SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 18, PART 2

22ND ANNUAL MEETING

ANAHEIM, CALIFORNIA

OCTOBER 25–30, 1992

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0–916110–38–9
Part 2 ISBN 0–916110–39–7
Both parts ISSN 0190–5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 18, Part 2, p. xxx, 1992.

Published by:

Abstracts in Session Order*
Wednesday, October 28–Friday, November 30 925
Key Word Index 1611
Author Index 1782

* 9,379 volunteer abstracts, 18 symposia abstracts, 17 history of neuroscience abstracts and 46 teaching of neuroscience abstracts.

1992 Program Committee

Stanley J. Watson, Jr., M.D., Ph.D.
Chairperson
University of Michigan School of Medicine

Dennis W. Choi, M.D., Ph.D.
Incoming Chairperson
Washington University School of Medicine

David G. Amaral, Ph.D.
The Salk Institute

Martha C. Bohn, Ph.D.
University of Rochester Medical Center

Andrew G. Bulloch, Ph.D.
University of Calgary Health Science Center

Marc G. Caron, Ph.D.
Duke University Center

Roland D. Ciaranello, M.D.
Stanford University School of Medicine

Antonio R. Damasio, M.D., Ph.D.
University of Iowa College of Medicine

Stephen M. Highstein, M.D., Ph.D.
Washington University School of Medicine

Janice M. Juraska, Ph.D.
University of Illinois

Harvey J. Karten, M.D.
University of California School of Medicine

James E. Krause, Ph.D.
Washington University School of Medicine

Irwin B. Levitan, Ph.D.
Brandeis University

James O. McNamara, M.D.
Duke University Medical Center
V.A. Medical Center

Mary L. Oster-Granite, Ph.D.
University of California

Urs S. Rutishauser, Ph.D.
Case Western Reserve University
School of Medicine

S. Murray Sherman, Ph.D.
SUNY, Stony Brook

Roger P. Simon, M.D.
University of California, San Francisco

Gerard P. Smith, M.D.
New York Hospital, Cornell Medical Center

W. Thomas Thach, Jr., M.D.
Washington University School of Medicine

Leslie G. Ungerleider, Ph.D.
National Institutes of Health

Charles J. Vierck, Ph.D.
University of Florida Health Science Center

Monte Westerfield, Ph.D.
University of Oregon

Robert D. Wurster, Ph.D.
Loyola University of Chicago

Richard E. Zigmond, Ph.D.
Case Western Reserve University School of
Medicine

Joseph T. Coyle, M.D., *ex officio*
Harvard Medical School

Ira B. Black, M.D., *ex officio*
UMDNJ-Robert Wood Johnson Medical School

Story C. Landis, Ph.D., *ex officio*
Case Western Reserve University
School of Medicine

CHRONOLOGICAL LIST OF SESSIONS

(See page xvi for Thematic List of Sessions)

Session Number & Title — Page

SUNDAY, OCTOBER 25

Decade of the Brain Lecture — 8:00 p.m.

1. The Human Brain and Behavior: Insights From Modern Imaging Techniques
M.E. Raichle. ..... No Abstract

MONDAY, OCTOBER 26

Symposia — 8:30 a.m.

2. Emerging Principles of Organization Within the Midbrain Periaqueductal Gray Matter
Chaired by: M.T. Shipley and R. Bandler 1
3. The Computational Neuron
Chaired by: T.J. Sejnowski 1

Special Lecture — 10:00 a.m.

4. Olfactory Mechanisms in an Insect Model
J.G. Hildebrand ..... No Abstract

Special Lecture — 11:45 a.m.

5. The Molecular Basis of Electrical Excitability in the Brain: Structure, Gating and Neuromodulation of Sodium Channels
W.A. Catterall ..... No Abstract

Slide Sessions — 8:30 a.m.

6. Biological rhythms and sleep I 1
7. Monoamines and behavior: human disease and animal models 3
8. GABA receptors: structure and function 4
9. Catecholamine receptors: dopamine I 6
10. Calcium channel toxins I 8
11. Visual cortex: functional circuits and oscillations I 10
12. Nerve growth factor I 12
13. Invertebrate learning and behavior I 15
14. Cell lineage and determination I 17
15. Degenerative disease: Alzheimer's—ß-amyloid I 19
16. Opioid and sigma receptors 21
17. Catecholamines 23
18. Control of posture and movement I 25
19. Oculomotor I 27

Poster Sessions — 8:30 a.m.

20. Genesis of neurons and glia I 29
21. Cell shape and differentiation I 31
22. Axon guidance mechanisms and pathways I 34
23. Formation and specificity of synapses I 39
24. Ion channels: development 41
25. Neuronal death: apoptosis 43
26. Neuronal death: toxins 45
27. Neuronal death: axotomy 47
28. Neuronal death: retina 48
29. Neuronal death: morphology 49
30. Neuronal death: sympathetic neurons 49
31. Neuronal death: cellular response 50
32. Molecular and pharmacological correlates of development I 52
33. Sensory development: auditory and olfactory 54
34. Sensory development: somatosensory 56
35. Transplantation: Parkinson's—fetal tissue 58
36. Transplantation: Parkinson's—adrenal, PC12 61
37. Neuroglia and myelin I 63
38. Cytoskeletal transport and membrane targeting 66
39. Gene structure and function I 69
40. Calcium-activated potassium channels 72
41. Potassium channels: physiology and molecular biology 74
42. Acetylcholine: neuronal nicotinic receptors I 78
43. Excitatory amino acids: excitotoxicity I 81
44. Excitatory amino acids: pharmacology I 85
45. Excitatory amino acids: receptors I 87
46. Serotonin receptors: $5HT_{1A}$ subtypes 90
47. Interaction between neurotransmitters I 94
48. Regional localization of receptors and transmitters: biogenic amines, misc. 97
49. Regional localization of receptors and transmitters: peptides and GABA 100
50. Second messengers I 102
51. Behavioral pharmacology: ethanol, GABA, et al. 107
52. Hypothalamic-pituitary-gonadal regulation: neuropeptides 110
53. Hypothalamic-pituitary-gonadal regulation: steroids 112
54. Neuroendocrine regulation: prolactin 114
55. Hypothalamic-pituitary-gonadal regulation: LHRH and LH I 116

Session Number & Title — Page

56. Neuroendocrine regulation: hypothalamus/pituitary 119
57. Neuroendocrine regulation: limbic system 122
58. Respiratory regulation: central networks/patterns 123
59. Regulation of autonomic function: genitourinary 126
60. Somatic and visceral afferents I 129
61. Spinal cord 131
62. Pain modulation: hyperalgesia 133
63. Retina and photoreceptors I 136
64. Subcortical visual pathways: LGN 139
65. Subcortical visual pathways: retina and colliculus 142
66. Visual cortex: physiology of extrastriate cortex 146
67. Auditory system: central physiology I 149
68. Brain metabolism and blood flow I 152
69. Genetic models I 156
70. Epilepsy: human studies and animal models I 158
71. Epilepsy: basic mechanisms I 162
72. Degenerative disease: Alzheimer's—ß-amyloid II 164
73. Degenerative disease: Huntington's disease 167
74. Trauma: behavioral studies 169
75. Trauma: mechanisms of injury and healing 171
76. Trauma: transmitters 172
77. Trauma: cellular reaction 173
78. Trauma: metabolic changes 175
79. Trauma: drug treatment 176
80. Trauma: glia/blood-brain barrier 178
81. Trauma: hypothermia 179

(History and Teaching Posters will be posted the entire week.)

82. History of neuroscience 180
83. Teaching of neuroscience: undergraduate and graduate education 183
84. Teaching of neuroscience: computer-assisted instruction 186
85. Teaching of neuroscience: elementary and secondary grades 189

Symposia — 1:00 p.m.

86. Protein Phosphatases and the Regulation of Neuronal Excitability
Chaired by: D.L. Armstrong 191
87. Motilities of the Auditory Periphery
Chaired by: R. Hallworth 191

History of Neuroscience Lecture — 1:00 p.m.

88. Neuropsychology: Whence and Whither?
B.A. Milner ..... No Abstract

Presidential Special Lecture — 4:15 p.m.

89. Molecular Biology of the Dopaminergic System
O. Civelli ..... No Abstract

Slide Sessions — 1:00 p.m.

90. Hypothalamic-pituitary-gonadal regulation 191
91. Peptides: biosynthesis, metabolism, biochemistry I 193
92. Biological rhythms and sleep II 195
93. Degenerative disease: Alzheimer's—other 197
94. Pain: pharmacology 199
95. Psychotherapeutic drugs 201
96. Stress 203
97. Degenerative disease: Alzheimer's—neuropharmacology and neurotransmitters I 205
98. Formation and specificity of synapses II 207
99. Visual cortex: functional organization of striate cortex 208
100. Molecular biology of serotonin receptors 210
101. Subcortical visual pathways 212
102. Oculomotor II 214
103. Motor systems and sensorimotor integration: cortex I 216

Poster Sessions — 1:00 p.m.

104. Process outgrowth, growth cones and sprouting I 218
105. Axon guidance mechanisms and pathways II 221
106. Other factors and trophic agents: BDNF, NT3, NT4 224
107. Other factors and trophic agents: *trks* 227
108. Hormones and development: non-gonadal hormones 228
109. Hormones and development: gonadal hormones I 230
110. Hormones and development: gonadal hormones II 234
111. Molecular and pharmacological correlates of development II 236
112. Gene structure and function II 238
113. Gene structure and function III 241
114. Presynaptic mechanisms I 244
115. Ligand-gated ion channels 247
116. Acetylcholine: release 251
117. Acetylcholine: muscarinic receptors I 253
118. Excitatory amino acids: pharmacology II 256
119. Excitatory amino acids: receptors II 258
120. GABA receptors: structure 261
121. Peptides: anatomical localization—non-primates 264
122. Peptides: biosynthesis and metabolism I 268
123. Peptides: physiological effects I 271
124. Catecholamines: receptors I 273
125. Catecholamines: dopamine—electrophysiology 277
126. Interactions between neurotransmitters II 280
127. Second messengers II 282
128. Pain pathways: hyperalgesia 285

Session Number & Title — Page

129. Pain modulation: peripheral neuropathy 287
130. Pain modulation: dorsal horn 290
131. Visual cortex: functional circuits and oscillations II 292
132. Visual cortex: anatomy of extrastriate cortex 293
133. Visual cortex: physiology of striate cortex 295
134. Visual cortex: anatomy of striate cortex 297
135. Invertebrate sensory systems 300
136. Basal ganglia and thalamus I 304
137. Basal ganglia and thalamus II 306
138. Spinal cord and brainstem I 310
139. Spinal cord and brainstem II 312
140. Circuitry and pattern generation I 316
141. Limbic system I 319
142. Limbic system II 323
143. Comparative neuroanatomy 326
144. Human cognition I 331
145. Human cognition: electrophysiology I 334
146. Learning and memory: physiology I 337
147. Learning and memory: pharmacology—acetylcholine 339
148. Neural plasticity I 343
149. Neuroethology: invertebrates, electric fish 346
150. Stress: chronic 350
151. Monoamines and behavior: serotonin 352
152. Neuropeptides and behavior I 356
153. Drugs of abuse: benzodiazepines and barbiturates 358
154. Drugs of abuse: amphetamine and other stimulants 362
155. Drugs of abuse: cocaine and development 363
156. Drugs of abuse: opioids 368
157. Drugs of abuse: cannabinoids and opioids 372
158. Psychotherapeutic drugs: clozapine and dopamine antagonists 375
159. Epilepsy: anticonvulsant drugs 379
82. History of neuroscience 180
83. Teaching of neuroscience: undergraduate and graduate education 183
84. Teaching of neuroscience: computer-assisted instruction 186
85. Teaching of neuroscience: elementary and secondary grades 189

Animals in Research Panel — 6:30 p.m
160. Antivivisectionist Attacks: Security and Law Enforcement ..... No Abstract

Presidential Symposium — 8:00 p.m.
161. Selective Neuronal Vulnerability
Inherited Neurodegeneration in *C. elegans*
M. Chalfie ..... No Abstract
The Regulation of Neuronal Survival During Development
R.W. Oppenheim ..... No Abstract
The Alzheimer Amyloid ßA4 Protein and Its Precursor (APP) in Health and Disease
K. Beyreuther ..... No Abstract
Huntington's Disease: Genetics to Neurobiology
A.B. Young ..... No Abstract

TUESDAY, OCTOBER 27

Symposia — 8:30 a.m.
162. Recent Advances in Neuropeptide Biosynthesis: Molecular and Cellular Biology of Neuropeptide-processing Enzymes
Chaired by: L.D. Fricker 381
163. Regeneration of Vertebrate Sensory Receptors
Chaired by: E.W. Rubel 381

Special Lecture — 10:00 a.m.
164. Nerve Growth Factor and Nociception
L.M. Mendell ..... No Abstract

Special Lecture — 11:45 a.m.
165. The Biology of Sexual Orientation
S. LeVay ..... No Abstract

Slide Sessions — 8:30 a.m.
166. Auditory system: central physiology II 382
167. Pain: physiology and behavior 384
168. Learning and memory: systems and functions—neuropsychology I 386
169. Visual cortex: anatomical studies 388
170. Other factors and trophic agents: general I 390
171. Retina and photoreceptors II 393
172. Excitatory amino acids: receptors III 395
173. Receptor modulation, up and down regulation I 397
174. Peptides: receptors I 399
175. GABA receptors: function I 401
176. Long-term potentiation I 402
177. Brain metabolism and blood flow II 404
178. Cerebellum I 406
179. Staining, tracing and imaging techniques I 408

Poster Sessions — 8:30 a.m.
180. Cell lineage and determination II 409
181. Cell shape and differentiation II 411
182. Formation and specificity of synapses III 413
183. Nerve growth factor II 415

Session Number & Title — Page

184. Molecular and pharmacological correlates of development III ... 418
185. Glia and other non-neuronal cells I ... 422
186. Regeneration I ... 424
187. Calcium channels: physiology I ... 428
188. Calcium channels: pharmacology and effects of transmitters ... 432
189. Acetylcholine: muscle nicotinic receptors ... 436
190. Excitatory amino acids: excitotoxicity II ... 439
191. Excitatory amino acids: anatomy and physiology I ... 442
192. Excitatory amino acids: pharmacology III ... 445
193. Peptides: receptors II ... 448
194. Peptides: receptors III ... 451
195. Sigma receptors and ligands ... 455
196. Catecholamine receptors: adrenergic I ... 457
197. Catecholamines: release ... 459
198. Serotonin receptors: molecular biology ... 462
199. Histamine and other biogenic amines ... 465
200. Transmitters in invertebrates I ... 468
201. Transmitters in invertebrates II ... 470
202. Uptake, storage, secretion and metabolism I ... 473
203. Second messengers III ... 475
204. Hypothalamic-pituitary-adrenal regulation: glucocorticoid and mineralocorticoid receptors ... 478
205. Water and osmotic regulation ... 480
206. Neural-immune interactions: other interleukins and cytokines ... 482
207. Regulation of autonomic function: gastrointestinal and visceral afferents ... 484
208. Respiratory regulation: transmitters/receptors ... 487
209. Temperature regulation and fever ... 489
210. Somatic and visceral afferents II ... 492
211. Pain pathways: dorsal horn ... 495
212. Pain modulation: cognitive, autonomic and endocrine ... 498
213. Motor systems and sensorimotor integration: cortex II ... 501
214. Motor systems and sensorimotor integration: cortex III ... 504
215. Vestibular system: neurochemistry ... 507
216. Vestibular system: morphology and physiology ... 509
217. Spinal cord and brainstem III ... 511
218. Control of posture and movement: arm movement I ... 515
219. Limbic system III ... 518
220. Learning and memory: physiology II ... 520
221. Learning and memory: pharmacology—opioids ... 523
222. Learning and memory: pharmacology—monoamines ... 524
223. Neuroethology: avian vocalization and audition ... 527
224. Invertebrate learning and behavior II ... 530
225. Stress and neuronal systems ... 533
226. Monoamines and behavior: 8-OH-DPAT and noradrenaline ... 536
227. Drugs of abuse: alcohol, barbiturates and benzodiazepines I ... 539
228. Drugs of abuse: cocaine—other studies ... 542
229. Drugs of abuse: nicotine, cocaine, et al. ... 545
230. Psychotherapeutic drugs: sigma receptors and antipsychotics ... 547
231. Epilepsy: human studies and animal models II ... 550
232. Epilepsy: basic mechanisms II ... 553
233. Degenerative disease: Alzheimer's—postmortem analysis ... 557
234. Degenerative disease: Alzheimer's—growth factors ... 559
235. Degenerative disease: Alzheimer's—animal models ... 560
236. Degenerative disease: Alzheimer's—CSF ... 561
237. Degenerative disease: Alzheimer's—TAU ... 561
238. Degenerative disease: Alzheimer's—plaques and tangles ... 564
239. Degenerative disease: Alzheimer's—clinical observations ... 566
240. Degenerative disease: Alzheimer's—etiologic toxins ... 568
241. Ischemia: neurotransmitters ... 569
242. Schizophrenia ... 570

82. History of neuroscience ... 180
83. Teaching of neuroscience: undergraduate and graduate education ... 183
84. Teaching of neuroscience: computer-assisted instruction ... 186
85. Teaching of neuroscience: elementary and secondary grades ... 189

Symposia — 1:00 p.m.

243. New Waves in Cell Calcium
Chaired by: M.R. Hanley ... 573
244. The Role of Sensory Information in the Guidance of Voluntary Movement
Chaired by: I. McCloskey and A. Prochazka ... 573

Warner-Lambert Lecture — 1:00 p.m.

245. Neuropeptides in Perspective
T. Hokfelt ... No Abstract

Special Lecture — 4:15 p.m.

246. Neurotrophic Factors, Their Receptors and the Signalling Pathways They Activate
G.D. Yancopoulos ... No Abstract

Session Number & Title — Page

Slide Sessions — 1:00 p.m.

247. Neuronal death ... 574
248. Presynaptic mechanisms II ... 575
249. Axon guidance mechanisms and pathways III ... 577
250. Formation and specificity of synapses IV ... 579
251. Uptake, storage, secretion and metabolism II ... 581
252. Human cognition: electrophysiology II ... 583
253. Ion channel modulation I ... 585
254. Gene structure and function IV ... 587
255. Catecholamine receptors: adrenergic II ... 589
256. Visual cortex: neuronal response properties ... 591
257. Neural plasticity II ... 593
258. Chemical senses: peripheral mechanisms ... 596
259. Acetylcholine: receptors ... 597
260. Second messengers IV ... 599

Poster Sessions — 1:00 p.m.

261. Cell shape and differentiation III ... 601
262. Process outgrowth, growth cones and sprouting II ... 603
263. Process outgrowth, growth cones and sprouting III ... 606
264. Axon guidance mechanisms and pathways IV ... 609
265. Development of neurotransmitter systems: amino acids ... 610
266. Nerve growth factor III ... 613
267. Other factors and trophic agents: CNTF ... 616
268. Pattern formation, compartments and boundaries I ... 619
269. Molecular and pharmacological correlates of development IV ... 622
270. Glia and other non-neuronal cells II ... 624
271. Regeneration II ... 627
272. Neuroglia and myelin II ... 631
273. Presynaptic mechanisms III ... 634
274. Long-term potentiation II ... 637
275. Chloride and other channels ... 643
276. Excitatory amino acids: excitotoxicity III ... 644
277. Excitatory amino acids: pharmacology IV ... 647
278. Excitatory amino acids: receptors IV ... 650
279. GABA receptors: function II ... 654
280. Opioids: behavior ... 657
281. Catecholamine receptors: dopamine II ... 660
282. Catecholamines: dopamine I ... 663
283. Hypothalamic-pituitary-adrenal regulation: CRF ... 666
284. Hypothalamic-pituitary-adrenal regulation: POMC, ACTH, other factors ... 668
285. Hypothalamic-pituitary-gonadal regulation: LHRH and LH II ... 671
286. Neuroendocrine regulation: osmotic regulation I ... 674
287. Neural-immune interactions: behavior and stress ... 677
288. Neural control of immune functions ... 679
289. Pain modulation: brainstem and thalamus ... 682
290. Pain modulation: descending ... 684
291. Pain modulation: pharmacology and endocrinology ... 686
292. Pain modulation: peripheral ... 689
293. Basal ganglia and thalamus III ... 692
294. Basal ganglia and thalamus IV ... 695
295. Oculomotor system: saccades ... 698
296. Oculomotor III ... 702
297. Learning and memory: physiology III ... 705
298. Motivation and emotion I ... 709
299. Invertebrate learning and behavior III ... 712
300. Stress: general ... 715
301. Monoamines and behavior: accumbens, striatum and frontal cortex ... 718
302. Drugs of abuse: pharmacology of cocaine ... 721
303. Psychotherapeutic drugs: lithium, benzodiazepines and antidepressants ... 725
304. Genetic models II ... 728
305. Degenerative disease: Alzheimer's—ß-amyloid III ... 731
306. Degenerative disease: Alzheimer's—cognition ... 734
307. Degenerative disease: Alzheimer's—neuropharmacology and neurotransmitters II ... 738
82. History of neuroscience ... 180
83. Teaching of neuroscience: undergraduate and graduate education ... 183
84. Teaching of neuroscience: computer-assisted instruction ... 186
85. Teaching of neuroscience: elementary and secondary grades ... 189

Social Issues Roundtable — 4:30 p.m.

308. Neural Circuitry and Free Will: Concepts of Responsibility in the Decade of the Brain
Sponsored by: Social Issues Committee of the Society for Neuroscience, H.J. Ralston, Chairperson ... No Abstract

The Grass Foundation Lecture — 8:00 p.m.

309. Molecular Biology of the Glutamate Receptors
S.F. Heinemann ... No Abstract

WEDNESDAY, OCTOBER 28

Symposia—8:30 a.m.

310. Strategies for the Study of Alzheimer Amyloidosis Using Animal Models
Chaired by: J.D. Buxbaum and A. Goate ... 740
311. Cell Biology of the Growth Cone
Chaired by: D.J. Goldberg ... 740

Session Number & Title — Page

Special Lecture — 11:45 a.m.

312. New Insights Into Synaptic Signal Termination: The Neurotransmitter Transporter Gene Family
S.G. Amara ..... No Abstract

Slide Sessions — 8:30 a.m.

313. Visual cortex: theoretical studies 740
314. Ingestive behavior: salt appetite and food intake 742
315. Human cognition: neuropsychology 744
316. Somatosensory system 746
317. Serotonin neuropharmacology 749
318. Presynaptic mechanisms IV 750
319. Hypothalamic-pituitary-adrenal regulation 752
320. Cardiovascular regulation I 754
321. Excitatory amino acids: excitotoxicity IV 756
322. Drugs of abuse: alcohol, barbiturates and benzodiazepines II 758
323. Long-term potentiation III 759
324. Peptides: physiological and behavioral effects 761
325. Degenerative disease: Alzheimer's—ß-amyloid IV 764
326. Neural-immune interactions 766

Poster Sessions — 8:30 a.m.

327. Genesis of neurons and glia II 768
328. Development of neurotransmitter systems: catecholamines and neuropeptides 771
329. Nerve growth factor IV 774
330. Development of cerebral cortex and limbic system I 777
331. Transplantation: gene therapy and cell lines 781
332. Neuroglia and myelin III 784
333. Gene structure and function V 787
334. Presynaptic mechanisms V 790
335. Potassium channels: pharmacology and effects of transmitters 793
336. Ion channel modulation II 797
337. Acetylcholine: neuronal nicotinic receptors II 801
338. Excitatory amino acids: anatomy and physiology II 803
339. Peptides: anatomical localization—human and primate ... 805
340. Ontogeny of serotonin receptors 807
341. Second messengers V 809
342. Behavioral pharmacology: benzodiazepines, et al. 813
343. Receptor modulation, up and down regulation II 815
344. Hypothalamic-pituitary-gonadal regulation: other 818
345. Neuroendocrine regulation: other 820
346. Neuroendocrine regulation: osmotic regulation II 822
347. Regulation of autonomic function: other 825
348. Respiratory regulation: chemoreception 826
349. Somatic and visceral afferents: touch 829
350. Pain pathways: supraspinal 831
351. Pain modulation: supraspinal 834
352. Retina and photoreceptors: photoreceptors, horizontal and bipolar cells 837
353. Auditory system: central physiology III 840
354. Chemical senses: peripheral mechanisms—taste 844
355. Motor systems and sensorimotor integration: cortex IV 846
356. Basal ganglia and thalamus V 849
357. Cerebellum II 852
358. Oculomotor IV 855
359. Spinal cord and brainstem IV 858
360. Control of posture and movement: clinically related studies 860
361. Brain metabolism and blood flow III 863
362. Learning and memory: pharmacology—other I 866
363. Neural plasticity III 869
364. Motivation and emotion II 872
365. Biological rhythms and sleep III 875
366. Biological rhythms and sleep IV 878
367. Neuroethology: tetrapods—bat echolocation 882
368. Monoamines and behavior: striatum and DA receptors 885
369. Hormonal control of reproductive behavior I 888
370. Hormonal control of reproductive behavior II 890
371. Hormonal control of reproductive behavior III 892
372. Hormonal control of reproductive behavior IV 894
373. Neuropeptides and behavior II 895
374. Neuropeptides and behavior III 898
375. Drugs of abuse: interaction of cocaine, DA-altering drugs and the VTA 900
376. Aging and behavior I 901
377. Epilepsy: human studies and animal models III 905
378. Epilepsy: basic mechanisms III 908
379. Schizophrenia: neurochemistry 911
380. Neurotoxicity: amphetamine 913
82. History of neuroscience 180
83. Teaching of neuroscience: undergraduate and graduate education 183
84. Teaching of neuroscience: computer-assisted instruction 186
85. Teaching of neuroscience: elementary and secondary grades 189

Symposia — 1:00 p.m.

381. Mechanisms of HIV-related Injury in the Central Nervous System
Chaired by: S.A. Lipton 914
382. Cognitive and Neurobiological Consequences of Normal Aging: From Rats to Primates
Chaired by: C.A. Barnes 914

Session Number & Title — Page

Presidential Special Lecture — 1:00 p.m.

383. Nitric Oxide: A Novel Neuronal Messenger
S.H. Snyder ..... No Abstract

Special Lecture — 4:15 p.m.

384. Specification of the Zebrafish Body Axis
C.B. Kimmel ..... No Abstract

Slide Sessions — 1:00 p.m.

385. Interactions between neurotransmitters III 915
386. Limbic system IV 916
387. Other factors and trophic agents: BDNF, NT3 918
388. Potassium channel permeation and gating 920
389. Visual development: neuronal and synaptic development 922
390. Cell migration and motility I 924
391. Receptor modulation, up and down regulation III 926
392. Neuroendocrine regulation I 928
393. Transplantation I 930
394. Human cognition: blood flow/metabolism 932
395. Degenerative disease: Parkinson's I 934
396. Ingestive behavior: NPY, galanin and insulin 936
397. Motor systems and sensorimotor integration: cortex V 938
398. Invertebrate learning and behavior IV 940

Poster Sessions — 1:00 p.m.

399. Process outgrowth, growth cones and sprouting IV 943
400. Formation and specificity of synapses V 946
401. Nerve growth factor V 948
402. Other factors and trophic agents: IGF 951
403. Other factors and trophic agents: FGF 953
404. Pattern formation, compartments and boundaries II 955
405. Glia and other non-neuronal cells III 958
406. Motor systems I 961
407. Regeneration III 963
408. Staining, tracing and imaging techniques II 966
409. Calcium channel toxins II 969
410. Calcium channels: physiology II 972
411. Acetylcholine: CNS I 974
412. Excitatory amino acids: receptors V 977
413. GABA receptors: function III 980
414. Peptides: biosynthesis and metabolism II 983
415. Peptides: physiological effects II 986
416. Peptides: physiological effects III 988
417. Opioids: anatomy and physiology I 991
418. Catecholamines: receptors II 994
419. Purines: adenosine 997
420. Purines: ATP and guanosine 1000
421. Uptake, storage, secretion and metabolism III 1001
422. Second messengers VI 1003
423. Hypothalamic-pituitary-adrenal regulation: stress—developmental aspects 1007
424. Neural-immune interactions: innervation and other 1009
425. Neural-immune interactions: interleukin-1 1012
426. Cardiovascular regulation: lower brainstem I 1014
427. Subcortical somatosensory pathways: lemniscal and spinothalamic 1016
428. Pain modulation: spinal I 1019
429. Pain modulation: spinal II 1022
430. Pain modulation: behavior 1025
431. Retina and photoreceptors: amacrine, ganglion and glial cells 1027
432. Subcortical visual pathways: cortico-tectal, Accessory Optic System, centrifugals 1030
433. Visual cortex: motion processing I 1033
434. Auditory system: neurochemistry 1035
435. Auditory system: anatomy I 1037
436. Chemical senses: pathways—gustation 1039
437. Basal ganglia and thalamus VI 1042
438. Cerebellum III 1045
439. Vestibular system: behavioral responses 1047
440. Spinal cord and brainstem V 1049
441. Control of posture and movement II 1051
442. Circuitry and pattern generation II 1054
443. Learning and memory: systems and functions— misc. I 1058
444. Learning and memory: systems and functions— misc. II 1061
445. Learning and memory: physiology IV 1064
446. Ingestive behavior: taste aversion and neural mechanisms 1066
447. Monoamines and behavior: behavioral effects of dopamine 1070
448. Drugs of abuse: alcohol, barbiturates and benzodiazepines III 1072
449. Drugs of abuse: stimulants I 1074
450. Drugs of abuse: cocaine and dopamine neuronal systems 1076
451. Degenerative disease: Parkinson's II 1080
452. Neuromuscular diseases I 1082

82. History of neuroscience 180

83. Teaching of neuroscience: undergraduate and graduate education 183

84. Teaching of neuroscience: computer-assisted instruction 186

Session Number & Title — Page

85. Teaching of neuroscience: elementary and secondary grades 189

THURSDAY, OCTOBER 29

Symposia — 8:30 a.m.

453. Molecular Analyses of Neuronal Physiology and Potential for Gene Therapy Using Herpes Simplex Virus Vectors
Chaired by: A. Geller 1085
454. Thalamic Mechanisms of Nociception
Chaired by: F.A. Lenz 1085

Presidential Special Lecture — 11:45 a.m.

455. Neurobiological Foundations of Speech and Language
P.A. Tallal ..... No Abstract

Slide Sessions — 8:30 a.m.

456. Neuroendocrine regulation II 1085
457. Trauma 1087
458. Neuroglia and myelin IV 1089
459. Gene structure and function VI 1090
460. Potassium channel expression and localization 1092
461. Process outgrowth, growth cones and sprouting V 1094
462. Pattern formation, compartments and boundaries III 1096
463. Nerve growth factor VI 1098
464. Visual cortex: motion processing II 1100
465. Neurotoxicity 1102
466. Transmitters in invertebrates III 1104

Poster Sessions — 8:30 a.m.

467. Genesis of neurons and glia III 1107
468. Cell lineage and determination III 1109
469. Formation and specificity of synapses VI 1112
470. Nutritional and prenatal factors: alcohol 1114
471. Glia and other non-neuronal cells IV 1116
472. Development of cerebral cortex and limbic system II 1119
473. Transplantation: cortex 1121
474. Transplantation: retina, olfactory bulb, SCN 1123
475. Staining, tracing and imaging techniques III 1125
476. Blood-brain barrier I 1128
477. Presynaptic mechanisms VI 1130
478. Sodium channels 1133
479. Calcium channel molecular biology 1138
480. Acetylcholine: CNS II 1140
481. Acetylcholine: muscarinic receptors II 1142
482. Excitatory amino acids: excitotoxicity V 1145
483. Excitatory amino acids: anatomy and physiology III 1148
484. Excitatory amino acids: pharmacology V 1151
485. Excitatory amino acids: receptors VI 1154
486. GABA receptors: function IV 1157
487. GABA receptors: function V 1160
488. Peptides: receptors IV 1162
489. Peptides: physiological effects IV 1165
490. Opioid receptors: coupling and biochemistry 1167
491. Catecholamines: receptors III 1170
492. Cardiovascular regulation: forebrain mechanisms 1173
493. Cardiovascular regulation: upper brainstem mechanisms 1176
494. Cardiovascular regulation: spinal cord and medulla 1178
495. Cardiovascular regulation: cardiac control and sympathetic rhythms 1180
496. Cardiovascular regulation: hypertension, reflexes and peripheral autonomics 1183
497. Cardiovascular regulation: lower brainstem II 1186
498. Subcortical somatosensory pathways: trigeminal 1189
499. Auditory system: cochlea 1190
500. Auditory system: anatomy II 1193
501. Chemical senses: peripheral mechanisms—olfaction, carotid body 1196
502. Chemical senses: central pathways—olfaction 1199
503. Basal ganglia and thalamus VII 1203
504. Cerebellum IV 1206
505. Human cognition II 1207
506. Learning and memory: systems and functions—models 1210
507. Learning and memory: systems and functions—neuropsychology II 1212
508. Learning and memory: physiology V 1215
509. Learning and memory: pharmacology—excitatory amino acids 1218
510. Biological rhythms and sleep V 1220
511. Biological rhythms and sleep VI 1223
512. Biological rhythms and sleep VII 1226
513. Ingestive behavior: water and salt intake 1229
514. Ingestive behavior: nutrients, serotonin and insulin 1232
515. Drugs of abuse: ethanol and GABA 1235
516. Drugs of abuse: cocaine's interaction with non-dopamine systems 1237
517. Epilepsy: basic mechanisms IV 1240
518. Degenerative disease: Alzheimer's—neuropharmacology and neurotransmitters III 1243
519. Degenerative disease: Parkinson's III 1247
520. Degenerative disease: other 1249
521. Ischemia: drug treatment I 1252
522. Ischemia: drug treatment II 1254
523. Ischemia: glucose 1257

Session Number & Title — Page

524. Ischemia: gene or protein induction 1258
525. Ischemia: free radicals 1261
526. Ischemia: vasculature 1262
527. Ischemia: imaging 1264
82. History of neuroscience 180
83. Teaching of neuroscience: undergraduate and graduate education 183
84. Teaching of neuroscience: computer-assisted instruction 186
85. Teaching of neuroscience: elementary and secondary grades 189

Symposia — 1:00 p.m.

528. Molecular Biology of Olfaction
Chaired by: G.M. Shepherd 1264
529. Regulation of Neuronal Peptide Gene Expression: Lessons from the Neurohypophyseal System
Chaired by: C. Sladek 1264

Special Lecture — 1:00 p.m.

530. The Molecular Genetics of Cell-Cell Interactions Regulating Cell Fate in the *Drosophila* Visual System
L. Zipursky ..... No Abstract

Special Lecture — 4:15 p.m.

531. Sensory Information Processing in Electric Fish: Computational Rules and Their Neuronal Implementation
W. Heiligenberg ..... No Abstract

Slide Sessions — 1:00 p.m.

532. Brain metabolism and blood flow IV 1266
533. Ischemia I 1267
534. Cardiovascular regulation II 1268
535. Calcium channel modulation 1270
536. Axon guidance mechanisms and pathways V 1272
537. Visual cortex: behavior and behavioral correlates 1274
538. Regulation of autonomic function 1276
539. Circuitry and pattern generation III 1278
540. Blood-brain barrier II 1280

Poster Sessions — 1:00 p.m.

541. Cell migration and motility II 1282
542. Process outgrowth, growth cones and sprouting VI 1284
543. Process outgrowth, growth cones and sprouting VII 1285
544. Nerve growth factor VII 1288
545. Other factors and trophic agents: glia 1291
546. Other factors and trophic agents: injury 1294
547. Other factors and trophic agents: cytokines 1297
548. Nutritional and prenatal factors 1299
549. Glia and other non-neuronal cells V 1301
550. Motor systems II 1303
551. Visual development: striate cortex I 1305
552. Visual development: striate cortex II 1307
553. Visual development: optic tectum 1309
554. Visual development: mammalian thalamus and midbrain 1310
555. Visual development: retinal ganglion cells 1312
556. Visual development: abnormal development of cortex 1314
557. Visual development: retina 1317
558. Regeneration IV 1320
559. Transplantation II 1322
560. Membrane composition and cell-surface macromolecules 1324
561. Gene structure and function VII 1330
562. Gene structure and function VIII 1332
563. Synaptic structure and function I 1335
564. Synaptic structure and function II 1338
565. Postsynaptic mechanisms I 1341
566. Postsynaptic mechanisms II 1344
567. Long-term potentiation IV 1347
568. Synaptic pharmacology I 1352
569. Synaptic pharmacology II 1355
570. Ion channels: cell function 1358
571. Excitatory amino acids: excitotoxicity VI 1360
572. Excitatory amino acids: receptors VII 1363
573. Peptides: receptors V 1366
574. Peptides: biosynthesis and metabolism III 1368
575. Opiate receptors: interactions with other systems 1370
576. Opioids: anatomy and physiology II 1372
577. Catecholamines: norepinephrine 1374
578. Catecholamines: tyrosine hydroxylase 1377
579. Serotonin receptors: behavioral actions 1379
580. Serotonin: receptor modulation 1381
581. Uptake, storage, secretion and metabolism IV 1384
582. Somatosensory cortex and thalamocortical relationships: anatomy 1386
583. Somatosensory cortex and thalamocortical relationships: physiology 1388
584. Somatosensory cortex and thalamocortical relationships: thalamus 1390
585. Visual cortex: brain imaging techniques 1393
586. Visual behavior: clinical studies 1394
587. Visual behavior: psychophysics and eye movements 1396
588. Auditory, vestibular and lateral-line hair cells 1398
589. Reflex function I 1402
590. Control of posture and movement III 1405

Session Number & Title — Page

591. Control of posture and movement IV 1408
592. Invertebrate motor function 1411
593. Other systems of the CNS: hypothalamus 1415
594. Association cortex and thalamocortical relations 1417
595. Learning and memory: systems and functions—spatial I 1421
596. Learning and memory: systems and functions—spatial II 1424
597. Ingestive behavior: peptides 1427
598. Drugs of abuse: ethanol and monoamines 1430
599. Drugs of abuse: cocaine and biochemistry 1432
600. Aging and behavior II 1434
601. Degenerative disease: Alzheimer's—ß-amyloid V 1437
602. Degenerative disease: Alzheimer's—ß-amyloid VI 1440
603. Degenerative disease: Parkinson's IV 1443
604. Developmental disorders 1445
82. History of neuroscience 180
83. Teaching of neuroscience: undergraduate and graduate education 183
84. Teaching of neuroscience: computer-assisted instruction 186
85. Teaching of neuroscience: elementary and secondary grades 189

FRIDAY, OCTOBER 30

Symposia — 8:30 a.m.

605. $GABA_B$ Receptors and Their Role in Neurotransmission, Neuromodulation and Neuropathology
Chaired by: N.G. Bowery 1448
606. Neurobehavioral Mechanism of Salt Intake Behavior
Chaired by: E. Stellar and B.S. McEwen 1448

Special Lecture — 10:00 a.m.

607. The Translation of Sensory Signals Into Commands for the Control of Saccadic Eye Movements: The Role of the Primate Superior Colliculus
D. Sparks ..... No Abstract

Slide Sessions — 8:30 a.m.

608. Glia and other non-neuronal cells VI 1448
609. Peptides: receptors VI 1450
610. Ischemia II 1452
611. Visual development: critical period and deprivation 1454
612. Drugs of abuse: cocaine and other stimulants 1456
613. Excitatory amino acids: pharmacology VI 1458
614. Process outgrowth, growth cones and sprouting VIII 1460
615. Regeneration V 1462
616. Degenerative disease: Alzheimer's—ß-amyloid VII 1464
617. Regional localization of receptors and transmitters 1466

Poster Sessions — 8:30 a.m.

618. Process outgrowth, growth cones and sprouting IX 1468
619. Development of neurotransmitter systems: acetylcholine and serotonin 1470
620. Other factors and trophic agents: general II 1472
621. Other factors and trophic agents: general III 1475
622. Transplantation: spinal cord 1479
623. Aging I 1480
624. Aging II 1483
625. Aging III 1486
626. Neuroglia and myelin V 1489
627. Blood-brain barrier III 1491
628. Long-term potentiation V 1494
629. Ion channel modulation III 1500
630. Acetylcholine: choline acetyltransferase and cholinesterase 1504
631. Acetylcholine: neuronal nicotinic receptors III 1506
632. Excitatory amino acids: receptors VIII 1509
633. Opiate receptor ligands 1511
634. Catecholamines: dopamine II 1514
635. Regulation of serotonin receptors 1517
636. Serotonin receptors: pharmacologic characterization 1519
637. Serotonin receptors: action on neurotransmission 1522
638. Serotonin: pharmacology I 1524
639. Serotonin: pharmacology II 1528
640. Interactions between neurotransmitters IV 1531
641. Behavioral pharmacology: dopamine, serotonin, NE 1533
642. Receptor modulation, up and down regulation IV 1536
643. Hypothalamic-pituitary-adrenal regulation: stress 1539
644. Somatosensory cortex and thalamocortical relationships: development and plasticity 1542
645. Somatosensory cortex and thalamocortical relationships: psychophysics and networks 1544
646. Reflex function II 1547
647. Control of posture and movement: arm movement II 1550
648. Control of posture and movement: locomotion 1553
649. Muscle I 1556
650. Muscle II 1558
651. Learning and memory: systems and functions—conditioning I 1559
652. Learning and memory: systems and functions—conditioning II 1562
653. Learning and memory: systems and functions—conditioning III 1564

Session Number & Title	Page
654. Learning and memory: pharmacology—benzodiazepines	1567
655. Learning and memory: pharmacology—other II	1568
656. Drugs of abuse: behavioral effects of cocaine	1571
657. Drugs of abuse: stimulants II	1574
658. Degenerative disease: Parkinson's V	1576
659. Ischemia: acidosis	1579
660. Ischemia: neurophysiology	1579
661. Ischemia: animal models	1581
662. Ischemia: cellular mechanisms	1583
663. Ischemia: glia	1585
664. Ischemia: temperature effect	1586
665. Ischemia: calcium	1588
666. Ischemia: clinical studies	1589
667. Infectious diseases	1590
668. Neuromuscular diseases II	1593
669. Affective disorders	1595
670. Affective disorders: serotonin	1598
671. Neurotoxicity: biological	1599
672. Neurotoxicity: excitotoxins	1602
673. Neurotoxicity: miscellaneous toxins	1604
674. Neurotoxicity: metals	1606
675. Neurotoxicity: metals—aluminum	1610
82. History of neuroscience	**180**
83. Teaching of neuroscience: undergraduate and graduate education	**183**
84. Teaching of neuroscience: computer-assisted instruction	**186**
85. Teaching of neuroscience: elementary and secondary grades	**189**

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only)

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
THEME A: DEVELOPMENT AND REGENERATION							
623.	Aging I	Poster					fAM
624.	Aging II	Poster					fAM
625.	Aging III	Poster					fAM
22.	Axon guidance mechanisms and pathways I	Poster	mAM				
105.	Axon guidance mechanisms and pathways II	Poster	mPM				
249.	Axon guidance mechanisms and pathways III	Slide		tuPM			
264.	Axon guidance mechanisms and pathways IV	Poster		tuPM			
536.	Axon guidance mechanisms and pathways V	Slide				thPM	
311.	**Cell Biology of the Growth Cone**	**SYMP**			**wAM**		
14.	Cell lineage and determination I	Slide	mAM				
180.	Cell lineage and determination II	Poster		tuAM			
468.	Cell lineage and determination III	Poster				thAM	
390.	Cell migration and motility I	Slide			wPM		
541.	Cell migration and motility II	Poster				thPM	
21.	Cell shape and differentiation I	Poster	mAM				
181.	Cell shape and differentiation II	Poster		tuAM			
261.	Cell shape and differentiation III	Poster		tuPM			
330.	Development of cerebral cortex and limbic system I	Poster			wAM		
472.	Development of cerebral cortex and limbic system II	Poster				thAM	
619.	Development of neurotransmitter systems: acetylcholine and serotonin	Poster					fAM
265.	Development of neurotransmitter systems: amino acids	Poster		tuPM			
328.	Development of neurotransmitter systems: catecholamines and neuropeptides	Poster			wAM		
23.	Formation and specificity of synapses I	Poster	mAM				
98.	Formation and specificity of synapses II	Slide	mPM				
182.	Formation and specificity of synapses III	Poster		tuAM			
250.	Formation and specificity of synapses IV	Slide		tuPM			
400.	Formation and specificity of synapses V	Poster			wPM		
469.	Formation and specificity of synapses VI	Poster				thAM	
20.	Genesis of neurons and glia I	Poster	mAM				
327.	Genesis of neurons and glia II	Poster			wAM		
467.	Genesis of neurons and glia III	Poster				thAM	
185.	Glia and other non-neuronal cells I	Poster		tuAM			
270.	Glia and other non-neuronal cells II	Poster		tuPM			
405.	Glia and other non-neuronal cells III	Poster			wPM		
471.	Glia and other non-neuronal cells IV	Poster				thAM	
549.	Glia and other non-neuronal cells V	Poster				thPM	
608.	Glia and other non-neuronal cells VI	Slide					fAM
109.	Hormones and development: gonadal hormones I	Poster	mPM				
110.	Hormones and development: gonadal hormones II	Poster	mPM				
108.	Hormones and development: non-gonadal hormones	Poster	mPM				
24.	Ion channels: development	Poster	mAM				
560.	Membrane composition and cell-surface macromolecules	Poster				thPM	
32.	Molecular and pharmacological correlates of development I	Poster	mAM				
111.	Molecular and pharmacological correlates of development II	Poster	mPM				
184.	Molecular and pharmacological correlates of development III	Poster		tuAM			
269.	Molecular and pharmacological correlates of development IV	Poster		tuPM			
406.	Motor systems I	Poster			wPM		

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
550.	Motor systems II	Poster				thPM	
12.	Nerve growth factor I	Slide	mAM				
183.	Nerve growth factor II	Poster		tuAM			
266.	Nerve growth factor III	Poster		tuPM			
329.	Nerve growth factor IV	Poster			wAM		
401.	Nerve growth factor V	Poster			wPM		
463.	Nerve growth factor VI	Slide				thAM	
544.	Nerve growth factor VII	Poster				thPM	
247.	Neuronal death	Slide		tuPM			
25.	Neuronal death: apoptosis	Poster	mAM				
27.	Neuronal death: axotomy	Poster	mAM				
31.	Neuronal death: cellular response	Poster	mAM				
29.	Neuronal death: morphology	Poster	mAM				
28.	Neuronal death: retina	Poster	mAM				
30.	Neuronal death: sympathetic neurons	Poster	mAM				
26.	Neuronal death: toxins	Poster	mAM				
548.	Nutritional and prenatal factors	Poster				thPM	
470.	Nutritional and prenatal factors: alcohol	Poster				thAM	
387.	Other factors and trophic agents: BDNF, NT3	Slide			wPM		
106.	Other factors and trophic agents: BDNF, NT3, NT4	Poster	mPM				
267.	Other factors and trophic agents: CNTF	Poster		tuPM			
403.	Other factors and trophic agents: FGF	Poster			wPM		
402.	Other factors and trophic agents: IGF	Poster			wPM		
547.	Other factors and trophic agents: cytokines	Poster				thPM	
170.	Other factors and trophic agents: general I	Slide		tuAM			
620.	Other factors and trophic agents: general II	Poster					fAM
621.	Other factors and trophic agents: general III	Poster					fAM
545.	Other factors and trophic agents: glia	Poster				thPM	
546.	Other factors and trophic agents: injury	Poster				thPM	
107.	Other factors and trophic agents: *trks*	Poster	mPM				
268.	Pattern formation, compartments and boundaries I	Poster		tuPM			
404.	Pattern formation, compartments and boundaries II	Poster			wPM		
462.	Pattern formation, compartments and boundaries III	Slide				thAM	
104.	Process outgrowth, growth cones and sprouting I	Poster	mPM				
262.	Process outgrowth, growth cones and sprouting II	Poster		tuPM			
263.	Process outgrowth, growth cones and sprouting III	Poster		tuPM			
399.	Process outgrowth, growth cones and sprouting IV	Poster			wPM		
461.	Process outgrowth, growth cones and sprouting V	Slide				thAM	
542.	Process outgrowth, growth cones and sprouting VI	Poster				thPM	
543.	Process outgrowth, growth cones and sprouting VII	Poster				thPM	
614.	Process outgrowth, growth cones and sprouting VIII	Slide					fAM
618.	Process outgrowth, growth cones and sprouting IX	Poster					fAM
186.	Regeneration I	Poster		tuAM			
271.	Regeneration II	Poster		tuPM			
407.	Regeneration III	Poster			wPM		
558.	Regeneration IV	Poster				thPM	
615.	Regeneration V	Slide					fAM
163.	**Regeneration of Vertebrate Sensory Receptors**	**SYMP**		**tuAM**			
33.	Sensory development: auditory and olfactory	Poster	mAM				
34.	Sensory development: somatosensory	Poster	mAM				
393.	Transplantation I	Slide			wPM		
559.	Transplantation II	Poster				thPM	
473.	Transplantation: cortex	Poster				thAM	
331.	Transplantation: gene therapy and cell lines	Poster			wAM		
36.	Transplantation: Parkinson's—adrenal, PC12	Poster	mAM				
35.	Transplantation: Parkinson's—fetal tissue	Poster	mAM				

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
474.	Transplantation: retina, olfactory bulb, SCN	Poster				thAM	
622.	Transplantation: spinal cord	Poster					fAM
556.	Visual development: abnormal development of cortex	Poster				thPM	
611.	Visual development: critical period and deprivation	Slide					fAM
554.	Visual development: mAMmalian thalamus and midbrain	Poster				thPM	
389.	Visual development: neuronal and synaptic development	Slide			wPM		
553.	Visual development: optic tectum	Poster				thPM	
557.	Visual development: retina	Poster				thPM	
555.	Visual development: retinal ganglion cells	Poster				thPM	
551.	Visual development: striate cortex I	Poster				thPM	
552.	Visual development: striate cortex II	Poster				thPM	
THEME B: CELL BIOLOGY							
476.	Blood-brain barrier I	Poster				thAM	
540.	Blood-brain barrier II	Slide				thPM	
627.	Blood-brain barrier III	Poster					fAM
38.	Cytoskeletal transport and membrane targeting	Poster	mAM				
39.	Gene structure and function I	Poster	mAM				
112.	Gene structure and function II	Poster	mPM				
113.	Gene structure and function III	Poster	mPM				
254.	Gene structure and function IV	Slide		tuPM			
333.	Gene structure and function V	Poster			wAM		
459.	Gene structure and function VI	Slide				thAM	
561.	Gene structure and function VII	Poster				thPM	
562.	Gene structure and function VIII	Poster				thPM	
87.	**Motilities of the Auditory Periphery**	**SYMP**	**mPM**				
37.	Neuroglia and myelin I	Poster	mAM				
272.	Neuroglia and myelin II	Poster		tuPM			
332.	Neuroglia and myelin III	Poster			wAM		
458.	Neuroglia and myelin IV	Slide				thAM	
626.	Neuroglia and myelin V	Poster					fAM
243.	**New Waves in Cell Calcium**	**SYMP**		**tuPM**			
529.	**Regulation of Neuronal Peptide Gene Expression: Lessons from the Neurohypophyseal System**	**SYMP**				**thPM**	
179.	Staining, tracing and imaging techniques I	Slide		tuAM			
408.	Staining, tracing and imaging techniques II	Poster			wPM		
475.	Staining, tracing and imaging techniques III	Poster				thAM	
THEME C: EXCITABLE MEMBRANES AND SYNAPTIC TRANSMISSION							
535.	Calcium channel modulation	Slide				thPM	
479.	Calcium channel molecular biology	Poster				thAM	
10.	Calcium channel toxins I	Slide	mAM				
409.	Calcium channel toxins II	Poster			wPM		
188.	Calcium channels: pharmacology and effects of transmitters	Poster		tuAM			
187.	Calcium channels: physiology I	Poster		tuAM			
410.	Calcium channels: physiology II	Poster			wPM		
40.	Calcium-activated potassium channels	Poster	mAM				
275.	Chloride and other channels	Poster		tuPM			
253.	Ion channel modulation I	Slide		tuPM			
336.	Ion channel modulation II	Poster			wAM		
629.	Ion channel modulation III	Poster					fAM
570.	Ion channels: cell function	Poster				thPM	
115.	Ligand-gated ion channels	Poster	mPM				

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
176.	Long-term potentiation I	Slide		tuAM			
274.	Long-term potentiation II	Poster		tuPM			
323.	Long-term potentiation III	Slide			wAM		
567.	Long-term potentiation IV	Poster				thPM	
628.	Long-term potentiation V	Poster					fAM
565.	Postsynaptic mechanisms I	Poster				thPM	
566.	Postsynaptic mechanisms II	Poster				thPM	
460.	Potassium channel expression and localization	Slide				thAM	
388.	Potassium channel permeation and gating	Slide			wPM		
335.	Potassium channels: pharmacology and effects of transmitters	Poster			wAM		
41.	Potassium channels: physiology and molecular biology	Poster	mAM				
114.	Presynaptic mechanisms I	Poster	mPM				
248.	Presynaptic mechanisms II	Slide		tuPM			
273.	Presynaptic mechanisms III	Poster		tuPM			
318.	Presynaptic mechanisms IV	Slide			wAM		
334.	Presynaptic mechanisms V	Poster			wAM		
477.	Presynaptic mechanisms VI	Poster				thAM	
478.	Sodium channels	Poster				thAM	
568.	Synaptic pharmacology I	Poster				thPM	
569.	Synaptic pharmacology II	Poster				thPM	
563.	Synaptic structure and function I	Poster				thPM	
564.	Synaptic structure and function II	Poster				thPM	
3.	**The Computational Neuron**	**SYMP**	**mAM**				
	THEME D: NEUROTRANSMITTERS, MODULATORS AND RECEPTORS						
411.	Acetylcholine: CNS I	Poster			wPM		
480.	Acetylcholine: CNS II	Poster				thAM	
630.	Acetylcholine: choline acetyltransferase and cholinesterase	Poster					fAM
117.	Acetylcholine: muscarinic receptors I	Poster	mPM				
481.	Acetylcholine: muscarinic receptors II	Poster				thAM	
189.	Acetylcholine: muscle nicotinic receptors	Poster		tuAM			
42.	Acetylcholine: neuronal nicotinic receptors I	Poster	mAM				
337.	Acetylcholine: neuronal nicotinic receptors II	Poster			wAM		
631.	Acetylcholine: neuronal nicotinic receptors III	Poster					fAM
259.	Acetylcholine: receptors	Slide		tuPM			
116.	Acetylcholine: release	Poster	mPM				
342.	Behavioral pharmacology: benzodiazepines, et al.	Poster			wAM		
641.	Behavioral pharmacology: dopamine, serotonin, NE	Poster					fAM
51.	Behavioral pharmacology: ethanol, GABA, et al.	Poster	mAM				
196.	Catecholamine receptors: adrenergic I	Poster		tuAM			
255.	Catecholamine receptors: adrenergic II	Slide		tuPM			
9.	Catecholamine receptors: dopamine I	Slide	mAM				
281.	Catecholamine receptors: dopamine II	Poster		tuPM			
17.	Catecholamines	Slide	mAM				
282.	Catecholamines: dopamine I	Poster		tuPM			
634.	Catecholamines: dopamine II	Poster					fAM
125.	Catecholamines: dopamine—electrophysiology	Poster	mPM				
577.	Catecholamines: norepinephrine	Poster				thPM	
124.	Catecholamines: receptors I	Poster	mPM				
418.	Catecholamines: receptors II	Poster			wPM		
491.	Catecholamines: receptors III	Poster				thAM	
197.	Catecholamines: release	Poster		tuAM			
578.	Catecholamines: tyrosine hydroxylase	Poster				thPM	
191.	Excitatory amino acids: anatomy and physiology I	Poster		tuAM			

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
338.	Excitatory amino acids: anatomy and physiology II	Poster			wAM		
483.	Excitatory amino acids: anatomy and physiology III	Poster				thAM	
43.	Excitatory amino acids: excitotoxicity I	Poster	mAM				
190.	Excitatory amino acids: excitotoxicity II	Poster		tuAM			
276.	Excitatory amino acids: excitotoxicity III	Poster		tuPM			
321.	Excitatory amino acids: excitotoxicity IV	Slide			wAM		
482.	Excitatory amino acids: excitotoxicity V	Poster				thAM	
571.	Excitatory amino acids: excitotoxicity VI	Poster				thPM	
44.	Excitatory amino acids: pharmacology I	Poster	mAM				
118.	Excitatory amino acids: pharmacology II	Poster	mPM				
192.	Excitatory amino acids: pharmacology III	Poster		tuAM			
277.	Excitatory amino acids: pharmacology IV	Poster		tuPM			
484.	Excitatory amino acids: pharmacology V	Poster				thAM	
613.	Excitatory amino acids: pharmacology VI	Slide					fAM
45.	Excitatory amino acids: receptors I	Poster	mAM				
119.	Excitatory amino acids: receptors II	Poster	mPM				
172.	Excitatory amino acids: receptors III	Slide		tuAM			
278.	Excitatory amino acids: receptors IV	Poster		tuPM			
412.	Excitatory amino acids: receptors V	Poster			wPM		
485.	Excitatory amino acids: receptors VI	Poster				thAM	
572.	Excitatory amino acids: receptors VII	Poster				thPM	
632.	Excitatory amino acids: receptors VIII	Poster					fAM
175.	GABA receptors: function I	Slide		tuAM			
279.	GABA receptors: function II	Poster		tuPM			
413.	GABA receptors: function III	Poster			wPM		
486.	GABA receptors: function IV	Poster				thAM	
487.	GABA receptors: function V	Poster				thAM	
120.	GABA receptors: structure	Poster	mPM				
8.	GABA receptors: structure and function	Slide	mAM				
605.	**$GABA_B$ Receptors and Their Role in Neurotransmission, Neuromodulation and Neuropathology**	**SYMP**					**fAM**
199.	Histamine and other biogenic amines	Poster		tuAM			
47.	Interaction between neurotransmitters I	Poster	mAM				
126.	Interactions between neurotransmitters II	Poster	mPM				
385.	Interactions between neurotransmitters III	Slide			wPM		
640.	Interactions between neurotransmitters IV	Poster					fAM
453.	**Molecular Analyses of Neuronal Physiology and Potential for Gene Therapy Using Herpes Simplex Virus Vectors**	**SYMP**				**thAM**	
100.	Molecular biology of serotonin receptors	Slide	mPM				
340.	Ontogeny of serotonin receptors	Poster			wAM		
633.	Opiate receptor ligands	Poster					fAM
575.	Opiate receptors: interactions with other systems	Poster				thPM	
16.	Opioid and sigma receptors	Slide	mAM				
490.	Opioid receptors: coupling and biochemistry	Poster				thAM	
417.	Opioids: anatomy and physiology I	Poster			wPM		
576.	Opioids: anatomy and physiology II	Poster				thPM	
280.	Opioids: behavior	Poster		tuPM			
339.	Peptides: anatomical localization—human and primate	Poster			wAM		
121.	Peptides: anatomical localization—non-primates	Poster	mPM				
122.	Peptides: biosynthesis and metabolism I	Poster	mPM				
414.	Peptides: biosynthesis and metabolism II	Poster			wPM		
574.	Peptides: biosynthesis and metabolism III	Poster				thPM	
91.	Peptides: biosynthesis, metabolism, biochemistry I	Slide	mPM				
324.	Peptides: physiological and behavioral effects	Slide			wAM		
123.	Peptides: physiological effects I	Poster	mPM				

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
415.	Peptides: physiological effects II	Poster			wPM		
416.	Peptides: physiological effects III	Poster			wPM		
489.	Peptides: physiological effects IV	Poster				thAM	
174.	Peptides: receptors I	Slide		tuAM			
193.	Peptides: receptors II	Poster		tuAM			
194.	Peptides: receptors III	Poster		tuAM			
488.	Peptides: receptors IV	Poster				thAM	
573.	Peptides: receptors V	Poster				thPM	
609.	Peptides: receptors VI	Slide					fAM
86.	**Protein Phosphates and the Regulation of Neuronal Excitability**	**SYMP**	**mPM**				
420.	Purines: ATP and guanosine	Poster			wPM		
419.	Purines: adenosine	Poster			wPM		
162.	**Recent Advances in Neuropeptide Biosynthesis: Molecular and Cellular Biology of Neuropeptide-processing Enzymes**	**SYMP**		**tuAM**			
173.	Receptor modulation, up and down regulation I	Slide		tuAM			
343.	Receptor modulation, up and down regulation II	Poster			wAM		
391.	Receptor modulation, up and down regulation III	Slide			wPM		
642.	Receptor modulation, up and down regulation IV	Poster					fAM
617.	Regional localization of receptors and transmitters	Slide					fAM
48.	Regional localization of receptors and transmitters: biogenic amines, misc.	Poster	mAM				
49.	Regional localization of receptors and transmitters: peptides and GABA	Poster	mAM				
635.	Regulation of serotonin receptors	Poster					fAM
50.	Second messengers I	Poster	mAM				
127.	Second messengers II	Poster	mPM				
203.	Second messengers III	Poster		tuAM			
260.	Second messengers IV	Slide		tuPM			
341.	Second messengers V	Poster			wAM		
422.	Second messengers VI	Poster			wPM		
317.	Serotonin neuropharmacology	Slide			wAM		
46.	Serotonin receptors: 5HT1A subtypes	Poster	mAM				
637.	Serotonin receptors: action on neurotransmission	Poster					fAM
579.	Serotonin receptors: behavioral actions	Poster				thPM	
198.	Serotonin receptors: molecular biology	Poster		tuAM			
636.	Serotonin receptors: pharmacologic characterization	Poster					fAM
638.	Serotonin: pharmacology I	Poster					fAM
639.	Serotonin: pharmacology II	Poster					fAM
580.	Serotonin: receptor modulation	Poster				thPM	
195.	Sigma receptors and ligands	Poster		tuAM			
200.	Transmitters in invertebrates I	Poster		tuAM			
201.	Transmitters in invertebrates II	Poster		tuAM			
466.	Transmitters in invertebrates III	Slide				thAM	
202.	Uptake, storage, secretion and metabolism I	Poster		tuAM			
251.	Uptake, storage, secretion and metabolism II	Slide		tuPM			
421.	Uptake, storage, secretion and metabolism III	Poster			wPM		
581.	Uptake, storage, secretion and metabolism IV	Poster				thPM	
	THEME E: ENDOCRINE AND AUTONOMIC REGULATION						
320.	Cardiovascular regulation I	Slide			wAM		
534.	Cardiovascular regulation II	Slide				thPM	
495.	Cardiovascular regulation: cardiac control and sympathetic rhythms	Poster				thAM	
492.	Cardiovascular regulation: forebrain mechanisms	Poster				thAM	

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
496.	Cardiovascular regulation: hypertension, reflexes and peripheral autonomics	Poster				thAM	
426.	Cardiovascular regulation: lower brainstem I	Poster			wPM		
497.	Cardiovascular regulation: lower brainstem II	Poster				thAM	
494.	Cardiovascular regulation: spinal cord and medulla	Poster				thAM	
493.	Cardiovascular regulation: upper brainstem mechanisms	Poster				thAM	
319.	Hypothalamic-pituitary-adrenal regulation	Slide			wAM		
283.	Hypothalamic-pituitary-adrenal regulation: CRF	Poster		tuPM			
284.	Hypothalamic-pituitary-adrenal regulation: POMC, ACTH, other factors	Poster		tuPM			
204.	Hypothalamic-pituitary-adrenal regulation: glucocorticoid and mineralocorticoid receptors	Poster		tuAM			
643.	Hypothalamic-pituitary-adrenal regulation: stress	Poster					fAM
423.	Hypothalamic-pituitary-adrenal regulation: stress—developmental aspects	Poster			wPM		
90.	Hypothalamic-pituitary-gonadal regulation	Slide	mPM				
55.	Hypothalamic-pituitary-gonadal regulation: LHRH and LH I	Poster	mAM				
285.	Hypothalamic-pituitary-gonadal regulation: LHRH and LH II	Poster		tuPM			
52.	Hypothalamic-pituitary-gonadal regulation: neuropeptides	Poster	mAM				
344.	Hypothalamic-pituitary-gonadal regulation: other	Poster			wAM		
53.	Hypothalamic-pituitary-gonadal regulation: steroids	Poster	mAM				
288.	Neural control of immune functions	Poster		tuPM			
326.	Neural-immune interactions	Slide			wAM		
287.	Neural-immune interactions: behavior and stress	Poster		tuPM			
424.	Neural-immune interactions: innervation and other	Poster			wPM		
425.	Neural-immune interactions: interleukin-1	Poster			wPM		
206.	Neural-immune interactions: other interleukins and cytokines	Poster		tuAM			
392.	Neuroendocrine regulation I	Slide			wPM		
456.	Neuroendocrine regulation II	Slide				thAM	
56.	Neuroendocrine regulation: hypothalamus/pituitary	Poster	mAM				
57.	Neuroendocrine regulation: limbic system	Poster	mAM				
286.	Neuroendocrine regulation: osmotic regulation I	Poster		tuPM			
346.	Neuroendocrine regulation: osmotic regulation II	Poster			wAM		
345.	Neuroendocrine regulation: other	Poster			wAM		
54.	Neuroendocrine regulation: prolactin	Poster	mAM				
538.	Regulation of autonomic function	Slide				thPM	
207.	Regulation of autonomic function: gastrointestinal and visceral afferents	Poster		tuAM			
59.	Regulation of autonomic function: genitourinary	Poster	mAM				
347.	Regulation of autonomic function: other	Poster			wAM		
58.	Respiratory regulation: central networks/patterns	Poster	mAM				
348.	Respiratory regulation: chemoreception	Poster			wAM		
208.	Respiratory regulation: transmitters/receptors	Poster		tuAM			
209.	Temperature regulation and fever	Poster		tuAM			
205.	Water and osmotic regulation	Poster		tuAM			
THEME F: SENSORY SYSTEMS							
435.	Auditory system: anatomy I	Poster			wPM		
500.	Auditory system: anatomy II	Poster				thAM	
67.	Auditory system: central physiology I	Poster	mAM				
166.	Auditory system: central physiology II	Slide		tuAM			
353.	Auditory system: central physiology III	Poster			wAM		
499.	Auditory system: cochlea	Poster				thAM	
434.	Auditory system: neurochemistry	Poster			wPM		
588.	Auditory, vestibular and lateral-line hair cells	Poster				thPM	

Session Number	Session Title	Type	Day and Time Mon.	Tue.	Wed.	Thu.	Fri.
502.	Chemical senses: central pathways—olfaction	Poster				thAM	
436.	Chemical senses: pathways—gustation	Poster			wPM		
258.	Chemical senses: peripheral mechanisms	Slide		tuPM			
501.	Chemical senses: peripheral mechanisms—olfaction, carotid body	Poster				thAM	
354.	Chemical senses: peripheral mechanisms—taste	Poster			wAM		
135.	Invertebrate sensory systems	Poster	mPM				
528.	**Molecular Biology of Olfaction**	**SYMP**				**thPM**	
430.	Pain modulation: behavior	Poster			wPM		
289.	Pain modulation: brainstem and thalamus	Poster		tuPM			
212.	Pain modulation: cognitive, autonomic and endocrine	Poster		tuAM			
290.	Pain modulation: descending	Poster		tuPM			
130.	Pain modulation: dorsal horn	Poster	mPM				
62.	Pain modulation: hyperalgesia	Poster	mAM				
292.	Pain modulation: peripheral	Poster		tuPM			
129.	Pain modulation: peripheral neuropathy	Poster	mPM				
291.	Pain modulation: pharmacology and endocrinology	Poster		tuPM			
428.	Pain modulation: spinal I	Poster			wPM		
429.	Pain modulation: spinal II	Poster			wPM		
351.	Pain modulation: supraspinal	Poster			wAM		
211.	Pain pathways: dorsal horn	Poster		tuAM			
128.	Pain pathways: hyperalgesia	Poster	mPM				
350.	Pain pathways: supraspinal	Poster			wAM		
94.	Pain: pharmacology	Slide	mPM				
167.	Pain: physiology and behavior	Slide		tuAM			
63.	Retina and photoreceptors I	Poster	mAM				
171.	Retina and photoreceptors II	Slide		tuAM			
431.	Retina and photoreceptors: amacrine, ganglion and glial cells	Poster			wPM		
352.	Retina and photoreceptors: photoreceptors, horizontal and bipolar cells	Poster			wAM		
60.	Somatic and visceral afferents I	Poster	mAM				
210.	Somatic and visceral afferents II	Poster		tuAM			
349.	Somatic and visceral afferents: touch	Poster			wAM		
582.	Somatosensory cortex and thalamocortical relationships: anatomy	Poster				thPM	
644.	Somatosensory cortex and thalamocortical relationships: development and plasticity	Poster					fAM
583.	Somatosensory cortex and thalamocortical relationships: physiology	Poster				thPM	
645.	Somatosensory cortex and thalamocortical relationships: psychophysics and networks	Poster					fAM
584.	Somatosensory cortex and thalamocortical relationships: thalamus	Poster				thPM	
316.	Somatosensory system	Slide			wAM		
61.	Spinal cord	Poster	mAM				
427.	Subcortical somatosensory pathways: lemniscal and spinothalamic	Poster			wPM		
498.	Subcortical somatosensory pathways: trigeminal	Poster				thAM	
101.	Subcortical visual pathways	Slide	mPM				
64.	Subcortical visual pathways: LGN	Poster	mAM				
432.	Subcortical visual pathways: cortico-tectal, Accessory Optic System, centrifugals	Poster			wPM		
65.	Subcortical visual pathways: retina and colliculus	Poster	mAM				
454.	**Thalamic Mechanisms of Nociception**	**SYMP**				**thAM**	
586.	Visual behavior: clinical studies	Poster				thPM	
587.	Visual behavior: psychophysics and eye movements	Poster				thPM	
169.	Visual cortex: anatomical studies	Slide		tuAM			
132.	Visual cortex: anatomy of extrastriate cortex	Poster	mPM				
134.	Visual cortex: anatomy of striate cortex	Poster	mPM				
537.	Visual cortex: behavior and behavioral correlates	Slide				thPM	
585.	Visual cortex: brain imaging techniques	Poster				thPM	

Session Number	Session Title	Type	Day and Time: Mon.	Tue.	Wed.	Thu.	Fri.
11.	Visual cortex: functional circuits and oscillations I	Slide	mAM				
131.	Visual cortex: functional circuits and oscillations II	Poster	mPM				
99.	Visual cortex: functional organization of striate cortex	Slide	mPM				
433.	Visual cortex: motion processing I	Poster			wPM		
464.	Visual cortex: motion processing II	Slide				thAM	
256.	Visual cortex: neuronal response properties	Slide		tuPM			
66.	Visual cortex: physiology of extrastriate cortex	Poster	mAM				
133.	Visual cortex: physiology of striate cortex	Poster	mPM				
313.	Visual cortex: theoretical studies	Slide			wAM		
	THEME G: MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION						
136.	Basal ganglia and thalamus I	Poster	mPM				
137.	Basal ganglia and thalamus II	Poster	mPM				
293.	Basal ganglia and thalamus III	Poster		tuPM			
294.	Basal ganglia and thalamus IV	Poster		tuPM

ADHESION, ANTI-ADHESION AND MIGRATION OF OLFACTORY NEURONS AND NEURONAL PRECURSORS ARE REGULATED BY DISTINCT MOLECULAR DOMAINS OF LAMININ. A.L. Calof*[1], P.D. Yurchenco[2], J.J. O'Rear[2], and A.D. Lander[3]. [1]U. of Iowa, Iowa City, IA; [2]R.W. Johnson Med. Sch., Piscataway, NJ; [3]Mass. Inst. of Tech., Cambridge, MA.

