CA++ CURRENT AND ITS FUNCTION IN TRIGGERING CA++ INFLUX IN EMBRYONIC *XENOPUS* SPINAL NEURONS.

Xiaonan Gu and Nicholas C. Spitzer. Department of Biology & Center for Molecular Genetics. UCSD, La Jolla, CA 92093

Previous studies have shown that spontaneous Ca^{++} influx during a critical period plays an important role in development of embryonic *Xenopus* spinal neurons in culture. We have used the whole cell voltage clamp technique to study low voltage activated (LVA) T-type Ca^{++} current and its role in regulating Ca^{++} influx during neuronal development. Blocking high voltage activated (HVA) N- and L-type Ca^{++} currents with intracellular F^- and replacing or removing extracellular Ca^{++} showed that LVA T-type Ca^{++} current is present in these cultured neurons.

This T current is a transient inward current and can be activated at membrane potentials between -60 and -45 mV. It has the lowest threshold among the voltage activated depolarizing currents recorded in young neurons, and reaches its peak at membrane potentials around -35 mV with an amplitude of 50 pA. The rates of both activation and inactivation are voltage dependent. With steps to -35 mV, the time to half maximum of activation and the time constant of inactivation are 3.6±0.2 ms and 17.5±1.8 ms, respectively. The T current is present in both young and mature neurons with no apparent change of its properties. Ni^{++} has been shown to block increases in intracellular Ca^{++} triggered by Ca^{++} influx. In the present study, we found that Ni^{++} can be used to selectively block T current with only a minor effect on HVA currents.

LVA T current may be involved in depolarizing cells and triggering HVA Ca^{++} currents, thus inducing Ca^{++} influx in cultured neurons at early stages in their differentiation. Supported by NIH NS15918 to NCS.

TRANSIENT AND SLOW CALCIUM CURRENTS IN EMBRYONIC MUSCLE GROWN IN THE PRESENCE AND ABSENCE OF NERVE.
N.S. Virgo* and F.L. Moody-Corbett. Div. Basic Sci., Fac. Med., Memorial University of Newfoundland, St. John's,NF A1B 3V6

Skeletal muscle displays two types of inward Ca^{++} currents: a slow, dihydropyridine sensitive current and a transient current which is less sensitive to dihydropyridines. The purpose of the present study was to determine if the developmental appearance of these two currents was influenced by the presence of the nerve. Muscle cells were removed from embryos of the frog Xenopus laevis at early stages (12-14) of development, 4-6 hr prior to innervation, and plated in culture (nerve-free, NF). The Ca^{++} currents in these cells were compared to those in muscle cells derived from older embryos (stage 19-21) and grown in the presence of neural tube cells (nerve-enriched, NE). Ca^{++} currents were examined using the whole cell recording technique in the absence of Na^+ or K^+ (extracelluar solution, in mM: 127.5 tetraethylammonium, 20 $BaCl_2$, 1.2 $MgCl_2$, 10 Hepes; electrode solution, in mM: 140 CsCl, 5 $MgCl_2$, 1 BAPTA, 10 HEPES; both solutions were pH 7.4). There was no difference between the NE and NF cultures in the number of cells with a transient or slow current, the developmental appearance of the two currents, or the current density. The two currents however, differ from each other in their developmental time course. By the first day in culture about 60% of the cells have a slow current compared to 11% with a transient current. By day 2 all cells had a slow current whereas by day 3 only 50% of the cells had a transient current. The results of the present study indicate that although the slow and transient Ca^{++} currents differ from each other in a number of ways the developmental appearance of these currents is not influenced by the presence or absence of the nerve.

461.12

PROPERTIES OF SINGLE VOLTAGE-GATED CALCIUM CHANNELS IN DISSOCIATED MEDIAL SEPTUM/DIAGONAL BAND (MS/DB) NEURONS.
W.H. Griffith and M.J. Davis*. Depts. of Medical Pharmacol. & Toxicol. and Medical Physiology. College of Medicine, Texas A&M University, College Station, TX 77843.

We have previously identified both low-voltage activated (LVA) and high-voltage activated (HVA) calcium currents in MS/DB neurons using the whole-cell patch-clamp technique (Neurosci Abstr. 16:676,1990). The present study identified the properties of single calcium channels contributing to these macroscopic currents. Calcium channels were recorded in MS/DB neurons acutely dissociated from adult guinea pig (175-700 gms) using the cell-attached recording configuration. Barium (100-110 mM) inside the pipette was used as the charge carrier and isotonic K-aspartate (140 mM) was used to zero the cell's resting potential. From a holding potential of -80 mV, two channel types were recorded most often, first a low conductance channel (6-7 pS) that was activated near -40 mV, and second, a large conductance channel (24-26 pS) activated near -20 mV. These latter channels were recorded in the presence of Bay K 8644 (1-5 μM). A third channel type (12-14 pS) was recorded less frequently and was activated near 0 mV. These three channel types differed in their voltage-dependence, open probability and sensitivity to Bay K 8644 and may resemble T, L and N type channels recorded in hippocampal and ganglion cells.

CALCIUM CHANNELS: CONOTOXINS AND OTHER LIGANDS

462.1

THE EFFECTS OF SPIDER VENOMS ON ω-CONOTOXIN GVIA (ω-CT)-SENSITIVE AND -INSENSITIVE $^{45}Ca^{++}$ INFLUX AND NEUROTRANSMITTER RELEASE.
R.A. Keith, P.A. DeFeo*, T.J. Mangano, and A.I. Salama, Dept. of Pharmacology, ICI Americas, Inc. Wilmington, DE 19897.

Recent studies have shown that some spider venoms contain toxins that interact with voltage-sensitive calcium channels (VSCC). The present study evaluated the effects of 10 spider venoms (Spider Pharm, Inc.) against K^+-evoked $^{45}Ca^{++}$ influx in chick (ω-CT-sensitive) and rat (ω-CT-insensitive) synaptosomes as a first step to find additional toxins with activity at VSCC. At a concentration of 0.3 ul venom/ml, venoms from Agelenopsis aperta, Hololena curta, Plectreurys tristis and Phidippus ardens inhibited K^+-evoked $^{45}Ca^{++}$-influx in both preparations by greater than 70%. Venoms from Alphonopelma chalcodes and Peucetia viridans inhibited $^{45}Ca^{++}$ influx by 50-70%. Venoms from Delana cancerides, Heteropoda venatoria and Loxosceles deserta inhibited $^{45}Ca^{++}$ influx by less than 50%, whereas Eriophora edax venom had no effect on $^{45}Ca^{++}$ influx. Basal $^{45}Ca^{++}$ influx was slightly inhibited (approximately 20%) by Plectreurys tristis and Peucetia viridans venoms, and slightly enhanced (approximately 20%) by Phidipus ardens venom. None of the active venoms exhibited substantial selectivity for inhibition of chick vs rat synaptosomal $^{45}Ca^{++}$ influx at 0.3 ul/ml. Selected venoms were characterized further against K^+-evoked ^{3}H-norepinephrine release (ω-CT-sensitive) and ^{3}H-D-aspartate release (ω-CT-insensitive) from rat hippocampal slices. For example, Agelenopsis aperta venom inhibited release of both transmitters with virtually identical potencies (IC_{50} ~ 0.03 ul venom/ml). The results suggest that spider venoms may be a rich source of toxins that inhibit ω-CT-sensitive and -insensitive VSCC.

462.2

THE EFFECTS OF VARYING [K^+] ON ω-CONOTOXIN GVIA (ω-CT) INHIBITION OF K^+-EVOKED RELEASE OF ^{3}H-NOREPINEPHRINE (^{3}H-NE) AND SYNAPTOSOMAL $^{45}Ca^{++}$ INFLUX.
T.J. Mangano, T.M. Piser, A.I. Salama and R.A. Keith. Department of Pharmacology, ICI Americas, Inc., Wilmington, DE 19897.

The effects of varying [K^+] on the inhibition of ^{3}H-NE release from rat hippocampal brain slices and evoked synaptosomal $^{45}Ca^{++}$ influx by ω-CT and neomycin (NEO) were examined. K^+ (15-100 mM) caused a concentration-dependent release of ^{3}H-NE that was greater than 90% dependent on extracellular calcium. The ability of ω-CT to inhibit ^{3}H-NE release was optimal at 25 mM K^+ and was substantially reduced at higher concentrations of K^+. ω-CT (0.1 uM) maximally inhibited ^{3}H-NE release by 49% (15 mM K^+), 63% (25 mM K^+), 20% (50 mM K^+), and 8% (75 mM K^+). In contrast, NEO caused a concentration-dependent and complete inhibition of ^{3}H-NE release at all concentrations of K^+, with IC_{50} values: 210 uM (15 mM K^+); 150 uM (25 mM K^+); 450 uM (50 mM K^+); and 1500 uM (75 mM K^+). ω-CT (1 uM) had little effect (less than 10% inhibition) on hippocampal synaptosomal $^{45}Ca^{++}$ influx at any concentration of K^+, whereas NEO could completely inhibit $^{45}Ca^{++}$ influx. The results suggest that inhibition by ω-CT of K^+-evoked ^{3}H-NE release is voltage dependent, or that ω-CT-resistant calcium channels are recruited at higher concentrations of K^+. The apparent absence of ω-CT-sensitive synaptosomal $^{45}Ca^{++}$-influx sites suggests that N-type calcium channels are a small subset of channels in synaptosomes. Dihydropyridines, selective L-channel antagonists, have been shown to have little effect on either ^{3}H-NE release or $^{45}Ca^{++}$-influx. Thus, NEO's inhibition of ω-CT-resistant responses may be due to activity at non-L/non-N voltage-sensitive calcium channels.

462.3

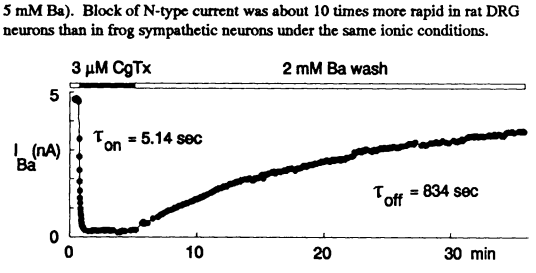
VENOM OF THE SPIDER, HOLOLENA CURTA, BLOCKS A DIHYDROPYRIDINE, ωCgTx RESISTANT VSCC IN MAMMALIAN SYNAPTOSOMES.
P.M. Lundy, A. Hong*† and R. Frew*, Defence Research Establishment Suffield, Box 4000, Medicine Hat, Alberta, T1A 8K6, Canada: †Applied Biosystems 850 Lincoln entre Drive, Foster City, Calif. 944404.

Two major high threshold VSCC's exist in neuronal tissue on nerve terminals (N and L type). Inhibition of the N or L type channel with omega conotoxin GVIA (ωCgTx) and the dihydropyridine (-) 202-791 respectively produces only slight reduction (– 25 percent) of measureable K^+ induced Ca^{2+} influx or the rise in intracellular [Ca^{2+}] in mammalian tissue (Lundy et al. Eur. J. Pharmacol. 206, 61. 1991). These results and others, suggest the existence of another undefined VSCC responsible for about 75 percent of the total measureable influx in rat synaptosomes. Venom from the funnel web spider Hololena curta potently (IC_{50} - 1:10,000 or 4.21 μg venom protein/ml) inhibited the Ca^{2+} influx in an apparently irreversible manner at depolarization times 1-30s. At higher concentrations (1:1,000 or 42.1 μg venom protein/ml) the inhibition was 90 percent complete. Inhibition was unaffected by prior incubation with ωCgTx plus (-) 202-791 (both 1 μM). The majority of this VSCC inhibitory activity was found in fractions with mol wt. > 3,000. The venom also blocked motor responses in a variety of electrically stimulated peripheral tissues and inhibited [^{3}H] noradrenaline release from the rat anococcygeus muscle without significant L channel activity. Hololena venom or the active constituent of hololena venom which inhibits this VSCC should provide useful tools to investigate the role of this novel Ca^{2+} channel in neuronal function.

462.4

ω-Conotoxin block of calcium channels in peripheral neurons: Reversibility and the influence of divalent cation concentration.
J. Morrill, L.M. Boland, and B.P. Bean, Dept. Neurobiology, Harvard Medical School, Boston, MA 02115

Ca channel block by ω-conotoxin (fraction GVIA) was investigated using whole-cell recordings from freshly dissociated peripheral neurons. ω-Conotoxin blocked about 50% of the high-threshold Ca channel current in rat DRG neurons and about 90% of the current in bullfrog sympathetic ganglion neurons. When frog sympathetic cells were bathed in 3 μM nimodipine, nearly all of the remaining Ba current was blocked by 3 μM ω-conotoxin. In frog sympathetic cells, with 2 mM Ba as charge carrier, block by 3 μM ω-conotoxin developed with a time constant of 7 sec. When the toxin was washed, recovery occurred with a time constant of about 800 sec (in cells with stable currents, see figure). Block was faster in lower external Ba and slower in higher Ba (τ ~3 sec with 0.5 mM Ba and τ ~54 sec with 5 mM Ba). Block of N-type current was about 10 times more rapid in rat DRG neurons than in frog sympathetic neurons under the same ionic conditions.



462.5

STRUCTURE-ACTIVITY ANALYSIS OF OMEGA-CONOTOXIN GVIA INTERACTION WITH NEURONAL CA++ CHANNELS. R.A.Lampe, J.H. Herman*, M.B.Horn*, R.A.Keith, R.Spreen*, M.W.McLane* and M.M.Lo. ICI Pharmaceuticals Group, Wilmington DE 19897.

Venom from the fish hunting snail species, Conus geographus, contains a 27 a.a. peptide known as omega-conotoxin GVIA (ω-GVIA). Preliminary structure-activity relationships (SAR) have demonstrated that this highly basic peptide, containing three intramolecular disulfide bonds, interacts with a subpopulation of mammalian neuronal Ca^{++} channels. To further evaluate the SAR of this peptide, biological profiles (ie, ω-GVIA binding to hippocampal membranes; Ca^{++} influx in chick synaptosomes) were obtained following either chemical modification or primary a.a. alteration of ω-GVIA.

Acetylation of primary amino moieties of Cys-1, Lys-2 and Lys-24, under non-saturating conditions, generated 7 (3 mono-, 3 di- and 1 tri-acetylated) distinct peptides. Positional assignment of acetylation was accomplished using a combination of tryptic digestion, RP-HPLC and MS. Biological assays indicate that successive acetyl additions lead to a loss of activity. From binding analyses, the N-terminal amine of Cys-1 is more significant than the ε-amino moieties of either Lys-2 or Lys-24. Selective modifications of the primary structure of ω-GVIA will be explored to evaluate the physiological relevance of other basic moities and of secondary structural features as a result of disulfide bridging.

462.6

ω–CONOTOXIN EXERTS FUNCTIONALLY DISTINCT LOW AND HIGH AFFINITY EFFECTS IN THE NEURONAL CELL LINE NG 108-15. J.L. Werth, L.D. Hirning, and S.A. Thayer. Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455, and Natural Product Sciences, Salt Lake City, UT 84108.

Depolarization-induced intracellular free Ca^{2+} concentration ($[Ca^{2+}]_i$) transients were recorded in single differentiated NG108-15 cells with the Ca^{2+} indicator indo-1 and a dual emission microfluorimeter. In differentiated NG108-15 cells a 30 second superfusion with 50 mM K^+ increased the $[Ca^{2+}]_i$ from a basal level of 142±10 nM to a peak level of 1655±287 nM. This $[Ca^{2+}]_i$ transient could be blocked completely and reversibly by the dihydropyridine Ca^{2+} channel blocker nitrendipine in a concentration dependent manner (IC 50= 1.9 nM). In contrast, 100nM ω-conotoxin GVIA (ω-CgTx) produced a maximal inhibition of the depolarization-induced rise in $[Ca^{2+}]_i$ of only 52%. The block was irreversible. Repeated applications of, or prolonged incubations with ω-CgTx failed to increase the maximal block. We have demonstrated that ω-CgTx distinguishes two populations of dihydropyridine-sensitive Ca^{2+} channels. Whole cell Ba^{2+} (5mM) current elicited by depolarization to 0 mV from -70 mV was inhibited 48% by 3μM ω-CgTx. Subsequent application of 3 μM nifedipine reduced the current by an additional 45% further indicating that there is a dihydropyridine-sensitve, ω-CgTx insensitive Ca^{2+} channel in these cells. ω-CgTx inhibition of indo-1 measured $[Ca^{2+}]_i$ increase was concentration-dependent but reversed in a graded manner at higher ω-CgTx concentrations. This entire U-shaped dose-response curve could be shifted in parallel fashion by modulation of the extracellular divalent metal concentration without changing the maximal inhibition. When divalents are reduced, treatment with a high (1 μM) concentration of ω-CgTx, which produced a modest (10%) inhibition of $[Ca^{2+}]_i$ increase, protected the cell from the effects of a second exposure to a normally effective concentration of ω-CgTx (10 nM). We conclude that there are two ω-CgTx binding sites on these cells, one to which ω-CgTx binds with high affinity and produces an irreversible Ca^{2+} channel blockade, and a second, lower affinity site to which ω-CgTx binds that does not block the channel but does prevent access to the high affinity site.

EXPRESSION OF AN [^{125}I] W-CONOTOXIN-SENSITIVE BINDING SITE IN MOUSE CORTICAL ASTROCYTES. M.C. Howell*, M.J. Litzinger, G.A. Skeen and H.S. White. Dept. of Pharmacol. & Toxicol. and Depts. of Biol., Physiol. and Pediatrics, Univ. of Utah, S. L. C. UT 84108

Previous investigations in this laboratory have demonstrated that mouse cortical astrocytes express a physiologically functional *w*-conotoxin-sensitive binding site. These results suggested that astrocytes possess an N-type voltage-sensitive Ca^{2+} channel (VSCC) since *w*-conotoxin is a rather specific marker of this VSCC type. Several reports have suggested that [^{125}I]*w*-conotoxin interacts with the L-type VSCC which is labeled with [^{3}H]nimodipine or [^{3}H]PN200. The present investigation was initiated in an attempt to ascertain whether nimodipine and *w*-conotoxin do interact with the same binding site. Results obtained thus far have demonstrated that [^{125}I]*w*-conotoxin binding increases pari passu with [^{3}H]nimodipine binding through the fourth culture week. After the fourth week in culture, [^{3}H]nimodipine binding decreases with culture age; whereas, [^{125}I]*w*-conotoxin binding plateaus. These results suggest that the ligands for the N- and L-type VSCC's are not interacting with the same binding site. Furthermore, physiological studies conducted with the Ca^{2+}-sensitive fluorescent probe Indo-1 have demonstrated that *w*-conotoxin completely blocks KCl (55 mM)-induced $[Ca^{2+}]_i$ transients, whereas nimodipine only attenuates KCl-induced $[Ca^{2+}]_i$ transients. The expression of distinctly different VSCC types on astrocytes may provide important pharmacological targets for drugs useful in the treatment of seizure disorders and stroke. Supported by NIH grant 2-RO1-NS22200 from the NINDS (HSW).

UNIQUE STRUCTURE OF THE PURIFIED ω-CONOPEPTIDE RECEPTOR FROM ELECTRIC RAY ELECTRIC ORGAN NERVE TERMINALS. M. Tsubokawa*, C. Kiraly*, A. Woppmann*, N. Liu*, G. Miljanich, and J. Ramachandran*, NEUREX Corporation, Menlo Park, CA 94025 and Biological Sciences, USC, Los Angeles, CA 98009.

Synthetic ω-conopeptides such as SNX-111 from *Conus magus* (see abstract by Miljanich, et al.) specifically block neuronal calcium channels. An SNX-111 receptor and putative calcium channel has been localized to the presynaptic membrane of nerve terminals of the electric organ of the electric ray, *Narcine brasiliensis*. The detergent solubilized receptor was purified 2,000-fold to near homogeneity using wheat germ agglutinin chromatography and SNX-111 affinity chromatography. In solution, the native receptor appears to be a multi-subunit complex (Mr=1,500,000-2,000,000) as shown by SDS-PAGE under nonreducing conditions. The molecular weight of the receptor shifted in two steps upon exposure to reducing agent. A single band of Mr=350,000 was observed with 0.1mM DTT and a doublet of Mr=200,000 and Mr=180,000 was observed with 25mM DTT. Cross-linking experiments with intact synaptosomes provided further evidence that the purified protein is the presynaptic conopeptide receptor. That is, ^{125}I-SNX-111 specifically labeled a band of Mr>1,000,000 under nonreducing conditions and a single band of approximately 210,000 under reducing conditions. Thus, it is likely that one of the affinity purified polypeptides contains the conopeptide binding domain and that it is disulfide-linked to the other polypeptide to form a heterodimer. Moreover, several heterodimers are linked through disulfide bonds to form a multi-channel complex.

NOVEL ω-CONOPEPTIDES REVEAL CALCIUM CHANNEL SUBTYPES: BINDING. G. Miljanich, K. Gohil*, R. Kristipati*, A. Woppmann*, S. Bowersox*, K. Tarczy-Hornoch*, L. Nadasdi*, J. Fox, J. Bell*, and J. Ramachandran*. NEUREX Corporation, Menlo Park, CA 94025 and Biological Sciences, USC, Los Angeles, CA 90089.

Synthetic ω-conopeptides, SNX-111 ("111") from *Conus magus* and SNX-183 ("183") from *C. striatus*, appear to define at least four subclasses of brain voltage-sensitive calcium channels (VSCC's). In rat brain synaptosomal membranes, 111 was more potent than 183 in displacing binding of [125I]-111 ("*111"; IC_{50}'s of 10pM and 2nM, respectively) whereas 183 was more potent than 111 at displacing *183 (IC_{50}'s of 4nM and 94nM), suggesting two binding sites. Thus, 111 displays high affinity for site 1 only, whereas 183 has about equal affinity for site 1 and site 2. These sites are likely to be associated with VSCC's, since binding behavior correlates with inhibition of calcium-dependent transmitter release (see abstract by Rivnay, *et al.*). Covalent cross-linking of *111 to its receptor and subsequent SDS-PAGE specifically labeled only a 210KDal polypeptide band representing the site 1 VSCC. Displacement by unlabeled 111 and 183 showed single site binding. *183 specifically cross-linked to polypeptide bands of 210, 172, 150, and 138KDal. Displacement by 111 and 183 revealed two co-migrating 210KDal polypeptides representing two binding sites and presumably reflecting site 1 and 2 VSCC's. Receptor autoradiography in brain slices with *111 showed relatively dense, localized binding in cortex, caudate, and hippocampus, for example, while large areas of midbrain exhibited much less labeling. As expected, *183 labeled regions that were labeled by *111 plus additional regions (some thalamic nuclei, for example). Surprisingly, some areas, such as substantia nigra, were labeled by *111 but not by *183. Thus, four subclasses of VSCC's may be defined as those binding 111 and 183, 183 only, 111 only, and neither.

NOVEL ω-CONOPEPTIDES REVEAL CALCIUM CHANNEL SUBTYPES: TRANSMITTER RELEASE. B. Rivnay*, J. Fox, R. Newcomb, K. Gohil*, S. Cain*, A. Palma*, P. Adriaenssens*, L. Nadasdi*, G. Miljanich, J. Bell*, J. Ramachandran*. NEUREX Corp., Menlo Park, CA, 94025.

Synthetic ω-conopeptides (see abstract by Miljanich et al) block the potassium induced release of radiolabeled norepinephrine (NE) or dopamine (DA) from rat hippocampal slices. SNX-111 blocked NE release partially (50-70%) with an IC_{50} of 1 nM whereas SNX-183 inhibited K^+ induced release completely with an IC_{50} of 400 nM. In contrast, SNX-183 was much more effective in blocking DA release (IC_{50} 160 nM) than was SNX-111 (IC_{50} > 1000 nM).

Two sets of experiments confirm that the conopeptides block neurotransmission in a more physiological setting. EPSP field potentials elicited by electrical stimulation in rat hippocampal slices *in vitro* were reversibly blocked by a variety of Neurex conopeptides and again were more completely blocked by SNX-183 (~100%) than SNX-111 (~50%). The compounds also blocked neurotransmitter release *in vivo* in the rat. Extracellular concentrations of Glu and GABA as monitored by *in vivo* microdialysis during potassium infusion through the probe were inhibited in the hippocampus and thalamus by about 50% by SNX-111 as compared to the levels of the nontransmitter amino acid serine.

These techniques provide functional evidence for the presence of multiple subtypes of voltage gated calcium channels and thus extend the binding data presented in the abstract by Miljanich et al.

462.11

METABOLISM OF VOLTAGE-OPERATED CALCIUM CHANNELS IN HUMAN NEUROBLASTOMA CELLS. E. Sher*, M. Passafaro*, P. Strata° and F. Clementi*, CNR Ctr. of Cytopharmacology, Dept. of Medical Pharmacology, Univ. of Milano, Milano, and °Dept. of Anatomy & Human Physiology, Univ. of Torino, Torino, Italy.

ω-Conotoxin (ωCTx) binds and blocks a particular subtype (ω) of voltage-operated calcium channels (VOCCs) present in both neuronal and endocrine cells. We have used human neuroblastoma cell lines (IMR32 and SH-SY5Y) to study the metabolism of the ω-type VOCC, and its modulation. We have determined the half-life of the channel with two procedures by measuring the rate of disappearance from the cell surface of ^{125}I-ωCTx labeled VOCCs, and by determination of the number of VOCCs present at the cell surface at different time points after treatment of the cells with cycloheximide. In both cases the measured half-life of ω-type VOCCs was between 16 and 20 hours (average 18±1). Toxin binding *per se* therefore did not affect channel turnover. By using an "acid-washing" procedure, we measured both the rates of channel internalization and degradation. At 37°C the two rates were parallel and at 4°C they were both blocked. At 20%C, however, channel internalization proceeded normally, but the channels were not degraded, and were intracellularly accumulated. The 20°C effects were mimicked by chloroquine and leupeptin in a dose-dependent manner. ω-type VOCC turnover could be modulated in neuroblastoma cells after differentiation induced by several drugs. The half-life was significatively increased leading to an increase of membrane VOCCs. On the other hand, anti-channel autoantibodies from Lambert-Eaton myasthenic syndrome patients induced an increase in the rates of channels internalization and degradation, leading to a reduction in surface channels.

DOSE RESPONSE RELATION FOR SYNTHETIC FTX BLOCK OF VOLTAGE-DEPENDENT CALCIUM CURRENTS IN DISSOCIATED PURKINJE CELLS M. Sugimori, B. Cherksey and R. Llinas
Dept. of Physiology and Biophysics, NYU Medical Center, New York, N.Y. 10016

Dissociated cerebellar Purkinje cells from guinea pig were studied using whole cell voltage clamp technique (Kay 1989, Dissection of tissue culture, Alan R. Liss Inc.). The properties of of synthetic arginine-polyamines derived as possible analogs of the naturally occurring FTX (Cherksey et al 1989, Biol. Bull., 177: 321) were tested as potential calcium channel blockers. Three structures were studied FTX(3:3), FTX(4:3) and FTX(3:4) (see Cherksey et al. this meeting).

The results indicate that of these three polyamines FTX(3:3), FTX(4:3) and FTX(3:4) have decreasing abilities of blocking. The most potent FTX(3:3) is capable of reducing calcium currents at the initial dose at the 100 nanomolar level. This block increases in magnitude such that at close to ten micromolar level calcium current is almost totally blocked. A similar set of experiments in which FTX(4:3) and FTX(3:4) permutations of polyamine were tested demonstrate that the FTX(4:3) was approximately one order of magnitude less potent than FTX(3:3) and that the FTX(3:4) permutation was basically not effective.