Neuronal precursors and immature neurons of the mouse olfactory epithelium (OE) are motile *in vivo*, and can be stimulated to migrate and are guided *in vitro* by the ECM protein laminin (LN) and its homologue merosin (MN). LN and MN are also anti-adhesive, i.e. they cause OE neuronal cells to adhere weakly to substrata that would otherwise be strongly adhesive (Calof and Lander (1991) J. Cell Biol. 115:779). Investigations into the domains of laminin responsible for its effects on OE cells have revealed the following: The **anti-adhesive** activity of LN is highly heat stable and maps to the E1' fragment of the molecule. Although integrin $\alpha1\beta1$ is a cell-surface receptor known to interact with this region of LN, function-blocking antibodies directed against this integrin do not inhibit anti-adhesion. The **migration-promoting** activity of LN is distinct from its anti-adhesive activity, and is not the result of adhesion-altering effects of LN. Migration-promoting activity is heat-labile, maps to the E8 fragment of LN, and can be completely blocked by a monoclonal antibody directed against integrin subunit $\alpha6$. Migration promoted by MN, however, is only partially blocked by this antibody. Surprisingly, although LN is not detectably **adhesive** for OE neuronal cells, some of its domains are. E8 is weakly adhesive, and a recombinant G-domain (rG) is strongly adhesive. Adhesion to rG was not dependent on $\alpha6$-containing integrins, nor could it be blocked by a peptide contained in rG that is thought to represent the binding site of integrin $\alpha3\beta1$. Adhesion to rG was blocked, however, by low concentrations of heparin (4 μg/ml) and by antibodies directed against LN fragment E3 (which is contained in rG). These data suggest that neuronal adhesion, anti-adhesion and migration can be independently regulated by distinct domains of LN and distinct receptors.

390.4

AVIAN NEURAL CREST CELLS RECOGNIZE LAMININ THROUGH ITS E8 AND T8 DOMAINS USING $\alpha_1\beta_1$ INTEGRINS Thomas Lallier*, Roberto Perris, Reiner Deutzmann, Mats Paulsson and Marianne Bronner-Fraser
Developmental Biology Center, University of California, Irvine, Ca. 92717

We have localized the sites of neural crest cell interaction with laminin by examining their ability to migrate on and attach to proteolitic fragments of the molecule. Neural crest cells preferentially migrate on and bind to the E8 domain on the long arm of laminin, but not the E1', E3, E4, or P1 fragments. When the E8 domain of laminin was further digested with trypsyn to yeild T8, E8R, T8R, T8', T8'A, G1-3 or 25kD fragments, neural crest cells migrated on and attached to the T8 - T8' fragments. Interestingly, combinations of the T8'A and 25kD fragments supported neural crest cell interactions, though neither was active alone. This suggests that simultaneous addition of the two fragments reconstitutes the active site within the T8' domain. The presence or absence of Ca^{2+} in the plating buffer appears to alter the mechanisms of neural crest cell attachment to laminin and its fragments. When substrata were plated in the presence of Ca^{2+}, these cells utilize the $\alpha_1\beta_1$ integrin heterodimer for "early" attachment to laminin and the E8 - T8' fragments. In contrast, when substrata were coated in the absence of Ca^{2+}, these cells utilize a β_1 integrins for "early" attachment only to laminin and the E8 and T8 fragments. With prolonged contact time, however, neural crest cells appear to modify their substrata such that "later" attachment was mediated by $\alpha_1\beta_1$ integrins to laminin and the E8 - T8' fragments regardless of the coating conditions. Our results suggest that neural crest cells preferentially migrate and attach to the T8' region within the E8 domain of laminin and that they modify laminin substrata as a result of prolonged cell-matrix interactions.

390.5

NEURONAL MIGRATION AND LAMININ - STUDIES ON THE ROLE OF LAMININ,THE NEURITE OUTGROWTH DOMAIN OF THE B2 CHAIN, AND CELLULAR MOVEMENTS AS REVEALED BY INFRARED VIDEO MICROSCOPY. P.Liesi*,E.Trenkner[2],H-U. Dodt[3],G. Hager[3], and W. Zieglgänsberger[3]. Institutes of Biotechnology*(Helsinki) and Basic Res.(New York)[2],and Max-Planck-Institut for Psychiatry[3](Munich).

Low magnification video microscopy on cerebellar neurons growing on a laminin substrate showed that neurons migrated by first sending out a process that contacted other neurites, which was followed by nuclear movement inside a preformed process.This was also verified on living slices of cerebellum by a novel technique of infrared video microscopy. This technique showed that external granule cells were bipolar cells attaching to the basement membrane and extending out another process towards the presumptive granule cell layer.These cells showed a back-and-forth movement that closely resembled that on a laminin substrate. The role of the neurite outgrowth domain of the B2 chain of laminin on granule cell migration was studied in the cable culture system. Neuronal movement in these cultures was totally inhibited by antibodies against this domainof laminin. Immunocytochemistry localized this domain in intimate cell-to-cell contacts between the migrating neurons and other neurons and glia. Studies on weaver granule cells on a laminin substrate revealed that these cells were proteolytically more active than their normal counterparts and deposited large amounts of the neurite outgrowth promoting peptide antigen on their surfaces. These results indicate that neuronal migration on laminin simulates that visualized in living slices of newborn rodent cerebellum in situ. The B2 chain of laminin may be essential for neuronal migration, and as weaver granule cells are proteolytically active, and over express the neurite outgrowth domain of the B2 chain of laminin, the reported neurotoxicity of this domain may provide a mechanism for granule cell death occuring in this mutation.

390.6

MINIMAL DISPERSION OF NEUROEPITHELIAL CELLS AND THEIR PROGENY DURING GENERATION OF THE CORTICAL PREPLATE

D.D.M. O'Leary* and D.J. Borngasser. MNL, The Salk Institute, La Jolla, CA 92037

Thalamocortical input promotes the differentiation of the developing cortical plate into architecturally and functionally specialized areas. Thalamic axons show remarkable specificity in targeting to appropriate cortical regions and invasion of the cortical plate, indicating the operation of an effective marking system. One way to generate this marking system would be for neuroepithelial cells to impart positional information to their progeny. However, the marking system is probably not found in the cortical plate since clonally related cells become widely dispersed across diverse regions (Walsh & Cepko, Science, '92). A candidate structure to contain the marking system is the subplate, a derivative of the preplate which is comprised of the earliest generated cortical neurons and is distinct from the later generated cortical plate. To evaluate this possibility, we investigated the dispersion of neuroepithelial cells and their progeny as the preplate develops. In rat, preplate neurons are generated from E12 to E14. Dorsal telencephalon from E12 or E13 rat embryos was cultured with the pial surface apposed to a Millicell membrane. A small group of neuroepithelial cells was labeled with DiI. A SIT camera was used to take fluorescence images of selected explants at 15 to 30 minute intervals over 48 hrs. Other explants were imaged at 1, 12, 24, 36 & 48 hrs after labeling. The great majority of labeled cells remain tightly clustered, but a small fraction move short distances from the main cluster. These observations were confirmed in the same explants sectioned transversely. Use of the neuron-specific marker TuJ1 (Lee et al, Cell Motil Cytoskel '90) shows that a preplate does form in the explants; DiI labeled cells are present in both the neuroepithelium and the preplate. Similar results were obtained with the ventricular surface apposed to the membrane, or in floating intact forebrains. These findings show that neuroepithelial cells and their progeny that form the preplate tend to remain clustered, indicating that positional information could be effectively imparted from the neuroepithelium to the preplate.

390.7

INVOLVEMENT OF THE T61 ANTIGEN IN CNS NEURONAL MIGRATION. S. Henke-Fahle* and S. Meyer. Dept. of Ophthalmology, University of Tübingen, and Max-Planck-Institut für Entwicklungsbiologie, W-7400 Tübingen, Germany.

Neuronal migration in various parts of the central nervous system depends on the motility of a leading process along a radial glia fiber. In order to investigate whether a monoclonal antibody that had previously been shown to inhibit outgrowth of retinal neurites by arresting their growth cones *in vitro* (Henke-Fahle and Bonhoeffer, Nature 303, 65, 1983) also interfered with neuronal migration, we performed perturbation experiments in living embryos.

Hybridoma cells producing antibodies against T61 antigen were injected into the mesencephalic ventricle of chick embryos at embryonic day 6 to provide a permanent source of antibody. After further incubation (4-9 days), the distribution of antibodies and the tectal lamination in sagittal brain sections were examined. The antibodies had penetrated the tectal wall completely, whereas the hybridoma cells remained confined to the ventricular cavity. Tectal lamination was disturbed in the following way: 1) The neuroepithelial cell layer appeared thicker and consisted of more cells when compared to controls. 2) The Stratum album centrale (SAC) was dislocated towards the pial surface. 3) The developing Stratum griseum et fibrosum superficiale (SGFS) was drastically reduced in size. These results suggest that young neurons were impaired in their ability to migrate radially towards the future target layers in the presence of T61 antibody.

Western blot analysis showed two bands of apparent molecular weight 380 and 170 kD. Solubilization properties of the antigen indicated that T61 is not a transmembrane protein.

390.8

GENERATION OF WIDESPREAD CEREBRAL CORTICAL CLONES C. Walsh & C. Cepko, Dept of Neurology, Mass. Gen. Hosp. and Dept. of Genetics, Harvard Med. Sch., Boston, MA 02115

Cell lineage in the cerebral cortex can be traced using a library of retroviruses that carry distinct DNA inserts as genetic tags. When the tags are analyzed using the polymerase chain reaction (PCR), they mark clones of cells independent of migration patterns of sibling cells. Cortical clones marked in this way often show widespread dispersion, in some cases covering much of the neocortex (Walsh and Cepko, 1992, Science 255: 434). Analyzing rats that received viral injections at E14-E15 6 days (E20-21) or 10 days (P3) later can show how this widespread dispersion occurs. Inoculations were made such that ≤5 clones per hemisphere were labeled. The brains were sectioned, reacted for ß-galactosidase histochemistry, and labelled cells were plotted using a three-dimensional computerized reconstruction program, CARP (Austin and Cepko, 1990, Development 110: 713). Labeled cells from tissue sections were processed using PCR to analyze the genetic tags and determine clonal patterns.

Widespread cortical clones were very common after short survival times. At E21, 32% of all cortical clones showed wide dispersion, whereas at P3 57% of cortical clones were widely dispersed, accounting for the overwhelming majority of labelled cortical neurons. At E21, there was extensive clonal dispersion in the rostro-caudal or caudo-rostral direction, and clones included cells in the cortex and the proliferative zones. This suggests movement of proliferating cells essentially parallel to the ventricle. At P3, dispersion in the medial-lateral plane was greater than at embryronic stages, which may reflect dispersion of postmitotic neurons in the intermediate zone (O'Rourke et al, 1991, Soc. Neurosci. Abst. 17:533). Thus, widespread clonal dispersion reflects several phenomena occurring in sequence. Supported by the Howard Hughes Medical Institute and the NIH.

LATERAL DISPERSION OF PREMIGRATORY, NEURAL PROGENITORS WITHIN THE VENTRICULAR ZONE OF CEREBRAL CORTEX G. Fishell*, C.A. Mason and M.E. Hatten. Dept. of Pathology in the Center for Neurobiology, College of Physicians and Surgeons, Columbia University, New York, N.Y., 10032.

In cortical regions of developing brain, neural precursors are generated in compact ventricular zones along the inner surface of the neural tube, after which postmitotic progeny migrate along the glial fiber system to establish the cortical laminae. Although recent evidence suggests significant dispersion of clonally related neural cells during development, the relative contribution of movements within the germinal zone and tangential movement across the radial glial fiber system have not been determined. To visualize the dispersion of neural progenitor cells within the ventricular zone of the mouse cerebral cortex, the lateral wall of the telencephalic vesicle was removed on embryonic day 15, and a random population of cells on the ventricular surface was labeled with a dilute solution of the lipophilic dye DiI. Immunostaining with the neural antigen nestin and with BrdU demonstrated that labeled cells were within the VZ. By correlated video-enhanced, fluorescence and phase-contrast microscopy short bursts of motility at rates between 10-100μm/h rapidly dispersed labeled cells across the ventricular zone. Labeled, dividing cells gave rise to daughter cells which separated and moved independently across wide areas of the cortical VZ. To determine whether cell dispersion was confined to the cortical VZ, we examined the behavior of labeled cells approaching the boundary with the lateral ganglionic eminence. Labeled cells did not cross from one proliferative zone to the other. Instead they contacted the boundary with filopodial extensions and moved rostro-caudally along the interface. These experiments suggest that boundaries establish and maintain a regional pattern of neurogenesis in developing brain. Within the germinal zone of the cerebral cortex, neural progenitors disperse widely prior to radial migration along the glial fiber system.

390.10

RESCUE OF *WEAVER* GRANULE NEURON DIFFERENTIATION BY TRANSPLANTATION OF THEIR PROGENITORS INTO WILD-TYPE DEVELOPING CEREBELLAR CORTEX. W.-Q. Gao* and M. E. Hatten. Dept. of Pathology, Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University, New York, NY 10032

The migration of postmitotic neurons away from compact, germinal zone in developing brain is a critical step in CNS neuronal differentiation. To examine the autonomy of expression of molecular signals for cerebellar granule cell migration *in vivo*, neuronal progenitors purified from the neurological mutant mouse *weaver*, an animal with phenotypic defects in migration, were tranplanted into the external germinal layer (EGL) of wild-type developing cerebellar cortex. In wild-type cerebellar cortex, dye-labeled, *weaver* EGL progenitors progressed through all of the classical stages of granule neuron differentiation, including the extension of parallel fibers, migration through the molecular and Purkinje cell layers, final posioning in the internal granule cell layer, and extension of dendrites. These observations provide evidence that *weaver* gene acts non-autonomously *in vivo*, and suggest that local interactions in the cerebellar EGL induces initial steps in neuronal differentiation required for granule cell migration.

390.11

GRANULE NEURON MIGRATION IN DEVELOPING CEREBELLAR CORTEX: A CORRELATED *IN VITRO* AND *IN VIVO* ANALYSIS. R.J. Rivas* W.-Q. Gao, and M.E. Hatten. Dept. of Pathology and Center for Neurobiology and Behavior, Columbia Univ., New York, NY 10032.

In order to compare the mechanism of neuronal migration with axon extension in vitro, granule neurons were purified from early postnatal cerebellar cortex (P4-P6) and labeled with the fluorescent lipophilic dye, PKH-26. Labeled neurons were co-cultured with unlabeled astroglial cells and neuronal migration was examined by a combination of time-lapse video and fluorescence microscopy using a light-intensified CCD camera. Examination of labeled neurons revealed frequent extension and retraction of the leading process during migration, as well as lamellopodial and filopodial extension along the entire length of the leading process. The dynamics of leading process motility differed from that of the growing granule neuron axon, where motility was confined primarily to the growth cone, which moved forward steadily without withdrawing. In order to compare migration and axon extension *in situ*, PKH-labeled neurons were transplanted back into the external granule layer (EGL) of P5 mice. The animals were then allowed to develop normally. After 1-10 days, coronal sections of cerebellar cortex were prepared and the disposition of labeled neurons was examined by confocal microscopy of fixed preparations or by time-lapse fluorescence microscopy. By 1-2 d after implantation, labeled neurons moved into the deeper aspect of the EGL and extended long parallel fiber axons (100-300 um in length) prior to migration along the Bergmann glial fibers. Migratory neurons with a leading process were observed after 2-4 d. 4-6 d after implantation, labeled neurons detached from the Bergmann glial fibers and entered the internal granule layer. These results suggest that cell soma migration and leading process motility differ from parallel fiber growth in both the timing of extension and in motile behavior.

RECEPTOR MODULATION, UP AND DOWN REGULATION III

391.1

THE EFFECT OF PHARMACOLOGIC INCREASE IN ENDOGENOUS DOPAMINE ON 11C-RACLOPRIDE BINDING MEASURED WITH POSITRON EMISSION TOMOGRAPHY (PET) IN THE BABOON BRAIN

G.S. Smith*, S.L. Dewey, J. Logan, J.D. Brodie, E. Meller, J.S. Fowler, N.D. Volkow, P. King, N. Pappas, R.R. MacGregor, T. Martin, D. Alexoff, C. Shea, A.P. Wolf Dept. of Psychiatry, New York University School of Medicine, New York, NY, 10016; Depts. of Chemistry and Medicine, Brookhaven National Laboratory, Upton, NY, 11973

Recent PET studies have demonstrated the sensitivity of ^{18}F-N-methylspiroperidol (a high affinity D2 dopamine ligand) binding to pharmacologic alterations in endogenous dopamine (Dewey et al., 1990, 1991, Logan et al., 1991). The present study was undertaken to further examine drug induced changes in dopamine using ^{11}C-raclopride, a lower affinity D2 ligand, and two drugs which increase dopamine by different mechanisms. PET studies were conducted in anesthetized, adult female baboons (Papio anubis) using the CTI 931 tomograph. Two ^{11}C-raclopride scans were performed, two hours apart, prior to and following drug intervention with either d-amphetamine, which releases cytosolic dopamine (1.0 mg/kg, IV, 5 minutes pre-injection) or GBR 12909, the selective dopamine reuptake inhibitor (1.5 or 3.0 mg/kg, IV, 20 minutes pre-injection). The data were analyzed with the distribution volume method (Logan et al., 1990). After both interventions, ^{11}C-raclopride binding was decreased, bilaterally, in the striatum (specific binding), but not in the cerebellum (non-specific binding). These decreases exceeded the test-retest variability of the ligand, determined in the same animals. The rate of metabolism of the radiotracer was unaltered. Therefore, ^{11}C-raclopride binding is sensitive to alterations in endogenous dopamine. This finding provides further support for the utility of PET in assessing the functional responsiveness of the dopamine system, in vivo. Supported by DOE/OHER, NIH: NS15638, NS15380.

SIMILARITIES AND DIFFERENCES IN DOPAMINE RECEPTOR SUBTYPE REGULATION: MOLECULAR MECHANISMS. Ian Creese* and S.-X. Xu, Center for Molecular & Behavioral Neuroscience, Rutgers-Newark, NJ 07102.

Steady state levels of cell surface receptors are determined by many distinct processes, each of which may be subject to different regulatory mechanisms. Both striatal D_{1A} and D_{2A} receptors show a similar developmental pattern where receptor number increases by 6-14 fold over the first 30 days postnatal. However, mRNA levels for both receptors increase by only 2 fold over this period. Whereas denervation, by a 6-OHDA lesion of the nigro-striatal pathway, increased D_{2A} receptor mRNA levels by 53% and receptor level by 38%, D_{1A} receptors and their mRNA were unchanged. In contrast, a 3 week administration of the D_1 receptor antagonist SCH23390 (0.5mg/kg/day s.c.) increased both D_{1A} receptor density and mRNA levels. However, treatment with the D_2 receptor antagonist haloperidol (0.5 mg/kg/day, s.c) had no effect on striatal D_{2A} mRNA levels, in spite of significant increases in receptor B_{max}. This was not the result of the intermittent receptor blockade following drug injection, as chronic infusion of haloperidol via osmotic mini-pump also did not increase D_{2A} mRNA, in spite of a 59% increase in receptor B_{max}. Interestingly, chronic dopamine depletion with reserpine did not affect mRNA levels for D_{1A} or D_{2A} receptors, with only D_{2A} receptors being significantly upregulated. These findings indicate that the various molecular mechanisms involved in receptor regulation (gene transcription, receptor degradation etc.) are differentially involved in the regulation of each dopamine receptor subtype.

INCREASED 5-HT2 AND NK-1 RECEPTOR BINDING ASSOCIATED WITH SEROTONIN/SUBSTANCE P HYPERINNERVATION IN RAT INFERIOR OLIVE. M. Paré, L. Descarries* and R. Quirion. Centre de recherche en sciences neurologiques (Département de physiologie), Université de Montréal, and Douglas Hospital Research Center and Department of Psychiatry, McGill University, Montréal and Verdun, Québec, CANADA.

Serotonin/5-HT2 and substance P (SP)/NK-1 receptors were measured by ligand binding autoradiography with [3H]ketanserin and [125I]BH-SP, in the inferior olive (IO) of adult rats previously subjected to cerebroventricular administration of 5,6-dihydroxytryptamine. This experimental treatment was previously shown to be followed by marked 5-HT hyperinnervation in most subdivisions of IO (e.g. thrice the normal number of 5-HT axon varicosities in the lateral dorsal accessory olive, lat DAO). It is also known to induce a parallel augmentation of the number of SP-immunoreactive varicosities in several parts of IO, which suggests a co-localization of both transmitters in the same hyperinnervating terminals. In normal IO, the density of 5-HT2 sites was relatively low and rather homogeneous. NK-1 binding appeared denser and more heterogeneously distributed. After 5-HT/SP hyperinnervation, considerable increases in the density of both classes of binding sites were observed. Specific [3H]ketanserin binding was now stronger in most IO subnuclei, including some in which it had not been detected in the normal. [125I]BH-SP binding showed even greater elevations or became detectable in a few subnuclei, remained unchanged in others, and was slightly decreased in the lat DAO. The normal and altered distributions of both ligands did not match the respective patterns of 5-HT and/or SP innervation and hyperinnervation. In view of current information on the cellular localization of 5-HT2 and NK-1 receptors in IO, it seemed likely that both increases in the hyperinnervated state were largely the result of an up-regulation, and not the mere reflection of an augmented number as autoreceptors on 5-HT and/or SP terminals. (Supported by MRC grants MT-3544 and MA-8580).

MUSCARINIC ANTAGONISTS INHIBIT THE PROLIFERATION AND EGF RECEPTOR EXPRESSION OF HUMAN OCULAR & NIH/3T3 FIBROBLASTS

Sek Jin Chew*, Jamie G.Lopez, R.Wilson‡, Roger W.Beuerman.
LSU Eye Center, New Orleans, LA 70005. ‡Pathology Dept, Tulane University.

Protein kinase C (PKC) and immediate early gene expression are increased by muscarinic agonists via G_p protein and diacyl glycerol. PKC reduces the binding of EGF and EGF-R synthesis in fibroblasts by phosphorylation of the epidermal growth factor receptor (EGF-R). Additionally, muscarinic antagonists retard scleral growth in avian form-deprivation and human physiological myopia. We hypothesize an inhibitory effect of muscarinic antagonists on the growth of ocular fibroblasts, possibly by modulating their EGF-R expression. Using NIH/3T3, human scleral, and corneal fibroblasts (keratocytes) in culture, we investigated the effect of muscarinic agents on cell proliferation, protooncogene expression, and EGF-R density. When confluent monolayers of fibroblasts were incubated with muscarinic agents (10nM to 10μM), atropine and pirenzepine caused a dose-dependent reduction of proliferation and the number of cells in the G2/M phase of the cell cycle. *c-fos* expression was induced by carbachol, an effect partly blocked by atropine. EGF-R were quantitated by labelling with biotinylated anti-EGF-R antibody and the fluorescence measured following the addition of streptavidin-R-phycoerythrin. Carbachol (1-10μM) caused an early reduction in EGF-R, followed by an increase to 1.5x the resting level, by 18 hours. Oxotremorine showed the opposite effect on EGF-R levels. When human EGF (1ng/ml) was added, downregulation of EGF-R in keratocytes was observed at 2 hours, followed by upregulation to resting levels by 12 hours. With atropine (100μM), EGF caused an identical downregulation, but the EGF-R density remained at 40% of resting levels even after 12 hours. We also demonstrated the inhibition of fibroblast proliferation by atropine *in-vivo*, using rabbit models of corneal wound healing.

391.5

AGE-DEPENDENT REGULATION OF CORTICAL AMINO ACID RECEPTORS. R.A. Lanius* and C. Shaw, Depts. of Neuroscience, Ophthalmology and Physiology, University of British Columbia.

We have used a 'living' rat cortical slice preparation to examine the regulation of $GABA_A$ ([3H]-SR 95531), AMPA ([3H]-CNQX), NMDA ([3H]-CGP 39653) and kainate ([3H]-kainate) receptor populations during postnatal development. Regulation of these receptor populations was acheived using either stimulation with the appropriate agonist or using veratridine and glutamate (V+G) to increase neural electrical activity. In adult cortex, V+G resulted in an up-regulation of $GABA_A$ receptors in contrast to a down-regulation of AMPA, NMDA, and kainate receptors. During postnatal development V+G showed age-dependant effects: in animals younger than 25d, $GABA_A$ receptor number was decreased while AMPA receptor number was increased; NMDA and kainate receptors decreased. After 40d, V+G treatment led to an increase in $GABA_A$ receptor number; at ages greater than 60 d AMPA receptors decreased. NMDA and kainate receptors showed decreases to V+G at all ages. Agonist stimulation led to down-regulation of all four receptor populations. Quisqualate stimulation of AMPA receptors increased down-regulation with increasing postnatal age, an opposite effect to that observed for $GABA_A$ and kainate receptors. The differing effects with age on receptor regulation for either changes in cell electrical activity or agonist stimulation may suggsest a role for such age-dependent receptor regulation in the events leading to neuronal critical period plasticity.

391.6

REVERSAL OF ENZYMATIC CONTROL OF CORTICAL AMINO ACID RECEPTOR REGULATION IN DEVELOPMENT. C. Shaw* and R. A. Lanius. Departments of Ophthalmology, Neuroscience, and Physiology, University of British Columbia, Vancouver, Canada.

We have used a rat neocortical slice preparation to examine the effects of phosphorylating / dephosphorylating reactions by alkaline phosphatase (AP) or protein kinase (PK) on $GABA_A$ and AMPA receptors in different stages of postnatal development. Cortical slices were frozen then thawed before exposure to varying concentrations of AP or PK. In adult rats, the addition of AP led to increases in binding of [3H]-SR 95531 ($GABA_A$) and [3H]-CNQX (AMPA) with a significant 20% increase at $2.5x10^{-7}$mg/mL in both receptor populations. In contrast, PK led to significant 30% decreases for both receptors at $5x10^{-6}$ pM/μg protein/mL. The effects of AP or PK on [3H]-SR 95531 binding were reversed in 12 to 14 day old rats. AP resulted in significant 24% and 28% decreases in [3H]-SR 95531 binding at $2.5x10^{-6}$ and $2.5x10^{-7}$ mg/mL, respectively. Conversely, PK led to significant 29% and 55% increases in [3H]-SR 95531 binding at $5x10^{-6}$ and 5x10-7pM/μg protein/mL, respectively. Similar effects of AP or PK on [3H]-CNQX binding were observed in 19 to 21 day old rats. AP led to a significant 37% decrease in [3H]-CNQX binding at $2.5x10^{-4}$mg/mL whereas PK resulted in significant 23% and 43% increases in [3H]-CNQX binding at $5x10^{-8}$ and $5x10^{-9}$ pM/μg protein/mL. These results suggest an age-dependent role for phosphatase and kinase reactions leading to amino acid receptor regulation in neocortex during postnatal development.

391.7

NMDA RECEPTOR (NMDAR1) ANTISENSE (AS) OLIGODEOXYNUCLEOTIDE HAS NEUROPROTECTIVE PROPERTIES IN RAT CORTICAL NEURONS. C.Wahlestedt, S.Regunathan, L.Lyandvert, F. Yee and D.J.Reis*. Div. Neurobiology, Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., N.Y., N.Y. 10021.

Based on the nucleotide sequence of rat NMDAR1 (Moriyoshi et al., *Nature* 354:31, 1991), we designed several AS, and corresponding sense (S), oligodeoxynucleotides (D-oligos) in an attempt to suppress synthesis of the NMDAR1 receptor protein. Herein described data were obtained with aminoterminally directed AS and matching S 18-mer D-oligos. These D-oligos were added under serum-free conditions to primary cultures of rat cortical neurons which were studied with respect to: (1) ^{3}H-MK-801 binding; (2) basal and NMDA-induced lactate dehydrogenase (LDH) release; and (3) basal and NMDA-induced $^{45}Ca^{2+}$ influx. A reduction of ^{3}H-MK-801 sites by 30-50% (*vs.* S or no D-oligo) could be achieved by 3-5 days incubation of the neurons with 1 μM of the AS D-oligo; this down-regulation was less dramatic than with an aminoterminal AS D-oligo of the NPY Y1-receptor (Yee *et al.*, this meeting). The AS D-oligo induced a concentration dependent (0.1-10 μM) reduction of spontaneous LDH release (measured 1-3 days after removal of serum) and evoked release (5 min exposure of 9-day old cultures to 100 μM NMDA). Finally, we found that spontaneous, but not NMDA-induced, $^{45}Ca^{2+}$ influx (measured over 2 min) was elevated, up to 2-fold, in neurons exposed to AS D-oligos, possibly also reflecting increased degrees of neuronal survival in these cultures. However, there may exist a "window" of optimum AS D-oligo concentration, since the S D-oligo, at 10 μM but not at 1 μM, showed minor effects *per se*. In conclusion, the present study indicates the usefulness of the antisense approach for down-regulation of (receptor) protein, such as the NMDAR1. It also lends direct support to the hypothesis that excitation through activation of the NMDA-receptor is associated with neuronal cell death.

391.8

ANXIOLYTIC AND ANTICONVULSANT DOSES OF ABECARNIL FAIL TO INDUCE TOLERANCE AND DEPENDENCE IN MICE AND CATS. M. Serra, C.A. Ghiani, M.C. Foddi, C. Motzo and G. Biggio*, Department of Experimental Biology, Chair of Pharmacology, University of Cagliari, Italy.

In mice, [35S]TBPS binding and exploratory motility were dramatically reduced by the acute administration of abecarnil (AB) (0.2 - 1 mg/kg i.p.). Chronic administration of this drug (1 mg/kg 3 times at day) induced in two weeks a significant increase in [35S]TBPS binding in the mice cerebral cortex with no change in motor behaviour. This biochemical effect was paralleled by the failure of a challenge dose of AB (1 mg/kg) to modify both [35S]TBPS binding and motor activity. On the contrary, in mice chronically treated with a lower but pharmacological effective dose (0.2 mg/kg) the exploratory motility was reduced (-30%) by a challenge dose of AB (0.2 mg/kg). This evidence may suggest that tolerance develops only with very high doses of AB. This conclusion is consistent with the finding that in the brain of this chronic treated mice the binding of [35S]TBPS was unchanged compared to control. Moreover, while in mice treated with the high dose of AB (1 mg/kg) the binding of [35S]TBPS was altered after drug discontinuation (increased by 26% at 48 h and decreased by 15% at 96 h), we found not change in mice chronically treated with 0.2 mg/kg at the same times. Our data indicate that chronic administration of AB is associated with the development of tolerance and with discontinuation syndrome only at very high doses while is devoid of these effects at lower, but pharmacologically effective, doses. This conclusion is also consistent with the finding that in cats chronically treated with AB (7 mg/kg 3 times for 15 days) the intraperitoneal administration of flumazenil (20 mg/kg) failed to precipitate an abstinence syndrome.

391.9

EFFECT OF LESIONS OF THE DORSAL RAPHE NUCLEUS ON SEROTONIN TRANSPORTER, 5-HT_{1A} AND 5-HT$_2$ BINDING SITES IN RAT.
M.D. Underwood, M.J. Bakalian, M.L. Miller, C.K. Katz, T.F. Lagattuta, J.J. Mann and V. Arango.* Labs of Neuropharm., Univ. of Pittsburgh, Pittsburgh, PA 15213

Decreases in the serotonin (5-HT) transporter and increases in 5-HT_{1A} binding are found in restricted cortical areas of suicide victims. We sought to determine whether 5-HT binding following lesions of the dorsal raphe nucleus (DRN) in rat parallel the 5-HT binding changes reported in man and to examine the extent of any subcortical changes. Three groups of rats were studied: unlesioned controls (n=5), DRN lesion (1 mA for 45 sec; n = 5) and sham-operated controls (n=5). Binding to the 5-HT transporter (^{3}H-cyanoimipramine; 0.4 nM), 5-HT_{1A} (^{3}H-DPAT; 2nM) and 5-HT$_2$ (^{3}H-ketanserin; 2 nM) sites were quantified in 25 regions by image analysis. 5-HT and 5-HIAA content in frontal lobe were determined by HPLC. In controls, specific 5-HT transporter binding was greatest in the DRN (409±66 fmol/mg tissue), least in the corpus callosum (8±3) and did not differ from sham-operated controls (p>0.05). DRN lesions reduced 5-HT and 5-HIAA by 78% and 92%, respectively, and reduced (p<0.05) transporter binding in all regions examined from 90% (perirhinal cortex) to 29% (rostroventrolateral medulla). 5-HT_{1A} binding was greatest in presubiculum (101±8) and least in the caudate nucleus (1±0.3). DRN lesions had restricted effects on 5-HT_{1A} binding with increases in frontal cortex (119% of control, p=0.06), inferior colliculus (137%, p=0.09) and hippocampus (115%, p=0.01). ^{3}H-ketanserin binding ranged from 31±10 fmol/mg (frontal cortex) to 2±1 fmol/mg (corpus callosum) and was unaffected by DRN lesions (p>0.05) in any brain region. We conclude that DRN lesions produce: 1) profound effects on 5-HT projections to the forebrain and brainstem; 2) restricted changes in ^{3}H-DPAT binding and 3) no effect on ^{3}H-ketanserin binding. These findings parallel those in suicides in several respects: 1) 5-HT transporter binding is reduced; 2) 5-HT_{1A} binding is increased and 3) ^{3}H-ketanserin binding is unchanged. Notable differences include: 1) widespread *vs.* localized reductions in transporter sites and 2) marked reduction *vs* no change in 5-HT and 5-HIAA. The cortical 5-HT receptor changes in suicide are consistent with a partial lesion of the DRN. Supported by NARSAD award to MDU and MH46745.

391.10

EFFECTS OF PARA-CHLOROAMPHETAMINE LESIONS ON PLATELET [^{3}H]-PAROXETINE BINDING IN RATS.
M.J. Owens,*D.L. Knight and C.B. Nemeroff. Lab. of Neuropsychopharmacology, Dept. of Psychiatry & Behavioral Sciences, Emory Univ. Sch. Med., Atlanta GA 30322.

Considerable evidence has accumulated to implicate serotonergic neuronal dysfunction in the pathophysiology of major depression. One such line of evidence is the reduction in the density of binding sites for [^{3}H]-imipramine or [^{3}H]-paroxetine, markers of the 5-HT transporter, in platelets of patients with major depression. In an attempt to determine whether changes in platelet [^{3}H]-paroxetine binding represents changes in CNS 5-HT function, we investigated whether depletion of 5-HT and destruction of 5-HT nerve terminals by para-chloroamphetamine alters [^{3}H]-paroxetine binding to the platelet 5-HT transporter

Rats received a single injection of para-chloroamphetamine (10 mg/kg, sc) or water. Because platelets have a lifetime of several weeks in plasma, groups of rats were killed at various time points (0, 1, 2, 4, and 10 weeks post-injection) following the lesion in order to allow for several complete turnovers of new platelet production. [^{3}H]-paroxetine binding (0.6 nM) in prefrontal cortex and platelets was determined in triplicate using 1 μM fluoxetine to determine non-specific binding. Para-chloroamphetamine administration decreased cortical [^{3}H]-paroxetine binding 40-50% at all time points studied. Although platelet [^{3}H]-paroxetine binding was highly variable, a small increase in binding was observed at the two week time point only. These preliminary findings suggest that at the magnitude of lesion produced here (50% destruction of 5-HT terminals), platelet 5-HT transporter binding is not greatly effected.

NEUROENDOCRINE REGULATION I

392.1

AMPLIFIED PULSATILE SECRETION OF GROWTH HORMONE (GH) IN CHRONIC RENAL FAILURE.
J.D. Veldhuis*, M.L. Wilkowski, A. Iranmanesh, W.K. Bolton, Dept. Internal Medicine, NSF Science Center in Biological Timing, Univ. Virginia Health Sciences Center, Charlottesville, VA 22908, and Salem Veterans Affairs Hospital, Salem, VA 24153.

Uremia evokes alterations in multiple neuroendocrine axes, including the gonadotropic, corticotropic, and somatotropic (GH) axis. We have studied the neuroendocrine control of episodic GH secretion and simultaneously estimated GH half-life in 7 middle-aged men (mean ages 39 ± 5.7 years) with endstage renal failure (ESRF) compared to a group of 7 age-matched controls (mean ages 42 ± 4.2 years). Multiparameter deconvolution analysis (PNAS 84:7686-90, 1987) of 24 hour serum immunoradiometric GH concentrations revealed a calculated half-life of endogenous GH of 21 ± 1.8 min in the men with ESRF compared to 17 ± 2.0 in controls. Uremia was accompanied by an increased frequency of pulsatile GH release namely 16 ± 1.0 secretory bursts/24 hour versus 12 ± 1.8 (control). The mass of GH secreted per burst was increased in uremia (4.5 ± 1.2 ng/mL versus 3.0 ± 1.1). Consequently, the 24 hour endogenous GH production rate was approximately 2-fold higher (73 ± 1.9 ng/mL/day) in uremics versus 36 ± 18 in age-matched controls. In contrast, the duration of GH secretory bursts was not altered in uremia. The mean 24-hr serum GH concentration was 1.5 ± 0.38 (uremia) versus 0.62 ± 0.28 ng/mL (control). In summary, uremia is accompanied by a small increase in the half-life of putatively intact immunoradiometric GH as well as an increased frequency and mass of pulsatile GH secretion. We therefore hypothesize that somatostatin withdrawal, and to a lesser extent decreased GH clearance, contribute to elevated plasma GH concentrations observed in uremia in humans.

392.2

pGLUTAMYLGLUTAMYLPROLINEAMIDE (EEP) MODULATION OF GROWTH HORMONE SECRETION IN THE CHICKEN.
V.L. Trudeau*, S. Harvey, R.J. Ashworth and S.M. Cockle. Dept. of Physiol., Univ. Alberta, Edmonton, Canada and Biochem. and Physiol., Univ. Reading, U.K.

A TRH-like tripeptide, EEP, originally isolated and characterized from rabbit prostate, also present in significant concentrations (63% total TRHir) in rat anterior pituitary, has no identified function. TRH is a physiological stimulator of GH secretion in birds; it is more effective in egg-laying than in meat-type broiler strains. EEP is present in low concentrations (6% total TRHir) in the pituitary of broiler but not layer strains. Given the structural similarities of these peptides, EEP may compete for pituitary TRH receptors (TRH-R) and affect GH release. EEP (10^{-5}-10^{-3}M) inhibited ^{3}H-Me-TRH binding to chicken pituitary membrane TRH-R but did not affect basal GH release from whole pituitaries in vitro, suggesting that EEP action is dependent on other (hypothalamic?) factors. Unlike TRH stimulation, EEP (1-100µg/kg; i.v.) decreased basal plasma GH levels by >50% within 10 min in anaesthetized immature males. Paradoxically, EEP potentiated submaximal TRH-induced GH release without changes in TRH-R, an effect very similar to that of benzodiazepine-type TRH antagonists. These studies demonstrate for the first time that EEP participates in regulation of GH release in the chicken possibly by interactions with the pituitary TRH-R. In addition, the relative lack of EEP in the avian pituitary may explain why TRH more effectively stimulates GH release in birds than in mammals. (Supported by NSERC).

392.3

PATCH CLAMP ANALYSIS OF GROWTH HORMONE-RELEASING FACTOR (1-44) EFFECTS IN HUMAN GROWTH HORMONE SECRETING CELLS IN CULTURE.
C. Chen*, P. Heyward, P. McNeill, J. Cummins and I. J. Clarke. Prince Henry's Institute of Medical Research, P.O. Box 152, Clayton (Melbourne), Victoria 3168, Australia

We have previously reported that local application of human growth hormone-releasing factor 1-44 (hGRF) in rat pituitary somatotropes causes a depolarization of cell membrane and growth hormone (GH) secretion that depends upon Ca influx (Chen et al., Neuroendocrinology 50:679, 1989). This effect can be obtained by conventional microelectrode intracellular recording but not by standard whole-cell patch-clamp recording. Alternatively in the present experiment, using the Nystatin-perforated patch-clamp technique in the whole-cell configuration, this effect has been observed in identified human growth hormone (GH) secreting tumour cells from acromegalic patients. With local application of hGRF (10nM), a slow depolarization occurs with the generation of multiple action potentials. Current-induced depolarization in the absence of hGRF causes a single action potential but in the presence of hGRF multiple action potentials are seen. The characteristics of the action potentials, in terms of Ca and Na flux, are similar to those previously seen in rat somatotropes (Chen et al., Life Sci. 46:983, 1990). In particular, hGRF increased the action potential due to Ca influx. The Ca current was enhanced by hGRF in cells treated with TEA (20mM) and TTX (1uM) in the bath solution and Cs in the electrode solution to eliminate K and Na currents. The voltage-dependent kinetics of Ca currents were also modified by hGRF application. These results show that hGRF can increase influx of Ca in human tumour derived somatotrophs *via* its effects on Ca channels in a manner similar to that seen in normal rat somatotropes. INHIBITORY REGULATION OF PULSATILE GnRH RELEASE FROM GT_1 GnRH CELL LINES BY VASOPRESSIN AND GABA .
R. I. Weiner and G. Martínez de la Escalera*. Reproductive Endocrinology Center, University of California San Francisco, CA 94143, and Instituto de Investigaciones Biomédicas, National University of México, México City 04510, México.

Arginine vasopressin (AVP) containing nerve terminals synapse with GnRH neurons and may play a role in stress-induced inhibition of LH secretion. γ-aminobutyric acid (GABA) neurons also synapse with GnRH neurons and substantial evidence support their role on GnRH release. GnRH cell lines (GT_1) release GnRH with a pulse frequency similar to that observed in castrated mice. Superfusion of GT_{1-1} cells with AVP (100 nM) inhibited pulsatile release of GnRH. The mechanism by which AVP inhibits GnRH release is not clear since 10-100 nM AVP for 1-10 min does not affect tyrosine phosphorylation (assessed by phosphotyrosine Western blots) nor adenylate cyclase activity (assessed by RIA of intracellular cyclic AMP) in GT_{1-7} cells. On the other hand, GABA (10 µM) showed a biphasic effect on GnRH release, with a brief and rapid stimulation followed by a long and sustained inhibition. The effect of GABA is correlated with a bicuculline- and saclofen-sensitive inhibition of the basal and stimulated intracellular levels of cAMP. These findings demonstrate that two putative inhibitory neurotransmitters in the regulation of GnRH release are capable of exerting their actions directly on GnRH neurons. (Work supported by NIH Grant HD 08924 and The Rockefeller Foundation).

392.5

PROLACTIN INHIBITION OF GnRH RELEASE FROM GT1 GnRH CELL LINE VIA PROLACTIN RECEPTORS. L. Milenkovic, G. D'Angelo and R.I. Weiner*, Reproductive Endocrinology Center, University of California San Francisco, CA 94143

Numerous observations have demonstrated an inverse relationship between prolactin (PRL) and LH secretion. We tested whether PRL directly acts on GT1 GnRH neurons to affect GnRH release. Prolactin (rat or mouse, 10^{-10} - 10^{-8} M) suppressed GnRH release in a dose-dependent fashion from both GT1-1 and GT1-7 cell lines in static culture. The maximal concentration of PRL suppressed 40% of GnRH released during 1 hour. Both the mRNA and protein for PRL receptors were shown to be present in GT1-7 cell line. A monoclonal antibody to rat liver PRL receptor (U5) stained a 42 kDa dublet, consistent with the short form of the PRL receptor, in western blot of GT1-7 cell membranes. Western blots of mouse liver membranes indicated a major band at 42 kDa, and a minor band at approximately 80 kDa. A cDNA probe which recognized all known forms of the PRL receptor hybridized to the bands of 2.4, 3.2 and 4.2 kb in northern blots of GT1-7 cell RNA. In conclusion PRL inhibits GnRH release via prolactin receptors expressed on GnRH neuronal cell lines. Further work is necessary to identify the PRL receptor form mediating this action. (This work was supported by NIH Grant HD 08924.)

SOMATIC AFFERENT REGULATION OF PLASMA PROLACTIN IN ANESTHETIZED RATS.
H. Hotta[1], A. Sato*[1], Y. Sato[2] and A. Suzuki[1]. [1]Department of Autonomic Nervous System, Tokyo Metropolitan Institute of Gerontology, Tokyo 173, [2]Laboratory of Physiology, Tsukuba College of Technology, Tsukuba 305, Japan.

These experiments examined the effects of noxious and non-noxious mechanical stimulation of various skin areas (forelimb and forepaw, abdomen, hindlimb and hindpaw) on levels of plasma prolactin in anesthetized rats. The experiments were performed on female Wistar rats on the day of estrus, which had been anesthetized with urethane (1.1 g/kg, i.p.) and artificially ventilated. Blood samples, for the determination of plasma prolactin by RIA, were collected from a femoral artery every 20 min. Noxious mechanical stimulation of the skin was delivered by pinching, using a surgical clamp, while non-noxious mechanical stimulation was provided by brushing with a tooth brush. Pinching of a hindpaw for 6 min significantly increased plasma prolactin during stimulation, while pinching of a forepaw or abdomen had no significant effect. Brushing of skin areas for 6 min did not significantly change plasma prolactin. These results indicate that when emotional factors were eliminated by anesthesia, cutaneous nociceptive sensory information contributes to the reflex regulation of prolactin secretion from the anterior pituitary, and also that this effect is highly dependent on the site of stimulation.

CHEMICAL PLASTICITY OF HYPOTHALAMIC TUBEROINFUNDIBULAR DOPAMINERGIC NEURONS : ROLE OF PROLACTIN. P. Ciofi*, W.R. Crowley [a], D. Croix, J.C. Beauvillain, V. Mitchell, G. Tramu[b] and M. Mazzuca. U.156 INSERM, 59045 Lille (France); [a]Dept. Pharmacol., Univ. Ten. Memphis, Memphis TN 38163; [b]Lab. Neurocyto. Fonct., URA CNRS 339, Univ. Bordeaux I, Talence 33405 (France).

Reports of increased immunoreactivity (IR) for enkephalin (ENK) (Soc. Neurosci. Abs. 15:702, 1989) and neuropeptide Y (NPY) (Endo.128:823, 1991) in TIDA neurons of lactating rats and mice led us to determine with immunohistochemistry 1) whether the expression of other peptides in the median eminence (ME) is also altered during lactation in rats and mice, and 2) whether prolactin (PRL) might be involved in these changes. IRs for NPY, ENK and neurotensin (NT) were dramatically decreased in the ME of post-partum (PP) day 8 lactating mice that were pup-deprived for two days, compared to continually nursing PP8 mice. Fluorescent triple-staining showed colocalization of these IRs in all tyrosine-hydroxylase-IR endings. Preliminary ultrastructural double-staining experiments suggest a nonhomogenous distribution of these neuropeptides among neurosecretory vesicles in the same nerve terminals. On PP-8, NPY- and ENK-IRs were visible in putative ME TIDA endings of both intact and PP1-ovariectomized lactating rats. Changes in NT-IR could not be discriminated. Considerable interanimal variation in NPY-IR suggested the influence of an underlying pulsatile phenomenon. When intact lactating rats were separated from their litters for four hours and then reunited, we detected a trend for increased NPY-IR, but not for ENK- or NT-IR, in the ME during the 30-60min following the onset of suckling, associated with elevated circulating PRL levels. NPY-IR, but not ENK- or NT-IR, was also expressed in putative TIDA endings in orchidectomized rats made hyperprolactinemic from implants of estradiol-filled capsules.

These results suggest that 1) an ovarian influence may not be required for the expression of NPY- and ENK-IRs in the TIDA neurons during lactation, 2) PRL may be responsible for inducing NPY expression in these cells, and 3) additional factors may regulate expression of ENK- and NT-IRs in TIDA neurons with both sex and species differences in their actions.

392.8

A TROPHOBLAST-SPECIFIC FACTOR(S) INCREASES TYROSINE HYDROXYLASE (TH) ACTIVITY IN FETAL HYPOTHALAMIC CELL CULTURES. L.A. Arbogast*, M.J. Soares, M.C. Robertson and J.L. Voogt, Physiology Dept., Univ. of Kansas Med. Ctr., Kansas City, KS 66103 and Physiology Dept., Univ. of Manitoba, Winnipeg, Manitoba.

We previously reported that a factor(s) from rat choriocarcinoma (Rcho) cells *in vivo* suppresses PRL and increases tuberoinfundibular dopaminergic neuronal activity. Rcho cells can differentiate into trophoblast giant cells which produce members of the placental PRL family. The aims of this study were: 1) to establish a neuronal culture system to characterize the Rcho factor(s) which increase TH activity and 2) to assess the ability of lactogenic hormones to alter TH activity. Ventral hypothalamic cells of fetal day 20 rats were dispersed with trypsin, plated at 200,000 cells/well and maintained in culture for 14 days. TH-immunopositive neurons were observed in the cultures. Cell contents of dopamine and dihydroxyphenylalanine (DOPA) were 186 pg and 50 pg, respectively, per 200,000 cells. TH activity was determined by a 1h incubation with Earles' Balanced Salts containing 100 µM brocresine, a DOPA decarboxylase inhibitor, and assessing DOPA in the medium. Medium DOPA was linear between 0-4h with or without brocresine, but was 3-fold higher with brocresine. Hypothalamic cells were co-cultured for 24h with 100,000 Rcho, HRP (placental line not expressing known placental PRLs), or MMQ (a PRL-secreting cell line) cells. Control DOPA accumulation was 94±17 pg DOPA/ 200,000 cells/h. Co-culture with Rcho cells increased DOPA accumulation 4-fold, whereas HRP and MMQ cells had no effect. A 2-fold or 3-fold increase in TH activity was observed with 25,000 or 50,000 Rcho cells, respectively. α-Methyl-p-tyrosine (1mM), a specific inhibitor of TH, markedly reduced DOPA accumulation in both control and Rcho-stimulated cultures. Incubation for 24 h with 1µg/ml of rPRL or recombinant rat placental lactogen I did not alter TH activity, whereas 1h incubation with 5 mM dibutyrl cAMP increased DOPA accumulation 3-fold. Conclusion: A trophoblast-specific factor(s), likely not placental lactogen I, specifically and in a dose-dependent fashion increases TH activity in hypothalamic cells *in vitro*. SUPPRESSED TYROSINE HYDROXYLASE (TH) AND INCREASED NPY GENE EXPRESSION IN THE ARCUATE NUCLEUS OF LACTATING RATS. H.-J. Wang and M.S. Smith*. Department of Physiology, University of Pittsburgh, Pittsburgh, PA 15261.

The suckling stimulus alters hypothalamic function, resulting in suppressed GnRH neuronal activity and increased prolactin secretion. To understand mechanisms responsible for these effects of suckling, we examined whether lactation was associated with changes in gene expression in the arcuate nucleus (AN). Animals were studied during diestrus-1, and on day 10 postpartum with 8 pups suckling or 24 hr after pup removal. *In situ* hybridization (ISH) was performed to assess mRNA levels for TH and NPY. For single label ISH,TH and NPY riboprobes were labeled with ^{35}S. For double label ISH, TH riboprobe was labeled with ^{35}S and NPY riboprobe with digoxigenin. TH mRNA (grain area/AN area) levels in lactating rats were suppressed to 65 % in the rostral AN and were undetectable in the remainder of AN, as compared to diestrous controls. In contrast, TH mRNA in the zona incerta did not differ between the two groups of animals. At 24 hr after pup removal, TH mRNA levels had increased to nearly 200% of diestrous controls. NPY mRNA levels were similar in diestrous and lactating animals except in the caudal area of the AN (at the level of the dorsomedial hypothalamic nucleus) where mRNA levels increased nearly two-fold in lactating rats. The change in NPY gene expression was reversed 24 hr after pup removal. Using double label ISH, we found TH and NPY expressing neurons in close proximity in some areas of the AN but no evidence for expression of TH and NPY in the same neurons. In summary, the suckling stimulus changes gene expression in specific subpopulations of dopamine and NPY neurons in the AN. These changes may possibly alter the dynamics of the transmitter released. Supported by Grant HD14643.

FOS-RELATED ANTIGENS AS MARKERS OF BASELINE NEURONAL ACTIVITY: EFFECTS OF LACTATION ON ARCUATE NUCLEUS DOPAMINE NEURONS. G.E. Hoffman*, W-S.Lee, R. Abbud and M.S. Smith. Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

In many areas of the brain, neurons express Fos-related antigens (FRAs), but not cFos, under baseline conditions. These studies assessed whether FRA expression can serve as a marker for both decreased as well as increased baseline neuronal activity. To test this hypothesis, we examined FRA expression in tuberoinfundibular (TI) dopamine (DA) neurons of the arcuate nucleus in cycling female rats and in pregnant and lactating animals. The TIDA neurons comprise the principal prolactin inhibitory system. Their activity tonically inhibits prolactin release. However, in the lactating rat, TIDA neuron activity is presumably inhibited, thereby facilitating prolactin release. Double label immunocytochemistry localized tyrosine hydroxylase (TH) and either FRAs or c-Fos. FRAs and c-Fos were distinguished using antisera generated against either the M-peptide region of c-Fos (capable of recognizing most FRAs as well as c-Fos) or the N-terminal of c-Fos (selective for c-Fos). Under resting conditions, cycling rats and pregnant rats showed FRA but not c-Fos expression in their TIDA neurons. Animals suckling 8 pups for 10 days had no FRA or cFos activity in TIDA neurons. FRA staining returned 3 hours after pup removal and was restored to full expression by 24 hours. The changes in FRA expression in the presence of the suckling stimulus and upon pup removal parallel changes we observed in TH gene expression in TIDA neurons of lactating animals (See abstract by Wang, H.-J. et al). These data suggest that FRA expression can effectively serve as a marker of baseline activity in identified populations of neurons. *Supported by NIH Grants HD 14643 and NS 28730.*

392.11

RAPID CHANGES IN OXYTOCIN AND VASOPRESSIN mRNA CONCENTRATIONS IN THE EARLY POSTPARTUM PERIOD: EVIDENCE FOR A ROLE OF FACTORS OTHER THAN SUCKLING. R.S. Crowley and J.A. Amico*. University of Pittsburgh School of Medicine and VA Medical Center, Pittsburgh, PA 15261.

Oxytocin (OT) and vasopressin (AVP) gene expression are enhanced in the rat hypothalamus in late gestation and during the second and third weeks of lactation. Increased OT gene expression during lactation is believed to be due to suckling, which is known to activate OT neurons resulting in coordinated electrophysiological activity of these neurons and release of OT from the posterior pituitary. We hypothesized that other factors such as ovarian steroids might modulate responses to stimulation of these neurons. We therefore investigated expression of hypothalamic OT and AVP mRNAs using Northern analysis and in situ hybridization during the first ten days of lactation when rats are continuously suckling but ovarian steroid concentrations are known to change markedly. We report that during the first three postpartum days, OT and AVP mRNAs decreased dramatically reaching less than one fifth of peak gestation levels by day 2 postpartum in both supraoptic (SON) and paraventricular (PVN) nuclei. OT and AVP mRNA returned to levels comparable to late gestation on or about day 10 lactation, and remained elevated after 15 and 23 days of lactation. We have also compared OT mRNA isolated from lactating day 3 rats to cohorts which had litters removed at the time of parturition. Lactating rats had significantly lower OT mRNA levels than their non-lactating cohorts. These data refute the hypothesis that lactation is characterized by persistently elevated OT and AVP mRNAs produced as a result of continuous stimulation by suckling.

392.12

OXYTOCIN (OT) AND VASOPRESSIN (AVP) GENE EXPRESSION IN THE OSMOTICALLY-STIMULATED FEMALE RAT. J.A. Amico, R.S. Crowley, S.M. Challinor*. Univ. of Pittsburgh Sch. of Med. and VA Medical Center, Pittsburgh, PA 15261.

Our finding that ovarian steroids, estradiol (E_2) and progesterone (P), modulate hypothalamic OT and AVP gene expression in the lactating rat, led us to question whether similar modulation occurs in the osmotically-stimulated female rat. Sustained hyperosmolality (4-14 days of oral 2% NaCl) is reported to enhance OT and AVP mRNA concentrations in intact male rats. Similar studies have not been done in female rats. If E_2 and P modulate signals for up-regulation of the OT and AVP genes during osmotic activation, the response of these genes to sustained hypernatremia in the female rat would likely be heterogeneous because E_2 and P levels rapidly fluctuate during the estrous cycle. Moreover upregulation of OT and AVP gene expression should not occur in salt-loaded ovariectomized (OVX) rats.

Adult female cycling Sprague-Dawley rats matched for age and weight were sham OVX (intact) or OVX (3 wks prior to study), administered oral 2% NaCl or tap H_2O, and sacrificed on the 5th day of study. Salt-loaded OVX and salt-loaded intact rats developed comparable degrees of hypernatremia, depletion of posterior pituitary stores of OT and AVP, and weight loss (no significant differences, ANOVA). At sacrifice, E_2 and P concentrations were non-detectable in OVX rats and varied among intact rats, depending upon the stage of the estrous cycle. Salt-loaded OVX rats (n=8) showed no upregulation of OT or AVP mRNAs, whereas salt-loaded intact, cycling rats (n=12), showed both up- and downregulation compared to intact (n=12) and OVX (n=8) rats given tap H_2O. The data support ovarian steroid-mediated mechanisms for up- and downregulation of OT and AVP genes during osmotic activation.

IMPLANTED SYNTHETIC DOPAMINE (DA) AND NOREPINEPHRINE (NE) MICROSPHERES ATTENUATE APOMORPHINE INDUCED ROTATIONAL BEHAVIOR AND STIMULATE GROWTH OF DA FIBERS IN PARKINSONISM RATS. *A. McRae*[1], S. Hjorth[2], A. Dahlström[1], E.A. Ling[3], L. Dillon[4], D. Mason[4] and T. Tice[4]. University of Göteborg, Depts of Histology[1] and Pharmacology[2] Göteborg, Sweden; National University of Singapore, Dept. of Anatomy, Singapore[3]; Southern Res. Inst., Controlled Release Div., Birmingham, AL 35205, USA[4].*

Implanted chromaffin tissue alleviates some parkinsonism symptoms in humans and in experimental animals. Functional recovery could be due the release of large amounts of both NE and DA from this tissue. Implantable biodegradable controlled-release microspheres containing NE or DA provide a novel means to compare DA- or NE-induced restitution of subnormal DA function. Rats were unilaterally 6-OH-DA lesioned in the MFB. Six to eight weeks later, a suspension of 3µl of DA- or NE-containing microspheres was implanted in 2 sites in the DA denervated striatum. Contralateral rotational behavior induced by apomorphine was used as an index of lesion success and, following implantation of the microspheres, also as an index of functional recovery. Interestingly, both DA- and NE-microsphere implanted rats displayed a 30-50% reduction in the number of apomorphine-induced rotations up to 8 weeks postimplantation. Upon conclusion of the studies, immunocytochemical examination revealed growth of DA and tyrosine hydroxylase IR fibers in the striatum of DA and NE microsphere implanted rats. Preliminary EM studies showed signs of axonal growth cones and of axonal sprouting in the vicinity of the injected microspheres. Thus, both microencapsulated NE and DA have the capacity to assure functional recovery and to promote DA fiber (re)growth in parkinsonism rats. This novel means to deliver these substances to the CNS could be of therapeutic usefulness in Parkinson's disease.

393.2

ENCAPSULATED EMBRYONIC MESENCEPHALIC CELLS SURVIVE INTRACEREBRAL IMPLANTATION

P. A. Tresco*, B. Zielinski, and P. Aebischer
ABC Section, Brown Univ., Providence, RI 02912

Polymeric cell encapsulation may be a useful technique for investigating the mechanism by which embryonic neural grafts ameliorate deficits in various animal models of CNS disease. Surrounding grafted cells with a biocompatible, semipermeable membrane that allows diffusional exchange of nutrients and metabolic products promotes sustained cell viability but also, isolates the enclosed cells preventing physical contact with cells of the host. This approach may reveal the relative importance of graft-derived reinnervation versus graft-derived molecular diffusion as mediators of graft efficacy. To test the feasibility of this approach, embryonic ventral mesenphalic cells were isolated from E17-19 day old fetuses and cultured in DMEM with 10 % FCS either on polystyrene culture plates directly or after being combined with an artificial extracellular matrix (Matrigel®). Semi-permeable capsules containing fetal mescencephalic cells seeded in Matrigel were implanted within the striatum of normal adult male Sprague-dawley rats within three hours of isolation. Animals were sacrificed at two (n=3) and four (n=4) weeks and analyzed histologically. The *in vitro* culture systems contained non-neuronal and neuronal cell types many of which stained positively for tyrosine hydroxylase (TH). Viable cells were present in all of the capsules *in vivo* explanted at two and four weeks which displayed morphological phenotypes similiar to those observed in *in vitro* cultures. Some of the cells stained positively for TH indicating that neuronal cells survived within the capsule over the four week period *in vivo*. Ongoing studies are aimed at optimizing neuronal cell survival and addressing functional efficacy.

393.3

SYNAPTOSOMAL UPTAKE OF [^{3}H]DOPAMINE IN THE STRIATUM OF WEAVER MUTANT MICE FOLLOWING INTRASTRIATAL TRANSPLANTATION OF MESENCEPHALIC CELL SUSPENSIONS. *L. C. Triarhou, B. Ghetti and J. R. Simon**. Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

The weaver (*wv*) mutation induces a genetic nigrostriatal dopamine (DA) deficiency. Assays of [^{3}H]DA uptake were carried out *in vitro* in striatal synaptosomal fractions from wild-type mice (+/+) and from the two hemispheres of weaver mutant mice (*wv*/*wv*) that had received unilateral grafts of mesencephalic cell suspensions to the right side. Amphetamine-induced turning behavior was used to monitor graft survival. Recipient mice rotated by an average of 22 turns to the left and 7 turns to the right during the five 1-min sessions; the mean value L/(L+R) was 64%. Net [^{3}H]DA uptake, expressed as pmol/mg protein/2-min, was on the average 50 in the striatum of wild-type mice (n=10), 8 in the non-grafted, and 10 in the transplanted striatum of weaver mutants (n=11). Paired comparisons of right vs. left side in the striatum of the weaver recipients showed a 38% increase on the grafted side [mean value (R-L)/L]. In general, animals with a strong rotational bias to the left tended to have higher DA uptake values on the right. These findings attest to the functional effects of the grafts. Since DA uptake was measured in entire striatal preparations, the regional extent of DA effects in areas strictly associated with motoric activity may be underestimated. (Supported by USPHS R29-NS29283).

393.4

TRANSFORMING GROWTH FACTOR ALPHA: A POTENTIAL ROLE IN THE EFFICACY OF INTRASTRIATAL TRANSPLANTS S.E. Loughlin*, T. Lee, T. Ibrahim, D. Twardzik and J.H. Fallon. Department of Anatomy and Neurobiology, University of California Irvine, CA 92717

Intrastriatal transplants of fetal mesencephalon reverse behavioral deficits assoiciated with loss of dopaminergic innervation of the striatum. Transforming growth factor alpha precursor like immunoreactivity (TGFa-LI) is present in a subpopulation of astrocytes (Fallon, et al, 1990) which is increased by fetal transplants (Loughlin, et al, 1989). Transplants of adrenal medulla also ameliorate lesion induced deficits, even when dopaminergic cells do not survive (Bohn, et al, 1989). Adult adrenal medulla transplants caused an increase in striatal TGFa-LI astrocytes (Loughlin, et al, 1992). We therefore hypothesized that TGFa might play a role in the efficacy of transplants. To test this hypothesis, animals received unilateral 6-OHDA lesions of the dopaminergic projection to the striatum and apomorphine (0.25 mg/kg ip)-induced rotation behavior was quantified. One group of animals then received intrastriatal infusions of 200 ul TGFa (0.05 ug/ul) in artificial cerebrospinal fluid (CSF) via an Alzet minipump (2002) over a two week period. A control group received infusions of CSF alone. Rotation behavior was quantified and animals were sacrificed. Brains were processed for localization of TGFa-LI. CSF infusions produced a modest increase in endogenous TGFa-LI, while TGFa infusions caused a greater increase in TGFa-LI. Rotation behavior was unchanged in animals which received CSF infusions ($p > .4$). Infusions of TGFa, however, decreased rotation behavior by 40% ($p < 0.005$). Thus, TGFa may facilitate recovery from 6-OHDA lesions. Whether such recovery reflects regeneration of dopaminergic afferents or other compensatory changes is not known. Since endogenous TGFa-LI is increased by transplants which have been shown to ameliorate lesion induced deficits, it is possible that the efficacious effects of transplants are mediated through TGFa. These data have important implications for the development of new treatments for Parkinson's Disease. Supported by NS 26761 and the American Parkinson Disease Association SCC.

SUPERPARAMAGNETIC CONTRAST AGENTS FACILITATE MAGNETIC RESONANCE IMAGING OF NEURAL TRANSPLANTS IN RAT BRAIN IN VIVO. Andrew B. Norman*, Stephen R. Thomas, Ronald G. Pratt and Robert B. Norgren. Departments of Psychiatry and Radiology, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267.

Although transplants of rat fetal striatal tissue can be observed in vivo using magnetic resonance (MR) imaging, the transplanted tissue is approximately isointense with the host brain, making it difficult to distinguish from host tissue. We have used superparamagnetic ferrite particles coupled to wheat germ agglutinin (WGA) to label and to visualize the transplant in vivo. Dissociated rat fetal striatal tissue (E 15-17) was incubated with WGA-ferrite particles for 15-20 min at 37°C and then transplanted unilaterally into rat striatum. Six days and 25 days following transplantation, rats were imaged at 0.14 T using a T_1 weighted protocol (TR=500 ms/TE=30 ms). After imaging, the rats were perfused and brain sections stained with cresyl violet or hematoxylin for iron. The labeled transplant was clearly visible on MR images as a feature characterized by very low signal intensity within the host brain. At higher concentrations of WGA-ferrite particles there was also a corona of high signal intensity representing a susceptibility artifact surrounding the area of low signal intensity. Histologically, the ferrite particles were observed to be mainly restricted to the area of the transplanted tissue and had a patchy distribution. The cells adjacent to the particles appeared to have normal morphology and cytochrome oxidase activity. These studies demonstrate that WGA-ferrite particles remain associated with transplanted cells for at least 3 weeks and permit the long-term monitoring of transplanted tissue using MR imaging in vivo. (Supported by NSF Grant BNS9015373)

IMPROVEMENTS IN THE KINEMATICS OF A TWO-DIMENSIONAL ARM MOVEMENT IN THE HEMIPARKINSONIAN MPTP MONKEY FOLLOWING ADRENAL MEDULLARY AUTOGRAFTS. P.J. Camarata, R.G. Parker, S. Park*, T.J. Ebner. Departments of Neurosurgery and Physiology, Univ. of Minnesota, Minneapolis, MN 55455, and Inje University, Seoul, Korea.

Most evaluations of hemiparkinsonian primates treated with 1-methyl-4-phenyl-1,2,5,6-tetrahydropyridine (MPTP) have employed quantification of turning behavior or evaluation of simple reaching tasks. Objective measurements involving skilled volitional limb movements are necessary to adequately assess results of adrenal medullary grafting. In a visually guided reaching task requiring 6 directions and 5 distances of movement we measured reaction time, velocity, and time-to-peak velocity in three Rhesus monkeys before and after unilateral treatment with MPTP, involving some 20,000 movements for each animal. With each animal, reaction times significantly increase, peak velocities decrease, and the times-to-peak velocity increase after MPTP. Two of these animals have been studied after transplantation of autologous adrenal medulla to the striatum. One animal who underwent an open surgical graft to the caudate showed no improvement following transplantation. The animal who underwent stereotaxic transplantation to the caudate and putamen at several sites showed significant improvement in all parameters at most distances, at times returning to control values. Stereotaxic grafting of autologous adrenal medullary cells to the striatum may improve kinematic abnormalities in the hemiparkinsonian primate. Supported by the American College of Surgeons, the United Parkinson Foundation, and Mr. Hal Seth.

393.7

ASSESSMENT OF BEHAVIORAL IMPROVEMENT IN HEMIPARKINSONIAN MONKEYS FOLLOWING COGRAFTING OR SURGICAL CONTROLS. **R.A.E. Bakay*, L.D. Byrd, R.L. Watts, A. Mandir. Yerkes Regional Primate Research Center, Emory Univ., Atlanta, GA 30322.**

Eighteen rhesus monkeys are being evaluated quantitatively as to the effectiveness of CNS transplantation using adrenal medullary/peripheral nerve cografts. The monkeys were trained on one of two different operant behavioral tasks to give quantitative measures of disability produced by unilateral carotid administration of MPTP. MPTP produced marked deterioration of performance in the affected hand. None of the unoperated monkeys demonstrated spontaneous recovery (N=4). Five to nine months after MPTP administration, a transcortical intraventricular cograft was placed in the caudate (N=8) or the surgical equivalent without tissue (N=6). Increased speed of performance on operant task, and in some cases return of operant behavior, was observed in all cografted monkeys and only one of the surgical controls. The degree of recovery appeared to be directly correlated with the number of surviving chromaffin cells and inversely correlated with the degree of deficit prior to grafting. Supported by VAR&D, RO1 NS24340 and RR-00165.

393.8

COMPARISON OF AUTOLOGOUS ADRENAL MEDULLARY AND FETAL VENTRAL MESENCEPHALIC BRAIN TRANSPLANTATION STRATEGIES FOR THE TREATMENT OF PARKINSON'S DISEASE. I. Madrazo*, R.E. Franco-Bourland, H. Castrejon, C. Cuevas, F. Ostrosky-Solis, MC. Aguilera, E. Magallon, E. Grijalva, G. Guizar-Sahagun. IMSS, UNAM, INNSZ. Mexico, D.F. Mexico.

In the treatment of Parkinson's disease (PD) with dopamine rich grafts we have adopted 4 unilateral transplantation strategies: autologous unisite, multisite or peripheral nerve cografted adrenal medulla (AM) brain grafting, and fetal ventral mesencephalic (VM) homotransplantation. One to two years postsurgery, compared to non-transplanted parkinsonian subjects, most grafted individuals have shown various degrees of amelioration of their PD signs, and improved response to L-dopa. However, 3 to 4 years post-transplantation, homotransplanted patients have shown a notably more benign course of the disease, with a slower rate of progression, than most, but not all, of the AM grafted individuals. The benefits obtained from both AM and VM brain grafting procedures merit their further development.

HUMAN FETAL DOPAMINE CELL IMPLANTS IN EIGHT PATIENTS WITH ADVANCED PARKINSON'S DISEASE. CR Freed, RE Breeze, NL Rosenberg, SA Schneck, EH Kriek*, JX Qi, YB Zhang, T Lone, TH Wells, LO Ramig, L Thompson, JC Mazziotta, SC Huang, G Schroter, and A.A. Ansari. Univ. of Colo. Sch. Med., Colo. Neurologic Institute, Den. Ctr. Performing Arts, Neuropsych Labs., Denver, CO; UCLA Sch. of Med., Los Angeles, CA; Winship Cancer Ctr., Emory Univ. Sch. of Med., Atlanta, GA.

We have transplanted human embryonic mesencephalic tissue containing dopamine cells into the caudate and putamen of eight patients with advanced Parkinson's disease. Implants were unilateral in caudate and putamen (n=2) or bilateral into the putamen (n=6). Fetal tissue of 7 to 8 weeks' gestation was used. Alternate patients were immunosuppressed with cyclosporine A and prednisone. Results showed that at best, postural stability and walking were restored, hand movement became normal, and "off" episodes were eliminated. Drug doses were reduced as much as 50%. 18-F-6-fluorodopa PET scans have been compatible with continued growth and survival of the transplant for up to 33 months. Both immunosuppressed and non-immunosuppressed patients improved, although improvement was variable and some patients did not benefit. Fetal tissue implants may offer substantial long term clinical benefit to some patients with advanced Parkinson's disease.

SELECTIVE EFFECTS OF INTRAHIPPOCAMPAL LOCUS COERULEUS GRAFTS ON THE DEVELOPMENT BUT NOT EXPRESSION OF KINDLED SEIZURES. J. Bengzon*, M. Kokaia, Z. Kokaia and O. Lindvall. Restorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden.

Intrinsic noradrenergic locus coeruleus (LC) neurons strongly suppress the development of seizures in the kindling model of epilepsy. We have previously shown (i) that transplantation of fetal LC tissue to the hippocampus or the amygdala-piriform cortex in 6-hydroxydopamine (6-OHDA) treated, hyperexcitable rats retards seizure development in hippocampal kindling; (ii) that kindling leads to a long-term decrease in basal hippocampal noradrenaline (NA) release from the intrinsic LC system as monitored by intracerebral microdialysis. We now report that this decrease in basal NA release can be reversed by LC grafts, but not by striatal tissue, implanted unilaterally into the previously kindled, non-denervated rat hippocampus. However, the LC grafts had no effect on the severity of the kindled convulsions despite a substantial noradrenergic hyperinnervation of the host hippocampus around the grafts. Bilateral implantation of fetal LC tissue into the hippocampus of previously 6-OHDA-treated, kindled rats, resulting in a normal or supranormal noradrenergic fiber density in major parts of the hippocampal formation, had no effect on the severity of fully developed generalized seizures. Finally, implantation of fetal LC tissue into the intact brain, producing a relatively dense noradrenergic hyperinnervation of the hippocampus up to about 1 mm from the grafts, did not influence the subsequent development of hippocampal kindling.

In conclusion, these data show that a graft-derived, noradrenergic hyperinnervation of the hippocampus fails to affect both kindling development and established seizures. Furthermore, LC grafts have no anticonvulsant effect when implanted into the hippocampus of noradrenaline-depleted, kindled rats, in contrast to the powerful antiepileptogenic effect exerted by the grafts during seizure development. The data thus point to a marked selectivity in the effects of noradrenergic transplants in the kindling model of epilepsy.

TRANSPLANTATION OF HCN-1A INTO RAT BRAIN. B. Morgan, D. Pizzo, K. Werrbach-Perez, L. Hutton, Y. Lu, K.N. Westlund, C. Hulsebosch, H.M. Eisenberg*, R. Perez-Polo. University of Texas Medical Branch at Galveston, TX 77555.

The HCN-1A is a human neural cell line that responds to the nerve growth factor (NGF) by fully differentiating and is a potential donor for transplantation into brain regions damaged by disease processes that have caused cell loss. It was developed from a child with megalencephaly. HCN-1A grown in 100% DMEM and 15% fetal calf serum with daily medium changes are differentiated in 10 ng/ml NGF, 1 mM forskolin, and 1 mM dibutyl cAMP (NGF cocktail). We have evaluated the cells using immunohistochemical methods and found the cells to contain GABA, glutamate, VIP, somatostatin, and cholecystokinin-8. Immunoreactivity of the cells for synaptophysin is increased with the differentiation of these cells. We have shown that these cells express $p75^{NGFR}$ mRNA using reverse transcription and the polymerase chain reaction (PCR) with primers for $p75^{NGFR}$ mRNA. The cells are also stained cytochemically with Me 20.4, an antibody to the human $p75^{NGFR}$. In preliminary experiments $5x10^5$ HCN-1A cells were implanted into rat motor cortex. Surviving cells were demonstrated two weeks after transplantation of HCN-1A differentiated with NGF cocktail and/or acetyl-L-carnitine arginyl amide into injured rat brain. Supported in part by a grant from the Moody Foundation and the Institute for Senescence, Pomezia, Italy.

AN ANATOMICAL STUDY OF FETAL RAT FRONTAL CORTICAL FRAGMENT GRAFTS TRANSPLANTED TO THE LESIONED MOTOR CORTEX OF ADULT RATS. B.W. Chopko*, T.J. Voneida. Dept. of Neurobiology, N.E. Ohio Univ. College of Medicine, Rootstown, Ohio 44272-9989, U.S.A.

The rostral motor cerebral cortical area of 13 adult rat hosts was unilaterally destroyed by aspiration. Within 3 hours after traumatization, fragments of embryonic day 15 (E15) fetal rat frontal cortical tissue were transplanted into the host lesion cavities. After a post-transplantation survival period of 2 to 33 weeks, grafts were anatomically investigated with Nissl, Weil, Bodian, HRP and Golgi techniques. Each graft was a viable, vascularized tissue mass attached to the host brain. Internal organization of graft parenchyma was never consistent with the laminar cytoarchitecture of normal cerebral cortex. Instead, graft cytoarchitecture was one of multiple subregions of varying cellular densities. Pyramidal and nonpyramidal shaped neurons were present. Dendrites both with and without spines were present, and typically, the apical dendrites of pyramidal shaped neurons were not oriented perpendicular to the pial surface. A spectrum of axonal morphologies developed, ranging from a loose feltwork of solitary axons to compact, curving fascicles. Beyond 2 weeks post-transplantation, all grafts contained myelin. Fetal cortical fragment grafts matured into tissue masses that contained cellular features consistent with cerebral cortex, but failed to develop the intercellular relationships, and hence the cytoarchitecture, of cortex. Further work is necessary in order to gain insight into the mechanisms responsible for the establishment of graft cellular organization.

TRANSPLANTED EMBRYONIC NEOCORTICAL NEURONS UNDERGO INCREASED DIFFERENTIATION IN SELECTIVELY NEURON-DEFICIENT CORTEX OF ADOLESCENT MICE. J.D. Macklis*, V.L. Sheen. Dept. Neurol., Prog in Neurosci, Harvard Medical School, Children's Hosp, Boston, MA, 02115

Embryonic day 17 (E17) neurons transplanted adjacent to photolytically induced pyramidal neuron-deficient cortex (lamina II/III) of early postnatal mice have revealed preferential migration and pyramidal phenotype within the lesioned zones. These results support involvement of potentially altered expression of environmental cues in guiding grafted neurons toward partial restoration of normal cytoarchitecture. The present experiments assess whether these normally developmentally age-specific cues may similarly guide directed repopulation in selectively lesioned older mice at times when non-specific developmental cues would no longer be expected.

Donor neocortical neurons from E14 or E17 mice prelabeled with combinations of fluorescent nanospheres and ^{3}[H] thymidine were transplanted into photolytically lesioned 4 or 6 week old mice (n=34). Photolysis of targeted pyramidal neurons followed unilateral injection of latex nanospheres (250 nl) containing the cytotoxic chromophore e_6, retrograde transport by callosal projection pyramidal neurons in contralateral laminae II/III and V, and transcranial laser illumination with a 670 nm continuous wave laser. After survival times of 1 to 6 weeks, serial sections were cut and processed for autoradiography, fluorescence, and routine histology. Preliminary results suggest that a subpopulation of transplanted neurons from both donor ages assume pyramidal morphology selectively within the neuron-deficient zone and extend processes. This suggests that E14 neurons "destined" to form deep cortical laminae may be influenced by a selectively altered environment to repopulate superficial laminae after normal development is completed. Supported by HD28478, MR Center grant HD18655, the Alzheimer's Association, and the Rita Allen Foundation.

HUMAN COGNITION: BLOOD FLOW/METABOLISM

394.1

PET STUDIES OF AUDITORY PROCESSING: PASSIVE PRESENTATION AND ACTIVE DETECTION. J.A. Fiez,*, P.A. Tallal, F.M. Miezin, S. Dobmeyer, M.E. Raichle, S.E. Petersen. Wash Univ., St. Louis, MO 63110, and Rutgers Univ. Newark, NJ 07102.

A positron emission tomography (PET) study of auditory processing was conducted using four classes of stimuli (vowels, syllables, words, and tone-triplets) and two auditory task conditions.

For each stimulus class, six different stimuli were presented ten times each. Activation of areas was assessed by defining areas of change on one group of subjects, and attempting to replicate these activations in other groups of subjects.

One set of subjects was instructed to listen passively to binaurally presented stimuli while fixating on a dot centered on a display monitor (passive task). Another set of subjects was trained to detect one of the stimuli within each set and to raise their left index finger whenever they heard the target stimulus, while also maintaining fixation (detection task). Maintaining fixation served as a control condition for all tasks (fixation task).

Areas which were more active during performance of the auditory detection than control task included: primary and surrounding auditory cortex, left prefrontal cortex, and the medial frontal cortex. A set of areas located bilaterally along the intraparietal sulcus were less active in the detection than control task. In contrast, none of the areas outside of auditory cortex were significantly changed during the passive task.

These results suggest that areas beyond the sensory processing regions are affected by task performance. Frontal regions might reflect processing necessary for accurate detection task performance; parietal regions may reflect a reduction due to shifting of attention from the visual fixation task to an active auditory task.

394.2

A PET STUDY OF VERBAL WORKING MEMORY. EA Raife, JA Fiez, ME Raichle, DA Balota, SE Petersen*. Wash. U., St. Louis, MO 63110.

A PET activation study was performed on 12 normal human subjects to examine areas related to working memory for verbal material. For the active tasks, subjects were serially presented 5 visual words or nonwords beneath a fixation cross prior to the start of the PET scan. Task instructions were to fixate while attempting to remember the items without verbalizing them or making mouth movements (monitored with EMG). Subjects recalled the items aloud when cued after the scan. Stimuli used in the active tasks were: 1) categorically-related nouns, 2) unrelated nouns, and 3) nonwords. Two control tasks were used: simple fixation, and a recitation control (subjects silently and slowly repeated the digits '12345' while maintaining fixation).

All active conditions relative to fixation showed increased flow in midline SMA and a right frontal area, and decreased flow at or near Rolandic cortex . The activations in the recitation control differed from those of the activation tasks; only a left Sylvian-insular region was activated in the recitation control as compared to fixation. While there was ceiling performance in the real word conditions, only half of the subjects recalled 100% of the nonwords. Activation differences found between good and poor performers included increased activation of a left premotor area in good performers in contrast to an anteromedial visual cortical area in the bad performers. There was a significant interaction between the two areas in the good vs. bad performers.

Several points are suggested by these results: 1) maintaining a representation of verbal material requires activation of certain areas (SMA, right prefrontal cortex) across many conditions; 2) inhibition of vocalization in these tasks produces decreases in Rolandic areas: 3) some areas differ with level of performance, suggesting a visual (bad performer) vs. phonological (good performer) strategy difference.

394.3

ACTIVATION OF LEFT POSTERIOR TEMPORAL CORTEX IN A VERBAL RESPONSE SELECTION TASK IS RATE DEPENDENT. ME Raichle*, JA Fiez, TO Videen, SE Petersen. Wash. U. Sch. Med., St. Louis, MO 63110.

The cerebral cortex in the area of the left temporoparietal boundary has been thought to play a significant role in word comprehension since the original observation of Wernicke in the 19th century. It was surprising, therefore, that initial PET activation studies, in which subjects were asked to say aloud an appropriate verb for visually-presented nouns, failed to detect activation in this area of cortex. As a control state, subjects were asked to repeat aloud visually-presented nouns, and the nouns were presented in both conditions at the rate of 1 per second. Five non-temporal areas showed significant activation: anterior cingulate, left prefrontal cortex and right cerebellum increased, while Sylvian-insular cortex decreased bilaterally.

A second study, using the same conditions, was performed at a rate of 1 word every 1.5 seconds. At this slower rate, there was a significant activation in the left posterior temporal cortex (x=59, y=-25, z=0); Talairach et.al, 1967) accompanied by the previously noted changes. Several explanations are suggested by these results including: 1) the left posterior temporal region acts as a short-term verbal memory buffer and is more active because the longer presentation time encourages longer storage times; 2) the region may be active because the slower presentation time allows more active and complete semantic processing above that demanded by the verb presentation task, per se. Other investigations have also suggested that slower word presentation rates produce greater temporal activation (Marrett et. al , Soc. Neuro. Abs, 16:27).

These data provide information into the role of left posterior temporal cortex in language processing, and also emphasize the crucial nature of paradigm design in the interpretation of imaging studies in the human brain.

394.4

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING STORY LISTENING. B. Mazoyer*, S. Dehaene, N. Tzourio, N. Murayama, L. Cohen, O. Levrier, G. Salamon, A. Syrota, J. Mehler. S.HF. Joliot, CEA, 91406 Orsay, and L.S.C.P., C.N.R.S. & E.H.E.S.S., Paris, France.

We have investigated regional cerebral blood flow (rCBF) changes during continuous speech listening in 10 right-handed French subjects. Each had six rCBF measurements using PET and [15O]-water, a series of three conditions being replicated twice: rest, listening to a text in a language unknown to them (Tamil), listening to a text in French (first protocol, N = 5); rest, listening to a list of French words, listening to a text in French (second protocol, N = 5). Auditory stimuli were presented binaurally over earphones. RCBF images were aligned with individual magnetic resonance images (MRI) and normalized CBF values within anatomically defined regions of interest were then compared across the three experimental conditions in each protocol (ANOVA).

Both left (LST) and right (RST) superior temporal gyri were activated in all conditions of auditory stimulation ($p<0.0005$). They were the only active regions during listening to stories in Tamil. A left inferior frontal gyrus activation (LIF, $p<0.01$) was found during word list listening. Listening to the stories in French in the first protocol activated the left and right temporal poles (LTP, $p<0.0001$; RTP, $p<0.0005$), and the left middle temporal gyrus (LMT, $p<0.005$). These activations were replicated in the second protocol (LTP: $p<0.001$; RTP: $p<0.005$; LMT: $p<0.005$). When pooling the two samples for this condition, extra-temporal activations were also found in LIF ($p<0.05$) and in left Brodmann's area 8 (LBA8, $p < 0.05$).

These results indicate that, besides regions devoted to single-word comprehension, story-level processing activates additional areas. Experiments are under way to separate the putative role of syntactic parsing, verbal memory and semantic integration.

394.5

FUNCTIONAL LOCALIZATION OF HUMAN OLFACTORY CORTEX WITH POSITRON EMISSION TOMOGRAPHY. R.J. Zatorre*, M. Jones-Gotman, A.C. Evans and E. Meyer. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B4.

The cortical representation of human olfactory processing mechanisms was studied by examining regional cerebral blood flow changes with positron emission tomography during olfactory stimulation. Eleven normal right-handed subjects were presented with a series of eight odorants birhinally during the activation phase; a baseline condition consisted of inhalation with no odor present. We used the paired-image subtraction procedure, averaging the responses across subjects; anatomical localization was provided by matched magnetic resonance imaging. The principal result was strong activation ($t>3.6$ in all cases) at the junction of the inferior frontal and temporal lobes bilaterally, corresponding to the piriform cortex, and unilaterally, in the right orbitofrontal cortex. The results agree with anatomical and behavioral data implicating these regions in olfactory processing, and indicate a functional asymmetry favoring the right orbital area in olfaction.

394.6

NETWORK MODELS FOR MAPPING COGNITIVE BRAIN FUNCTION USING POSITRON EMISSION TOMOGRAPHY (PET) AND REGIONAL CEREBRAL BLOOD FLOW (rCBF). R. Horwitz* and P. Kirschner. Lab. Neurosci., Natl. Inst. on Aging, NIH, Bethesda, MD 20892.

Understanding how the brain mediates cognitive behavior has been aided by the use of PET and [O15]-water to measure rCBF during specific cognitive tasks. However, given that multiple regions often are activated during specific tasks, the complex interrelationships that occur during cognition need to be understood in terms of neural networks. The starting point for such analyses is to use correlations among rCBF in different brain loci to investigate brain interactions (e.g., Horwitz et al., J. Cogn. Neurosci., in press; Friston et al., Proc. R. Soc. London B, 1991). However, the appropriate way to perform such analyses, and to use the results to generate network models to account for the cognitive behavior under study, is not clear. We recently have developed an explicit network model for simulating rCBF/PET data that allows one to examine brain functional interactions (Horwitz, Abstr. Soc. Neurosci. 17, 540, 1991). Here, we use this simulation model to determine some of the conditions under which two different correlational approaches (Horwitz et al., which is a within-task design; Friston et al., which is an across-task design) produce similar or divergent results. Because the functional couplings between brain regions are specified in the model, we demonstrate for those cases with divergent results that the within-task correlational method better reflects the underlying functional configuration among the brain regions.

394.7

AGE-RELATED CHANGES IN REGIONAL CEREBRAL BLOOD FLOW (rCBF) ACTIVATION DURING VISUAL SELECTIVE ATTENTION. CL Grady*, B Horwitz, JA Salerno, E Wagner, SI Rapoport, MB Schapiro, LG Ungerleider, JV Haxby. Lab. of Neurosciences, Nat. Inst. on Aging, Bethesda, MD 20892.

Nine young (27 ± 3 yrs) and 6 old subjects (67 ± 3 yrs) performed visual tasks during positron emission tomographic measurements of rCBF using [15O]water: face and location matching without selective attention (NSA, where stimuli differed between tasks), and with selective attention (SA, where stimuli were the same for both tasks but task demands differed). Young subjects showed no change in reaction time in SA vs. NSA; old subjects were slower in both NSA tasks than the young ($p<0.001$) and showed further slowing during SA for faces ($p<0.02$). Image data were analyzed using Statistical Parametric Mapping. Neither group showed significant rCBF increase in SA vs. NSA for either face or location matching. However, a significant age by condition interaction was seen for face matching, in which the old group showed a larger SA-NSA difference in rCBF than the young ($p<0.005$) in left hemisphere lingual, fusiform and inferior occipital gyri, and right hemisphere fusiform, superior and mid temporal, and inferior frontal gyri, insula and cerebellum. During location matching, old subjects had a larger SA-NSA rCBF difference than did young subjects ($p<0.005$) in left hemisphere parahippocampal and superior temporal gyri, and cerebellum. Age-related differences in rCBF during visual SA thus are task dependent. During SA for faces, old subjects show greater use of ventral occipital areas known to mediate face perception. During SA for location, old subjects show involvement of parahippocampal cortex, an area not previously identified in perception of location, which may indicate the use of memory systems by older subjects to perform spatial attention tasks.

394.8

THE EFFECTS OF CLONIDINE ADMINISTRATION ON REGIONAL CEREBRAL BLOOD FLOW AND COGNITION IN THE ALCOHOLIC KORSAKOFF SYNDROME R.E. O'Carroll, A. Moffoot, K.P. Ebmeier, N. Dougall, C. Murray, G.M. Goodwin, G. Fink*. MRC Brain Metabolism Unit, Royal Edinburgh Hospital, Edinburgh, EH10 5HF, Scotland, UK.

McEntee & Mair (TINS 1990 13, 340-344) reported that administration of the α_2 agonist clonidine improved memory in the Alcoholic Korsakoff Syndrome (AKS). In an attempt to replicate and extend these findings, eighteen AKS subjects were recruited for a two phase trial. In phase 1, half the subjects received an acute infusion of 150μg/kg of clonidine in a single dose, half received an infusion of saline. All subjects underwent functional neuroimaging using Single Photon Emission Computerised Tomography (SPECT) before and 30 minutes following infusion. Clonidine infusion resulted in a highly significant increase in anterior cingulate cerebral blood flow, with an associated improvement in verbal fluency. Subjects then entered phase 2, a chronic double-blind placebo-controlled cross-over trial of clonidine 0.3mg twice daily for two weeks, and matched placebo for two weeks, incorporating an intervening two week 'wash-out' period. Detailed neuropsychological assessments were carried out at the end of each two week treatment period, including measures of anterograde memory, attention, staff ratings of cognitive failures and 'frontal lobe' measures. Clonidine treatment had no significant advantage over placebo on any of the cognitive measures employed. We conclude that acute administration of clonidine activated the thalamic-anterior cingulate system, resulting in an improvement in selective attention in general, and target detection in particular. However, chronic treatment resulted in no cognitive enhancing effect, possibly as a consequence of receptor down-regulation.

394.9

PET ACTIVATION STUDIES COMPARING BLOOD FLOW ACROSS FOUR MEMORY TASKS. T.A. Blaxton, S.Y. Bookheimer, T. Zeffiro, W. Gaillard and W. Theodore*, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

Blood flow was measured following H_2O^{15} injections in 14 human subjects using a Scanditronix II PET scanner. Following study phases in which word lists were presented, subjects performed implicit and explicit versions of word association and word fragment completion memory tasks. Memory-specific activation was assessed against control tasks which were identical to the memory tests except that they contained no previously studied items. Mesial temporal regions showed left hippocampal activation and right hippocampal deactivation for the implicit and explicit versions of fragment completion. The opposite pattern was observed for the word association tasks, however, which produced left hippocampal deactivation and right activation. Deactivation was also observed laterally for implicit and explicit word association in the left middle temporal gyrus. These and other deactivations were interpreted as a possible neurological correlate of "priming" or "transfer" of learning operations from encoding to retrieval.

394.10

INCREASED ATTENTIONAL EFFORT DURING A PITCH DISCRIMINATION TASK ELEVATES REGIONAL BRAIN GLUCOSE UTILIZATION H.H. Holcomb*, B. Gordon, H.L. Loats, E. Gastineau, D. Medoff, C.A. Tamminga University of Maryland, MPRC, Baltimore, MD 21228, Johns Hopkins Medical Institutes, Baltimore, MD, 21205, Loats Associates, Inc., Westminster, MD

The neural mechanisms associated with different aspects of task performance, such as accuracy, skill, practice, attention, and fatigue, are currently the subject of intense investigation. Among the problems complicating these investigations is the likelihood that these different aspects interact in some yet-to-be determined fashion. For example, attention can be expected to vary in the course of a task lasting for 20-30 minutes, yet skill and practice can also be expected to vary.

The patterns of regional cerebral metabolic activity associated with two levels of difficulty in an auditory tone discrimination task were assessed. Four normal subjects were asked to respond with their left hand when they heard a tone of one frequency, and with their right hand when they heard a tone of the other frequency (750 Hz vs 1500 Hz). The two tones were presented at the same loudness. The discrimination was made DIFFICULT by addition of white noise; in the EASY condition, there was little or no white noise. Noise level was varied to maintain two different levels of accuracy (75% versus 95%) and response times for the DIFFICULT and EASY conditions during the course of the task. The DIFFICULT discrimination session promoted greater glucose use in the left middle temporal, left temporo-occipital and right inferior frontal cortices than did the EASY condition. Significant individual differences in the patterns and extent of regional glucose utilization were noted.

394.11

HERITABILITY OF COGNITIVELY-RELATED CEREBRAL FUNCTION: A POSITRON EMISSION TOMOGRAPHY STUDY OF MONOZYGOTIC TWINS. Karen Faith Berman*, Jill L. Ostrem, Daniel Z. Press, Christopher Randolph, Daniel R. Weinberger. Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032.

To examine the role of genetic determination in the pattern of cerebral response to cognitive challenges, we used the oxygen-15 water method for measuring regional cerebral blood flow (rCBF) with PET to study five pairs of healthy monozygotic twins (two female and three male pairs; mean age 31 years, range 19 to 54). rCBF was measured while subjects performed neuropsychological tests including the Wisconsin Card Sorting Test (WCS), which is a sensitive indicator of the integrity of the dorsolateral prefrontal cortex in man, and Raven's Progressive Matrices (RPM), which is another complex abstract reasoning task that may involve more posterior cortical areas. Sensorimotor control task were designed to be similar to each neuropsychological task in visual characteristics and response mode (verbal for RPM and finger movement for the WCS). rCBF values were normalized (i.e. expressed on a pixel-by-pixel basis as a percent of the whole brain mean). The similarity of regional brain function within twin pairs was assessed by determining the correlation between first- and second-born twins for each of a variety of brain regions.

Significant ($p \leq .05$) correlations were found: for WCS-right inferior frontal gyrus ($r = .98$, $p = .002$), right anterior cingulate ($r = .89$, $p = .04$), and left thalamus ($r = .91$, $p = .03$); for the WCS control-none; for RPM-left inferior frontal gyrus ($r = .89$, $p = .04$), right temporal cortex ($r = .96$, $p = .008$); and for RPM control-right inferior frontal gyrus ($r = .92$, $p = .02$), left anterior cingulate ($r = -.97$, $p = .005$), and right temporal cortex ($r = .87$, $p = .05$). These data may reflect the differential neural systems subserving the various cognitive operations involved in these tasks and may further suggest a high degree of heritablity in cognitively related function in the implicated areas.

394.12

SEX DIFFERENCES IN CEREBRAL BLOOD FLOW DURING SPEECH. S.Y.Bookheimer*, T.A. Zeffiro, W. Gaillard , T. A. Blaxton, and W. Theodore, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

Gender differences in cognitive skills and aphasia patterns have led to the speculation that the sexes differ in cortical language organization. To test this hypothesis, 16 male and female subjects underwent Positron Emission Tomography to measure cerebral blood flow while reading or naming objects. We found both general and task-specific differences in blood flow patterns. On all tasks, females showed greater activity in the posterior cingulate, while males showed stronger activation in motor areas. Females had greater left mid-occipital and angular gyrus activity during reading, while males showed increased mid-temporal activity. Left hemisphere area 44 (Broca's area) appeared more anterior among female subjects. Both groups showed strong left hemisphere dominance on language tasks. Contrary to some theoretical accounts, there was no evidence for relatively greater bilaterality in either group.

DEGENERATIVE DISEASE: PARKINSON'S I

395.1

NEUROTROPHIC ACTIVITY IN HUMAN CEREBROSPINAL FLUID (CSF) IS ELEVATED IN PARKINSON'S DISEASE. S.J. Yu*, L.R. Ptak, E.S. Lo, C.M. Buhrfiend, and P.M. Carvey Rush Medical College, Rush-Presbyterian St. Luke's Medical Center

Human striatal extracts added to rat rostral mesencephalic tegmentum (RMT) cultures stimulates dopamine (DA) neuron growth and neurite extension. This growth promoting activity (GPA) is elevated in Parkinson's disease (PD) striatal extracts, suggesting a compensatory trophic response to DA neuron loss. Initial findings suggest that GPA is soluble and diffusible. Therefore, we postulated that human CSF may also contain GPA. Ventricular CSF from PD and non-PD patients (n=3 for each group) was crudely separated into >10kDa and <10kDa fractions using Centricon 10 microconcentrators. Fractions from each patient were subsequently diluted (1:4) using Hank's Balanced Salt Solution and 50 μl added to freshly plated RMT cultures (8 replicates / patient) growing in 200 μl defined media. 24 hr. later, the number of neurons with processes (dependent measure of GPA) was counted by an individual "blinded" to treatment history. CSF from PD patients consistently exhibited significantly higher GPA than non-PD patients as well as BSA treated controls (PD = 104, non-PD = 27, BSA = 11; $F=31.01$, $p<0.001$). Additionally, post-hoc comparisons revealed a significant difference in GPA between PD and non-PD groups and between non-PD and BSA. GPA was only observed in >10kDa fractions. A >10kD sample from a non-PD patient was separated into 7 fractions using FPLC and added to RMT cultures. GPA was significantly elevated in two of these fractions.These data suggest that 1) the factor(s) responsible for striatal GPA are also present in the CSF of normal patients, 2) CSF-derived GPA is elevated in PD similar to striatal-derived GPA, and 3) this factor(s) is >10kDa and may be amenable to further fractionation and purification. Studies are in progress to ascertain the approximate MW (ion-exchange chromatography) as well as the cellular specificity of CSF-derived GPA. Preliminary observations indicate that the cells with processes are tyrosine hydroxylase positive implying specificity for DA neurons. If confirmed, CSF-derived GPA may be useful in the diagnosis of PD.

395.2

STRIATAL-DERIVED GROWTH PROMOTING ACTIVITY IS DECREASED IN THE AGED RAT: IMPLICATIONS IN PARKINSON'S DISEASE. P.M. Carvey*, L.R. Ptak, D.K. Sierens, S.J. Yu, and Donghui Lin. Rush-Presbyterian St. Luke's MC, Chicago IL 60612

Extracts of adult human and rat striatal tissue stimulate the growth of dopamine (DA) neurons in primary culture. This growth promoting activity (GPA) is elevated in patients with Parkinson's disease (PD). We have proposed that the increased GPA in the PD brain represents a compensatory response to the loss of DA neurons which could slow disease progression by stimulating DA terminal sprouting. However, if striatal GPA is decreased in the aged brain, compensatory increases resulting from DA neuron loss may be inadequate to overcome PD progression. In an effort to determine if GPA varies with age, we evaluated the effects of striatal and cerebellar extracts from 2, 8, 16, and 24 month old rats (n=16) on the growth of low cell density (3,500 cells/well), E15.5 rostral mesencephalic tegmentum, dissociated, primary cultures growing in defined media. Cultures incubated with extracts from 2 month old rats possessed significantly more viable, neuron specific enolase immunoreactive neurons with processes (263%) then cultures incubated with extracts from 24 month old animals ($F=8.06$). Moreover, neuron viability in culture was inversely correlated with age ($r = -0.699$). In contrast, extracts of the cerebellums from these animals possessed very little GPA which was not correlated with age. If DA neurons in vivo are dependent on this trophic activity for continued viability, the age related decline in this GPA may contribute to DA neuron loss. Furthermore, a compensatory increase in GPA brought about by the DA neuron loss of PD may be inadequate to maintain DA neuron viability provided that striatal GPA in humans exhibits a similar relationship to age. An age-related decline in striatal-GPA would therefore predispose older patients to PD.

395.3

MPTP INDUCED CHANGES IN STRIATAL D2-LIKE DOPAMINE RECEPTORS WITHOUT CHANGES IN MESSENGER RNA. R. D. Todd*, J. Colvin, J. Carl, J. S. Perlmutter[1], Departments of Psychiatry and Genetics, and Department of Neurology and Neurosurgery[1], Mallinckrodt Institute of Radiology[1], Washington University School of Medicine, St. Louis, MO 63110.

MPTP induced destruction of dopamine producing cells has been used both as a model for Parkinson's disease and as a denervation agent for studying the regulation of dopamine receptors. In the present study we have determined the temporal pattern of receptor expression in MPTP treated primates.

Baboons were unilaterally lesioned by intracarotid artery injection of MPTP resulting in a hemilateral Parkinsonian syndrome. Striata from injected animals were analyzed for tritiated spiperone binding, messenger RNA levels for dopamine D2, D3, and D4 receptors and dopamine content. In both caudate and putamen there was an increase of two to seven-fold of eticlopride displaceable tritiated spiperone membrane binding which reached peak levels in about 100 days and declined to baseline levels by about 400 days following MPTP injections. These increases and decreases in binding site number occurred in the presence of 98% reductions in dopamine in the ipsilateral caudate and putamen. Putamen messenger RNA levels were quantified by reverse transcription coupled to polymerase chain reaction amplification using receptor specific oligonucleotides. In contrast to results for D2-like binding sites, there were no observable changes in the amounts of messenger RNAs for D2, D3, or D4 receptors. These studies suggest that MPTP induced changes in striatal D2-like receptors are secondary to translational or post-translational effects on receptor number.

395.4

THE RELATIONSHIP BETWEEN ONSET OF SYMPTOMS AND DOPAMINE FIBER LOSS STUDIED BY 11C-CFT AND PET IN A PRIMATE MODEL OF PARKINSON'S DISEASE. P. Hantraye*¶, A.-L. Brownell†, U. Wüllner¶, D. Elmaleh†, R.D. Spealman§, G.L. Brownell†, B.K. Madras§ and O. Isacson¶, †Department of Neurology, Harvard Medical School and Neuroregeneration Laboratory, McLean Hospital, MRC 119, Belmont, MA 02178, ¶Dept. of Nuclear Radiology, Massachusetts General Hospital, Boston, §Dept. of Psychiatry, Harvard Medical School, NERPRC, Southborough, MA 01772-9102

A progressive degeneration of mesencephalic dopamine neurons was induced in Macaca fascicularis monkeys by chronic administration of MPTP (0.5-0.7 mg/kg i.v. at weekly intervals for up to 50 weeks). The progression of striatal dopamine fiber loss was determined in vivo by positron emission tomography (PET) and 11C-CFT (a specific dopamine transporter ligand) as a marker. The behavioral alterations produced by the chronic MPTP treatment was followed in parallel with PET studies.

In the PET experiments, chronic MPTP injections resulted in a progressive decrease of 11C-CFT specific binding in striatal regions. This decrease was characterized by a rapid initial reduction of 11C-CFT specific binding (up to 70 % of the pre-treatment values), in both caudate and putamen, followed by an apparent plateau lasting several months, and concluding with a more severe reduction in the putamen (91%) than the caudate. The animals remained largely asymptomatic during the initial decline and plateau of dopamine fiber degeneration. During the third final phase of 11C-CFT reduction in the putamen, parkinsonian symptoms such as hypokinesia, bradykinesia and tremor progressively appeared.

The present study using 11C-CFT as an index of dopamine terminals, indicates that non-human primates remain asymptomatic despite more than 70% reduction in striatal dopamine terminals as assessed by PET. Parkinsonian symptoms appeared when putaminal 11C-CFT was specifically reduced to less than 10% of control values.

MODELING CHAOTIC DOPAMINERGIC NEURODYNAMICS. J. Sale, S.H. Price, A.D. Will and J.M. Tosk*. Neurology and Psychiatry Services, Jerry L. Pettis Veterans' Affairs Medical Center, Loma Linda, CA and Depts. of Neurology and Psychiatry, Loma Linda University School of Medicine, Loma Linda, CA 92350.

A nonlinear dynamical model of the nigrostriatal dopaminergic system was proposed by King, Barchas and Huberman (PNAS *81*:1244, 1984) who demonstrated the model's potential for explaining the rapid fluctuations in movement observed among certain Parkinson's patients following chronic treatment with L-dopa. We have explored the complex dynamics of a modification of this model. The modifications may be equated with biological variables involved in the pathophysiology of Parkinson's disease. We show that by varying one or both of two parameters, x, representing mean firing rate of nigrostriatal neurons and s, a variable proportional to postsynaptic dopamine D_2 receptor density, the system exhibited a wide range of dynamics. When the variable x, representing the mean firing rate, was decreased we observed the appearance of a novel family of solutions which exhibited a decreasing incidence of chaotic states. Additionally, we observed the chaotic regime breaking up into a collection of discrete groups of firing rates. When the variable s, which is proportional to dopamine D_2 receptor density, was decreased we observed a shift in dynamics from chaotic to nonchaotic states. On this basis we predict that premorbid nigrostriatal dopamine D_2 receptor densities will influence sensitivity to chaotic dynamics and may influence susceptibility to Parkinson's disease and other movement disorders. We believe these findings may also have important implications in light of recent work being done in the area of experimental control of chaotic dynamics.

PARKINSONIAN SIGNS IN MPTP-TREATED MONKEYS ARE ALLEVIATED BY THE HIGH EFFICACY D_1 DOPAMINE RECEPTOR AGONIST SKF 81297. B.K. Madras, D. Elmaleh, P. Meltzer, D.E. Lee-Parritz, P. Hantraye, O.Isacson*, G.L. Brownell and A.L. Brownell. Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772, Organix, Inc. Woburn, MA, 01801, Massachusetts General Hospital, Boston, 02115.

The therapeutic potential of a high efficacy D_1-selective dopamine receptor agonist was evaluated in two cynomolgus monkeys (*Macaca fascicularis*) treated with the neurotoxin MPTP (3 doses of 0.6 mg/kg) and maintained with a D_2 dopamine receptor agonist quinelorane. Dopamine nerve terminal degeneration was > 90% as monitored by striatal accumulation of a positron emission tomography (PET) marker for dopamine terminals, [^{11}C]CFT (WIN 35,428). The D_1-selective drug SKF 81297 (0.3 or 1.0 mg/kg) reduced postural rigidity and increased mobility in both monkeys. Involvement of D_1 dopamine receptors was implicated as SKF 81297 eliminated striatal accumulation of the D_1 receptor PET ligand [^{11}C]SCH 39166. In a single experiment, the combination of ineffective doses of quinelorane and SKF 81297 also alleviated Parkinsonian signs. High efficacy, selective D_1 dopamine receptor agonists may be useful for reducing Parkinsonian signs when dopamine levels are severely depleted and may allow for dose reduction of D_2 agonists. ON-OFF EFFECTS OF DIRECT DOPAMINE AGONISTS IN UNILATERAL NIGRAL RATS. P.B. Silverman*, Dept. of Psychiatry, University of Texas Health Sci. Ctr., Houston, TX 77030.

As Parkinson's disease and its treatment progress, the response to pharmacotherapeutic agents becomes increasingly erratic with the development of dyskinesias and "on-off" effects. In the unilaterally 6-hydroxydopamine lesioned rat, with respect to extent of dopamine depletion, a condition of advanced hemi-parkinsonism exists. Here lesioned rats were tested repeatedly with selective direct-acting dopamine agonists and their rotational (circling) response recorded. A remarkable degree of response fluctuation was seen when the selective D2 agonist, bromocriptine, or one of the selective D1 agonists, SKF-82958 or SKF-77434, was administered for a few days. In consecutive daily sessions responses of individual animals varied from zero to hundreds of rotations per hour. When treated daily for 2 weeks with SKF-77434, some rats showed what appeared to be a 2 to 3 day cycle of response fluctuation. In others, as well as in the group as a whole, no consistent pattern was obvious, other than the general appearance of an all-or-none phenomenon. Response fluctuations continued when treatments were spaced at 3 day intervals. This approach may prove useful for the study of "on-off" effects.

RESPONSE TRAJECTORIES AND ACCURACY OF NORMAL AND PARKINSONIAN SUBJECTS IN A POINTING TASK. W. A. Hening*[1,2], J. Gordon[3], and M. Rolleri[1], Neurology Depts, VAMC[1], Lyons, NJ & UMDNJ-RWJohnson Med Sch[2], New Brunswick, NJ; and Ctr for Neurobiology & Behavior[3], Columbia Univ, NY, NY

We used a digitizing tablet based pointing task developed by Gordon and Ghez (CSH Symp Quant Biol 55:837-847, 1990) to examine how sensory information and instructions influence basic task performance in normal middle aged adults and patients with Parkinson's disease. With arms hidden, 9 subjects (6 normals, aged 39 to 62, and 3 patients with Parkinson's disease (PD), Hoehn and Yahr stages I or II, aged 61-72) moved a cursor to 6 distances (2.4 to 26.4 cm) in an oblique right or leftward direction to match targets seen on a computer monitor. Without reaction time constraints, subjects were told to make uncorrected, straight movements. In 6 different session types, accuracy, brief movement time or both were stressed while we provided or withheld continous feedback of hand position and/or knowledge of results. All subjects (43 sessions to date) reached different distances by scaling both velocity and duration, although velocity had a quantitatively greater role (ascertained by multiple regression) in every session but one. Not only velocity and duration, but acceleration and time to peak acceleration were scaled to distance. PD patients had trajectory formation and accuracy similar to normals, but one patient (Stage II) had prolonged trajectories which further slowed and undershot distant targets if knowledge of results was unavailable. Therefore, basic performance in the task may be normal in the PD subjects while still revealing evidence of both bradykinesia (slowing) and excessive dependence on visual cues.

DEMENTIA IN PARKINSON'S DISEASE: CORTICAL INVOLVEMENT WITH A FRONTAL PREDOMINANCE USING THE IMMUNODETECTION OF ABNORMAL TAU PROTEINS . P. Vermersch*[1], A. Delacourte[1], F. Javoy-Agid[2], J.J. Hauw[3], Y. Agid[2]. [1]U 156 INSERM, 59045 Lille, [2]U 289 INSERM and [3]Lab. Neuropathologie R. Escourolle, 75651 Paris, France.

The dementia, frequently associated with Parkinson's Disease (PD), is generally considered to be of the subcortical type but the high frequency of Alzheimer pathology in PD have suggested that dementia may be due to coexisting Alzheimer's Disease (AD). In this study we analyzed the neurobiochemical basis of the cortical lesions from demented PD patients.

Material and methods: Cortical samples from 24 parkinsonian patients not demented and with various degree of dementia were analyzed by western blotting. An anti-Paired Helical Filaments antibody was used for the immunodetection of the abnormally phosphorylated Tau proteins named Tau 55, 64 and 69, known to be specific and reliable biochemical markers of the neurofibrillary degeneration of the Alzheimer type.

Results: The frequency of immunodetection of the abnormal Tau triplet was statistically higher in the demented subgroups than in the non demented subgroup of PD in the prefrontal ($p < 0.05$), the temporal ($p < 0.01$) and the entorhinal cortex ($p < 0.02$) but not in occipital and cingular cortex. A quantification of abnormal Tau triplet by densitometry showed that, in opposition to the results obtained in AD patients, the intensity was higher in the prefrontal than in the temporal cortex of most of the demented PD patients.

Conclusion: This study: (i) gives a biochemical evidence for the presence of AD changes in demented parkinsonian patients; (ii) suggests that lesions of the prefrontal cortex may significatively contribute to the occurence of cognitive changes at least in some PD patients.

PROBLEM-SOLVING ABILITY IN PARKINSON DISEASE
R.F. Zec*, M. McCool, E. Grames, E. Landreth, A. Hasara, W. Fraizer, S. Fritz, S. Wairman, J. Belman, R. Harris, C. O'Connell, R. Robbs, B. Manyam and R. Elble. Alzheimer Disease and Related Disorders Center, So. Illinois Univ. Sch. of Med., Springfield, IL 62708.
Problem-solving ability in Parkinson disease (PD) patients, elderly control subjects, and young control subjects was studied using the Halstead Category Test. The subjects were 41 PD patients, 40 age-matched elderly controls, and 46 young controls. Errors on the Category Test did not differ significantly (t tests) between the PD group (M=62.6) and their age- and educationally-matched control group (M=65.9). The PD group and the elderly control group did make significantly more errors than the young control group (M+SD: 36.6+20.4). The degree of impairment was -1.3 SD difference from the young control group mean for the elderly control group and -1.4 SD for the PD group. The only indication of greater problem-solving difficulty in the PD group was the somewhat greater percentage of PD patients (43%) as compared with elderly controls (29%) who were impaired by ≥2 SDs from the young control group mean. However, an equal percentage of PD patients and elderly controls (26%) scored above the mean of the young control group. Our findings do not support previous reports of impaired complex problem-solving ability in PD patients.

DOES LEVODOPA INFLUENCE THE SPEED OF COGNITIVE PROCESSES IN PARKINSON`S DISEASE? G.Ransmayr*, G. Künig, D. Soucek, E. Sofic, P. Riederer. Dept. of Neurology, A-6020 Innsbruck; Dept. of Psychiatry, Neurochemistry Unit, D-7800 Würzburg.
The aim of the study was to determine whether the speed of serial comparisons of sets of 2,3 or 4 memorized digits with a target digit (Sternberg paradigm) is different in "on" and "off" states of Parkinson`s disease and related to the levodopa plasma level. 18 parkinsonian patients (age 61.3±10.1, disease duration 6.8±3.1 years) were tested in drug-free states ("off") and in states of optimal response to oral levodopa ("on"). Central processing time was not different in "on" and "off" (134±129 and 151±148 msec) and significantly slower in "off" than in 13 age-matched normal controls (82±20 msec, Mann-Whitney U test). Moreover, central processing time was not related to the levodopa plasma level and the motor scores (Spearman rank correlation). In 3 patients significant improvement of arousal was observed under levodopa (affect-arousal scale of Bond&Lader) and in parallel marked acceleration of cognition suggesting that levodopa might have an activating effect on cognition in single patients with deficient arousal in "off" states.

395.12

MAGNETIC RECORDING OF RESTING TREMOR RELATED BRAIN ACTIVITY IN PARKINSON'S DISEASE J. Volkmann, F. Lado, A. Ioannides, A. Mogilner, M. Joliot, U. Ribary, E. Fazzini*, R. R. Llinás Center for Neuromagnetism, Dept. of Physiology and Biophysics, New York University Medical Center, New York, NY 10016.

A 14- and a 37-channel magnetoencephalography (MEG) system (BTi) are being used to evaluate the spatial and temporal organization of dynamic brain activity accompanying resting tremor in patients suffering from early stage idiopathic Parkinson's disease. The study is based on the simultanous recording of tremor (acceleration of the middle finger and the rectified-filtered EMG of the superficial flexor and extensor digitorum muscles) and spontanous neuromagnetic activity over 37 to 56 positions of the contralateral hemisphere. Data acquisition is performed at a sample rate of 512 Hz. In a first analytic step, the frequency and phase relationship between tremor and neuromagnetic signals is studied by cross spectral analysis of 200 subsequently recorded epochs of 3 sec duration. In a second analytic approach, approximately 1000 overlapping epochs of 1 sec duration triggered on flexor EMG onset are cut out of the original recordings and averaged. The resulting averaged signals are used for source localization by means of current dipole analysis and recently introduced Magnetic Field Tomography (Ribary et al, Natl Acad Sci 1991 88 11037-11041). Results are displayed on 3-D MRI reconstructions of the patient's brain.

Preliminary analysis of 10 patient recordings indicates the presence of synchronized tremor related neuromagnetic activity over wide areas of the frontal, parietal and temporal cortex. The magnetic field pattern suggests source localizations in premotor, motor and sensory cortex. Magnetic Field Tomography (MFT) obtained in 3 patients shows a rhythmic subsequent activation of frontal areas, precentral and postcentral gyrus with each tremor beat. Analysis of diencephalic magnetic activity using MFT is currently under way .

Our MEG data demonstrates that this technique can be used for a non-invasive monitoring of the functional network underlying resting tremor in Parkinson's disease.

INGESTIVE BEHAVIOR: NPY, GALANIN AND INSULIN

396.1

REFEEDING AFTER STARVATION INCREASES HYPOTHALAMIC NEUROPEPTIDE Y (NPY) MESSENGER RNA. R. Briones-Urbina* and S.R. George. Depts of Medicine and Pharmacology, University of Toronto, Toronto, Ont, CANADA M5S 1A8.