These results indicate that FTX action-like polyamines, which have a dose response curve suggesting a powerful binding to these channels, have been shown to be specific blockers for the so-called P-channel (Llinas et al 1989, PNAS 86:1689). Moreover these polyamines, which do not block the L, T or N type calcium channels (Fox et al 1987, J. Physiol. 394: 149) or the sodium or potassium currents at the levels utilized, may ultimately represent an element of a family of polyamines, normally present in the brain, that regulate channel activity.

EFFECTS OF (+) AND (-) ENANTIOMERS OF SDZ 202-791 ON 15mM K$^+$-STIMULATED [^{3}H]5-HT RELEASE IN RAT SPINAL CORD SYNAPTOSOMES. V.C. Gandhi and D.J. Jones. Depts. Anesth. & Pharm., Univ. Texas Hlth. Sci. Ctr., San Antonio, TX 78284-7838

Previous studies from this laboratory established that L-type calcium channels activated by the dihydropyridine (DHP) agonist Bay K 8644 modulate the K$^+$-stimulated release of [^{3}H]monoamines from spinal cord synaptosomes (Eur. J. Pharmacol. 187:271-281, 1990). Under similar conditions, activation of protein kinase C (PKC) by phorbol 12-myristate 13-acetate (PMA)also enhanced 15mM K$^+$-stimulated release. The enhancement due to either PMA or Bay K 8644 was blocked by DHP antagonists as well as inhibitors of PKC suggesting a coupling of these two systems. The present studies further evaluated this relationship by examining the effects of enantiomers of the DHP SDZ 202-791 on K$^+$-stimulated release of [^{3}H]5-HT from spinal cord synaptosomes.

Bay K 8644 (1uM) typically produced a 40-60% enhancement of 15mM K$^+$-stimulated [^{3}H]5-HT release. Whereas (+) SDZ 202-791 (1uM) increased release 38 ± 4.8% over control, (-) SDZ 202-791 was inactive. The effects of (+) SDZ 202-791 were blocked by nifedipine (1uM). Activation of PKC with PMA (0.2uM) in the presence of 15mM K$^+$ increased release of [^{3}H]5-HT 30-40%. This effect is blocked by PKC inhibitors and also the DHP antagonist nifedipine. PKC inhibitors also antagonized the enhanced release of [^{3}H]5-HT due to Bay K 8644 or (+) SDZ 202-791. (-) SDZ 202-791 antagonized the PMA-induced enhancement in K$^+$-stimulated release. The present results suggest a common pathway linking the L-type voltage dependent Ca^{++}-channel and PKC in enhancing K$^+$-stimulated release of [^{3}H]5-HT from spinal cord synaptosomes. The L-type channel site demonstrates stereospecificity for DHP binding, activation, Ca^{++} influx and enhanced [^{3}H]5-HT release. Supported by NSF BNS-8820008.

HIGH AFFINITY [^{3}H]RYANODINE BINDING SITES IN POSTMORTEM HUMAN BRAIN. M.B. Stein*, R.A. Padua, J.I. Nagy, and J.D. Geiger, Depts. Pharmacology and Psychiatry, Univ. Manitoba. Winnipeg, Manitoba R3E 0W3.

[^{3}H]Ryanodine binding sites have been characterized pharmacologically and localized autoradiographically in rat brain [Padua et al., Brain Res. 542 (1991): 135-140; Soc. Neurosci. Abs. 1991]. Here we examined high affinity [^{3}H]ryanodine binding sites in crude membrane preparations of postmortem human brain. Saturation analyses revealed a single class of high affinity sites with a K_D value of 3.6 nM and a B_{max} value of 99 fmol/mg protein. In competition studies, unlabelled ryanodine displaced its radiolabelled counterpart with a K_i value of 7 nM. Binding was found to be dependent on the concentration of free Ca^{2+} with an EC_{50} value of 139 μM. Binding was reduced by 25% in the presence of 5 mM Mg^{2+} and was restored with the addition of 10 mM caffeine. Caffeine alone did not significantly alter the levels of binding. The distribution of [^{3}H]ryanodine binding sites in human brain was heterogeneous with high levels observed in putamen and caudate nucleus, intermediate levels in cortex, hippocampus and globus pallidus, and low levels in cerebellum. The high levels of binding seen in basal ganglia suggest that ryanodine receptors may be particularly important here in the regulation of intracellular calcium and may be relevant to such disorders as neuroleptic malignant syndrome, Huntington's disease, and Parkinson's disease.

462.15

PHARMACOLOGY AND CELLULAR LOCALIZATION OF [^{3}H]RYANODINE RECEPTORS IN RAT BRAIN. R.A. Padua, W. Wan, D. Fyda, T. Yamamoto, J.D. Geiger and J.I. Nagy. Depts. Physiol. and Pharmacol., Univ. Manitoba. Winnipeg, Manitoba R3E OW3.

[^{3}H]Ryanodine binding sites were previously found in various crude subcellular fractions of rat brain (Padua et al., Brain Res. 542 (1991): 135-140). Here we examined the pharmacological characteristics of these sites, their localization in purified subcellular fractions, and their distribution throughout rat brain. Saturation analyses of binding in crude membrane preparations revealed a single class of high affinity sites with a K_D value of 7.6 nM and a B_{max} value of 193 fmol/mg protein. Competition studies with unlabeled ryanodine showed the presence of both high and low affinity sites with K_D and B_{max} values of 1.6 nM and 24 μM, and 86 fmol/mg protein and 23 pmol/mg protein, respectively. Association and dissociation rate constants were $3x10^7$ $M^{-1}min^{-1}$ and 0.001 min^{-1}, respectively. [^{3}H]Ryanodine binding was Ca^{2+}-dependent; EC_{50} 119 μM. Binding was inhibited by Mg^{2+}, ADP, dB-cAMP, nifedipine, verapamil, trifluoperazine and various benzodiazepines, but not by IP_3 or caffeine. Synaptosomes isolated from crude mitochondrial/synaptosomal fractions, displayed high affinity (K_D 6.1 nM) and a 4 fold greater level of [^{3}H]ryanodine binding (B_{max} 67 fmol/mg protein) compared with that found in purified mitochondria. Binding was enriched in a subfraction of microsomes that contained low activities of enzyme markers for plasma membrane and endoplasmic reticulum. Autoradiographically, the highest levels of [^{3}H]ryanodine binding sites were found in regions of the cortex, hippocampus and olfactory bulb. Lesions in the hippocampus revealed the presence of these sites in neurons. In addition, evidence was found for their localization in mossy fiber terminals suggesting that ryanodine receptors in these terminals may be involved in the regulation of Ca^{2+} mobilization and/or neurotransmitter release.

462.16

DISTRIBUTION OF RYANODINE RECEPTORS IN THE CNS Y. Ouyang*+, T. J. Deerinck*+, P. D. Walton*‡, J. A. Airey*‡, S. J. Young+, J. L. Sutko*‡, and M. H. Ellisman+. San Diego Microscopy and Imaging Resource, + Dept. of Neurosciences, Univ. of Calif. San Diego, La Jolla, Calif.92093; ‡Pharmacology, Univ. of Nevada, Reno, Nevada, 89557.

We recently identified two ryanodine binding proteins (α and β ryanodine receptors, RR's) in the chicken CNS using antibodies against the purified skeletal muscle RR (Ellisman et al., Neuron, 5:135-146, 1990). In skeletal muscle, RR's are associated with Ca release from the intracellular SR membrane system. A similar function is probable in neurons as these proteins are most concentrated in intracellular membranes of cerebellar Purkinje cells, known to manifest fluctuations in cytosolic Ca. In order to gain a better understanding of the functional significance of neuronal RR's we have studied the distribution of these receptors throughout the chicken CNS with a monoclonal antibody, 34C, that recognizes both isoforms. Nuclei demonstrating the strongest RR-immunoreactivity include those containing very large neurons such as: nucleus ruber, nucleus reticularis pontis oralis, nucleus cerebellaris, paleostriatum primitivum (globus pallidus), nucleus vestibularis lateralis, nucleus laminaris, and the nucleus magnocellularis cochlearis. Prominent staining was also found in spinal motor neurons, the olfactory bulb, and in spinal ganglia. Staining was observed in perikarya, dendrites and axons. The subcellular pattern of staining appears similar to that previously noted for cerebellar Purkinje neurons in that no labeling of dendritic spines was detected.

We also determined whether RR-like immunoreactivity outside the cerebellum was a consequence of the presence of the α, β, or both forms. Monoclonal antibodies 110F and 110E, which are specific for the α and β forms, respectively (Airey et al., J. Biol. Chem. 265:14187-14194, 1990), were used to probe alternate sections of the same brains. As in the Purkinje neurons, immunoreactivity to both α or β forms occurred in other brain regions. However, in contrast to the Purkinje neuron where the α form predominates, we observed the strongest immunoreactivity for the β form in neurons outside the cerebellum. Differences in the distributions of these distinct RR isoforms will be investigated further.

MULTIPLE BRAINSTEM PROJECTION TARGETS OF LATERODORSAL TEGMENTAL (LDT) AND PEDUNCULOPONTINE TEGMENTAL (PPT) NUCLEUS CHOLINERGIC NEURONS IN THE RAT. M. Yanagihara, K. Ito*, L. Dauphin*, D. Fuchs*, & R. W. McCarley. Lab. Neurosci., Dept. Psychiatry, Harvard Med. Sch./VAMC, Brockton Ma 02401.

Our laboratory has shown cholinergic LDT/PPT neurons have projections to both ipsilateral and contralateral giant cell field (here abbreviated GCF, = FTG in cat) of pontine reticular formation (PRF); these projections have been implicated in the production of REM sleep phenomena. The present study used triple-labeling techniques to examine whether the same LDT/PPT neuron projects to brainstem GCF and also to other brainstem regions. Projection targets were identified by retrograde transport of either rhodamine- or fluorescein-conjugated latex beads stereotaxically placed in GCF and, contralaterally, in other brainstem sites. After 2-3 days survival, rats were sacrificed and ChAT-immunoreactive neurons were labeled with aminomethylcoumarin (AMCA). RESULTS: Double-labeling data confirmed PPT/LDT cholinergic projections to pontine GCF, with PPT density > LDT. Triple labeling studies showed that approximately 10% of cholinergic PPT neurons projecting to pontine GCF also projected to the small cell PRF zone just ventral to locus coeruleus (often termed LC_α) that is implicated in the production of muscle atonia of REM sleep. Cholinergic ipsi- and contra-lateral PPT/LDT projections to Motor V nucleus were present, and many of these neurons also projected to pontine GCF. Finally, cholinergic PPT projections to bulbar GCF were present (less dense than PPT-->pontine GCF), and some cells also projected to a small cell bulbar reticular zone. We conclude that this innervation of multiple brainstem targets may provide a substrate for coordination of REM sleep phenomena.

463.2

CHOLINERGIC NEURONS IN THE LATERODORSAL TEGMENTAL NUCLEUS RECEIVE SYNAPTIC INPUT FROM CATECHOLAMINERGIC AXON TERMINALS IN THE RAT. Y. Kubota and S.R. Vincent. Kinsmen Lab. of Neurol. Res., Dep. of Psychiatry, Univ. of British Columbia, Vancouver, BC V6T1Z3, & Neural Systems Lab., Frontier Research Program, RIKEN, Wako, Saitama 351-01, Japan

The cholinergic neurons of the laterodorsal tegmental nucleus (TLD) are located just medial to the locus coeruleus in the pontine and have connections with cortex, septum, thalamus, hypothalamus, basal ganglia, tectum, and spinal cord. We studied the ultrastructure of choline acetyltransferase (ChAT) immunoreactive neurons and the synaptic relationship between them and tyrosine hydroxylase (TH) immunoreactive axon terminals in TLD. Many large ChAT immunoreactive neurons were present in TLD. They have a few processes, sometimes closely apposed to the blood vessel and received many synaptic contacts from non-immunoreactive axon terminals on their cell soma, dendrites and spines. Using double immunohistochemistry, ChAT-immunoreactive cells stained with β-galactosidase, showed blue colored reaction product in the light microscope and dot like immunoreactivity in the electron microscope, while TH immunoreactivity detected with a glucose-oxydase DAB reaction was dark brown in the light microscope and showed difuse electron dense material in the electron microscope. Therefore we could distinguish the difference between these two different kinds of immunoreactivity quite easily at both light and electron microscopic level. Using this double staining technique, ChAT immunoreactive neurons were found to receive synaptic contacts from TH immunoreactive axon terminals on their soma and proximal dendrites in TLD.

463.3

SEROTONIN HYPERPOLARIZES CHOLINERGIC LATERODORSAL TEGMENTAL NUCLEUS NEURONS IN THE RAT BRAIN SLICE

J.I. Luebke, R.W. Greene, K. Semba^, McCarley, R.W., A. Kamondi^^ and P. Reiner^^Neurosci. Lab., Harvard Med. Sch.\VAMC, Brockton, MA., ^Dept. Anat. Dalhousie U. Med. Sch. Halifax, Nova Scotia, ^^Kinsman Lab., U. British Columbia, Vancouver, B.C.

Intracellular and whole cell patch clamp techniques in the rat brainstem slice were employed to examine the response to serotonin (5-HT) and carboxamidotryptamine maleate (5-CT) of identified cholinergic and non-cholinergic low threshold burst (LTB) and non-LTB neurons in the laterodorsal tegmental nucleus (LDT). Two-thirds of the neurons were LTB and one-third were non-LTB. The majority (83%) of the LTB neurons were identified as cholinergic, while the minority (33%) of the non-LTB neurons were cholinergic. The principal finding was that most **cholinergic** LDT neurons responded to 5-HT and 5-CT with a membrane hyperpolarization and decrease in membrane resistance. Voltage and patch clamp recordings revealed that the hyperpolarizing response was the result of an inwardly rectifying current having a reversal potential of -90mV and associated with an increase in membrane conductance. Serotonin altered the firing pattern of LTB neurons in response to hyperpolarizing and depolarizing steps. In control conditions, when the membrane potential was relatively depolarized, LTB neurons responded to hyperpolarizing but not depolarizing current steps with a low threshold burst. In the presence of serotonin the LTB neurons were relatively hyperpolarized and responded to depolarizing but not hyperpolarizing current steps with a burst firing pattern. Thus the effect of serotonin can be to alter the firing pattern of cholinergic LTB neurons in the LDT in response to hyperpolarizing and depolarizing inputs.

463.4

5-HT AND MUSCARINE HYPERPOLARIZE A SUBPOPULATION OF NEURONS IN RAT NUCLEUS RAPHE MAGNUS IN VITRO. Z.Z. Pan* and J.T. Williams. *Vollum Institute, Oregon Health Sciences University, Portland OR 97201*

Both 5-HT and Ach have been implicated in the antinociceptive function of nucleus raphe magnus (NRM). Intracellular recordings were made from NRM cells in a slice preparation. 5-HT and 5-HT_1 receptor agonists hyperpolarized most NRM neurons. The hyperpolarization (X_{max} =12 mV) was blocked by spiperone (1 μM), but not dopamine receptor antagonists, suggesting that a 5-HT_{1A} receptor mediated the response. In a proportion of neurons that were hyperpolarized by 5-HT, muscarine also caused a dose-dependent hyperpolarization (X_{max}=10 mV). The dose response curve for muscarine was shifted to the right by pirenzepine (300 nM - 3 μM) and methoctramine (50 nM - 200 nM). Schild regression analysis indicated that a non-M_1 (possibly M_2) muscarinic receptor is probably involved. Both 5-HT and muscarine caused an outward current with similar voltage dependance, showing inward rectification that was abolished by $BaCl_2$. The reversal potentials were about -90 mV in normal potassium and shifted to less negative potentials when extracellular K^+ was increased. In addition, the currents induced by 5-HT and muscarine were not additive. The results suggest that both 5-HT and muscarine inhibit a population of the NRM neurons by increasing the same inwardly rectifying K^+ conductance, an effect that may be involved in the modulation of opioid analgesia in NRM. Supported by NIH grants DA04523 and MH45003.

EFFECTS OF TETRAHYDROACRIDINE (THA) ON SYNAPTIC TRANSMISSION AND SENSITIVITY TO ACH OR GLUTAMATE OF VISUAL RELAY NEURONES. C. Berti*, R. Levy and A. Nistri[1]. Dept. Old Age Psychiatry, Inst. Psychiat., Univ. London; [1]Pharmacol. Dept., Queen Mary and Westfield College, London E1 4NS, U.K.

In lower vertebrates neurotransmission between the optic nerve and relay neurones is probably glutamatergic and upregulated by nicotinic receptors. The action of the antiChE agent THA (currently studied for treating Alzheimer's disease) on glutamatergic and cholinergic responses of the isolated frog optic tectum was investigated with electrophysiological recordings. THA (0.1-1 μM) increased by up to 30% the half amplitude of population EPSPs elicited by optic nerve stimulation but it failed to do so in the presence of 100 μM neostigmine. No change in afferent volley spikes was noted. The EPSP-enhancing action of ACh was potentiated by 1 μM THA (without changing the maximum response) whereas it was antagonized by 10 μM THA. In neostigmine solution 1 μM THA increased responses to low doses of ACh but depressed those to large ones. No change in responses to 100 μM carbachol was found. The EPSP-enhancing action of low doses of glutamate was augmented by 0.1 - 1 μM THA, while no change in responses to 0.5 mM GABA was seen. These data suggest that THA possesses cholinomimetic activity partly due to its antiChE properties. The enhancement of responses to exogenous glutamate by THA indicates an additional postsynaptic action of this compound leading to facilitation of excitatory synaptic transmission.

463.6

DENDRITIC MORPHOLOGY OF CHOLINERGIC AND NON-CHOLINERGIC RETICULAR FORMATION NEURONS PROJECTING TO THE THALAMUS IN THE RAT. Kazue Semba. Dept. of Anatomy, Dalhousie Univ., Halifax, Nova Scotia, Canada B3H 4H7.

Neurons in the brainstem reticular formation (RF) are known to play important roles in the activation of the thalamus during waking and REM sleep. Many of RF neurons projecting to the thalamus are cholinergic, and acetylcholine has been shown to facilitate sensory transmission in the thalamus. However, there are also non-cholinergic RF neurons with thalamic innervation, and current data correlating physiology, transmitter phenotype, projection, and morphology of RF neurons are discrepant. To clarify the relationship between transmitter phenotype and morphology of RF neurons innervating the thalamus, we used a combination of retrograde fluorogold tracing, immunofluorescence for choline acetyltransferase, single cell injection with lucifer yellow in fixed slices, and/or immunohistochemistry with an antibody to fluorogold. Cholinergic RF neurons projecting to the thalamus had large somata with 4-5 thick primary dendrites. Secondary and tertiary dendrites tended to have a wavy appearance and extended in several directions up to 500 μm from the somata, sometimes beyond the boundary of the nucleus. Spines were frequent, particularly on distal dendrites. At least some non-cholinergic RF neurons with thalamic projection that were intermixed with cholinergic neurons displayed similar morphology. In contrast, non-cholinergic neurons in the central tegmental field with thalamic projection had smaller, round somata with 3-4 thinner, aspinous dendrites oriented perpendicular to the central tegmental tract. These findings indicate that cholinergic RF neurons projecting to the thalamus have morphology similar to cortically projecting basal forebrain neurons. The morphological differences of RF neurons innervating the thalamus may reflect their distinct roles in the control of waking and REM sleep. DUAL PROJECTIONS OF SINGLE CHOLINERGIC AND AMINERGIC BRAINSTEM NEURONS TO THE BASAL FOREBRAIN AND THALAMUS IN THE RAT. Bruno J. Losier and Kazue Semba. Departments of Psychology and Anatomy, Dalhousie University, Halifax, N.S., Canada B3H 4H7.

Recent evidence indicates that during waking cholinergic basal forebrain neurons are strongly activated, whereas in the thalamus spindle activity is suppressed and sensory transmission facilitated. Both of these subcortical structures receive projections from the brainstem cholinergic and aminergic neurons, and these neurons are known to be active during waking. However, it remained unclear whether single transmitter-specific brainstem neurons contributed to both of these ascending projections. In the present study we examined this possibility of dual projections by injecting two fluorescent retrograde tracers into the thalamus and basal forebrain, followed by immunohistochemistry with antibodies to choline acetyltransferase, tyrosine hydroxylase, serotonin, and histidine decarboxylase. Cholinergic neurons projecting to both the basal forebrain and thalamus were found in the pedunculopontine and laterodorsal tegmental nuclei, and noradrenergic dually projecting neurons were seen in the locus coeruleus. However, few serotonergic neurons in the brainstem appeared to have the dual projection. In conclusion, subpopulations of cholinergic and aminergic neurons in the brainstem have branching axons that innervate both the basal forebrain and the thalamus. Through these dual projections, these single transmitter-specific neurons can concurrently modulate the activity of both subcortical structures during cortical arousal. Supported by the MRC, Alzheimer Society, and Scottish Rite Charitable Foundation of Canada.

CORTICAL CHOLINERGIC FIBERS IN THE HUMAN BRAIN: AN IMMUNOCYTOCHEMICAL STUDY OF THE HIPPOCAMPAL FORMATION. C. Lim, S. de Lacalle and C.B. Saper. Department of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637, USA.

The cholinergic innervation of the hippocampal formation is thought to play an important role in regulating memory consolidation. We investigated the organization of the cholinergic innervation of the human hippocampal formation by using polyclonal antisera against human placental choline acetyltransferase (ChAT - gift of Dr. L. Hersh) and acetylcholinesterase (AChE - gift of Dr. S. Younkin) in a series of normal individuals. Staining in selected sections was intensified by a modification of the Fontana-Masson method. Fine, varicose ChAT-immunoreactive (ir) fibers were found densely innervating the different hippocampal fields in a laminar pattern that was similar to that previously reported in other species. In the dentate gyrus, there was dense ChAT-ir innervation of the granular, and the infra- and supra-granular layers. Diffuse ChAT-ir innervtion was seen in the CA3 field and mainly in the infrapyramidal layer of CA1, but little innervation was seen in CA2. A much larger number of fine, smooth AChE-ir fibers were seen in the hippocampal formation providing a more extensive and somewhat different pattern of innervation than was revealed by the ChAT staining. For example, the CA2 field was the most densely innervated in AChE-stained material. These observations indicate that cholinergic innervation plays a major role in the function of the human hippocampus, but that the AChE-stained fiber distribution does not provide an accurate estimate of the cholinergic innervation.

463.9

PROJECTIONS OF THE BASAL FOREBRAIN TO VISUAL CORTICAL AREAS IN THE CAT. Christopher C. Nabors* and Kenneth E. Kratz, Department of Anatomy, Louisiana State University Medical Center, New Orleans, LA 70112.

Cells of the basal forebrain provide cholinergic input to the entire neocortex. In the present study retrograde tracer techniques (rhodamine labelled latex microspheres and WGA-HRP) combined with ChAT immunocytochemistry were used to examine the topography of the forebrain projections to functionally defined visual cortical areas in the cat. Our results indicate that primary visual cortex (area 17) is heavily innervated by the nuclei of the diagonal band with a less dense innervation from the more lateral and caudal cell groups of the basal forebrain. On the other hand areas 18 and 19 along with the visual association areas of the lateral suprasylvian gyrus and areas 20 and 21 receive a substantial input from the diagonal band nuclei but receive their most dense projection from the substantia innominata, neurons within the putamen and globus pallidus, and neurons scattered within the internal capsule. It appears that the processing of visual information in functionally distinct areas of cortex may be subject to different regulatory inputs from the cell groups of the basal forebrain. The diagonal band nuclei may play an important role in the gating of sensory information into the primary areas of visual cortex while the more lateral cell groups may have a greater influence over higher order processing of visual information.

463.10

PRIMATE NUCLEUS BASALIS NEURONS DEVELOP RESPONSES TO STIMULI ASSOCIATED WITH WATER REWARD. R.T. Richardson Dept. Neurology, Johns Hopkins Univ., Baltimore, MD 21205

We have previously reported that a large proportion of neurons of the nucleus basalis in naive monkeys had altered discharge rates following arousing stimuli (water reward, air puff, hypertonic saline). In contrast, far fewer basalis neurons responded to neutral stimuli such as tones and perturbations of the forearm. We now report that many more basalis neurons respond to neutral stimuli that have become associated with a water reward.

Conditioning procedures have been completed in one juvenile male rhesus monkey. In the first phase of testing, one of two torques (150 g to the left or right applied to the forearm) was a CS+ which preceded a water reward by 1.5 to 2 s, and the other stimulus of the same modality was a CS- which never preceded a water reward. After several months, one of two tones (500 Hz and 1000 Hz) became the CS+ and the other was the CS-. The CS+ and CS- were periodically reversed.

In the naive monkey, 21% of 141 basalis neurons responded to the somatosensory stimuli, but in the conditioned animal, 72% of 68 neurons responded to torques. Of the 49 responsive neurons, 47% had noticeably larger responses to the CS+ than to the CS-, and 8% had larger responses to the CS- than to the CS+. Similar results were obtained for the auditory stimuli. Only 3% of 74 basalis neurons responded to tones in the naive animal, compared to 55% of 78 neurons in the conditioned animal. Of the 43 neurons responding to tones, 42% had larger responses to the CS+, and 5% had larger responses to the CS-. These findings provide further evidence that many basalis neurons are primarily responsive to stimuli that are inherently arousing to the animal (aversive or appetitive stimuli) or that have become arousing through conditioning procedures.

CORTICAL AND BASAL FOREBRAIN NEURONAL ACTIVITY FOLLOWING PERIPHERAL NERVE TRANSECTION. H.H. Webster and R.W.Dykes. Dept. of Physiology, University of Montreal, Montreal, Canada. H3C-3J7.

Recent reports have shown that acetylcholine (ACh) acts as a neromodulator to influence cortical reorganization after damage to the peripheral sensory system. some of these conclusions have been deduced from a depletion of the transmitter following destruction of cells in the basal forebrain or of the fibers projecting from those cells. However, other reports have also suggested that ACh may not be the main neuromodulatory agent involved in this process or that the basal forebrain cholinergic neurons may not be the source of the ACh. In order to further investigate the role these cells may be playing in response to peripheral nerve lesions we recorded spontaneous, extracellular single unit activity from the hindpaw somatosensory cortex and from in the basal forebrain before and 4 days after transection of the sciatic nerve in adult rats. Typically, one penetration was made with a tungsten-in-glass microelectrode over the hindpaw cortex at AP -1.8; and ML 3.0, sampling continuously from the surface of the cortex to 8.0 ml below the surface where cholinergic cells of the basal forebrain are located. The location of the electrode tract and tip was confirmed in sections stained for Nissl substance. These results show that in the cortex and basal forebrain, in general spontaneous activity is higher and spike duration is longer in transected than in controls, and support idea that the basal forebrain participates in the reoganization process following peripheral nerve lesions.

MEMBRANE PHOSPHOLIPIDS IN FRONTAL CORTEX ARE DECREASED FOLLOWING NUCLEUS BASALIS LESIONS IN THE RAT. T.C. Holmes, R. Nitsch, and R.J. Wurtman. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Membrane phospholipid (PL) metabolism is abnormal in Alzheimer's disease (AD) brain. Levels of glycerophosphocholine and glycerophosphoethanolamine are increased by 50-100 % whereas free choline and ethanolamine are reduced by 25-50 %. In order to develop a rat model for these changes, we examined the effects on PL metabolism in frontal cortex (FC) by lesioning the cholinergic nucleus basalis (nBM). Rats received ibotenic acid (10 mg/ml in PBS, 0.5 ul) in one nBM, and FC sections were obtained after 1 week. Choline acetyltransferase (ChAT, nmol acetylcholine/μg protein/hr) activity in FC was lower ($P<0.01$, n=9) on the lesioned side (275±17) than the contralateral side (371±12). Total membrane PL (nmol/mg protein) in adjacent FC sections exhibited concomitant decreases in total membrane PL ($p<0.01$, n=9, Newman-Keuls test, 417±9 vs. 435±9). These data show that impaired cholinergic neurotransmission results in depletion of membrane phospholipids in cholinergic target regions. Supported by NIMH grant MH-28783.