NPY is a potent orexigenic when administered into the CNS. Physiologically, it appears to be involved in promoting eating behavior. Hypothalamic NPY gene regulation in response to starvation and re-feeding was studied in male Sprague Dawley rats to assess a possible role of NPY not only in the initiation of feeding but also in the maintenance of feeding and body weight. Animals weighing 180-200 g at the onset of the study were housed in environmental rooms in 12h dark/light cycles, with free access to chow and water, handled and weighed daily. After an adjustment period of 2 weeks, groups of rats were starved for 12, 24, 48 and 72 h with free access to water. Weight losses of 10, 17, 23 and 30% occurred in each group respectively. Hypothalamic NPY mRNA levels were detected by Northern blotting analysis using a 32P labelled oligodeoxynucleotide probe complementary to bases 1623-1669 of the rat NPY gene. Increased NPY mRNA was detected as early as 12h, peaked at 48h and remained elevated until 72h. Groups of rats were then starved for 24 or 48h followed by free access to chow and water for a further 12, 24 and 48h. After 12 and 24h of refeeding following both 24 and 48h of starvation, there was a further increase in NPY mRNA levels coinciding with weight regained of up to 80%, but no further increase was noted after 48h refeeding. We report time-dependent further increases in hypothalamic NPY mRNA levels in refeeding following starvation coinciding with the period of enhanced food intake, rapid weight gain and reversal of body weight to prestarvation levels. These results suggest a physiological role for NPY in the initiation and maintenance of feeding behavior and likely in the control of body weight as a reflection of energy balance.

396.2

HYPOTHALAMIC EXPRESSION OF NEUROPEPTIDE Y AND GALANIN mRNA IN THE GOLDEN-MANTLED GROUND SQUIRREL, A HIBERNATING MAMMAL
T. Boswell, G.J. Kenagy, A.J. Sipols, D.G. Baskin* and M.W. Schwartz. Depts. of Biological Structure, Medicine and Zoology, Univ. of Washington, Seattle, WA 98195 and V.A. Medical Center, Seattle, WA 98108.

Neuropeptides such as neuropeptide Y (NPY) and galanin may play a role in regulating circannual cycles of feeding in the golden-mantled ground squirrel (Spermophilus saturatus). To investigate this, we analyzed the distribution of NPY and galanin mRNA in ground squirrel brain using in situ hybridization histochemistry. As in rats and mice, NPY mRNA was abundantly expressed in the hypothalamic arcuate nucleus and was also present in the cortex, hippocampus and reticular nucleus of the thalamus. Hypothalamic galanin mRNA was concentrated in the arcuate nucleus and the dorsomedial nuclei. Preliminary findings show that seasonal changes in feeding in ground squirrels are related to changes in the hypothalamic expression of neuropeptide mRNA. Thus, in hyperphagic (food intake = 29.8 ± 0.7 g/day; n=4) and pre-hibernation hypophagic (12.1 ± 1.3 g/day; n=4) animals, the reduction in food intake was paralleled by a decrease in hypothalamic expression of NPY and galanin, although a larger sample size is necessary to confirm this. Thus, golden-mantled ground squirrels express the genes encoding hypothalamic NPY and galanin in a distribution comparable to non-hibernating rodents. Seasonal changes in the expression of these neuropeptides may contribute to circannual cycles of feeding.

396.3

EFFECTS OF FASTING ON GLUTAMIC ACID DECARBOXYLASE (GAD) mRNA LEVELS IN RAT HYPOTHALAMUS. A. J. Sipols*, M. W. Schwartz and D. G. Baskin. Departments of Medicine and Biological Structure, University of Washington and Seattle VA Medical Center, Seattle, WA 98108

Evidence indicates that the inhibitory neurotransmitter γ-aminobutyric acid (GABA) plays a role in the central regulation of feeding behavior. Since food deprivation increases hypothalamic GAD activity, we proposed that fasting may influence GAD gene expression in the hypothalamus. To test this hypothesis, we measured the effect of fasting on hypothalamic mRNA for two GAD isoforms (GAD_{65} and GAD_{67}) using *in situ* hybridization. Following 0, 24, or 48 hr of food deprivation, coronal brain sections from male Wistar rats (initially weighing 275-300g) were hybridized with ^{35}S-labelled oligonucleotide probes complimentary to either GAD_{65} or GAD_{67} mRNA. Northern blot analysis revealed that these probes recognize separate mRNA transcripts. Film autoradiographs were quantified by computer image analysis of hybridization density (μCi/g) in the arcuate nucleus (ARC), dorsomedial nucleus (DMN), and ventromedial nucleus (VMN). The hypothalamic distribution of mRNA encoding the two isoforms was identical. In fed rats, GAD_{65} hybridization was highest in DMN (0.177 ± 0.012) and ARC (0.161 ± 0.011) and lowest in VMN (0.123 ± 0.002). Likewise, in fed rats, GAD_{67} hybridization was highest in the DMN (0.190 ± 0.009) and ARC (0.170 ± 0.007) with lower values in VMN (0.118 ± 0.007). Food deprivation for 24 or 48 hrs did not alter levels of GAD_{65} or GAD_{67} mRNA in any area. However, we observed significant associations between GAD_{65} mRNA expression in ARC and plasma insulin (r=-0.61) and glucose (r=-0.54) levels. We conclude that: 1) GAD_{65} and GAD_{67} mRNA have identical quantitative distributions in hypothalamus; 2) hypothalamic expression of GAD_{65} and GAD_{67} genes is not regulated by food deprivation; and 3) GAD_{65} gene expression in ARC may be influenced by changes in circulating levels of insulin and/or glucose.

396.4

NEUROPEPTIDE Y PROJECTION FROM ARCUATE NUCLEUS (ARC) TO PARVOCELLULAR DIVISION OF PARAVENTRICULAR NUCLEUS (pPVN): SPECIFIC RELATION TO CARBOHYDRATE FEEDING. M. Jhanwar-Uniyal*, B. Beck, Y.S. Jhanwar, C. Burlet and S.F. Leibowitz. The Rockefeller Univ. New York, N.Y. 10021 and Faculty de Medicine, INSERM U.308, Nancy, France.

Neuropeptide Y (NPY) injection into the PVN stimulates food intake, specifically of carbohydrate (CARB). The pPVN is particularly rich in NPY-containing terminals which originate primarily from the ARC. This study examines: a) the relation between endogenous NPY and natural preference for CARB; and b) the specific importance of the ARC-pPVN NPY projection in this relationship. Sprague-Dawley rats were given pure macronutrient diets (CARB, protein and fat), and daily food intake was recorded. Rats were sacrificed 3 wks later, their brains removed, and eight hypothalamic nuclei were micropunched and examined via RIA for endogenous NPY. The results demonstrate that: 1) High CARB eaters, compared to low CARB eaters, have significantly elevated NPY levels specifically in the pPVN ($p<0.01$) but not the magnocellular PVN; in ARC ($p<0.01$); and in dorsomedial nucleus (DMN; $p<0.05$). No such relationship was seen for fat or protein intake; 2) Endogenous NPY content is positively correlated with 24 hr CARB intake, in the pPVN ($r=0.71; p<0.001$), ARC ($r=0.57; p<0.001$) and DMN ($r=0.52; p<0.01$) only and 3) Endogenous NPY levels in ARC, where NPY cell bodies are concentrated, are positively correlated with NPY levels in the pPVN ($r=0.54; p<0.001$) and DMN ($r=0.56; p<0.001$), to which the ARC projects. This demonstrates a close relationship between endogenous NPY, specifically of the ARC-pPVN projection, and natural preference for CARB.

396.5

IN VIVO AND *IN VITRO* EVIDENCE THAT STREPTOZOTOCIN (STZ)-INDUCED DIABETIC HYPERPHAGIA IS DUE TO INCREASED NEUROPEPTIDE Y (NPY) SECRETION IN THE PARAVENTRICULAR NUCLEUS (PVN). A. Sahu*, C.A. Sninsky[a], C.P. Phelps[b], M.G. Dube, P.S. Kalra and S.P. Kalra, Depts. Obstet. & Gynec. and [a]Medicine, Univ. Fla., Gainesville, FL 32610, [b]Dept. Anatomy, Univ. South Fla., Tampa, FL 33612

Since a large body of evidence shows that increased feeding under normal conditions is due to enhanced NPY release in the PVN (PNAS, 88:1093, 1991), we evaluated the levels and pattern of *in vivo* and *in vitro* NPY release from the PVN of STZ-induced diabetic rats displaying hyperphagia. Expt 1: NPY levels were measured by RIA in 7 microdissected brain nuclei of rats 18 days after STZ or vehicle treatment. STZ rats exhibited marked hyperglycemia, hyperphagia and elevated NPY levels in 4 hypothalamic sites including the PVN as compared to controls. Expt 2: NPY release from the microdissected PVN and ventromedial nucleus (VMN) of STZ rats was then studied *in vitro*. Both basal and KCl-induced NPY release was significantly higher from the PVN of STZ-treated than that of control rats. However, NPY release from the VMN of STZ-treated rats was unaffected. Expt 3: NPY release *in vivo* from the PVN of STZ-treated rats was assessed. Push-pull cannulae (PPC) were implanted in the region of the PVN and 1 week later (18-20 days after STZ-treatment) the PVN was perfused via the PPC for 3-4 hours with artificial CSF. Compared to controls, NPY levels in PVN perfusates collected at 10 min intervals from STZ-treated rats were significantly enhanced in association with increased food intake. Cumulatively, these results show that NPY release is augmented in the PVN of STZ-treated rats. Since NPY is a potent, naturally-occurring orexigenic signal, our results support the hypothesis that increased NPY secretion, selectively in the PVN, may be the underlying cause of hyperphagia in diabetes. (Supported by UF DSR KG 717 (AS) and NIH DK37273 (PSK & SPK), VA Merit Review (CAS)).

396.6

NEUROPEPTIDE Y (NPY) CONCENTRATION IS DECREASED IN THE PARAVENTRICULAR NUCLEUS (PVN) OF RATS EXHIBITING EXCESSIVE WEIGHT GAIN PRODUCED BY VENTROMEDIAL HYPOTHALAMIC (VMH) LESIONS. M.G. Dube*, A. Sahu, C.P. Phelps[a], P.S. Kalra and S.P. Kalra, Dept. Obstet. and Gynec. Univ. Fla., Gainesville, FL 32610, [a]Dept. of Anatomy, Univ. South Fla., Tampa, FL 33612

Our observations that central administration of NPY evokes robust feeding and that NPY level and release is upregulated selectively in the PVN in association with increased appetite, implicates NPY as a physiological signal for initiation of feeding in the rat. Since VMH lesions produce profound hyperphagia and obesity, we tested the hypothesis that VMH lesions may increase PVN NPY neurosecretory activity. Adult male rats received either bilateral electrolytic lesions of the VMH, a sham operation or no surgery. Animals were sacrificed either 2 or 21 days later. NPY levels were determined by RIA in several microdissected hypothalamic nuclei. Both short and long-term lesioned rats displayed marked hyperphagia and steady weight gain ($p < 0.01$). Quite unexpectedly, VMH ablation decreased NPY concentrations in the PVN within 2 days (64% of sham levels, $p < 0.05$), a further diminution occurred 21 days post-lesion (28% of sham levels, $p < 0.0001$). Of the other sites investigated, NPY levels also decreased in the dorsal medial nucleus and lateral hypothalamic area of the 21-day post-lesion group. These results show that hyperphagia and body weight gain in the VMH-lesioned rats may be due to a deficiency in PVN NPY which may result either in a compensatory post-synaptic supersensitivity or intervention of other hypothalamic appetite excitatory or satiety signals. (Supported by NIH DK 37273).

396.7

GALANIN IN THE CENTRAL NERVOUS SYSTEM OF LEAN AND OBESE ZUCKER RATS. Beck* B., Burlet A., Nicolas J.P., Burlet C. - INSERM U.308 MRCA , 38 rue Lionnois, 54000 NANCY (France)

Galanin (GAL), a 29 aminoacid peptide, is widely distributed in the central nervous system and especially in the hypothalamus. It strongly stimulates food intake when it is injected in the paraventricular nucleus (PVN). The obese Zucker rat with a well-established hyperphagia is characterized by a general dysregulation of some important neuropeptides involved in the regulation of feeding behavior e.g. neurotensin, NPY or CCK but nothing is known about the central status of galanin in these rats. The aim of this study was therefore to measure GAL in different microdissected brain areas in lean and obese male Zucker rats. As feeding status may modulate the central concentrations of the peptide, it was measured in ad libitum fed rats and in 48h-fasted rats. Bilateral arcuate nuclei (ARC) and parvocellular (PVNp) and magnocellular (PVNm) parts of the PVN as well as the median eminence (ME) were microdissected and sonicated. GAL was measured by a specific radioimmunoassay. The two-way analysis of variance revealed a very significant effect of genotype in the PVNp ($p<0.001$) and in the ME ($p<0.02$). No variations at all were noted in the ARC or in the PVNm. Fasting did not influence GAL concentrations in any areas. GAL concentrations were more than doubled in the ad lib obese rats when compared with the ad lib lean rats ($p<0.005$). On the other hand, in the ME where GAL concentration was about 4-fold greater than in the other nuclei, there was a 20 to 30 % decrease in GAL concentrations in the obese rat ($p<0.05$). Opposite variations of GAL were therefore observed between obese and lean rats in two distinct areas. Increased PVN levels might be related to the hyperphagia of the rats but GAL did not behave exactly like NPY, an other orexigenic peptide, because fasting has no effect on its levels. Its biological action might therefore be fairly different.

396.8

GALANIN-LIKE IMMUNOREACTIVITY (IR) IN HYPOTHALAMIC NUCLEI: RELATION TO FAT INTAKE. *Leibowitz, S.F., Akabayashi, A., Koenig, J.I.[1] and Alexander, J.T. The Rockefeller University, N.Y., N.Y. 10021 and [1]Georgetown Univ. Sch. Med., Washington D.C., 20007

This study examined the relationship between hypothalamic galanin (GAL) levels and macronutrient intake in rats. Albino rats (N=30) were maintained ad lib on diets of protein, carbohydrate and fat. After 3 weeks, the rats were sacrificed by decapitation, 10 hypothalamic nuclei and the posterior pituitary (PP) were microdissected, and GAL-IR was measured by RIA. Among the 10 hypothalamic areas examined, only the magnocellular paraventricular nucleus (mPVN) revealed a significant relationship between endogenous GAL and daily nutrient intake. In this region, where dense GAL cell bodies exist, positive correlations were observed between GAL levels and 24 hr fat ingestion ($r = +0.62$, $p<0.01$), 24 hr fat preference ($r = +0.62$, $p<0.01$), fat intake during the first 90 min of the feeding cycle ($r = +0.68$, $p<0.01$), and body weight gain ($r = +0.37$, $p<0.05$). While a small inverse correlation between mPVN GAL and carbohydrate intake ($r = -0.41$, $p<0.05$) was also detected, there was no apparent relation between GAL and either protein intake, total caloric intake or body weight. GAL in the PP was similarly related to fat intake ($r = +0.40$, $p<0.05$), as well as to GAL levels in the mPVN ($r = +0.40$, $p<0.05$). No such correlations with the other hypothalamic areas were seen. This relationship, between natural fat ingestion and endogenous GAL specifically in the mPVN, agrees with studies of GAL mRNA and also with central injection studies showing the PVN to be the most sensitive brain site to the selective stimulatory effects of exogenous GAL on fat ingestion.

INSULIN TRANSPORT FROM PLASMA INTO THE CENTRAL NERVOUS SYSTEM IS SATURABLE IN VIVO. G.D. Baura, D.M. Foster, D. Porte Jr., R.N. Bergman and M.W. Schwartz*. Depts. of Bioengineering and Medicine, Univ. of Washington and Seattle VA Medical Center, 98108, and Dept. of Physiology and Biophysics, Univ. of Southern California, Los Angeles, CA 90033.

Circulating insulin enters the central nervous system (CNS) where it acts as a regulator of food intake and body weight. We have previously shown that the kinetics of insulin uptake into cerebrospinal fluid (CSF) from plasma can best be explained by passage through an intermediate compartment, hypothesized to be brain interstitial fluid. To determine if an insulin receptor contributes to this uptake, we subjected anesthetized dogs (n=9) to 90 min euglycemic intravenous insulin infusions to obtain a wide range of plasma insulin levels (69-5064 μU/ml). Plasma and CSF samples were collected over 8 hr for determination of immunoreactive insulin levels, and the kinetics of CSF insulin uptake were analyzed using a mathematical model with three components (plasma→ intermediate compartment→CSF). Frequent sampling during rapid changes of plasma and CSF insulin levels enabled the model to precisely identify rate constants (mean standard deviation=14%) characterizing the uptake of insulin from plasma, through the intermediate compartment and into CSF (k_1k_2), and clearance of insulin from both intermediate compartment (k_3) and CSF (k_4). At physiological plasma insulin levels (83μU/ml), k_1k_2 was determined to be 11.5×10^{-6} min^{-2}. However, with increasing plasma levels, k_1k_2 decreased progressively, being reduced seven-fold at supraphysiologic levels (5064 μU/ml). The apparent Km of this saturation curve was 500-800 μU/ml (~3-5 nM). In contrast, the rates of insulin clearance from both the intermediate compartment and CSF did not vary with plasma insulin ($k_3 = 0.011 \pm 0.0019$ min^{-1} and $k_4 = 0.046 \pm 0.022$ min^{-1}). We conclude that transport of plasma insulin into CNS is saturable. This mechanism is consistent with insulin binding to blood-brain barrier insulin receptors and transcytosis through microvessel endothelial cells.

INTRAVENOUS INSULIN INFUSION INCREASES DAILY FOOD INTAKE AND ENERGY EXPENDITURE IN RATS. A.E. Willing, H.S. Koopmans* and E.K. Walls. Dept. of Medical Physiology, Univ. of Calgary, Calgary, Alberta, Canada, T2N 4N1.

Chronic insulin treatment in diabetic rats can significantly increase daily food intake, but insulin has previously been found to both increase and decrease energy expenditure (EE). To study the relationship between feeding and EE in diabetic rats, daily food intake, EE and respiratory quotient (RQ) were measured during chronic low dose (2 U/day) or increasing (2 to 6 U/day) insulin infusions into the vena cava of 12 Lewis rats (VC fixed and VC varied). In the VC varied group, daily food intake increased from a Ringer's baseline value of 71.5 ± 1.5 to 93.9 ± 1.3 and 112.2 ± 0.9 kcal/day at the 2 and 3 U/day insulin doses ($p < .01$). EE increased from a baseline value of 54.2 ± 4.1 kcal/day to 63.0 ± 4.9 kcal ($p < .05$) during the 3 U/day insulin infusion and the rats gained weight rapidly. RQ increased from 0.88 ± 0.03 during baseline to 0.95 ± 0.02 at 2 U ($p < .01$) and remained constant. In the VC fixed controls, daily food intake increased from 73.5 ± 0.7 to 98.2 ± 1.4 kcal/day at 2 U/day ($p < .01$) where it remained. There was no significant increase in EE, but RQ increased from 0.87 ± 0.02 during baseline to 0.94 ± 0.02 ($p < .01$) at 2 U/day. Over time, RQ decreased to 0.79 ± 0.03 ($p < .01$). These results suggest that the observed increases in EE that are often obtained when exogenous insulin is administered are a result of the increased food intake that accompanies the insulin infusion. Insulin administration also shifts substrate utilization from fat to carbohydrate. This shift occurs even when there is little change in daily food intake.

396.11

IVT INSULIN DECREASES RESPIRATORY QUOTIENT IN RATS. C.R. Park*, M. Chavez, S.C. Woods. Dept. of Psychology, University of Washington, Seattle, WA 98195

Centrally administered insulin decreases food intake and body weight in several species. In some studies the observed decrease in body weight appeared greater then what would be predicted solely on the basis of decreased food intake. It is therefore possible that central insulin affects metabolic rate independently of its behavioral effect. Male Long-Evans rats (n=6) received either insulin or saline vehicle into the third ventricle. Bolus injections (4 mU in 4 μl) were given twice, 12 hours apart. Water, but not food was available. Respiratory quotient (RQ) was measured by indirect calorimetry. All animals were exposed to both conditions in a counter-balanced design. IVT insulin resulted in a statistically significant decrease of RQ from 0.79 in the vehicle condition to 0.72 in the insulin condition. This change of RQ was accompanied by a significantly greater weight loss during insulin treatment than during saline treatment. Peripheral injections of insulin at the same dosage and time schedule increased RQ. We conclude that central insulin affects metabolic activity and appears to do so by increasing the utilization of fat stores. These results further support the hypothesis that central insulin serves as a negative feedback signal in the central nervous system for body adiposity.

DIFFERENCES AND SIMILARITIES OF THE FEEDING RESPONSES TO BACTERIAL CELL WALL COMPONENTS AND INTERLEUKIN-1ß. W. Langhans*, S. Weingarten, C. Bauer and M. Senn, Institute of Animal Sciences, Swiss Federal Institute of Technology, 8092-Zurich, Switzerland.

As a primary endogenous mediator of the host's acute phase responses to bacterial infections, interleukin-1ß (IL-1ß) is presumably involved in many pathophysiological effects of bacterial cell wall components, like lipopolysaccharides (LPS) and muramyl dipeptide (MDP). To investigate whether endogenous IL-1ß also mediates the anorectic effects of LPS and MDP, the feeding responses of adult male rats to IL-1ß, LPS nd MDP were compared. All compounds were injected intraperitoneally (IP) at dark onset. Paracetamol (50mg/kg, IP), which preferentially blocks brain cyclo-oxygenase, clearly attenuated the anorectic effect of IL-1ß (50,000 LAF units/kg) more than the anorectic effects of LPS (100μg/kg) and MDP (1.6mg/kg). When injected together, IL-1ß (12,500 LAF units) and MDP (0.4mg/kg) had an additive effect on feeding, whereas the hypophagia after combined injection of IL-1ß (12,500 LAF units/kg) and LPS (25μg/kg) was less than the sum of both compounds' individual effects. Finally, lesion of the area postrema and the adjacent caudal medial region of the nucleus of the solitary tract (AP/NST) did not affect the anorectic effect of IL-1ß, but enhanced the effects of LPS and MDP. The results indicate that stimulation of eicosanoid synthesis in the brain is involved in the hypophagia induced by IP injected IL-1ß. Furthermore, an intact AP/NST is obviously not essential for IL-1ß's anorectic effect, but modulates the effects of LPS and MDP through some as yet unknown mechanism. In summary, endogenous IL-1ß appears to mediate only part of the anorectic effects of LPS and MDP.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: CORTEX V

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING ACTIVE AND PASSIVE FINGER MOVEMENTS: A PET STUDY.
T. A. Zeffiro* and M. Hallett Medical Neurology Branch, 10-5N226, NINDS, National Institutes of Health, Bethesda, MD, 20892.

Studies in subhuman primates have shown that many cortical neurons that modulate their activity in relation to voluntary limb movement also modulate their activity during passive movement of the same body part, suggesting a relatively tight relationship between a movement and its' sensory consequences. In order to examine this input-output coupling in man, we used $H_2{}^{15}O$ positron emission tomography to record regional cerebral blood flow (rCBF) in 8 subjects during active and passive index finger movements. We studied two different tasks. In the active condition, each subject executed repetitive index finger abduction/adduction movements twice per second. In the passive condition, the index finger was moved with the same rate and range while the subject lay quietly. In the control condition there was no movement. Significant changes in rCBF were detected using covariance analysis and the t statistic.

We found significant contralateral rCBF increases during both active and passive tasks in primary motor cortex, primary somatosensory cortex, supplementary motor area, cingulate motor area and putamen ($p<0.01$). In all these areas the rCBF increase was greatest in the active condition. Significant rCBF increases ($p<0.01$) limited to the active condition were detected in ipsilateral anterior cerebellar cortex, ipsilateral primary motor cortex, contralateral insula and contralateral superior parietal lobule.

In many motor areas, sensorimotor processing of repetitive movement is characterized by tight spatial coupling between activity related to active and passive movement of the same body part.

397.2

FUNCTIONAL MAGNETIC RESONANCE IMAGING OF MOTOR CORTICAL AREAS DURING REPETITIVE FINGER MOVEMENT.
R.Turner, T.A.Zeffiro, P.Jezzard, D.LeBihan and P.Herscovitch* NHLBI, NINDS and CC, National Institutes of Health, Bethesda, MD, 20892.

Focal activation of human sensorimotor cortex during voluntary movement is seen utilizing $H_2{}^{15}O$ positron emission tomography (PET) to record task-related regional cerebral blood flow (rCBF) increases. We have observed similar task-related activation patterns with a rapid, noninvasive MR imaging method that relies on the paramagnetic character of deoxyhemoglobin to measure blood oxygenation changes.

Measurements were made using a gradient-echo version of the echo-planar imaging sequence (EPI) on a 1.5 Tesla whole-body magnet. A gradient set dedicated to head imaging was used to provide a rapidly switching magnetic field gradient in the z direction and a 5" surface coil was used for radiofrequency reception. Gradient echo time was 40ms and image acquisition time was 25ms. Images were collected every 3 seconds for a total of 64 images per run. Five healthy volunteers were studied during alternating 30 second periods of unimanual finger opposition and rest. Task minus rest difference images were computed for each run.

We found focal, task-related, 2-5% increases in signal intensity in the hand representation of the contralateral primary motor and somatosensory cortex. Although these increases are somewhat smaller than the 10-30% rCBF increases seen in the same cortical areas with PET, there is a correspondingly lower image noise that allows clear identification of task-related signal changes. The high spatial and temporal resolution of deoxyhemoglobin echo-planar imaging make it an attractive tool for functional neuroimaging studies of human movement.

397.3

MOTOR SYSTEM CBF RESPONSES DURING FINGER MOVEMENTS ARE RATE INDEPENDENT Scott T. Grafton, Roger P. Woods, Michael Phelps*, and John C. Mazziotta U.C.L.A. School of Medicine, Los Angeles, CA 90024

The goal of this study was to determine the effect of performance rate on the magnitude of regional cerebral blood flow (rCBF) responses in the human brain. Four normal subjects performed a visually guided tracking task with their dominant index finger during serial positron emission tomography (PET) imaging of rCBF. Target speed was set at 0, 8.2, 16.4, 24.6, and 32.8 cm/sec. Tracking at these rates spanned the physical limits of non-ballistic finger movements. Significant changes of rCBF were identified using analysis of covariance and the t statistic after stereotaxic normalization. Movement (versus no movement) was associated with significant ($p<0.05$) rCBF responses in the contralateral primary motor cortex, supplementary motor area, premotor cortex, and ipsilateral anterior cerebellum. The magnitude of the responses in these areas was constant across tracking rates. No other linear or non-linear differences of rCBF associated with a rate effect could be identified in any other cerebral area.

The results are in contrast to previous studies of the visual system that have shown a relationship between photic stimulus rate and the magnitude of rCBF responses in V1. Motor system rCBF responses, representing the integral of local neuronal activity, remain constant across performance rates. These results suggest that the observed longitudinal changes in the magnitude of motor system rCBF responses during skill acquisition and functional recovery are not secondary to a rate effect.

397.4

ROLE OF THE PARIETAL LOBE IN THE GENERATION OF DIRECTED MOTOR RESPONSES. Roger P. Woods, John C. Mazziotta*, Simon R Cherry, Mark J. Morrow, and Robert C .Knowlton. U.C.L.A. School of Medicine, Los Angeles,CA 90024.

Using oxygen-15 labeled water and positron emission tomography (PET), we have found bilateral parietal increases in blood flow in normal humans performing both immediate and delayed visually guided oculomotor saccades to visual targets. These changes are sufficiently robust that they are consistently seen in individual subjects. To determine which components of these tasks are required for parietal responses, we have varied the lateralization of visual input and motor output, dissociated the spatial and temporal information provided by the visual cues, and compared visual to auditory temporal cues. Restriction of targets to a single visual hemifield did not result in lateralized changes, but when subjects maintained central visual fixation and pointed to the targets with one hand, parietal responses were stronger contralaterally. When subjects pointed to locations that they chose at random, a robust contralateral parietal response was still seen. The timing of movements in this task was still cued visually by the disappearance of the central fixation target. Substitution of an auditory temporal cue resulted in a decrease in the parietal response contralaterally, but did not eliminate the response as compared to a motionless control state. A contralateral parietal response was even elicited by pointing to randomly chosen locations using auditory temporal cues in darkness with eyes closed. The contralateral parietal lobe plays an important role in movements to visible external targets and in movements to internally generated targets in the absence of any visual input. Because all of the movements were cued either visually or auditorily, we cannot yet say whether the role of the parietal lobe is more closely related to evaluation of the status of the cue or to the actual initiation of the motor output.

397.5

TASK-SPECIFIC CHANGES OF LOCAL BLOOD FLOW WITHIN THE HUMAN ANTERIOR CINGULATE CORTEX: RELATIONSHIP TO LEVEL OF PERFORMANCE. T. Paus*, M. Petrides, A.C. Evans. Montreal Neurological Institute, McGill University, Montreal, Quebec H3A 2B4, Canada.

Overpractised and Reversal versions of **Speech Oculomotor**, and **Manual** tasks were used to study the role of the anterior cingulate cortex (ACC) in higher-order motor control. In two separate PET experiments, cerebral blood flow was measured in 18 healthy volunteers, using the ^{15}O-water-bolus method . For each subject, one "baseline" and six "task" scans were performed. Accuracy and latency of motor responses were also measured. On the basis of performance in the **Reversal Speech** task, subjects could be classified into two groups: "passed" and "failed". These groups did not differ in performance on the **Overpractised Speech** task. In both experiments, significant CBF changes within the ACC were obtained not only in the reversal minus overpractised speech subtractions (Exp.I:both groups, Expt.II:"passed" group only), but also in the overpractised minus baseline speech subtraction in the "failed" groups. The presence of ACC activation in a well practised speech task represents an atypical pattern of brain activity, the occurrence of which might signal failure in a more challenging task.

397.6

LOCALIZATION OF MOTOR AREAS WITH TRANSCORTICAL MAGNETIC STIMULATION AND MAGNETIC RESONANCE IMAGING IN HUMAN SUBJECTS. M. Daffertshofer, M. Syren, H. Henningsen and M. Zimmermann. Departments of Neurology and Physiology, University of Heidelberg, Germany (Spon: ENA)

Transcortical magnetic stimulation (TMS) and magnetic resonance imaging (MRI) were combined to map motor fields of the human cortex. We used focal "eight-shaped" coils (Novametrix 2 T) to stimulate the cortex as revealed by recording motor potentials by surface EMG electrodes over several muscles of the upper and lower limbs. Focal areas associated with distinct muscles were labelled on the skull surface with a cream rich in water, and numbers were assigned to these labels. Up to 80 sites of stimulation could be discerned. Subjects were then investigated by MRI (Siemens 2 T), and the labelled motor foci were projected to the image of the cortex.

In all 5 subjects studied so far the localizations of the points of motor excitations were consistent with precentral cortical motor fields associated with the limb muscles as were previously established by invasive electrical cortex stimulation. Thus, TMS enables the non-invasive mapping of motor fields with a rather high resolution. This method is valuable to detect changes in the topography of the motor cortex as might occur in amputees.

397.7

Projecting transcranial magnetic stimulation (TMS) maps into brain MRI. E.M. Wassermann*, B. Wang, C. Toro, T.A. Zeffiro, J. Valls-Solé, A. Pascual-Leone and M. Hallett. Human Motor Control Section, NINDS & Biomedical Engineering & Instrumentation Program, NCRR, NIH, Bethesda, MD 20892.

TMS can be used to map motor representations noninvasively, but it has not been possible to correlate these maps with brain anatomy. Ten TMS stimuli were delivered to each of a grid of points 1 cm apart on the left scalp while EMG was recorded and averaged from the right first dorsal interosseous muscle (FDI) in 4 subjects. EMG amplitude maps of the area accessing FDI were roughly circular with a diameter of 1-2 cm for responses more than 60% of maximum response. In each subject the 3-D coordinates of the grid and about 300 points on the head surface were acquired with a magnetic digitizer. A sphere was fitted to the grid to determine the line perpendicular to the scalp at the maximum. The other points were used as a surface for registration with the subject's head surface on MRI. The parameters obtained from the registration were used to map the maxima into the MRI and to compute the intersection of the perpendicular line with each slice. The intersections were within about 1 cm of the precentral gyrus. This technique can also be used to map other types of electrophysiological data into images.

397.8

FAST MODULATION OF HUMAN MOTOR OUTPUTS DURING ISCHEMIC NERVE BLOCK IS MEDIATED BY UNMASKING OF INTRACORTICAL SYNAPTIC CONNECTIONS. J.P. Brasil-Neto, J. Valls-Sole, A. Pascual-Leone, A. Cammarota, V.E. Amassian, M. Hallett and L.G. Cohen*. Human Cortical Physiology Unit, Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892 and Department of Physiology, State University of New York Health Science Center at Brooklyn.

The amplitudes of motor-evoked potentials (MEPs) elicited by transcranial magnetic stimulation (TMS) in muscles proximal to a transiently ischemic limb segment increase for the duration of ischemia, and return to baseline level afterwards.

To determine the level in the central nervous system at which this fast modulation of human motor outputs takes place, we recorded H reflexes, maximal M responses, MEPs to transcranial electrical stimulation (TES), MEPs to TMS, and MEPs to spinal electrical stimulation (SES) from muscles immediately proximal to an ischemic limb segment.

MEPs induced by TMS were larger during ischemia, whereas those induced by TES or SES were unchanged. Maximal H/M ratios were also unchanged, indicating that alpha-motoneuron excitability to segmental inputs was unaffected by ischemia.

Given the predominantly presynaptic activation of pyramidal tract neurons by TMS, as opposed to a more direct axonal activation by TES and SES, these findings suggest that intracortical unmasking of synaptic connections is the likely mechanism for short-term modulation in the human motor system during ischemic nerve block.

397.9

CEREBRAL NEURAL NETWORK APPROACH SHOWS HOW ANALOGICAL REASONING MAY EMERGE FROM SENSORIMOTOR ACTIONS.
M. Dufossé*S. Allemand, F. Blanc, Inst. Méditeranéen. Technol, 13013 Marseilles, Y. Burnod, Inst. Des Neurosci., Univ. P&M Curie, 75005 Paris, France.

It is not very easy to account for reasoning in terms of connectionist theory. Its distributed mode of parallel processing at a subsymbolic level makes it more suitable for dealing with imprecise reasoning, however. Our aim was to demonstrate the emergence of analogical reasoning within a neural network which mimics the cerebral cortex, using a previously built connectionist model of the human cerebral cortex (Burnod, 1989). This parallel distributed process includes both a network of cerebral areas and a network of cerebral micro-columns.

We studied a robotic task which involves camera-vision, robotic arm manipulation and analogical reasoning ability. The task consisted of first sequentially looking at a list of elementary symbols, secondly finding the next most plausible symbol, and finally drawing that symbol on a vertical board under visual control.

Our algorithm mimicked a network of eight cerebral areas, each simulated on a Transputer microcircuit. These maps were connected through a bus of data and arranged in a ring corresponding to an imaginary circular circuit going through the visual, temporal, infero-temporal (Miyashita, 1988), prefrontal (Fuster, 1989), premotor, motor, somato-sensory, parietal cortical areas and then back to the visual area. Recurrent information exchange between the cortical maps simulated the parallel cortico-cortical interactions. As shown by Caminiti (1991), the columnar activity corresponded to a mathematical bilinear relation between two input vectors.

We demonstrated that analogical reasoning ability may emerge from sensorimotor interactions. As a result, the prefrontal and infero-temporal areas send back to the postcentral associative areas a prediction about a forthcoming sensorimotor event.

ANATOMIC ASYMMETRY AND CELL NUMBERS. A.M.Galaburda*, G.F. Sherman, J.M. Richman, and G.D. Rosen. Beth Israel Hospital and Harvard Med. School, Boston, MA 02215.

Previous research has demonstrated that symmetric brain regions are larger than their asymmetric counterparts and that this difference resulted from a greater number of neurons in the symmetric brain (Galaburda, et al., *Cortex* **22**, 151-160, 1986; *Neuropsychologia* **25**, 853-868, 1987). In this study, we tested the hypothesis that this relationship between cell number and asymmetry would be consistent for different cell types as characterized by immunohistochemical labeling.

Nineteen Wistar rats were sacrificed in adulthood by transcardial perfusion with saline followed by 4% paraformaldehyde. The brains were post-fixed for 48 hours before being placed in graded buffered sucrose solutions, sectioned coronally at 30 µm, and one series of every tenth section stained for Nissl substance with Thionin. Adjacent series were immunohistochemically stained for vasoactive intestinal peptide (VIP) or parvalbumin. The somatosensory/somatomotor cortices of the right and left hemispheres were parceled on the Nissl-stained sections, their volumes determined, and the number of labeled neurons within these architectonic regions estimated.

Consistent with previous findings, symmetric brain regions are larger that asymmetric brain regions. In addition, there is a greater number of parvalbumin- and VIP-immunoreactive neurons in the larger of the two sides. There also appeared to be greater cell packing density of parvalbumin-, but not VIP-immunoreactive neurons on the larger of the two sides. These results suggest that there may be asymmetric concentration of neuronal types associated with architectonic asymmetry. Because of the different proportion of parvalbumin-immunoreactive neurons in the large side, the latter may have different functional properties consistent with cerebral dominance.

CORTICAL NEURONAL PROTEIN SYNTHETIC CAPABILITY IN HYDROCEPHALIC AND DECOMPRESSED ANIMALS. C.L. Wolfgang J.P. McAllister II and J.S. Way*. Dept. of Anatomy and Cell Biology, Temple Univ. School of Medicine, Phialdelphia, PA.

The biochemical etiology of neurological deficits observed in hydrocephalic neonates and the utility of surgical decompression remains obscure because of the lack of a sensitive marker of neuronal function. Therefore, the present study quantified cytoplasmic RNA and nucleolar volume in order to assess the protein synthetic capability (PSC) of neurons in the cerebral cortex of hydrocephalic kittens. The effect of decompression via ventriculoperitoneal (VP) shunt placement was analyzed using the same techniques. Hydrocephalus was induced in cats at 10 days of age by intracisternal injection of kaolin. Some hydrocephalic animals received "early" (7-8 days post-kaolin, moderate ventriculomegaly) and "late" (11-14 days post-kaolin, severe ventriculomegaly) VP shunts; all animals were compared to age-matched controls. Brain sections were stained with azure B for stoichiometric binding to cytoplasmic and nucleolar RNA. Cytophotometric analysis revealed a 19-48% depletion in the PSC from motor, association and visual cortices of both moderately and severely hydrocephalic animals. After shunting, PSC returned to control levels only after early treatment; late shunt produced slight improvement, but PSC remained 26-52% below control levels. Since the normal function of neurons is dependant on the PSC, it follows that cerebrocortical neuronal function is adversely affected by infantile hydrocephaly, and that surgical decompression may restore function, but only if performed at early stages of the disorder.

INVERTEBRATE LEARNING AND BEHAVIOR IV

MOTOR NEURON CORRELATES OF DISHABITUATION AND SENSITIZATION OF THE GILL-WITHDRAWAL REFLEX IN *APLYSIA*. R.D. Hawkins*, T.E. Cohen, and E. R. Kandel. Ctr. Neuro. & Behav., Columbia Univ., HHMI, NY, NY 10032.

We have developed a simplified preparation, consisting of the isolated mantle organs of *Aplysia*, which undergoes habituation, dishabituation, sensitization, and classical conditioning of the gill-withdrawal reflex (Hawkins et al., 1987, 1990). We previously established that the LE siphon sensory neurons contribute to the reflex in this preparation (Cohen et al., 1991). To investigate the role of different motor neurons, we hyperpolarized them and found that LDG1 contributes approximately 70% of the reflex. We next recorded correlates of habituation, dishabituation, and sensitization in LDG1. There is a decrease in evoked firing of LDG1 during habituation, and an increase 12.5 but not 2.5 min after shock during dishabituation and sensitization. Conversely, there is an increase in spontaneous firing of of LDG1 2.5 but not 12.5 min after shock. To further analyze the mechanisms of these effects, we first hyperpolarized LDG1 and measured the area of the evoked complex PSP. As in evoked firing, there is a decrease in the PSP during habituation, and an increase 12.5 but not 2.5 min after shock during dishabituation and sensitization. We also measured the gill-withdrawal produced by a constant number of spikes in LDG1, and found an increase 2.5 but not 12.5 min after shock. These results suggest that habituation in this preparation is largely due to depression at central synapses, whereas dishabituation and sensitization are due to central and peripheral facilitation with different time courses. 2.5 min after shock there is a large peripheral effect, perhaps due to PTP at the neuromuscular junction, and no central facilitation, presumably because of competing transient inhibition. 12.5 min after shock there is no peripheral effect and significant central facilitation.

398.2

IDENTIFIABLE CNS GILL MOTOR NEURONS OF *APLYSIA*: FINAL COMMON PATH OR HIDDEN LAYER? J. L. Leonard*, J. Edstrom, M. Martinez-Padron, J. I. Goldberg, and K. Lukowiak. Mark O. Hatfield Marine Science Center, Newport, OR 97365; Dept. of Med. Physiol., Univ. of Calgary, and Dept. of Zool., Univ. of Alberta, Edmonton, Canada.

The hypothesis that *Aplysia* gill-withdrawal behaviors could be adequately explained by parallel monosynaptic reflex arcs between six PVG gill motor neurons (GMNs) and the LE sensory cluster (Kupfermann et al. 1974; review in Kandel 1978) made clear, falsifiable predictions that have stimulated experimental work for many years. Results show that the hypothesis is incorrect, both in detail (LE cells fire after motor neurons, Cohen et al. 1991; other cells active, Zecevic et al. 1989; etc.) and in principle (PVG necessary for neither behavior nor learning, Peretz et al. 1976; behavior not reflex, Leonard et al., 1989; behavior not necessarily correlated with MN actifity, Colebrook & Lukowiak 1988; Leonard et al. 1991; in press). Further experimental work requires a new hypothesis consistent with the available data, i.e. that the PNS is sufficient for these behaviors and that the CNS mediates behavioral state and the two interact to produce the behaviors of the intact preparation. We propose that the known CNS GMNs along with a set of inhibitory GMNs, can vary in efficacy, both individually and in concert, with learning and behavioral state and that the parallel CNS pathways act to set the gain of the gill behavior and to phase shift the Int II network. The model suggests that the CNS GMNs are a biological realization of the hidden layer of a neural network. Supported by MRC (Canada), AHFMR, NIMH & NSF.

398.3

A STUDY OF NEURONAL RESPONSE IN APLYSIA ABDOMINAL GANGLION DURING HABITUATION OF THE GILL-WITHDRAWAL REFLEX. Chun X. Falk*, Jian-young Wu, Larry B. Cohen, Akaysha Tang, Yang Tsau. Dept. of Physiology, Yale U. Sch. of Med., New Haven, CT 06510.

Previous studies indicated that habituation results in a decrease in the number of active neurons responding to the siphon touch and demonstrated the diversity of habituation effect on individual neurons. In the present experiments, a longer habituation training (up to 80 stimuli with 30 sec of inter-stimulus interval) were employed. The habituation effects on both the overall neuronal response and the response pattern of individual neurons were examined. The overall neuronal response shows a excellent correlation with the decrease in gill contraction during habituation. They both have two phases: a rapid decease at the beginning of habituation followed with a plateau (zero for the gill contraction). The plateau in the overall neuronal response indicates that the system maintains a constant response level (20-30% of control level) even after complete habituation was achieved. Additional analysis will aim at attributing these two phases to individual neurons or groups.

SECOND MESSENGERS CONTRIBUTING TO THE SEROTONIN-INDUCED PRESYNAPTIC FACILITATION IN THE SENSORYMOTOR SYNAPSES OF APLYSIA IN CULTURE. M. Ghirardi, O. Braha, B. Hochner, P.G. Montarolo*, E.R. Kandel, N. Dale. Ctr. Neurobiol. & Behav., Columbia P&S, HHMI, N.Y., N.Y. 10032; Dip. Anat. & Fisiol. Umana, Univ. Torino, 10125 Italy.

Two second messenger pathways, mediated by cAMP-dependent protein kinase A (PKA) and by protein kinase C (PKC), are known to contribute to the presynaptic facilitation of the gill withdrawal reflex in Aplysia (Braha et al., 1986; Sacktor and Schwartz, 1986; Sugita et al. 1992). We studied the relative contribution of each of these on 5HT-induced short term facilitation at nondepressed, partially depressed (reduced to 40% of their initial level) and highly depressed synapses (reduced to 10% of their initial value) and on the spontaneous release. We used Rp-cAMPS, a specific PKA inhibitor, and H7, a general kinase inhibitor that preferentially blocked PKC in intact Aplysia neurons. Our results show that the PKA inhibitor 1) completely prevents the facilitation of nondepressed synapses, 2) blocks 50% of the facilitation of moderately depressed synapses, 3) blocks only a small component of the facilitation of highly depressed synapses and 4) has no effects on the modulation of spontaneous transmitter release by 5HT. By contrast, H7 1) has no effect on the facilitation of nondepressed synaptic connections, 2) blocks only partially the facilitation of moderately depressed synapses, 3) blocks a large component of the facilitation of highly depressed synapses and 4) blocks completely the enhancement of spontaneous release by 5HT. Our results suggest that whereas activation of PKA is sufficient to trigger the facilitation of nondepressed synapses, activation of both PKA and PKC is required to facilitate depressed synapses and that the contribution of PKC becomes progressively more important as synaptic transmission becomes more depressed.

EARLY STEPS IN LEARNING-RELATED SYNAPTIC GROWTH: cAMP SIMULATES THE HETEROLOGOUS ENDOCYTOSIS OF apCAMS INDUCED BY 5-HT IN SENSORY NEURONS OF *APLYSIA*: C. H. Bailey*, M. Chen, and E. R. Kandel. Ctr. Neurobiol. & Behav., Columbia P&S, NYSPI, & HHMI, NY, NY 10032.

The synaptic growth that accompanies 5-HT-induced long-term facilitation of the sensory-to-motor connection in dissociated cell culture is associated with a down-regulation of cell adhesion molecules (apCAMs) on the surface membrane of the sensory neuron (Mayford et al., Science, 1992). Down-regulation is achieved by a protein synthesis-dependent activation of the endosomal pathway leading to internalization of apCAM (Bailey et al., Science, 1992). Unlike classical receptor-mediated endocytosis, the endocytosis of apCAM is triggered by the binding of ligand to a *heterologous* receptor, the 5-HT receptor, and consequent internalization of apCAM. To explore the mechanisms of this novel form of transmitter-mediated endocytosis in sensory neurons, we examined the effects of cAMP, a second messenger activated by 5-HT, on the distribution of gold-conjugated mAb specific to apCAM. We found that a 1.5-hr incubation in cAMP + IBMX (10^{-4}) simulated the action of 5-HT. It led to a 50% decrease in gold-labeled complexes at the surface membrane (10.8 ± 1.1) when compared to either untreated cells (22.6 ± 1.8; $p < 0.001$) or cells bathed in IBMX alone (22 ± 2.4; $n = 5$; $p < 0.01$). Accompanying the decrease in surface labeling was a sevenfold increase in the percentage of gold within the cell (31.6 ± 1.4 vs 4.3 ± 0.3 or 4.9 ± 0.2, $n = 5$, $p < 0.001$). These findings suggest the endocytic activation triggered by 5-HT can be mediated through the cAMP cascade (either alone or in combination with other second messengers) and now allow us to track the steps within the sensory cells whereby 5-HT binding to its extracellular receptor leads to the internalization and degradation of apCAM.

398.6

LONG-TERM FACILITATION IN *APLYSIA* SENSORY NEURONS IS ASSOCIATED WITH AN INCREASE IN THE LIGHT CHAIN OF CLATHRIN AND COATED VESICLES. Y. Hu*, C. Bailey, M. Chen, and A. Barzilai. Ctr. Neurobiol. & Behav., Columbia P&S, HHMI, NY, NY 10032.

One characteristic feature of long-term memory to the tail-withdrawal reflex is that it requires both RNA and protein synthesis, accompanied by structural changes. In an attempt to identify the proteins involved we have cloned and sequenced one of the serotonin (5-HT)-induced proteins in the sensory neurons of the tail-withdrawal reflex of *Aplysia*. The protein sequence inferred from the cDNA clone demonstrated that it is the light chain of clathrin. S1 mapping analysis showed that the steady-state level of clathrin light chain mRNA was also increased by 5-HT. Whereas in mammalian cells there are light chains A and B, both of which have neuron-specific isoforms in the nervous system, in *Aplysia* we have found only one form of light chain and no neuron-specific clathrin light isoforms. Genomic Southern blot analysis indicates that the *Aplysia* light chain is encoded by a single gene. This one chain has all the important structural and functional domains of both light chain A and B of mammalian clathrin, suggesting that it may represent the original form from which the vertebrate chains developed. Serotonin increases the number of clathrin-coated pits and vesicles in *Aplysia* sensory neurons. These coated vesicles are involved in the internalization of *Aplysia* cell adhesion molecules and probably contribute to the structural change of sensory neurons during long-term facilitation.

TEMPORAL DISSOCIATION OF 5HT-INDUCED SPIKE BROADENING AND EXCITABILITY IN *APLYSIA* SENSORY NEURONS. L. L. Stark*, N. J. Emptage, and T. J. Carew. Interdept. Neurosci Prog., Depts. of Psych. and Biol., Yale Univ., New Haven, CT 06520.

Tail shock-induced sensitization in *Aplysia* produces spike broadening and increased excitability in tail sensory neurons (SNs). Both of these effects are mimicked by serotonin (5HT) but can be pharmacologically dissociated: cyproheptadine blocks 5HT-induced spike broadening but not increased excitability (Mercer *et al.*, 1991). We report here that these two modulatory effects of 5HT can also be dissociated by their time course.

We recorded from tail SNs and examined both spike broadening and excitability. A range of 5HT concentrations (0.5μM-5μM) all produced significant excitability increases and spike broadening; higher concentrations produced progressively greater effects. In preliminary experiments (N=2), low 5HT concentrations (0.5μM-2.5μM) produced some spike broadening (x increase=6.5%) but no facilitation of the SN monosynaptic EPSP (x= -0.7%), suggesting that spike broadening may have to exceed a threshold level to produce synaptic facilitation. We next measured the time course of both 5HT effects following 5HT washout. At the lowest concentrations (0.5-1μM) only marginal differences were observed. However, at 2.5μM, 5HT-induced spike broadening lasted significantly longer than increased excitability (9.33 min vs. 2.75 min,respectively, $p<.01$, N=4). Increasing 5HT concentration (5μM) increased the duration of the spike broadening effect with no change in the duration of excitability (15.92 min vs. 2.33 min, $p<.005$, N=6). Thus 5HT-induced spike broadening and excitability were dissociated in two ways: (1) spike broadening lasted longer, and (2) the time course of spike broadening (but not excitability) increased at higher 5HT concentrations.

Our data collectively show that the modulatory effects of 5HT in SNs can be both pharmacologically and temporally dissociated.Since 5HT contributes to different forms of plasticity in the SNs,we can now examine the contribution of these modulatory effects of 5HT to different forms of learning and memory.

LONG-TERM SYNAPTIC FACILITATION DOES NOT REQUIRE SHORT-TERM FACILITATION IN *APLYSIA* SENSORY NEURONS: A PARALLEL PROCESSING HYPOTHESIS FOR SHORT- AND LONG-TERM MEMORY. N.J. Emptage* and T.J. Carew, Yale University, Depts. of Psychol. and Biol., New Haven, CT 06520.

Both short- term (ST) and long-term (LT) memory for sensitization in *Aplysia* involve an increase in synaptic transmission from sensory neurons (SNs) onto their follower cells. ST effects of sensitizing stimuli are mimicked by a single application of serotonin (5HT) while LT effects are mimicked by repeated 5HT applications (Montarolo *et al.* 1986). We recently found that the 5HT antagonist cyproheptadine (CYP) blocks ST 5HT-induced synaptic facilitation in tail SNs (Mercer *et al.* 1991). Here we ask whether the block of ST facilitation by CYP prevents the production of LT facilitation.

Five 5HT (5μM) applications (5 min each at 12 min intervals) produced both ST (<30 min) and LT (>24hrs) synaptic facilitation from tail SNs (ST increase, $\bar{x}$: = 92.2%, $p<0.006$; LT increase, $\bar{x}$: = 76.8%, $p<0.02$; N=4). When CYP (200μM) was present during 5HT applications (N=5), ST increases in synaptic facilitation were blocked ($\bar{x}$ = -8.9%, N.S), but significant LT synaptic facilitation was still observed ($\bar{x}$ increase = 73.1%, $p< 0.006$). Moreover, a between-group analysis showed that, even though ST synaptic facilitation was blocked in CYP+5HT SNs compared to 5HT SNs ($p<0.001$), both groups showed comparable, significant LT facilitation. Finally, Stark *et al.*, (this vol.) showed that low (0.5-2.5μM) concentrations of 5HT produce excitability increases in SNs without producing synaptic facilitation. In preliminary experiments (N=2) we found that these same low concentrations, while producing no ST synaptic facilitation, produced LT facilitation ($\bar{x}$ increase = 65.9%).

Our findings show that preventing ST facilitation either pharmacologically or with low 5HT concentrations does not block expression of LT facilitation, suggesting the hypothesis that ST and LT memory in *Aplysia* SNs are processed in parallel.

SUBSTRATE TARGETING BY SUBUNITS OF cAMP-DEPENDENT PROTEIN KINASE IN APLYSIA NEURONS. R.G. Panchal, S. Cheley, & H. Bayley*. Worcester Foundation for Experimental Biology, Shrewsbury MA 01545

Protein kinase A (PKA) has been implicated in presynaptic facilitation in Aplysia. Four forms of the catalytic (C) subunit of the holenzyme (R_2C_2) are the products of a single gene: N1A1, N1A2, N2A1, N2A2 (PNAS 89, 1641 (1992)). The A1 and A2 polypeptides arise through alternative splicing of exon cassettes encoding residues near the active site and exhibit different substrate specificities and affinities for a regulatory (R) subunit (Biochemistry 30, 10246 (1991)). The N1 and N2 forms arise from alternative promoters and contain alternative N termini originating at a point distant from the active site. Thus, the N termini may be involved not in the direct modulation of catalysis but in substrate targeting i.e. the binding of free C subunit at cellular locations in the vicinity of substrates. Evidence for this now comes from in vitro phosphorylation of neuronal membranes using recombinant N1A1 or N2A1 subunits. The N1A1 form phosphorylates two polypeptides of ~30 kDa and ~10 kDa significantly more rapidly than does N2A1. In Aplysia neurons, there exist at least five forms of R subunit, four of which are homologs of vertebrate RI (Neuron 8, 387 (1992)). We now provide evidence for RII subunits in Aplysia neurons: (i) high molecular weight RII-binding proteins have been demonstrated by using ^{32}P-labeled bovine RIIα to probe protein blots; (ii) rapid cAMP-independent phosphorylation of two ~50 kDa cAMP-binding polypeptides is stimulated by N1A1 or N2A1 subunits. By contrast, the recombinant Aplysia R_{APL-N4} (type I) subunit is not phosphorylated by C in vitro. RII-binding proteins may anchor PKA holoenzyme near selected substrates. (Supported by the NIH).

HABITUATION AND DISHABITUATION OF THE PROLEG WITHDRAWAL REFLEX IN LARVAL *MANDUCA SEXTA*. D.E. Wiel* and J.C. Weeks. Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

The proleg withdrawal reflex is a simple behavior in which mechanical stimulation of sensory hairs on a larval locomotory appendage, the proleg, causes withdrawal of the proleg toward the body wall. Each sensory hair is innervated by a single sensory neuron that mono- and polysynaptically excites motoneurons innervating proleg retractor muscles (Weeks & Jacobs, 1987, *J. Comp. Physiol. A* **160**: 315-329). Because the monosynaptic component of this circuit exhibits several forms of synaptic plasticity (Trimmer & Weeks, 1991, *J. Comp. Physiol. A* **168**: 27-43), we tested for simple behavioral plasticity in the proleg withdrawal reflex.

Habituation was tested by repetitively deflecting a single hair while measuring proleg retraction using either video analysis or a force transducer. Interstimulus intervals ranging from 30 s to 10 min produced significant response decrement. Dishabituation in response to a tactile stimulus delivered to the body wall of the habituated segment was also significant. These studies indicate that the proleg withdrawal reflex of the tobacco hornworm is capable of behavioral habituation and dishabituation. Studies of the neural correlates of these behavioral plasticities are underway.

Supported by grants from NIH, NSF and Patricia Roberts Harris Foundation.

HABITUATION OF THE JUMP REFLEX TO OLFACTORY CUES IN NORMAL AND MUTANT *DROSOPHILA*. T. Tully* and S. Koss. Beckman Neuroscience Center, Cold Spring Harbor Laboratory, Cold Spring Harbor NY 11724 and Department of Biology, Brandeis University, Waltham MA 02254.

We are interested to know whether the molecular mechanisms of memory formation after nonassociative and associative learning are similar. Since learning through different sensory modalities may involve different molecular mechanisms and since our associative learning assay is based on odor-shock pairings (Tully & Quinn, 1985, *J. Comp. Physiol. A* **157**: 263), we have developed an assay for nonassociative learning based on olfactory cues. We found that flies would jump up – as if to fly away – when presented with a concentrated, noxious odor stimulus (10% benzaldehyde), as described by McKenna et al. (1989, *PNAS* **86**: 8118). We then semi-automated the olfactory jump procedure to deliver 4-s presentations of an airborne odor stimulus repeatedly to individual flies. With such a procedure, the flies eventually stopped jumping.

This response decrement in wild-type (normal) flies shows many definitive behavioral properties of vertebrate habituation: More stimulus trials are required for a fly to stop jumping if the interval of time between trials (ITI) is longer. Fewer trials are required for a fly to stop jumping if the odor concentration is lower. After habituating, 80% of flies will jump in response to the odor stimulus if they have been dishabituated by a novel, strong stimulus (75 s of vortexing).

Analysis of the (associative) learning/memory mutants has revealed that a) acquisition of habituation is slower than normal, spontaneous recovery (memory retention) is faster than normal and dishabituation is normal in *rutabaga* mutants, b) acquisition can be faster -- or slower -- than normal (depending on ITI), spontaneous recovery is faster than normal and dishabituation is abnormally low in *dunce* mutants and c) acquisition, spontaneous recovery and dishabituation is normal in *amnesiac* and *latheo* mutants. In addition, acquisition of habituation is faster than normal in mutants with abnormal olfaction or locomotion. These results are consistent with the notions that a) the *rutabaga* mutation affects memory, b) the *dunce* mutation affects both memory and sensory or motor processes and c) short-term memory is normal in *amnesiac* and *latheo*.

ABSORPTION VOLTAGE-SENSITIVE DYES FOR INTRACELLULAR APPLICATION. D.Zecevic# and S. Antic. Sch.Biology. Univ.Belgrade, Yugoslavia.

Absorption optical signals corresponding to membrane potential changes were investigated in neurons filled with voltage-sensitive dyes. We are looking for signals that are large enough to allow the analyses of subthreshold signal integration at the level of individual neurons in invertebrate ganglia. Absorption dyes, as compared to fluorescent molecules, might be more successful since they cause less photodynamic damage. Dyes were tested on individual neurons from the isolated ganglia of young (.3-1 g) snails (Helix). We determined the potential dependent response spectra of several analogs of the most successful potentiometric probes characterized by three different basic chromophores. By comparing signals obtained with most sensitive negatively charged pyrazolone-oxonol probes (RH155, RGA509, RH479, RH482, RGA565A, RGA577, RGA574, JPW1249, JPW1247,JPW1245, JPW1037) with newly synthesized positively charged close analogs (JPW1177, JPW1241) we found that positively charged probes are about 10 times more sensitive in intracellular application. These results indicate that further improvement in signal size might be obtained by synthesizing positive analogs of negatively charged merocyanine and barbituric-acid-oxonol compounds that give relatively large absorption signals in intracellular application. Those are: WW375, JPW1124, NK2367 and WW781.

MORPHOLOGICAL AND BEHAVIORAL DEVELOPMENT IN THE EMBRYONIC MEDICINAL LEECH. Shirley A. Reynolds, Andreas Baader, and William B. Kristan,Jr.* U.C.S.D. Biology Dept., 0322, La Jolla, CA 92093

As a preliminary to studying the development of neuronal circuits responsible for different behaviors, we have been studying the normal course of behavioral development in the medicinal leech, *Hirudo medicinalis*. Most leech behaviors are first seen during embryogenesis. To establish staging criteria which cover the time of behavioral development, we have been tracking the development of several morphological features as well as the development of both spontaneous and mechanically-evoked behaviors. We have found that behavioral responses to light mechanical stimulation vary among different body regions. At the anterior and posterior ends, the predominant response to mechanical stimulation is shortening. The predominant response at the midbody region early in development is circumferential indentation, which is replaced by local bending. A single mechanical stimulus will sometimes produce a combination of two simple behaviors, which can occur either sequentially or simultaneously. The percentage of mechanical stimuli which produce at least some behavioral response reaches maximum at about one week after the animal first becomes responsive. Swimming develops as progressive refinements of the early swim-like behavior. In contrast, crawling is a complex behavior resulting from the successive integration of simpler behaviors, namely progressive elongation and contraction, rear sucker use, and front sucker use. Both crawling and swimming appear to be fully developed by the end of embryogenesis when the juvenile leech emerges from the cocoon. This work was supported by an NIMH research grant (MH43396) and by Deutsche Forschungsgemeinschaft.

399.1

A RETINA SPECIFIC PROTEIN EXPRESSED TRANSIENTLY ON ZEBRAFISH OPTIC NERVES. H.Chang and W.Gilbert*. Dept. of Cell. and Dev. Biology, Harvard Univ., Cambridge, MA 02138

We are interested in identifying molecules involved in neural development and axonal pathfinding in vertebrates. Zebrafish provide an ideal system because it can be easily studied at early stage and its nervous system is relatively simple.

We have generated a monoclonal antibody, 7A11, which recognized an antigen expressed specifically in zebrafish retina. Immunostain shows that 7A11 MAb first stains retinal ganglion cells around 38 hours after fertilization, later(3 days) it also stains inner plexiform layer(IPL) and inner nuclear layer(INL), at adult retina it only stains IPL and amacrine cells. Most interestingly, 7A11 antigen expressed on the optic nerves during the initial out growth of retina ganglion axons at embryonic stage, but no longer expressed at the adult optic nerve. The expression pattern of 7A11 antigen suggested it may involve in the development and guidance of optic nerve.

Immunoblots showed that 7A11 MAb stained a single band at 28kD , following SDS-PAGE of zebrafish retina sample.

Studies are in progress to clone the gene for 7A11 antigen and to determine its role in retina development.