463.13

THE EFFECT OF SOMAN ON THE VISUAL EVOKED RESPONSE OF THE CAT. A.W. Kirby, A.T. Townsend*, C.D. Pope*, B.A. Lanoue*, T.A. Tapia* and J.B. Lopez*. USAARL, Ft. Rucker, Al 36362.

Both diisopropylfluorophosphate (DFP) and soman are irreversible inhibitors of cholinesterase (ChE). DFP is used widely to investigate cholinergic function, while soman is a chemical warfare agent. Last year at this meeting we presented evidence suggesting that DFP has some noncholinergic effects. Soman was used in this study to validate the previous findings with DFP.

All experiments were done on fully anesthetized adult cats. Following collection of baseline visual evoked responses (VER) and measurement of blood ChE activity, i.v. soman was administered. VERs then were recorded and ChE activity measured periodically.

Preliminary results from eight cats show a preferential loss of low spatial frequency information similar to that following DFP. The VER loss can be reversed, at least partially, with atropine. At similar levels of blood acetylcholinesterase activity, blood pseudocholinesterase inhibition, ChE inhibition in visual cortex, and VER reduction is less after soman. Neurochemical changes in tissue from visual cortex also will be discussed.

BRAIN ACETYLCHOLINE AND CHOLINE LEVELS IN ANIMALS SUBJECTED TO CROSS COUPLED MOTION DURING THE DARK PHASE OF A LIGHT-DARK CYCLE. **J.O. Owasoyo and C.A. Walker. UAPB Research Center, Univ. of Arkansas at Pine Bluff, Pine Bluff, AR 71601.**

Land, sea or air travel sometimes causes motion sickness in humans. The mechanisms responsible for motion sickness are not entirely clear. Results from recent studies in our laboratory suggest that brain biogenic amines are involved in the mechanism of motion sickness. The present study examined the effect of cross-coupled motion on brain acetylcholine-choline in animals exposed to the motion during the dark phase of a light-dark cycle. Adult, male Fisher rats were used in this study. Control and sham animals, as well as animals (n=6) subjected for 20 min. to cross-coupled motion during the dark phase of a light-dark cycle were sacrificed at 30, 60 and 120 min. after exposure to motion. The brain was removed and dissected into cerebral cortex, medulla and cerebellum for HPLC analysis of acetylcholine and choline. Exposure to cross-coupled motion resulted in a significant decrease in the choline level of the cortex and medulla with no change in acetylcholine level of either brain area. No changes in the acetylcholine and choline levels were observed in the cerebellum. These findings suggest an involvement of brain cholinergic system in motion sickness. (Performed at NCTR, Jefferson, AR and supported by NASA grant #NAG 2-427).

DIRECT CYTOTOXIC EFFECT OF THE CHOLINERGIC TOXIN AF64A ON CEREBRAL CAPILLARY ENDOTHELIAL CELLS IN CULTURE. C. Gómez*, C. Martin* and C. Estrada. Dep of Physiology. Sch of Medicine. UAM, Madrid.

The ethylcholine mustard aziridinium ion (AF64A)has been reported to selectively destroy cholinergic neurons, and is currently used to provide animal models of cholinergic hipofunction. A previous study in the rat retina showed that, in addition to cholinergic neuron damage, ultrastructural alterations were also observed in endothelial cells. The purpose of the present investigation has been to evaluate and compare the direct cytotoxic effect of AF64A on cultured cerebral capillary endothelial cells (CCE) , on a choline acetyltransferase-containing neuroblastoma cell line (IMR32), and on cultured cerebrovascular smooth muscle cells (CVSM).

Cells grown in 24 well plates were washed with PBS, and incubated with DMEM containing different concentrations of AF64A (1-100 μM) for 2 or 24 hours. Control and 0.1% Triton X100-treated cultures were run in parallel. After the incubation period, media were collected, centrifuged and the supernatant was used for lactate dehydrogenase (LDH) measurements. Cell injury index was calculated as (A-C/T-C) x 100, where C,A and T represent LDH activity in the media from control, AF64A-treated, and TX100-treated cultures respectively.

Two hour incubation with AF64A did not increase LDH release in CCE or CVSM; however, a slight enhancement in LDH concentration was observed in IMR32 supernatants after exposure to 100μM AF64A. After 24 hour, morphological alterations and floating cells were observed in CCE and IMR32 cultures, but not in CVSM. Accordingly, LDH release increased in a concentration-dependent manner in CCE and IMR32 treated with AF64A, but no changes were observed in CVSM cultures. Half of the maximal cell injury was obtained with 30 μM AF64A in CCE , and with 15 μM AF64A in IMR32.

These results show that a) AF64A has a direct toxic effect on cerebral endothelial cells, b) the sensitivity of cultured endothelial cells is close to that found in neuroblastoma cells, and c) such cytotoxic effect is not nonspecific, because it was not observed in cerebrovascular smooth muscle cells.

EXCITATORY AMINO ACIDS: RECEPTORS IV

464.1

REGULATION OF NMDA RECEPTORS BY GLYCINE AT SYNAPSES AND IN OUTSIDE-OUT PATCHES. G. Tong, R. A. J. Lester* and C. E. Jahr.
Vollum Institute, Oregon Health Sciences University, Portland OR 97201

Although glycine is a required co-agonist for the activation of NMDA receptors, its modulation of synaptic NMDA function is less clear. The actions of glycine agonists and antagonists on postsynaptic NMDA currents recorded between pairs of hippocampal neurons in culture have been studied. Additionally we have examined these interactions on NMDA receptors in outside-out patches. Synaptic stimulation of NMDA receptors is mimicked by brief application (~ 5 ms) of L-glutamate (200 μM) to outside-out patches, which in the presence of saturating concentrations of glycine (10 μM) produces a long-lasting response. In the absence of glycine and/or the presence of glycine antagonists an NMDA response is barely detectable Subsequent addition of glycine at various intervals following brief activation by transmitter/L-glutamate allows NMDA channels to open and produces a current with a time course and amplitude dependent on the interval. Following synaptic stimulation in the presence of glycine, rapid removal of glycine has little effect on the decay of the NMDA current, indicating that glycine binds with high affinity, whereas removal of a lower affinity ligand, L-alanine, rapidly curtails the synaptic NMDA current. These data are consistent with the requirement for occupation of the glycine site to allow NMDA channels to open.

464.2

GLUTAMATE OPENS NMDA CHANNELS WITH A HIGH PROBABILITY C.E. Jahr, Vollum Institute, Portland, OR 97201.

NMDA receptor-channels require both glutamate and glycine binding sites to be occupied for channel opening to occur. If free glutamate is present only briefly, as is probable at excitatory synapses, then the agonists could unbind before the channel has the chance to open. Outside-out patches containing many NMDA channels were used to determine the probability of a liganded channel opening. Four ms pulses of a saturating concentration of glutamate (200 μM) were applied to patches in the continued presence of 20 μM glycine every 10 or 15 s. After stable responses were obtained, one pulse of glutamate was applied in the continued presence of the channel blocker, MK-801 (10 μM), which at -60 mV will block open, but not closed, NMDA channels in about 2-3 ms, on average. These channels will remained blocked for prolonged periods if held at -60 mV. Responses to subsequent glutamate pulses (in the absence of MK-801) resulted in currents about 30% of control. These results indicate that once NMDA channels are fully liganded, the probability that they will open is about 0.7. The currents activated in the presence of MK-801 describe a first-latency distribution and indicate that of those channels destined to open, over 80% open for the first time within about 30 ms of glutamate binding. If NMDA channels in outside-out patches mimic those at the synapse and spontaneous synaptic release results in receptor saturation, then there must be very few NMDA receptors present adjacent to release sites as spontaneous NMDA minis are very small (Bekkers and Stevens, Nature 341:230, 1989). Supported by the McKnight Endowment Fund for Neuroscience and NIH grant NS21419.

464.3

EFFECTS OF ANIRACETAM AND WHEAT-GERM AGGLUTININ ON FAST EXCITATORY SYNAPTIC TRANSMISSION IN CULTURED HIPPOCAMPAL NEURONS. L. Vyklicky, Jr.*, D. K. Patneau and M. L. Mayer. Section on Neurophysiology and Biophysics, LDN, NICHD, NIH, Bethesda, MD 20892.

The rapid time course of desensitization at AMPA/kainate receptors suggests that desensitization may determine the rate of decay of excitatory synaptic responses (Trussell and Fischbach, 1989). Concanavalin-A, a lectin which decreases desensitization, fails to slow the decay of EPSCs (Mayer & Vyklicky, 1989). To reassess the role of desensitization in fast excitatory synaptic transmission, we have examined the action of two other drugs which modulate responses at non-NMDA receptors.

Monosynaptic EPSCs were evoked between pairs of neurons in low-density cultures of rat hippocampal neurons. The nootropic drug aniracetam (5 mM) increased the amplitude and slowed the decay time constant of EPSCs by 1.8 and > 2-fold, respectively. Variance analysis indicated a postsynaptic action. The lectin wheat-germ agglutinin (WGA; 300 µg/ml) also slowed decay of the EPSC (1.3-fold). In the presence of both drugs τ_{EPSC} increased from 4.1 ± 1.0 ms to 10.1 ± 1.7 ms.

Both drugs markedly reduced desensitization of whole-cell responses to fast application of L-glutamate (2 mM): The amplitude of steady-state responses was increased 8.2 ± 3.5-fold by aniracetam, and 9.4 ± 6.0-fold by WGA. The time constant of the fast component of desensitization (τ_f) was slowed from 7.5 ± 2.0 ms to 34.4 ± 8.2 ms by aniracetam and to 18.0 ± 2.6 ms by WGA. In the presence of both drugs τ_f was increased to 47.7 ± 5.9 ms.

Aniracetam's effects on EPSCs suggest that desensitization at AMPA/kainate receptors may affect both the amplitude and time course of synaptic currents. The smaller effect of WGA is consistent with its effect on L-glutamate induced desensitization. It is also possible that these drugs modulate ion channel gating independent of desensitization. Brief applications of L-glutamate and single channel recordings can provide additional information on the specific mechanism of action of these drugs, and by inference, whether the time course and amplitude of synaptic currents can indeed be modulated by desensitization.

464.4

NOVEL WILLARDIINE DERIVATIVES EXHIBIT VARYING DEGREES OF DESENSITIZATION AT AMPA/KAINATE RECEPTORS. D. K. Patneau, M. L. Mayer, D. E. Jane* and J. C. Watkins*. Sect. of Neurophysiology and Biophysics, LDN, NICHD, NIH, Bethesda, MD 20892; and Dept. of Pharmacology, School of Medical Sciences, University of Bristol, Bristol BS8 1TD, England.

AMPA/Kainate receptors on CNS neurons are activated by two broad classes of agonists. Quisqualate, AMPA and L-glutamate produce strongly desensitizing responses, while kainate and domoate evoke little or no desensitization. Willardiine, a heterocyclic amino acid derived from *Acacia willardinia*, and its derivative 5-bromowillardiine, have previously been characterized as quisqualate-like and kainate-like agonists, respectively (Evans et al., 1980; Agrawal & Evans,1986).

The biologically active S enantiomers of willardiine and five derivatives, formed by substitution of fluorine, chlorine, bromine, iodine or NO_2 at the 5-position carbon atom of the willardiine uracil ring, were synthesized. Their action at AMPA/ kainate receptors was measured using fast perfusion techniques during whole-cell recording from cultured mouse hippocampal neurons voltage-clamped at -60 mV. The equilibrium potency sequence was F > NO_2 > Cl > Br > I > Will. (S)-5-fluorowillardiine (EC_{50}, 1.5±0.4 µM) is considerably more potent than (R,S)-AMPA (EC_{50}, 11±1.5 µM).

Willardiine and its derivatives all produced rapidly desensitizing responses at AMPA/kainate receptors, but exhibited varying degrees of desensitization. The amplitude of the equilibrium response to a maximally effective dose of willardiine was similar to that of AMPA and L-glutamate (<10% of the response to 6 mM kainate). Responses to 5-substituted willardiine derivatives were larger, and ranged from 15±6% (fluorowillardiine) to 89±8% (iodowillardiine) of the kainate response, reflecting different degrees of desensitization. The desensitization sequence was I < Br < Cl < NO_2 < F. Cross-desensitization experiments confirmed that willardiine derivatives activate the same receptor(s) as AMPA and kainate: Responses to kainate and AMPA were inhibited by 5-nitrowillardiine, while the steady-state response to the weakly desensitizing agonist 5-iodowillardiine was inhibited by the more strongly desensitizing agonists 5-fluorowillardiine and willardiine.

464.5

MAGNESIUM DEPENDENCE OF CALCIUM FLUXES EVOKED BY GLUTAMATE AGONISTS IN CULTURED CEREBELLAR GRANULE CELLS. S.S. Oja, V. Varga*, R. Janáky*, I. Holopainen* and P. Saransaari. Tampere Brain Res. Ctr, Dept. Biomed. Sci., Univ. Tampere, Finland.

Glutamate activates at least three subtypes of membrane receptors defined by their agonists N-methyl-D-aspartate (NMDA), kainate and quisqualate. The activation results in enhanced influx of calcium ions into neurons. The responses to glutamate and NMDA are known to be blocked by magnesium whereas the effects of Mg on the actions of kainate and quisqualate are less well characterized. We studied now the effects of all these agonists on the influx of Ca into glutamatergic cerebellar granule cells in culture. Kainate was most potent of the selective agonists tested. Glutamate, a mixed agonist, evoked responses which were largely similar to those of kainate. These results thus demonstrate the dominance of kainate receptors in cerebellar granule cells. The NMDA and quisqualate-evoked influx of Ca was totally and the kainate and glutamate-evoked influx partially blocked in 1.3 mM extracellular Mg. NMDA was most effective in totally Mg-free medium whereas the maximal effects of glutamate, kainate and quisqualate were seen at 0.1 mM Mg. The mechanism of Mg sensitivity of kainate responses seems to be complex and apparently involves the kainate-evoked release of endogenous excitatory amino acids from the cells. D-2-Amino-5-phosphonovalerate blocked partially and phencyclidine completely the enhancement of Ca influx by quisqualate in 0.1-mM Mg medium. The biphasic dose response curve for quisqualate also indicates that this agonist apparently acts at two receptors, activating at high concentrations NMDA receptors as well. (Supported by the Emil Aaltonen Foundation, Finland.)

464.6

GLUTAMATE RECEPTOR RESPONSES IN NEURONS OF THE CHICK NUCLEUS MAGNOCELLULARIS. I.M. Raman & L.O. Trussell. Neuroscience Training Program & Dept. of Neurophysiology. University of Wisconsin, Madison 53706.

Neurons of the nucleus magnocellularis of the chick receive strong, somatic excitatory innervation from the auditory nerve. While this synapse is believed to use glutamate receptors, the detailed properties of these receptors are unknown. We have therefore explored the action of glutamate receptor agonists on neurons acutely isolated from day 17-20 embryos. Neurons were voltage clamped with the patch electrode technique and solutions were applied rapidly (<6 ms exchange) from an array of 400 µm diameter glass tubes.

Glutamate (19 of 19 cells), kainate (12/12), quisqualate (13/13), and AMPA (8/8) activated inward currents at the resting potential. CNQX (10 µM) blocked quisqualate-evoked currents (N=3). Responses to these agonists reversed near 0 mV and often showed a striking degree of outward rectification in their steady-state current: the ratio of slope conductance between voltages of 30 & 90 mV to the slope conductance between -40 & -90 mV was 4.0±2.4 (±s.d., N=19 cells). Glutamate-, quisqualate-, and AMPA-induced currents showed rapid and profound desensitization. For example, the average peak response to 1 mM glutamate at -60 mV was 4.3±1.8 nA (N=8) while the steady-state current was 119±17 pA. The decay could be fit with two exponentials having time constants of 4.1±1.4 ms (83% of total current) and 14.5±5.6 ms (N=6). The faster decay rate may be an underestimate, since its measurement is limited by the exchange rate of our drug application system for whole cells. Desensitization was therefore measured in excised patches, where the solution exchange occurs within 1 ms. A single exponential fit to patch responses decayed with a τ of 1.5±0.2 ms (N=4). These rapid kinetics may be reflected in the fast time course of magnocellularis synaptic currents (see Trussell, L.O., Neurosci. Abstr., 1991).

464.7

SYNAPTIC CURRENTS RECORDED IN VOLTAGE CLAMPED NEURONS OF THE CHICK NUCLEUS MAGNOCELLULARIS. L.O. Trussell. Dept. of Neurophysiology, University of Wisconsin, Madison, 53706.

The adendritic neurons of the nucleus magnocellularis of the chick receive auditory nerve input directly onto their cell bodies. Thus, the preparation offers the opportunity to study the postsynaptic electrical properties of a putatively glutamatergic CNS synapse under nearly ideal voltage clamp conditions. Tight-seal whole-cell recordings were made from 100-200 µm thick slices maintained at 31°C on the stage of an upright microscope equipped with differential interference contrast optics.

During voltage clamp recordings (V_{hold}=-60 mV) spontaneous, small inward synaptic currents were apparent. In the presence of 1 mM bath Mg^{++}, these currents reversed near 0 mV and were blocked by 5 µM CNQX or by 5 mM kynurenic acid. Their variable amplitude (5 to 150 pA) and random nature suggest that they may correspond to "miniature" synaptic currents observed in other neuronal preparations. A striking feature of the synaptic currents was their rapid kinetics. Their mean rise time was 220±20 µsec (10-90% rise, N=7 cells) and their exponential decay constant was 450±70 µsec. Many synaptic currents had a slower secondary phase of decay which was probably due to activation of NMDA receptors as it was blocked by 500 µM 2-APV or 1 mM Mg^{++} and was resistant to 5 µM CNQX.

The very rapid time course of the EPSC's non-NMDA component may reflect a novel form of non-NMDA receptor and is consistent with the role of this synapse in precise encoding of auditory input. However, the presence of an NMDA component is unexpected, and may play a role in the trophic maintenance of these neurons by synaptic activity or in the slow regulation of excitability. Current experiments are exploring the properties of the nerve-evoked rapid non-NMDA synaptic current and the possible roles of the NMDA component.

A SIMPLE MODEL DESCRIBES RAPIDLY DESENSITIZING QUISQUALATE-ACTIVATED CURRENTS. D.O. Smith and W.T. Cumming*. Depts. of Physiology and of Electrical and Computer Engineering, Univ. of Wisconsin, Madison, WI 53706.

Rapid desensitization of post-synaptic currents in quisqualate receptors has been observed in numerous preparations. To understand the kinetics of this reaction, we developed a sequential model where 2 transmitter molecules bind to the receptor followed by a rate-limiting transition to the conducting state and where desensitization occurs from the closed state with 2 bound agonist molecules. Using rate constants for desensitization, resensitization, and channel opening and closing from our quisqualate data and binding rate constants from ACh data (Wathey et al., 1979), the model achieves a reasonable fit to our experimental results in most respects. To improve the fit, we needed only to increase the forward desensitization rate constant and the inverse rate constant for the second binding step by factors of 2 and 5, respectively. These results imply that the connection between our experimental data and the rate constants of the model may be slightly more complex than we predicted. Supported by NIH grant NS13600.

464.9

EFFECTS OF SPERMINE ON NMDA-INDUCED CURRENTS IN RAT HIPPOCAMPAL NEURONS: A WHOLE CELL AND SINGLE CHANNEL STUDY. R. C. Araneda, R.S. Zukin and M.V.L. Bennett. Dept. Neuroscience, Albert Einstein Coll. of Med., Bronx, NY 10461.

Recent studies have shown that polyamines potentiate NMDA-induced currents in *Xenopus* oocytes injected with rat brain mRNA (McGurk *et al.*, PNAS 87: 9971, 1990), as well as increasing the binding of [^{3}H]-glycine and [^{3}H]-MK-801 to the NMDA receptor complex. These observations suggest a physiological role for polyamines in modulating NMDA-evoked responses. To gain further insight into the actions of polyamines on NMDA receptors, we studied the effects of the polyamine, spermine, on NMDA-induced currents in rat hippocampal neurons. At the whole-cell level, application of 100 μM NMDA in the presence of low glycine (0.3 μM) and absence of external Mg^{2+} induced an inward current which reversed near 0 mV. Co-application of spermine (100-300 μM) increased the NMDA-induced current by about two-fold. Single NMDA-activated channels in outside-out patches were characterized by unitary conductance of 50 pS and an open time distribution that could be fit by a single exponential with a mean open time of 4.5 ms. Perfusion of the patches with 3 μM NMDA (plus 0.3 μM glycine) in the presence of spermine (100-300 μM) increased the open probability of the channels by about 50%, primarily due to an increase in the duration of the openings of the channel. These studies should clarify the mode of action of polyamines on NMDA-activated channels.

GLUTAMATE RECEPTOR CHANNELS IN RAT DRG NEURONS: SELECTIVE INHIBITION BY LANTHANUM AND GADOLINIUM. J. E. Huettner. Department of Neurobiology, Harvard Medical School, 220 Longwood Ave., Boston, MA 02115

Rat sensory neurons express a novel form of non-NMDA receptor that exhibits strong desensitization to the agonists kainate and domoate (*NEURON* 5:255, 1990). In a search for selective antagonists able to distinguish the receptor in DRG cells from conventional non-NMDA receptors in CNS neurons, the inorganic cations La and Gd were found to inhibit kainate current in DRG cells at 100 μM, a concentration that had little effect on kainate current in neurons from cerebral cortex. Blockade of kainate current in DRG cells by 100 μM La or Gd was rapid and complete at holding potentials up to +60 mV. Lower concentrations produced partial block. Full recovery took 60 to 90 sec.

The divalent cations Cu, Mn, Zn, Cd, Co, and Ni produced slight inhibition (5-20% at 100 μM) of kainate current in DRG neurons but did not reduce the current gated by kainate in cortical neurons.

NMDA RECEPTOR BLOCK BY H^+, Mg^{2+}, AND Zn^{2+} FOLLOWING ALKYLATION OF THE REDOX MODULATORY SITE. Lian-Hong Tang and Elias Aizenman, Dept. of Physiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

We have used the alkylating agent N-ethylmaleimide (NEM) to permanently modify the NMDA receptor via its redox modulatory site (Aizenman et al., *Neuron*, 2:1257; 1989). In addition, we have examined the actions of known endogenous blockers of the NMDA receptor, H^+, Mg^{2+}, and Zn^{2+}, following alkylation. The purpose of these experiments was to study any possible relation between the redox site and the sites responsible for block by these various agents. In cultured rat cortical neurons, NEM (300 μM; 2 min) can effectively "lock" the enhancement of whole-cell voltage-clamped NMDA-induced responses produced by the reducing agent dithiothreitol (DTT, 4 mM; 2-4 min). Under these conditions, the oxidizing agent 5-5-dithio-*bis*-nitrobenzoic acid (DTNB, 500 μM; 1-2 min) can no longer reverse the potentiating effects of DTT. When we measured the block produced by H^+ (pH 6.8), Mg^{2+} (1 mM), and Zn^{2+} (20 μM) on NMDA responses before and following alkylation of the redox site (DTT treatment always preceded NEM application), we observed that all three agents could effectively block NMDA responses under both conditions, except that the inhibition produced by Mg^{2+} and Zn^{2+} decreased slightly after alkylation, while the proton block increased (%block alkylated/%block control): 1.3, H^+; 0.8, Mg^{2+}; 0.7, Zn^{2+}. Supported by NIH grant NS29365.

EVIDENCE FOR KAINATE RECEPTOR SUBTYPES BASED ON DIFFERENTIAL ETHANOL SENSITIVITY OF BRAIN AND GLUR3 RECEPTORS EXPRESSED IN XENOPUS OOCYTES. J. E. Dildy-Mayfield*, J. M. Sikela, and R. A. Harris. VAMC & Dept. of Pharmacology, Univ. of CO Health Sci. Ctr., Denver, CO 80262.

Ethanol's (EtOH) effect on kainate (KA) receptor-operated channels was initially examined in *Xenopus laevis* oocytes expressing mRNA from rat hippocampus (E_m clamped at -70 mV). EtOH (50, 100 mM) significantly inhibited KA-induced currents in the presence of 400, 200, 100, 50, 25, or 12.5 μM KA but did not significantly alter the EC_{50} for KA (~78 μM). DNQX inhibited maximum KA responses (400 μM) with an IC_{50} of ~1 μM; EtOH (50, 100 mM) did not alter the IC_{50} for DNQX but did produce further inhibition of KA-induced currents. Despite the apparent noncompetitive inhibition produced by EtOH on KA receptor-mediated responses, the EtOH inhibition of KA-stimulated current increased as the KA concentration decreased. For example, 50 and 100 mM EtOH inhibited 400 μM KA responses by 15 & 25%, respectively, compared to 45 & 51% inhibition of 12.5 μM KA responses. This differential inhibition was not due to different current amplitude stimulated by low vs. high KA concentrations. Oocytes expressing rat cerebellar mRNA also demonstrated greater ethanol inhibition of low vs. high KA responses (e.g. 100 mM EtOH inhibited 12.5 μM KA-stimulated current by 60% compared with 31% inhibition of 400 μM KA responses). However, in oocytes injected with the rat glutamate receptor subunit clone, GluR3, 100 mM EtOH produced similar inhibition of 400 and 12.5 μM KA-induced currents (46 & 52%, respectively). Thus, EtOH's differential inhibition of KA responses in oocytes may reflect selective actions of EtOH on individual KA receptor subtypes.

ENHANCEMENT OF NMDA-MEDIATED RESPONSES BY CYANIDE. M.N. Patel, R.W. Peoples, G.K.W. Yim and G.E. Isom.* Dept. of Pharmacol. & Toxicol., Purdue Univ., W. Lafayette, IN 47907 and Section of Electrophysiology, National Institute of Alcohol Abuse and Alcoholism, Rockville, MD 20852.

The effect of cyanide on NMDA-induced Ca^{+2} influx and inward current was studied. $[Ca^{+2}]_i$ was measured in cultured rat hippocampal neurons using fura-2 microfluorimetry. Removal of extracellular Mg^{+2} resulted in a five-fold increase in NMDA-induced peak $[Ca^{+2}]_i$. NaCN (1-10 mM) enhanced the peak responses obtained with NMDA in the presence, but not in the absence of extracellular Mg^{+2}. Similar results were obtained in whole-cell patch clamp recordings from cultured rat hippocampal neurons. Cyanide enhanced NMDA-activated current in the presence, but not the absence of extracellular Mg^{+2}. Enhancement of NMDA-activated current was observed within 1 sec of cyanide application. From these results it appears that cyanide alters the Mg^{+2} block of the NMDA receptor. (Supported by PHS Grant ES04140)

Ca IONS CHANGE THE AFFINITY OF GLYCINE TO NMDA RECEPTOR COMPLEX. Yanping Gu[1] and Li-yen Mae Huang[1,2]. Marine Biomedical Institute[1] and Department of Physiology and Biophysics[2], University of Texas Medical Branch, Galveston, TX 77550.

Ca ion play an important role in regulating the function of NMDA receptor channels. To better understand the interaction between Ca and NMDA-receptor channels, we examined the properties of NMDA-activated currents in various external Ca solutions. The whole cell currents were recorded from isolated trigeminal neurons using the patch clamp technique. We found the effects of Ca ions on NMDA-activated currents depend on the concentration of glycine. In the low external glycine, the NMDA-activated currents were increased as we raised the Ca concentration from 2 mM to 20 mM. But in the high external glycine, the NMDA-activated currents were decreased as we increased the external Ca. To study the mechanism of the actions of Ca, we determined the dose response for the action of glycine on NMDA-activated currents in different Ca solutions. Ca was found to have dual effects on NMDA-activated responses: It inceased the binding of glycine to the NMDA receptor complex, and it blocked monovalent cation permeation through NMDA receptor channels. SPERMINE ENHANCES NMDA RECEPTOR CURRENTS IN CULTURED RAT CORTICAL NEURONS. D.M. Rock# and R.L. Macdonald+. Neuroscience Program# and Depts. of Neurology and Physiology+, Univ. of Michigan, Ann Arbor, MI 48109.

Spermine modulates the activity of NMDA in a variety of receptor binding and electrophysiological studies. At μM concentrations, spermine enhances the action of NMDA but at higher concentrations spermine is less effective. We studied the effect of spermine on NMDA receptor currents using whole cell and single channel recording techniques.

Whole cell NMDA currents in cultured rat cortical neurons were enhanced by spermine (0.1 μM - 1 mM) in a concentration-dependent manner. At concentrations above 10 μM, this enhancement was limited at -75 mV but not at +75 mV. The percent enhancement of NMDA current by spermine varied among preparations and in some cases no enhancement was observed.

In excised outside-out patches, spermine (1 μM - 1 mM) produced a concentration-dependent increase in channel opening frequency with a 40% increase over control at 1 μM. The effect of spermine on opening frequency was independent of external glycine concentration.

These results demonstrate that spermine enhances NMDA current by increasing channel opening frequency. The limitation of enhancement may be due to the other actions of spermine. Spermine is found in high concentrations in the nervous system and appears to act at an important regulatory site on the NMDA receptor-ion channel complex.

***trans*-ACPD BLOCKS HIGH THRESHOLD CALCIUM CURRENTS ON CULTURED HIPPOCAMPAL NEURONS.** Y. Sahara & G.L Westbrook. Vollum Institute, Oregon Health Sciences University, Portland, OR.

The metabotropic receptor (mGluR), the best characterized G protein coupled glutamate receptor, triggers inositol trisphosphate production and the release of intracellular calcium in mRNA-injected *Xenopus* oocytes and in hippocampal neurons. Although quisqualate and AP4 (2-amino-4-phosphonobutyrate) both inhibit high threshold calcium currents (Lester & Jahr, Neuron, 1990; Trombley & Westbrook, Soc.Neurosci.Abst.,1990), the receptor and coupling mechanism involved are unclear. For example, L-AP4 does not activate mGluR and appears to be a membrane-delimited interaction of a G protein with the calcium channel. These data suggest either multiple G protein coupled glutamate receptors or coupling mechanisms. We have examined whether the selective mGluR agonist, (1S,3R)-1-aminocyclopentane-1,3-dicarboxylate (*trans*-ACPD) can also inhibit high threshold calcium currents on cultured hippocampal neurons. Whole-cell voltage clamp recordings were made with patch pipettes containing GTP or a 5:1 ratio of GTP/GTPγS with calcium buffered to pCa = 7. High threshold calcium currents were evoked by 30 ms voltage jumps to 0 mV from a holding potential of -60 mV using 2.5 mM barium as the charge carrier. *trans*-ACPD (50-300 μM) or L-AP4 (50 μM) were delivered by flow pipes. *trans*-ACPD produced reversible and dose-dependent decreases in the barium current; at 200 μM the reduction was 29.5 ± 4.5 % (n=10). Decreasing the GTP/GTPγS ratio resulted in irreversible reduction of the barium current by *trans*-ACPD. L-AP3 (500 μM), a reported mGluR antagonist, partially antagonized the action of *trans*-ACPD. Under the same conditions, L-AP4 produced a 24.4 ± 3.1 % inhibition (n=6) of the barium current. Repeated applications of *trans*-ACPD in barium/ 0 calcium solutions caused similar percent inhibition, suggesting that release of intracellular calcium was not responsible for block of the current. Supported by NIH grant #NS26494 and the Klingenstein Foundation.

L-TRANS 1-AMINO-1,3-CYCLOPENTANE DICARBOXYLIC ACID (ACPD) STIMULATES INTRACELLULAR CA^{++} MOBILIZATION IN A MG^{++} AND DAPV SENSITIVE MANNER IN CULTURED CA1 PYRAMIDAL NEURONS. K. Curry and K.G. Baimbridge. Department of Physiology, University of British Columbia, Vancouver, B.C. V6T 1Z3 Canada.

Trans ACPD has been said to activate a glutamate G-protein linked (Glu_G) receptor which is metabotropic rather than ionotropic in nature. This action mobilizes intracellular Ca^{++} and we have studied this effect using the D and L isomers of trans ACPD and monitoring the Ca^{++} levels intracellularly with the dye Fura 2.

Application of the D-isomer produced no effect on neurons at concentrations of up to 1 mM when applied to the bathing medium while the L-isomer produced elevated intracellular Ca^{++} levels at 200 μM. This action of the L-isomer was found to be sensitive to Mg^{++} and D-2-amino 5-phosphonovaleric acid (DAPV). The results indicate that L-trans ACPD operates through the N-methyl-D-aspartate rather than the Glu_G receptor and we conclude that the action of the compound may be sensitive to different areas of the CNS and to the age of the neurons being studied.

NMDA BUT NOT AMPA/KAINATE ANTAGONISTS BLOCK SPONTANEOUS EPILEPTIFORM DISCHARGES (SED) IN THE RAT CORTICAL WEDGE. L.J. Robichaud, T. Malone' and P.A. Boxer, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

We examined functional responses to glutamate antagonists (30 min treatment) in the low Mg^{++} rat cortical wedge preparation. As previously described, SED was inhibited by the NMDA recognition site antagonist CPP (IC_{50} = 0.35 μM), the NMDA/ion channel antagonist MK-801 (IC_{50} = 0.5 μM). Similarly, the novel NMDA/ion channel antagonist PD137889 [(+)-1,2,3,4,9,9a-hexahydro-N-methyl-4aH-fluoren-4a-amine monohydrochloride] inhibited SED with an IC_{50} = 0.6 μM. Antagonists of the strychnine-insensitive glycine site also inhibited SED: 7-chlorokynurenic acid (IC_{50} = 10 μM), 5,7-dichlorokynurenic acid (IC_{50} = 5 μM), and (±) HA-966 (IC_{50} = 120 μM). This inhibition was completely reversed by glycine at concentrations that had no effect on SED alone. NBQX, a selective antagonist of AMPA/kainate (vs NMDA) receptors, blocked AMPA-induced depolarizations at 10 μM, but at concentrations up to 100 μM did not inhibit SED. DNQX, which is both an AMPA/kainate and glycine site receptor antagonist inhibited SED (IC_{50} = 12 μM), however glycine completely reversed the inhibitory actions of DNQX. Glycine did not reverse the inhibition of SED by NMDA recognition site or ion channel blockers. These data demonstrate that glycine can only reverse the inhibition produced by glycine-site antagonists and therefore that the inhibitory effect of DNQX on SED can be attributed to its glycine antagonism alone. In summary, spontaneous epileptiform discharges in the rat cortical wedge are not inhibited by AMPA/kainate antagonists, but are sensitive to modulation by antagonists of several sites of the NMDA-receptor ion channel complex.

INCREASED REQUIREMENT FOR HIGH-ENERGY PHOSPHATES BY NMDA-RECEPTORS IN ACUTELY DISSOCIATED KINDLED GRANULE CELLS. G. Köhr and I. Mody. Dept. of Neurology & Neurological Sciences, Stanford Univ. Sch. of Med., Stanford, CA.

Previous studies in hippocampal slices have shown that kindling increases synaptic activation of NMDA receptors in the dentate gyrus. Furthermore, whole-cell dialysis in cultured neurons has uncovered the requirement for intracellular high-energy phosphates (P_i) for the full expression of NMDA channel activity. We have examined if alterations in the P_i requirement of NMDA channels may be present following kindling-induced epilepsy.

Whole-cell NMDA-currents were evoked in acutely dissociated control and kindled dentate gyrus granule cells in Mg^{2+}-free extracellular medium containing 3 μM glycine using a solenoid-operated double-barrelled θ-tubing (200 μM NMDA/4-20 s). In the presence of P_i (Mg-ATP + phosphocreatine + creatine-phosphokinase) the amplitudes of NMDA currents were comparable in control and kindled preparations (range: 90-100 pA) and did not wash-out over 20 min of whole-cell recordings. Fluctuation analysis revealed mean open times of 3.1 to 7.9 ms and single channel conductances of 20 to 49 pS which were not significantly different between control and kindled neurons, and did not change in the absence of P_i. However, in the absence of P_i the control and kindled NMDA responses were reduced by 27% and 45% respectively. The significantly diminished kindled NMDA currents recorded without P_i are consistent with an altered phosphorylation state of NMDA receptors after kindling, but other mechanisms cannot be excluded. Presently no estimate can be made about the *in situ* phosphorylation level of NMDA receptors, but our data show that a covalent modification of NMDA receptors may have occurred during kindling.

L-ASPARTATE RECEPTORS IN MULLER CELLS: TROPHIC INTERACTIONS. M. Romo-de-Vivar* and A.M. López-Colomé. Instituto de Fisiología Celular, UNAM. Apartado Postal 70-600, 04510 México, D.F. México.

Receptors for L-^{3}H-aspartate have been biochemically characterized in Muller cells from the chick retina in primary culture. Two binding sites with affinity in the nM and uM range were detected, showing pharmacological profiles similar to those for neurotransmitter (QA) and high-affinity-uptake systems, respectively. Since these receptors became apparent at different stages of development in vitro, we tried to determine if culture conditions could influence their expression and properties. Glial cells were maintained in medium containing 10% FCS. The effect of low serum (1%), diBcAMP, L-glutamate, quisqualate and NMDA on ^{3}H-L-asp binding was studied at days 1,5,8 and 12 in vitro. At concentrations 50-200 uM, neither compound showed effect; diBcAMP was tried up to 1 mM without effect. In cells cultured in low serum, ^{3}H-L-asp binding was increased at all stages: 0.497 to 0.762 pmole/mg protein at 1 DIV, 0.123 to 1.05 at 5 DIV, 0.190 to 1.0 at 8 DIV and 0.24 to 0.82 at 12 DIV. Pharmacologically these sites show the properties of high affinity transport sites. These results suggest that in contrast with cells cultured in the presence of FCS, Muller cells in low serum do not express high affinity binding sites with properties similar to QA transmitter receptors. Partially supported by CONACyT P228CCOX891617.

$GABA_B$ RECEPTOR-MEDIATED PAIRED PULSE DISINHIBITION REVEALS AN NMDA COMPONENT OF THE EPSP. D. D. Mott, C. W. Xie, R. A. Morrisett, H. S. Swartzwelder, W. A. Wilson and D. V. Lewis. Depts. of Pharmacology, Pediatrics (Neurology), Medicine (Neurology) and Neurobiology, Duke Univ. and V. A. Med. Ctrs, Durham, N.C. 27710.

We have previously reported that, during paired stimulation of the molecular layer in the rat dentate gyrus, the NMDA component of the second response is enhanced by an underlying $GABA_B$ receptor-mediated depression of inhibition. During 5 Hz stimulation, this enhancement of the NMDA component can cause development of long term potentiation (Mott and Lewis, Science, in press). In this study we sought to further investigate the stimulus parameters necessary for expression of this paired pulse disinhibition.

Paired pulse disinhibitionwas studied in the dentate gyrus and area CA1 of the rat hippocampal slice. In the dentate gyrus, paired stimulation in the inner two-thirds of the molecular layer caused the EPSP of the second response to be prolonged and display 1-3 additional population spikes. This enhancement was maximal when stimuli were delivered 150-250 ms apart and was blocked by D-APV (50 uM) or by 2-OH saclofen (400 uM). Enhancement of the second response was most evident with higher intensity stimuli and when the stimulating electrode was placed in the molecular layer within 100 um of the recording electrode. As the stimulating electrode was moved away from the recording electrode, the degree of enhancement of the second response diminished.

Similarly, in area CA1 the EPSP of the second response to paired stimuli delivered to *stratum radiatum* within 100 um of the recording electrode was prolonged. This enhancement diminished as the stimulating electrode was moved away from the recording electrode and was also blocked by D-APV (50 uM) or 2-OH saclofen (400 uM).

EVIDENCE THAT ETHANOL REDUCES $GABA_B$-MEDIATED DISINHIBITION AND SYNAPTIC PLASTICITY INDUCED BY A PRIMING PARADIGM IN RAT DENTATE GYRUS.

R.A.Morrisett, W.A.Wilson, H.S.Swartzwelder. Neurology Research, Duke Univ. and the Veterans Admin. Med. Ctrs., Durham, NC, 27705.

Priming stimulation paradigms (5 Hz) delivered to the molecular layer of the rat dentate gyrus result in hyperexcitability and enhancement of NMDA-mediated synaptic potentials. In this case, the activation of $GABA_B$ receptors leads to a reduction of synaptic inhibition. If at least 10 pulses are delivered at 5 Hz, the resultant excitatory effect is of sufficient magnitude to elicit long-term potentiation of synaptic transmission (Mott and Lewis, Science, in press).

We hypothesized that ethanol would inhibit the the NMDA component of synaptic transmission induced by a priming paradigm since ethanol inhibits NMDA population epsps (Lovinger et al., *J Neurosci.*, 1990; Morrisett et al., *Neuropharmacol.*, in press). Orthodromic test stimuli were applied to the dentate gyrus 200 msec after an identical conditioning stimulus. When slices were treated with ethanol, the disinhibitory effect of paired stimulation was markedly reduced in a concentration-dependent manner (25-100 mM). We also examined the effects of ethanol on long-term potentiation of synaptic transmission. In the presence of 75 mM ethanol, 5 Hz-2 sec trains induced only the decremental form of synaptic plasticity. However, after ethanol washout, identical trains elicited non-decremental potentiation of both epsp slope and population spike.

We conclude that inhibition of priming by ethanol may represent one mechanism responsible for its amnesic effects. (This work was supported by AA 07207, MH 15177-13, NS 17701 and NS 27488).

465.3

NON-SYNAPTIC MODULATION OF AXONAL CONDUCTION BY GABA-B RECEPTORS IN THE NEONATAL RAT OPTIC NERVE: BACLOFEN IMPROVES HIGH-FREQUENCY IMPULSE CONDUCTION IN THE PRE-MYELINATED OPTIC NERVE. A.Z. Hassan*, W. Ching*, and K. Sakatani Dept. of Neurosurgery, NYU Medical Center, New York NY 10016

Recent studies have shown GABA-A receptor sensitivities in a number of white matter preparations, including rat optic nerve. However, the presence of GABA-B receptors in axonal preparations remained unknown. We have addressed this issue by comparing the effects of GABA-A and -B receptors on axonal conduction in the neonatal (1 to 12 days of age) rat optic nerve *in vitro*. The compound action potential (CAP) of isolated optic nerves was elicited by submaximal stimulation (50-60% of maximal responses, 0.2 Hz), and recorded with glass micropipettes.

GABA (100 μM), at first, decreased the latency of the CAP. This initial effect was followed by progressive decrease in the amplitude and increase in the latency. The later effect of GABA was blocked by the GABA-A blockers, picrotoxin and bicuculline, and mimicked by the GABA-A agonist, isoguvacine (100 μM). However, the initial effect of GABA on the latency was resistant to the GABA-A blockers. The GABA-B agonist, baclofen (1-100 μM), mimicked the initial effects of GABA. The GABA-A blockers failed to block the effect of baclofen. Furthermore, baclofen increased the population conduction velocity, estimated from two points recordings, suggesting that the effects of baclofen were along the length of the axons. To evaluate the effects of baclofen on high-frequency impulse conduction, stimulus trains were delivered at frequencies of 10-33Hz, for 103 pulses. At 33 Hz, the control stimulus train depressed the amplitude by 78.6 ± 17% (mean ± SD) and increased the latency by 26.3 ± 12.9% (n=7) by the 103rd test pulse. In the presence of baclofen (100 μM), the amplitude of the 103rd response was decreased by only 27.8 ± 13.0% and the latency was increased by only 20.1 ± 4.1% (n=4).

Our results demonstrate that: (1) functional GABA-A and -B receptors coexist in the neonatal rat optic nerve; (2) baclofen improves high-frequency impulse conduction of the pre-myelinated axons. Supported in part by NIH grant NS10164.

A NOVEL $GABA_B$ RECEPTOR-MEDIATED IPSP ELICITED IN CA1 PYRAMIDAL CELLS BY MICROAPPLICATION OF GLUTAMATE IN *STRATUM LACUNOSUM-MOLECULARE* OF THE RAT HIPPOCAMPUS *IN VITRO*. S. Williams and J.-C. Lacaille. Département de physiologie, Centre de recherche en sciences neurologiques, Université de Montréal, Qué., Canada H3C 3J7.

Two types of GABAergic responses ($GABA_A$ and $GABA_B$) are present in the hippocampus. Interneurons located in str. lacunosum-moleculare (L-M) may mediate the electrically-evoked late ($GABA_B$) inhibitory postsynaptic potential (IPSP). To verify this hypothesis, IPSPs were elicited in CA1 pyramidal cells (n=88) by glutamate (500 μM) applications to str. L-M (glut-IPSPs) in hippocampal slices. For comparison, early and late IPSPs were evoked by stimulation of the Schaffer collaterals. In 20 cells, the mean amplitude of the glut-IPSPs was -2.0 mV and the mean equilibrium potential was -70 mV. Glut-IPSPs showed little or no response reversal (13/14 cells). Perfusion with TTX (1 μM; n=3) blocked the glut-IPSPs, suggesting that they were generated by local interneurons. Local application of the $GABA_A$ antagonist bicuculline (100 μM; n=2) or perfusion with picrotoxin (10-20 μM; n=6) reduced the early IPSP but not the late IPSP and glut-IPSP. Local applications of the $GABA_B$ antagonist 2-OH-saclofen (1-4 mM; n=7) reduced the late IPSP (46% of control) and the glut-IPSP (47% of control). However, the $GABA_B$ antagonist phaclofen (20 mM; n=4) did not antagonize the glut-IPSP (101% of control) at doses that reduced the late IPSP (47% of control). The K^+ channel blocker barium (1 mM; n=4) diminished the late IPSP (64% of control) but increased the glut-IPSP (116% of control). Repetitive electrical stimulation (3 Hz for 10 sec; n=6) depressed the early, late and glut-IPSP, suggesting that interneurons activated with glutamate were also activated electrically. It is concluded that the late IPSP may be composed of an heterogeneity of $GABA_B$ receptor-mediated mechanisms and that IPSPs elicited presumably from interneurons in str. L-M may mediate one of the $GABA_B$ components. [Supported by MRC, FRSQ, and Savoy Foundation].

465.5

GABA RECEPTOR-MEDIATED SYNAPTIC POTENTIALS IN RAT HIPPOCAMPAL CA1 PYRAMIDAL CELLS ELICITED BY GLUTAMATE MICROAPPLICATION AT THE ORIENS/ALVEUS BORDER OR IN STRATUM PYRAMIDALE. D.D. Samulack and J.-C. Lacaille. Département de physiologie and Centre de recherche en science neurologiques, Université de Montréal, QC, Canada H3C 3J7.

Inhibitory postsynaptic potentials (IPSPs) in hippocampal pyramidal cells arise from a combination of $GABA_A$ and $GABA_B$ receptor-mediated mechanisms. In contrast to interneurons in stratum (str.) lacunosum-moleculare, which may mediate a $GABA_B$ component, interneurons at the str. oriens/alveus border (O/A) or in str. pyramidale (PYR) may mediate portions of the $GABA_A$ component. This hypothesis was tested through the micropressure application of glutamate (500 μM; drop diameter 30-80 μm) at O/A or in PYR, while recording intracellularly from different CA1 pyramidal cells in rat hippocampal slices. The pyramidal cell IPSPs evoked by glutamate application in O/A (peak: -4.0 mV; peak latency: 126 ms; decay: 398 ms; n=8), were very similar to those elicited from PYR (peak: -4.1 mV; peak latency: 104 ms; decay: 404 ms; n=12). Electrical stimulation in str. oriens or radiatum of the CA1 region elicited IPSPs with little difference in early and late components between experimental groups. The glutamate evoked IPSPs from O/A or PYR were both sensitive to the local application of the $GABA_A$ antagonist bicuculline (100-200 μM). However, the reduction in the O/A evoked IPSP (58%; n=5) was less than that of the PYR IPSP (84%; n=5). The glutamate evoked IPSP from PYR showed little sensitivity (6%, n=2) to the $GABA_B$ antagonist 2-OH-saclofen (1 mM). In one cell tested, the IPSP evoked from O/A was reduced by saclofen (33%). These results indicate that interneurons activated from both O/A and PYR may be responsible for the $GABA_A$ mediated component of the electrically evoked IPSP. O/A interneurons may also contribute to the $GABA_B$ component of the late IPSP.

CALCIUM CURRENTS IN GOLDFISH RETINAL GANGLION CELLS ARE BLOCKED BY BACLOFEN. V.P.Bindokas and A.T.Ishida. Dept. Animal Physiology, University of California, Davis CA 95616.

Goldfish (*Carassius auratus*) retinal ganglion cells receive synaptic input from GABAergic amacrine cells *in situ* [Muller & Marc (1990) J Comp Neurol 291:281], and have a $GABA_A$-receptor-coupled anionic conductance [e.g. Ishida & Cohen (1988) J Neurophysiol 60:381]. We have investigated whether these cells also possess $GABA_B$-type receptors by using whole-cell patch-clamp recording methods. Calcium currents were isolated as previously described [Ishida (1991) Vision Res 31:477]. Calcium currents activated by voltage steps (250 msec) from -90 to 0 mV display at least two components: transient and sustained. All concentrations of (-)baclofen tested (0.3 to 100 μM), preferentially blocked the sustained component; 100 μM baclofen produced roughly 70% reduction in sustained current (n=10). The residual voltage-activated inward current in the presence of baclofen was fully blocked by replacement of bath Ca^{2+} (2.5 mM) by 2.4 mM Co^{2+} plus 100 μM Ca^{2+}; no outward current appeared under these conditions. Calcium currents activated by voltage steps to -30 mV were reduced less by baclofen than were currents activated by jumps to 0 mV, and peak (transient) currents were less affected than sustained currents at all voltages. The action of baclofen (all doses tested) was at least partially reversible with wash. 750 μM phaclofen did not antagonize the block produced by 300 nM or 30 μM baclofen. Baclofen sensitivity was observed in over 95% of all ganglion cells sampled (n=27). These results indicate that at least some of the voltage-gated calcium current in retinal ganglion cells is sensitive to $GABA_B$-receptor agonists.

THE ACTION OF $GABA_B$ ANTAGONISTS IN THE TRIGEMINAL NUCLEUS. G.H. Fromm, K. Sato* and M. Nakata*. Dept. of Neurology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

D-baclofen blocks the action of L-baclofen in the trigeminal nucleus and spinal cord but not in neocortical or hippocampal slices. This discrepancy could be due to a difference in baclofen concentration used or a difference in receptor type.

The iontophoretic administration of the $GABA_B$ antagonists 2-hydroxy-saclofen and CGP 35348 blocked the action of iontophoretically applied L-baclofen on neurons in the trigeminal nucleus of rats anesthetized with halothane, with CGP 35348 being 3-6 times as potent as saclofen.

The iontophoretic administration of GABA resembled L-baclofen in depressing excitatory transmission and facilitating segmental inhibition in the trigeminal nucleus. CGP 35348 also blocked the depression of excitatory transmission and partially blocked the facilitation of segmental inhibition produced by GABA.

Our observations indicate that CGP 35348 is not only a baclofen antagonist but actually a $GABA_B$ receptor antagonist, and that baclofen is acting at $GABA_B$ receptors in the trigeminal nucleus. The portion of the GABA effect not blocked by CGP 35348 is probably mediated by $GABA_A$ receptors, since we have previously found that segmental inhibition in the trigeminal nucleus can be modulated by $GABA_A$ agonists and antagonists. (Supported by NS-19889)

DISCRIMINATIVE-STIMULUS EFFECTS OF THE $GABA_A$ AGONIST THIP AND THE $GABA_B$ AGONIST BACLOFEN. N. A. Ator. Div. Behav. Biol., Dept. of Psychiat. and Behav. Sci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

The discriminative-stimulus effects of specific agonists for the two major GABA receptors were studied in rats trained to discriminate either the $GABA_A$ agonist THIP (gaboxadol, an analogue of the naturally occuring $GABA_A$ agonist muscimol) or the $GABA_B$ agonist baclofen (a central muscle relaxant) from the no-drug condition. Criterion performance was achieved more rapidly under the THIP (5.6 mg/kg, i.p.) than under the baclofen (3.2 mg/kg, i.p.) training condition. In tests, there was dose-dependent generalization to novel doses of the training drugs within each training drug condition, but discriminative control by each training drug was specific in that baclofen did not occasion drug-lever responding reliably in rats trained to discriminate THIP and vice versa. Administration of the specific benzodiazepine-receptor antagonist flumazenil dose-dependently decreased drug lever responding in combination with THIP but not in combination with baclofen. The baclofen training condition was less specific than the THIP training condition, because rats trained to discriminate baclofen were more likely to generalize to midazolam (MDZ) and to pentobarbital (PB) than were rats trained to discriminate THIP. The effects of MDZ and PB are mediated by the $GABA_A$ receptor. Thus, a major part of the baclofen/$GABA_B$ discriminative-stimulus complex may be a generalized muscle-relaxant effect. (Supported by NIDA Grant DA04133)

465.9

THE DEVELOPMENT OF $GABA_b$ ACTIVITY IN THE RAT DENTATE GYRUS: EVOKED POTENTIAL STUDIES IN THE HIPPOCAMPAL SLICE PREPARATION. P.G. DiScenna & T.J. Teyler. Neuroscience Program, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

The development of $GABA_b$ activity in the dentate gyrus was studied by examining $GABA_b$-mediated effects on orthodromically-evoked field potentials. The effects of the $GABA_b$ agonist, baclofen (5-10uM: 0.5ml/min), were examined in 8 slices from PN6-PN8 (PN6 was the first day that a population spike was elicited). The population EPSP slope was reduced by an average of 36% and population spike amplitude by 44%. Baclofen did not produce overt multiple spiking, but rather a low amplitude ripple after the primary spike. Short-latency (10-20ms IPI) paired-pulse spike inhibition converted to spike facilitation within 5min. of baclofen perfusion in all slices. This reversal was not caused by decreased pop. spike amplitude of the conditioning pulse response. All effects were reversed, but not totally eliminated by perfusion with the $GABA_b$ antagonist, phaclofen (1mM).

The results suggest that at least a subpopulation of $GABA_b$ receptors matures quickly in DG, the effects being present before the peak generation of DG's primary neurons, the granule cells, occurs.

THE EFFECTS OF A BENZODIAZEPINE PARTIAL AGONIST, RO16-6028, ON RAT EEG. K.L. Skinkle and C.M. Sinton. Neurogen Corp., Branford, CT 06405.

Recently developed partial agonists at the benzodiazepine receptor may be less sedating than the classical full benzodiazepine agonists. This study was therefore designed to evaluate the changes produced in the frequency spectrum of the cortical electroencephalogram (EEG) in the rat as a way of quantifying the sedative properties of these compounds. RO16-6028 (1.0, 0.25, 0.03 mg/kg iv) and CGS 9896 (1.0, 0.2 mg/kg iv) were thus compared with Diazepam (0.5, 0.04 mg/kg iv) and Alprazolam (0.125, 0.02 mg/kg iv). Rats were chronically implanted with cortical electrodes, and ipsilateral frontal-occipital EEG was recorded in all cases. Drugs were administered via a cannulated tail vein. Spectral analysis of the EEG signals was performed on-line using a microcomputer, and drug effects were evaluated for up to an hour following compound administration. Vigilance was maintained throughout the experiment by using a randomized disturbing noise source. All compounds at all doses increased power in the 8 to 30 Hz frequency band, which has been suggested to represent idling in thalamo-cortical circuits. This EEG change is characteristic of this type of compound: similar EEG effects are seen in man. Interestingly, the highest dose of RO16-6028 modified the EEG in other ways which were not observed with CGS 9896. These changes included a reduction in the 1 to 5 Hz band and an increase in theta frequencies (5-7 Hz). RO16-6028 thus modifies the EEG in the rat in a way which might reflect such underlying processes as recruitment of attentional systems. These processes may partially compensate for the sedative properties of the benzodiazepines, especially as higher doses of RO16-6028 are administered. The results may have implications for the design of novel non-sedating anxiolytics.