399.2

A NEW MEMBRANE PROTEIN ON CHICK SENSORY NEURONS. R.G. Perez*, Y.P.L. Yip, W. Halfter, and J. Yip. Dept. of Neurobiology and Dept. of Physiology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

A 140 kD cell surface protein was identified by a monoclonal antibody (1A12) obtained from a mouse immunized with dorsal embryonic chick spinal cords. The protein is present on afferent neurons in the CNS and PNS, but absent on motoneurons and their axons. In spinal cord, the protein is present on a subset of primary afferents that project in the dorsal funiculi (DF). During early development, the 1A12 antigen is found in dorsal root ganglia, sensory components of peripheral nerves, and central projections in the DF. Later in development (E16-hatching), 1A12 ceases to be found in the DF and is present only in the lateral dorsal horn of spinal cord. In the visual system, 1A12 is present in the retina, optic nerve and optic tract in early stages of axon outgrowth. It is not present in the optic fiber layer of tectum indicating that the expression of the antigen ceases as optic fibers reach this tissue. By E10, the antigen disappears entirely from the visual system indicating that expression of the antigen is developmentally regulated. The restricted spatiotemporal distribution of the antigen suggests that it is important for the development of afferent projections.

399.3

Mab E1 (SG III-1) delineates neuronal cell classes in neuron-glial cell interaction and affects neurite outgrowth.
A. Zimmermann* and A. Sutter, Institute of Zoology, Technical University, Schnittspahnstr. 3, 61 Darmstadt and Dept. of Immunopharmacology-Neuroimmunology Group, E. MERCK, 61 Darmstadt FRG.

Axonal growth processes are controlled by neurotrophic factors as well as neuron-glial contacts. We describe a neural cell surface antigen E1, which appears to be involved in axonal growth regulation.

Mab E1 defines an early glial antigen of chick embryonic dorsal root ganglia (drg). In the drg E1 antigen is exclusively represented on glial cells until embryonic day 7 (E7). At later times it also appears on a fraction of drg neurons. When antigen expression was analyzed in indirect immunofluorescence staining in single cell neuron-glial cultures of chick drg or in drg explant cultures grown in the presence of nerve growth factor (NGF), it became apparent that E1 positive neurons displayed a growth behaviour different from E1 negative neurons. E1 negative neurons grew associated and became ensheathed with E1 positive glial cells while E1 positive neurons did not. When Mab E1 was added to neuron-glial cultures of chick drg (E8), the NGF induced neurite outgrowth was blocked completely, suggesting a role of E1 antigen in neurite outgrowth which would appear to be glia mediated in the case of the E1 negative neurons. Also in the CNS the E1 epitope is widely distributed. Here, motoneurons of the spinal cord constitute one example for an E1 negative neuronal cell class growing out into the periphery in close association with E1 positive glial cells.

CLATHRIN IS POSSIBLY INVOLVED IN NEURITE FORMATION INDUCED BY A PROTEASE INHIBITOR IN PC12 CELLS. Y.SAITO, T.KADOTA[1], S.TSUBUKI, T.HAMA[2]* AND S.KAWASHIMA. Dept. Molec. Biol. Tokyo Metropol. Inst. Med. Sci. Tokyo 113. [1]Dept. Anat. Chiba Univ. School Med., Chiba 280. [2]Dept. Neurosci. Mitsubishi Kasei Life Sci. Inst., Tokyo 194 Japan.

We have shown that a protease inhibitor of leupeptin analogue, acetyl-Leu-Leu-Nle-aldehyde (ALLNal) or benzyloxycarbonyl-Leu-Leu-Leu-aldehyde (ZLLLal) induces neuronal differentiation in PC12 cells. In an attempt to identify a target molecule(s), Leu-Leu-Leu-al was immobilized and used as a ligand for affinity chromatography. Proteins of 33K, 35K and 180K were isolated from the membrane and cytoplasmic fraction of PC12 cells. ZLLL-COOH had no ability to induce neurite outgrowth in PC12 cells, and 33K, 35K and 180K did not bind to the LLL-COOH affinity column. Several lines of evidence suggest that these proteins are clathrin light chains (33K and 35K) and clathrin heavy chain (180K), components of clathrin which is well known for its role in endocytosis. Separation of clathrin into its heavy and light chains showed the clathrin heavy chain had ability to bind to the LLLal affinity column directly. Furthermore, ZLLLal but not ZLLL-COOH enhanced the rate of polymerization of clathrin triskelion to the coat structure. These results suggest that the role of clathrin should be incorporated into a model describing pathways during the initiation of neurite outgrowth.

399.5

NEURITE OUTGROWTH FROM CULTURED EMBRYONIC MOUSE RETINAL CELLS IS SUBSTRATE DEPENDENT. *C.E. Lagenaur and †M.H. Hankin. *Univ. Pittsburgh, Pittsburgh, PA and †Medical College of Ohio, Toledo, OH.

Is neurite outgrowth from mouse retinal ganglion cells (RGCs) of different development ages substrate-dependent? Previous studies indicate that RGC neurite outgrowth may be influenced by specific substrate molecules, but it is not clear whether the early developing RGCs show a preference for outgrowth on any particular substrate.

To address this issue, we have monitored neurite outgrowth *in vitro* from dissociated fetal (E12-16) or early postnatal (P0-6) CD-1 mouse retinal cells on purified substrate molecules (L1, NCAM & laminin). RGCs from fetal retinae were identified by staining with an antibody to neuron-specific β-tubulin (TuJ1), a specific marker for early differentiating RGCs (Watanabe et al., *J Neurobiol* 22:85). RGCs from neonatal animals were identified in vitro after retrograde labelling *in vivo*. The ability for given substrates to support neurite outgrowth was also compared with their expression *in vivo*.

Cultured embryonic cells expressed a variety of morphologies (unipolar, bipolar and multipolar), and all cells were TuJ1$^+$. Neurite outgrowth on L1 was apparent shortly after cell attachment, and was vigorous after 18-24h (many cell with neurites extending 500 μm). After 48-56h, neurite length in many cells exceeded 1500 μm (indicating a growth rate of about 1mm/day). Few neonatal RGCs survived beyond 24h, although other retinal neurons survived on L1.

Outgrowth from embryonic retinal neurons on non-L1 substrates was detectable only from a few cells per coverslip. The majority of cells on NCAM had growth cone-like membrane expansions, but elongation was not seen. Neurite outgrowth from RGCs on laminin was seen only rarely. In contrast, cortical cells from the same embryos showed vigorous outgrowth on L1 and NCAM substrates.

These data show that developing (E12-16) RGCs prefer to grow on L1 substrates; at some point between E16 and birth, RGCs lose their ability to survive and extend neurites on L1.

RETINAL AXON EXTENSION IS ENHANCED ON L CELL MONOLAYERS EXPRESSING TRANSFECTED NCAMS Li Liu and Richard A. Akeson*, Division of Basic Research, Children's Hospital, Cincinnati Ohio, 45229

The neural cell adhesion molecule NCAM has been reported to enhance axon outgrowth from several neural sources including retina. To investigate the full extent of NCAM function, we examined the biologic activities of distinct NCAM isoforms particularly those which vary in the fourth immunoglobulin-like domain by the presence or absence of a ten amino acid exon termed VASE. Axon outgrowth from chick retinal neurons was tested on control fibroblast L cells and L cells transfected to express rat 140 kD NCAM± VASE. Axon outgrowth from retinal strips cultured from 6 day embryos was analyzed as a function of the density of substrate cells upon which they were explanted. No changes in axon outgrowth compared to control laminin layers were observed when substrate cell monolayers were 10-20% confluent. Monolayers of control L cells which were more than half confluent inhibited axon outgrowth by >60%. Axon outgrowth on NCAM expressing L cells at this confluency was 2-3 times greater than that on control L cells but less than that on laminin. Thus NCAM expression by the transfected cells partially, but not totally, overcame the inhibitory capability of the L cell itself. At greater cell confluencies, axon outgrowth was further diminished but at all densities tested NCAM expressing cells supported greater axon outgrowth and L cells expressing NCAM without the VASE exon supported consistently greatest axon outgrowth. To further test the effects of NCAM on axon outgrowth, dissociated retinal cells were plated on monolayers of L cell±NCAM, B35 neuronal tumor cells which express NCAM, and B35 derivatives that had been selected to lack NCAM. B35 cells both with and without NCAM supported much more extensive axon outgrowth than any of the L cell derivatives. The combined results confirm that while NCAM is one substrate factor which supports axon outgrowth, other substrate components are also active. They further indicate that NCAM+VASE which is present in mature neural tissue is less supportive of axon outgrowth than NCAM lacking VASE which is found in embryonic tissues. Supported by grants EY08490 and HD21065.

MODULATION OF LAMININ'S NEURITE-PROMOTING ACTIVITY.
D. Muir.* Developmental Neuro-Oncology Lab., Departments of Pediatrics and Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610

Purified laminin (LN) promotes neurite outgrowth by regenerating neurons and NGF-treated PC12 cells. Schwann cells secrete LN and other extracellular matrix molecules including proteoglycans (PGs) that bind to LN but do not affect its activity. In contrast, neurite-promoting activity is completely inhibited when LN is complexed with a Schwann cell-derived, high-density, chondroitin sulfate/heparan sulfate PG. The inhibitory PG appears to specifically address LN since it did not substantially inhibit the neuritic response of PC12 cells to other matrix molecules. Initially I observed that, in contrast to purified LN, LN activity in crude extracellular matrix extracts was not vulnerable to inhibition by the high-density PG. Recombination experiments demonstrated that LN in the extract was bound to low-density PG(s) which protected its activity by preventing the inhibitory PG from complexing with LN. Other LN-binding proteins including entactin and collagen type IV were not protective. In addition, when purified LN was first complexed with the inhibitory PG, inhibition was not reversed by the addition of LN-binding molecules including other PGs. Neurite-promoting activity was, however, restored (de-inhibited) by treating inhibited LN-PG complex with the metalloprotease stromelysin. Apparently, stromelysin selectively abolishes the inhibitory activity allowing LN to express its neurite-promoting activity. This mechanism for de-inhibition may be particularly relevant since PC12 cells secrete stromelysin at the onset of neurite-outgrowth.

These findings suggest the neurite-promoting activity of LN is modulated by forming complexes with either protective or inhibitory PGs and this modulation is counteracted by protease(s) secreted during neurite outgrowth. (Supported by Telios Pharmaceuticals, Inc.)

DEGRADATION FRAGMENTS OF L1 ANTIGEN ENHANCE TYROSINE HYDROXYLASE-POSITIVE NEURITE OUTGROWTH IN MESENCEPHALIC CELL CULTURE.
M. Poltorak*, J.R. Williams and W.J. Freed. NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032.

The L1 antigen is implicated in axonal elongation during formation of major fiber tracts and promotes neurite outgrowth in culture. It is possible that during injury of brain tissue, neuronal surface molecules such as L1 antigen are shed, and degradation fragments may therefore be present adjacent to the damage. These L1 fragments might then influence regeneration and injury-induced growth. We have evaluated neurite outgrowth from tyrosine hydroxylase-positive (TH+) E13 mesencephalic neurons grown *in vitro* on intact mouse L1 antigen and three degradation fragments separated by molecular weight. Mouse MAG, laminin, fibronectin, poly-D-lysine, and fetal calf serum served as control substrates. L1 antibodies were added to one set of cultures (experimental), and compared to control cultures containing normal rabbit serum. After 3 days *in vitro*, the cultures were stained using an antibody against TH, and the length of the TH+ neurites was measured by computer assisted image analysis in a double blind fashion. TH+ neurites were significant longer when grown on intact L1 antigen, as well as on each of the three degradation fragments, as compared to the control substrates. As compared to control normal rabbit serum, L1 antibodies blocked fasciculation and eliminated the neurite-promoting effect of the L1 substrate and of the L1 degradation products. These data suggest that the presence of L1 fragments *in vivo* might influence regeneration or synaptic restructuring.

NCAM-POLYSIALIC ACID AND L1 EXPRESSION ON GROWING AXONS OF ISOLATED NEURONS.
W. T. Kim, W. F. Collins*, and A. N. van den Pol. Sect. Neurosurgery, Yale Univ. School Med., New Haven, CT 06510.

Although NCAM has been considered to be a homogeneously distributed neuron adhesion molecule with a general role in development, NCAM expression at the cellular level may vary in molecular density and the amount of polysialic acid (PSA), thereby influencing adhesion and axonal growth. To study the relative densities of NCAM and PSA on the different surfaces of single isolated rat hippocampal neurons, we used immunogold cytochemistry and digitally-processed backscatter electron imaging in an Amray 1810 scanning electron microscope. Based on the gold particle density per membrane area from thousands of images representing all surface membrane domains of isolated cells, we found NCAM immunoreactivity distributed evenly throughout the plasmalemma of single cells. NCAM labeling among different cells in the same culture dish varied as much as 225%. PSA, which may reduce the homophilic binding of NCAM, was strongly expressed on axonal growth cones and their filopodia. PSA immunoreactivity was found at higher densities (37% $\pm$ 12% S.E.) on axons than on dendrites of the same cell in 6 out of 7 neurons, and at higher densities (35% $\pm$ 11%) on the distal axon near the growth cone than on the proximal part of the same axon in all 7 cells. Since NCAM may influence the homophilic binding of the L1 molecule, we undertook parallel examinations of L1. Neurons after one day in vitro showed L1 immunoreactivity on all processes; as soon as one process, the putative axon, extended farther than the others, it showed a higher level of expression. L1 immunoreactivity was 417% greater on axons than on dendrites at five days in vitro. Axonal growth cones and their filopodia were strongly immunoreactive for L1. The presence of NCAM-PSA and L1 on the growth cone of axons, together with evidence of a strikingly heterogeneous distribution of these molecules in the cellular microenvironment, support the hypothesis that NCAM-PSA and L1 may participate in some aspects of axonal extension and guidance.

399.10

DIFFERENTIAL MODULATION OF NEURONAL POLARITY BY EXTRACELLULAR MATRIX AND CELL ADHESION MOLECULES.
A. Lochter* and M. Schachner. Department of Neurobiology, Swiss Federal Institute of Technology, CH-8093 Zurich, Switzerland.

The effects of extracellular matrix glycoproteins and cell adhesion molecules on neurite growth have been discussed mainly in the context of promotion of neurite initiation and axonal elongation. Only recently have polarity and inhibition of neurite growth been investigated. To gain insight into the mechanism of establishment of neuronal polarity, we have studied the kinetics of the morphological differentiation of hippocampal neurons in vitro on polyornithine-substrates coated with different proteins. On the extracellular matrix substrates tenascin, laminin and fibronectin an initial phase of increased neurite outgrowth was followed by an increased growth rate of the axon-like, major neurite and a cessation of growth of dendrite-like, minor neurites, when compared with neurons on control substrates without coated proteins. In contrast, neurite growth on the cell adhesion molecule L1 and the lectin concanavalin A showed an initial burst of neurite outgrowth and continuous growth of major neurites but no decreased growth of minor neurites. Therefore polarity was not increased.

The pronounced polarity of neurons grown on tenascin substrates could be reduced strongly with inhibitors of protein kinases, suggesting that specific intracellular signalling mechanisms participate in the establishment of different neuronal compartments.

GROWTH CONE COLLAPSE INDUCED BY MEMBRANE-BOUND MOLECULES MAY BE MEDIATED BY PERTUSSIS TOXIN (PTX)-SENSITIVE G PROTEINS.
M. Igarashi*, T. Vartanian, S.M. Strittmatter, and M.C. Fishman, Developmental Biology Lab. and Cardiovascular Res. Ctr., Massachusetts General Hospital-East, Charlestown, MA 02129.

Inhibitory signals to growth cones are crucial for the regulation of axonal pathfinding. The transduction mechanisms that mediate such "stop signals" are poorly understood. The collapse of growth cones in culture has been used to partially isolate inhibitory substances associated with brain membranes (Neuron 4: 21-9) and myelin (J. Cell Biol. 106: 2181-8). We have previously demonstrated that G_o is one of the major proteins in growth cone membranes. In the present study, we examined the potential roles of G proteins in growth inhibition, using the growth cone collapse assay. CHAPS-solubilized collapsing activity of chick brain membranes causes growth cone collapse of both DRG and retinal explants. PTX-pretreatment blocks growth cone collapse completely in DRG, and partially (about half of the newly induced collapse) in retinal neurons. Mastoparan (MP), a direct activator of G_i/G_o, mimics the collapsing activity of brain membranes, such that 1 μM MP collapses 70% of DRG growth cones, an activity blocked by PTX-pretreatment. The collapsing activity of rat CNS myelin solubilized by octylglucoside induces 65% growth cone collapse in DRG neurons, and this effect is also inhibited by PTX. These results suggest that some of the membrane-bound inhibitory signals to growth cones may act by stimulating certain receptors coupled to PTX-sensitive G proteins. Blockade of such G proteins appears to abrogate the inhibitory signals, thereby permitting continued growth cone advance.

399.12

PURIFICATION OF GROWTH CONE COLLAPSE-INDUCING GLYCOPROTEIN FROM ADULT CHICKEN GREY MATTER.
Geoffrey M.W. Cook, Alan R. Johnson, Marina S. Gordon, Scott A. Akker & Roger J. Keynes*.
Department of Anatomy, University of Cambridge, Cambridge, U.K.

Adult avian grey matter contains a glycoprotein fraction that causes growth cone collapse *in vitro* (Abstr. Soc. Neurosci. 16, 77.6, 1990). We have also found collapse activity in mammalian (human, sheep, rat and mouse) grey matter. The avian activity is removed by immobilized peanut agglutinin (PNA), and may be related to a somite-derived, PNA-binding glycoprotein that is involved in the generation of a segmented pattern of spinal nerves. As a further test of similarity between brain and somite activities, chick CNS (E7 retinal) neurons have been grafted into the spinal region of E3 chick embryos; like outgrowing spinal nerves, retinal axons avoid posterior half-somite and grow exclusively through anterior half-somite. A purification schedule for the isolation of the grey matter-derived molecule(s) has been devised. On ultrafiltration, activity is retained with a membrane of 100,000 M.W. cutoff. The macrosolute is then fractionated by chromatography on immobilized reactive dyes in combination with nondenaturing gel electrophoresis. Material electroeluted from a single band, running just behind a BSA marker on a 10% gel, induces growth cone collapse. We hypothesize that this component may inhibit growth of normal and regenerating axon terminals in the adult brain.

399.13

PURIFICATION AND CHARACTERIZATION OF INHIBITORY PROTEINS FROM RAT CNS MYELIN. **F. Keller*, B. Rubin, C. Bandtlow and M.E. Schwab. Brain Research Institute of the University of Zürich, CH-8029 Zürich, Switzerland.**

CNS myelin and mature oligodendrocytes are inhibitory for neurite outgrowth. When myelin proteins from rat CNS are separated by SDS-PAGE, inhibitory activity can be eluted from the 35 kD and 250 kD region. Two monoclonal antibodies (IN-1 and IN-2) were raised against the gel-purified inhibitory fractions and were found to neutralize the inhibitory properties of CNS myelin and oligodendrocytes (Caroni and Schwab, 1988). In addition, IN-1 was found to promote regeneration of transected corticospinal and septo-hippocampal axons in young and adult rats (Schnell and Schwab, 1990; Cadelli and Schwab, 1991). In Western blots of rat CNS myelin, IN-1 and IN-2 bind to a partially overlapping set of bands of approx. 35, 45, 55 and >200 kD. These bands appear to be specific for CNS myelin, since they are not found in PNS myelin. Interestingly, and in contrast to several of the major myelin proteins, some of these bands are resistant to extraction with nonionic detergents, and can only be solubilized with SDS. An immunoaffinity column was prepared by covalently crosslinking the IN-1 antibody to an anti-IgM matrix. After adsorption of SDS-extracted, CHAPS-diluted CNS myelin to the column, part of the inhibitory activity was retained by the column and could be eluted by moderately increasing the salt concentration. This suggests that the activity binds to the column by means of weak interactions. The inhibitory fraction eluted from the column contained several protein bands between 35 kD and 250 kD that are recognized by the IN-1 antibody. Other proteins eluted by lowering the pH did not show inhibitory activity, nor did they crossreact with the IN-1 mAb.

399.14

THE IDENTIFICATION OF A CANDIDATE GLYCOPROTEIN FROM ADULT CHICK BRAIN THAT INDUCES COLLAPSE OF DORSAL ROOT GANGLIA GROWTH CONES. Yuling Luo* and Jonathan A. Raper. Department of Neuroscience, University of Pennsylvania, School of Medicine, Philadelphia, PA 19104.

Factors that inhibit growth cone extension are likely to play a role in both axon pathfinding and regeneration. We previously reported that a growth cone collapsing activity can be recovered from embryonic chick brain membranes and enriched by column chromatography (Raper, J. A. and Kapfhammer, J. P. (1990) Neuron 2, 21-29). Here we report the further enrichment of this collapsing factor and the identification of a protein that is likely to comprise the activity. Detergent-solubilized collapsing activity was enriched over 2,500 fold with a yield of approximately 5% by chromatography on a combination of Q-Sepharose, S-Sepharose, Wheat Germ Agglutinin, and Mono S FPLC columns. The enriched material was highly active, inducing collapse of over 50% of DRG growth cones at a concentration of about 6 ng/ml. After further separation of this highly enriched material by Mono S FPLC, active fractions, in contrast with other fractions, were found to contain one prominent protein band of approximately 100 kDa on Coomassie Blue stained SDS-PAGE gels. This protein band was estimated to comprise 10-20% of the total staining intensity. When highly enriched material was run on a Superose-12 FPLC gel filtration column, the collapsing activity was found to be eluted between apparent molecular weights of 80-160 kDa. Together our results indicate that the 100 kDa protein is likely to possess collapsing activity. The very high specific activity of our most enriched preparation is consistent with the hypothesis that collapse is mediated by a signal transduction event.

399.15

IDENTIFICATION OF A NONPERMISSIVE SUBSTRATE PROTEIN IN THE PLASMA MEMBRANE OF MAMMALIAN BRAIN AND SPINAL CORD. L. Quan, E. Ling, L.M. Jordan and K.W. Cheng*. Spinal Cord Res. Ctr., Dept of Physiology, Univ. of Manitoba, Winnipeg, Manitoba, Canada, R3E 0W3.

In higher vertebrates, lesions in the central nervous system (CNS) are irreversible due to the lack of regenerative growth from the injured axons. Recent studies have identified neurite outgrowth inhibitory proteins from rat CNS myelin, and glycoproteins of growth cone collapsing activity from embryonic chick brain, posterior somite and optic tectum. Using cultures of neuroblastoma X glioma hybrid NG108-15 cells as an *in vitro* neurite outgrowth assay we have identified a nonpermissive substrate protein from cell-surface plasma membranes, isolated from adult rat brain and spinal cord. The enriched plasma membrane fraction was prepared by homogenizing tissues in isotonic buffer, followed by ultracentrifugation on a sucrose step gradient. Upon extraction under alkaline conditions of NH_4OH, a solubilized protein fraction was obtained for coating dishes as substrate for cell cultures. Precoating with the solubilized membrane proteins from rat CNS not only prevented cell adhesion and differentiation of NG108-15 cells, which remained undifferentiated as clusters of round cells even after 24 hrs, but was also nonpermissive for primary cultures of fetal rat brain cortical neurons, which formed clumps and adhered only loosely upon further culture. This solubilized inhibitory protein was partially purified by gel filtration on Sepharose CL-4B, and by adsorbing onto DEAE-cellulose, followed by elution with 0.2 M NaCl. Upon basic polyacrylamide gel electrophoresis (PAGE) and SDS-PAGE, the inhibitory activity appeared to be an acidic protein of Mr 50-70 KDa. A similar acidic protein of nonpermissive substrate activity was also observed in extracts of rabbit brain and spinal cord. These results indicate that cell-surface plasma membranes of the mammalian CNS is a nonpermissive substrate for neuritogenesis, and an acidic membrane-protein is responsible, totally or partly, for the inhibitory effect.

399.16

ARE INDUCED ACTION POTENTIALS THE TRIGGER FOR GROWTH CONE COLLAPSE IN SYMPATHETIC PREGANGLIONIC NEURONS?. C.B.McCullum, J.J.Walker, R.I.Hume*, Department of Biology, University of Michigan, Ann Arbor MI 48109.

When the growth cones of chick sympathetic preganglionic neurons (SPNs) contact dorsal root ganglion neurons (DRGs) *in vitro*, the growth cones exhibit rapid, oscillatory increases in calcium and collapse. One possible mechanism for this pattern of calcium change is that contact with DRGs induces the generation of action potentials in the SPN. The depolarizing phase of the action potential might create a brief, rapid influx of calcium that would oscillate with the frequency of induced action potentials. To test this hypothesis, SPNs were retrogradely labelled with DiI *in vivo*, dissociated into single cells, and plated at low density on a laminin substrate. After 16 to 32 hours, the culture medium was replaced with a standard recording medium and whole cell current-clamp recordings were made from SPNs. These neurons had stable resting membrane potentials and did not spike spontaneously. Once a stable resting potential was established, a DRG was manipulated onto the SPN growth cone and the SPN membrane voltage was monitored for the occurrence of action potentials. Our major finding was that in recordings made at either room temperature or at 33° to 37°C, we never detected voltage changes from baseline levels during the ten to twenty minutes of contact with a DRG. This failure to observe action potentials was not due to compromised cell integrity, since action potentials could be evoked in all cells studied. These results suggest that the previously observed calcium oscillations were not due to DRG induction of action potentials in the SPN and indicate that other mechanisms for increasing intracellular calcium should be explored.

PRODUCTION OF ANTIPROLIFERATIVE AND NEURITE-MODULATING FACTORS BY THE CG4 CELL LINE OF O-2A PROGENITORS. S. Takayama, S. Varon* and J.C. Louis. Department of Biology 0601, University of California, San Diego, La Jolla CA 92093.

CG4 is a permanent cell line of oligodendrocyte-type 2-astrocyte progenitor cells (O-2A) that can be continuously maintained in the proliferative stage or differentiated to oligodendrocytes (OC) (Louis et al., *J. Neurosci. Res.* 1992, 30:193-204). The availability of the CG4 line offers a unique opportunity to analyze which factors are produced by O-2A progenitors and their derivatives. Here, we report evidence that culture media conditioned by CG4 cells contain i) an activity that inhibits their own proliferation and ii) an activity that modulates the neuritic outgrowth of CNS and PNS neurons. The antiproliferative activity is present in the media conditioned by CG4 cells that are expanded as undifferentiated O-2A progenitors, as well as by CG4 cells induced to differentiate to OC. The inhibition of mitotic activity is nearly complete and fully reversible, and is accompanied by the conversion of the CG4 cells' phenotype from $A2B5^+/O4^-$ progenitors to $A2B5^-/O4^+$ pro-OC. The production of the growth inhibitory activity does not depend on the nature of the mitogen used to propagate the source CG4 cells (medium conditioned by the B104 neuroblastoma cells, PDGF or FGF) and similarly, is not dependent on which mitogen is used in the test CG4 proliferation assay. These observations indicate that O-2A cells constitutively secrete and remain responsive to an autocrine antiproliferative factor. Cultures of newborn rat hippocampal neurons and E8 chick ciliary ganglion neurons, were used to determine that after conversion to OC, CG4 cells also release into the medium a polyornithine/laminin-binding neurite-promoting activity for CNS as well as PNS neurons. A preliminary characterization by gel filtration and cation-exchange chromatography, indicates that the neurite-modulating activity resides in a heat-stable, strongly acidic fraction of Mr > 50 kDa.

SIMULTANEOUS MULTI-SITE RECORDING OF ELECTRICAL ACTIVITY AND INTRACELLULAR CALCIUM IN PATTERNED NEURONAL NETWORKS. A. Kawana*, H.P.C. Robinson, Y. Jimbo, E. Maeda and K. Torimitsu., NTT Basic Res. Labs., Musashino, Tokyo, 180 Japan

To study signal transmission and processing in large assemblies of neurons, patterned networks in which connections may be localized or even specified would be advantageous. We have already developed an effective method for the formation of organized neuronal networks in culture (A. Kawana et al; Soc. for Neurosci.,1991). Here, we describe simultaneous multichannel recording of the extracellular electrical activity and intracellular calcium concentration in such simplified neuronal networks.

A silica glass substrate was employed with 16 or 60 transparent electrodes in wells which were connected by microgrooves. A metal mask with holes at positions corresponding to the substrate wells was used to locate rat hippocampal or cerebral cortex neurons selectively in the wells. Intracellular calcium concentration was measured using fluo 3 and an Ar laser(488 nm) for excitation whose light was fed to the optical microscope by an optical fiber. Under low magnesium conditions, intermittent bursts of action potentials were detected from multiple substrate electrodes. Intracellular calcium concentration transients were synchronized to the electrical activity. The period of bursting could be controlled by single-site electrical stimulation through individual substrate electrodes. By plating different types of neurons in different wells, specific types of synapses were reconstituted. This method offers a promising approach for the study of information processing in multi-neuron networks.

OPTICAL MAPPING OF NEURAL RESPONSE PATTERNS TO GLOSSOPHARYNGEAL NERVE STIMULATION IN THE EMBRYONIC CHICK BRAIN STEM. T. Sakai, Y. Momose-Sato, K. Sato, A. Hirota and K. Kamino*. Department of Physiology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo 113, Japan.

In an effort to understand the functional organization/architecture of the brain stem, we have used multiple-site optical system and a voltage-sensitive merocyanine-rhodanine dye (NK2761) to record neural activity in the embryonic chick brain stem. The intact and slice preparations including the brain stem and glossopharyngeal nerve were dissected from 7- and 8-day old chick embryos and stained with the dye. When a brief electrical stimulation was applied to the glossopharyngeal nerve, optical signals were evoked in the brain stem. They were recorded simultaneously from 127 contiguous sites using a 12 x 12-element photodiode array. In the evoked optical signals, two components, a fast spike-like signal and a slow signal were identified. The fast signal reflected action potentials, and the slow signal revealed glutaminergic excitatory postsynaptic potentials. Based on these results, we have constructed maps representing the spatial pattern of the neural response, and we have suggested a possible embryonic origin of the functional organization of the nucleus of solitary tract in the embryonic chick medulla oblongata. EXPRESSION OF NITRIC OXIDE SYNTHASE IN THE DEVELOPING VISUAL SYSTEM OF THE CHICK. C.V. Williams*, D. Nordquist and S.C. McLoon. Dept. Cell Bio,Univ. of Minnesota, Minneapolis, MN 55455.

Normal function of the mature visual system requires precise patterns of axonal connections between the retina and visual nuclei. Development of this precise pattern involves formation of a rough prepattern followed by refinement in the pattern. Evidence suggests this refinement process involves communication from the postsynaptic cell to presynaptic elements. The neurotransmitter nitric oxide (NO) has characteristics that would allow it to participate in this retrograde communication. This study examined the expression of NO in the developing chick tectum to determine whether it might be present in cells upon which retinal axons terminate. Diaphorase histochemistry was used to reveal the presence of nitric oxide synthase (NOS), the enzyme responsible for NO production. The expression of NOS by cells in the developing tectum coincided spatially and temporally with the arrival of retinal axons in the tectum. NOS expression reached a peak in the tectum at the time that refinement of the initial pattern of connections is occurring. Anterograde labeling of retinal axons with WGA/HRP showed that the processes of NOS positive cells in the tectum were coincident with the region of retinal axon termination. Diaphorase histochemistry with anophthalmic chick embryos showed that NOS expression is dependent on the presence of retinal axons. Northern blot analysis using a cDNA probe for NOS from rat brain (Bredt et al., 1991) verified the histochemical results. These results in the developing chick suggest that retinal axons interact with tectal cells that express NO which is consistent with the possibility that NO has a role in the refinement of the pattern of retinotectal connections.

THE FORMATION OF THE TOPOGRAPHICAL RETINO-TECTAL PROJECTION: A TWO-DIMENSIONAL NEURAL NETWORK MODEL S.E. Hua, L.L. Massone*, and J.C. Houk Dept of Physiology, Northwestern Univ., Chicago, IL 60611.

The topographical projection from the retina to the tectum is thought to form by two mechanisms. First, a gross topographical map is formed by axon guidance and position cues, and later a refined map is formed by correlated activity in the retina. We have simulated the formation of a topographical retino-tectal map by constructing a two-dimensional neural network based on correlated activity, Hebbian modifiable synapses, and adhesive marker gradients. We first show that in a two-dimensional model of the retina and the tectum, two gradients of adhesive markers are necessary to establish the correct orientation of the map in both axes. The model also shows specificity as well as plasticity in the connections when retinal rotation and hemi retinal ablation experiments are simulated.

Recent evidence has shown that temporal retinal fibers are repelled by posterior tectal membranes while nasal retina shows no preference. To test whether a hemi-retinal adhesion difference is enough to generate a topographical map, we constructed a neural network without gradients which specified that the temporal retina is less attracted to the posterior tectum and the dorsal retina is less attracted to the medial tectum while the nasal and ventral retinas show no preference. We show that a topographical map is formed, and under certain conditions, the map can form more rapidly than the map formed using the two dimensional gradient model. Thus the retina and tectum need not be specifically labeled by two gradients. Instead, hemi-retinal and hemi-tectal differences in adhesion or repulsion that separate each surface into quadrants of differential adhesion/repulsion provide enough positional information to allow proper map formation.

THE CHOLINERGIC SYSTEM IN GOLDFISH TECTUM MAY BE NECESSARY FOR RETINOTOPIC SHARPENING **W.M. King* and J.T. Schmidt, Dept. Biol. Sci., SUNY Albany NY 12222**

The cholinergic feedback loop in tectum, which mediates a presynaptic augmentation of retinotectal transmitter release, was either removed using the cholinergic neurotoxin AF64A or blocked using nicotinic antagonists. Intracranial injection (IC) of AF64A (30-130 nmoles) resulted at one week in the selective elimination of the cholinergic-mediated polysynaptic field potential following optic nerve shock with monosynaptic transmission unaffected, and in the loss of virtually all immunostaining for choline acetyltransferase (ChAT). ChAT staining later recovered in some deep cell bodies but not in the fibers of SFGS, the retinal terminal layer. IC injection of AF64A at 18 days postcrush, when regenerating retinal fibers are beginning to form synapses, resulted in unsharpened projections when mapped at 60-80 days. There was a rough retinotopic map but the multiunit receptive fields (MURFs) recorded at each tectal point averaged 34° vs 11° in vehicle-injected control regenerates. AF64A treatment before nerve crush also blocked sharpening, ruling out a direct effect on retinal growth cones or fibers, as AF64A rapidly decomposes.

IC infusion of α-Bungarotoxin (αBTX) during regeneration also prevented sharpening (MURFs of 29.4°). Pure αBTX does not, however, substantially block the polysynaptic component, the carbachol augmentation of the monosynaptic field potentials or the carbachol depolarization of the optic nerve terminals, as curare (10μM) does. Neuronal Bungarotoxin (nBTX), a possible contaminant of αBGT, blocked the polysynaptic component, but did not fully block the carbachol augmentation of field potentials. We are still determining if and to what degree αBTX or nBTX prevent sharpening by blocking the cholinergic system. Supported by NEI grant EY-03736.

FUNCTIONAL MAP FORMS BEFORE ANATOMICAL MAP IN THE CORTICORUBRAL PATHWAY OF KITTENS. W.-J. Song*, K. Okawa, H. Oikawa+, M. Kanda+, M. Kanda+, K. Mikatsuki+, T. Ohno and F. Murakami, Dept. Biophys. Engn., Fac. Engn. Sci., Osaka Univ., Toyonaka 560, Japan. + Abrahi Labs., Shionogi & Co., Ltd., Shiga, Japan.

The development of topographic maps has been studied in many regions of the CNS. For technical reasons, however, the development of maps of functional synaptic connection has rarely been an object of study. We studied this issue using the corticorubral (CR) system of the cat as a model. CR axons elaborate their terminal arbors during the first postnatal month, and adult-like topographic distribution of the axons within the red nucleus is observed only after postnatal day (P)13 (Higashi et al., 1990). Here we carried out intracellular recording from rubrospinal neurons of P1-P28 kittens and examined monosynaptic EPSPs evoked from different sites of the sensorimotor cortex, under Nembutal anesthesia. As expected from the anatomical results, most (26/28) rubrospinal cells in kittens aged P13-P28 showed responses indicating the presence of adult-like functional maps: cells antidromically activated only from C1 and those both from C1 and L1 receive inputs mainly from the forelimb and hindlimb cortical regions, respectively. However, against what is expected from the anatomical results, cells in kittens aged P1-P10 showed similar results to the older animals' (50/60). These findings suggest that the basic feature of excitatory connectional map in the CR system is established at birth, before the maturation of CR axons and before clear topography of the axons is observable.

SEGREGATION OF SPINOCEREBELLAR MOSSY FIBER TERMINALS IN +/*LC* MUTANT MICE. M.W. Vogel* and J. Prittie.
MD Psychiatric Research Center, Baltimore, MD 21228.

Spinocerebellar mossy fiber afferents segregate during early postnatal development into sagittal columns. Studies of other mouse mutants and x-irradiated rats (Nunes et al, 1988. J. Comp. Neurol. 273:120-136) suggest that Purkinje cells provide cues for the parasagittal sorting of these afferents. We have examined the distribution of spinocerebellar mossy fiber terminals in the +/*Lc* mutant to determine if mossy fiber terminal segregation is affected by the death of +/*Lc* Purkinje cells during the early weeks of postnatal development.

The distribution of spinocerebellar mossy fibers in 1 juvenile (P38) and 4 adult (P>90) +/*Lc* mutants and 1 juvenile (P44) and 2 adult wild type mice (P>90) was visualized by injecting 2% WGA-HRP into the anterior lumbar region of the spinal cord (T13-L2). Cerebella were subsequently processed for TMB histochemistry.

Although the granule cell layer is reduced in size in +/*Lc* mutants due to increased granule cell death, the distribution of spinocerebellar mossy fiber terminals is similar to that seen in wild type mice. Lumbar mossy fiber terminals predominate in anterior and posterior vermis. While mossy fiber terminal columns are present, they are less distinct than in the wild type. In some areas of the granule cell layer there are clear gaps between regions of dense terminal fields. In other areas, terminal fields are separated only by regions with less dense staining. The poorly defined columns in the +/*Lc* mutant may be explained either by a failure to form well segregated columns due to +/*Lc* Purkinje cell death, or by the merging of well formed columns subsequent to granule cell death. SYNAPTIC REPLACEMENT IN THE INTERPEDUNCULAR NUCLEUS. T. Graessle and M. Murray.* Department of Anatomy and Neurobiology. Med. Coll. PA., Philadelphia, PA 19129.

The interpeduncular nucleus (IPN) receives its major projections from the medial habenulae via the fasciculi retroflexi (RF). Substance P (SP) neurons project to the lateral subnuclei and the cholinergic neurons to the intermediate and central subnuclei. The SP projection is present at birth; the cholinergic projection develops in the second postnatal week. We compared the synaptic populations in these subnuclei in control IPN and in IPN at least 8 weeks after bilateral FR lesions made in adult or 10 day old rats. The lateral subnuclei contain simple synaptic contacts, about 1/3 of which have dense core vesicles (DCV). The number of terminals with DCVs is decreased after adult but not after neonatal lesions. There are few changes in the terminal population in the central subnucleus after FR lesion at either age. The intermediate subnuclei contain large numbers of crest synapses, normally formed by one terminal from the left and one from the right habenula. Similar numbers of crest synapses are present after bilateral FR lesions in adults but fewer develop when FR is lesioned neonatally and they are likely to be morphologically aberrant. Our results are consistent with reactive reinnervation, but the pattern of synaptic replacement differs depending on whether the lesion is made in neonates or adults. Supported by NS-16556.

DEVELOPMENTAL REGULATION OF LOW AFFINITY NGF RECEPTORS IN THE HABENULO-INTERPEDUNCULAR SYSTEM IN THE RAT. **K.S. Bozek, F. Haun, A.F. Pimenta* and M. Murray. Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.**

Part of the habenular projection to the interpeduncular nucleus (IPN) is nicotinic cholinergic and therefore may be subject to regulation by NGF internalized via membrane bound NGF receptors. Immunocytochemical studies indicate that cholinergic habenular neurons innervate their target subnuclei in the IPN in the second postnatal week, the only period during which lesion induced sprouting can be demonstrated. This suggests that either NGF production or NGF receptors might be developmentally regulated in this system. We therefore used immunohistochemistry to examine the distribution and expression of low affinity NGF receptors (antibody 192, a gift from Dr. Eugene Johnson) during the development of the IPN in the rat. At postnatal day 4, NGF receptor staining is present on axons in the pathway from the habenula that innervates the IPN but is absent in the IPN. By 10 days, recognizable immunoreactivity appears in the intermediate subnuclei of the IPN, the subnuclei receiving densest cholinergic innervation from the habenula. This staining reaches its maximum by 14 days. Thereafter, the receptor staining decreases and is no longer detected by day 28. These observations indicate that habenular axons express the low affinity NGF receptor transiently during the time that they innervate their targets.

DEVELOPMENT OF AXONAL AND DENDRITIC ARBORIZATIONS IN THE DORSAL HORN OF THE EMBRYONIC RAT SPINAL CORD. I Silos-Santiago* and W.D. Snider. Dept. Neurology, Washington University Medical School, St. Louis, MO, 63110.

Both the axonal and dendritc arborizations that comprise the circuits of the mammalian dorsal horn have been carefully studied with classical neuroanatomical techniques and intracellular staining. However, little is known about how this complex circuitry develops. We have approached this problem using lipid-soluble tracers to label both afferent and efferent components of dorsal horn circuits during embryonic development in the rat.

Using focal applications of DiI we labeled single primary dorsal root afferents and single interneurons in laminae I-V. The major classes of primary afferent fibers had entered the thoracic spinal cord by E17. We could clearly distinguish between fibers entering medially and projecting to laminae III-V and short fibers in lamina I and II which enter more laterally and project rostrocaudally. By E19, several classes of afferents could be recognized on the basis of characteristic morphology. These afferents were in their target fields by E19 and no evidence of rearrangement was seen through the first postnatal week. We also studied the morphology of the target neurons in the dorsal horn. By E17, we could distinguish 2 different cell types in lamina I , 4 types in lamina II, 4 types in lamina III, and 6 types in lamina IV on morphological grounds. Many of these have been observed in the adult, but we found several classes of dorsal horn neurons not previously described. In most cases, the dendritic arbors of these cells were not limited to the lamina where the soma was located.

We have shown that most of the classes of primary afferents and dorsal horn neurons described in adult animals can be recognized on the basis of characteristic morphology in embryonic rats. In contrast to other areas in the CNS, we find no morphological evidence of rearrangement during development in this system.

SPECIFICITY OF SYNAPTIC CONNECTIONS BETWEEN MUSCLE AFFERENTS AND MOTONEURONS IN THE DEVELOPING RAT SPINAL CORD. B.S. Seebach* and L. Ziskind-Conhaim. Dept. Physiol. and Ctr. Neurosci., Univ. of Wisconsin, Madison WI 53706.

Mature vertebrates have specific synaptic connections between muscle afferent fibers and motoneurons that innervate limb muscles. Motoneurons receive monosynaptic excitatory inputs from homonymous and synergistic muscles, and polysynaptic inhibitory inputs from antagonistic muscles. To determine whether specific sensory-motoneuron contacts are established during early synaptogenesis in the mammalian spinal cord, we have studied the pattern of these synaptic connections in embryonic (E20-22) and newborn rats (P0-4). Nine hindlimb nerves were stimulated and the evoked potentials were recorded intracellularly from motoneurons of isolated spinal cords. Monosynaptic potentials were distinguished from polysynaptic potentials by their shorter latency and resistance to high-frequency stimulation. Depolarizing IPSPs reversed at -50mV membrane potential. In the embryonic spinal cord, 20% of motoneurons received monosynaptic excitatory inputs from antagonistic muscles. These inappropriate connections persisted until at least 3-4 days after birth, suggesting that some reorganization of synaptic connectivity occurs in the rat during postnatal development.

TRKAn: AN ALTERNATIVELY SPLICED FORM OF TRKA EXPRESSED BY NEURONS. P.A Barker*, C. Lomen-Hoerth, S.O. Meakin, E.M Gensch, E. M. Shooter, Department of Neurobiology. Stanford University School of Medicine, Stanford, California. 94305.

The product of the Trk proto-oncogene has been identified as a signal-transducing receptor for nerve growth factor. This tyrosine kinase receptor was originally cloned from human K562 cells, a human leukemic cell line. We have identified a variant of the TrkA receptor, TrkAn, which differs from originally cloned form of TrkA by virtue of a small insertion within the extracellular domain. Both forms of Trk receptors are found within rats and humans and the amino acid sequence of the insertion is strictly conserved between species. The inserted domain is encoded by a distinct exon whose presence appears to be regulated by tissue-specific alternative splicing. Several nonneuronal tissues contain both forms of TrkA mRNA. However, only TrkAn is expressed within CNS and PNS neurons of rat and humans.

Rat TrkA and TrkAn have been expressed in Cos cells and shown to specifically bind NGF and display slow dissociation kinetics and trypsin sensitivity characteristic of the slow NGF receptor. Although the functional role subserved by these distinct forms of the TrkA protein remain unknown, the evolutionary conservation of the inserted domain across species together with the tissue-specific expression of the alternative transcripts indicates some functional role.

401.2

COLOCALIZATION OF NGF BINDING SITES TO *TRK* AND P75-EXPRESSING CELLS IN BASAL FOREBRAIN CULTURES. J.L. Tassone, M. Yokoyama, I.B. Black, and C.F. Dreyfus.* Department of Neuroscience and Cell Biology. Robert Wood Johnson Medical School/UMDNJ. Piscataway, NJ 08854 and Rutgers College, New Brunswick, NJ 08903

A recent controversy in the neurotrophin field concerns the identity of the biologically active NGF receptor. The *trk* proto-oncogene product and the p75 molecule have been tentatively identified as NGF receptors, but the exact role of each molecule remains unclear. To approach this problem, we have localized either *trk* or p75, and NGF binding sites on cultured basal forebrain neurons dissociated from embryonic day 17 (E17) rat. *Trk* was visualized using 43-4 IgG from a polyclonal antiserum corresponding to the 14 carboxy terminal amino acid residues of gp140^{trk} (a gift of R. Klein, F. Lamballe, and M. Barbacid, Bristol Myers-Squibb Pharmaceutical Research Institute, Princeton, NJ). These antibodies can react with all *trk* receptors. p75 was visualized using 192 IgG (a gift of M. Chao, Cornell Medical College, New York, NY and E. Johnson, Washington University Medical School, St. Louis, MO). Cultures were grown for seven days in serum-containing media to allow the growth of both neurons and glia. To visualize low and high-affinity NGF binding sites, cultures were incubated in 125I-labeled NGF (.2nM). Autoradiographic and immunocytochemical techniques were employed to visualize the expression of NGF binding sites and *trk* or p75. Our results indicate that the great majority of cells which bind NGF express both *trk* and p75. We conclude that in cultured normal primary basal forebrain neurons, NGF binding is associated with expression of both *trk* and p75. A QUANTITATIVE REVERSE TRANSCRIPTION - PCR ASSAY TO STUDY p75 NERVE GROWTH FACTOR RECEPTOR GENE EXPRESSION IN DEVELOPING RAT BRAIN. Chu-Kuang Chen*, Stephen Kinsman, and Michael Johnston. The Kennedy-Krieger Research Institute and Dept. of Neurology, Johns Hopkins Medical Institutions, Baltimore, MD

The action nerve growth factor (NGF) as well as other neurotrophins BDNF and NT-3 are mediated through the activation of specific receptors. Expression of these receptors occurs not only in the adult brain but also during important developmental periods. Recent investigations suggest that p75 is one component of the high affinity NGF receptor complex. Transient elevation in levels of p75 mRNA in perinatal rat cerebellum have been demonstrated using RNAse protection assay. However, a more sensitive assay will allow a more detailed examination of the ontogeny of p75 gene expression.

We developed a sensitive quantitative RT-PCR assay to study p75 message in regions of low abundance expression or where tissue availability is limited. Our assay is based on using a shortened p75 cRNA an an internal RNA standard to control for variability in reverse transcription and polymerase chain amplification of the endogenous p75 assayed. To make our method quantitative, we have examined the kinetics of the PCR reaction for two p75 templates (endogenous and shortened standard p75 cRNA). p75 mRNA levels are determined in total RNA samples by comparison of co-amplified endogenous p75 mRNA with a known amount of shortened p75 standard cRNA. We have used this assay to examine the expression of p75 during ontogeny of the cerebellum and striatum.

Our results demonstrate this assay to be roughly 1,000-fold more sensitive than current methods for assaying a low abundance message such as p75. In Sprague-Dawley rat cerebellum, p75 mRNA level was most abundant at PND 2 (2.7 pg/µg total RNA), and then declined to a lower level throughout development and in adult (<1 pg/µg total RNA). Levels of p75 mRNA are over 7-fold higher in immature P10 striatum than they are in adult striatum. This extremely sensitive assay will facilitate studies of the role of neurotrophic factors during development.

THE TRK PROTO-ONCOGENE PRODUCT p140 IS EXPRESSED BY GANGLION CELLS OF THE HUMAN RETINA. A. Merighi', G. Carmignoto, S. Ghidella', M. Lipartiti*, A Zanellato and C. Comelli. 'Dip. Morfofisiologia Veterinaria, 10100 Torino, and Fidia Research Laboratories, 35031 Abano Terme, Italy.

In the retina of different animal species including non-human primates a significant number of ganglion cells (RGCs) has been reported to express the low affinity NGF receptor (p75-NGFR). The finding that following axotomy in the adult rat the same neurons can be rescued from degeneration by intraocular administrations of NGF led to the hypothesis that RGCs represent a neuronal population of the central nervous system sensitive to the action of NGF. Since the biological activity of NGF is mediated by a high affinity membrane-bound receptor, we have studied the immunocytochemical distribution of both the trk proto-oncogene product p140, which likely corresponds to the high affinity NGFR, and the p75-NGFR in tranverse sections of human and rat retina. We found that in the human retina p75-NGFR immunoreactivity is restricted to Müller cells while a high number of neurons in the GC layer is immunopositive for the p140-trk. On the basis of morphological criteria at least part of these neurons can be classified as RGCs. Conversely, in the rat retina a sub-population of RGCs and Müller cells are immunoreactive for both antigens. Binding studies and affinity cross linking/immunoprecipitation experiments performed in purified *in vitro* preparations of RGCs from neonatal rat retinae confirm the presence of the high affinity NGF receptor. These results suggest that RGCs in humans could be sensitive to the action of NGF and raise the possibility that NGF, or a closely related molecule, could represent a new therapeutic approach for the treatment of retinal neurodegenerative pathology.

NGF GENE EXPRESSION IN MOUSE AND MAN: ROLE OF RETINOIC ACID RECEPTORS(RARs). C. Jiang*, M. Cartwright and G. Heinrich. Biomolecular Medicine, Boston University Hospital, BOSTON, MA 02118.

Retinoic Acid(RA) induces NGF mRNA in mouse L cells and high affinity NGF binding in chicken embryonic sympathetic neurons, suggesting an important role in coordinating induction of neuronal NGF dependence, responsiveness and NGF production by targets. We previously cloned the mouse, rat and recently the human NGF gene promoter regions. An intronic AP-1 element is conserved in the NGF promoter region of all species, but an upstream AP-1 consensus sequence is human specific. Gel shift analysis showed that the RAR-alpha can bind to the upstream AP-1 consensus sequence in the human NGF but not to the conserved intronic AP-1 elements in either human or mouse NGF promoters. Furthermore, the RAR-alpha suppressed binding of AP-1 complexs to all AP-1 sites. Several RA response element(RARE) like motifs are found within 1,000bp upstream of both mouse and human NGF promoters, suggesting direct binding of RARs and transcriptional regulation of NGF by RA in vivo. We are analyzing the differential binding of additional RARs(beta and gamma) to mouse and human NGF promoters and their functional significance, also beginning to address the relationship between the structurally and functionally defined RAREs and the AP-1 consensus sequences.

NGF INDUCES *C*-FOS IN THE BASAL FOREBRAIN NEURONS EXPRESSING NGF RECEPTOR (NGFR): A DOUBLE IMMUNOCYTOCHEMICAL STUDY IN THE RAT. Z.-C. Peng, S. Chen, M. Fusco°, M.G. Nunzi°* and M. Bentivoglio, Institute of Anatomy, University of Verona; °Fidia Research Laboratories, Abano Terme, Padova; Italy.

NGF (10 µg in 10 µL) was administered into the lateral cerebral ventricle in adult male Wistar rats through a previously implanted cannula. Cytochrome c was injected with the same procedure in control animals. All cases were sacrificed 3 hrs later and the brains were processed with a double immunocytochemical protocol for the visualization of *c*-Fos (using antibodies raised in sheep) and the low affinity NGFr (using monoclonal antibodies raised in mouse), exploiting two different chromogens. A considerable number of *c*-Fos-immunoreactive (ir) neurons was evident after NGF treatment throughout the basal forebrain, in contrast to the control cases in which this region was devoid of *c*-Fos-ir cells. In the areas that contain NGFr-ir neurons - including the medial septal and basal nuclei, and the horizontal and vertical limbs of the diagonal band - almost all the *c*-Fos-ir cells were also NGFr-ir. Double immunostained (NGFr-ir and *c*-Fos-ir) neurons ranged from 5% to 12% of the total NGFr-ir cell population. Single and double immunopositive cells were intermingled, and the latter were slightly more numerous on the side ipsilateral to NGF administration. After the injection of a higher concentration of NGF (20 µg in 10 µL) a striking increase of *c*-Fos-ir neurons, up to at least 30% of the NGFr-ir cell population, was observed in the basal forebrain. Altogether these data demonstrate that the administration of NGF *in vivo* elicits a selective, specific and dose-dependent activation of the basal forebrain neurons which express NGFr.

LAR TYROSINE PHOSPHATASE RECEPTOR: EXPRESSION IN THE MAMMALIAN NERVOUS SYSTEM. F.M. Longo[1] and J.M. Le Beau*[2]. Depts of Neurology, UCSF Sch. of Med[1]., S.F., CA 94143 & the Diabetes Institutes, Eastern Virginia Med. Sch[2]., Norfolk, VA 23510

The Leukocyte Common Antigen-Related (LAR) gene expresses a tyrosine-phosphatase receptor with extracellular domain sequence similarity to N-CAM. Tyrosine phosphatase receptors may influence cell growth or differentiation by modulating effects of tyrosine kinase receptors. In a previous study we demonstrated LAR expression by northern blot analysis of poly (A) RNA obtained from various brain regions during development, cultured neurons and astrocytes and PC-12 cells (Longo et al, Soc Neurosci Abst 17:762, 1991). The expression of LAR mRNA *in vivo* in the mammalian nervous system has not been reported and it is not known if neurons *in vivo* express LAR. We used sense and antisense riboprobe derived from a 2.2 kb cDNA insert corresponding to the 3' cytoplasmic domain of rat LAR to perform in-situ hybridization of adult rat brain and dorsal root ganglia. Tissue was fixed and frozen sections were probed as described by Le Beau et al (J Neurosci Res 28:299, 1991). Tissue incubated with LAR anti-sense probe showed significant hybridization compared to tissue treated with sense probe. Significant hybridization signal was associated with neurons in the following regions: cortex, cerebellum, hippocampus, striatum and olfactory tubercle. Hybridization was also associated with non-neurons such as glia. In dorsal root ganglia, significant mRNA was detected in sensory neurons and little if any mRNA was found in their corresponding satellite cells. These findings suggest that the LAR tyrosine phosphatase receptor is expressed by neurons *in vivo* in the mammalian central and peripheral nervous system. Supported by United Cerebral Palsy (1) and the Diabetes Institutes (2).

401.8

LAR TYROSINE PHOSPHATASE RECEPTOR: A NOVEL GC-RICH TRANSCRIPT EXPRESSED IN RAT CNS. J.S. Zhang and F.M. Longo* Dept of Neurology, UCSF Sch. of Med., San Francisco, CA 94143

The Leukocyte Common Antigen-Related (LAR) gene codes for a tyrosine-phosphatase receptor with extracellular domain sequence similarity to N-CAM. Tyrosine phosphatase receptors may influence cell growth or differentiation by modulating effects of growth factors acting through tyrosine kinase receptors. LAR is expressed during neural development and in rat PC-12 cells (Longo et al, Soc Neurosci Abst 17:762, 1991). While screening a rat brain cDNA library for additional LAR transcripts, we found an approx 4 kb insert suggestive of an alternative LAR transcript: rat LAR-2. Sequencing of LAR-2 revealed a 33 bp-insert just upstream from the first tyrosine phosphatase domain which maintained the open reading frame. PCR with primers flanking the potential splice junctions using genomic DNA template was consistent with 2.3 kb and 0.7 kb introns upstream and downstream of a 33 bp cassette exon. In addition, the 3' untranslated region of LAR-2 contains GC-rich repeats similar to those found in genes associated with myotonic dystrophy and fragile X syndrome in which the repeat becomes unstable. The discovery of GC-rich repeats in an LAR transcript is especially intriguing in light of recent mapping of human LAR to 1p32-33 (Streuli et al, EMBO 11:897, 1992) and deletions observed at 1p32 in neuroblastoma. In preliminary experiments, antisense (but not sense) oligonucleotides directed to LAR splice junctions inhibited NGF-induced PC-12 cell differentiation. Functional implications of alternative sequences in LAR-2 include: i) the 33 bp insert could modify activity of the nearby tyrosine phosphatase domain and ii) the alternative 3' untranslated region could result in a LAR transcript with altered stability. (Supported by United Cerebral Palsy).

DISTRIBUTION AND REGULATION OF MEMBERS OF THE *TRK* FAMILY IN THE RAT BRAIN. J.P. Merlio[1,3], P. Ernfors[1], J. Bengzon[2], M. Jaber[1], Z. Kokaia[2], B. Dufy[3]*, O. Lindvall[2] and H. Persson[1]. [1]Laboratory of Molecular Neurobiology, Karolinska Institute, S-104 01 Stockholm. [2]Restorative Neurology Unit, University Hospital, S-221 85 Lund. [3]URA CNRS 1200-Laboratoire d'Histologie-Embryologie. Université de Bordeaux II. F-33076 Bordeaux.

Tyrosine protein kinases *trk*, *trk*B and *trk*C are signal transducing receptors for the neurotrophins Nerve Growth Factor, Brain-Derived Nerve Growth Factor, neurotrophin-3 and neurotrophin-4. We have isolated cDNA fragments encoding a part of rat *trk* and *trk*B proteins respectively and characterized a full-length cDNA clone encoding rat *trk*C. Cells expressing mRNAs for the different members of the *trk* family were identified in the rat central nervous system by in situ hybridization using oligonucleotide probes designed from the isolated cDNA sequences. The expression of *trk* mRNA was found to be restricted to neurons of the basal forebrain, caudate putamen with features of cholinergic cells and magnocellular neurons of several brainstem nuclei. In contrast, cells expressing *trk*B and *trk*C mRNAs were widely distributed in many areas of the brain, including olfactory formations, neocortex, thalamic and hypothalamic nuclei, brainstem nuclei, cerebellum and spinal cord motoneurons.Comparison between our data and previous analyses of cells expressing mRNAs for neurotrophins and the low-affinity NGF receptor suggests that different mode of action and different combination of receptors mediate biological responses to neurotrophins in the adult rat brain. Moreover, seizures induced by hippocampal kindling lead to a rapid and transient increase of mRNA in the hippocampus for *trk*B, a functional receptor for BDNF. No change was seen in mRNAs for *trk* or *trk*C, components of the high-affinity NGF or NT-3 receptors, respectively. The increase of *trk*B mRNA was blocked by the AMPA receptor antagonist NBQX. The transient increase of *trk*B mRNA showed the same time course and distribution as previously reported increases of BDNF mRNA. This suggests that BDNF and its receptor could play a local role within the hippocampus in kindling-associated neural plasticity.

401.10

NEUROTROPHIN RECEPTORS IN THE ADULT RAT BRAIN: RELATIVE DISTRIBUTIONS OF THE LOW-AFFINITY NGF RECEPTOR (LNGFR) AND MEMBERS OF THE *TRK* FAMILY OF TYROSINE KINASE RECEPTORS. S.J. Wiegand,* P. Wright, C. Alexander, L. Pan, R.M. Lindsay, G.D. Yancopoulos and N.Y. Ip. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

The neurotrophins, NGF, brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3), appear to bind with similar affinities to the LNGFR, but with markedly different affinities to the *trk* family of tyrosine kinase receptors. NGF binds to the product of the *trk* proto-oncogene (trkA), while BDNF and NT-3 are ligands for the related trkB and trkC receptors. While the relative contributions of the trks and the LNGFR to binding affinity and specificity and to signal transduction are now being elucidated *in vitro*, little is known regarding the co-distribution of LNGFR and trk receptors *in vivo*. We have examined the relative distribution of cells expressing these different neurotrophin receptors in the adult rat brain using *in situ* hybridization and immunohistochemistry. LNGFR message and protein are present in relatively restricted sets of neural and non-neural elements. trkA mRNA appears to be expressed predominantly if not exclusively in neurons, and shows a close correspondence in its neuronal distribution to that of LNGFR. However, non-correspondence of expression of trkA ,mRNA and LNGFR is apparent in some brain areas. In agreement with retrograde transport and binding studies, cells expressing trkB mRNA are much more numerous and widely distributed than those which express either trkA or LNGFR. Most neurons which express trkB did not contain detectable levels of LNGFR mRNA or protein.

401.11

DISSECTION OF NGF SIGNALLING PATHWAYS BY PERTURBATIONS OF LOW-AFFINITY RECEPTOR ($gp75^{NGFR}$) INTERACTIONS. S.M. Dostaler, R.A. Murphy*, and R.J. Riopelle*. Queen's University, Kingston, Ontario, Canada K7L 3N6, and *University of Alberta, Calgary, Alberta, Canada, T2N 2T2.

Growth factors share many signalling events but different biological effects indicate that signalling routes diverge. NGF signal transduction selectivity likely begins at the receptor level because this growth factor interacts with two receptors. To address this suggestion, a peptide (R3) identical to a cytoplasmic domain of $gp75^{NGFR}$ with predicted amphiphilic properties (Myers et al., Soc. Neurosci. Abstr. 17, 1498, 1991) was coincubated with NGF using a PC12 pheochromocytoma target. R3 accelerated NGF-mediated neurite growth in a time frame consistent with its uptake into cells. The wasp venom, mastoparan (MP), a cationic amphiphilic peptide, did not influence NGF-mediated neurite growth, but both R3 and MP accelerated NGF-mediated $cfos^{mRNA}$ induction in these cells. R3 did not influence the effects of NGF on PC12 cell mitochondrial succinate MTT reductase. These observations indicate that the R3-like domain of $gp75^{NGFR}$ is involved in neurite growth but not in mitochondrial respiratory activity induced by NGF. Further, while $cfos^{mRNA}$ induction involves an interaction with $gp75^{NGFR}$, this event is not essential for neurite growth. The present studies suggest that at least some of the specificity of NGF signalling subserving neurite growth occurs at the level of one of its receptor monomers, and that further downstream signal divergence occurs. This signalling may involve interactions with both or either of two proteins (70 and 90 kDa) that can be detected in extracts of PC12 cells using R3 as an affinity probe, and thus, likely interact with the amphiphilic domain of $gp75^{NGFR}$. Supported by the Canadian Federal Networks of Centres of Excellence Program in Neural Regeneration and Functional Recovery.