BOTH DOPAMINE AND GABA INHIBIT MELANOTROPH POMC GENE EXPRESSION AND BETA-ENDORPHIN RELEASE VIA A SIMILAR PERTUSSIS TOXIN SENSITIVE MECHANISM. Dominic J. Autelitano[1,2], Joel Parker*[3], Richard Allen*[3] and James L. Roberts[2]. Baker Medical Research Inst., Prahran, Australia[1], Mt.Sinai Med. Ctr., N Y., USA[2] and CROET, Oregon Health Sci. Univ., OR, USA[3]

The melanotroph cells of the rat intermediate lobe (IL) are directly innervated by tuberohypophyseal neurons that contain the two neurotransmitters dopamine (DA) and GABA. Although the long term effects of both DA and GABA on IL pro-opiomelanocortin (POMC) gene expression and peptide release are inhibitory, GABA has been shown to have an acute biphasic action on peptide release from either intact neurointermediate lobes (NIL) or cultured NIL cells. Previous studies have shown that the rapid stimulatory effects of GABA on alpha-MSH release can be mimicked by the GABA-A agonist isoguvacine, while the more prolonged inhibitory action is baclofen sensitive, suggesting a GABA-B receptor mediated effect. Using isolated rat NIL in short term culture (2h or 18h) we have demonstrated that 10μM GABA or the mixed GABA-A/B receptor agonist muscimol (100μM) inhibit ß-endorphin (ßEP) release by around 50%. Both these agents have similar inhibitory effects on POMC cytoplasmic mRNA and nuclear primary RNA transcripts in 18h cultures. In addition, both baclofen and isoguvacine inhibit ßEP release in 2h or 18h cultures, indicating that both GABA-A and -B receptors may have long-term inhibitory actions. Neither the GABA-A antagonist bicuculline nor the GABA-B antagonist 2-hydroxysaclofen completely block the inhibitory actions of GABA on ßEP release. A dose dependent inhibition of ßEP release from NIL is seen with increasing doses of the DA-D2 receptor agonist quinpirole. GABA (10μM) or muscimol (100μM) when given together with sub-maximal doses of quinpirole give additive effects on the inhibition of ßEP release, though no additivity is seen with maximal inhibitory doses of the DA agonist. Similarly, 100μM muscimol, or the DA agonist bromocriptine (0.1μM) each lead to a 50% inhibition of POMC mRNA in 18h cultures but showed no additive effects when administered together. In NIL cultures pretreated for 18h with 100 ng / ml pertussis toxin (PTX), these inhibitory effects of quinpirole, GABA and muscimol are abolished. These data suggest that in the rat IL, GABA can inhibit POMC expression via a complex mechanism that involves both GABA-A and GABA-B receptors. The PTX sensitivity, and lack of additivity of DA and GABA responses suggests that a common or similar G-protein may mediate the inhibitory effects of these receptors.

PERIPHERIAL TYPE GABA-A RECEPTORS INHIBIT FIELD STIMULATED CONTRACTIONS OF RABBIT URINARY BLADDER. M.R.Ruggieri. Urology Research Laboratories, Temple University, Phila, PA 19140.

Gamma amino butyric acid (GABA) is an established inhibitory neurotransmitter in the central nervous system, and may also be involved in inhibitory circuits of the autonomic nervous system and peripheral organs. GABA-A receptors in different regions exhibit differential sensitivity to GABA and GABA receptor modulators such as benzodiazepines indicating receptor heterogeneity. The specific binding of [3H]-flunitrazepam to rabbit bladder homogenates and the effect of GABA and flunitrazepam on electric field stimulated contractions of in vitro bladder strips was determined. Bladder body strips (1 X 0.2 cm) were suspended in oxygenated Tyrode's solution and stretched to within 10% of the length for maximum tension. Three frequency response curves to electric field stimulation (60 V, 1 msec duration, 1 - 32 Hz) were generated - control, 30 min following exposure to 10^{-4} M GABA or flunitrazepam, and 30 minutes after adding both compounds. Results are displayed at the right. [3H]-flunitrazepam (0.5 - 125 nM) demonstrated specific, saturable binding to rabbit bladder membranes (Kd=21nM, Bmax=2.7pMol/mg protein) which was inhibited by unlabeled diazepam (10^{-11} - 10^{-5} M), but not by unlabeled clonazepam, a "central" type benzodiazepine receptor agonist. The Kd for diazepam was determined by Hill plot to be 28 nM, demonstrating a similar binding affinity of these two ligands. This suggests a role for GABA in inhibitory regulation of bladder function at the end organ.

$GABA_A$ RECEPTORS: SUB-TYPES AND ALTERATIONS IN CHRONIC HYPERAMMONEMIA. B.A. McLaughlin, M.B. Robinson and D.B. Pritchett. Children's Seashore House; Depts. Ped. and Pharm., Univ. of PA; Philadelphia, PA, 19104.

Multiple subtypes of $GABA_A$ receptors have been identified. Through the use of molecular biology, it has been possible to demonstrate that the diversity of the heteromeric $GABA_A$ receptors may be due to variations in the subunit composition. It was recently shown that the type of α subunit confers specificity for benzodiazepine interactions with the receptor. Transfection of cells with cDNAs encoding the α1, ß3, and γ2 subunit results in a [^{3}H]RO-15-1788 binding site that is potently displaced by zolpidem (IC_{50} = 40 nM). If an α5 subunit is substituted, binding is less potently inhibited by zolpidem (IC_{50} = 30 μM). This raises the possibility that each of the subunits may be independently regulated. Previous studies using [^{3}H]GABA have shown that the density of the $GABA_A$ receptors is increased during acute hyperammonemia induced by hepatic encephalopathy. The binding of [^{3}H]RO-15-1788, a non-selective α1–α5 antagonist, was examined in the sparse fur mouse (*spf/*Y), a model of congenital hyperammonemia. The (*spf/*Y) has an X-linked deficiency of liver ornithine carbamoyltransferase which leads to 2-3 fold elevations in plasma ammonia levels. No differences were observed in cortical, cerebellar or hippocampal homogenate binding of *spf/*Y mice compared to controls. Therefore, we were unable to confirm previously reported alterations in GABA receptors in hyperammonemia. This result could be due to the use of [^{3}H]RO-15-1788 which is non selective. To begin to elucidate subunit alterations, zolpidem displacement of [^{3}H]RO-15-1788 was examined. In normal animals, homogenate binding was consistent with two sites in cortex and hippocampus (Hill Coefficients < 0.7).

REGIONAL DEVELOPMENTAL SWITCHES IN mRNA ENCODING TYPE I AND TYPE II $GABA_A$ RECEPTORS. R.E. Williamson*, M.A. Dichter, & D.B. Pritchett.Children's Seashore House, Depts Pediat & Pharm Univ Pennsylvania, Phila PA 19104.

Molecular biological studies of the $GABA_A$ receptor reveal pharmacologically distinct receptor subunits consisting of α, β, and γ components. Photoaffinity labelling of certain combinations of subunits with tritiated benzodiazepines generates 2 functional $GABA_A$ complexes that display type I (α1) and type II (α2, 3, & 5) receptor pharmacologies. Previous studies suggest a developmental switch in rat cortex and cerebellum from type II to type I receptors. To investigate this switch, we used the ribonuclease protection assay to hybridize rat brain mRNA with anti-sense mRNA synthesized from probes specific for the α1, α2, α3, and α5 subunits. In *in vivo* experiments using rat cerebellum and cortex, α3 and α5 mRNAs were most abundant at birth and decreased over time. α1 mRNA, which was virtually non-existent at birth, became most abundant by day 15 in cerebellum and day 9 in cortex. The same switch in receptor subtypes did not occur in *in vitro* experiments where mRNA was extracted from rat fetal cortical neurons grown in culture. The cultured neurons harvested at 1 week intervals (7 to 54 days) were the same age as or older than the brain tissue used in the *in vivo* experiments. The same shift in receptor subtypes was observed in mutant reeler mice that have Purkinje cells malpositioned in the granule cell layer of the cerebellum but that still express nearly intact synapses. When the DNA synthesis inhibitor 5-Fluorodeoxyuridine was injected into 2-day old rats, interfering with postnatal neurogenesis of cerebellar granule neurons, the same switch was seen. Further experiments are needed to establish if this developmental shift is a result of synaptogenesis or if it is an intrinsic property of the neuron.

SEX DIFFERENCES IN TRANSPUBERTAL HYPOTHALAMIC AND HIPPOCAMPAL $GABA_A$ RECEPTOR BINDING OF [^{3}H]-SR-95531 IN THE RAT. W. Jacobson and G.A. Cottrell. Division of Reproductive Science, Dept. of Obstetrics and Gynecology, and Dept. of Pharmacology, University of Toronto, Toronto, Canada M5G 1L7.

The inhibitory neurotransmitter γ-amino benzoic acid (GABA) has been implicated in the control of LH release in the rat. Numerous studies suggest that during the pubertal transition, inhibitory influences on LH release are diminished. Using the technique of in vitro autoradiography, and the arylaminopyridazine derivative SR-95531 (SR), a specific $GABA_A$ antagonist, we investigated the ontogeny of these binding sites in selected mediobasal-hypothalamic nuclei and in the rostral hippocampus in both male and female rats. In males, significant changes in hypothalamic binding were evident only in the medial preoptic area, where the binding on d25 and d32, but not on d37 was increased compared to d15. No changes were seen in other hypothalalmic regions examined, including the Bed Nucleus Stria Terminalis, the anterior hypothalamic area, or the ventromedial nucleus. Hippocampal binding increased sharply in the dentate gyrus, CA1 and CA3 regions transpubertally, while in the CA2 region it returned to d15 levels by d37. In females, significant differences in the amount of [^{3}H]-SR bound to various regions of the hypothalamus were not found transpubertally, while the hippocampus showed large increases with development. Interestingly, significant levels of SR binding were not seen in the BNST in either sex at D15. Thus, it appears that $GABA_A$ receptor patterns demonstrate sex-specific regional heterogeneity with development. The significance of these findings with regard to the pubertal transition are currently under investigation. Supported by the Canadian MRC, MA-10911.

465.16

DEVELOPMENTAL CHANGES IN 35S-TBPS BINDING SITES IN THE CEREBRAL CORTEX OF THE RAT. M.G. Corda, E. Cancedda*, M. Orlandi* and O. Giorgi.

Department of Experimental Biology, Neuroscience Section, Cagliari University, Italy.

The postnatal development of the GABA-gated chloride ionophore was analyzed in the cerebral cortex of the rat by measuring the binding parameters of 35S-t-butylbicyclophosphorothionate (35S-TBPS) at intervals (1 to 90 days) after birth. The density (Bmax) of 35S-TBPS binding sites at birth was only 25% of the adult (90-day-old) value and, after a rapid increase up to 30% above the adult value by postnatal day 15, it decreased to adult levels by postnatal day 45. In contrast, the binding affinity (Kd) of 35S-TBPS remained constant from birth through adulthood. It is well known that the binding of 35S-TBPS to the GABA-gated chloride channel is allosterically modulated by drugs acting on different sites of the GABA-A receptor complex. Thus, GABA, benzodiazepines and barbiturates decrease 35S-TBPS binding whereas an opposite effect is induced by the GABA receptor antagonist, bicuculline, and by convulsant ligands for benzodiazepine receptors, such as methyl 6,7-dimethoxy-4-ethyl-β-carboline-3-carboxylate (DMCM). The allosteric modulation of 35S-TBPS binding sites was already evident at early stages of postnatal development. In fact, the magnitude of the effects of positive and negative modulators of the GABA-A receptor complex on 35S-TBPS binding did not change significantly from birth through adulthood. These results reflect the early development of the functional link between the different components of the GABA-A receptor.

OPIOIDS; ANATOMY AND PHYSIOLOGY II

466.1

ESTRADIOL AND PROGESTERONE MODULATION OF BETA-ENDORPHIN SECRETION IN HYPOTHALAMIC CULTURES L.P. Kapcala and C.F. Weng* Dept. of Med., Univ. of Maryland, SOM Baltimore, MD 21201.

Hypothalamus is the major source of brain β-endorphin (β-E), a neuropeptide involved in the regulation of a variety of brain functions. Considering previous work showing sex steroid (estrogen, progestogen, androgen) alterations of levels of hypothalamic β-E and/or pro-opiomelanocortin (POMC-precursor of β-E) mRNA, it is believed that sex steroids modulate synthesis of POMC and secretion of its derivatives. Despite conflicting results regarding sex steroid effects on POMC mRNA, indirect studies have suggested that estrogen stimulates and progesterone inhibits hypothalamic β-E secretion. To address the issue directly, we tested the hypothesis that estrogen stimulates and progesterone inhibits hypothalamic β-E secretion. We studied β-E (RIA) secretion and concentration in dissociated fetal rat hypothalamic cells (11-20 days in culture) exposed to estradiol (E_2) and progesterone (P_4). Although basal β-E release was not altered by 48 hr pre-incubation with E_2 (10^{-12}-10^{-9}M), depolarization (60 mM KCl)-induced β-E secretion was potentiated variably, up to 2 fold over control. There was no potentiation of secretion following 24 hr E_2 pre-incubation. Low P_4 concentrations ($2x10^{-8}$M) did not alter E_2 (10^{-11}M) potentiated β-E release. However, high P_4 concentrations ($2x10^{-7}$M) significantly blunted the % increment of KCl-induced β-E release/basal release by 55% and 64% respectively vs that produced by pre-incubation with E_2 alone and E_2+P_4 (low dose). E_2 (10^{-11}, 10^{-9}M) treatment (48 hr) increased hypothalamic β-E concentrations in cells by 28 and 56% over that of control. These data are compatible with the hypotheses that E_2 potentiates stimulated hypothalamic β-E secretion by increasing the releasable β-E pool and that P_4 blunts E_2-potentiated release.

CONCLUSION: E_2 and P_4 modulate the secretion of hypothalamic β-E secretion in a counterregulatory fashion.

ONTOGENY OF MU OPIATE TOLERANCE: EFFECTS ON THE HYPOTHALAMIC PITUITARY-ADRENAL AXIS. P.J. Little and C.M. Kuhn. Dept. Pharmacol. Duke Medical Center, Durham, NC 27710.

Our laboratory has reported two disparate responses of developing rats to chronic opiate treatment. Tolerence has been demonstrated in both pups and adults for stimulation of corticosterone secretion by morphine. In contrast, no tolerance was observed in pups to the antinociceptive effects of morphine, while robust tolerance was demonstrated in weanlings. In order to help resolve these differences, dose-response curves for morphine-induced stimulation of ACTH were determined in developing rats following a chronic morphine treatment which did not cause tolerance to morphine antinociception. Rats were treated between days 4-8 (pups) or 21-25 (weanlings) with morphine (5-25 mg/kg, sc, b.i.d.)and 48 h later dose-response curves for morphine-induced stimulation of ACTH were determined. Morphine (1-10 mg/kg, sc) produced dose-dependent increases in serum ACTH in saline treated pups and weanlings. The dose-response curve for chronically treated morphine pups was similar to that of the saline treated pups. In contrast, there was a significant shift to the right of the morphine dose-response curve in weanlings treated chronically with morphine. This study supports the hypothesis that mu receptor are relatively refractory to the development of tolerance in the neonatal rat. Supported by DA 02739.

466.3

NEONATAL OPIATE ABSTINENCE IN THE ABSENCE OF TOLERANCE. R. T. Windh, P.J. Little and C. M. Kuhn. Dept. of Pharmacol. Duke Medical Center, Durham, NC 27710.

We have demonstrated that neonatal rats are more refractory to developing opiate tolerance to morphine analgesia than are weanling rats. Therefore, neonatal rats provide a useful model for addressing the question of the obligate association of opiate tolerance and abstinence. The following work was performed to determine whether the same chronic morphine regimen which did not cause neonatal tolerance to analgesia can result in abstinence. Rats were treated with 5-25 mg/kg morphine (2x/day, s.c.)on days 4-8 or 21-25, given naloxone 12 hours after the last morphine injection, and then scored for spontaneous behavior for 30 min. or killed for analysis of serum corticosterone. Weanling rats displayed an abstinence syndrome that consisted of ptosis, lacrimation, piloerection, abnormal posture, forepaw treading, and hostility on handling. Neonatal rats also showed an abstinence syndrome, characterized by abnormal posture, spontaneous vocalizations, locomotor hyperactivity, and tremor. Furthermore, morphine-treated pups and weanlings that received naloxone had significantly elevated corticosterone levels compared to animals that did not. Thus, abstinence is observed in pups which show no tolerance to morphine analgesia. Supported by DA 02739.

466.4

MU OPIOID AGONISTS STIMULATE GROWTH HORMONE SECRETION IN IMMATURE RATS. M. Eason and C. Kuhn. Dep't of Pharmacology, Duke Medical Center, Durham, NC 27710.

It has been shown that *d*-opioid receptors mediate the stimulation of growth hormone (GH) release in rats. However, in suckling rats, *d*-opioid receptors are not abundant, but opioid agonists still stimulate GH secretion. Therefore, we chose to investigate the possibility that *u*-opioid receptors are involved in GH release. In this study it was shown that *u*-opioid agonists stimulated GH release in twenty day-old rats. Sufentanil and [D-Ala^2, *N*-methyl-Phe^4, Gly^5-ol]enkephalin (DAMGO), selective *u*-opioid agonists, each stimulated GH release in a dose-dependent manner. [D-Pen^{2,5}]enkephalin, a *d* selective agonist, did not stimulate GH release when given in the same doses as DAMGO. Morphine (5 mg/kg), a non-selective opioid agonist, also stimulated GH release. Naloxone (1 mg/kg) completely blocked the GH response to morphine (5 mg/kg) and sufentanil (2.5 ug/kg). Beta-funaltrexamine (B-FNA, 10 mg/kg), an irreversible and selective *u*-opioid antagonist, diminished the GH response to morphine (5 mg/kg) and sufentanil (2.5 ug/kg). Naltrindole (NTI, 1 mg/kg), a relatively selective *d*-opioid antagonist, blocked neither the response to morphine nor sufentanil. These results suggest that *u*-opioid receptors are involved in the mediation of GH release in developing rats while *d*-opioid receptor-mediated GH secretion might play a more important role later in ontogeny. Supported by DA 02739.

466.5

SPINAL CORD OPIOID PEPTIDE LEVELS ARE ELEVATED DURING GESTATION. V.M. Medina* and A.R. Gintzler. Dept. of Biochem. SUNY Health Science Ctr., Brooklyn, NY. 11203.

In laboratory animals and humans, pregnancy is associated with an opioid receptor-mediated increase in the threshold for maternal responsiveness to aversive stimuli. Pharmacological and behavioral experiments indicate that, at least in part, this analgesia results from the activation of a spinal cord dynorphin/kappa opioid receptor system. We now demonstrate that during late pregnancy there is a significant elevation in the content of opioid peptides in specific regions of the rat spinal cord. Opioid content was assessed by RIA using antibodies selective for either dynorphin (1-17 or 1-8) or met-enkephalin. On day 22 of gestation, in 5 out of 5 rats, the content of dynorphin (1-17) and dynorphin (1-8) increased by 34 and 48%, respectively in the lumbar spinal cord ($p < .01$). In contrast, levels of both these opioid peptides did not show any consistent change in the cervical or thoracic spinal cord at this stage of pregnancy. Levels of met-enkephalin increased in the lumbar and thoracic cord (66% and 32%, respectively; $p<.05$) in 4 out of 5 pregnant (day 20) rats. In addition, there was a numeric, but not statistical, increase in met-enkephalin content in the cervical region. These results provide the first biochemical evidence that during gestation, there is a positive modulation of spinal cord opioid systems.

466.6

ENDOGENOUS OPIOID PEPTIDES (EOP) ARE INVOLVED IN THE SUCKLING INDUCED PROLACTIN INCREASE IN FEMALE RATS. P. Callahan, M. Stanik and J. Janik. Miami University, Oxford, OH 45056.

The purpose of these experiments was to identify the specific EOP involved in the suckling induced prolactin secretory response. Post-partum, lactating female Sprague-Dawley rats were used for all experiments. Animals were implanted with chronic intraventricular (ivt) cannulae into the lateral ventricle of the brain. Following a 5 - 7 day recovery period and one day prior to an experiment, each animal was implanted with a chronic jugular cannulae. On the day of the experiment, pups were removed from the dams. After 6 hours of separation, saline or antiserum to β-endorphin, met-enkephalin or leu-enkephalin (0.75 or 1.5 µg, ivt in 5ul) was administered. Immediately following administration of antiserum, dams were replaced with the pups and monitored for suckling response. Blood samples were withdrawn immediately prior to antiserum administration and 15, 30, 45 and 60 minutes after the onset of suckling.

Antiserum to leu-enkephalin most potently inhibited the suckling induced prolactin increase. This antiserum effectively blocked prolactin release at both concentrations administered. Neither β-endorphin nor met-enkephalin antiserum significantly attenuated the prolactin release at the two concentrations administered. However, a 10 fold increase in the dose of anti-β-endorphin totally abolished the suckling induced prolactin increase. These results clearly indicate that the EOP are involved in the suckling induced prolactin increase.

466.7

EFFECTS ON NEUROHYPOPHYSIAL HORMONE RELEASE, DIURESIS AND ELECTROLYTE OUTPUT OF μ- AND κ-OPIOIDS. B. van de Heijning & T.B. van Wimersma Greidanus*. Rudolf Magnus Institute, Dept. of Pharmacology, Utrecht, the Netherlands.

Opioids alter fluid metabolism and electrolyte balance. The mechanism of action is assumed to involve opioid modulation of neurohypophysial hormone output. The effects of the κ-agonist U69,593 and the μ-agonist DALDA on urinary output and renal electrolyte handling were investigated in normally-hydrated, non fluid-loaded, male rats. Using a protocol of hourly urine sampling up to 6 h, it was found that the s.c. applied κ-agonist (dose range 0.01-5 mg/kg) induced a prominent diuresis up to 3 h post injection. The diuretic effects of the μ-ligand DALDA (same dose range) were less pronounced. Both agonists had no effect on diuresis when given I.c.v. (0.2-10 µg/2µl). No major effects were found on renal sodium or potassium output of either drug administered by either route.

The μ-agonist DALDA (dose range 0.01-5 mg/kg) strongly inhibited the release of both vasopressin (VP) and oxytocin (OT), an effect that was maximal 30-60 min after s.c. injection. The same was found for the s.c. applied κ-agonist U-69,593. I.c.v. applied (0.5 and 5 µg/kg), only DALDA (μ) and not U69,593 (κ) suppressed plasma hormone levels 30 min after injection.

Thus, although both agonists suppress VP and OT release upon s.c. application, the μ-induced diuresis is only marginally compared to the κ-agonist. I.c.v. applied, the μ-agonist did not affect urination but inhibited VP and OT release. We conclude with respect to the data on suppressed VP and OT plasma levels, that the profound κ-induced diuresis cannot be explained entirely by an inhibition of neurohypophysial hormone output, and we suggest that additional mechanisms and sites of action (e.g. in the kidney cortex) are involved.

EXPRESSION AND PHARMACOLOGICAL CHARACTERIZATION OF A CANINE 5-HT_{1D} RECEPTOR SUBTYPE. J.M. Zgombick, R.L. Weinshank*, M.Macchi*, L.E. Schechter, T.A. Branchek, and P.R. Hartig. Neurogenetic Corporation, Paramus, N.J. 07652

RDC4, a guanine nucleotide-binding protein- (G protein) coupled receptor originally isolated in a canine thyroid cDNA library by Libert and colleagues, was identified as the canine homolog of the human 5-HT_{1D} receptor. Clone RDC4 is an intronless gene encoding a protein of 377 amino acids and containing three consensus sequences for N-linked glycosylation in its amino terminus. The deduced amino acid sequence of clone RDC4 exhibits greatest sequence identity (43%) with the 5-HT_{1A} receptor and lower overall homology to other serotonergic and catecholaminergic receptors. This sequence information suggested that clone RDC4 encoded a novel serotonergic receptor. In order to determine the pharmacological identity of clone RDC4, murine LM (tk$^-$) fibroblasts were stably transfected with the DNA encoding this gene and radioligand binding studies were conducted using [^{3}H]5-HT. Membranes prepared from stable transfectants displayed an apparently homogeneous population of high affinity (K_d = 3.6 nM), saturable (B_{max} = 275 fmol/mg protein) [^{3}H]5-HT binding sites. High affinity [^{3}H]5-HT binding was unchanged using assay conditions (1 μM pindolol and 1 μM SCH 23390) to pharmacologically mask 5-HT_{1A}, 5-HT_{1B}, and 5-HT_{1C} receptors. Serotonergic ligands displaced specific [^{3}H]5-HT binding with a rank order of potency expected of a 5-HT_{1D} receptor subtype: 5CT > 5HT > Yohimbine > DPAT > Ketanserin = Spiperone > Zacopride. These binding properties are supportive of the designation of clone RDC4 as encoding a 5-HT_{1D} receptor subtype.

467.2

IDENTIFICATION OF A NOVEL G PROTEIN-COUPLED RECEPTOR WHICH EXHIBITS HIGH HOMOLOGY TO CLONED SEROTONIN RECEPTORS. Y. Shen, F.J. Monsma, Jr., C.R. Gerfen, L.C. Mahan*, P.A. Jose, M.M. Mouradian & D.R. Sibley. Experimental Therapeutics Branch, NINDS and Laboratory of Cell Biology, NIMH, NIH, Bethesda, MD 20892.

We have utilized the polymerase chain reaction (PCR) technique to selectively amplify G protein-coupled receptor cDNA sequences from rat kidney proximal convoluted tubule (PCT) mRNA. Poly (A)$^+$ RNA was used to synthesize cDNA by reverse transcription followed by PCR amplification using sets of highly degenerate primers derived from the transmembrane sequences of previously cloned dopaminergic, adrenergic, and serotoninergic receptors. This process resulted in the amplification of a number of discrete cDNA fragments. Sequence analysis of some of these fragments revealed several previously identified receptors as well as some putatively novel receptor cDNA sequences. One cDNA was identified which, when compared to all G protein linked receptors cloned thus far, appears to be most closely related to the serotonin receptor family. Within the transmembrane domains, the rank order of homology is 5HT_{1A}>5HT_{DRO}>5HT_{1D}>>5HT_2>5HT_{1C}. Northern blot analysis reveals a ~3.6 kb transcript with the following rank order of abundance in CNS tissues: hypothalamus>hippocampus=mesencephalon>olfactory bulb>cerebral cortex>olfactory tubercle>striatum. In peripheral tissues, this mRNA is most abundant in the spleen with lesser amounts seen in the kidney, ovary, lung and uterus. In contrast, this transcript is not detectable in the cerebellum, pituitary, retina, testes, stomach, prostate, skeletal muscle, liver, gut or heart. *In situ* hybridization analysis confirms the Northern blot data and also reveals a high level of transcript in the thalamic reticular nucleus. Full length cDNA clones have been isolated and are being expressed to establish the specific pharmacology and function of this novel receptor subtype.

5-HYDROXYTRYPTAMINE BLOCKS $GABA_B$ BUT NOT $GABA_A$ SYNAPTIC POTENTIALS IN DOPAMINE NEURONS. S.W. Johnson, N.B. Mercuri and R.A. North. Vollum Institute, O.H.S.U., Portland, OR 97201.

Intracellular recordings were made from presumed dopamine neurons in slices cut from the midbrain of the rat. Focal electrical stimulation produced a long-lasting hyperpolarization (1 - 1.5 s) which was blocked by the $GABA_B$-receptor antagonist 2-hydroxy-saclofen (300 μM). Serotonin (5-HT; 3 - 100 μM) reduced the amplitude of this synaptic potential 20 - 74% with an EC_{50} of 10 μM, but did not reduce the amplitude of synaptic potentials mediated by $GABA_A$ receptors. The effect of 5-HT was mimicked by the 5-HT_{1B} agonist 1-[3-(trifluoromethyl)-phenyl]-piperazine (300 nM), but not by the 5-HT_{1A} agonist N,N-dipropyl-5-carboxamidotryptamine (1 μM) or the 5-HT_2 agonist (±)-1-(2,5-dimethoxy-4-iodophenyl)-2-amino-propane (10 μM). Cyano-pindolol (30 nM), a 5-HT_{1B} antagonist, blocked the effect of 5-HT. Hyperpolarizations produced by superfused GABA (1 mM) were not affected by 5-HT (30 μM), suggesting that 5-HT does not act post-synaptically. We conclude that 5-HT activates presynaptic 5-HT_{1B} receptors which inhibit the release of GABA onto $GABA_B$ but not $GABA_A$ receptors.

FUNCTIONAL SUBSENSITIVITY OF SEROTONIN RECEPTORS MEDIATING CLONIDINE-INDUCED INCREASES IN GROWTH HORMONE IN FAWN-HOODED RAT STRAIN RELATIVE TO WISTAR RAT STRAIN. C. S. Aulakh[a], J. L. Hill[b], C. C. Chiueh and D. L. Murphy[a] Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

Brain serotonin changes have been implicated in the etiology of affective illness and the mode of action of antidepressant and antimanic drugs (Meltzer and Lowy, 1987). Various investigators have demonstrated altered responses to serotonin agonists in the Fawn-Hooded (FH) rat strain relative to Wistar and Sprague-Dawley rat strains (Gudelsky et al., 1985; Aulakh et al., 1988, 1989). In the present study, we investigated the effects of various serotonin receptor subtype selective antagonists (mesulergine, metergoline and others) on clonidine-induced hypoactivity and increases in growth hormone levels in male Wistar rats. In addition, we compared the effects of various doses of clonidine on growth hormone levels and locomotor activity in male FH and Wistar rats. Pretreatment with mesulergine and metergoline, did not affect clonidine-induced hypoactivity but completely blocked clonidine-induced increases in growth hormone levels. Furthermore, clonidine-induced increases in growth hormone levels were significantly less in the FH rats relative to Wistar rats. On the other hand, clonidine-induced hypoactivity was not significantly different between these two rat strains. These findings support other evidence indicating that FH rat strain may prove to be a useful genetic model for some brain disorders with possible abnormalities in serotonergic function such as depression, obsessive-compulsive disorder, eating disorders and other neuropsychiatric disorders.

467.5

ANALYSIS OF SEROTONIN BRAIN RECEPTORS IN FAWN-HOODED, SPRAGUE-DAWLEY AND WISTAR MALE RATS.

R.A. Hullihan-Gibilin, Y. Park*, C. S. Aulakh*, and D. Goldman. NIAAA/LCS Bethesda, Maryland 20892

Rats of the Fawn-Hooded (FH) strain exhibit a hemorrhagic disorder known as platelet storage pool deficiency. Behavioral studies have demonstrated that serotonergic function in the CNS is altered in this rat strain relative to Wistar and Sprague-Dawley (SD) animals. In addition, FH rats drink excessive amounts of EtOH and display symptoms related to an animal model of depression compared to control animals. In the present study, specific brain regions from FH, SD and Wistar rats were examined for differences in 5-HT brain receptors. [^{3}H]8-OH-DPAT was used to label 5-HT_{1a} receptor sites and the kD values for frontal cortex, hippocampus, striatum, hypothalamus and brainstem were similar in all three rat strains. However, the Bmax values for [^{3}H]8-OH-DPAT binding in the striatum of FH rats were significantly lower than those of the SD and Wistar rats. [^{3}H]8-OH-DPAT may be labelling presynaptic autoreceptors in the striatum. Preliminary results from 5-HT_2 receptor studies using [^{3}H]Ketanserin to label the binding sites indicate that there are no significant differences in kD values in these brain regions comparing the three strains, but the Bmax values for the cortex and striatum were significantly higher in FH compared to SD rats. Ongoing autoradiographic studies and comparison of mRNA levels will provide further information on these 5-HT receptor differences.

467.6

CHARACTERIZATION OF A 5-HT_4 RECEPTOR ANTAGONIST OF THE AZABICYCLOALKYL BENZIMIDAZOLONE CLASS: DAU 6285. H. Ladinsky[o], A. Dumuis[δ*], H. Gozlan[∞*], M. Sebben[δ*], M. Turconi[o*], C.A. Rizzi[o*], H. Ansanay[∞*], E. Giraldo[o*], P. Schiantarelli[o*] and J. Bockaert[δ*]. [o]Istituto De Angeli, Boehringer Ingelheim Italia 20139 Milan, Italy, [δ]Centre CNRS-INSERM 34094 Montepellier, France and [∞]INSERM 75634 Paris, France.

The benzimidazolone derivative, DAU 6285 (endo-6-methoxy-8-methyl-8-azabicyclo [3.2.1] oct-3-yl-2,3-dihydro-2-oxo-1H-benzimidazole-1-carboxylate HCl) was found to be 3-5 times more potent than ICS 205-930 in blocking adenylate cyclase activity in mouse embryo colliculi neurons stimulated by different chemical classes of 5-HT_4 agonists (5-HT, renzapride and BIMU 8), with respective Ki's of 220, 181 and 158 nM, as calculated from Schild plots. DAU 6285 showed poor activity on 5-HT_3 receptors with respect to ICS 205-930 as determined in vitro, in binding studies (Ki, 332 vs 2.8 nM) and in vivo, on the Bezold-Jarisch reflex (ID_{50}, 231 vs 0.5 μg/kg, i.v.). No significant binding of DAU 6285 to 5-HT_{1A}, 5-HT_{1B}, 5-HT_{1C}, 5-HT_{1D}, 5-HT_2, α_1, α_2, D_1, D_2, or M1-M3 receptor subtypes (Ki >10 μM) was found. The data show that DAU 6285 has somewhat higher affinity for 5-HT_4 receptors, and much lower affinity for 5-HT_3 receptors, than does ICS 205-930. The compound thus represents a new tool for investigating the 5-HT_4 receptors.

467.7

CALMODULIN ANTAGONISTS INHIBIT TRITIATED IMIPRAMINE BINDING TO THE SEROTONIN UPTAKE APPARATUS. D.M. Helmeste and S.W. Tang. Veterans Administration Medical Center, Long Beach, CA 90822. Dept. Psychiatry, University of California, Irvine CA 92715, USA.

In an effort to evaluate potential ligands for the tritiated imipramine (IMI) binding site, we recently observed that calmodulin antagonists inhibit ^{3}H-IMI binding to the 5HT uptake complex. It has previously been found that calmodulin antagonists may regulate uptake and release of precursors or neurotransmitter themselves. Specifically we found that calmodulin antagonists with naphthalenesulfonamide type structures inhibited ^{3}H-IMI binding to either calf cerebral cortex or human platelets with affinities equal to or greater than those reported for calmodulin itself. However, calmodulin antagonists calmidazolium and calmodulin binding domain did not inhibit ^{3}H-IMI binding. Binding inhibition was not affected by the presence or absence of EDTA or calcium.This is inconsistent with an action on calmodulin since these antagonists require calcium for their interaction with this protein. Scatchard analysis of the interaction of W-7 (N-6-Aminohexyl-5-chloro-1-naphthalenesulfonamide) with ^{3}H-IMI binding suggested direct competition rather than an allosteric interaction (as shown by increased Kd rather than Bmax decrease). These results suggest that naphthalenesulfonamide derivatives may directly interact with the ^{3}H-IMI binding site, rather than modulate its binding through calmodulin.

IC_{50} (Human Platelets, 2nM ^{3}H-IMI):

N-(6-aminohexyl)-5-chloro-1-naphthalenesulfonamide (W-7) = 15μM; N-(6-aminohexyl)-1-naphthalene sulfonamide (W-5) = 75μM; N-(6-aminohexyl)-5-chloro-2-naphthalenesulfonamide = 18μM; N-(6-aminohexyl)-2-naphthalenesulfonamide = 40μM; N-(5-aminopentyl)-5-chloro-1-naphthalenesulfonamide = 5μM ; N-(5-aminopentyl)-1-naphthalenesulfonamide = 40μM; Calmidazolium (R24571) no activity at 1μM. Calmodulin binding domain (Calbiochem 208734), no activity at 100μM.

467.8

IDENTIFICATION OF A NOVEL PHOSPHOINOSITIDE-LINKED INDOLEAMINE BINDING SITE WITH [3H]NOSCAPINE. A. Khan, R.J. Mourey, T.M. Dawson and S.H. Snyder. Depts. of Neuroscience and Pharmacology, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Noscapine, a clinical antitussive phthalideisoquinoline alkaloid isolated from opium, has been used to identify a high affinity binding site in guinea pig brain (Karlsson, M.O. et. al. Eur. J. Pharm., 145:195, 1988). Based on the clinical specificity of noscapine, i.e., cough suppression while lacking analgesic, sedative, respiratory depressant, euphoric and addictive properties, we were interested in further characterizing the pharmacological and neurophysiological properties of the noscapine binding site.

Approximately 1200 drugs, encompassing most drug classes, were screened by a filtration binding assay for the ability to compete for [3H]Noscapine binding. Only drugs which contained an indoleamine or isoquinoline structure had affinity: the vasodilators, papaverine (13nM), hydrastine (32 nM); beta-carbolines (60nM-500nM), and serotonin analogs (100nM-10uM). GABA and serotonin receptor antagonists failed to compete. Structure-binding studies with beta-carboline and serotonin analogs were conducted to learn about chemical structure requirements for binding. The noscapine binding site was also shown to be brain-specific and insensitive to ions.

Using [3H]cytidine as a measure of phosphoinositide (PI) turnover (Hwang, P.M. et. al. Science, 249:802, 1990.), noscapine was shown to potently inhibit carbachol-stimulated PI turnover in guinea pig striatal slices. Noscapine by itself had no affect. More importantly, this effect displayed the proper pharmacology. Drugs which competed for [3H]noscapine binding also inhibited carbachol-stimulated PI turnover in the proper rank order. Drugs which resembled noscapine and papaverine, but were inactive at binding, were either inactive or weakly potent at inhibiting PI turnover.

EVIDENCE THAT THE SEROTONIN RELEASER P-CHLOROAMPETAMINE ELEVATES BLOOD PRESSURE, PLASMA RENIN AND PLASMA CORTICOSTERONE THROUGH CENTRAL MECHANISMS. Rittenhouse PA, Levy AD, Li Q, Yracheta JM, Kunimoto K, Van de Kar LD. Loyola University Chicago, Maywood, IL 60153.

PCA is a serotonin (5-HT) releaser that reliably increases both plasma corticosterone (CORT) and plasma renin concentration (PRC) when injected peripherally. The aim of these studies was to determine the role of central 5-HT receptors in mediating this hormonal response. PCA was injected intracerbroventricularly (ICV) in conscious male rats at doses (50, 500, 1000 μg/kg) below those peripherally effective. Trunk blood was collected 1 hour later. CORT was elevated in a dose dependent manner, while PRC did not change. Pretreatment with the 5-HT_2 antagonist LY53857 (20 μg/kg, ICV) did not affect either the CORT or PRC response. Since an increase in blood pressure (BP) due to PCA could inhibit the PRC response, femoral arterial catheters were implanted to record BP. We found that 1.0 mg/kg PCA significantly raised BP ($p<.01$) at 2 and 5 minutes after ICV injection, but not after peripheral intra-arterial injection. An additional experiment showed that a dose of 500 μg/kg PCA (ICV) significantly increased PRC ($p<.01$) if preceded by the α_1 antagonist prazosin (1.0 mg/kg, sc). Thus, by masking the cardiovascular effects with prazosin, PCA's stimulatory effect on renin was exposed. Finally, ibotenic acid lesions were made in the hypothalamic paraventricular nucleus (PVN). Ibotenic acid destroys cell bodies, but leaves fibers of passage intact. Two weeks after surgery rats were injected with 8 mg/kg PCA (ip). Rats with histologically verified PVN ibotenic acid lesions had significantly attenuated CORT ($p<.01$) and PRC ($p<.05$) responses compared to vehicle treated controls. Thus, cell bodies in the PVN mediate the CORT and renin response to PCA. Supported by AHA, Chicago.

IDENTIFICATION OF 5-HT RECEPTORS IN THE DOG DENTAL PULP. M. LIU*, S. KIM*, A.L. KIRCHGESSNER, P.R. WADE & M.D. GERSHON. Dept. of Endodont., Dept. of Anat. & Cell Biol., Columbia Univ., N.Y., N.Y.

5-Hydroxytryptamine (5-HT) causes vasoconstriction of dental pulp blood vessels (Kim et al. 1985) and excitation of intradental nerves (Olgart 1974). We tested the hypothesis that the dog dental pulp contains 5-HT receptors and 5-HT-containing nerve fibers. [^{3}H] 5-HT was used as a radioligand. Binding of [^{3}H] 5-HT to membranes derived from dental pulp was studied. An excess of 5-HT (10 μM) was used to define non-specific binding. 5-HT-containing nerve fibers were detected by immunocytochemistry. Saturable binding of [^{3}H] 5-HT was observed, which could best be described by a 2-site model (K_{d1} = 1.3 nM, B_{max1} = 162.5 fmol/mg protein; K_{d2} = 7.7 μM, B_{max2} = 23.5 nmol/mg protein). The binding of [^{3}H] 5-HT to dental pulp membranes was inhibited only by compounds, such as N-acetyl-hydroxytryptophyl-5-hydroxytryptophan amide (5-HTP-DP), that act at enteric 5-HT_{1P} receptors (Gershon et al. 1990). Radioautography revealed [^{3}H] 5-HT binding sites on intradental nerve bundles. Immunocytochemistry demonstrated 5-HT-immunoreactive (IR) non-varicose nerve bundles running throughout the dental pulp. 5-HT-IR fibers were less common than those which showed neuropeptide immunoreactivity (NYP, CGRP, SP). These preliminary results suggest that 5-HT_{1P} receptors play a role in the regulation of pain and blood flow in the dental pulp. Supported by NIDR DEO-5605 and NS 12969.

NOVEL HIGH AFFINITY ^{3}H-SEROTONIN BINDING SITES IN BRAIN TISSUE:EVIDENCE FOR FURTHER 5-HT_1 RECEPTOR SUB-TYPES. E. Weisberg and M. Teitler. Dept. Pharmacology and Toxicology, Albany Medical College, 47 New Scotland Avenue, Albany, New York 12208

We report herein that high affinity ^{3}H-5HT binding to homogenates of bovine and rat caudate and cortical tissues cannot be interpreted without including additional "5-HT_1-like" receptors other than the well-characterized $5HT_{1A}$, $5HT_{1B}$, $5HT_{1C}$ and $5HT_{1D}$ receptors. Competition studies were performed in rat and bovine frontal cortex and caudate tissues, using pharmacological blockade of $5HT_{1A}$, $5HT_{1B}$, and $5HT_{1C}$ receptors to facilitate examination of other possible sites. Our hypothesis was that if one other site exists in rat or bovine brain tissue, then the affinity of 5CT and/or ergotamine for that site should be the same in the four tissues studied. As shown in the table, the affinities of 5CT and ergotamine for the specific binding of ^{3}H-5HT, with $5HT_{1A}$, $5HT_{1B}$, and $5HT_{1C}$ receptors pharmacologically blocked (with pindolol and mesulergine) are different in each of the four tissues studied. Further data to be presented support the argument that there are additional "5-HT_1-like" binding sites in mammalian brain tissue and these sites may be heretofore uncharacterized, functional 5HT receptors.

DRUG	Rat cortex	Rat striatum	Calf cortex	Calf striatum
5CT	101±22 nM	82±5 nM	14±4 nM	0.8±0.1 nM
ergotamine	130±30 nM	51±5 nM	7±0.5 nM	5±0.8 nM

5-HT_1 RECEPTOR-MEDIATED INHIBITION OF PORCINE PIAL VENOUS TONE. M. Ueno, T.J-F. Lee. Dept. Pharmacol., Southern IL Univ. Sch. Med., P.O. Box 19230, Springfield, IL 62794-9230

We have demonstrated that 5-HT inhibits, via 5-HT_1-like receptors, the spontaneous rhythmic constriction (SRC) and KCL-or U46619-induced sustained active muscle tone (SAT) of porcine pial veins. In this study, we further characterized the 5-HT receptors mediating inhibition of SRC and KCL-or U46619-induced SAT of porcine pial vein, using an *in vitro* tissue bath technique. Changes in isometric vessel wall tension were measured. The results indicated that α-Me-5-HT_1 a 5-HT_2 agonist, induced a small enhancement of SRC and SAT. 2-Me-5-HT, a 5-HT_3 agonist, did not affect SRC and SAT. 8-OH-DPAT (a 5-HT_{1A} agonist), TFMPP (a 5-HT_{1B} agonist) and 5-methoxytryptamine (5-MT, a 5-HT_{1C} agonist) inhibited SRC and SAT in a dose-dependent manner. Based on the ED_{50} values, 5-MT is the most potent preferential 5-HT_1 agonist in inhibiting SRC and SAT. On the other hand, GR43175 (a 5-HT_{1D} agonist) did not affect SRC or SAT. Ketanserin, a 5-HT_2 antagonist, did not significantly affect the 5-MT inhibition of the SRC and SAT. Methysergide, a 5-$HT_{1\text{ and }2}$ antagonist, however, significantly blocked 5-MT induced inhibition of SRC and SAT. Results of this study indicate that multiple 5-HT_1 receptor subtypes are involved in 5-HT inhibition of SRC and SAT in porcine pial veins, although 5-HT_{1C} agonist appears to be most potent in inhibiting these contractions. (Supported by NIH HL27763, AHA/IHA and SIU-CRC)

CISAPRIDE EXCITES HIPPOCAMPAL PYRAMIDAL CELLS THROUGH 5-HT4-LIKE RECEPTORS. S.M.Roychowdhury* and E.G.Anderson. Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

5-HT typically inhibits then facilitates hippocampal pyramidal cell firing. The inhibition involves 5-HT1A receptors. The mechanism of facilitation remains uncertain. We examined the effects of 5-HT on hippocampal CA1 pyramidal neurons in slices incubated in a low calcium (0.1 mM)-high magnesium buffer (2.5 mM) buffer that blocked synaptic transmission and induced a slow, rhythmic bursting discharge (0.1-3 Hz), reflecting cell excitability. 5-HT commonly inhibited cell discharge, followed by off-stimulation upon washout. The inhibition was mimicked by 5-carboxamidotryptamine or 8-OH-dipropylaminotetralin and blocked by spiroxatrine, suggesting mediation by 5-HT1A receptors. The off-stimulation was blocked by 1-10μM of ICS 205-930. Alpha-methyl 5-HT, like 5-HT, produced inhibition followed by off-stimulation. The off-stimulation was blocked by 5 μM ICS 905-230. Cisapride, a 5-HT3 antagonist/5-HT4 agonist, stimulated pyramidal cell burst firing in a dose-dependent manner (10-100μM) which was blocked by 1-10 μM of ICS 205-930 but not by MDL 72222. The 5-HT3 agonist 2-methyl 5-HT had no effect on cell discharge. The phosphodiesterase inhibitor isobutyl methyl xanthine (IBMX) increased the cell firing rate at 10μM or more. Co-administration of subthreshold doses of IBMX (1μM) and cisapride (1μM) increased the excitation produced by 1 μM cisapride. We conclude that the 5-HT induced inhibition is mediated by 5-HT1A receptors while the off-stimulation appears to be mediated by 5-HT4 receptors.

467.14

AUTORADIOGRAPHIC LOCALIZATION OF SEROTONIN RECEPTORS IN THE RAT SPINAL CORD. K.B. Thor, S. Nickolaus*, M. Seggel and C. Helke. Lilly Research Laboratories, Indianapolis, IN 46285; USUHS and NIH, NINDS, LNP, Bethesda, MD.

Serotonin (5HT) is present in the spinal cord, where it exerts multiple effects. The present study describes the distribution of 5HT1A, 5HT1B, and 5HT1C/2 receptor subtypes using 2nM ^{3}H-8-OHDPAT or 100 pM ^{125}I-8-MeODPAT, 50 pM ^{125}I-cyanopindolol with 30 uM isoproterenol, and 200 pM ^{125}I-DOI, respectively, as ligands. 5HT1A and 5HT1B specific binding was determined by blockade with 1 μM 5HT, while 5HT1C/2 specific binding was determined by blockade with 1μM ketanserin. 5HT1A sites were located in laminae (L) I, II, and III, around the central canal (CC) and dorsal commissure gray (DCG), in sympathetic (SYM) and parasympathetic (PSYM) nuclei, and in the lateral subdivision of Onuf's nucleus. 5HT1B sites were preferentially located in L I and III (obviously less dense in L II), around the CC and DCG, in SYM and PSYM nuclei, and in the corticospinal tract. 5HT1C/2 sites were located throughout the gray matter, but were significantly more dense in the lateral motor nuclei and the intermediolateral portion of the SYM nuclei with greater densities at rostral thoracic levels than at lower thoracic and lumbar levels. PSYM nuclei showed no preferential localization of 5HT1C/2 sites. Differentiation of 5HT1C from 5HT2 sites is underway.

467.15

SEGMENTAL AND LAMINAR PATTERNS OF SEROTONIN BINDING IN CAT SPINAL CORD. L.M. Pubols, N.A. Bernau, L.A. Kane* and A.L. Burleigh. R.S. Dow Neurol. Sci. Inst., Good Samaritan Hosp. and Med. Ctr., Portland, OR 97209 and Dept. Physiol, OR Health Sci. Univ., Portland, OR.

Serotonin (5HT) binding sites in spinal cord segments C7-8, T8-9, L2, L6,and S1-2 were labelled for autoradiography with 2 nM [^{3}H]5HT, without and with 10 μM 5HT for total and nonspecific binding, respectively. Grain density was quantified using the video counting mode of a Bioquant image analysis system. Tritium standards were used to estimate the amount of binding. The level of specific binding in each region was classed as low (<46 fmol/mg), moderate (46-90 fmol/mg), or high (>90 fmol/mg).

All segments examined showed significant amounts of serotonin binding. In general, laminae V-VII showed low levels of specific binding, laminae IV, VIII, IX and X moderate levels, and laminae I-III high levels. As in the rat (Seybold and Elde, 1984), the thoracic intermediolateral cell column had a high level of specific binding. Clarke's nucleus in the thoracic and lumbar cord had moderate levels of binding. Overall, the segmental and laminar pattern of serotonin binding we observed in the cat is similar to the segmental and laminar pattern of serotonin immunoreactivity seen in rat spinal cord (Steinbusch, 1981).

REGULATION OF THE 5HT$_{1B}$ RECEPTOR IN OPOSSUM KIDNEY CELLS BY SEROTONIN. R.C. Pleus and D.B. Bylund. Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198-6260.

The polyclonal cell line of the Opossum kidney (OK) is unique in that the only serotonin (5HT) receptor subtype it expresses is the 5HT$_{1B}$. In a time course experiment, OK cells were plated, 6 x 10^{6} cells per 150 mm culture disk and grown in serum substitute for 7 d. We observe a maximal decrease of ~39%, for 18-40 h of exposure, in 5HT$_{1B}$ receptors when cells are treated with 10 μM 5HT using [^{125}I]cynapindolol (10 to 1000 pM) as the radioligand. At 3 h of 5HT exposure, 5HT$_{1B}$ number decreased by 15%, whereas there was no down-regulation after 1 h of exposure to the same concentration. We tested the effect of 5HT exposure to the signal transduction system. The 5HT$_{1B}$ receptor is negatively coupled to adenylate cyclase through G$_{i}$ protein. We pretreated OK cells (plated at 6 x 10^{5}/35 mm culture dish, in serum substitute for 4 d) with 1 μM 5HT and [^{3}H]adenine followed by 3 m of 30 μM forskolin for cAMP stimulation. Data was expressed as % conversion of [^{3}H]cAMP/[^{3}H]ATP+[^{3}H]cAMP. The results demonstrate that 5HT for 1 h causes desensitization measured as a 15% decrease in efficacy at saturating concentrations of 5HT. Therefore, it appears that agonist exposure to 5HT$_{1B}$ receptor causes both down-regulation and desensitization. (NIH grant MH47354).

REGULATION OF 5-HT$_{1B}$ RECEPTORS IN OPOSSUM KIDNEY (OK) EPITHELIAL CELLS. C. D. Unsworth* and P. B. Molinoff. Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Serotonin receptors present on membranes prepared from OK cells maintained in culture demonstrate pharmacological properties consistent with the 5-HT$_{1B}$ subtype, with high affinities for 5-HT and cyanopindolol and low affinities for other serotonergic compounds including 8-OH-DPAT, quipazine, and ketanserin. The density of receptors measured with ^{125}I-ICYP binding is approximately 40 fmoles/mg protein. Serotonin-mediated inhibition of forskolin-stimulated cAMP formation can be demonstrated in these cells with an IC$_{50}$ value of 3 nM and a maximal inhibition of 70-80%. Exposure of cells to 5-HT (0.1-10 μM) for a period of 16 hr led to a concentration-dependent decrease in receptor density, with a maximum decrease of 60-65%. Characterization of 5-HT-mediated inhibition of forskolin-stimulated adenylyl cyclase following exposure to 5-HT is complicated by a time- and concentration-dependent sensitization of the adenylyl cyclase system to forskolin. Exposure to 100 nM 5-HT for 16 hr did not result in a significant reduction of 5-HT$_{1B}$ receptor-mediated inhibition of cAMP formation despite a 40% decrease in receptor density. Exposure of cells to higher concentrations of 5-HT (1-10 μM) resulted in a progressive increase in the IC$_{50}$ for inhibition of cAMP formation together with a dose-dependent decrease in receptor density. A loss of receptors with no concomitant desensitization could be explained by the presence of "spare" receptors on these cells. This cell line represents a valuable model system in which the cellular mechanisms involved in the regulation of 5-HT$_{1B}$ receptor density and its coupling to adenylyl cyclase may be characterized. (Supported by USPHS grant MH 48125).

EFFECTS OF IBOTENATE, AMPA & 5,7-DHT LESIONS ON 5HT TRANSPORTER SITES IN RAT CORTEX AND HIPPOCAMPUS. I.A. Lawrence*, K. Shirakawa*, H.J. Olverman*, J.S. Kelly and S.P. Butcher*, University Department of Pharmacology, 1 George Square, Edinburgh, EH8 9JZ, Scotland.

Cholinergic neurones in the substantia innominata were destroyed by direct injection of either ibotenate or AMPA. After 7 days brain tissue was prepared for measurement of ChAT activity and ligand binding studies. [^{3}H]Citalopram was used to label the 5HT transporter sites. Similarly, serotonergic neurones were destroyed by intraventricular injection of 5,7-DHT. 14 days later, brain 5HT levels were measured and binding studies carried out.

ChAT activity in the cortex was reduced by 49.8% and 67.6% for ibotenate and AMPA lesions respectively but no significant changes were detected in density or affinity for the transporter site. While the destruction of serotonergic fibres reduced 5HT levels by a similar amount in cortex (77.8%) and hippocampus (83.4%) the reduction in the transporter site density in cortex (55.1%) and the hippocampus (> 95%) was significantly different ($P < 0.001$). These results support previous accounts of the localisation of 5HT transporter sites on serotonergic terminals, however, they raise the question of the heterogeneity of the 5HT innervation of the cortex as opposed to the hippocampus.