401.12

OVEREXPRESSION OF THE CYTOPLASMIC DOMAIN OF $p75^{NGFR}$ RESULTS IN DOWN-REGULATION OF $p140^{trk}$ TYROSINE KINASE ACTIVITY. M. BENEDETTI[+], A. LEVI[+], and M.V. CHAO*. [+]Istituto di Neurobiologia, CNR, Rome, Italy 00157; Dept. of Cell Biology & Anatomy, Cornell University Medical College, New York, New York 10021.

The low affinity p75 NGF receptor participates in the formation of high affinity NGF binding sites with the product of the trk proto-oncogene. To further investigate the function of $p75^{NGFR}$ in the NGF signal transduction pathway, a mutant $p75^{NGFR}$ was engineered, containing the transmembrane and cytoplasmic domain of $p75^{NGFR}$, 3' to an exogenous signal peptide and a myc tagging epitope. This truncated receptor lacked the ligand binding domain. When stably transfected in PC12 cells, several independently selected clones displayed altered responses to NGF. Most notably, in cells overexpressing this construct, trk tyrosine kinase activity was markedly lower. Also, the products of the VGF8a, tyrosine hydroxylase, and $p75^{NGFR}$ genes were lower than parental cells. Although the transfected cells were still capable of differentiation by NGF, there were no detectable high affinity binding sites. These results suggest that the truncated receptor may disrupt an interaction between $p75^{NGFR}$ and $p140^{trk}$ that prevented correct formation of high affinity binding sites, and resulted in down-regulation of the trk tyrosine kinase.

401.13

EVIDENCE FOR KINASELESS AND ALTERNATE 5' TERMINAL FORMS OF TRKB AND TRKC IN CHICK. A. S. Garner* and T. H. Large, Department of Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

The *trk* family of tyrosine kinase receptors mediate neurotrophin-induced responses as diverse as proliferation, survival, and process outgrowth. Alternative splicing is one potential mechanism for generating diversity at the level of ligand binding and/or signal transduction. To examine possible splice variants and as a prelude to investigating the role of *trk* receptors in the developing chick visual system, we have isolated cDNA clones of chick *trk*B (ch*trk*B) and *trk*C (ch*trk*C).

An E13 chick brain cDNA library, screened initially with a mouse *trk*B cRNA probe, yielded a total of 23 ch*trk*B and 16 ch*trk*C clones. Amino acid alignment of a full length ch*trk*B clone with mouse *trk*B identifies conserved domains that are likely to be functionally important. Within the extracellular domain, the second immunoglobulin-like domain is strongly conserved (85%). The *trk*B juxtamembrane domain (between the transmembrane and kinase domains) is also highly conserved (98%) and may be the principal regulator of kinase activity and/or specificity, especially given the small size of the C-terminus (15 aa) and kinase insert (11 aa) domains.

Alternate 5' and 3' splice variants of ch*trk*B have also been identified. Similar to those reported for rat and mouse, a kinaseless ch*trk*B clone is truncated just after the transmembrane domain and the 11 alternatively spliced C-terminal amino acids are completely conserved. In alternate 5' terminal clones (ch*trk*B-Δ5'), the start ATG, signal sequence and first cysteine cluster are replaced with a sequence that contains an upstream stop signal. This sequence is also found in the 5' untranslated region of the full length clone and is flanked by a splice donor site, indicating ch*trk*B-Δ5' results from the splicing of 5' untranslated sequence into the extracellular domain.

We have also identified full length, kinaseless, and alternate 5' terminal clones of ch*trk*C. As with ch*trk*B, ch*trk*C-Δ5' clones replace the start ATG, signal sequence, and first cysteine cluster with a novel sequence encoding an upstream, in-frame stop. Alternate 5' transcripts lacking a start ATG may represent an unusual method of regulating expression. Alternatively, translation may be initiated at a downstream ATG or non-ATG codon, resulting in a *trk* receptor with a truncated extracellular domain.

401.14

TRANSDUCTION OF THE trkA GENE BY A DEFECTIVE HSV-1 VECTOR INTO CULTURED NODOSE GANGLION NEURONS RENDERS THEM NGF RESPONSIVE. H.Xu*, L.Parada#, H.J.Federoff and J.A.Kessler, Albert Einstein College of Medicine, Bronx, NY 10461, #NCI-FCR, Frederick, MD 21702.

The gp140^{trk} (trk) gene encodes the signaling tyrosine kinase component of the NGF receptor (Kaplan et al., Science 252:554,1991) that upon stimulation phosphorylates neuronal substrates that transduce the NGF signal. As a first step in exploring the generality of the neurotrophin transduction mechanism, we have examined whether the expression of trkA could convert NGF unresponsive nodose ganglion neurons into NGF responsive neurons. A full length rat trk cDNA was cloned into a defective HSV-1 vector (pHSVtrkA), packaged into virions and used to infect primary cultures of neonatal nodose neurons. Infections were carried out for 8 hours in the presence of BDNF (10 ng/ml), after which time the virus and BDNF were removed and replaced with NGF (10 ng/ml)-containing media. Neuron survival was determined on day 1 through 6 after infection with pHSVtrkA virus. Survival in cultures infected with pHSVtrkA virus and treated with NGF was 56.1% ± 5.3 on day 6, whereas survival in uninfected cultures was only 10.8% ± 3.0. Survival of neurons cultured continuously in BDNF was 61.1%± 6.9. Each percentage represents the mean of 7 experiments. These data indicate that the transduction of the trkA gene into nodose neurons renders them NGF responsive. Moreover, the ability of trkA to confer NGF responsiveness suggests that the neuronal substrates required for transduction of the NGF signal are found in neurons that are not normally NGF responsive.

401.15

DORSAL ROOT GANGLION NEURONS EXPRESSING TRK ARE SELECTIVELY SENSITIVE TO NGF DEPRIVATION IN UTERO. S.L. Carroll, K. Ruit, S.E. Frese, J. Milbrandt and W.D.Snider*, Departments of Pathology, Laboratory Medicine, and Neurology, Washington University School of Medicine, St. Louis, Mo. 63110.

In utero immune deprivation of the neurotrophic molecule nerve growth factor (NGF) results in the death of most, but not all, mammalian dorsal root ganglion (DRG) neurons. The recent identification of trk, trkB, and trkC as the putative high affinity receptors for NGF, brain-derived neurotrophic factor (BDNF), and neurotrophin-3 (NT3), respectively, has allowed an examination of whether their expression by DRG neurons correlates with differential sensitivity to immune deprivation of NGF.

NGF deprivation in fetal rats was produced by injecting a specific, high titer anti-NGF antibody into embryonic rats in utero (Ruit et al, Neuron 8:573-587). We then performed in situ hybridization on DRG sections from control and experimental animals with probes for trk, trkB, trkC, and p75NGFR, the low affinity NGF receptor. We have found that more than 90% of DRG neurons expressing trk are lost when deprived of NGF in utero. In contrast, most, if not all, neurons expressing trkB and trkC survive this treatment. The low affinity NGF receptor, p75NGFR, is expressed in both NGF deprivation-resistant and sensitive neurons.

These experiments show that DRG neurons expressing trk require NGF for survival and that DRG neurons which do not require NGF express the high affinity receptor for another neurotrophin. Furthermore, they provide evidence that trk, and not p75NGFR, is the primary effector of NGF action in vivo.

401.16

EFFECTS OF NGF ON RAT PERITONEAL MAST CELLS—SURVIVAL PROMOTION AND IMMEDIATE EARLY GENE INDUCTION. K. Horigome, P.A. Lampe,* and E.M. Johnson, Jr. Department of Molecular Biology & Pharmacology, Washington University School of Medicine, St. Louis, MO 63110

Rat peritoneal mast cells (RPMC) express only one of the NGF receptor molecules, p140*trk* (see Pryor *et al.*, accompanying abstract). In analogy to the effects of NGF on neuronal cells or PC12 cells, we determined whether NGF or other neurotrophins were able to promote the survival of RPMC *in vitro*.

When RPMC were maintained in 10% FCS/MEM, all the cells died within 6 days. NGF prevented the death of the vast majority of RPMC in a dose-dependent manner (EC_{50} = 1 nM). The antimitotic drug, FUdR, had no effect on cell numbers remaining after 6 days in culture and [^{3}H]-thymidine was not significantly incorporated into RPMC; therefore, NGF promoted the survival but not the growth of RPMC. The activity of conditioned medium prepared after 3-day cultivation was neutralized by anti-NGF antiserum. The immediate early genes, c-*fos* and NGFI-A, were also induced in RPMC with a timecourse similar to that seen in PC12 cells. Other neurotrophins, BDNF and NT-3, had no effect on RPMC survival or gene expression.

The secretory response of RPMC to NGF was completely dependent on a specific phospholipid, lysophosphatidylserine (lysoPS) *in vitro*. Although the dose dependency and ligand specificity of the secretory, survival-promoting, and gene-expression responses to NGF were very similar, only the secretory response required lysoPS. This suggests a difference in the signal transduction pathways leading to the secretory response and the survival-related responses, although they were all triggered by the same tyrosine kinase receptor, *trk*. (Supported by NIH grant NS24679 and the Sumitomo Chemical Company.)

MAST CELLS EXPRESS *TRK* BUT NOT LOW AFFINITY NERVE GROWTH FACTOR RECEPTOR. J.C. Pryor, K. Horigome, and E.M. Johnson, Jr.* Departments of Molecular Biology & Pharmacology and Neurological Surgery, Washington University School of Medicine, St. Louis, MO 63110.

The physiologic response to nerve growth factor (NGF) is best understood in sympathetic and sensory neurons and PC12 cells. Rat peritoneal mast cells (RPMC) release histamine in response to NGF when lysophosphotidylserine is present. We have studied the expression of the LANGFR and *trk* in mast cells to understand the receptor(s) mediating the physiologic response to NGF in these cells.

Total RNA was isolated from RPMC, non-mast peritoneal cells (non-RPMC) and PC12 cells; Northern blots were done with probes to *trk* and LANGFR. These blots showed a strong signal at the appropriate length for *trk* in mast cells and PC12 cells, but a very low signal in the non-RPMC fraction. A strong message was detected for LANGFR in PC12 cells, but no signal was detected in mast cells or non-RPMC. RNA from mast cells, PC12 cells, and superior cervical ganglion sympathetic neuron culture (SCG) were reverse transcribed and PCR was performed by using oligonucleotides specific for *trk* and LANGFR. Message for *trk* was stronger in the mast cell fraction than in PC12 cells; the signal in the non-RPMC was weak. A strong signal for LANGFR was detected in PC12 cells and SCG cultures, but none was seen in mast or non-RPMC fractions. Radioiodinated NGF was cross-linked to mast cells and PC12 cells; the solubilized receptor NGF complex was immunoprecipitated with polyclonal anti-NGF or monoclonal anti-LANGFR. Bands consistent with LANGFR were demonstrated with PC12 cells, but were not observed in mast cells. Our results strongly suggest mast cells have only one NGF receptor species, *trk*, yet are capable of responding to NGF with a physiologic response. This immunoregulatory function of NGF does not appear to require interaction between the *trk* proto-oncogene and LANGFR in mast cells. (Supported by NIH grants NS24679 and NINDS 5 T32 NF07205-10, and the Sumitomo Chemical Company.)

HIGH-AFFINITY NGF RECEPTORS ON C6 ASTROCYTOMA CELLS: GROWTH-DEPENDENT EXPRESSION. A. Zanellato, L. Facci*, R. Dal Toso and S.D. Skaper. Fidia Research Labs, Abano Terme, Italy

Both neurons and glia present receptors for nerve growth factor (NGF). Rat C6 astrocytoma cells, which contain low-affinity NGF receptors, were used to study the possible expression of high-affinity NGF receptors. NGF receptors crosslinked with ^{125}I-NGF revealed both molecular forms of the receptor, upon immunoprecipitation using anti-NGF antibodies. Phosphotyrosine antibodies labeled the high-affinity receptor on immunoblots after a 5-min treatment of cells with NGF. Antibodies against low (IgG 192) and high (gp 140trk) affinity NGF receptors showed a largely overlapping, albeit heterogeneous, distribution of immunoreactivity for the two antigens in non-synchronized C6 cells. Exposure of growth-arrested C6 cells to serum demonstrated anti-trk immunoreactivity that was localized to immediate nuclear, plasma membrane or cytoplasmic regions as a function of cellular growth state, suggesting the presence of different maturational (glycosylated) forms of the trk protein. This in vitro model may help in delineating regulatory elements of NGF receptor expression.

401.19

EVIDENCE FOR THE EXPRESSION OF FUNCTIONAL LOW AFFINITY AND trkA NGF RECEPTORS IN CULTURED HIPPOCAMPAL NEURONS. V. L. Smith-Swintosky* and M. P. Mattson. Sanders-Brown Research Center on Aging and Department of Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536.

There is considerable evidence that nerve growth factor (NGF) promotes the survival and maintenance of specific populations of sympathetic, sensory and CNS neurons. Recent data suggest that NGF can protect/rescue CNS neurons from insults such as hypoglycemia and ischemia, including neuronal populations (e.g. hippocampus) previously believed to be unresponsive to NGF (*Neuron* 7:1031, 1991). Previous studies identified both a low affinity 75 kDa NGF receptor and a high affinity receptor which is identical to the trkA proto-oncogene product. Both types of NGF receptors have been proposed to be important for the biological actions of NGF. Immunocytochemical and Western blot studies using polyclonal antibodies to the 75 kDa NGF receptor (REX) and trkA (generous gifts from G. Westkamp, F. Lefcort, and L. Reichardt) demonstrated the presence of these proteins in neurons in embryonic rat hippocampal cell cultures. In order to determine which NGF receptors might mediate actions of NGF in hippocampal neurons, we employed antisense oligonucleotides (AO) directed against rat 75 kDa NGF receptor or trkA (sequence provided by D. Clary). Levels of the 75 kDa receptor and trkA were reduced in neurons exposed to the respective AOs. Administration of AOs for either NGF receptor resulted in neuronal death. However, neuronal death was more rapid in cultures exposed to trkA AO (< 24 hr) as compared to 75 kDa NGF receptor AO (2-3 days). The NGF receptor AOs also eliminated the neuroprotective effect of NGF in glucose-deprived cultures. Taken together, our data suggest that hippocampal neurons in culture possess both the low affinity NGF receptor and trkA. Both NGF receptors may play a trophic role and protect hippocampal neurons against environmental insults. (NIH and Alzheimer's Association support).

Purine analogs inhibit a trk-associated kinase activity.

C.Volonté* D.M. Loeb and L.A. Greene. *Department of Pathology, College of Physicians and Surgeons, Columbia University, New York, NY 10032.*

Previous studies showed that purine analogs block with varying potency and specificity certain of the effects of NGF on PC12 cells. These analogs inhibit protein kinase activities with varying specificity; for example, 2-aminopurine (2-AP) blocks several kinases whereas 6-thioguanine (6-TG) specifically inhibits protein kinase N (PKN), an NGF-activated protein kinase. In the present work, immunoprecipitates of trk-NGF receptors from PC12 cells (+/- NGF treatment) were assayed for kinase activity using myelin basic protein (MBP) and histone HF1, under conditions optimized for PKN and in the presence or absence of purine analogs. Activity was detected and approximately 50-80% was inhibited by 2-AP and 6-TG. The purine analog-sensitive activity was maximally stimulated by NGF within 5 min, was partially decreased by 30 min and still remained over basal levels after 15 hours of NGF treatment. Neither 2-AP nor 6-TG inhibits the NGF-dependent induction of the purine analog-inhibited trk-associated kinase activity. Analysis of MBP phosphorylated by the anti-trk immunoprecipitates revealed mainly phosphothreonine. Phosphorylation on threonine, but not phosphorylation on tyrosine, was inhibited by 6-TG, indicating that this analog does not inhibit the tyrosine kinase activity associated with the NGF receptor. The purine analog-sensitive, trk-associated kinase activity is in many aspects similar to cytosolic PKN and therefore suggests interaction between PKN and functional NGF receptors.

401.21

INFECTION OF DISSOCIATED COCHLEAR GANGLION CELL CULTURES WITH pHSVtrkA CHANGES THE SURVIVAL RESPONSE OF AUDITORY NEURONS TO EXOGENOUS NGF. T.R. Van De Water*, P.P. Lefebvre, W. Liu, H. Xu, G. Moonen, J.A. Kessler, and H. Federoff. Depts. of Otolaryngology, Neuroscience, Medicine & Neurology, Albert Einstein College of Medicine, Bronx, NY 10461, Dept. of Physiology, University of Liege, B 4020 Liege, Belgium.

Auditory neurons in cell cultures of dissociated cochlear ganglia of the mouse after embryonic day 13 are not responsive to the survival promoting effects of nerve growth factor (Lefebvre et al., 1991, Acta Otolaryng. 111:301-311). Transfection of $PC12_{nnr}$ cell mutants deficient in high affinity NGF binding with a full length rat trk cDNA restored the responsiveness of this $PC12_{nnr}$ cell line to NGF (Loeb et al. Cell 66:961-966, 1991).

A defective herpes simplex virus-1 vector (HSV-1) containing a gp 140^{trk} construct (i.e. pHSVtrkA) was used to infect cultures of dissociated cochlear ganglia that contained auditory neurons that were unresponsive to NGF. The expression of gp 140^{trk} was driven by the HSV IE 4/5 promoter so that all infected cells of the culture would express the gp 140^{trk} construct. When infected cultures were compared to uninfected ones, a significant enhancement of the survival of auditory neurons in the pHSVtrkA infected cochlear ganglion cell cultures treated with exogenous human recombinant NGF (i.e. 100 ng/ml) was evident in contrast to the uninfected control cultures treated with hrNGF.

OTHER FACTORS AND TROPHIC AGENTS: IGF

402.1

EXPRESSION OF INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-4 AND -5 mRNAs IN ADULT RAT BRAIN. Kaye L. Stenvers[1]*, Michela Gallagher[1], Ellen M. Zimmermann[2], and P.Kay Lund[1]. [1]Curriculum in Neurobiology and [2]Dept. of Medicine, University of North Carolina, Chapel Hill, NC 27599.

Insulin-like growth factors (IGFs) are believed to serve as neurotrophic factors in developing and adult rat brain. The IGFs are associated with a family of at least six IGF binding proteins (IGFBPs) which prolong the half-life of plasma IGFs and modulate IGF action. Although IGFBP-4 and -5 are widely expressed in adult rat tissues, their cellular sites of synthesis are still poorly characterized. To localize sites of IGFBP-4 and -5 mRNA expression, we performed *in situ* hybridization histochemistry using ^{35}S-labeled antisense riboprobes specific for either rat IGFBP-4 or IGFBP-5 mRNA (provided by Drs. Nicholas Ling and A.J. D'Ercole, respectively). We examined fresh-frozen, post-fixed sections of adult rat brain. Specificity of hybridization was confirmed by negative results in sections hybridized with sense strand riboprobes or pre-treated with RNase A prior to hybridization. The two IGFBP mRNAs were abundantly expressed within discrete regions of brain. Generally, the expression patterns of the two genes were non-overlapping. Notably, IGFBP-4 mRNA was highly expressed within hippocampal and cortical areas, whereas IGFBP-5 mRNA was not detected above background in these areas. Within hippocampus, strong hybridization of the IGFBP-4 probe was detected in pyramidal neurons of a medial segment of the CA1 subfield and throughout the CA2 subfield of Ammon's horn. Strong hybridization was also detected within the indusium griseum and subiculum. In cortex, IGFBP-4 mRNA was widely expressed in most cortical areas and layers. In contrast, IGFBP-5, but not IGFBP-4, mRNA was detected within thalamic nuclei. The distinct expression patterns of IGFBP-4 and -5 mRNAs within brain suggest that these IGFBPs may modulate compartmentalization of the IGFs or paracrine/autocrine actions of the IGFs in discrete brain regions. Furthermore, expression of IGFBP-4 mRNA by hippocampal pyramidal neurons suggests a role for IGFBP-4 in modulating neuronal effects of the IGFs.

402.2

ASSOCIATION OF INSULIN-LIKE-GROWTH FACTOR 1 RECEPTORS (IGF1r) ON BASAL FOREBRAIN CHOLINERGIC NEURONS.

A. Beaudet*, C. Desjardins and M-P Faure. Neuroanatomy Lab, Montreal Neurological Institute, McGill University, Mtl, Que, Canada H3A 2B4.

IGF1 was previsouly shown to stimulate the release of acetylcholine in adult rat brain slices. It remains unknown whether IGF1 exerts its effects directly on central cholinergic neurons. To test the hypothesis that IGF1 receptors may be associated with basal forebrain cholinergic cells, we examined by double immunofluorescence, the labeling of IGF1r and ChAT in rat serial sections. Primary antibodies were revealed with secondary antibodies conjugated with FITC and Texas Red, respectively. In the medial septal nucleus, diagonal band of Broca and substantia innominata a large proportion of ChAT positive neurons exhibited IGFr immunoreactivity. Reconstruction of serially sectioned images using confocal laser microscopy (CLSM) substantiated that IGF1r and ChAT immunoreactivity were present in the same neurons. The cellular staining pattern of IGF1 was mostly membranous and took the form of highly fluorescent punctate dots. Hybrid cells derived from septal cholinergic neurons, produced by the fusion of embryonic murine septal cells with murine neuroblastoma cells, were used to characterize the biological effect of IGF1. The hybrid cells were treated for different times and concentrations with nerve growth factor, basic fibroblast growth factor, platelet-derived growth factor and IGF1. Stimulation with IGF1 (10 ng/ml) for 48 hours produced a change in cell shape and significant neurite outgrowth (15-2μm) whereas none of the other factors produced any effect under these conditions. Moreover, fluorescence ChAT immunoreactivity was evaluated by CLSM and expressed a 10 fold increase following IGF1 stimulation. These results suggest that IGF1 may play an important role in the growth and transmitter regulation of basal forebrain cholinergic neurons and, consequently, that the impairment of its interaction with IGF1r may be involved in the degeneration of cholinergic systems such as occurs in Alzheimer's disease.

402.3

A RAPID INCREASE IN ACTION POTENTIAL FIRING RATE IN RESPONSE TO GROWTH FACTORS. R.H. Selinfreund* and L.A.C. Blair. Department of Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

The role of growth factors in the adult mammalian central nervous system is unknown. We have examined the rapid modulation of action potential frequency and ionic currents by growth factors known to be present in the central nervous system. Patch clamp recording techniques were used to indentify spontaneous electrical activity and ion channel events in GH_4C_1 pituitary cells. It was found that culturing in serum-depleted conditions blocked the firing of spontaneous action potentials. Brief exposure to serum or to a pool of 14 growth factors normally contained in serum fully reconstituted electrical activity. Subsequent experiments demonstrated that addition of insulin, IGF-I and IGF-II are sufficient to restore normal action potential behavior. Specifically, using on-cell single channel recordings or whole-cell recordings in the current clamp configuration, the reconstitution of electrical activity was rapid (requiring 30 seconds to 5 minutes) and stable. Furthermore, preliminary whole-cell voltage clamp analysis suggests that both outward potassium currents and inward calcium currents are altered by the presence of growth factors. One of these growth factor-modulated currents is tetraethylammonium-sensisitive but insensitive to 4-aminopyridine, indicating that Kv1 might be one of the potassium channels regulated by growth factors. Together, these experiments suggest that the insulin family of growth factors may be capable of inducing rapid changes in calcium channels and one or more potassium channels.

NEUROTROPHIC EFFECTS OF INSULIN-LIKE GROWTH FACTORS ON PC12 CELLS. Margarita L. Contreras*, Julia M. Pearson, and Alethea Gordon. Dept. of Pharmacology/Toxicology and Neuroscience Program, Michigan State Univ., East Lansing, MI 48824.

Since receptors for insulin-like growth factor I and II (IGF-I and IGF-II) are present on PC12 cells (Biochem. Biophys. Res. Commun. 154:1018, 1988), the effect of insulin-like growth factors on neuronal differentiation in these cells was examined. PC12 cells were treated with or without IGF-I or IGF-II (10 nM) for 2 days. Neither IGF-I nor IGF-II stimulated neurite outgrowth. However, in the presence of 50 ng/ml nerve growth factor (NGF), IGF-I and IGF-II potentiated the NGF-stimulated neurite outgrowth. Compared to the percent of neurite-bearing cells seen in the presence of NGF alone, there was approximately a 50% increase in the percent of cells with neuronal processes when either IGF-II or IGF-I was included in the media. The IGF-mediated potentiation of neurite outgrowth was dose-dependent, with the maximal effect apparent at approximately 3 nM of either IGF-I or IGF-II.

To determine whether the mannose-6-phosphate/IGF-II receptor was involved in the potentiating effects of IGFs on neuronal differentiation, the effect of mannose-6-phosphate (M6P) on NGF-stimulated neurite outgrowth was assessed. M6P did not potentiate the neurite promoting effect of NGF. Also, the percent of cells bearing neurite outgrowths seen in the presence of IGF-II and NGF was unaffected by the inclusion of M6P in the growth medium, suggesting that the M6P/IGF-II receptor was not involved in mediating the potentiating effects of IGF-II on neuronal differentiation in PC12 cells. The IGF-I receptor may therefore mediate the potentiating effect of IGFs on neuronal differentiation in the PC12 cells. NSF supported.

402.5

INSULIN LIKE GROWTH FACTOR I AND ITS RECEPTOR ARE PRESENT IN NEURON CELL CULTURES. R.Schechter, J.Whitmire, D.Beju, R.Harlow, K.Jackson, J.R.Gavin III and M.E.O'Connor*. St. Francis Med. Res. Inst., Univ. of Okla. Hlth. Sci. Ctr., Univ. of Tulsa, Tulsa and OK City, OK 74136 and 73190.

We have studied the presence of insulin like growth factor I (IGFI) and its receptors in 22 day and 18 day gestation neuron cell cultures (NCC) from fetal rabbit brains. The 22 day NCC were incubated in IGFI free/serum free medium (ISFM) and the 18 day NCC in serum medium. The 18 day NCC died in an ISFM. The peroxidase anti-peroxidase method using rabbit anti-IGFI antibody (RIGF) (1/100)(E.Lilly) showed IGFI present. Antibody absorbed with IGFI (E.Lilly) and rabbit serum lacked immunoreaction. In situ hybridization using a 36 base biotinylated oligonucleotide revealed IGFI mRNA. Electron microscopy using RIGF (1/10000) and anti-neuronfilament (1/10000) showed IGFI in the neurons' endoplasmic reticulum, Golgi, cytoplasm and prolongations. RIA of ISFM revealed IGFI. IGFI receptors were detected by using ^{125}I IGFI binding of NCC in both NCCs. The 18 day NCC survived when IGFI (100ng/ml) was added to ISFM. We conclude: A) fetal NCC produce IGFI, B) IGFI promotes cell survival, and C) exogenous IGFI may be needed in early brain development.

402.6

EFFECTS OF INSULIN, INSULIN-LIKE GROWTH FACTOR I, AND BASIC FIBROBLAST GROWTH FACTOR ON RETINAL CELL PRODUCTION. Andreas F. Mack* and Russell D. Fernald. Institute of Neuroscience, University of Oregon, Eugene, OR 97403 and Neuroscience Program, Stanford University, Stanford, CA 94305.

Rod photoreceptors are added to the fish retina from unique progenitor cells in the outer nuclear layer continuously throughout life. To investigate the regulation of cell production in the teleost retina we tested the effects of several growth factors on proliferation and differentiation of rod photoreceptor cells. Using organotypic slice cultures for the differentiated fish retina, we labelled dividing cells with ^3H-thymidine and revealed specific phenotype expression with an antibody staining rod photoreceptors exclusively. We found that insulin and insulin-like growth factor I (IGF-I) increased the number of neuronal progenitor cells undergoing cell division in culture significantly. Basic fibroblast growth factor (bFGF) did not have a significant effect on the number of dividing cells. In the presence of bFGF, however, a greater proportion of the cells that had divided in culture expressed a rod photoreceptor-specific phenotype compared to control slices. This suggests that bFGF promotes the differentiation of neuronal progenitor cells whereas insulin and/or the related IGF-I are involved in the regulation of neuronal cell division in retinal slice culture. Supported by NIH grant GM 07257.

INSULIN LIKE GROWTH FACTOR-1 HAS A ROLE IN THE DEVELOPING RAT OLFACTORY BULB: EVIDENCE FROM INTRAOCULAR GRAFTING

MB Giacobini[1], M Eriksdotter-Nilsson*[1], R Zetterström[1], V Sara[2], L Olson[1]. [1]Dept of Histology & Neurobiology, Karolinska Institutet, Stockholm Sweden, [2]Dept. of Pathology, Karolinska Hospital, Stockholm, Sweden.

Recent studies have indicated that insulin like growth factor-1 (IGF-1) and IGF-1 receptor mRNA are abundant in both the developing and in the mature rat brain olfactory bulbs (Ayer-Le Lievre et. al. 1991, Werther et. al. 1990, Bondy et.al. 1992). By using the method of intraocular transplantation we were able to study effects of truncated IGF-1 (tIGF-1), antibodies against IGF-1 and IGF-1 binding protein-1 on developing olfactory bulbs. E16 olfactory bulbs were grafted to the anterior chamber of adult host rats. Grafts were treated with either 20 µg/ml tIGF-1, a polyclonal antibody against IGF-1, 1 mg/ml IGF binding protein or vehicle solution alone prior to grafting. Similar solutions were administered by intraocular injections 5, 10 and 15 days postgrafting. Growth of grafts was monitored by direct observation and measurement through the cornea of the living animals. Grafts treated with IGF-1 antibody grew significantly larger than grafts receiving any other treatment. When similar experiments were carried out on E16 and E17 parietal cortex grafts, no enhancement in graft size was seen after IGF-1 antibody treatment. However tIGF-1 has in previous studies (Giacobini et. al. 1990) been shown to enhance growth of intraocularly transplanted fetal parietal cortex. Thus, IGF-1 appears to influence brain development in a regionally specific manner. Immunohistochemical studies of the olfactory bulb grafts are currently under investigation.

402.8

INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) INCREASES RATE OF FUNCTIONAL RECOVERY FROM SCIATIC NERVE CRUSH IN MICE. P.C. Contreras*, C. Steffler and J. L. Vaught. Pharmacology, Cephalon, Inc. West Chester, PA 19380.

IGF-1 has been shown to stimulate several growth associated processes and to support the survival of α-motor neurons in vitro. IGF-1 has also been shown to enhance neuronal sprouting after sciatic crush in rats. The purpose of this study was to assess whether IGF-1 also increases rate of functional recovery from sciatic crush in mice. After Swiss-Webster mice (25-35 g) were anesthetized, both sciatic nerves were exposed and crushed for 10 sec with a hemostat, covered with plastic tubing. Mice were injected with vehicle (1%BSA) or IGF-1 (1mg/kg) s.c. after recovery from the anesthetic and for the next 17 days. Functional recovery from the sciatic crush was measured by 1) determining the number of times/5 trials the mice were able to grasp an inverted screen with both hindpaws; and 2) assessing changes in gait. Mice treated with IGF-1 were able to grasp the inverted screen and returned to normal responses sooner than vehicle-treated mice. There were also parallel improvements in several parameters used to measure gait, such as toe spread, in IGF-1-treated mice compared to vehicle-treated mice. These results indicate that IGF-1, which enhances survival of α-motor neurons, also enhances functional recovery. These data support the utility of rhIGF-1 for the treatment of ALS

403.1

BASIC FGF AND FGF RECEPTOR-4 OCCUR IN CHICKEN. P. C. Evers and M. Bothwell*. Dept of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195.

The fibroblast growth factor (FGF) family presently consists of 7 members: aFGF, bFGF, int-2, k-FGF, FGF-5, FGF-6, and KGF. These ligands bind, with specificity which is not fully defined, to receptors encoded by 4 genes: FGF receptor-1 (FGFR1), FGFR2, FGFR3, and FGFR4. Our previous results show FGFR1 expressed in the developing chick neuroepithelium, where it is likely to have a role in proliferation and differentiation. To further explore the role of FGFs in neural development, we plan to describe the expression of the FGFs and other FGFRs in neural tube. Hence, we have sought to clone segments of each FGF and FGFR gene for use as in-situ hybridization probes. We have cloned portions of 6 genes: aFGF, bFGF, FGFR1, FGFR2, FGFR3, and FGFR4 from chicken using PCR and degenerate oligonucleotides. The sequences for two of these genes, bFGF and FGFR4, have not been reported previously. Sequence identity between the putative chicken bFGF and the mouse bFGF is 83% at the nucleotide level and 94% at the amino acid level. The nucleotide sequence identity between the putative chicken FGFR4 and the three known chicken FGFR genes is 72-79%, whereas the nucleotide sequence identity between the putative chicken FGFR4 and the human FGFR4 is 79%. Sequence comparisons suggest that the two cDNAs are portions of the bFGF and FGFR4 genes in chicken. The bFGF and FGFR4 cDNAs along with the cDNAs for aFGF, FGFR1, FGFR2, and FGFR3, will be useful in determining the roles of FGF in neural development.

403.2

FGF-5 mRNA DISTRIBUTION IN THE RAT BRAIN: AN IN SITU HYBRIDIZATION STUDY. F. Gómez-Pinilla* and C.W. Cotman. Dept. of Psychobiology, U. California Irvine, CA 92717

Fibroblast growth factors (FGFs) are potent growth factors with roles ranging from development to adult plasticity in the brain. FGF-5 is a new member of the FGF family with a potential role in brain function and pathology. In order to evaluate a possible action of FGF-5 in the brain, we have examined the locus of synthesis of FGF-5 in the rat brain using *in situ* hybridization of S^{35}-labelled cRNA probe complementary to FGF-5 mRNA. FGF-5 mRNA was expressed in neurons in selected regions of the rat brain. FGF-5 mRNA *in situ* hybridization labelling was particularly intense in the olfactory bulb within periglomerular elements and mitral cell layer. The primary olfactory cortex also showed strong FGF-5 mRNA labelling and mostly within cell layer II, throughout its rostro-caudal extent. In the hippocampal formation, the greatest intensity of FGF-5 mRNA labelling was shown in hippocampal pyramidal cells within subfields CA3 and CA2, and granular cells within the dentate gyrus. The cerebral cortex (neocortex) showed a modest labelling throughout its rostro-caudal extent, mostly within external layers. The entorhinal cortex showed a slightly higher labelling intensity as compared to the neocortex. The cerebellum, thalamus and striatum displayed light labelling. Glial-like cells scattered throughout the brain appeared to express low levels of FGF-5 mRNA. In general FGF-5 mRNA was mostly shown by limbic structures, suggesting the possibility that FGF-5 may play a role in limbic system function or pathology.

403.3

BASIC FIBROBLAST GROWTH FACTOR (bFGF) GENE EXPRESSION IN RAT BRAIN: AGE AND REGIONAL COMPARISON BY QUANTITATIVE RT-PCR. A. El-Husseini[1], J.A. Paterson[2]* and R.P.C. Shiu[1], Departments of Physiology[1] and Anatomy[2], Faculty of Medicine, University of Manitoba, Winnipeg, Manitoba, Canada R3E 0W3.

Investigations *in vitro* have shown the importance of bFGF as a mitogen for astrocytes and as a neurotrophic factor for many neuronal types. This study seeks to compare bFGF gene expression in selected regions of the brain of rats at different postnatal ages. The reverse transcription-polymerase chain reaction (RT-PCR) was used to measure the levels of bFGF mRNA. These levels were quantitated relative to the levels of mRNA for glyceraldehyde-3-phosphate dehydrogenase, the latter being constant at the ages being studied. We first compared the levels of bFGF mRNA in the cerebrum from male rats of ages 1, 3, 7, 14, 21 and 28 days and one year. Our results showed that by the end of the first month, the cerebral bFGF mRNA was about 10-fold that of the 1 day old rat, with the greatest increase occurring between the first and the second postnatal weeks. One year old cerebrum showed high levels of bFGF mRNA similar to those of 28-day old. Analysis of different regions of the 28-day old brains revealed that the lowest levels of bFGF mRNA occur in the cerebellum, and that the highest levels occur in hippocampus (7 times the levels in cerebellum, 7X), followed closely by cingulate cortex, occipital cortex, and inferior colliculus (4-5X). The hypothalamus and combined pons-medulla showed intermediate levels (2X). Preliminary studies of these regions from 1 day old rats rats showed there is a different pattern of regional expression at this age. Our results are consistent with the hypothesis of a role of bFGF in brain development.

403.4

CO-LOCALIZATION OF bFGF WITH NEUROPEPTIDES AND FGF-RECEPTOR IN THE RAT BRAIN: EFFECTS OF COLCHICINE. C. Grothe*. Dept. of Anatomy and Cell Biology, University of Marburg, D-3550 Marburg, Germany.

Recently, it was shown that basic fibroblast growth factor (bFGF) is present in distinct neuronal subpopulations of the brainstem (Grothe et al., J. Comp. Neurol. 305, 1991). Immunocytochemical analysis revealed a partial overlap of bFGF and neuropeptides (SOM, SP, CGRP) or tyrosine hydroxylase in some brainstem nuclei but no strict co-localization of bFGF with one of the neuropeptides or tyrosine hydroxylase.

To identify bFGF-responsive cells in the brain, immunocytochemistry and binding studies were performed. FGF-receptor could be localized in the cortex and, like bFGF, in neuronal subpopulations of several motor and sensory brainstem nuclei.

After colchicine treatment bFGF-IR disappeared in brainstem nuclei expressing the FGF-receptor and appeared or increased in nuclei lacking the FGF-receptor. Whether this change in the bFGF-IR is exclusively due to transported bFGF has to be clarified by in situ hybridization.

403.5

EXPRESSION OF bFGF mRNA AND IDENTIFICATION OF FGF-RECEPTOR-POSITIVE CELLS IN RAT SENSORY GANGLIA. T. Janet, K. Unsicker*, C.Grothe. Dept. Anat. Cell Biol., Univ. Marburg, Germany.

We have shown that bFGF-immunoreactivity (IR) is present in a neuronal subpopulation of postnatal and adult crest- and placode-derived sensory ganglia (Weise et al., Cell and Tissue Res.,267, 125-130, 1992). In dorsal root ganglia (DRG), bFGF was strictly co-localized with the somatostatin-IR subpopulation. Northern blots of total RNA from DRG using a rat cDNA probe revealed 7.0 and 3.7 Kb mRNA. In situ hybridization showed that the bFGF mRNA is present in nearly all DRG neurons. To identify neurons with putative bFGF responsiveness, FGF-receptor immunocytochemistry and binding studies were performed. FGF-receptor IR was present in all bFGF-immunoreactive neurons suggesting that the protein mediates its effects in an autocrine and/or paracrine manner. The possible explanations of the discrepancy in the distribution of bFGF-IR and bFGF mRNA may include i) different translational regulation in distinct neuronal subpopulations, ii) different stabilities of mRNA and proteins.

403.6

DEVELOPMENTAL EXPRESSION OF ACIDIC AND BASIC FIBROBLAST GROWTH FACTORS IN SUBSTANTIA NIGRA AND SENSORY NEURONS.
A.J. Bean*, R. Elde, C. Oellig[a], L. Taylor[a], R. Pettersson[a], and T. Hökfelt. Dept. Histology and Neurobiology, Karolinska Institute, and [a]Ludwig Inst. for Cancer Res. Stockholm S-104 01, Sweden.

Fibroblast growth factors (FGFs) are a family of related peptides which have been characterized by their ability to induce cellular differentiation and their mitogenic/angiogenic properties. We have observed the acidic and basic FGF (aFGF, bFGF) mRNA and protein in sensory and motor neurons of the rat including the substantia nigra (SN). In contrast to the widespread distribution of bFGF, aFGF expression is quite restricted. We examined the expression of aFGF and bFGF in the rat SN and dorsal root ganglia (DRG) from E16-18 to PN90.

In DRGs, aFGF mRNA and protein were present at E18 and were observed through adulthood. bFGF mRNA was present in the SN at all ages tested. aFGF mRNA was first detectable in the SN at PN20 and was expressed through adulthood. The differential developmental expression of aFGF and bFGF in the SN may indicate different functional roles in this brain region.

BASIC FIBROBLAST GROWTH FACTOR (bFGF) PROMOTES THE SURVIVAL AND PROLIFERATION OF MESENCEPHALIC NEURONAL PRECURSORS IN VITRO. M.M. Bouvier* and C. Mytilineou, Dept. Neurology, Mt. Sinai Sch. of Medicine, New York, N.Y., 10029.

We recently demonstrated that treatment with epidermal growth factor (EGF) results in the survival and proliferation of neuronal and glial stem cells from embryonic day 16 (E16) rat mesencephalon (Mytilineou et al., 1992). To determine whether dopaminergic neuronal precursors could also be induced to proliferate in vitro, we used ventral mesencephalic cultures from E12 rat embryos, a developmental stage that coincides with the beginning of the birth of mesencephalic dopamine neurons. Mesencephalic cells were treated with EGF (10ng/ml), bFGF (10ng/ml) or a combination of EGF and bFGF at the day of plating. Control and trophic factor-treated cultures were observed with phase contrast microscopy and analyzed after 7 days in vitro (DIV) by immunocytochemistry with antibodies to neuron specific enolase (NSE), tyrosine hydroxylase (TH) and glial fibrillary acidic protein (GFAP) to identify differentiated neurons, dopaminergic neurons and astrocytes, respectively. Some cell division, resulting in colony formation, occurred in the first 24-48 hrs after plating in all trophic factor-treated cultures, as well as in untreated controls. However, treatment with bFGF resulted in greater cell number and the formation of larger colonies. EGF had no apparent effect in these cultures. Cell loss was prominent in control and EGF-treated cultures after 7DIV, but it was less apparent in cultures treated with bFGF. At 7DIV the majority of surviving cells were positive for NSE while <1% stained with GFAP. TH immunocytochemistry revealed clusters of dopamine neurons in control and EGF-treated cultures, but their numbers were higher after treatment with bFGF. (Supported by NIH grant NS-23017 and the United Parkinson Foundation).

PROTECTIVE ACTIONS OF INTRAVENTRICULAR HUMAN RECOMBINANT BASIC FIBROBLAST GROWTH FACTOR INFUSION ON MPTP-INDUCED DEGENERATION OF THE NIGROSTRIATAL DOPAMINE SYSTEM IN THE BLACK MOUSE. A STEREOLOGICAL, IMAGE AND BEHAVIOURAL ANALYSIS.

G. Chadi[1], K. Fuxe[1], A Møller[2], A.M. Janson*[1], L. Rosén[1], A. Cintra[1], Y. Cao[3], M. Goldstein[4], S.O. Ögren[1] and R. Petterson[3]. [1]Dept. of Histology and Neurobiology, Karolinska Inst., Stockholm, Sweden; [2]NeuroSearch, Glostrup, Denmark; [3]Ludwig Inst. for Cancer Research-Stockholm Branch, Karolinska Inst., Stockholm, Sweden; [4] Dept. of Psychiatry, New York Medical Center, N.Y., USA.

Basic fibroblast growth factor (bFGF) immunoreactivity (IR) has recently been demonstrated in the vast majority of dopamine (DA) neurons of the ventral midbrain of the rat and neuroprotective actions of the bFGF in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) model have been reported. The actions of bFGF have now been further analyzed in a combined morphological and behavioural analysis in the MPTP model of the adult black mouse. Four hours after the injection of MPTP (40 mg/kg, s.c.) a 7 day continuous intraventricular (i.v.t.) infusion of human recombinant bFGF (1 µg/24 h) or of mock cerebral spinal fluid (CSF) was started using Alzet osmotic minipumps. On day 6 the locomotion of the MPTP+mock-CSF group was significantly reduced versus the saline+mock-CSF treated group and the locomotor activity was restored by the bFGF treatment. Tyrosine hydroxylase (TH) immunocytochemistry in combination with computer assisted microdensitometry demonstrated significant counteractions of the MPTP-induced disappearance of neostriatal nerve terminal TH IR following bFGF treatment. This counteraction was present also 1 week after cessation of treatment. Unbiased estimates of the total number of nigral TH IR neurons, using the optical disector (Olympus) and stereological methods, showed that the MPTP treatment reduced the total number of DA nerve cells from 13,700±1,000 (n=5) to 6,000±1,000 (n=4). bFGF significantly increased this number of DA nerve cells to 10,000±700 (n=4), an action which was maintained also 1 week after cessation of treatment. These results demonstrate that human recombinant basic FGF upon i.v.t. infusion exerts protective actions on nigrostriatal DA neurons exposed to the MPTP neurotoxin.

EFFECTS OF BASIC AND ACIDIC FGF ON GROWTH AND DOPAMINE NERVE FIBER PRODUCTION OF INTRAOCULARLY TRANSPLANTED FETAL MESENCEPHALIC GRAFTS

S Almström[1], MB Giacobini*[1], I Strömberg[1], Y Cao[2], R Pettersson[2], L Olson[1]. [1]Dept. of Histology & Neurobiology, Karolinska Institutet, Stockholm, Sweden, [2]Ludwig Institute for Cancer Research Stockholm Branch, Stockholm Sweden

Basic FGF has been shown to increase dopamine neuron survival in mesencephalic cultures (Ferrari et. al. 1988) as well as inducing regrowth of damaged DA neurons in vivo (Otto, Unsicker, 1990). We have followed the growth and survival of developing E14-E16 mesencephalic grafts under chronic intermittent treatments with either aFGF or bFGF in the anterior eye chamber of adult rat hosts. Pieces to be grafted were incubated in either 25 µg/ml aFGF, 25 µg/ml bFGF or vehicle solution alone prior to grafting and 5 µl of similar solutions were injected intraocularly on day 5, 10 and 15. Host animals were sympathetically denervated 2 weeks prior to grafting enabling evaluation of catecholaminergic fiber outgrowth onto the host iris in whole-mount preparations by use of the Falck-Hillarp technique. Both aFGF and bFGF significantly increased the volume of transplanted mesencephalic grafts when compared to grafts treated with the vehicle alone, bFGF being a more potent growth stimulator than aFGF. Both bFGF and aFGF increased the area of the host iris innervated by graft-derived catecholamine containing fibers. Immunohistochemical evaluations of grafts are currently under study as well as studies of treatment of mesencephalic grafts using the described model with other growth factors.

INTRACEREBRAL GRAFTING OF CELLS GENETICALLY MODIFIED TO EXPRESS BASIC FIBROBLAST GROWTH FACTOR.

H. Takayama[1], J. Ray[1]*, A. Baird[2], A.S. Beutler[1] and F.H. Gage[1].

Dept. of Neurosci., Univ. of Calif. San Diego[1] and Dept. of Mol. & Cell Growth Biology, Whittier Institute[2], La Jolla, CA 92093

Basic fibroblast growth factor (bFGF) has been recognized as a neurotrophic factor and affects survival and differentiation of a variety of central neurons as well as other cells. We have previously reported the expression and characterization of bFGF producing primary fibroblasts (Soc. Neurosci. Abst. 17:43,1991). This study was undertaken to assess the biological effects of bFGF producing fibroblasts grafted into the adult rat nervous system.

Primary skin fibroblasts were infected with a retroviral vector containing a cDNA for rat bFGF. Those cells revealed positive immunoreactivity for bFGF protein in vitro. Radioimmunoassay showed the amount of bFGF in the cells lysate was between 5-18 times higher than non-infected control fibroblasts. bFGF producing primary fibroblasts and those infected with a retroviral vector containing the cDNA for *E. coli* ß galactosidase (ß gal) were grafted into Fischer rat striatum. At 8 weeks after grafting, the rats were perfused and sections of the brain were processed for immunohistochemistry. The bFGF immunoreactive cells were more prominent in the bFGF grafts than in the ß gal grafts, though some endothelial cells and astrocytes-like cells were also stained within both grafts. Staining with neurofilament(200kd) or tyrosine hydroxylase antibodies revealed immunoreactive axonal profiles within both grafts. The density of axonal growth was higher in bFGF grafts, compared to ß gal ones. No significant differences were seen following staining with NGF receptor and choline acetyl transferase antibodies between two grafts. Vascularization revealed by laminin staining was greater in bFGF grafts, whereas glial fibrillary acidic protein staining showed no noticeable difference. These results suggest that implanted bFGF producing fibroblasts have some biological effects in the adult rat nervous system.

403.11

THE COMBINED ACTION OF BASIC FGF AND SUBSTRATA PROMOTES DIFFERENT CHROMAFFIN CELL FATE

C.H.Chu*,J.Crabtree ,A.M.Tolkovsky,Dept.of Human Anatomy, University of Oxford,South Parks Road,Oxford OX1 3QX, U.K.

Basic fibroblast growth factor (bFGF),like NGF,induces cell division and neurite outgrowth from adrenal chromaffin cells . In vitro , we found that human recombinant bFGF , unlike NGF , promotes different neurite outgrowth responses on neonatal rat chromaffin cells with different substrata.To determine the extent of chromaffin cell transformation into neurons , we counted the number of cells with tyrosine hydroxylase positive staining and neurites and cell division was assayed by [3H] thymidine incorporation. A marked increase of transformed neurons, up to 80% was seen when chromaffin cells were cultured on laminin , whilst cell survival and bFGF-stimulated cell division were significantly reduced on laminin compared with collagen Type I. By contrast,in cultures grown on collagen Type I , bFGF elicited little neurite outgrowth , and promoted the proliferation and survival of chromaffin cells.In addition, dexamethasone inhibited neurite outgrowth in response to bFGF on laminin and increased the proportion of surviving and proliferative cells .These results show that bFGF and laminin act synergisticly to promote sympathetic neuronal transformation , whilst on collagen Type I or in the environment of glucocorticoids, bFGF acts as a mitogen and survival factor of chromaffin cells.

403.12

REGULATION OF BASIC FIBROBLAST GROWTH FACTOR (bFGF) EXPRESSION IN CULTURED ADRENAL MEDULLARY CELLS.

E. Stachowiak, E. Puchacz, A. Gibson*, R. Florkiewicz*, M.K. Stachowiak. Barrow Neurological Inst. Phoenix AZ 85013, *The Whittier Inst. La Jolla CA 92057.

Basic FGF is expressed in catecholaminergic cells of substantia nigra and in sympatho-adrenal system. We have recently shown that in adrenal medullary (AM) cells exogenous bFGF modulates expression of tyrosine hydroxylase and proenkephalin genes, suggesting that it may serve as an autocrine or paracrine regulator in catecholamine and enkephalins biosynthesis. The present study was undertaken to determine subcellular localization of bFGF in AM cells and to examine whether bFGF expression is regulated by stimuli that affect synthesis of AM hormones. In cultured bovine AM cells stained with different antibodies against recombinant bFGF, granular cytoplasmic and nuclear bFGF-immunoreactivity (bFGF-IR) was observed. In majority of cells bFGF staining was more intense in the nuclei than in the cytoplasm. Incubation of cells with exogenous 18 kDa bFGF ($5x10^{-10}$ M) led to an increase in nuclear bFGF-IR within 10 min, which reached a maximum between 1-3 hrs. Incubation with forskolin produced a dramatic increase in nuclear bFGF-IR, which attained a maximum after 12 hours. Less pronounced increases in nuclear staining, were observed in cells treated with angiotensin II or with the depolarizing agent, veratridine. Western blot analysis revealed the presence of at least 3 bFGF isoforms (18,23 and 24 kDa). Their levels were upregulated by forskolin and angiotensin II. Those changes were associated with induction of bFGF mRNA. Regulation of bFGF gene expression, protein levels and nuclear translocation in AM cells by hormonal (angiotensin) and neural (depolarization) stimuli, and by 2nd messenger (cAMP), supports the hypothesis that bFGF plays an active role in the plasticity of the adult nervous system. It also suggests that the long-term genomic effects of bFGF may be mediated directly in the nucleus.

403.13

MITOGENIC EFFECTS OF ACIDIC FIBROBLAST GROWTH FACTOR AND TRANSFORMING GROWTH FACTOR BETA ON BOVINE AND PORCINE ENDOTHELIUM IN VITRO. T.C. Ryken and V.C. Traynelis*. Department of Surgery, Division of Neurosurgery, University of Iowa College of Medicine, Iowa City, Iowa 52242.

The mitogenic effects of acidic fibroblast growth factor (aFGF) and transforming growth factor beta (TGF-beta) were assayed alone and in combination on cultured bovine and porcine endothelium. Triplicate growth-arrested cultures of each cell type were grown in the presence of aFGF (300 ng/ml) and/or TGF-beta (5 ng/ml) for 96 hours, renewing the media each 24 hours. The mitogenic effects were assayed by cell counting at the conclusion of the 96-hour period. Results are reported as a stimulation index (ratio of final cell number to initial cell number).

Both bovine and porcine endothelial cell cultures incubated with aFGF underwent a marked increase in mitogenic activity, increasing in stimulation index from 1.60 (± .05) for control to 4.51 (± .27) and 3.81 (± .06), respectively. Endothelium incubated in the presence of TGF-beta underwent a decrease in mitotic activity with a stimulation index of 1.16 (± .10) and 1.17 (± .05) in the bovine and porcine cultures. Cells incubated in a combination of aFGF and TGF-beta demonstrated an attenuation of the mitogenic effects observed in the presence of aFGF alone, decreasing the stimulation index to 3.25 (± 11) in bovine endothelium and 1.80 (± .30) in porcine endothelium.

These results suggest that the mitogenic effect of aFGF in cultured endothelium can be antagonized by TGF-beta. The interaction of growth factors on endothelium is of interest to elucidate the mechanisms involved in angiogenesis and transformation.

403.14

EFFECTS OF ACIDIC FIBROBLAST GROWTH FACTOR ON RAT PRIMARY CULTURED NEURONS AND HIPPOCAMPAL LTP. H.Hisajima, K.Abe, N.Nishiyama, H.Saito*. Dept. of Chem. Pharmacol., Faculty of Pharmaceut. Sci., Univ. of Tokyo 113, Japan.

Effects of human recombinant acidic fibroblast growth factor (haFGF) on brain neurons of various regions in primary culture and hippocampal long-term potentiation (LTP) in rats were investigated. Dissociated cells from 8 regions of embryonic day 16 rats were cultured in medium containing 10% serum for 1 day and chemically-defined serum-free medium with haFGF for 3 days. 10-100 ng/ml haFGF enhanced neuronal survival in the cortex, hippocampus and substantia nigra, while 10 ng/ml CS23 (modified human basic FGF) was effective in all regions tested. Next, effects of haFGF and CS23 to the increases of the spike amplitude induced by tetanic stimulation were measured in the dentate gyrus of 24 hr fasted and non-fasted rats. Ten ul of drug was i.c.v. injected before the application of tetanic stimulation. haFGF (400 ng) didn't influence the LTP induced by the tetanus of 100 pulses at 100 Hz in both fasted and non-fasted rats, but significantly facilitated the generation of LTP by tetanus of 20 pulses at 60 Hz only in fasted rats. However, 400 ng CS23 induced LTP when the tetanus of 20 pulses at 60 Hz was applied in both fasted and non-fasted states. Protein kinase C activities of hippocampal cytosol fraction was decreased with the i.c.v. injection of 400 ng haFGF in 24 hr fasted rats but not in non-fasted rats. These results suggest that haFGF might be one of regulating factors of feeding and memory and there might be different regulational mechanisms on FGF receptors from those of basic FGF.

403.15

Gene Expression of bFGF, NGF and c-fos by Glutamate Receptor Activation in Astrocytes and Hippocampal Neurons.

W. Gerdes, P. Pechan, B. Flott-Rahmel and W.Seifert*
Max-Planck-Intsitut für biophy. Chem. P.O. Box 2841, 3400 Göttingen, Germany

Basic fibroblast growth factor (bFGF) and nerve growth factor (NGF) are multifunctional proteins for neurons and astrocytes in culture. The mechanisms regulating the expression of bFGF and NGF in neurons and astrocytes of developing or injured rat brain are not well understood. Previous work demonstrated that hydrogen peroxide induces bFGF, NGF and c-fos in astrocytes[1]. It has been shown that excitatory amino acids (EAA) induce calcium influx in hippocampal neurons.

In this study we demonstrate that EAA treatment increases c-fos and growth factor mRNA in a time dependent manner. When neurons and astrocytes were incubated in the presence of DNQX and APV the expression of the mRNA was reduced. These findings suggest a possible interaction between glu-receptor activation and growth factor expression as an important aspect of neuronal-glial communication.

SUPPRESSIVE EFFECT OF bFGF ON NEURONAL DIFFERENTIATION OF NEURAL TUBE CELLS IS DIRECTED TO POST-MITOTIC MOTONEURON PRECURSOR CELLS. Y. Kinoshita*, C. Kinoshita, H. Tanaka[1] and M. Bothwell. Dept. of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195 and [1]Inst. for Medical Genetics, Kumamoto University Medical School, Kumamoto 862, Japan.

bFGF does not always act as a neurotrophic factor. We previously showed an adverse effect of bFGF on dissociated brachio-thoracic neural tube cells from E2.5 chick embryos, resulting in decreased number of neurons. (Soc. Neurosci., Abst. p. 44, 1991). Here we characterized these bFGF-sensitive neurons after 1.5-2 days in culture. Only about 10% of the neurons identified with anti-neurofilament antibody incorporated BrdU as visualized by double immunostaining with anti-BrdU antibody both in control and bFGF-treated cultures. Most neurons differentiating in our culture system appeared to be motoneurons: SC1 monoclonal antibody, which specifically labels motoneurons in the neural tube at this stage, stained about 90% of neurons in control cultures. With bFGF this percentage dropped to 70-80%. When neurons were stained with SC1 antibody, the bFGF effect of reducing the number of neurons was more profound as compared to that determined with anti-neurofilament antibody. Adverse effects of bFGF on neuronal differentiation were also detected in slice cultures of neural tube and whole embryo in collagen gel, although the effect was less noticeable with increasing size of explants.

These results suggest that post-mitotic motoneuron precursor cells are susceptible to the bFGF action. bFGF may alter the developmental fates of those post-mitotic cells or simply force them to remain undifferentiated or stem cell-like.

PATTERN FORMATION, COMPARTMENTS AND BOUNDARIES II

404.1

In vivo imaging of gene expression in zebrafish embryos: an insertional mutagenesis approach to neural development. C. Fulwiler*, Pamela Yelick & Walter Gilbert. Prog. in Neuroscience, Harvard Med. Sch. & Biological Labs, Harvard University.

We are interested in the genetic control of pattern formation in the nervous system. For a mutational analysis of this problem in the zebrafish, we have developed methods for insertional mutagenesis that will lead directly to the molecular characterization of the genetic loci involved.

A gene trap construct containing the LacZ reporter gene (a gift from J. Rossant & A. Joyner) allows us to identify insertions into zebrafish genes. After microinjection of DNA into eggs, expression of the reporter during development of the animal is visualized with a vital stain for ß-galactosidase. This assay allows us to pre-screen transgenic lines for insertions likely to produce phenotypes. Since the precise timing and localization of the endogenous gene's expression is revealed by the reporter, we can also screen transformants for insertions into specific genes of interest.

In our initial experiments, 599 animals were tested. We saw 19 examples of expression: 5 localized and 14 diffuse. These were pooled and 14 tested for germline integration. 6 are positive (43%), compared with 2/20 (10%) animals injected with the same construct without pre-screening.

The first of these six pre-screened lines has now been tested for a phenotype by incrossing transgenic F1's. About 1/4 of the F2's share a characteristic abnormality in their circulation which can be identified as early as 1.5 days. When the same parents are crossed to non-transgenic F1 siblings, all the F2's develop normally. We are currently attempting to determine if the trangene insertion is always associated with the phenotype by testing the individual F2 offspring.

404.2

STAGE AND CONCENTRATION SPECIFIC EFFECTS OF RETINOIC ACID ON THE DIFFERENTIATION OF *XENOPUS* HINDBRAIN AND EAR. T. J. Neary* and B. Fritzsch. Anatomy Div., Creighton University, Omaha, NE 68178.

Retinoic acid (RA) causes developmental defects of certain brain areas (Papalopulo et al., Development **113** (1991) 1145) that could result either from abnormal inductive interactions between mesoderm and neuroectoderm or from direct effects of RA on the developing CNS. To discriminate between these possibilities we exposed *Xenopus laevis* embryos (stages 15 - 21; from completion of gastrulation to completion of neurulation) to 30 min. RA pulses (5×10^{-7} - 5×10^{-6} M RA). Reticulospinal projections, known to be altered by RA (Manns and Fritzsch, Neurosci. Lett. **136** (1992) 1) and connections of the inner ear were examined in later stages with fluorescent dextran amines. Effects on the reticular formation, (supernumerary Mauthner-like cells) were found with increasing concentrations of RA as late as st 21. In the ear, the separation of the utricular and saccular macula and the formation of the horizontal canal is suppressed with exposure to increasing concentrations of RA as late as st. 21. Reductions in the numbers of sensory ganglia and efferent cells were concomittant with this effect. These data suggest that RA has a direct effect on the CNS and inner ear. Supported by Health Future Foundation.

404.3

A MONOCLONAL ANTIBODY THAT RECOGNIZES A NOVEL POSITIONALLY- REGULATED EPITOPE IN THE RAT CNS

S. Tole,* Z. Kaprielian, S. Ou, and P. H. Patterson 216-76, Division of Biology, Caltech, Pasadena, CA 91125

In an attempt to generate mAbs against downstream products of homeobox genes expressed on neuronal surfaces, we employed NT2D1 embryonic carcinoma cells. Retinoic acid induces homeobox gene expression and a neuronal phenotype in these cells. After the mouse's immune response to normal NT2D1 cell membranes was suppressed with cyclophosphamide, membranes from the same cells treated with retinoic acid were injected. Hybridoma supernatants from this fusion were screened on sagittal sections of whole E14.5 and E18.5 rat embryos.

mAb OTO (olfactory-telencephalic-otic) staining is detected from E10.5 to E14.5 in the procencephalon and part of the diencephalon. The only other areas positive for OTO are the nasal pits and the otic placodes. The rest of the nervous system and all non-neural tissues are negative. At E15, staining also appears in the glomerular layer of the olfactory bulb, the olfactory epithelium, and the lateral nasal gland. From E18 through P1, limited staining is also detected in some regions of the cortex and thalamus. In the adult, the entire brain is positive.

Immunoblotting identifies high molecular weight, proteoglycan-like antigens with a tissue distribution consistent with the immunohistochemical localization at E14.5.

Supported by an Evelyn Sharp fellowship, a Helen G. and Arthur McCallum fellowship, a Markey internal grant in Developmental Biology, and an individual NRSA.

404.4

THE MURINE *HOX-1.2* GENE CONTAINS A CNS REGION SPECIFIC REGULATORY DOMAIN. M. Hunter-Ensor, A.-Q. Yu, S. Scherer, A. Messing† and J. Y. Garbern*. Dept. of Neurology, Univ. Penn., Philadelphia, PA 19104 and †Dept. Pathobiol., Univ. Wisc. Sch. Vet. Med., Madison, WI 53706.