ACTIONS OF BUFOTENINE ON THE STORAGE AND RELEASE OF SEROTONIN (5HT) FROM RAT SPINAL CORD SYNAPTOSOMES. P.J. Monroe, D.L. Smith*, G.M. Williams, and D.J. Smith. Dept. of Anesthesiology, West Virginia University Health Sciences Center, Morgantown, WV 26506

The 5HT3 receptor agonist bufotenine was found to evoke a dose-dependant (100 nM - 10 μM) increase in [3H]-efflux from rat spinal cord synaptosomes which had been preloaded with [3H]-5HT. The effect of bufotenine on [3H]-efflux was not altered by the inclusion of ICS205-930 (a 5HT3 recetor antagonist) in, nor the removal of Ca^{++} from, the superfusion buffer. Furthermore, *in vivo* reserpine pretreatment did not alter the ability of bufotenine to evoke increases in [3H]-efflux until the tissue was almost totally depleted of 5HT stores. The ability of bufotenine to promote release was restored, however, with the addition of an inhibitor of monoamine oxidase.

Inhibition of 5HT uptake with fluoxetine blocked the bufotenine-induced increase in [3H]-5HT efflux, while having no effect on the increased [3H]-5HIAA efflux. Furthermore, those concentrations of bufotenine which were effective in promoting release were found to coincide with those that inhibited [3H]-5HT uptake (IC50 = 300 nM), and inhibited radioligand binding to the uptake carrier (Ki vs. [3H]-citalopram = 408 nM). Nevertheless, an interaction with the uptake carrier can not entirely explain the releasing action of bufotenine since other 5HT uptake inhibitors, including fluoxetine, do not promote release.

These data suggest that bufotenine is capable of releasing 5HT from a reserpine-resistant (presumably cytoplasmic) store. Furthermore, bufotenine apparently does not require the uptake carrier to enter the synaptosome since increases in [3H]-5HIAA efflux are observed in the presence of uptake inhibition. On the other hand, the sensitivity of bufotenine-induced 5HT efflux to uptake inhibiton suggests the carrier may be involved in the outward transport of the amine. It is somewhat paradoxical that bufotenine may use the uptake carrier as a mechanism to promote release, while also equipotently inhibit carrier-mediated transport into the synaptosome, however these actions are consistent with several other 5HT releasing agents, including parachloroamphetamine (Wong, Horng, and Fuller, Biochem. Pharmacol. 22:311-322,1972).

BIOCHEMICAL EFFECTS OF EXPOSURE TO NITROUS OXIDE (N_2O) ON RAT BRAIN MONOAMINES. D. Emmanouil*, Z. Papadopoulou-Daifoti*, I. Kotsi* and R.M. Quock. Univ. Athens, Greece and Univ. Illinois Col. Med. at Rockford, IL 61107, U.S.A.

N_2O is reported to influence brain monoaminergic transmission (Passino et al., Soc. Neurosci. Abst. 13:913, 1987). To further explore possible effects of N_2O upon brain monoamines, male Sprague Dawley rats, 200 ± 20 g, were individually exposed to either 70% N_2O or room air for 15 min then sacrificed. The frontal cortex, striatum, hippocampus and hypothalamus were dissected for measurement of the monoamines dopamine and 5-hydroxytryptamine (5HT) and metabolites DOPAC, HVA and 5HIAA using HPLC with electrochemical detection. Our results show that N_2O exposure significantly raised levels of 5HIAA and increased the 5HIAA/5HT ratio in the hypothalamus but lowered the 5HIAA/5HT ratio in the frontal cortex due to elevated levels of 5HT. Recent work implicating an action of N_2O on benzodiazepine and perhaps GABA mechanisms (Emmanouil and Quock, IBRO 3rd World Congr. Abst., in press) suggests that the decreased 5HT turnover rate in the frontal cortex might be due to stimulation of GABA receptors that modulate 5HT release. The opposite effects of N_2O on hypothalamic 5HT transmission may also provide a basis for a distinct GABAergic or other system regulating 5HT turnover in that region. In conclusion, our data suggest adaptive changes of 5HT systems after N_2O exposure. (Supported by N.I.H. Grants DE-06894 and DE-09378.)

EARLY INDUCTION OF RAT BRAIN TRYPTOPHAN HYDROXYLASE (TPH) mRNA FOLLOWING PARACHLOROPHENYLALANINE (PCPA) TREATMENT. D.H. Park, D.M. Stone, H. Baker, K.S. Kim and T.H. Joh. Lab. Mol. Neurobiol., Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605.

PCPA is a potent and selective inhibitor of TPH, the first and rate-limiting enzyme in the biosynthesis of serotonin. Thus, it might be a useful tool for studying the regulation of TPH gene expression. In the present study we assessed the time course and magnitude of the changes in TPH activity and mRNA as well as that of its product, serotonin (5-HT) in three brain regions, the dorsal raphe nucleus (DRN), hypothalamus (H) and caudal brainstem (CB). PCPA (300 mg/kg) was injected subcutaneously and rats were killed at 12 hrs, 1, 2, 4, 7, and 14 days post-treatment. TPH mRNA in the DRN, demonstrated by *in situ* hybridization, increased almost 2-fold by 1 day post-PCPA and returned to control levels by 4 days. In contrast, TPH activity in the DRN, H and CB was reduced to about 10% of control levels 1-2 days post-treatment returning to control levels by 2 weeks. The decrease and return of 5-HT immunostaining in fibers followed the same time-course as TPH activity. No effect was observed on aromatic-L-amino acid decarboxylase activity, immunoreactivity or mRNA levels. These data suggest that inhibition of TPH by PCPA-treatment results in the specific up-regulation of TPH mRNA expression and new enzyme synthesis.

PROTEIN KINASE A PHOSPHORYLATES BUT DOES NOT ACTIVATE RAT TRYPTOPHAN HYDROXYLASE. P.A. Johansen, M. Zhu*, K. Sankaran*, R.G.H. Cotton[1], and D.M. Kuhn. Lafayette Clinic & CCN Program, Wayne State Univ. Sch. of Med., Detroit, MI, and [1] The Murdoch Institute, Royal Children's Hosp., Melbourne, Australia.

The activity of tryptophan hydroxylase (TPH), the initial and rate-limiting enzyme in the biosynthesis of serotonin, is increased by Ca^{2+}/calmodulin-dependent protein kinase, presumably as a result of phosphorylation of TPH. Several studies suggest that cAMP also activates TPH, but a role for protein kinase A (PKA) in this process has not been established. Concentrations of cAMP, dibutyryl-cAMP and 8-thiomethyl-cAMP which activate endogenous PKA did not alter TPH activity in tegmentum, striatum or pineal gland, even when purified activator protein (protein 14-3-3) was added to the assay. Similarly, the catalytic subunit of PKA failed to activate TPH. To determine whether TPH is phosphorylated by PKA, crude extracts from rat striatum, tegmentum, and pineal were incubated with ^{32}P-ATP (2 μCi/tube). Proteins were subjected to SDS-PAGE and Western blotting, and autoradiograms were produced from the blots. TPH, identified on blots with a monoclonal antibody (PH8), was excised and it's ^{32}P content was determined by scintillation counting. The results clearly show that 20 μM cAMP or 1 μg purified PKA catalytic subunit increase the phosphorylation of TPH in each brain area. The cAMP-mediated phosphorylation of TPH was inhibited by 50 μM of the PKA inhibitor H-7. These results indicate that PKA phosphorylates TPH, however this phosphorylation does not appear to produce an increase in catalytic activity.

ORIGIN OF TRYPTOPHAN HYDROXYLASE-IMMUNOREACTIVE (TPOH-I) NERVE FIBERS IN RAT CEREBRAL BLOOD VESSELS. Z. Cohen[1,*], G. Bonvento[1,2*], P. Lacombe[1,2*], J. Seylaz[2*], E.T. MacKenzie[3] and E. Hamel[1]. [1]Montreal Neurological Institute, Montréal, H3A 2B4, Canada, [2]CNRS UA 641 75010 Paris, and [3]Cyceron, 14021 Caen, France.

Fibers immunoreactive for TPOH, the synthesizing enzyme for serotonin (5-HT), have been visualized around cerebral blood vessels (Neurosci. Lett., 1990, 116:269-274). In order to determine their origin(s), rats were subjected to bilateral removal of the superior cervical ganglion or to a neurotoxic lesion of brain 5-HT pathways (stereotaxic injection of 5,7-dihydroxytryptamine, J Neurochem, 1991, 56:681-689). Seven days later, major cerebral and small pial arteries were dissected free and processed for TPOH-immunoreactivity. Destruction of brain 5-HT ascending pathways did not significantly alter the distribution of TPOH-I fibers in major and small pial arteries as compared to controls (though efficacy of the lesion was confirmed by a considerable decrease in cortical TPOH-I terminals). Bilateral ganglionectomy markedly reduced TPOH-I fibers in all segments of the cerebrovascular bed; suggesting that cerebrovascular TPOH-I fibers are closely related to the sympathetic system. However, no TPOH-I cells could be clearly evidenced in rat superior cervical ganglion though in adjacent sections, cells were immunoreactive for dopamine ß-hydroxylase, the synthesizing enzyme for NA. Our failure to identify TPOH-I cells might suggest that a minute population of these cells exists in the ganglion and has eluded our detection, that the levels of TPOH within the cells are too low to be immuno-detected or, alternatively, that the cells of origin are located outside the core of the ganglion itself. Supported by MRC, QHSF and a France-Québec Scientific Collaboration.

MEASUREMENT OF EXTRACELLULAR SEROTONIN DURING SUCKLING-INDUCED PROLACTIN RELEASE J.J. Rutter*, M.J. Baumann, S.B. Auerbach, and J. Rabii. Dept. Biol. Sci., Rutgers Univ., Piscataway, NJ 08855.

A role for serotonin (5-HT) in CNS modulation of prolactin (PRL) surges is supported by physiological and pharmacological experiments. We have used microdialysis and peripheral blood sampling concurrently in unrestrained lactating rats to reexamine the possibility that 5-HT exerts a PRL releasing effect.

Dialysis probes were implanted in the anterior preoptic area (APOA) of lactating female rats. A 90 minute suckling bout, following 4 hours of pup separation, significantly increased PRL levels at 30 minutes to 215 ± 26 ng/ml (mean ± s.e.m., n=5) from a baseline of 6 ± 1 ng/ml, and levels remained elevated while the pups were present. In contrast, extracellular 5-HT release in the APOA was unchanged during suckling.

The APOA had been implicated as a PRL modulating site in earlier 5-HT turnover studies, so we verified probe placement in the hypothalamus by locally infusing the 5-HT releasing agent, fenfluramine (30 ug over 30 minutes). This resulted in a large increase in 5-HT (5337 ± 698 % of baseline) and PRL (118 ± 25 ng/ml from a baseline of 9 ± 1 ng/ml) at 30 min.

EXCITABILITY IS DECREASED DURING THE SEROTONIN-INDUCED SLOW DEPOLARIZATION OF MUDPUPPY CARDIAC NEURONS. R.L. Parsons, L.M. Konopka and J.C. Hardwick. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Many small intrinsic neurons in the mudpuppy cardiac ganglion exhibit 5-HT immunoreactivity. Local application of 5-HT produced a biphasic depolarization in approximately 50% of the mudpuppy parasympathetic postganglionic neurons responding to 5-HT. This biphasic 5-HT-induced depolarization was comprised of a fast, brief component followed by a slower, longer lasting period of depolarization. The fast depolarization was consistently accompanied by a decrease in membrane resistance (R_m). The slow 5-HT-induced depolarization was accompanied by an increase in R_m in 14 cells and a decrease in R_m in 12 cells. During the 5-HT-induced fast depolarization, action potentials often were initiated. In contrast, during the slow 5-HT-induced depolarization, no spiking occurred regardless of whether R_m decreased or increased. Application of long duration suprathreshold depolarizing current pulses to the parasympathetic neurons initiates multiple action potential activity. During the 5-HT-induced slow depolarization, fewer spikes were produced by the application of identical depolarizing current pulses. These results show that during the 5-HT-induced slow depolarization membrane excitability was depressed. Supported by NIH Grants NS-23978 and NS-25973.

INTRACEREBROVENTRICULAR 5,7-DIHYDROXYTRYPTAMINE INCREASES GFAP mRNA IN THE HIPPOCAMPUS BUT NOT IN THE STRIATUM OF RAT BRAIN:COMPARISON WITH d-FENFLURAMINE. C.Bendotti,S. Baldessari*,R. Rivolta*,R.Samanin*. Istituto"Mario Negri", Milan,Italy.

GFAP mRNA levels were measured by Northern blot analysis in different regions of rat brain to get information on potential neurotoxicity of drugs on central serotonin(5-HT) containing neurons. Intracerebroventricular administration of 5,7-dihydroxytryptamine(150µg/20µl)30 min after 25mg/kg intraperitoneally of desipramine,to protect noradrenergic nerve terminals,caused a significant increase of GFAP mRNA levels in the hippocampus but not in the striatum,5 days later. Intraperitoneal administration of d-fenfluramine (10 mg/kg b.i.d. for 4 days), a potential neurotoxic agent for 5-HT neurons, caused similar decreases of 5-HT in hippocampus (about 80%) and striatum (about 60%) but did not change GFAP mRNA levels in either region. Since 5-HT has been found to exert an inhibitory influence on GFAP synthesis in brainstem astrocytes culture (Le Prince et al.Dev. Brain Res. 1990,51,295), it is not clear whether the changes of GFAP mRNA levels were secondary to modifications in the serotonergic control of GFAP synthesis,to astrocytes hyperplasia or both.

468.9

D-LYSERGIC ACID DIETHYLAMIDE (LSD) POTENTLY ENHANCES A HYPERPOLARIZATION-ACTIVATED CATION CURRENT (I_h) IN FACIAL MOTONEURONS (FMNs).
J.C. Garratt[2] and G.K. Aghajanian[1,2]. Depts. of Pharmacology.[1] and Psychiatry[2], Yale University. New Haven CT. 06508.

The facial motor nucleus has a high density of binding sites and mRNA for 5-hydroxytryptamine$_2$ (5-HT$_2$) receptors. 5-HT has been shown to induce a slow depolarization/inward current in FMNs via 5-HT$_2$ receptors. In the present study, the effects of LSD on two components of the 5-HT response, a slow depolarization and an increase in a hyperpolarization-activated cation current (I_h), were examined in an *in vitro* slice preparation of rat facial motor nucleus by current clamp and voltage clamp methods. 5-HT increased the electrical excitability of FMNs and induced a slow depolarization. LSD (10-100nM) produced a slowly developing, sustained increase in the excitability of FMNs but, in contrast, produced little or no inward current and progressively blocked the depolarization produced by 5-HT.

Since LSD produced an increase in excitability without an inward current this led us to examine the effects of LSD as well as 5-HT on voltage-dependent currents. 5-HT was found to produce a small enhancement of I_h current in FMNs. Interestingly LSD (100nM) was more efficacious than 5-HT at increasing this current. The effects of LSD on I_h persisted over 1hr, with maximal effect seen after 20 mins. The reversal potential for I_h was -30mV, thus having the characteristics of a mixed Na^+/K^+ channel. The 5-HT$_2$ agonists, 1-(2,5-dimethoxy-4-methylphenyl)-2-aminopropane (DOM) and (2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) also enhanced I_h to a degree intermediate between 5-HT and LSD.

Our findings suggest that LSD has dual actions in FMNs: (1) as a full agonist on an I_h current (2) as a low efficacy partial agonist on the 5-HT induced inward current.

SEROTONIN (5HT) EXCITES HYPOGLOSSAL MOTONEURONS IN DECEREBRATE CATS. H. Tojima*, L. Kubin, A.I. Pack* and R.O.Davies. Department of Animal Biology and Center for Sleep and Respiratory Neurobiology, University of Pennsylvania, Philadelphia, PA.19104.

There has been increased interest in the central mechanisms controlling the activity of hypoglossal (XII) motoneurons due to their importance in maintaining upper airway patency during sleep. A recent report showed that 5HT tonically depressed XII nerve activity in an isolated brainstem-spinal cord preparation from a newborn rat (Monteau et al. Neurosci.Lett. 111:127,1990). In contrast, it increased excitability of adult rat facial motoneurons both in vivo and in vitro (Rasmussen and Aghajanian, Synapse 5:324, 1990). The 5HT receptors that mediate these excitatory effects are present in both facial and XII motor nuclei (Pazos et al. Brain Res. 346:231, 1985). We assessed the effects mediated by 5HT receptors localized within the XII motor nucleus on XII motoneurons in decerebrate, paralyzed, vagotomized, artificially ventilated cats. 5HT or its antagonists were injected into one XII motor nucleus while monitoring the activity of both genioglossal branches of the XII nerve. The antagonists were: methysergide, ketanserin and LY53857 (1-2.5 mM in saline, 80-250 nl). All depressed XII nerve activity (20-90% of control). Injections of 5HT (10 mM, 100-300 nl) were excitatory. The 5HT-induced excitation was strong enough to overcome the XII motoneuron depression induced by injections of carbachol into the pons, a depression functionally similar to that occurring during the atonia of REM sleep (Kimura et al. J. Appl. Physiol. 60:2280, 1990). Thus, in the decerebrate cat, XII motoneurons receive a tonic excitatory drive mediated by serotonergic receptors located within the XII nucleus. These receptors are likely of type 1C or 2. Withdrawal of the serotonergic excitatory drive may underlie, at least in part, the depression of XII motoneuron activity during REM sleep. (Supported by HL42236.)

ELECTROPHYSIOLOGICAL AND BIOCHEMICAL STUDIES ON THE MECHANISM OF ACTION OF THE 5- HT$_2$ ANTAGONIST MDL 28,133 ON MDMA-INDUCED SLOWING OF A9 DOPAMINE (DA) NEURONS. Stephen M. Sorensen, Teresa M. Humphreys*, Vicki L. Taylor*, and Christopher J. Schmidt , Marion Merrell Dow Research Institute, Cincinnati, OH 45215

Recent clinical reports of the therapeutic efficacy of 5-HT$_2$ receptor antagonists in schizophrenia have renewed interest in the mechanism by which serotonin (5-HT) modulates dopaminergic neurotransmission.. Here we discuss electrophysiological and biochemical experiments using the 5-HT$_2$ receptor antagonist MDL 28,133 (1-4-fluorophenyl)-2[4-[(4-methanesulfonamido-phenyl)carbonyl]-1-piperidinyl]-ethanone) and the DA/5-HT releasing drug, methylenedioxymethamphetamine (MDMA) to further characterize the modulation of DA metabolism produced by 5-HT in A9 neurons. Extracellular recording was used to record from A9 DA neurons in chloral hydrate anesthetized rats. Following systemic MDMA (15 mg/kg i.v.) there was a marked slowing (80%) in the majority of DA neurons recorded. Pretreatment with MDL 28,133 (0.2 mg/kg i.v) blocked this slowing . Coadministration of L-DOPA (100 mg/kg i.v.) eliminated the blockade of MDMA-induced slowing by the 5-HT$_2$ antagonist so that MDMA again significantly slowed the firing rate of the A9 neurons. In biochemical studies, MDL 28,133 blocked the long-term serotonergic deficits produced by the administration of a high dose of MDMA. The ability of MDL 28,133 to prevent MDMA-induced neurotoxicity was lost in animals pretreated with L-DOPA. These results support the hypothesis that 5-HT acting through 5-HT$_2$ receptors may be permissive for the DA synthesis produced by DA releasing agents such as amphetamine and MDMA.

468.12

INVESTIGATIONS INTO THE SEROTONERGIC-DOPAMINERGIC INTERACTIONS MEDIATED BY 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA). C.J. Schmidt, G.M. Abbate*, C.K. Black* and V.L. Taylor*. Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

We have examined several potential mechanisms through which 5-HT$_2$ receptors could regulate the effects of MDMA on the dopaminergic system. Administration of the selective 5-HT$_2$ receptor antagonist, MDL 28,133, had no effect on the accumulation of striatal dopamine (DA) produced acutely by gamma-butyrolactone (GBL), but did block the same effect when produced by MDMA. In animals treated with α-methyl-p-tyrosine, neither MDMA nor MDMA plus MDL 28,133 altered the rate of DA depletion. Pretreatment with MDL 28,133 was also without effect on the ability of apomorphine to reduce the accumulation of DOPA in GBL-treated rats. These results suggest that 1) the stimulation of DA synthesis produced by MDMA is not due to blockade of a tonically active, inhibitory 5-HT input, and 2) the effect of MDMA on DA cell firing is not mediated by 5-HT$_2$ receptor activation directly but requires release from the newly synthesized pool of DA. Furthermore, the sensitivity of the DA autoreceptors controlling striatal synthesis does not appear to be modified by MDL 28,133. We conclude that 5-HT$_2$ receptors play a direct role in the effects of MDMA on the dopaminergic system at the level of the MDMA releasable pool of DA.

468.13

EFFECTS OF NEONATAL REMOVAL OF SUPERIOR CERVICAL GANGLION ON 5-HT AND TRH IMMUNOREACTIVITY IN THE INTERMEDIOLATERAL CELL COLUMN OF THE RAT SPINAL CORD. *P. Poulat[1], L. Marlier[1], N. Rajaofetra[1], C. Oliver[2], A. Privat[1] and N. König[1].* [1] U.336 INSERM, USTL, pl. E. Bataillon, 34095 MONTPELLIER. [2]U.297 INSERM, Blvd P. Dramart, 13000 MARSEILLE, FRANCE.

The intermediolateral cell column (IML) contains serotonin (5-HT) and thyrotropin-releasing hormone (TRH) expressing fibers. Pups (1-3 days) were anaesthetized and the right SCG was removed. After various delays, the rats were sacrificed by intracardiac perfusion with 5% glutaraldehyde. Sections from C8-T4 levels of the spinal cord were processed for 5-HT and TRH immunocytochemistry using the PAP procedure. Image analysis revealed a significant 60% loss of 5-HT-immunoreactivity (IR) at C8-T1 levels on the lesioned side at all stages. At T2-T4 levels, this loss was 15% at 1 month and 30% at 3 months. For TRH-IR, there was a significant loss of 20% at 2 weeks, and 60% at 1 and 3 months, at C8-T1 levels on the lesioned side. At T2-T4 levels, a loss of 30% of TRH-IR appeared at 3 months. These results bring further evidence for 5-HT and TRH colocalisation in the same fibers in the IML. Neonatal removal of SCG presumably induces degeneration of a subset of sympathetic preganglionic neurons which in turn induces severe loss of 5-HT immunoreactive fibers innervating them. (supported by IRME, FRMF & HEUMANN).

SEROTONIN INHIBITION OF GLUTAMATE-EVOKED FIRING IS ATTENUATED IN THE NUCLEUS ACCUMBENS OF RATS FOLLOWING PRETREATMENT WITH P-CHLOROAMPHETAMINE. J. Smith, S.R. White and K. Paros*. Dept. of VCAPP, Washington State Univ., Pullman, WA 99164.

The amphetamine derivative, p-chloroamphetamine (PCA) is neurotoxic to fine caliber serotonin-containing axons that arise from the dorsal raphe nucleus (Mamounas and Molliver, *Exp. Neurol.* 1988, 102:23). The nucleus accumbens (NA), a major component of the brain reward pathway, receives part of its serotonin (5HT) innervation from the dorsal raphe nucleus. This study examined whether responses of nucleus accumbens cells to locally applied serotonin would be altered in rats that had been pretreated with neurotoxic doses of PCA. Male Sprague-Dawley rats received PCA (10 mg/kg, ip) on two successive days. Two weeks later the rats were anesthetized with urethane and prepared for single cell recording. 5HT applied by microiontophoresis (20-60 nA for 60 s) produced a significant decrease in glutamate-evoked firing of NA cells within 30 s of 5HT ejection onset in the control animals. This inhibition by 5HT was significantly depressed in PCA-pretreated rats compared to controls for all doses of 5HT that were tested. Thus, partial 5HT denervation by neurotoxic amphetamine derivatives alters responses of NA cells to subsequently applied 5HT, and presumably to 5HT that may be released from spared terminals.

RAPHE GRAFTS IN THE ENTORHINAL CORTEX OR IN THE HIPPOCAMPUS: EFFECTS ON HIPPOCAMPAL ELECTROPHYSIOLOGY AND BEHAVIOUR. G. Richter-Levin and M. Segal, The Weizmann Inst., Center for Neuroscience, Rehovot 76100, Israel.

The dentate gyrus (DG) and the entorhinal cortex (EC) are major targets of the midbrain raphe serotonergic fibers. Depletion of forebrain serotonin (5-HT) (by 5,7-DHT, icv) increased the responsiveness of the DG to perforant path (PP) stimulation and reduced its responsiveness to the serotonin releasing drug - fenfluramine (FFA). We compared 5-HT - depleted rats, grafted with embryonic raphe tissue into either the DG (DGG) or the EC (ECG). DGG rats responded to both PP stimulation and FFA application like controls, whereas ECG rats had a significantly different responsiveness profile. The differences between the two grafted groups are not due to the inability of raphe grafts to survive in the EC, since in all of the rats, examined with ^{3}H-imipramine binding, we detected grafted serotonergic terminals. When the septo-hippocampal connection is disrupted, depletion of forebrain 5-HT adversly affects the ability of rats to perform a spatial memory water-maze task. In rats that were injected with colchicine into the septum (1.5 ug/0.5 ul x2) together with 5,7-DHT, DGG but not ECG rats performed the task significantly better than double-lesioned rats that were not grafted. These results suggest that the serotonergic modulation of the DG responsiveness to afferent stimulation has a role in memory, the importance of which is revealed when other hippocampal modulatory systems are disrupted. *Supported by a grant from MINERVA foundation, Munich, Germany.

SEROTONERGIC DRUGS INCREASE MHPG-SO_4 IN RAT HYPOTHALAMUS. K. W. Perry* and R. W. Fuller, Lilly Research Laboratories, Eli Lilly & Co. Lilly Corporate Center, Indianapolis, IN 46285.

Previous neuroanatomic and functional evidence suggests that serotonergic input can modify noradrenergic neuron function. We have used concentrations of MHPG-SO_4 (3-methoxy-4-hydroxy-phenylglycol sulfate) as an index of norepinephrine release and metabolism in brain after administration of serotonergic drugs. Quipazine, a direct acting serotonin agonist, caused ~80% increase in MHPG-SO_4 in rat hypothalamus at 1 hour after a 2.5 mg/kg s.c. dose. 8-Hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT), a selective 5-HT_{1A} agonist, increased MHPG-SO_4 ~50% 1 hr after a 0.3 mg/kg s.c. dose. The increases were dose-related for both drugs and occurred over the same dose range which caused a decrease in 5-HIAA (5-hydroxyindoleacetic acid), the metabolite of serotonin which decreases in response to direct or indirect acting serotonin agonists. The quipazine-induced increase in MHPG-SO_4 was antagonized by metergoline, and the 8-OH-DPAT-induced increase was antagonized by pindolol. The serotonin uptake inhibitor fluoxetine increased MHPG-SO_4 by 50-60% at 1-2 hrs after a 10 mg/kg i.p. dose. MHPG-SO_4 levels returned to normal within 6 hrs after fluoxetine although 5-HIAA levels remained decreased for 24 hrs. These findings extend earlier literature suggesting that modification of serotonergic input to noradrenergic neurons alters norepinephrine release.

REDUCTION BY SEROTONIN OF GABAERGIC SYNAPTIC TRANSMISSION IN HIPPOCAMPAL CA3 PYRAMIDAL CELLS IN VITRO. S. Oleskevich and J.-C. Lacaille. Centre de recherche en sciences neurologiques, Département de physiologie, Université de Montréal, Montréal (Qué.), Canada H3C 3J7.