The patterns of *Hox* gene expression during mammalian central nervous system development are remarkable for their spatial restriction. In general, within a cluster of *Hox* genes, each gene has a more rostral extent than does its immediate 5' neighbor. We have begun a study of the murine *Hox-1.2* gene to investigate mechanisms of this intriguing spatial control of gene expression.

We have examined two lines of transgenic mice bearing 3.7 kB of the *Hox-1.2* gene upstream of the translational start site fused to the E. coli β-galactosidase reporter gene. At embryonic day 12.5 there are high levels of reporter protein staining in the dorsal medulla, conforming with *in situ* hybridization studies. Staining appears to be localized to a small group of neuroblasts, which we have provisionally identified as the nucleus tractus solitarius (NTS), which is supported by labelling of this region by the carbocyanine dye dil applied to the glossopharyngeal/vagal ganglia. Interestingly, the vagus, trigeminal and facial nerves and ganglia are also stained. These latter nerves also have projections to the NTS, suggesting that *Hox* genes may participate in the specification of functionally integrated neural pathways.

The reporter gene is also expressed in the ventral horns of the caudal spinal cord and in a few lateral cells of the thoracic dorsal root ganglia. In one transgenic strain, at embryonic days 13 to 15, virtually the entire peripheral nervous system is stained, including the sympathetic chain and ganglia. In this same strain, reporter expression persists into adulthood, with prominent staining in the granular layer of the cerebellum, prepontine nuclei and the dorsal horns but not the ventral horns of the spinal cord. Our results demonstrate that one *Hox* gene has temporally regulated expression in several distinct and noncontiguous regions of the CNS. Therefore, expression of these genes is not confined to a single timepoint or single region of the neuraxis, although they may participate in positional or functional specification within those areas.

404.5

EVIDENCE FOR LINKAGE OF *TES-1* AND *DLX-1*, TWO HOMEOBOX GENES EXPRESSED IN THE DEVELOPING MAMMALIAN FOREBRAIN. T. L. McGuinness, G. P. MacDonald, T. K. Koch*, and J. L. R. Rubenstein. U.C.S.F., San Francisco CA 94143.

Tes-1 and *Dlx-1* are members of the *Distal-less* family of homeobox genes and are likely candidates for regulating positional identity or cell differentiation in the developing forebrain. *Tes-1* and *Dlx-1* are both transiently expressed in the cells of the embryonic ventral forebrain that give rise to the basal ganglia, ventral thalamic nuclei, and olfactory bulb. The present studies used pulsed-field gel electrophoresis (PFGE) to determine if *Tes-1* and *Dlx-1* are physically linked to each other, as is the case for the *Hox* genes. Mouse fibroblast (A9) genomic DNA aliquots were digested with nine rare-cutting restriction enzymes, subjected to PFGE, transferred to nylon filters, and sequentially hybridized to ^{32}P-labeled *Tes-1* and *Dlx-1* cDNA probes. The probes co-hybridized to fragments generated by the four restriction enzymes: *Nru* I, *Not* I, *Sal* I, and *Sfi* I. The physical linkage of these two genes was further demonstrated by co-hybridization of the probes to DNA fragments generated by digestion with combinations of restriction enzymes. The smallest DNA fragment (generated by digestion with *Sfi* I and *Not* 1) that was recognized by both probes was approximately 45 kb. These results indicate that *Tes-1* and *Dlx-1* are physically linked within approximately 45 kb on the genome. These two genes may exist as part of a larger gene complex that acts in a coordinated fashion to regulate forebrain development.

404.6

GENETIC CONTROL OF SEGMENT-LIKE PATTERNS OF GENE EXPRESSION IN THE MOUSE CEREBELLUM. J.D. Oberdick*, R.J. Smeyne, C. Bocchiaro and J.I. Morgan. Dept. of Neurosci. Roche Institute of Molecular Biology, Nutley, NJ 07110.

We have previously shown that the gene for a Purkinje cell-specific marker, L7, can be used to drive expression of β-galactosidase in cerebellar Purkinje cells of transgenic mice. Although all Purkinje cells in the adult express both the transgene and endogenous gene, early developmental expression of both reveals a series of positive and negative bands. The number of bands increases in the medio-lateral direction during development until all Purkinje cells are positive. Truncation of the promoter region of the transgene disrupts this normal developmental pattern. Animals carrying these truncated constructs show precocious lateral expression in early dvelopment. There is also a delay in the normal "filling in" of the bands. This suggests a series of positive and negative elements in the promoter important for control of the banding pattern. In addition, these truncations have identified a minimal promoter sufficient for driving Purkinje cell-specific expression. This small promoter fragment contains within it a number of consensus binding sites for known families of developmental control genes and these sites can be footprinted by purified proteins from these families or by crude cerebellar nuclear extracts. By specifically mutating these elements we are assaying their affect on cell-specific transgene expression. We are using a PCR strategy to identify the cerebellar transcription factors themselves.

404.7

A MOLECULAR APPROACH TO CEREBELLAR COMPARTMENTATION: THE CLONING OF ZEBRIN II

A.H. Ahn*, S. Dziennis, R. Hawkes, K. Herrup. Prog. Neurosci., Harvard Med. Sch., Boston, MA 02115; Dept. Anat., Univ. Calgary, Calgary, Alb T2N 4N1; Alzheimer Res. Ctr., Cleveland, OH 44106.

The Zebrins are Purkinje cell-specific antigens that represent striking examples of the parasagittal organization of the cerebellar cortex. Zebrin staining by immunohistochemistry appears as sharp anterior to posterior bands in the vermal region and islands (or less well registered bands) in the hemispheres. The bands have been likened to "compartments" and probably reflect a basic organizing principle of the cerebellum. To study the molecular genetic basis of Zebrin's periodic pattern of expression, we have cloned Zebrin II, a 32 kd intracellular antigen, from a cDNA expression library of postnatal day 20 C57BL/6J mouse cerebellum. Several independent recombinants expressed a single class of cDNA recognized by the Zebrin II monoclonal antibody. Partial sequence from these clones reveals a near perfect identity to that previously published for rat and human aldolase C, one of the three known aldolase isozymes. Aldolase is a glycolytic enzyme that hydrolyzes fructose-1,6-bisphosphate, and previous reports show that the expression of aldolase C is heterogeneously restricted to Purkinje cells of the cerebellum; no higher-order organization of its expression has been previously recognized. To determine whether the banded pattern of Zebrin/aldolase antigen in cerebellum was due to differential transcription, *in situ* hybridization of horizontal sections of mouse brain was performed. A strong and specific signal appears in the cerebellar Purkinje cell layer, with regional heterogeneity. The registration of this heterogeneous pattern with that of Zebrin II bands will be assessed.

FURTHER CHARACTERIZATION OF MEANDER TAIL, A GENETIC MUTATION AFFECTING CEREBELLAR MORPHOGENESIS. C. Fletcher°, N. Heintz°, M.E. Hatten‡ and C. Mason‡*. ‡Dept. of Path., Columbia Univ. of Phys. and Surgeons, N.Y., N.Y. 10032 and °The Howard Hughes Med. Inst., The Rockefeller University, N.Y., N.Y. 10021.

We have previously described the effects of a genetic mutation on the cellular and foliar structure of the mouse cerebellum (Ross et al., PNAS 87:4189, '90). We now present further analysis of this phenotype, including a three dimensional reconstruction of the mutant cerebellum and the cellular details of early postnatal development. Frontal and coronal sections were examined to determine the lateral extent of the affected region. These sections show that the affected region includes the more medial anterior lobes (the lingula cerebelli, lobulus centralis, and the culmen) as well as lateral aspects of the declive. Specifically, the foreshortened declive fails to bifurcate laterally. The meander tail cerebellum is not only disorganized in the anterior lobes, but is significantly reduced in size. This was examined by three dimensional reconstruction of the mutant cerebellum. This analysis demonstrates that a rather large volume, comprising the "anterior" cerebellum, is completely missing. Thus, the mea cerebellum is a posterior half-cerebellum. We have also analyzed the appearance of the phenotypic features. There is a progressive failure of organization, with altered foliation and glial cell structure apparent at P0. The cells in the anterior external granule layer do not proliferate and the Purkinje cells never organize into a monolayer. By P7 the mutant phenotype is fully established. These results further implicate the regional specification of the developing cerebellum.

DEVELOPMENTAL REGULATION OF THE POU-HOMEODOMAIN GENE SCIP/TST-1 DURING CEREBRAL CORTICAL DEVELOPMENT. G.D. Frantz, L.M. Burstein, A.P. Bohner and S.K. McConnell*, Department of Biological Sciences, Stanford University, Stanford, CA 94305.

Homeodomain genes have been implicated in the generation of patterning in the mammalian CNS, but most reports have focused on segmental organization in the hindbrain. Many forebrain structures, in contrast, are patterned into layers of neurons. He et al. (Nature 340:35-42,1989) have reported that the POU-homeodomain gene Tst-1 [also known as SCIP (Monuki et al., Neuron 3:783-793, 1989) or Oct-6 (Suzuki et al., EMBO J. 9:3723-3732, 1990)] is specifically expressed in the deep layers of the rat cerebral cortex. We have examined in detail the expression of the mRNA encoding SCIP/Tst-1 using probes to both the SCIP 3' untranslated region and the POU domain of Tst-1; both probes show similar patterns of hybridization but the SCIP probe provides a somewhat cleaner signal. In the adult rat, SCIP/Tst-1 mRNA is strongly expressed in layer 5 throughout the cerebral cortex, with little labeling in other layers. The signal is clearly localized to pyramidal neurons in layer 5, which are easily identified by their large pale nuclei and low density. Expression is also apparent in other brain regions, particularly in the CA1 region of the hippocampus. The regulation of SCIP/Tst-1 gene expression during cortical development is quite complex. By E20 a strong signal is seen in the top half of the cortical plate; at this time layer 5 and 6 neurons occupy their final positions in the cortical plate but upper-layer neurons are still migrating (Berry and Rogers, J. Anat. 99:691-709, 1965). Thus the label is most likely in layer 5. During postnatal cortical development, however, SCIP/Tst-1 expression is not restricted to layer 5 neurons. In postnatal rats through at least P17, we observe a bilaminar pattern of hybridization that includes the upper layers 2/3 as well as layer 5. During later life, labeling of the upper cortical layers decreases and the adult pattern is achieved. Although SCIP/Tst-1 gene expression is not strictly confined to layer 5 pyramidal neurons during the course of cortical development, these results show that neurons within an individual layer of the adult cortex can exhibit a unique molecular phenotype. Whether SCIP/Tst-1 gene expression is involved in the generation of cell commitment to a particular laminar phenotype remains unclear.

We thank G. Lemke and M.G. Rosenfeld for providing the SCIP and Tst-1 probes. Supported by PEW Scholars, Searle Scholars, NSF PYI, and NIH EY06342.

NEURON SPECIFIC ENOLASE PATCHES IN THE DEVELOPING RAT STRIATUM. W.F. Silverman* and Y. Solberg. Unit of Morphology, Corob Center for Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.

One of the initial events signaling the development of patch and matrix domains in the embryonic striatum is the appearance of *islands* or patches of dopamine (DA) terminals originating in a subset of mesostriatal neurons. Cells in the patches subsequently produce opiate receptors and substance-P (SP). A complementary pattern, the *matrix*, is produced postnatally following ingrowth of fibers from the remaining DA cells into the areas between the patches, followed by synthesis of neurotensin, calcium binding protein and other peptides by neurons there. This sequence of neuropeptide expression preceded by the ingrowth of DA terminals suggests an inductive role for the mesostriatal projection. We have examined the ontogeny of immunoreactivity for neuron-specific enolase (NSE), a metabolic enzyme-marker for synaptogenesis and neuronal activity with respect to that of tyrosine hydroxylase, SP and neurotensin in the striatum and ventral mesencephalon of the developing rat at the light and ultrastructural levels. The most striking findings were that NSE appeared exclusively in striatal patches until the 2nd postnatal day, where it co-localized with SP in neuronal perikarya; after P2 NSE also appeared in neurotensin-positive cells in the matrix. The data obtained support the hypothesis that DA fibers establish connections in the striatum, and induce metabolic activity and expression of neuropeptides, initially in the patches and then in the matrix. Supported by The Israel Ministry of Science and Technology.

THE DISTRIBUTION OF CHOLINERGIC NEURONS CHANGES FROM A PREFERENCE FOR THE PATCH COMPARTMENT TO A HOMOGENENOUS DISTRIBUTION IN THE DEVELOPING STRIATUM. E.H.S. van Vulpen* and D. van der Kooy. Neurobiology Research Group, Dept. Anatomy, University of Toronto, Toronto, Ontario, M5S 1A8.

Striatal cholinergic interneurons in the rat are generated early in development (E12-E17) and choline acetyl transferase activity (CHAT) can be detected as early as E13.5 in the striatum. Early born neurons in the striatum preferentially end up in the patches and late born neurons in the matrix compartment. This birthdate data leads one to expect that the cholinergic neurons will be located mainly in the patches. However, in the adult rat these large sized cholinergic cell bodies are distributed more or less homogenously in the two compartments of the striatum. To study the distributions of cholinergic cells during development, a retrograde tracer was injected in the substantia nigra at postnatal day (PND) 2 to label the patches. The pups were sacrificed after different survival times and vibratome sections were cut and stained with an antibody against CHAT. The results show that early in development (PND 3), cholinergic neurons are located preferentially in the patches. Within the patches they are located primarily near the border between patch and matrix. At PND 17, an increased proportion of cholinergic neurons are found in a small region of the matrix just around the patches. Thus, we hypothesize that during early postnatal development some cholinergic neurons may migrate out of the patches or perhaps cholinergic neurons in the patches undergo cell death. An additional possibility is that some cholinergic neurons in the matrix do not express CHAT until relatively late in development. Absolute counts of the number of CHAT staining cells in relation to other striatal neurons during development may help to discriminate among these possibilities.

DEVELOPMENT OF MORPHOLOGICAL CORTICAL COLUMNS IN HUMAN CORTEX. E. Armstrong* and D. Buxhoeveden, A.F.I.P., Washington, D.C. and Anthropology Department, University of Chicago, Chicago, IL.

A new method that quantifies the morphology of cortical cell columns was used to analyze the changes from single-cell ontogenetic columns to the adult configuration in Tpt of the human brain. Nissl stained coronal sections of normal brains from the Yakovlev Collection were digitized. Seven adult, three children and nine fetal brains were analyzed.

Results indicate that in layer III the cells continue to grow apart horizontally, possibly as a result of the growing space between cell columns until late in maturation. The adult configuration had not been reached by 11 years. On the other hand, the pattern of the cellular arrangement is established as early as 29 or 32 gestational weeks. Laminae II and IV differ from III in that the adult pattern of cell arrangement develops much later.

The data show the complexity of anatomical plasticity. Even a small structure like a morphological cell column has nonuniform rates of development. Furthermore in the language area, anatomical plasticity extends into late childhood. This raises interesting questions about the evolution of language and the importance of late childhood for human behavior.

ANONYMOUS MARKERS OF CELLULAR SIGNALLING DURING CORTICAL DEVELOPMENT. W.E. Kaufmann* and P.F. Worley. Neuropathology Laboratory and Departments of Neuroscience and Neurology, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Cellular interactions are critical during brain development and play a role in neuronal migration and cytodifferentiation. Histochemical markers that are sensitive to these intercellular signals will be extremely useful for studying normal and aberrant neocortical histogenesis. Differential screening techniques have been used to identify two clones representing previously uncharacterized genes that are expressed in brain as early as E15 and that are rapidly induced by synaptic activity in the adolescent brain. Both are expressed primarily in cortex and hippocampus but exhibit distinct laminar patterns. At E21-P1, clone # 8 is expressed in highest levels in the most superficial layers of the neocortex and in pyramidal (CA1-CA4) hippocampal neurons. By contrast, at the same developmental stage, clone # 59 is expressed in all layers in the dorsomedial (somatosensory and cingulate) neocortex and the dentate gyrus. Our preliminary observations suggest that histochemical markers for these genes may be useful to study the role of activity in development of discrete populations of cortical neurons.

POSTNATAL DEVELOPMENT OF THE STRIATAL MOSAIC IN RHESUS MONKEY. L.J. Martin* D.M. Spicer and L.C. Cork. Johns Hopkins Univ. Sch. Med., Baltimore, MD. 21205.

The postnatal striatal ontogeny in *Macaca mulatta* was studied immunocytochemically in 6 male monkeys (1 day and 1,4,6,9,12 months), 2 female monkeys (1 and 4 months), and 2 adults. Sections were concurrently processed for substance P (SP), leucine-enkephalin (LENK), tyrosine hydroxylase (TH), calbindin (CAL), choline acetyltransferase or Nissl. In the first postnatal year, monkey striatum undergoes considerable changes in cyto- and chemoarchitecture. Striatal maturation progresses ventral to dorsal and medial to lateral. Early postnatally, neuronal density decreases significantly; ingrowth of dopaminergic nigrostriatal afferents (islands enriched in TH processes) overlap patches enriched in SP neurons but devoid of LENK and CAL neurons. Regions destined to become matrix initially contain sparse TH processes and few SP neurons but are densely populated with LENK neurons. After 4 months, TH afferents densely innervate matrix; SP neurons and processes increase in matrix; LENK neurons decrease in matrix and increase in patches; cholinergic neurons decrease. At 12 months, striatal chemoarchitecture is similar to, but does not completely match, adult patterns. Developmental patterns of male and female monkeys are similar, but striatal maturation is accelerated in females. Maturation of primate striatum is dynamic, gender-specific with synchronous changes in neuronal density, afferent ingrowth, and neuronal phenotype expression.

EXCITATORY AMINO ACID RECEPTORS COLOCALIZE WITH ACETYLCHOLINESTERASE-RICH STRIOSOMES IN FETAL CAT STRIATUM. Leon S. Dure IV*, Anne B. Young, John B. Penney, Massachusetts General Hospital, Boston, MA. 02114

Afferent connections to mammalian striatum are compartmentalized within caudate and putamen. These compartments, termed striosomes and matrix, differ with respect to efferent connections as well, allowing for modulation and integration of striatal neurotransmission. Striosomes and matrix may be identified by differences in acetylcholinesterase (AChE) activity The primary corticostriatal neurotransmitters are excitatory amino acids (EAA), which are divided pharmacologically into *N*-methyl-D-aspartate (NMDA), α-amino-3-hydroxy-5-methylisoxazole propionic acid (AMPA), kainic acid (KA), and phosphoinositol-related metabotropic receptor (metabotropic 1) subtypes depending on agonist affinity. We have previously demonstrated in the adult human that AMPA binding sites are primarily localized in matrix, and KA binding sites are localized in striosomes. To investigate the distribution of EAA binding sites among striatal compartments during development, we have studied binding to receptor subtypes in fetal cat striatum using quantitative *in vitro* receptor autoradiography. Using AChE as a marker for striosomes, we have determined that NMDA, AMPA, KA, and metabotropic 1 binding sites are located primarily in the AChE-rich striosomal compartment during the latter half of gestation in the fetal cat. Since EAA are known excitotoxins, these findings may in part explain the inhomogeneous striatal pathology observed as a sequel of perinatal hypoxia/ischemia in the human. STRIOSOMAL ORGANIZATION OF DOPAMINE TERMINALS AND ACETYLCHOLESTERASE DURING POSTNATAL DEVELOPMENT OF THE RAT. H.K. Happe*, L. Arqueros and L.C. Murrin, Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198-6260.

In postnatal striatum several neurochemical markers are concentrated in striosomes. We examined the organization of dopamine (DA) uptake sites by autoradiography with [^{125}I]RTI-55 and acetylcholinesterase histochemistry (AChE). [^{125}I]RTI binding is found in striosomes on day 1. Binding in striosomes and matrix increases through day 7 with 40% more sites in striosomes. By day 10 matrix sites have increased so striosomes are less apparent. There is a lateral to medial and a rostral to caudal gradient in the appearance of striosomes. On day 1 the head of the striatum has only a lateral subcallosal streak, but by day 3 striosomes are found. In the body of the striatum both the callosal streak and lateral patches are seen on day 1. On day 3 patches appear in a gradient from dorso-lateral to the ventromedial region. More caudally there is no callosal streak but there are patches on day 1 and a large single patch in the ventro-medial region. In the tail of the striatum there is a single streak of [^{125}I]RTI binding extending ventro-dorsally near the center of the structure. This streak is present day 1 through day 10. AChE corresponds extremely well to [^{125}I]RTI binding sites at day 1. The close match continues through day 5 in the lateral striatum and through day 10 in the more caudal regions. By days 7 and 10 AChE increases from lateral to medial, however correspondence of patches can still be observed in the body of the striatum. In the central and medial regions there is a lack of prominent patches for AChE staining. It has been suggested that AChE may be produced by DA neurons. However 6-hydroxydopamine lesions on day 2 deplete >95% of striatal DA by day 4 but do not affect the distribution or apparent density of AChE. Therefore AChE staining is not likely to be on DA neurons and may be a useful marker for cholinergic terminals during early postnatal development. DEVELOPMENT OF TOPOGRAPHY IN THE GENICULOCORTICAL PROJECTION OF THE RAT. Gavin Dixon* Department of Physiology, University of Sydney NSW 2006 Australia.

Relay neurons of the adult rat dorsal lateral geniculate nucleus (DLG) project onto area 17 of the cerebral cortex with a high degree of topographic order. To study the timecourse of development of this precision, small particles (~20μm diameter) of DiI and DiA were placed superficially into rostral and caudal sectors (respectively) of presumptive area 17 of albino rats at three ages: post-conceptional days (PCD) 20, 24 and 30. Coronal sections through the DLG at PCD20 revealed two large, diffuse and overlapping populations of single-labelled relay cells. By PCD24 two distinct, partially-overlapping groups of single-labelled cells were oriented along separate lines of projection within the DLG. Further, when taking into account the cortical position of the dye placements, these groups were located in the topographically appropriate parts of the DLG as determined electrophysiologically in the adult animal. These features were observed at PCD30, at which time the geniculo-cortical projection was first observed to arborize within cortical layer 4. However, compared to PCD24, each group of labelled cells had a smaller locus (as seen in coronal section) with respect to the areal size of the DLG. These findings indicate that considerable order exists within the geniculocortical projection several days before afferents reach cortical layer 4, the main termination zone within area 17.

MOUSE CEREBRAL NEOCORTEX IS ORGANISED INTO DEVELOPMENTAL MODULES. S-S Tan*, Embryology Laboratory, Department of Anatomy, The University of Melbourne, Parkville 3052, Victoria, Australia.

Cell lineage plays an important role during development of the mammalian neocortex, providing a link between cell division and cell migration. Transgenic mice carrying the *lacZ* marker gene provide a genetic method of marking progenitors cells in the ventricular zone. Following X-chromosome inactivation, the marker in half of these cells is switched off, generating functional genetic mosaicism in the neocortex. The resulting pattern did not show a "salt and pepper" mixture of marked and unmarked cells, instead the neocortex was delineated into broad bands of variable widths which we termed developmental modules. These bands were first seen in the ventricular zone layer but later extended into the cortical plate. In the adult brain, each module appeared either as a blue or clear band with clearly defined borders, suggesting that a module has arisen from radial cell migration. However, there was also a significant degree of horizontal migration across modules, these were seen as blue cells in clear areas, and vice versa. These horizontally-migrating cells were mostly neurons, and they comprised about one-third of the total cortical cells in a given area. Taken together, the results suggest that the cortex is basically assembled by modules whose final positions reflect the initial mosaicism of the germinal neuroepithelium. It would also appear that the neuroepithelium is not completely devoid of form-generating capability, and that the non-dispersing modules may serve to provide a stabilizing scaffold upon which the growing cortex is built. More importantly, this study would provide support for the radial column hypothesis, while also affirming the presence of other cortical cells that are capable of extensive horizontal migration.

GLIA AND OTHER NON-NEURONAL CELLS III

405.1

GLIAL CELL RESPONSE TO SUBSTRATE-BOUND ADHESION MOLECULES. H.R. Payne* and V. Lemmon. Department of Neurosciences, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

During neurogenesis and regeneration, both soluble and nondiffusible factors provide environmental cues for glial cell development. We examined the influences of purified extracellular matrix molecules and cell adhesion molecules on the development and proliferation of glial cells from neonatal rat optic nerves. Dissociated optic nerve glia were plated on nitrocellulose-bound fibronectin, laminin, collagen type IV, L1, n-cadherin, and NCAM. Cultures were grown in chemically-defined medium to promote formation of oligodendrocytes. Other cultures were grown in 10% serum to support type-1 astrocytes and the differentiation of progenitor cells to type-2 astrocytes. Short term adhesion assays were used to measure cell affinity for the different substrates. In these experiments, glial cell types displayed characteristic patterns of substrate preference. The glial cells developed distinctive morphologies on different substrates after incubation for 4 days. Measurements of BUdR incorporation showed that the substrates did not significantly influence cell proliferation rates. Our results indicate that progenitor cells, oligodendrocytes, type-1 astrocytes, and type-2 astrocytes possess different complements of receptors for the adhesion molecules in their environment. Transduction of this substate-receptor binding signal may induce cytoskeletal alterations that produce the observed morphological differences in glial cells.

405.2

NEURITE OUTGROWTH OF OLFACTORY SENSORY AXONS ON IMMORTAL OLFACTORY BULB ASTROCYTE AND ENSHEATHING CELL LINES. M. N. Goodman*, J. Silver, J. W. Jacobberger. Depts. Genetics and Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106.

Rat primary olfactory synapses are located in glomeruli and can be regenerated during adulthood. It has not been determined whether the unusual structure or the regenerative capacity of the glomerular synapses is due to unique growth properties of the olfactory sensory neurons (OSNs), to unique properties of the olfactory bulb (OB) glia that surround the OSN axons and glomeruli, or both. However, the organization and phenotypes of two types of OB glia, OB astrocytes and ensheathing cells, suggest that the formation of neural circuitry in the OB, as in other areas of the nervous system, is controlled by glial-neuronal interactions. OB astrocytes resemble type-1 astrocytes, and some of the OB astrocytes encircle the glomeruli and express the molecules J1 and chondroitin sulfate proteoglycan (CSPG) that have been associated with cordones or axon barriers. Ensheathing cells resemble Schwann cells and ensheath OSN axons from the glial limitans to the glomeruli. Further, OB astrocyte cell lines with the characteristics of the glomeruli-encircling glia promote very low neurite outgrowth by chick retinal ganglion neurons (CRGNs), as expected of glia which form barriers, while other OB astrocyte lines and ensheathing cell lines support high CRGN outgrowth, as expected of glia that form axon-growth permissive pathways. In this study, rat OSN neurite outgrowth has been tested over the same cell lines. The results are that neonatal OB astrocyte lines that express J1 and CSPG support very low OSN outgrowth, while other neonatal astrocyte lines and ensheathing cell lines support higher outgrowth, and adult ensheathing lines support higher OSN outgrowth than any other OB glial cell lines. Together, the chick and OSN outgrowth results are consistant with the following hypotheses: 1) during development, some OB astrocytes may form cordones that delineate the glomeruli, while ensheathing cells guide the axons to the glomeruli, and 2) during adulthood, ensheathing cells and perhaps also some of the OB astrocytes permit OSN axon growth, allowing regeneration of the glomerular synapses.

405.3

THE NG2 PROTEOGLYCAN INHIBITS NEURITE OUTGROWTH FROM CEREBELLAR GRANULE NEURONS. C.Dou* and J.M.Levine, Dept. of Neurobiology and Behavior,SUNY at Stony Brook,Stony Brook,NY 11794

The NG2 antigen is a high molecular weight, chondroitin-sulfate proteoglycan. It is a cell surface marker for O2A progenitor cells *in vitro* and identifies a population of developing glial cells *in vivo*, some of which differentiate into oligodendrocytes. Proteoglycans can play important roles in the regulation of axon elongation. Therefore, we tested the ability of immuno-affinity purified NG2 to either support or inhibit neurite elongation *in vitro*.

Tissue culture surfaces were coated with poly-L-lysine followed by either laminin alone ($0.3\mu g/cm^2$) or laminin mixed with NG2 ($6\mu g/cm^2$). Cerebellar granule neurons were isolated from postnatal day 5 and 6 rat pups on discontinuous Percoll gradients and seeded onto these surfaces in media supplemented with bFGF. After 24hr, the cultures were fixed and the extent of cell attachment and neurite outgrowth quantitated.The neurons attached equally well to both substrates, however, 66% of the cells extended neurites on laminin, while only 23% of the cells grew processes on the laminin plus NG2 coated surfaces. The extent of neurite outgrowth also differed between the 2 types of surfaces. On laminin, the mean neurite length was 92.5±11.4 microns whereas on laminin plus NG2, mean neurite length was 54±12.2 microns. Digestion of NG2 with chondroitinase ABC did not remove the growth-inhibitory activity. When the laminin concentration was increased to $8\mu g/cm^2$, NG2 no longer inhibited neurite outgrowth. The glycosaminoglycans, chondroitin sulfate and hyaluronic acid , each inhibited neurite outgrowth when used at $15\mu g/cm^2$ in this assay. These data suggest that NG2 is one of a number of proteoglycans that can inhibit neurite outgrowth. Cells that carry the NG2 proteoglycan on their surfaces within developing neural tissues may provide an unfavorable substrate for axon elongation.

405.4

INCREASED EXPRESSION OF THE NG2 PROTEOGLYCAN AFTER BRAIN INJURY. J.M.Levine* and A.K.Levine, Dept.of Neurobiology and Behavior,SUNY at Stony Brook,Stony Brook,NY 11794

The NG2 antigen is a chondroitin-sulfate proteoglycan that is a cell surface marker for neonatal O2A progenitor cells *in vitro*. It also marks a population of unusual glial cells in adult animals. To determine whether these adult cells participate in the glial reaction to injury, we made small puncture lesions in the cerebelli of anesthetized adult rats and analyzed the distribution of NG2-immunoreactivity at intervals after the lesion. The distribution of the NG2 proteoglycan was compared to that of markers for astrocytes, ramified microglia and monocytes.

At 24hr after lesion, NG2-positive cells adjacent to the damaged area had enlarged processes. By 48hr post-lesion, the number of NG2-positive cells had increased. These cells had large cell bodies with punctate deposits of NG2-immunoreactivity at their surfaces. At this same time, ED1-positive monocytes invaded the damaged tissue and the number of OX42-positive microglia increased. NG2-immunoreactivity in the damaged tissue continued to increase up to 5-7 days post-lesion and declined thereafter. At 4-5 days post-lesion, GFAP immunoreactivity increased as an astrocytic scar formed around the damaged area. An increased density of NG2-positive fibers persisted within the damaged tissue for up to 45 days post-lesion. These changes in NG2-immunoreactivity were confined to the damaged tissue; areas distant from the lesion site appeared normal. The increase in NG2-positive cells at the lesion site is likely due to cell division since NG2-positive cells bodies became labeled with silver grains after administration of a pulse of ^3H-thymidine at 24 and 48hr post-lesion. These studies demonstrate that the NG2-positive glia of adult animals participate in the reaction to brain injury. The NG2 proteoglycan inhibits neurite outgrowth *in vitro* (Dou and Levine,this volume); increased expression of NG2 after injury may contribute to the failure of CNS neurons to regenerate successfully.

405.5

Differential effects of median and lateral mesencephalic astrocytes on neuritic growth. L.A. Cavalcante*, V. Moura-Neto, J. Garcia and S.L. Carvalho. Instituto de Biofisica, UFRJ, 21941 Rio de Janeiro, RJ, Brazil.

Radial glia in median and lateral sectors of the mesencephalon are heterogeneous in several respects (Barradas et al., Glia 2:103, 1989). In this study, we have tested for regional differences of mesencephalic astrocytes on neuritic growth. Dissociated cells from either median or lateral sectors of mouse embryo mesencephali (MMN or LMN) were (1) cultivated onto confluent cultures of astrocytes from either sector (MMG or LMG) for 2 days and co-cultures reacted with an anti-MAP2 antibody, (2) cultivated onto poly-l-lysine in serum-free medium with addition of conditioned medium from MMG or LMG cultures. Both MMN and LMN on LMG grow long and varicose neurites whereas both MMN and LMN on MMG tend to aggregate and show diminutive neurites. These features are also mimicked by conditioned medium from LMG or MMG. These results suggest (1) permissive vs. non-permissive effects of LMG vs. MMG on neuritic growth, respectively, (2) mediation of effects, at least, partially by soluble factors.

CULTURED ENSHEATHING GLIA FROM ADULT RAT OLFACTORY BULB ENFOLD OLFACTORY NEURITES. A.Ramón-Cueto, J.Pérez, P. Bovolenta* and M. Nieto-Sampedro. Cajal Institute, 37 Doctor Arce, 28002 Madrid, Spain.

Ensheathing glia is a type of macroglia exclusively present in the olfactory bulb. To gain insight into the mechanisms underlying axonal regeneration in the olfactory bulb, we have studied ensheathing glia and its interaction with olfactory neurites in culture at the ultrastructural level. Three morphologically and ultrastructurally different cell types were identified in secondary cultures from adult rat olfactory bulb: process bearing cells, macrophage-like cells and endothelial-like cells. Examination of these cultures showed that only process bearing cells were immunoreactive for GFAP and NGF receptor (NGFR). These cells shared immunocytochemical and ultrastructural properties with those described for ensheathing glia *in vivo* and were the only type capable of enfolding olfactory neurites *in vitro*. Therefore, process bearing cells are ensheathing cells. When cells from adult rat olfactory bulb were co-cultured with olfactory epithelium explants, olfactory neurites preferentially grew over NGFR positive cells. Olfactory neurites were NGFR-positive when growing either alone or over NGFR positive cells, but lost NGFR-immunoreactivity when enfolded by ensheathing cells. NGFR immunoreactivity disappeared from both, neurite and glial contact surfaces, but was kept in the glial membrane not involved in ensheathing in a comparable way to that descibed for Schwann cells *in vivo*. In summary, ensheathing cells retained *in vitro* both, the *in vivo* ultrastructure and the ability to ensheath olfactory neurites.

405.7

COAGGREGATION OF NEURONS AND GLIAL CELLS IN RAPHE AND CORTICAL CELL CULTURES. F. C. Zhou* and S. Bledsoe. Indiana Univ. Sch. Med., Dept. Anatomy, Indianapolis, IN 46202.

5-HT and cortical neurons from fetal brain have distinct morphological and aggregational patterns in cell culture. Raphe and cortical cells from E14 fetal brain were plated on 24-well plates coated with poly-D-lysine and laminin. Immunostained 5-HT neurons dispersed along with raphe cells throughout the well, while cortical cells form large aggregations after 2 days in culture (DIC). Mainly, diffused fibers were formed in raphe culture, and fasciculated fibers in cortical culture at 14 DIC, with distinct cell aggregation pattern described above. These cultures, when stained for astrocytic marker glial fibrillary acidic protein (GFAP), showed distinct astrocytic patterns closely resembling corresponding neuronal groups. Astrocytes aggregated around neurons with a diameter 3-5 times that of neuronal aggregation. Neuron-glial interactions may play a role in formation of distinct morphology. To test if glia and/or neurons from one brain area can influence another, raphe cells were co-cultured with cortical cells. A mixture of aggregated and diffused neurons as well as astrocytes were found, with 5-HT neurons diffused and non-5-HT neurons aggregated. These results suggest (a) glial cells from raphe and cortex which shared same GFAP marker are morphologically and functionally different, (b) interactions between neurons and corresponding glial cells are regional specific, and (c) specific aggregations between glial cells and neurons are probably contact-based and are not altered by diffusible factors.

405.8

BIOPHYSICAL PROPERTIES OF GAP JUNCTION CHANNELS BETWEEN SCHWANN CELLS. M. Chanson, K. Chandross, R. Dermietzel, J. Kessler and D.C. Spray.* Dept. of Neuroscience, A. Einstein Coll. Med., Bronx, N.Y. 10461.

Observations *in vivo* and *in vitro* suggest that direct intercellular communication participates in the control of proliferation and differentiation of Schwann cells. To characterize the gap junction channels expressed by these cells, we applied the dual whole cell voltage clamp technique on primary and cultured cell pairs. Because macroscopic junctional conductance (g_j) of Schwann cells is very low, averaging 500 ±120 pS (mean±SEM, n=32 cell pairs), and is steeply dependent on transjunctional voltage (V_j), recording of unitary junctional conductance (γ_j) without the use of uncoupling agents was possible. Frequency histograms of γ_j values revealed a distribution well described by a single Gaussian curve with a mean of about 40 pS (n=2,193 events, 25 experiments). This observation indicates that the junctional current (I_j) is carried through only one type of channel. Therefore, relaxation of I_j elicited by V_j can be modeled by a Boltzmann relation; best fit values for Boltzmann parameters were V_0 (V_j at which g_j is reduced by half) = 15 mV, g_{min}/g_{max} (ratio of minimal to maximal g_j) <0.1 and n (the number of equivalent charges moving through the field) =3. Compared to V_0 values for other gap junctions, Schwann cell junctions are among the most voltage-sensitive. Time courses of junctional current relaxations were always well fit (r^2>0.9) by a single exponential for V_j ±10 to 60 mV. Calculation of rate constants indicates that the fraction of channels that are in the open state is predominately determined by the closing rate constant. The connexin (Cx) protein encoding these channels is unknown but differs from Cx43, 32 and 26 as determined by immunostaining with specific antibodies and Northern blot analysis with specific cDNA probes. Molecular cloning of the cDNA encoding this novel gap junction channel is underway.

GROWTH FACTOR INDUCED PHENOTYPIC CHANGES IN CULTURED SCHWANN CELLS INCLUDE ALTERED GAP JUNCTIONAL CONDUCTANCE. K.J. Chandross*, M. Chanson, D.C. Spray, J.A. Kessler. Albert Einstein College of Medicine, Bronx, New York 10461.

Schwann cell proliferation, morphology, and gene expression are altered after nerve injury. These changes are reproduced in vitro by agents which elevate intracellular levels of cAMP and by growth factors which are released after nerve damage. We have examined changes in gap junctional conductance in cultured Schwann cell pairs which occurred in association with other phenotypic changes. After treatment with forskolin (F:2uM) in combination with bovine pituitary extract (BPE:10ug/ml), the cells became more spindle shaped, and cell proliferation and low affinity nerve growth factor receptor (NGF-R) expression were increased. Junctional conductance was significantly elevated from 0.56 nS$\pm$0.11(SEM, n=27) before treatment to 1.23 nS$\pm$0.24(SEM, n=19)($p < 0.01$). By contrast, after exposure to transforming growth factor beta, (TGFβ_1:10ng/ml) cells displayed a flatter, multipolar morphology, cell proliferation was not increased and NGF-R expression was decreased. Further, compared to control values, TGFβ_1 significantly reduced cell coupling in a time dependent manner; after 48 hours of treatment junctional conductance was 0.05 nS$\pm$0.03(SEM, n=7)($p < 0.03$). Neither F+BPE nor TGFβ_1 altered the characteristics of the gap junction channels (i.e. voltage dependence or unitary conductance), suggesting that changes in coupling resulting from these treatments reflected the number but not the type of channels that were expressed. Electrical or chemical coupling may help to coordinate Schwann cell responses to injury and other stimuli. These observations indicate that the strength of intercellular communication between Schwann cells changes in response to alterations in the cellular milieux providing a possible mechanism for modulating functional interactions between Schwann cells and their environment.

THE EFFECT OF CENTRAL AXOTOMY ON REMOTE MICROGLIA IN THE RAT SPINAL CORD. S. Hong,*P.J. Reier, W.J. Streit, Depts. Neurological Surg. and Neuroscience, Univ. Florida Coll. Med., Gainesville, FL, USA.

Microglial responses in the rat spinal cord following a hemisection at T9 were examined at levels rostral and caudal to the lesion. Microglia were visualized histochemically using the *Griffonia simplicifolia* B_4-isolectin (GSA). Expression of Ia-antigens on microglia was shown immunohistochemically with OX-6 mAB. In addition, astrocytes were visualized by GFAP staining. Lectin staining showed two distinct patterns of the microglial response. First, activated microglia appeared 1 day post-injury (DPI) and were widespread in both the white and gray matter rostral and caudal (C4-C5, T4-T5, T12 and L1) to the level of the lesion. Activated microglia remained prominent for up to 2 weeks in the white matter and 4 weeks in the spinal gray areas. The second pattern of microglial reactivity was confined to the area of fiber tracts undergoing degeneration. The onset of this response was as early as 3 DPI and lasted as long as 2 months. In the dorsal funiculus rostral to the level of the lesion the microglial reaction was confined to the fasciculus gracilis (FG) of the lesioned side without involving the adjacent corticospinal tract (CST). Caudally, the response was confined to the degenerating CST without involvement of the FG. By 5 days post-injury, a subpopulation of activated microglial cells showed expression of Ia antigen. The localized activation of microglia in regions of degenerating white matter (i.e. FG rostral to the lesion), and not in adjacent, intact regions (i.e. CST rostral to the lesion) suggests a non-diffusible triggering mechanism for the initiation of the degeneration-induced microglial response. The astrocytic reaction, on the other hand, showed a delayed onset (5 DPI), mostly in the degenerating fiber tracts, and the reaction was less intense than the microglial response during the early survival times. At longer survival times (>4 weeks), however, microglia and astrocytes displayed a largely parallel response in temporal and spatial distribution patterns. (Supported by NIH P01-NS 27511)

MICROGLIAL RESPONSES TO NEUROTOXIC ABLATION OF SEROTONERGIC AXON TERMINALS. M.A. Wilson* and M.E. Molliver. Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

Microglial cells are a heterogeneous class of non-neuronal cells in the CNS which respond to neuronal damage. Microglia exhibit a number of characteristic features which are altered in response to CNS injury: "activated" microglia undergo morphologic changes, up-regulation or novel expression of macrophage/monocyte antigens, and may proliferate and become phagocytic[1]. The response of microglia varies, depending on the nature of the particular injury; e.g., neuronal death vs. axotomy[2].

We have examined the response of microglial cells in the forebrain to the selective chemical axotomy of 5-HT axon terminals induced by p-chloroamphetamine (PCA). Rats were treated with PCA (10 mg/kg, s.c., x2) and sacrificed 3 days, 6 days, 3, 6, or 9 weeks later. This drug destroys fine 5-HT axon terminals in the forebrain, but spares preterminal 5-HT axons and cell bodies. Antisera directed against 6 microglial antigens were utilized as markers for microglial activation in PCA treated rats, untreated controls, and in rats with unilateral facial nerve transection. Morphologic changes in microglial processes and increases in staining for two of the antigens were detectable 6 days after PCA treatment. Three weeks after PCA, increased expression of four of the microglial antigens was detected, as well as increased branching of microglial processes and changes in the intracellular distribution of one of the antigens. By 6 weeks after treatment, these alterations were less marked; at nine weeks the microglia in treated animals resembled those in controls.

A QUANTITATIVE ANALYSIS OF MICROGLIAL AND ASTROGLIAL CELL REACTIONS IN PRIMARY SENSORY PROJECTION AREAS FOLLOWING PERIPHERAL NERVE INJURY IN THE ADULT RAT. P. Eriksson, J. Persson, M. Svensson, J. Arvidsson, C. Molander and H. Aldskogius*. Dept. Anat., Karolinska Institutet, Box 60400, S-104 01, Stockholm, Sweden.

Recently, it has become clear that proliferation of microglial cells and hypertrophy of astrocytes may be a general component in association with the central processes of peripherally axotomized sensory ganglion cells. For that purpose, by the use of a computerized scanning system, we have analyzed the time course for the microglial (antibody OX-42) and astroglial (antibodies to GFA and in situ hybridisation for mRNA-GFA) cell reaction in the L4 dorsal horn, the column of Clarke and the gracile nucleus after sciatic nerve transection as well as in the trigeminal nucleus after infraorbital nerve transection. In all areas examined the microglial cell reaction started 24 to 48 hours and peaked one to two weeks postoperatively. Thereafter there was a gradual decline in the reaction over a period of several months. The astroglial cell reaction seemed to parallell the microglial cell reaction. These observations demonstrate that peripheral nerve injury induces a rapid and prominent response among microglial and astroglial cells in all the appropriate primary sensory projection areas.

CALCIUM PERMEABLE CHANNELS IN MICROGLIA. M. Jia, M. X. Li, C. A. Colton, and D. L. Gilbert*. Lab. of Biophysics, NINDS, NIH, Bethesda, MD 20892 and Dept. of Physiology and Biophysics, Georgetown Univ. Med. School, Washington, DC 20007.

Cytosolic calcium is important for the activation of microglia. An influx of calcium through calcium-permeable channels may be a means of increasing cytosolic calcium. To study these channels, whole cell recording and single cell recording experiments were performed on cultured rat microglia cells. The bath solution was (in mM): 145 KCl, 1 $CaCl_2$, 1.8 $MgCl_2$, and 10 HEPES; the patch solution was (in mM): 110 $BaCl_2$ and 10 HEPES. Non-inactivating inward currents were observed at hyperpolarized membrane potentials. The single channel conductance was about 8 pS. The open probability was voltage-independent. We also report on a voltage-gated L-type calcium channel utilising a whole-cell recording mode. The bath solution was (in mM): 120 TEA-Cl, 15 $CaCl_2$, 2 $MgCl_2$, 10 TRIS-HEPES; the pipette solution was (in mM): 120 CsCl, 20 TEA-Cl, 10 Cs-HEPES, 2 $MgCl_2$, and 10 EGTA. Small long-lasting inward currents were activated with depolarizing pulses at a holding potential of -40 mV. The currents were enhanced with 1 µM Bay K 8644. Due to a lack of an outward K^+ current, a slight activation could result in a sustained membrane depolarization (H. Kettenmann et al., 1990. J. Neurosci. Res. 26:278-287). Increased K^+ from injured surrounding cells could possibly depolarize the microglia and activate this L-type channel.

405.14

POTASSIUM MODULATION OF MICROGLIAL SUPEROXIDE RADICAL ION PRODUCTION. C. A. Colton*, J. Keri, and D. L. Gilbert. Lab. of Biophysics, NINDS, NIH, Bethesda, MD 20892 and Dept. of Physiology and Biophysics, Georgetown Univ. Med. School, Washington, DC 20007.

Microglia are the resident CNS macrophages and are found at sites of trauma in the brain. Since injured cells release potassium into the extracellular fluid, we have examined the effect of high extracellular potassium on microglial function. Using a cytochrome c reduction assay in the presence and absence of superoxide dismutase (SOD), we have measured the production of oxyradicals by resting and stimulated cultured neonatal rat microglia. In order to maintain a normal ionic strength and osmolarity, potassium was substituted for sodium in all experiments. When potassium concentration was changed from a normal of 5 mM to a high of 55 mM, there was no change in resting superoxide radical ion production. A significant increase was seen, however, when phorbol myristate acetate (PMA) was used to activate the microglia to produce the superoxide radical ion. In the presence of 5 µg/ml PMA, potassium concentrations of 25 and 55 mM initiated a 115 percent and a 127 percent increase, respectively, over the PMA stimulated release in normal potassium. This enhancement was partially blocked by 10 µM nifedipine. These data suggest that changes in extracellular potassium at sites of injury may serve to modulate microglial release of oxyradicals.

MODULATION OF MOUSE MICROGLIA FORM AND IMMUNE REACTIVITY BY GOLDFISH OPTIC NERVE FACTOR(S).

Robert W. Keane*[1] and G.W. Perry[2]. [1]Department of Physiology and Biophysics, University of Miami School of Medicine, Miami, FL 33101 and [2]Program in Complex Systems and Brain Sciences, Florida Atlantic Univesity, Boca Raton, FL 33431.

Damage to central nervous system tissue is associated with infiltration of immune cells and the activation of microglia at the site of injury. The factors regulating activation of microglia have not been characterized. We have utilized the goldfish optic nerve (GFON), a well-characterized neural system which demonstrates a vigorous regenerative capacity following injury, to establish whether this neural tissue produces substance(s) that affect microglia morphology and immune reactivity. Microglia purified from mouse brain were grown in medium conditioned (CM) by GFON, optic tectum, vagal lobe, cerebrum and cerebellum, and medium conditioned by rat optic and sciatic nerves. Microglia maintained in GFON-CM assumed an ameboid morphology, whereas microglia grown in media conditioned by the other nerves produced long crenellated processes that resembled the ramified microglial form. Microglia maintained in all types of CM functioned as antigen-presenting cells in a MHC-restricted manner when tested on conalbumin-specific T_{helper} cells, except for microglia maintained in GFON-CM. The failure of these microglia to present antigen was not changed by treatment of the GFON-CM with neutralizing antibodies against TGF-β or TNF-α. These studies demonstrate that microglia form and immune reactivity can be modulated by factor(s) released by GFON.

CHANGES IN LOCOMOTION AND NEUROMUSCULAR DEVELOPEMENT IN THE NEONATAL RAT ACCOMPANY SIMULATED WEIGHTLESSNESS. K.D. Walton[1], J. Jacoby*[2], K. Ko[2], S.A. Williams[1] and R. Llinas[1], Depts. Physiology & Biophysics and Ophthalmology, NYU Medical Center, 550 First Ave., NY, NY, USA, 10016

Tail suspension of rat pups postnatal day 8 (P8) to P13 leads to abnormal swimming and stepping (Walton et al, Neurosci. Soc. Abst. 16, 937, 1991). This study asked if: (1) irreversible deficits in motor skills result from an extended period of susp. and (2) susp. alters hindlimb (HL) muscle devel. Pups were susp. P8-P13, P8-P21, P13-P21, or P13-P31. Each susp. (S) animal had a non-suspended companion (C). Free walking was videotaped with high speed camera (nac, 200 fps) and analyzed with Peak 2D motion analysis system. Swimming was unaffected in pups S on P13. Stepping in all S was slow with hyperextension of foot and ankle joints. Animals taken down on P13 or P21 recovered. Deficits persisted in those S until P31, e.g. maximum ankle extension on P60 was $128 \pm 2.8°$ in S ($n=6$) and $97.6 \pm 3.2°$ in C ($n=6$) ($p<0.001$). Effects of susp on HL muscle devel. were complex. The % slow twitch fibers in soleus (SOL) was decreased in S pups at the end of suspension (P13, P21, P31), as assayed by a McAb for type 1 (slow/beta) myosin HC. Slow fibers in SOL were signif. smaller and neonatal myosin expression in SOL and peroneus muscles was different in S pups. Pups S from P13-P31 showed persistence of neonatal myosin on P31. Studies of righting reflexes (Skorina et al, Neurosci. Soc. Abst. 1992) and swimming, suggest a set of critical periods for motor development. Patterns of changes in devel. muscle should be interpreted in terms of these critical periods. (Supp: NASA, and NIH EY06232 to J.Jacoby)

406.2

HINDLIMB SUSPENSION IN NEONATAL RATS LEADS TO PERMANENT DEFICITS IN AIR RIGHTING REFLEXES. Jane Skorina[1], Kerry D. Walton*[2], Dean Hillman[2] and Rodolfo Llinás[2], Depts. of [2]Physiology & Biophysics and [1]Otolaryngology, NYU Medical Center, 550 First Ave, NY, NY U.S.A. 10016

Unloading the hindlimbs (HL) of rats by tail suspension from P8 to P21 leads to reversible slowing of the air righting reflex (ARR) (Walton et al, IBRO Absts. 1991). In this study rats were suspended from P13 to P31 to find if the critical period for development of the ARR was the same as that for other motor behaviors and if extending the suspension period would lead to persistent deficits. The pups were suspended by their tails at 30°, and each suspended (S) animal had a non-suspended companion (C). The ARR, elicited by dropping the animals from 50cm onto a padded surface, was videotaped at 200fps. Righting of the head (H), forelimbs (FL), and HL were measured. Righting of the HL was slower in S than C pups on P19 (241.8 ± 5.1 msec compared to 212.3 ± 11.9 msec, $p \leq 0.004$). On P31 the mean S and C HL righting times were significantly different at the $p \leq 0.0001$ level (250 ± 3.1 and 221 ± 6.4msec) Righting times for the H and FL were not significantly different in the two groups. The differences in HL righting persisted at P60 indicating the existence of a critical period in the development of the central vestibular system (Dieter's nucleus and the vestibulo-spinal tract) beginning near P14 and ending by P31, a period different than that for swimming, but similar to that for walking These data suggest the existence of a set of "critical periods" organized in a hierarchical manner corresponding to the acquisition of particular motor skills. Preliminary morphological results indicate that the density of neurotransmitters, specifically glycine, may be decreased in Dieter's nucleus in S animals. Supported by NASA.

A KINEMATIC AND ELECTROMYOGRAPHIC STUDY OF LOCOMOTION IN THE KITTEN. L. Girard*, T. Cabana, and T. Drew, Depts. Physiology and Biology, Université de Montréal, Québec, Canada, H3C 3J7.

To better understand the developmental processes of locomotion, a detailed kinematic and electromyographic (EMG) analysis has been undertaken in the kitten. Eight (8) kittens between the ages of 2 and 3 weeks were chronically implanted for the recording of EMG activity from flexor and extensor muscles of the fore- and/or hindlimbs. Video recordings were always made simultaneously with the EMG recordings. Most kittens were capable of steady treadmill locomotion at a slow speed ($0.1\ m.s^{-1}$) at 3 weeks of age, but they had difficulty in supporting their weight, and the hindlimbs were placed in abduction. Analyses of the changes in joint angle, at this age, showed that there was a pronounced yield at the beginning of stance at the ankle and, to a lesser degree, at the elbow. By 6 weeks of age, joint angles resembled those measured in adult cats. Even at 3 weeks of age the EMG recordings resembled closely those seen in the adult cat, with flexor and extensor muscles showing strict alternation, with little evidence of co-contraction. Although at 3 weeks there were some subtle differences in the relative timing of several of the muscles, in particular with respect to the flexor muscles of the hindlimb, these disappeared by 6 weeks. These results suggest that kittens are capable of generating a normal pattern of locomotor activity at an early age, and that many of the differences in the locomotor capacities of young kittens, compared to adults, are due to their inability to fully support their weight. Supported by the FCAR and the FRSQ.

406.4

EARLY CHANGES OF PARVALBUMIN-IMMUNOREACTIVE PRIMARY AFFERENT FIBERS IN THE RAT SPINAL CORD FOLLOWING NEONATAL NERVE INJURY. L.Greensmith, J. Dekkers & R. Navarrete* Dep. Anatomy, Charing Cross & Wesminster Med. Sch. and Univ. College London, U.K.

Neonatal nerve injury leads to rapid changes in motoneuron synaptic excitation from afferents in the injured nerve (Navarrete, J.Physiol. 438:220P,'91). Here we have studied the distribution of primary afferent fibres around injured motoneurons using a monoclonal antibody to parvalbumin (PV) which preferentially labels large diameter primary afferent fibres (Zhang et al, J.Comp.Neurol. 302:715,'90). Motoneurons were pre-labelled by injection of fluorescent tracers into ankle flexor muscles at birth (P0). At P2, the common peroneal (CP) or the sciatic nerve was crushed unilaterally. At P7 and P14 spinal cords were processed for PV immunocytochemistry. In some cases, motoneurons were injected intracellularly prior to processing. At 7 and 14 days after sciatic crush, the density of PV staining in the ventral horn was markedly decreased on the lesioned side. After CP crush, decreased PV staining was largely confined to the area occupied by the CP motoneuron pool. On both sides of the spinal cord some PV immunoreactive fibres were found in close aposition to the soma and dendrites of labelled flexor motoneurons. We are mapping the distribution of PV-immunoreactive fibers on the somatodendritic surface of injured and uninjured motoneurons.

These results show that neonatal nerve injury causes a rapid decrease in PV-immunoreactive primary afferent fibres around lesioned flexor motoneurons. This may, in part, be attributed to death of dorsal root ganglion neurons.

406.5

DOES BUOYANCY MASK THE POTENTIAL FOR COORDINATED MOTILITY *IN OVO*? S.H. Chambers* and N.S. Bradley. School of Physical and Occupational Therapy, McGill Univ., Montreal, QC, Canada H3G 1Y5.

Spontaneous embryonic motility is characterized by orderly recruitment of agonist and antagonist muscles but corresponding coordinated movement may be masked by mechanical variables such as buoyancy (Bradley & Bekoff, *Devel. Psychobiol.* '91). As part of ongoing kinematic studies, we are now examining motility in chick embryos under conditions of reduced buoyancy *in ovo*.

Amniotic fluid (2 ml) was extracted and continuous video recordings (1 hr) were made on embryonic day 9 for each of 5 embryos. Video records of entire movement sequences (40 s) for 2 embryos were computer analyzed at 60 Hz, the data filtered and corrected for movement out of plane, to measure concurrent wing and leg activity and to compare findings to data for 4 control embryos.

Preliminary findings indicate that reduced buoyancy does not alter the primary features of motility. Movement sequences consist of 5-11 cycle periods (peak extension) for both wing and leg in experimental and control embryos. Time between movement episodes (152 s) and movement duration per episode (33 s) is also similar between groups. Further, linear trend analyses for experimental embryos suggest that relative timing of shoulder/elbow (r^2=0.51) excursions and hip/knee/ankle (r^2=0.43) are similar to controls (r^2=0.47;0.44). While reduced buoyancy does not appear to alter primary features of motility, experimental embryos are not posturally displaced during movements or amniotic contractions and their movements appear more orderly as compared to controls. This work was supported by FCAR and NSERC.

406.6

CHRONIC SPINAL GAP TRANSECTION IN CHICK EMBRYOS: A KINEMATIC ANALYSIS. N.S. Bradley* and S.H. Chambers. School of Physical and Occupational Therapy, McGill Univ., Montreal, QC, Canada H3G 1Y5.

EMG (Bradley and Bekoff, *J. Neurobiol.* '92) and observation studies (Oppenheim, *J. Comp. Neurol.* '75) suggest that development of motility is altered in the absence of descending neural inputs in chick embryos. Thus, a kinematic study was undertaken to examine these changes as part of a series of studies underway to explore the interaction of neural and extraneural factors in motor development.

Midthoracic spinal transections were performed on embryonic day 2 (E2) and continuous video recordings (1 hr) made on E9 *in ovo* for each of 9 embryos with histologically verified transections (silver stain, 12μ sections). Video records of entire movement sequences (90 s) for 2 embryos were computer analyzed at 60 Hz, the data filtered and corrected for movement out of plane, to measure concurrent wing and leg activity and to compare findings to data for 4 control embryos.

Linear trend analyses for spinal embryos suggest that relative timing of shoulder/elbow (r^2=0.35) excursions and hip/knee/ankle (r^2=0.45) are similar to controls (r^2=0.47;0.44). However, leg cycle periods (peak extension) are shorter for spinals (1-3s) vs controls (2-7s). Also, movement sequences for spinals contain more cycles (leg 16-25; wing 16-20) vs controls (leg 3-9; wing 4-12). While leg and wing intra- and inter-episode durations are similar between groups, spinal embryos are more active per episode (49 vs 27%) due to disassociation of wing and leg activation. These findings suggest that loss of descending neural control significantly alters temporal features of both intra- and interlimb coordination. This work was supported by FCAR and NSERC.

406.7

THE EFFECT OF VARYING THE SEGMENTAL LEVEL OF SPINAL CORD HEMISECTION ON REACTIVE SYNAPTOGENESIS IN THE PHRENIC NUCLEUS. H.G. Goshgarian* and X.-J. Yu. Dept. of Anatomy, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Previous results have shown that a spinal cord hemisection at C2 causes an increase in the number of multiple synapses (MS) contacting phrenic motoneuron profiles at the C3-C6 levels of the spinal cord. The reactive synaptogenesis may be caused by lesioning the descending bulbospinal respiratory pathways to the phrenic nucleus or by the generalized effects of spinal cord injury (i.e., edema, ischemia, and the interruption of other inputs) in the immediate area of the phrenic nucleus. To evaluate these possibilities, we carried out a hemisection at either C2, C7, or T4 in 3 groups of rats and allowed a survival period of 7 days. The number of terminals forming multiple synapses and the number of synaptic active zones (SAZ) contacting HRP labeled phrenic motoneurons profiles were counted at EM levels in the phrenic nucleus ipsilateral to hemisection. Seven days post hemisection the percent decrease in synaptic active zones was 86% (C2), 90.7% (C7), and 91.6% (T4) as compared to controls (100%). In spite of the decrease in SAZ, the number of multiple synapses increased after cervical hemisections (35.5 ± 5.2 (C2), 34.0 ± 7.4 (C7) as compared to controls (28.3 ± 3.3), but the number of multiple synapses decreased following the T4 lesion (22.8 ± 4.4). These results suggest that the degree of reactive synaptogenesis in the phrenic nucleus is dependent upon the distance of the spinal cord hemisection site from the target neurons.

406.8

THE EFFECT OF A CONDITIONING LESION AT DIFFERENT LEVELS IN THE SPINAL CORD ON THE QUANTITATIVE ASSESSMENT OF CROSSED PHRENIC NERVE ACTIVITY IN RATS. X.-J. Yu* and H.G. Goshgarian. Dept. of Anatomy, Wayne State University Sch. of Med., Detroit, MI 48201.

Previous studies have demonstrated a rather weak expression of the crossed phrenic reflex (CPR) following C2 spinal cord hemisection and an immediate contralateral phrenicotomy in young adult rats (Exp. Neurol. 111:244-250, 1991). There is a significant increase in reflex activity, however, if there is a delay following C2 hemisection before contralateral phrenicotomy. The present study was carried out to determine if conditioning lesions at either the C7 or T4 levels of the spinal cord may also influence the CPR when a postlesion delay of seven days is allowed before the reflex is induced. There were 4 groups of rats: a control group (left C2 hemisection and right phrenicotomy with no interoperative delay), and 3 experimental groups each receiving a C2, C7, or T4 hemisection with a 7 day delay before induction of the reflex . Quantitative assessment of the CPR was accomplished by determining the mean integrated area of phrenic nerve compound action potentials under standardized recording conditions. The results showed that the CPR is significantly increased in the C2 hemisection group (97 ± 30mm^2, P=0.0003), C7 hemisection group (57 ± 14mm^2, P=0.01), and T4 hemisection group (31 ± 8 mm^2, P=0.04) as compared to reflex activity in the control group (12 ± 2 mm^2). These results suggest that a conditioning lesion in the spinal cord causes an increase in CPR activity. Furthermore, the amount of the increase is dependent upon the spinal cord level of the conditioning lesion.