The adult rat hippocampus receives a relatively dense and heterogeneous serotonin (5-HT) innervation. We have characterized electrophysiologically the effects of 5-HT on CA3 pyramidal cells and on GABAergic synaptic transmission in rat hippocampal slices. A microdrop of serotonin (500μM) was applied locally in stratum lucidum during intracellular recording from CA3 pyramidal cells. Several direct effects of 5-HT on pyramidal cells were obtained such as a membrane hyperpolarization, an increase in membrane conductance and a decrease in the slow afterhyperpolarization (sAHP) that follows a burst of action potentials (n=7 cells). These effects were similar to those previously shown for CA1 pyramidal cells. Inhibitory postsynaptic potentials (IPSPs) were elicited orthodromically in CA3 pyramidal cells by electrical stimulation of mossy fibers. These IPSPs were biphasic, consisting of an early $GABA_A$, Cl^--mediated component and a late $GABA_B$, K^+-mediated component. Both the early and late IPSPs were attenuated by serotonin (n=7 cells). Monosynaptic IPSPs were elicited by direct electrical stimulation of interneurons during bath application of the excitatory amino acid antagonists CNQX (20μM) and AP-5 (40μM). 5-HT caused a decrease in the amplitude of the early and late monosynaptic IPSPs (n=7 cells). The possiblity of a presynaptic effect of 5-HT on the glutaminergic afferents onto interneurons thus appears unlikely. Overall, the results suggest that 5-HT reduces GABAergic synaptic transmission in CA3 pyramidal cells. Studies of 5-HT actions on direct postsynaptic responses mediated by $GABA_A$ and $GABA_B$ receptors will be necessary to discriminate between pre- and postsynaptic sites of action of serotonin in the CA3 hippocampal region. AGING EFFECTS ON GABAERGIC AND SEROTONINERGIC SYSTEMS OF THE RAT SUPERIOR COLLICULUS. C. De la Roza[1*], V. Steffen[2*], A. Machado[2*], I. de Andres[1] and J. Cano[2*]. 1. Dep. Morfología, Fac. Medicina, Univ. Autónoma Madrid. 28029. 2. Dep. Bioquímica, Bromatología y Toxicología, Fac. Farmacia, Univ. Sevilla. 41012 Spain.

Biochemical (HPLC-UV detector) and immunocytochemical (HRP) techniques were used to study the GABAergic and serotoninergic neurotransmitter systems in the superior colliculus (SC) of adult and aged rats. GABA concentration was determined according to the slightly modified method of Maldonado et al. (1989) using a precolumn derivatization technique with Phenylisothyocyanate as the tagging reagent using Pico-tag and UV detection. To determine the cellular distribution of the neurotransmitters, 70 μm serial sections of brain tissue -fixed with a mixture of aldehydes- were processed for GABA or serotonin immunohistochemistry and were analized with light microscopy. GABA concentration did not show statistically significant changes in aging. However, since there was a significant decrease of the weight of the SC in aged rats, there is an age-related loss of GABA in the SC. This finding is consistent with a conspicuous decrease in the number of GABA immunoreactive neurons in aged rats. Likewise, serotonin immunoreactive fibers showed networks of remarkably swollen varicosities in aged rats, suggesting a possible axonal degeneration.

INTERACTIONS BETWEEN SEROTONIN (5HT) AND TRH ON SLOW K^+ CURRENTS OF HIPPOCAMPAL CA1 NEURONES. L. Ballerini*, R. Corradetti, A. Nistri[1] and A.M. Pugliese*. Pharmacol. Depts., Univ. Florence, Italy and [1] Queen Mary and Westfield College, London, U.K.

At spinal synapses 5HT and TRH act as co-transmitters by blocking K^+ currents. In rat hippocampal slices the effects of 5HT and TRH were studied using single electrode clamping of CA1 cells. At -60 mV holding potential (in the presence of 1 μM tetrodotoxin) 30 μM 5HT elicited an outward current (0.15 $\pm$ 0.03 nA) associated, in 50% of neurones, with a 27 $\pm$ 3% fall in input resistance. Depolarizing steps activated slow K^+ currents which, after leak subtraction, were found to be depressed (-35% at -20 mV) by 5HT. TRH (10 μM) had little effect on steady current or input resistance, but it reduced by 18% (at -20 mV) the slow K^+ current. Co-application of 5HT and TRH gave smaller (40%) reductions in this current than those predicted by the sum of the effects of the two drugs. The slow K^+ current remaining in Ca^{2+} free solution was identified as the delayed rectifier (I_K) which was attenuated by 9% and 26% in the presence of 5HT or TRH, respectively. Co-application of these agents did not change I_K. We suggest that since 5HT diminished the total slow K^+ current (mainly by blocking its Ca^{2+}-sensitive component) this action would reduce the efficacy of inhibitory K^+ conductance systems. TRH appeared to occlude the effect of 5HT on the slow K^+ current, suggesting a modulatory role of this peptide in some excitatory actions of 5HT present at depolarized membrane potentials.

SELECTIVE INCREASE IN EXTRACELLULAR SEROTONIN IN RAT MOTOR N. V DURING ORO-BUCCAL ACTIVITY. S.B. Auerbach, E. Auerbach* and B.L. Jacobs. Biol. Sciences, Rutgers Univ., New Brunswick, NJ 08855,

The activity of some mesencephalic serotonin (5-HT) neurons is selectively increased during jaw and tongue movements (Neuropsychopharm. 3:473-479, 1990). We have used in vivo microdialysis to determine if extracellular 5-HT in the rat CNS is also increased during feeding or grooming. Measurements were made in motor n. V (MoV) and striatum before and after grooming, or feeding and drinking. In the first sample collected after the end of a 24 hr fast, extracellular 5-HT in MoV was increased 47 $\pm$ 11% (n=5). Similarly, when grooming was induced by application of moistened soil to the body, 5-HT in MoV was increased 78 $\pm$ 37% (n=7). In contrast, striatal 5-HT was not consistently changed during periods of either feeding or grooming. Together with electrophysiological data, these results suggest that 5-HT in brainstem motor nuclei may be involved in facilitating repetitive movements. INCREASED 5-HT AND DOPAMINE RELEASE IN RAT LATERAL HYPOTHALAMUS AND N. ACCUMBENS FOLLOWING SYSTEMIC ETHANOL INJECTION. D. Benjamin, D.J. Knapp, E.R. Grant*, and L.A. Pohorecky. Rutgers University, Center of Alcohol Studies, Piscataway, NJ 08855-0969.

Ethanol (ET) has previously been shown to increase extracellular levels of serotonin (5-HT) and dopamine (DA) in the nucleus accumbens (NA). To determine if this effect is regionally specific, levels of these neurotransmitters and their metabolites were measured in the lateral hypothalamus (LH) and NA concurrently using intracerebral microdialysis followed by HPLC-EC, prior to and following intraperitoneal injection of ET. Male Wistar rats were prescreened for ET preference, then implanted with guide cannulae that terminated 0.5 mm above the NA and the LH. Following recovery from surgery, 2 mm dialysis probes were implanted and testing was initiated on the following day. Probes were perfused with pH 7.6 Ringer's solution at a rate of 1 uL/min, and dialysate samples were taken every 20 min. At least 3 baseline samples were taken prior to injection with vehicle or ET (0.5 or 1.0 g/kg). While vehicle injection had no substantial effect on the concentration of 5-HT or DA in either area, injection of ET resulted in dose-related increases in the concentration of 5-HT, DA, and 3,4-dihydroxybenzeneacetic acid (DOPAC) in dialysate. DOPAC and 5-HT increased before DA in both regions. Tenfold increases in 5-HT and DA were observed in both areas within 1 h of ET injection, and increases in the NA were preceded by increases in LH. These results demonstrate that ET injection increases 5-HT and DA release in LH as well as NA, and suggests that the primary site of action for ET effects on brain monoamines remains to be determined. ELECTROCONVULSIVE SHOCK MODIFIES THE INHIBITORY EFFECT OF SELECTIVE μ and δ OPIOID AGONISTS ON [^{3}H]5HT RELEASE IN RAT HIPPOCAMPAL SLICES. F. Orzi,G. Lapucci and F.Passarelli - Neurosci.Dept.,University "La Sapienza" III Neuro-V.le dell'Universita' 30 00185 Rome (Italy)

It has been shown an involvement of opiate-receptors in the mechanism of action of electroconvulsive shock (ECS) (Belenky G.L. and Holaday J.W., 1979). We previously reported the inhibition of [^{3}H]5HT-release by a delta-selective agonist [D-Pen^2,D-Pen^5]enkephalin (DPDPE) and μ-selective agonist [D-Ala^2,N-methyl-Phe^4,Gly^5-ol]enkephalin (DAGO)(Passarelli and Costa, 1989). The aim of present study is to determine whether repeated ECS affects the modulation of 5HT release by both selective μ and δ opioid agonists in hippocampal slices. Male Sprague-Dawley rats submitted to repeated ECS, once a day for 7 days, were killed 24 hrs after the last of the 7 ECS sessions and the brain quickly dissected. Hippocampal slices (0.4 mm thickness) were incubated for 30 min at 37°C in Krebs' medium containing 0.1 μM [3H]5HT creatinin sulphate (s.a. 12.3 Ci/mmol) and bubbled with a mixture of 95% O2 and 5% CO2. The slices were then transferred to superfusion chambers and superfused with Krebs'medium. Each slice was stimulated twice at 60 min (S1) and 104 min (S2) after the onset of superfusion by exposure to a medium containing 30 mM of KCl for 4 min. The fractional release was expressed as the ratio S2/S1. The S2/S1 value was 1.00 ± 0.12 (n=5)in control animals, 0.94 ± 0.2 (n=4) in repeated ECS-treated animals and 0.94 ± 0.2 (n=3) in single ECS-treated animals respectively. After the addiction of DPDPE (1μM) and DAGO (0.1 μM) 20 min before the second stimulation, a clear reduction of K^+-evoked release of 5-HT was observed showing S2/S1 values of 0.45 ± 0.03 (n=3) and 0.44 ± 0.05 (n=5) respectively.ECS-treatment, by itself, did not alter the K^+-evoked release of 5-HT as reported before.In contrast repeated ECS treatment did reverse the inhibitory effect of both DPDPE and DAGO.The S2/S1 values in repeated ECS-treated animals were 1.08 ± 0.2 (n=3) in presence of DPDPE and 0.95 ± 0.16 (n=6) in presence of DAGO. The results suggest that repeated ECS treatment is
followed by opioid receptors desensitization.

REGULATION OF 5-HT TRANSPORTER ACTIVITY BY PROTEIN KINASES. B. J. Hoffman, Laboratory of Cell Biology, NIMH, Bethesda, MD 20892.

Protein kinases are regulated by receptor activation via second messenger cascades. Phosphorylation by protein kinase C (PKC) and cAMP-dependent protein kinases have been shown either to enhance or to inhibit function of receptors and ion channels. The effects of signal transduction pathways on 5-HT transporter activity was investigated by analyzing ^{3}H-5-HT uptake into rat basophilic leukemia cells (RBL). Uptake was determined by incubation for 20 min in 0.2 uM ^{3}H-5-HT with or without 10 uM paroxetine. RBLs cultured in the presence of 10 uM cAMP analogues, 8-(4-chlorophenylthio)-cAMP or dibutyrylcAMP, for 16 hrs. exhibited a 225 +/- 11% increase in uptake compared to control. Under identical conditions, treatment of RBLs with 100 nM 12-myristate, 13-acetate phorbol (TPA) inhibited uptake by 53 +/- 3% relative to control. These data indicate that PKC and cAMP-dependent protein kinases have opposing effects on the 5-HT transporter. These results suggest that neurotransmitters and hormones may influence synaptic 5-HT levels not only by regulating release but also by modulating re-uptake.

Essential Sulfhydryl Groups in Neuronal Serotonin Transporter Function: Evidence for Differential Mechanisms in the Binding of Cocaine and Amphetamines to the Serotonin Transporter. W.A. Wolf* and D.M. Kuhn. Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ., and Lab of Neurochemistry, Lafayette Clinic, Detroit, MI 48207.

The neuronal serotonin (5-HT) transporter, as studied by ^{3}H-paroxetine binding, was slowly inactivated by the sulfhydryl-selective alkylating agent, N-ethylmaleimide (NEM), in brain membrane preparations ($T_{1/2}$>120 min at 25°C using 3 mM NEM). ^{3}H-Paroxetine binding to digitonin-solubilised 5-HT transporter was more potently and more rapidly inactivated by NEM ($T_{1/2}$=12 min at 25°C using 3 mM NEM). Some ligands (5-HT, fluoxetine, citalopram, cocaine) which bind to the neuronal 5-HT transporter could protect against the inactivation of ^{3}H-paroxetine binding caused by NEM in digitonin-solubilised preparations while others (p-chloroamphetamine) could not. Hydrophobic sulfhydryl reagents (p-OHmercuribenzoate, dithiobis-[2-nitrobenzoic acid], N-phenylmaleimide, methyl methanethiosulfonate) were more potent than NEM at inactivating ^{3}H-paroxetine binding while the hydrophilic sulfhydryl reagents, iodoacetate and iodoacetamide, were completely ineffective in this regard. Finally, a distinct class of reduced sulfhydryls unassociated with the ligand binding site was found to be required for 5-HT translocation in nerve terminal membrane vesicles. ^{3}H-5-HT uptake in nerve terminal membrane vesicles (Km = 50 nM, Vmax = 0.14 pmoles/mg prot/sec) was rapidly inactivated by NEM (approximately 50% inhibition within 15 min incubation at 25°C with 1 mM NEM), although ^{3}H-paroxetine binding in these NEM-treated preparations was unaltered (98 $\pm$ 4% of control). Neither 5-HT (100 uM) nor cocaine (10 uM) could protect against the transport-inactivating effects of NEM.

AUTORADIOGRAPHIC COMPARISON OF IMIPRAMINE AND CITALOPRAM BINDING IN THE HUMAN HYPOTHALAMUS.

K.Y. Little, G.E. Duncan, Depts. of Psychiatry and Cell Biology and Anatomy, University of North Carolina, Chapel Hill, NC 27599.

^{3}H–imipramine binding in post mortem brain tissue has been considered a measure of serotonin uptake sites, and altered binding in suicides suggested as evidence of a serotonergic abnormality. In an initial evaluation of these assumptions, we compared the autoradiographic topography of ^{3}H–imipramine binding (5nM) in hypothalamus to that of ^{3}H–citalopram binding (2nM), a highly selective ligand for the serotonin transporter. Hypothalamic tissue was obtained at autopsy from acute trauma victims within 24 hours of death, as authorized by the Chief Medical Examiner. ^{3}H–imipramine binding in the hypothalamus was dense in the supraoptic and paraventricular nuclei, but was relatively low and diffuse elsewhere. In contrast, high densities of ^{3}H–citalopram binding sites were distinctly concentrated in the ventromedial, arcuate, and lateral nucleii. At these concentrations, highly selective hypothalamic binding of ^{3}H–imipramine and ^{3}H–citalopram occurs in distinct nucleii, demonstrating that ^{3}H–imipramine binding cannot be considered a specific label for serotonin terminals in human hypothalamus. Further, an autoradiographic study in rats found different binding patterns in the hypothalamus for both ligands compared to those in humans, suggesting that rat modeling of human serotonergic function may have limited validity.

PRESENCE OF ^{3}H-PAROXETINE BINDING SITES IN THE HYBRIDOMA CELL LINE NG 108-15. X. Zhang, J.E. Rubinstein and P.M. Whitaker-Azmitia. Dept. of Psychiatry, State Univeristy of New York, Stony Brook, New York, 11794.

NG 108-15 cells are a hybridoma cell line of mixed glial-neuronal origin, which we are currently studying as a model for effects of serotonin receptors on the development of serotonin neurons. In the course of these studies, we tested for the presence of the serotonin transporter by using the radiolabelled specific uptake inhibitor ^{3}H-paroxetine.

Cells were grown in complete media in 25 cm^2 flasks for homogenate binding assays, or on two-well slides for autoradiography. In both systems, non-specific binding was determined by 100 nM fluoxetine. Saturation analysis (using 0.1 to 6.0 nM ^{3}H-paroxetine) indicated a single population of sites with a B_{max} of 85 fmoles/mg and a K_d of 1.2 nM. Preliminary autoradiographic analysis showed that the density of label was higher in a subpopulation of the cells.

IODINATED LIGANDS FOR SEROTONIN (5-HT) REUPTAKE SITES. H. Kung, S. Chumpradit, M.P. Kung, J. Billings, S.M. Tejani-Butt, A. Frazer. Dept's of Radiology & Psychiatry, U. of Pennsylvania, Phila., PA 19104.

Pharmacological actions of many antidepressants are based on blockage of presynaptic reuptake sites for 5-HT or norepinephrine (NE). In order to develop radioactive ligands for 5-HT reuptake sites, a series of iodinated ligands with high selectivity and affinity was developed.

	X	Y	Z
Tomoxetine(TMT)	CH_3	H	H
Nisoxetine	OCH_3	H	H
Fluoxetine	H	H	CF_3
4-Iodo-TMT	CH_3	H	I
3-Iodo-2-Demethyl-TMT	H	I	H

Optical isomers (R- and S-) of iodinated tomoxetine and its related derivatives were prepared. The affinity and selectivity of the synthesized compounds for 5-HT and NE uptake sites were determined in *in vitro* binding studies with [^{3}H]paroxetine (for 5-HT uptake sites) or [^{3}H]nisoxetine (for NE uptake sites]. S-3-iodo-2-demethyl-tomoxetine and R-4-iodo-tomoxetine display the highest affinity to the 5-HT uptake sites (Ki = 0.8 nM for both compounds for 5-HT sites versus Ki = 2 and 134 nM, respectively, for NE sites). Other pairs of isomers (R-3-iodo-2-demethyl-tomoxetine and S-4-iodo-tomoxetine) show lower affinity to both 5-HT and NE reuptake sites. The ^{125}I-labeled derivatives of these compounds have been prepared from the corresponding tributyl-tin derivatives. These ligands may be useful as potential tools for mapping serotonin neuron projections *in vivo* and *in vitro*. (USPHS grant support NS-24538 & MH 48125)

469.6

GINKGO BILOBA EXTRACT INCREASES AND PROLONGS THE SYNAPTOSOMAL ^{3}H SEROTONIN UPTAKE ACTIVITY.

C. RAMASSAMY*, F. CLOSTRE, Y. CHRISTEN and J. COSTENTIN*.
* Neuropsychopharmacologie Expérimentale, U.R.A. 1170 du C.N.R.S., Faculté de Médecine et de Pharmacie de Rouen, 76803 Saint-Etienne du Rouvray, France. Institut Ipsen, 30 rue Cambronne, 75015 Paris, France.

A Ginkgo biloba extract (EGb 761, 4 to 16 µg/ml) increased ^{3}H serotonin (^{3}H 5HT) uptake (≈ +25%) by synaptosomes incubated in pH 7.4 Krebs-Ringer buffer previously oxygenated (95% O_2, 5% CO_2). Such an increase was also obtained when mice were treated with EGb 761 (100 mg/kg, 16h and 2h) before sacrifice. This increase in ^{3}H 5HT uptake was not observed in the presence clomipramine 10^{-6} M (which abolished the 5HT uptake). EGb 761 (4 to 16 µg/ml) did not increase the ^{3}H dopamine uptake by synaptosomes prepared from mouse striatum. Synaptosomes lost their ^{3}H 5HT uptake ability after about 1h at 37°C. This decrease in uptake activity was prevented by EGb 761 (from 4 to 16 µg/ml). The prevention also concerned the ^{3}H dopamine uptake. The decrease in amine uptake induced by 1h exposition at 37°C was not reversed by EGb 761. We suggest that the oxygenated buffer could induce a lipoperoxydation of the synaptoplasmic membrane and modify the amine uptake system. EGb 761 could protect synaptosomes from alteration during the exposition at 37°C by its free radicals scavenger properties.

BEADED SEROTONERGIC AXONS ARE NOT TYPICALLY ASSOCIATED WITH CALBINDIN- OR PARVALBUMIN-POSITIVE NEURONS IN RAT BRAIN. K.J. Axt and M.E. Molliver. Dept. Neuroscience, The Johns Hopkins Univ. Schl. Med., Baltimore, MD 21205.

In cat and marmoset neocortex, and rat hippocampus, serotonergic (5-HT) axons have been shown to form basket-like terminals upon a subset of GABA-ergic neurons which express calbindin D_{28k} (CaBP). 5-HT axons do not appear to be associated with GABA-ergic neurons which express parvalbumin (PV). The 5-HT axons which surround CaBP-positive neurons have distinctive large, spherical varicosities (beaded axons). Two morphologic subtypes of 5-HT axons (fine and beaded) can be differentiated pharmacologically with the 5-HT neurotoxin p-chloroamphetamine (pCA), which selectively ablates fine 5-HT axons, while sparing beaded axons. In this study, the pCA-lesion model is used to reveal whether beaded 5-HT axons, which have a specific, limited distribution, are typically associated with CaBP- or PV-immunoreactive neurons (CaBP and PV antibodies were gifts of M.R. Celio and P. Emson).

We examined areas which are densely innervated by beaded 5-HT axons: cingulate cortex, lateral entorhinal area (LEA), septum, olfactory bulb, and hippocampus. Generally, in these areas no association is found between beaded 5-HT axons and CaBP- or PV-positive cell bodies. For example, in LEA, beaded 5-HT axons densely innervate layer III, whereas CaBP-positive cell bodies are located predominantly in layer II. In septum, 5-HT axons form baskets around neurons which are immunonegative for CaBP or PV. Occasionally, we observed beaded 5-HT axons around CaBP-positive cells in CA3 of hippocampus. In summary, in the rat, most CaBP- and PV-positive neurons are not innervated by beaded 5-HT axons, and most 5-HT beaded axons are not associated with CaBP- or PV-positive cell bodies; these 5-HT axons are likely to be associated with other types of neurons. [Support: NS 15199 and PMAF]

DUAL SEROTONERGIC PROJECTIONS TO RAT OLFACTORY BULB: p-CHLOROAMPHETAMINE (PCA) SELECTIVELY DAMAGES DORSAL RAPHE AXONS WHILE SPARING MEDIAN RAPHE AXONS.

M.E. Molliver and L.A. Mamounas. Dept. of Neuroscience, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The serotonergic (5-HT) innervation of the main olfactory bulb (MOB) in the rat arises from the dorsal (DR) and median raphe (MR) nuclei of the midbrain (McLean and Shipley, 1987). As in cerebral cortex, the MOB is innervated by two morphologically dissimilar types of 5-HT axons: fine axons with minute varicosities found primarily in the infraglomerular layers of the MOB and beaded axons with large, spherical varicosities located in the glomerular layer. In neocortex, fine 5-HT axons arising from the DR are selectively damaged by the amphetamine neurotoxin PCA, while beaded axons from the MR are spared (Mamounas and Molliver, 1988). The present study evaluates whether PCA is selectively toxic to DR axons in the MOB, while sparing MR axons in this area. We compared retrograde axonal transport of the fluorescent tracer Fluoro-Gold from the MOB to the raphe nuclei in PCA-treated (10 mg/kg) and control rats; 5-HT axons in the MOB that are ablated by PCA should not transport the tracer to their cell bodies of origin in the raphe nuclei, thus allowing us to specify the brainstem origins of the damaged axons. PCA caused extensive loss of fine 5-HT axons in the MOB, while beaded 5-HT axons were spared. Concomitant with the loss of fine axons, there was a large reduction (79%) in the number of retrogradely-labeled 5-HT neurons in the DR after treatment with PCA; in contrast, there was no reduction in the number of retrogradely-labeled 5-HT neurons in the MR. These results indicate that the DR projection to the olfactory bulb is selectively damaged by PCA, while the MR projection is preferentially spared. Moreover, the results suggest that fine 5-HT axons located in the infraglomerular layers of the MOB arise from the DR, while beaded axons in the glomerular layer arise from the MR. Support: NS-15199; NIDA 271-90-7408.

469.9

ABERRANT REINNERVATION OF RAT CEREBRAL CORTEX BY SEROTONERGIC AXONS AFTER DENERVATION BY p-CHLORO-AMPHETAMINE (PCA). L.A. Mamounas and M.E. Molliver. Dept. of Neuroscience, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The neurotoxic amphetamine PCA causes extensive degeneration of fine serotonergic (5-HT) axons in cerebral cortex, yet spares beaded 5-HT axons and most 5-HT cell bodies in the raphe nuclei. The present study employs 5-HT immunocytochemistry to evaluate regrowth of 5-HT axons into denervated regions at longer survival times after PCA administration. From one to six months after PCA administration, normal-appearing fine 5-HT axons slowly reinnervate cerebral cortex; beaded 5-HT axons, which survive drug treatment, do not sprout into zones denervated of fine axons. An increase in 5-HT axon density is first detected in frontal cortex at 1-2 months after PCA, and reinnervation extends to posterior regions of neocortex at 4-6 months; however, the density of fine 5-HT axons never reaches control levels in caudal areas of cortex. At survival times of 6-12 months after PCA, there is a subsequent decrease in the density of normal-appearing fine 5-HT axons in cortex concomitant with the emergence of structurally abnormal 5-HT axons which are unusually tortuous, thickened, and form numerous tangles. One year after PCA, these aberrant axon tangles form a large proportion of the 5-HT axon plexus in cortex. In age-matched control rats, aberrant axons of this type are not seen in young adults, yet they appear in increasing frequency, thickness, and tortuosity in aged rats (1-2 years of age); nonetheless, the overall 5-HT innervation density is not diminished in aged rats. These findings suggest that neurotoxic amphetamines administered to young rats may lead to initial regenerative sprouting followed by accelerated aging of 5-HT projections later in life. Thus, despite the early regenerative response of 5-HT neurons after PCA-induced injury, the normal 5-HT innervation pattern is not re-established. Support: NIDA DA-04431 & 271-90-7408.

FLUOXETINE ATTENUATES FENFLURAMINE INDUCED INCREASES IN EXTRACELLULAR SEROTONIN *IN VIVO* K.E. Sabol, I.B. Richards, L.S. Seiden. University of Chicago, Dept of Pharm./Phys. Sci.,Chicago, Il 60637

Fenfluramine is an amphetamine derivative that causes acute increases in extracellular serotonin *in vivo*, and long term decreases in serotonin tissue concentrations. Fluoxetine, a serotonin uptake inhibitor, protects against the long term decreases in serotonin concentrations caused by fenfluramine. The purpose of the present experiment was to determine whether fluoxetine prevents the acute increase in extracellular serotonin induced by fenfluramine. Rats were implanted with BAS 4 mm dialysis probes in the right hippocampus. Fourteen to eighteen hrs later, baseline extracellular serotonin was measured. Perfusion flow rate was 0.65 ul/min; samples were analyzed by HPLC-EC. After a minimum of six 20-min samples were collected, rats were given one of the following treatments: 12.5 mg/kg fenfluramine (FEN, N=4); 10.0 mg/kg fluoxetine (FLUOX, N=4); or 10.0 mg/kg fluoxetine followed by 12.5 mg/kg fenfluramine 20 mins later (FLUOX+FEN, N=4). Pre-drug baseline serotonin was 0.4±0.09 pg/10 ul for the FEN group; 0.4±0.08 pg/10 ul for the FLUOX group; and 0.3±0.08 pg/10 ul for the FLUOX+FEN group. Forty mins post injection, extracellular serotonin was 37.7±3.41 pg/10 ul for the FEN group; 1.9±0.51 pg/10 ul for the FLUOX group; and 6.5±1.18 pg/10 ul for the FLUOX+FEN group. These results demonstrate that fluoxetine substantially attenuates the increase in extracellular serotonin induced by fenfluramine. They are consistent with the view that the serotonergic effects of fenfluramine and fluoxetine are both mediated through the serotonin uptake carrier mechanism.