406.9

ULTRASTRUCTURAL CHANGES IN THE RAT PHRENIC NUCLEUS 2 HOURS AFTER SPINAL HEMISECTION. M.A. Sperry*and H.G. Goshgarian. Dept. of Anatomy, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

This study extends our earlier analysis of injury-induced morphological changes in the rat phrenic nucleus (JCN, 284:519,1989) by examining the nucleus at 2 hrs. post-hemisection (p.h.). Phrenic motoneurons were identified at EM levels by horseradish peroxidase labeling. Micrographs were analyzed qualitatively and quantitatively in both normal and spinal hemisected rats. Our results showed a significant increase in the percentage of dendrodendritic appositions from a normal level of 4.73±0.18% to 8.58±0.54% at 2 hrs. p.h. Although there was not a significant increase in the mean percentage of single and multiple synapses at 2 hrs. p.h. (as first seen at 4 hrs. p.h. in our earlier study), a new finding showed a significant increase in the mean lengths of asymmetrical and symmetrical synaptic active zones from normal lengths of 0.372±.009μm and 0.404±.007μm to 0.410±.011μm and 0.513±.032μm respectively in hemisected rats. Lengthening of active zones in the phrenic nucleus could enhance synaptic efficacy by increasing contact area, and thus may be part of the mechanism underlying functional recovery in our spinal cord injury model.

406.10

DECREASED NUMBER OF DOPAMINERGIC SUBSTANTIA NIGRA NEURONS AFTER NEONATAL QUINOLINATE STRIATAL LESION. A. Macaya*, E.M. Janec, D.C. De Vivo, R.E. Burke. Departments of Pediatric Neurology and Neurology, Columbia Univ., New York, NY 10032.

We have reported that a neonatal axon-sparing striatal injury induced by hypoxia-ischemia results in a diminished adult number of substantia nigra (SN) tyrosine hydroxylase (TH)-positive neurons (Soc Neurosci, 1991). This decrease occurs in the absence of direct nigral injury. To examine the specific role of striatal injury, we made selective axon-sparing striatal lesions in the newborn rat with quinolinate (40, 80, 120 and 480 nmols). We then counted the number of SN TH-positive neurons and measured by image analysis the area of SN pars compacta when animals reached adulthood (12-16 weeks). Striatal lesions resulted in a decrease in the number of TH-positive neurons in the ipsilateral SN, and the decrease was correlated with the reduction in striatal area (r=0.76, p<.01). There was no direct injury to the SN. At 50-60% striatal area loss, there was a 25-30% reduction in SN TH-positive neurons. The area of SN pars compacta (SNpc) in animals with 120 (N=5) and 480 (N=10) nmol lesions was reduced 12% and 15%, respectively (p<.01) and this reduction also correlated with the loss of striatal area (r=0.63, p<.01). In animals with the 480 nmol lesion, there was no alteration in individual TH-positive neuron size determined by image analysis (C:173±3; E:167±3 um^2) or neuron packing density (C:713±38; E:717±44 neurons/mm^2) in the SN on the experimental side. We conclude that the adult number of SN dopaminergic neurons depends on developmental support by the striatum. We hypothesize that the smaller striatum provides less trophic support to SNpc, resulting in an accentuated developmental cell death, and a diminished adult number of neurons.

REHABILITATION OF MOTOR DISFUNCTIONS IN PATIENTS WITH INFANTILE CEREBRAL PALSY. M.S.Sinyaya[*2], O.V. Bogdanov [1], D.U.Pinchuc [1], A.M.Shelyakin [1]. Institute of Exper .Med.[2]Pavlov Institute of Physiology of the Acad.Sci.RAN, St.Petersburg,Russia, 199034.

Previous studies demonstrated that one of the main factors of normal formation and development of structure of central nervous system is afferentation from motor apparatus. In recent studies we used the local stimulation of the periferal neuro-muscular system and polarization of the motor cortex. Using this data we developed a method of functional biocontrol (FBC) which aids to increase the rehabilitation of motor disfunctions. Application of this method had high clinical efficiency. We observed the reconstruction of movement, normalization of EEG, EMG, reflex responses of spinal motoneurons and normalization of the habituation process on long-term stimulation of sensory systems. We have shown that this method restors the functional asymmetry in the cortex and spinal cord. Using the method of FBC allows to provide rehabilitation and to decrease the period of treatments 1,5- 2,5 time.

CALBINDIN D-28k DOES NOT SEEM TO BE CO-LOCALIZED WITH TYROSINE HYDROXYLASE IN CULTURES OF DISSOCIATED RAT SUBSTANTIA NIGRA NEURONS. P.-Y. Côté*, E. Roy, F. Tardif, P.J. Bédard and A. Parent, Neurobiology Res. Center, Fac. of Med., Laval Univ., Québec, Canada.

Despite its wide distribution in the central nervous system, the role of calbindin D-28k (CB), a calcium-binding protein, is still poorly understood. Recently, Lavoie et al. (1991) have suggested a possible neuroprotective role for this protein, in the primate model of Parkinson's disease since tyrosine hydroxylase (TH)-positive neurons containing CB seem to be less severely affected by the toxin 1-methyl-4-phenyl-1,2,3,6 tetrahydropyridin (MPTP) than those who do not contain CB. The aim of this study was to investigate the ontological appearance of CB in neurons of rat substantia nigra and the degree of co-localization of CB with TH-positive cells *in vitro*. In sterile conditions, ventral midbrain tissue containing groups A9 and A10 was dissected from rat embryos at 14 days gestation, enzymatically and mechanically dissociated, then plated on 13 mm-culture disks coated with poly-L-ornithine as substrate. These cultures were grown from 1 hour to 10 days before being fixed by cold paraformaldehyde. The culture disks were then immunohistochemically reacted following standard procedures to reveal TH- and CB-immunoreactive profiles.

TH-positive neurons are present in all cell cultures. In cultures grown for 1 hour, round to oval cell bodies without neurites display TH-immunoreactivity. Immunoreactive neurites appear in cultures grown 6 hours. The immunoreactive neurons form clusters and have the characteristic shape of dopaminergic neurons, being mostly polygonal and elongated with two main processes arising at each pole of the cell body. In contrast, the immunoreactivity for CB appears in cultures grown for 6 days. CB-immunoreactive cells are oval, smaller than the TH-positive neurons and also tend to aggregate in the form of clusters. In double-labelling experiments *in vitro*, CB-positive cells were clearly distinct from the TH-positive cells. [Supported by FRSQ and MRC and Canadian Network of Centres of Excellence].

THE EFFECTS OF NEONATAL CORTICAL OR CEREBELLAR LESIONS ON THE NUMBERS OF CORTICOSPINAL (CS) NEURONS IN ADULT RATS. D.L. O'Donoghue*, +D.R. Humphrey and C.R.D. Poff. Dept. Anatomical Sciences, the University of Oklahoma Health Science Center, Oklahoma City, OK 73190; +Lab. of Neurophysiology, Emory University, Atlanta, GA 30322.

Previously, we showed that 40,000 cortical cells have transient spinal axons that are eliminated by the second postnatal week. The present study determined if increased numbers of CS cells could be retained into adulthood when the terminal fields for growing corticofugal axons are modified. Targets available to growing axons were expanded in the spinal cord by the ablation of the opposite cortex. Brain stem targets, such as the basilar pontine nuclei, were removed after cerebellectomy. Aspiration lesions were performed on postnatal day (PND) 2 prior to cortical axons reaching the mid-cervical (C5) spinal cord or the development of corticopontine projections. The left frontal and parietal cortices or the cerebellum were removed from pups anesthetized by hypothermia. Pups matured to PND 30 when they were re-anesthetized with methoxyflurane. Fast Blue (FB) soaked pledgets were inserted into the CS tract at C5 of all animals. Serial section analysis of FB labeled cells indicate that neonatal cortical lesions do not alter the distribution or number labeled CS cells as compared to litter-mate controls. Cerebellectomy, although incomplete in cases, caused qualitative and quantitative increases in the distribution and number of CS cells that could be labeled. These data indicate that enlarged spinal target areas do not result in more CS cells. By contrast, the loss of either the brain stem targets (i.e. basilar pons), or the ascending inputs from the cerebellum, resulted in an increased number of labeled CS neurons. Neonatal hemispherectomy or cerebellectomy result in similar alterations in microstimulation maps of evoked forelimb movements from the cerebral motor cortex. However, the present study indicates the substrate for these alterations in stimulation mapping are different. (Grant support by OU BRSG funds (DOD) & NIH-NS20146 (DRH).

REGENERATING FROG OPTIC NERVE AXONS: DO GLIA GUIDE THE GROWING TIPS? P.M. Orkand* and R.E. Blanco. Inst. of Neurobiology and Dept. of Anatomy, Univ. of Puerto Rico Sch. of Med., San Juan, PR 00901

Unlike those of mammals, injured optic nerves of frogs can regenerate and eventually form functional connections. Since frog retinal ganglion cell (RGC) axons are slow to degenerate after separation from their cell bodies, the regenerating tips may follow the course of the degenerating axons after a crush injury. In preliminary experiments aimed at studying the relationship of glial cells with regenerating axons in the absence of the degenerating ones, we looked at the structure of the proximal tip of the optic nerve 1-12 weeks following transection and deflection of the distal stump.

At early time periods, there is macrophage activity at the cut end, and glial cells are phagocytosing debris of retrograde degeneration in the nerve stump, where regenerating axons begin to appear. After 4 weeks, bundles of putative regenerating fibers lie along phagocytic cells and astrocytes that appear to have migrated into the cut end. Their identification will be confirmed by HRP fillings of RGCs.

LEPTOMENINGEAL CELLS CAN INDUCE CHANGES IN ASTROCYTES IN VITRO. R. Ness and S. David*. Centre for Research in Neuroscience, Montreal General Hospital Research Institute and McGill University, Montreal, Canada.

Leptomeningeal (Lm) cells rapidly migrate into penetrating wounds of the CNS. Astrocytes in the parenchyma of the CNS that interface with these Lm cells transform to form the glia limitans. We have used an in vitro approach to study whether direct interactions with Lm cells induce morphological and functional changes in astrocytes.

DiI labeled astrocytes purified from the neonatal rat cerebral cortex were plated onto monolayers of Lm cells, astrocytes or polylysine coated glass coverslips. 18-20 hours later the cultures were fixed and the size of the DiI labeled astrocytes determined using an IBAS image analysis system. Astrocytes were smaller in size when plated on Lm as compared to astrocytes or polylysine. When neurite outgrowth on these astrocytes was assessed by plating purified cerebellar granule cells, there was a 40% reduction in the ability of the astrocytes plated on Lm to support neurite growth, compared to astrocytes plated on astrocyte monolayers. These results suggest that leptomeningeal cells can induce both morphological and functional changes in astrocytes, and may account for some of the astrocytic changes at the site of CNS lesions. ASTROGLIAL RESPONSE TO REGENERATING CNS AXONS PROMOTED BY PNS TISSUE TRANSPLANTATION IN INJURED RAT SPINAL CORD. M. Hasegawa*, H. Taguchi, N. Uchiyama, T. Yamashima, J. Yamashita. Dept. of Neurosurg., Kanazawa Univ. Sch. of Med., Kanazawa, 920, Japan

We have recently developed a useful model to promote axonal regeneration in the unilaterally injured rat spinal cord (Advance in Neurotrauma Research 3: 41-44, 1991). Central neurons in the injured rat (female Wistar rat, 90-190 g body weight) spinal cord showed regrowth and remyelination in the autografted PNS bridge of peroneal nerve. HRP study demonstrated that the regenerated and remyelinated axons originated from the neurites of the spinal cord. In this paper, we examined relationship between astroglia and regenerated nerve fibers in this model. The examination of the graft-spinal cord interface revealed that GFAP-positive zone did not inhibit the regrowth of CNS axon into the graft. The A2B5 antibody-positive cells were less conspicuous at the graft-inserted site of the spinal cord, whereas glial processes at the anterolateral column located far from the graft-inserted site were clearly stained with the A2B5 antibody. Electron microscopically, in the graft close to the graft-inserted site, many processes of Schwann cells as well as some of astrocytic processes were attached to the surface of basal lamina scaffolds. Regenerating axons were always engulfed by the processes of Schwann cells. There was neither invasion of astrocytic process into the periaxonal space between myelin and axolemma, nor phagocytic activity of PNS myelin by astrocytes during the period of observation. In the spinal cord, regenerated nerve fibers with PNS type myelin could be seen especially along the perivascular space. Astrocytic processes were closely apposed to the regenerated axons with or without glial basal lamina. These results indicate that astrocytic reaction does not impede the regeneration, rather astrocytes, especially type-1, might support the regeneration of CNS nerve fibers in the milieu of this model.

THE FUNCTIONAL PROPERTIES OF PURIFIED POPULATIONS OF CULTURED HUMAN SCHWANN CELLS STUDIED IN VIVO. A.D.O. Levi[1], V. Guenard[1], P. Aebischer[2], R.P. Bunge[1]*. [1]The Miami Project and Dept. of Neurological Surgery, Univ. of Miami School of Medicine, Miami, FL 33136 and [2]Brown Univ., Artificial Organ Laboratory, Providence, RI 02912.

Methods are now available to purify populations of Schwann cells (SCs) derived from adult human nerve (Morrissey et al, J. Neurosci. 11:2433-2442, 1991). To determine the functional capacity of human SCs isolated in culture, these cells were introduced into an immunodeficient rat using a peripheral nerve injury model. Permselective guidance channels were seeded with 30:70 solution of Matrigel[R]: DMEM (M/D) with or without human SCs at a density of 80 million cells/ml. Channels were implanted within an 8 mm gap of the transected sciatic nerve of nude female rats for a period of 4 weeks. The number of myelinated axons and cable surface area was uniformly greater in channels seeded with human SCs when compared to channels containing M/D only. Survival of the transplanted human Schwann cells was established by dissociating explants taken from the regenerated cable after 5 days in culture and immune staining for primate and rat specific nerve growth factor receptor and S100. These results also indicated that the regenerated cable contained a mixture of human and rat (host) SCs. Myelination of regenerating rat axons appeared to be occurring by both donor and host SCs. We are using immune staining for HNK-1, an antigen found in human but not rat myelin, to establish the presence of human myelin segments within the regenerating cable. These studies indicate that purified populations of cultured human SCs survive and enhance axonal regeneration when transplanted into the injured peripheral nervous system of the immune deficient rat. INTERACTION OF CENTRAL AXONS WITH SCHWANN CELLS OF PERIPHERAL NERVOUS TISSUE. W.K.D. CHAU, P. DOCKERY, K.-F. SO* and K.C. LAU. Dept. of Anatomy, University of Hong Kong, 5 Sassoon Rd., Pokfulam, Hong Kong.

Optic nerve of SD rat aged 6 weeks was cut intra-orbitally and replaced by a sciatic nerve graft. After 9 months, the graft containing the regenerating optic axons was processed for electron microscopic examination. Various morphometric measurements were made on the myelinated fibers of the regenerating (n=6), aged-matched normal optic (n=6) and sciatic (n=6) nerves.

The relationship between myelin and axon was examined by plotting the myelin area against the axon area (based on perimeter). It was found that the mean slope of linear regression line for the regenerating group (0.54± 0.043) showed a closer resemblance to that of the optic (0.64±0.024) rather than to the sciatic group (1.29± 0.081). The mean g-ratio (axon diameter/fiber diameter), which indicates the relative sheath thickness, was different among the three groups. However, there is a tendency for the regenerating group to overlap with the optic group (eg. 16%, 64% and 98% of sciatic, regenerating and optic fibers respectively have a g-ratio above 0.68).

Thus, central axons regenerating in peripheral nerve environment seem to be able to alter the myelin production of the Schwann cells in such a way that it supports the idea of axon-dependence in the process of myelination.

407.6

MAPPING THE ROLE OF TRANSPLANTED ADULT RAT SCHWANN CELLS IN PROMOTING VENTRAL ROOT REGENERATION M.L. McCormack[1]*, T.K. Morrissey[2], D.C. Xiong[1], R.P. Bunge[2], and P. Aebischer[1] Brown University, Providence, RI[1], and The Miami Project, Univ. of Miami School of Medicine, Miami, FL[2]

Semipermeable guidance channels do not support the regeneration of ventral root axons across a large gap in adult rats. The guidance channel's luminal environment was modified using inbred adult rat-derived primary Schwann cells (SC) seeded in a laminin-containing gel (LCG) to provide an axonal outgrowth-promoting substrate. Adult Fisher rat-derived SCs were cultured and used at passages 0 to 5 post-dissociation. Culture purity ranged from 94 - 46% SCs. Semipermeable channels were seeded with SCs (5-6 x 10^7 cells/ml) in LCG, or the LCG alone, and tested in a L5V root 8 mm gap injury model in adult male Fisher rats. Twenty-one rats received SC grafts and 8 rats received LCG grafts. Regeneration was assessed at 4 weeks post-implantation by counting the total number of axons on cross sections at the channel's midpoint. Regenerated cables were found in 19 out of 21 of the SC graft recipients (mean total axons = 2630 ± 270), while only 2 of the LCG grafts resulted in cables containing a small number of axons (mean = 302 ± 225). Passage number and SC purity did not significantly affect the total number of axons in the regenerated cables. In order to delineate the role that the grafted SCs play in the regeneration process, a recombinant retrovirus encoding human placental alkaline phosphatase (AP) was used to generate a population of AP-expressing primary adult inbred rat SC cultures which were then tested in the L5 ventral root model. Histochemical analysis of the regenerated cables at 4 weeks revealed the presence of AP-positive cells and demonstrated the ability of transplanted SCs to myelinate and ensheath host axons.

SUPPRESSION OF MYELINATION EXTENDS THE PERMISSIVE PERIOD FOR FUNCTIONAL REPAIR FOLLOWING INJURY OF THE EMBRYONIC CHICK SPINAL CORD. H.S. Keirstead, S.J. Hasan, G.D. Muir and J.D. Steeves*. Depts. of Zoology & Anatomy, UBC, Vancouver, B.C., V6T 1Z4.

Previous studies have demonstrated that a transected embryonic chick spinal cord loses it's capacity for anatomical repair and functional recovery on embryonic day (E) 13. The onset of spinal cord myelination is coincident with this transition from permissive to restrictive repair periods. To assess a possible inhibitory role of myelin in regeneration, we have delayed the onset of myelination (dysmyelination). In such an unmyelinated embryonic cord, the subsequent assessment of spinal cord repair after a restrictive period transection (eg. E15) would serve as a test of whether myelin inhibits anatomical and functional repair. On E9-E12, direct injection into the thoracic spinal cord of a galactocerebroside monoclonal antibody with a source of serum complement resulted in dysmyelination until E17, as determined by myelin basic protein immunocytochemistry. A subsequent thoracic cord transection as late as E15 (i.e. during the normal restrictive period for repair) resulted in neuroanatomical repair and functional recovery (normally myelinated embryos showed no anatomical repair or functional recovery after an E15 transection). Retrograde labelling of brainstem regions, after lumbar injection of a fluorescent tracer, indicated that anatomical repair of brainstem-spinal projections in dysmyelinated, transected chicks was indistinguishable from unoperated control animals. Behavioral and physiological observations from dysmyelinated chicks were also indistinguishable from unoperated control hatchlings. This indicates that that the myelination process is inhibitory to the repair of transected spinal cord in embryonic chick. (supported by Canadian NCE for Neural Regeneration and Functional Recovery)

407.8

PROTEINS ASSOCIATED WITH SPINAL CORD INJURY, MYELINATION, AND THE TRANSITION FROM PERMISSIVE TO RESTRICTIVE PERIODS FOR SPINAL CORD REPAIR. Douglas W. Ethell* and John D. Steeves. Depts. of Zoology & Anatomy, UBC, Vancouver, B.C., V6T 1Z4.

Previous studies in our lab have established that embryonic chick loses its capacity for substantial spinal cord regeneration around embryonic day (E) 13. Correlating with this transition, we have examined changes in protein expression using high resolution two dimensional gel electrophoresis (2D). We have identified 2 sets of proteins; early neural proteins (ENPs) which are continuously present during spinal cord development between E7-E12 and then decrease to relatively low levels, and late neural proteins (LNPs) which are only expressed at high levels after E13. Some of these ENPs and LNPs may play direct or indirect roles in establishing permissive or non-permissive environments for the outgrowth of axotomized fibers. Spinal cord myelin also appears at E13 and has been suggested to inhibit axonal regeneration. We have also examined changes in the levels of these ENPs and LNPs after: 1) spinal cord injury (transection) and 2) delaying the onset of myelination (dysmyelination).

Embryos were subjected to complete spinal cord transections during the permissive (E10) and restrictive (E15) periods for axonal repair. Expression profiles of the ENPs and LNPs were examined for recovery periods, in increments of 2 days, and compared with the unperturbed developmental expression profiles. Two of the ENPs appear to be up-regulated in response to spinal cord injury. In dysmyelinated animals, the higher expression of some LNPs was delayed until well after E13, suggesting that they are myelin associated. These preliminary studies have used high resolution silver staining to visualize the proteins. Currently, we are attempting to confirm and expand on these results with isotopic labelling techniques. 407.9

RESPONSE OF MACROPHAGES IN DORSAL ROOT GANGLION TO PERIPHERAL NERVE INJURY. X. Lu and P.M. Richardson*. Div. of Neurosurgery, Montreal Gen. Hosp. & McGill University, Canada H3G 1A4 The signals following peripheral nerve injury that induce a regenerative programme in the nerve cell bodies may involve cells in the vicinity of nerve cell bodies. Previously, the recruitment of inflammatory cells to a dorsal root ganglion was shown to stimulate axonal regeneration in the corresponding dorsal root. More recently, immunohistochemistry with monoclonal antibodies to a cytoplasmic macrophage marker (ED-1), the Ia antigen (OX-6), and the complement 3 receptor (OX-42) were performed on cryostat sections of fifth lumbar dorsal root ganglia removed 0-16 days after sciatic nerve transection. With all three antibodies, immunopositive cells were present in normal ganglia, the total number being several thousand per ganglion. Immunopositive cells had increased in number by 4 days after injury and were 3-8 times more numerous than normal after 16 days. The higher counts could result from recruitment of macrophages and/or increased immunoreactivity of resident macrophages. The modest inflammatory response surrounding sensory nerve cell bodies is a potential stimulus to regeneration of their axons.

407.10

RESPONSES OF RETINAL GANGLION CELLS TO AXOTOMY: DIFFERENCES WITH AND SIMILARITIES TO PERIPHERAL NEURONS. M. R. Wells* and U. Vaidya. Nerve Regeneration Research Laboratory, Dept. of Veterans Affairs Med. Center, Northport, N.Y. 11768 and Dept. of Neurology, SUNY, Stony Brook, N.Y. 11794.

The reaction of retinal ganglion cells to intraorbital crush lesions of the optic nerve was investigated over the first two weeks after injury using the binding of [^{3}H]Actinomycin D (Act. D) to nuclei of neurons in tissue sections. Changes in nuclear binding of Act. D reflect structural changes in chromatin associated with transcriptional activity. Adult, male,Wistar rats received intraorbital crushes of the optic nerve and were utilized at 0,1,2,3,4,5,7,8,9, 11, and 14 days after injury. Binding of nuclei for Act. D decreased sharply at one day after injury followed by a transient increase to above normal levels at days 2-3. The remaining pattern of response was characterized by below normal binding 4-7, 9 and 14 days, separated by increases to normal levels at 8 and 11 days after injury. Alterations of Act.D binding were also observed in the contralateral eye. Below normal binding was observed at 3-4 and 9 days and a primary increase in binding at 7 days after the operation. Except for magnitude, the basic pattern of Act. D binding to surviving axotomized retinal ganglion cells is similar to dorsal root ganglion neurons after axotomy. Binding ratios of retinal ganglion cells were characterized by statistically normal or below normal binding as contrasted to the large increases in binding of dorsal root ganglion neurons after axotomy. The sharp decrease in binding at 1 day after injury was also unique to retinal ganglion cells. The results suggest that the basic pattern of response of surviving central and peripheral neurons to axon injury is similar, but the magnitude of the response is much less in central neurons.

407.11

SEAL FORMATION IN TWO TRANSECTED GIANT AXONS SUGGESTS TWO MODELS OF SEALING. Todd L. Krause, Harvey M. Fishman,*Martis L. Ballinger, and George D. Bittner. University of Texas at Austin, 78712 and University of Texas Medical Branch at Galveston, 77555.

Severed axons could seal according to the following two models: **MODEL 1.** Constriction at a cut end reduces the opening and increases the resistance of the conducting path between axoplasm and external solution; sealing is completed if axolemmal fusion occurs. **MODEL 2.** Injury-induced vesicles migrate to the cut end, occlude it, and subsequently fuse with each other and the axolemma to form a complete seal. Previous studies have not distinguished between these two models; in fact, we now show they have not determined whether complete sealing indeed occurs. To distinguish between these two models and to determine whether complete sealing has occurred, we have used several electrophysiological measures (membrane potential, complex impedance, and injury current) together with video-enhanced, light, and electron microscopic observations to assess sealing in giant (80-500 μm diameter) axons of squid (Lolgio pealei and Sepioteuthis lessoniana) and earthworm (Lumbricus terrestris). We found recovery of resting potential and input resistance (R_{in}) in both axons. However, injury current (I_i) persisted at a substantial level relative to precut level (background) in squid giant axon (GA) for 2.5 hr following transection whereas I_i in earthworm medial giant axon (MA) decayed to background within 30 min. Further, the decay of I_i to background in MGAs correlated with the time course of R_{in} recovery. Morphological observations of the cut end, together with the electrical data, indicate that MGAs seal completely by vesicle plugging of a slightly constricted end whereas squid GAs constrict at the cut end to produce an increase in the resistance but the end remains open. Support: ONR (N00014-90-J-113), TX ATP, and NSF (ECS-891-5178).

SIGNALS THAT INDUCE SPROUTING IN THE CENTRAL NERVOUS SYSTEM: SPROUTING IS DELAYED IN A MUTANT MOUSE EXHIBITING DELAYED WALLERIAN DEGENERATION. O. Steward*. Departments of Neuroscience and Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

This study evaluates whether sprouting in the CNS is initiated by signals related to the degeneration of presynaptic axons. We evaluate the time course of sprouting of cholinergic septohippocampal fibers after unilateral entorhinal cortex lesions in a substrain of mice carrying a mutation which leads to a substantial delay in the onset of Wallerian degeneration. This is the "Ola" mutation, which has been characterized in detail by Perry and colleagues (Perry, V.H., Lunn, E.R., Brown, M.C., Cahusac, S., and Gordon, S. Eur. J. Neurosci., 2: 408-413, 1990). It is thought that axonal degeneration is delayed because the mutation affects a signaling mechanism for macrophage activation.

We assessed the time course of Wallerian degeneration after entorhinal cortex lesions using the Fink-Heimer technique. Cholinergic sprouting was evaluated using a histochemical technique for acetyl-cholinesterase (AChE).

In normal control mice, both the time course of Wallerian degeneration, and the time course of cholinergic sprouting after EC lesions occur with a time course that is comparable to that described in rats. Argyrophilic degeneration debris was prominent by 4 days postlesion, and increases in AChE staining were well-developed by 8-10 days. In mice carrying the Ola mutation, however, argyrophilic degeneration debris was not detectable at 4 or 6 days postlesion, began to appear in the dentate gyrus by 8 days postlesion, and did not become prominent until 12 days. Increases in AChE staining in the molecular layer of the dentate gyrus were not detectable even at 12 days postlesion, but developed gradually after 14 days. These results indicate that the signals which initiate at least one form of CNS sprouting are related to the degeneration of presynaptic axons. Supported by NIH grant NS12333.

PROTEINS FROM SCIATIC NERVE CONTAIN A SIGNAL PEPTIDE THAT MEDIATES TRANSPORT THROUGH THE AXON TO THE CELL BODY AND INTO THE NUCLEUS. C. C. Huang, R. Schmied, R. T. Ambron, and C. Noback*. Otolaryngology, Anatomy and Cell Biology, Columbia University, New York, NY 10032.

Axons undergo structural changes in response to environmental clues or injury. While these changes require transcription, it is not clear how the needs of the periphery are communicated, often over long distances, to the nucleus. Using exogenous protein constructs, we discovered a pathway in Aplysia neurons that conveys proteins retrogradely from the axon periphery to the nucleus (J Neurosci, in press.) Access to the transport system depends upon a signal peptide (sp), H_2N-Pro-Lys-Lys-Lys-Arg-Lys-COOH. To obtain a probe that might be used to identify endogenous axonal molecules that use this pathway, we coupled sp to keyhole limpet hemocyanin and injected the conjugate into rabbits. A polyclonal antibody fraction was obtained which was then affinity purified using immobilized sp. When proteins extracted from sciatic nerves were separated by SDS-PAGE; a soluble 35 Kd peptide (sp35) was the major constituent detected by the antibody. Interestingly, when these soluble proteins were subjected to gel filtration on Sephacryl S-200, the major immunoreactive fractions, detected by dot-blot assay, were found in a high molecular weight (105 Kd) fraction. However, Western blots showed that this fraction contains sp35. To look for transport, the 105 Kd proteins were coupled to rhodamine (TRITC) and microinjected into axons of Aplysia neurons in vitro. 24 h later, TRITC-protein was found in the nucleus. In contrast, sp35 excised from a gel after SDS-PAGE was not transported after injection. These results indicate that endogenous sp-containing proteins exist in mammalian nerve, and suggest that these proteins must be in their native form, or complexed to a carrier molecule, in order to be transported.

THE APPEARANCE OF PRE-MITOTIC MICROGLIA ASSOCIATED WITH AXOTOMIZED MOTOR NEURON PERIKARYA IS INDEPENDENT OF AXON STUMP LENGTH

T O Crawford M.D.*, and J W Griffin M.D. Johns Hopkins University School of Medicine, Baltimore, USA 21205.

Following axonal injury tritiated thymidine labeled cells, identified as microglia, appear in the region of the perikaryon. These cells are implicated in the separation of synapses from the motor neuron that is seen following axotomy. We report that the timing and relative peak abundance of these labeled cells does not vary with location of the axonal lesion.

At age 3 weeks both tibialis anterior muscles of Sprague-Dawley rats were injected with 1% fast blue. At age 8 weeks the left innervating nerve was severed, either by ventral root section of L4 and L5 (13 mm from the spinal cord) or the peroneal nerve at the level of the fibular head. One, 2 and 4 days later, 4 hours following intraperitoneal injection of 5 mCi/gm tritiated thymidine, the animal was perfused. The number of labeled cells touching, or within one perikaryal diameter to, fluoresently labeled motor neurons were counted on each side. At day 2 neuron-associated labeled cells were abundant (0.99 / neuron for proximal axotomy, 1.17 / neuron for distal axotomy). At 1 and 4 days labeled cells were less profuse, although variable for the proximal axotomy group. Labeled cells on the control side were rare at all time points. These findings are consistent with the hypothesis that neuron-associated microglia are regulated by factors emanating from the terminal axon or target muscle.

A SOLUTION TO THE CRIMPING PROBLEM IN THE CYLINDRICAL MODELLING OF BIOLOGICAL STRUCTURES:G. Sun, Z. Xu and P. Ramm*. Imaging Research Inc., Brock University, St. Catharines, Ontario, Canada L2S 3A1

Many biological structures, such as blood vessels and neuronal processes may be modelled in two or three dimensions as cylinders. From the computer model, morphometric and volumetric measurements may be derived. A typical approach to cylindrical modelling consists of two steps: 1) define the skeleton of the cylinder, which has a main axis (a 3D polyline) and a planar cross-section at each joint of the polyline; 2) define the surface of the cylinder by connecting each pair of adjacent cross-sections. Using this approach, the model is limited to the reconstruction of structures which yield a smooth main axis. The major difficulty arises from the so-called "crimping problem". That is, adjacent cross sections intersect each other at high curvature segments of the main axis. Our algorithm solves the crimping problem, and faithfully reconstructs the original cylindrical structure. The algorithm includes four major steps: 1) find the main axis and cross sections; 2) find all the crimping sections; 3) replace the crimping sections by interpolation; 4) define the cylindrical surface by connecting adjacent surfaces. The resulting cylindrical model provides continuous and true-to-life sweeping of cross sections along the main axis. It can be easily extended to 2D cylindrical modelling, in which it is very useful for the analysis of density distributions across structures containing abrupt changes in axis orientation. For example, accurate measurements of reaction product density in a tortuous neuronal process may be obtained. These density measurements may be taken from regions as small as one pixel in width, and integrated across any height.

A COMPARISON OF STEREOLOGICAL ESTIMATES OF MOTONEURON SOMAL VOLUME VERSUS DIRECT 3-D MEASUREMENTS USING CONFOCAL MICROSCOPY. Y.S. Prakash* and G.C. Sieck. Mayo Clinic and Foundation, Rochester, MN 55905.

Previous studies on motoneuronal morphometry have assumed geometry and orientation of neuronal soma in estimating somal volumes, based on two-dimensional (2D) measurements. The "optical sectioning" property of the confocal microscope allows direct 3D measurements. We retrogradely labelled phrenic and lumbar (medial gastrocnemius) motoneuron pools in adult and 21-day old rats, using fluorescent dyes. Motoneurons in the two pools are known to differ in shape and size. Series of digital images ("optical slices") of labelled motoneurons were obtained using a Bio-Rad Laser Confocal microscope. Minimal overlap between adjacent optical slices was ensured. From these images, direct measurements of somal axis dimensions in three orthogonal directions were taken using ANALYZE®. Somal volumes were directly measured using a volume rendering program, with minimal image manipulation. These volumes were compared to estimates based on a variety of geometrical shapes used in previous studies. The 2D paramaters were assumed to be those measured in the plane of section, in keeping with previous techniques. In the adult phrenic pool we found significant errors (upto 300% overestimation) in estimated volume assuming prolate spheroidal shape in cases where the minor axis was not equal to the third dimension. These errors were less apparent in the adult lumbar pool. Significant errors also arose in cases where the orientation of soma differed from the general population within the pool. In the 21-day phrenic pool, there were upto 100% underestimation of somal volume, while in the 21-day lumbar pool errors were dependent on individual somal features. We conclude that, using confocal microscopy, it is possible to obtain true volumes of neuronal soma without the assumption of geometrical shape and orientation. Supported by NIH grants HL34817 and HL37680.

COMBINATION OF INTRACELLULAR STAINING OF RETROGRADELY LABELED NEURONS AND ANTEROGRADE FLUORESCENT TRACING: USE OF THE CONFOCAL LASER SCANNING MICROSCOPE. C-J Shi and M.D. Cassell*. Dept. of Anatomy, Univ. of Iowa, Med. College, Iowa, IA 52242.

This report describes a combined retrograde tracing, intracellular injection and anterograde fluorescence labeling method using the application of confocal laser scanning microscopy to simultaneously view the morphology of identified projection neurons and the distribution of anterogradely labeled fibers and terminals to characterize the anatomical relationship between these two elements. With this approach, the retrograde tracer Fast Blue was injected into the bed nucleus of stria terminalis (BNST) and the anterograde tracer tetramethylrhodamine-conjugated dextran was injected into the insular cortex in adult rats. After one week survival time, the brains were fixed and sectioned on a vibratome. Individual BNST projecting neurons identified in the amygdaloid complex on 120 um thick sections were intracellularly injected with Lucifer Yellow under visual control and analysed with confocal laser scanning microscopy. The results demonstrate that images from very thin optical sections can clearly show potential synaptic contacts between anterograde labeling and intracellularly labeled projecting neurons. Stacked images from optical sections show, in very great detail, the morphology of projection neurons in three-dimensions. In comparison with other combinations, the present method provides a more simple and efficient means to trace three successive components of a putative neuron chain.

THREE-DIMENSIONAL TERRITORIAL COVERAGE BY GENICULATE NEURONS USING COMPUTERIZED LIGHT AND CONFOCAL MICROSCOPY. J. Gemmill*, L-A. Coleman and M.J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294 USA.

The relationship of growth and territorial coverage of three-dimensional (3D) space by dendrites during development can be quantified using computerized microscopy. We estimated the 3D coverage of Area 18 projecting dorsal lateral geniculate nucleus (LGNd) neurons and compared coverage during postnatal development. LGNd volume was calculated using camera lucida drawings of wet mounted serial sections of the LGNd and then integrating over section thickness using Simpson's rule. Green and red fluorescently labeled latex microspheres were retrogradely transported to the LGNd neuronal somata from cortical injection sites. Cell densities were estimated by the disector method applied to optical sections from image volumes captured on a confocal microscope and compared with total densities obtained from tissue counterstained with Acridine Orange and analyzed in the same manner. Complete dendritic arbors of neurons at each age were analyzed directly from slides using a 3D computer reconstruction system; complete branches also were measured for diameter and spine location. The volume within the LGNd occupied by an individual neuron's dendritic arborization was estimated by finding the spherical volume occupied by the dendrites, computing 3D branch angles for all branches, and using a tortuousity measure for individual dendritic segments. Total LGNd volume, density of cells, and individual cell volume metrics can be used together to describe coverage and overlap within an anatomically defined region such as the LGNd.

THREE DIMENSIONAL IMAGING OF FACIAL NUCLEUS MOTOR NEURONS USING LASER SCANNING CONFOCAL MICROSCOPY. B. F. Lofthus*[1], N. H. Donegan[1] and T. H. Brown[1,2]. Depts. of Psychol.[1] and Cell. & Molec. Physiol.[2], Yale Univ., New Haven, CT 06520.

The rat eye blink reflex is useful for neurophysiological studies of adaptive gain control and Pavlovian conditioning. We have been interested in methods that might help elucidate the neurobiology of use-dependent plasticity in this reflex. For circuit tracing, one promising approach involves laser scanning confocal microscopy (LSCM) applied to thick brain slices.

The lid closure during a reflex blink is generated by a passive downward force plus active contraction of the orbicularis occuli (oo), whose motor neurons are located in the facial motor nucleus (FMN). The oo receives innervation from 2 branches of the facial nerve, the upper zygomatic and the temporal. *In vivo* injections of tetramethyl rhodamine or fluorescein into these 2 branches resulted in retrograde labeling of motor neurons in the FMN. After fixation, the FMN was transversely sliced (400 μm thick sections), mounted and coverslipped. Optical sections were taken through the FMN (at 0.5 - 1.0 μm intervals) using a Bio-Rad MRC 600 LSCM system and a long-working distance (500 μm) 63X objective (NA = 1.25).

The amount of detail discerned with LSCM was significantly better than with conventional microscopy. Optical sectioning enabled convenient 3D imaging, which is important for cell classification, morphometric analysis, and dual labeling of pre- and postsynaptic structures. We are currently exploring other dyes that may be useful with LSCM in elucidating the reflex circuitry and its sites of modulation. In particular, we are examining projections onto this circuitry from the amygdala, which has been implicated in conditioned potentiation of the eye blink reflex. *Supported by an NIH grant (THB) and an NSF fellowship (BFL).*

THREE-DIMENSIONAL RECONSTRUCTION OF NEURONS USING CONFOCAL MICROSCOPY AND VOLUME RENDERING. D. Birt*, C. Cepeda, S.H. Chandler(1), N.A. Buchwald and M.S. Levine. Mental Retardation Research Center and Department of Physiological Science(1), UCLA, Los Angeles, CA 90024.

Our laboratory has been using confocal microscopy to visualize neurons in three-dimensions. Intracellular recordings and dye injection (Lucifer Yellow (LY) or biocytin) were performed in neurons obtained from brain slices of neostriatum or neocortex of rats or trigeminal motor nucleus of guinea pigs. LY-filled cells were examined in whole mounts while biocytin-filled cells were examined in 60-80 μm thick sections processed by standard immunofluorescent techniques. Neurons were first optically sectioned with a laser scanning confocal microscope (Biorad MRC600). Sections were obtained at intervals of 1-5 μm (z-axis) with the confocal aperture set at its minimal diameter. Depending upon the numerical aperture and the magnification of the objective, optical section thickness varied from 1-4 μm. Three-dimensional visualization was obtained as a series of optical sections, stereo pairs or by volume rendering. Volume rendering to permit three-dimensional imaging was performed with commercially available software (VoxBlast, VayTek, Inc.) which uses alpha blending to create a three-dimensional projection. The software permits rotation around any axis, changes in the source of illumination and changes in the transparency of the image. Rotation around different axes provides a clearer picture of the three-dimensional characteristics of the neuron. Changes in source of illumination and transparency allow shadowing and surface landmarks to be visualized. Three-dimensional reconstructions permit perspectives to be reconstructed that were difficult or impossible to view in the serial optical sections or stereo pairs.

***IN-VIVO* CONFOCAL MICROSCOPY OF THE RABBIT OPTIC NERVE HEAD**

Hilary W. Thompson*, Sek Jin Chew, Roger W Beuerman LSU Eye Center, New Orleans, LA 70112

The tandem scanning confocal microscope (TSM) allows repeated, noninvasive examination of living tissue, in real-time, with the advantage of serial optical sections, superior contrast, lateral and vertical resolution. We used a reconfigured TSM to examine the optic disc in the rabbit in two modes: as a scanning ophthalmoscope and as an ex-vivo imaging technique to investigate the human lamina cribrosa. Using a Noran TSM with a 35mm camera objective lens, and a Goldmann 3-mirror fundus contact lens we examined the retina, and optic disc of the rabbit. At this low magnification of 30x, we were able to ascertain the depth of the optic cup and to perform densitometry of the nerve fiber layer at the neuroretinal rim. Following transection of the optic nerve, we monitored the development of optic atrophy by repeated reflectometry. The fibrous structure and astrocyte content of the lamina cribrosa has been described in histological studies. However, the relationship of its fibers to the axons exiting the optic nerve have not been established. Additionally, these studies did not measure the lamina cribrosa pores in absolute units, nor examine serial levels of the lamina. Furthermore, fixation, sectioning, and freeze fracture induce shrinkage artefacts in this delicate web-like tissue. We used the TSM with a 25x water immersion lens to map the 3-dimensional architecture of the fibrous trabeculae in normal, unfixed and unstained eye bank eyes. We performed morphometry of the anterior 400μm of the lamina cribrosa, which showed a wide variation in the size (30-150μm in diameter, 6000-10,000μm^2 in area), configuration and complex interconnections of canals in the lamina. 3-dimensional volume rendering of the serial optical sections was also performed.

***IN-VIVO* MONITORING OF CORNEAL NERVE INJURY BY TANDEM SCANNING CONFOCAL MICROSCOPY**

Lauren W. Underwood*, Christopher Kelly, Sek Jin Chew, Roger W. Beuerman LSU Eye Center, New Orleans, LA 70112

With its superior contrast, lateral and vertical resolution, the tandem scanning confocal microscope (TSM) allows repeated, noninvasive examination of the cornea in vivo. We used a reconfigured TSM to examine the nerves in the rabbit, following two modes of injury (mechanical and laser damage) and in human contact lens wearers. In NZW rabbits, the positions of large myelinated limbal nerves were identified and marked. They were then transected by penetrating circular (4mm) perilimbal corneal incisions. Using a reconfigured TSM and a 25x water immersion objective lens, we then examined the eyes at regular intervals. Within 24 hours after wounding, ruptured axon pieces could be observed. Reinnervation of the denervated cornea was observed by regenerating nerves that penetrated the limbal scar tissue. Long, large caliber, dense neurites that coursed perpendicularly to the wound margins. The recovery of corneal sensation in the affected quadrant was also monitored by aesthesiometry. The regenerating neurites. Secondary degeneration was observed after one week. Computerized morphometric evaluation of the corneal neural density was also performed after image capture using a CCD camera. Excimer laser photorefractive keratectomy was performed, with the ablation of the anterior 75μm of corneal stroma. The regeneration of epithelial nerve endings were observed with the TSM. Histology, using the gold chloride impregnation technique was used to confirm these observations.The epithelial nerves of human contact lens wearers were compared with those of non-contact lens wearers.

CONFOCAL FLUORESCENCE IMAGING OF $[Ca^{2+}]_i$-TRANSIENTS IN ACUTE RAT-BRAIN SLICES USING FLUO-3-AM AND A SMALL VOLUME SUBMERGED CHAMBER SYSTEM.

A.Them, A.Villringer, U.R.Büttner*, U.Dirnagl. Dept. of Neurology, University of Munich, 8000 Munich 70, F.R.G.

In order to establish a simple system for the imaging of intracellular-ion concentrations in brain slices using fluorescent dyes we developed a small volume slice chamber. The chamber volume is < 0.5 ml, affording rapid (< 5 s) exchange of the bathing medium and small amounts of dyes. Imaging was performed with a confocal laser scanning microscope (Bio-Rad MRC 600; KrAr-Laser), equipped with a Zeiss x40, NA 0.75 water immersion objective corrected for a cover slip. Wistar rats (age 2-4 days and 2-4 weeks) were anesthetized with halothane and decapitated. The brain was removed in cold artificial cerebrospinal fluid (ACSF) and sliced to 500 μm using a vibratome. Slices were incubated with FLUO-3-AM (1, 10, or 50 μM in ACSF; DMSO/Pluronic (3:1) < 0.1%; Molecular Probes) for 15, 30, 60 or 180 min. $[Ca^{2+}]_i$-changes were stimulated by switching the bathing medium to L-GLU (500μM), high K^+ (50mM), or low pO_2 (< 170mmHg) containing ACSF. Cells were resolved up to a depth of 50 μm. Signal intensity increased with loading time and dye concentration. Density of loaded cell-bodies was highest in the neonatal slices, where spontaneous $[Ca^{2+}]_i$-transients were imaged. In the cortex and hippocampus, the density of loaded cells appeared similar. Only neonatal slices responded to stimulation and best results were obtained with minimal dye concentrations and loading time (1μM, 15min) resulting in a low basal fluorescence level and strong increase after stimulus onset. We conclude that Ca^{2+}-imaging in acute brain slices is feasible. This system may allow the investigation of intracellular-ion concentration dynamics under various experimental conditions.

THREE-DIMENSIONAL ANALYSES OF GRANULE NEURONS IN THE RAT DENTATE GYRUS LABELED WITH FLUORESCENT DYES.

M. O'Boyle[1], R. Gonzales[1], T.H. Brown*[2] and B. Claiborne[1]. [1]Div. of Life Sciences, Univ. of Texas, San Antonio, TX 78249, and [2]Depts. of Psychology and Cellular and Molecular Physiology, Yale Univ., New Haven, CT 06520.

Efforts to analyze the 3-D structure of fluorescently-labeled neurons have been hindered by the lifespan of the fluorochrome. Dense labels, which are more difficult to use, have been required. Here we report a technique that allows neurons labeled with DiI or Lucifer Yellow (LY) to be quantified using a computer-microscope system equipped with epi-fluorescence optics.

Granule neurons in 400-um-thick slices of the rat dentate gyrus were labeled either by retrograde transport of DiI in fixed tissue (Claiborne et al., Neurosci. Abstr. 17: 35) or by intracellular injection of LY in vitro or in fixed tissue (Felthauser & Claiborne, Neurosci. Lett. 118: 249). To minimize bleaching of the dye, the intensity of the mercury excitation (Nikon G2A or Omega LY filter) was decreased using neutral density filters, and the final field area of excitation was reduced. To compensate for the concurrent decrease in fluorochrome emission, we used a Hamamatsu C2400-08 camera and a Rolyn KG2 heat filter. With these modifications, all labeled dendrites could be digitized.

Total dendritic length per neuron ranged from 366 to 1524 um (n=9) for DiI-labeled granule neurons from 3-day-old rat pups, and from 412 to 2235 um (n=5) for neurons from 8-day-old pups, reflecting the wide variability in granule cell structure at these ages; from 1470 to 2950 um (n=6) for LY-injected granule neurons from 14-day-old pups; and from 4241 to 5356 um (n=4) for LY-injected cells from 40- to 60-day-old rats. The last two results are similar to our previous data on HRP-labeled granule neurons (Rihn & Claiborne, Dev. Br. Res. 54: 115), illustrating the reliability of the system for 3-D analysis of fluorescently-labeled neurons. (Supported by MBRS and ONR.)

QUANTITATIVE OPTICAL IMAGING OF THE DIFFUSION OF DEXTRANS OF DIFFERENT MOLECULAR WEIGHTS IN RAT CEREBRAL CORTEX.

L. Tao* and C. Nicholson. Dept. of Physiology and Biophysics, New York University Medical Center, 550 First Ave., New York, NY 10016.

Many neuroactive substances have molecular weights of 1 - 100 kDa and it is important to know how they diffuse in brain tissue. We have developed a quantitative optical imaging system and analyzed the diffusion of 3, 10, 40, and 70 kDa fluorescent dextran molecules in the cortex.

Dextrans tagged with the fluorescent dye Texas Red (Molecular Probes, OR) were pressure-injected into rat cortical slices maintained in a perfused chamber at 34°C and imaged as they spread in the tissue, using a compound epi-fluorescent microscope with a 10x water-immersion objective. About 20 images were taken with at 2 - 10 second intervals and recorded by a cooled CCD camera (Photometrics, AZ) with 576 x 384 pixels and 14 bits and transferred to a 486 PC. The apparent diffusion coefficient, D^*, was determined by fitting an integral expression relating the measured 2-dimensional image intensity to the 3-dimensional dextran concentration. Measurements in dilute agarose gel provided a reference value of D.

Values of the ratio, $(D/D^*)^{1/2}$, for the 3 and 10 kDa dextrans were consistent with tortuosities derived from tetramethylammonium measurements in cortex (Cserr et al. J. Physiol., 442: 277, 1991) but the 40 and 70 kDa dextrans showed markedly larger ratios. This suggests that extracellular space may not be uniform but has constrictions that hinder diffusion of molecules above a critical size that lies in the range 10 - 40 kDa. This implies that the concept of tortuosity, as a simple parameter describing the diffusion properties of the extracellular space, is valid only for molecules below this critical size. Supported by NIH Grant NS 28642.

CCD-IMAGING OF VOLTAGE SENSITIVE DYE SIGNALS FROM WHOLE BRAIN OF LOWER VERTEBRATES

K.R. Delaney[1,2*], D. Kleinfeld[2] and D.W. Tank[2] Dept. of Biosciences, Simon Fraser Univ., Burnaby B.C. V5A-1S6 [1] & Biological Computation Research Dept. AT&T Bell Laboratories, Murray Hill NJ 07974 [2]

We used the fluorescent potentiometric membrane probe Di-4-ANEPPS to image distributed neural activity *in vivo* and in isolated whole brain preparations of frog, lamprey and turtle. Shot noise limited images were obtained with a CCD at a rate of 13 Hz and processed to produce movies of the spatio-temporal patterns of voltage changes. Small arrays of diodes were used to measure voltage changes with higher temporal resolution from selected regions. Simultaneous recording of optical and electrical signals was possible for periods >8 hours without light-induced toxicity.

Optical recordings reliably showed the initiation and propagation of neural responses that were evoked by stimulation of cranial nerves or brainstem structures, by disinhibition with picrotoxin (PTX) and by light or odor stimuli. Optical signals generally differed from field potential recordings by the presence of long lasting slow components, that often persisted many seconds after a stimulus. In contrast, a close correspondence between the time course of optical signals and intracellularly measured voltage was seen suggesting the slow components are not glial in origin. Spontaneous activity induced by PTX originated in various brain regions and propagated along several defined paths (e.g. ant. dorsal telencephalon to thalamus/ hypothalamus). Repeated initiation of these "epileptiform" events from the same sites was observed over the course of several hours. Telencephalon initiated events occurred more frequently and recovered faster than those in diencephalon, tectum, cerebellum or brainstem. Odors or olfactory nerve shock produced optically recorded oscillatory activity in olfactory bulb and activity extending into ipsilateral and contralateral caudal telencephalon.

SIMULTANEOUS KINETIC IMAGING OF INTRACELLULAR CALCIUM AND pH IN SINGLE MELANOTROPES. Stephen J. Morris*, Diane M. Beatty†, and Bibie M. Chronwall†. Div. of Molecular Biology and Biochemistry and †Div. of Cell Biology and Biophysics, Univ. of Missouri-Kansas City, Kansas City, MO 64110

There is a growing interest in the use of multiple fluorescence probes to analyze the relationships between $[Ca^{2+}]_i$ and pH_i. We have designed an epifluorescence video microscope for dual excitation and four wavelength emission which will simultaneously capture all four emission images at 405, 475, 575 and 640 nm from the two ratio dyes indo 1 (for $[Ca^{2+}]_i$) and SNARF 1 (for pH_i) at video rates (*SPIE Proc* **1428**:148,(1991), *Optical Microscopy: New Technologies and Applications*. B Herman and JJ Lemasters, eds, Academic Press (1992-in press)).

Popular dyes for measuring intracellular calcium, such as indo 1 and fura 2, have pH-dependent Kd's; thus changes in pH_i can be misinterpreted as changes in $[Ca^{2+}]_i$. SNARF sensitivity to pH between 6.5 and 8.0 was unchanged by $[Ca^{2+}]$. The indo/Ca^{2+} Kd, examined at 20° and 37°C, shifted more than ten fold between pH 6.5 and 8.0. Rat pituitary melanotropes, grown in explant cultures, were double-labelled and Ca^{2+}/pH interactions were examined during exposure to various stimuli. SNARF ratio maps were used to correct the pH-dependent changes in local cell calcium. Under most circumstances, pH correction modified the apparent $[Ca^{2+}]_i$; small changes in $[Ca^{2+}]_i$ disappeared or were greatly attenuated and kinetics changed. Cells were later positively identified as melanotropes by immunohistochemistry.

K^+-induced depolarization of melanotropes produced increases in $[Ca^{2+}]_i$ which were closely coupled to reductions in pH_i. Chronically applied dopamine agonists suppressed this activity, which returned when the drugs were removed. Cells responded to both NH_4Cl alkalinization and subsequent acidification upon NH_4Cl withdrawal with calcium transients from intracellular stores. We conclude that the new video microscope will be an invaluable tool for the study of intracellular dynamics.

Supported by NSF grant DIR 9019648 and NIH grants GM44071 and NS28019, and grants from Kansas Affiliates-AHA and the PS Astrowe Trust of Menorah Hospital.

DO GLIA CELLS REGULATE PERINEURAL CALCIUM? D.Manor, N. Moran and M. Segal*, Neurobiology Dept., The Weizmann Inst., Rehovot 76100, ISRAEL.

We studied the effects of rapid changes of $[Ca]_o$ and $[K]_o$ on $[Ca]_i$, imaged with Fluo-3, in cultured neural cells, using a confocal laser scanning microscope. In constant, 2.8 mM $[K]_o$, changing $[Ca]_o$ (range 0 - 10 mM) caused a proportional shift in $[Ca]_i$ (range 50 - 150 nM). The effect was more prominent in C6 glioma and primary glia than in cultured hippocampal neurons. $[Ca]_i$ increased 2.5 fold in C6 cells with half maximum at 2.5 mM $[Ca]_o$ and with T1/2 of 15 s. In neurons too, $[Ca]_o$ modulated $[Ca]_i$, but with a lower $[Ca]_i$ range (30-100 nM) and had a slower time course ($T_{1/2}$ > 50 sec.). The two cell types differed more strikingly in their response to $[K]_o$ variations. As expected, high $[K]_o$ triggered a marked elevation of $[Ca]_i$ in neurons, which was prevented by verapamil. In contrast, increasing $[K]_o$ in glia resulted in a marked decrease of $[Ca]_i$. Significant variations in $[Ca]_i$ could be observed also in the physiological range of $[K]_o$. $[Ca]_o$ control of $[Ca]_i$ was unaffected by verapamil, cadmium, sodium vanadate, ouabain or low sodium. However, a 10 s perfusion with 10 mM Lanthanum (La) induced a 5 min suppression of basal $[Ca]_i$. In neurons, La efects lasted up to a minute. Involvement of intracellular calcium stores in this regulation in glia is suggested by a marked reduction of $[Ca]_i$ responses to 5-HT_2 and α1-NA ligands - known Ca mobilizers - during $[Ca]_i$ reduction by high $[K]_o$ or La. These results suggest that glial cells possess unique, fast $[Ca]_i$-based $[Ca]_o$ regulating mechanisms.

THREE-DIMENSIONAL RECONSTRUCTION OF LARGE SUBCELLULAR STRUCTURES: A METHOD FOR COMBINING AXIAL TILT TOMOGRAPHY WITH SERIAL THICK SECTIONS G. E. Soto, M. E. Martone, S. Lamont, S. J. Young*, T. J. Deerinck, M. H. Ellisman. San Diego Microscopy & Imaging Resource, Dept.Neurosci., UCSD, La Jolla, CA 92093-0608

Cells and cellular organelles can extend for tens of microns and therefore cannot be encompassed in a single thin section normally examined with conventional electron microscopy. Even with the use of high voltage electron microscopy, section thickness is limited to no more than a few microns. In an effort to overcome these limitations we have been exploring a method of linking serial thick sections by first extracting their three-dimensional (3D) information using axial tilt tomography and then aligning and linking the resulting serial volumes to form a single volume. We have used this method to investigate the 3D structure of the Golgi apparatus in dorsal root ganglion neurons . Briefly, four 2µm serial sections were cut from an osmium impregnated bullfrog dorsal root ganglion (Lindsey et al., J. Neurosci. 12:3111, 1985). A tomographic volume was derived for each section from a single axis tilt series taken through ±60 degrees in 2 degree increments with a JEOL 4000 intermediate voltage electron microscope operated at 400KeV. Alignment of the serial volumes was accomplished by slicing each volume into individual planes orthogonal to the depth dimension and registering the last slice of one volume to the first slice of the next with the aid of fiducial marks . The aligned slices of the 4 volumes were then merged into a single volume. The resulting volume was rendered and examined using the program ANALYZE (Robb et al., IEEE Trans. Med Image. MI-8:217, 1989). The continuity of components of the Golgi apparatus could be observed through a depth of 8µm with spatial resolution near to 100nm. This method appears promising for characterizing the 3D organization of subcellular structures over many microns while maintaining resolution sufficient to discern fine structural detail. While the alignment of the serial volumes appeared accurate, we are currently validating this technique by using a specimen of known 3D geometry. We are also exploring the use of this technique to investigate the continuity of neuronal endomembrane system components in bullfrog dorsal root ganglion and in cerebellar Purkinje cell dendrites.

TOWARDS A DIGITAL THREE-DIMENSIONAL NEUROANATOMIC ATLAS OF THE HUMAN BRAIN.

B. Quinn*, K. Ambach, & A.W. Toga, Laboratory of Neuro Imaging, Dept. of Neurology, UCLA Medical School, Los Angeles CA 90024.

We have generated high resolution, full color three-dimensional (3D) data sets from human brains cryosectioned with the cranium intact. Whole human heads were perfused via the common carotid and vertebral arteries with formol-saline fixative delivered by a constant-pressure perfusion system, followed by post-fixation perfusion using glycerol and polyvinylpyrrolidone, which act as cryoprotectant and plasticizing agents. After decalcification of the cranium, specimens were pre-chilled to near freezing and then rapidly frozen in isopentane chilled with liquid nitrogen. Frozen specimens were sectioned on an automated PMV Cryo-Microtome equipped with a Digistat 1024^2 high resolution camera. Color images were captured from the specimen blockface at serial intervals of 400 or 800 microns and reassembled into a 3D volume. An important feature of this system is direct volume reconstruction from in-register images without need for complex registration algorithms. The reconstructed volume data set could be oriented in a Cartesian coordinate system and extensively manipulated for visual display including planar transection and surface modeling. The ultimate objective of digital reconstruction is the development of a digital 3D neuroanatomic atlas of a prototypic human brain intact in the cranium through application of warping algorithms to an array of multiple specimens.

A HISTOLOGICAL APPROACH TOWARDS A HUMAN BRAIN REFERENCE ATLAS FOR COMPUTER ASSISTED IMAGING TECHNIQUES. J.K. Mai, T.A. Voß, J. Assheuer, L. Lanta, T. Sievert and L. Teckhaus (SPON: European Neuroscience Association). Abt. für Neuroanatomie, Heinrich-Heine Universität, D-4000 Düsseldorf 1; MPI für Systemphysiologie, D-4600 Dortmund 1, FRG.

In spite of high resolution obtained by modern imaging techniques it is necessary to supplement these image data with histological and histochemical data from the microscopical examination of brain sections. In order to integrate the two different sets of data we have created a 3-D human-brain-reference-atlas. This atlas is based on one paraffin-embedded brain (death to fixation interval: 2h), which was serially sectioned vertical to the intercommissural line. Cytomorphologic and morphometric studies of this brain and correlations with immunohistochemical findings have been published by numerous authors. From 630 sections contourlines representing pial and ventricular surfaces, as well as subcortical nuclei and their subdivisions, were extracted manually. The contourlines were adjusted into a 3-D metric grid. Points of intersection between the contourlines and the grid were used for cubic spline-approximation. The resulting curves with damped extrema were transformed after estimating deformation and shrinkage due to tissue preparation. The smoothed contourlines were used for 3-D reconstruction. Contourlines of main thalamic subnuclei have been quantitatively compared, regarding to the interindividual variability, with those derived from paraffin-embedded brains (applying the same procedure of in-vitro - in-vivo transformation; 25 hemispheres) and MR Imaging (18 hemispheres).

408.18

THREE-DIMENSIONAL STRUCTURE OF LOCAL PARENCHYMAL MICROVASCULAR SYSTEMS IN RAT BRAIN. J.A. DeMaro, W. Finnegan, V. Acuff, G. Richardson, D. Bereczki, L. Wei, and J. Fenstermacher*. Dept. Neurological Surgery, SUNY, Stony Brook, NY 11794-8122

Past methodologies for analyzing cerebral microvascular system structure have employed single histological sections and stereological theory. Such approaches do not yield information on microvascular branching, length, and tortuosity. Since there is reason to suspect that some of these features vary among brain areas, three-dimensional reconstructions of local microvascular systems were made using serial histological sections and an image analysis system.(MCID M1, Imaging Res. Inc) The results indicate that cerebral microvascular systems vary considerably in branching and tortuosity. For example, the capillaries in the hippocampus are fairly straight, long, and arise by simple division of the terminal arteriole, whereas those in the paraventricular nucleus form tortuous networks of many relatively short capillaries. Microvascular system organization, thus, seems to vary among brain areas, possibly in accordance with the structure and function of the surrounding tissue.

An Improved Approach to Quantitative *In Situ* Hybridization. J.T. McCabe, E.F. Wheeler* and R.P. Bolender Dept. of Anatomy & Cell Biology, USUHS, Bethesda, MD and Depts. of Physiology & Biophysics, Biological Structure, Univ. of Washington, Seattle, WA

In neuroscience research, *in situ* hybridization is often the method of choice for measurement of mRNA levels. Compared with other procedures used to assess gene activity, this method allows one to study changes at the morphological level, and estimate both the amount of mRNA/cell and the number of cells containing the mRNA of interest. Quantification of *in situ* hybridization results, however, is not a simple procedure. If cell volume changes, estimates of the number of labeled cells/brain region and amount of mRNA/cell can be grossly inaccurate. We have developed a quantitative morphological method that estimates the total number of labeled cells/structure, and converts the conventionally used parameter, *grain density* (grains/cell profile area), to both grains/cell and grains per total cell population: $N = V \times N_A \times 1/t$, where N = total number of grains/cell, V = cell volume, N_A = grains/cell profile, and t = the effective depth of the radioactive source (*Anatomical Record*, **231**: 407-15, 1991). Our presentation demonstrates how conventional approaches can lead to inaccuracy and misinterpretation, and how the proposed method gives reliable estimates of the number of labeled cells, mRNA levels/cell, and mRNA levels/brain region. DISTRIBUTION OF AROMATIC L-AMINO ACID DECARBOXYLASE mRNA IN MOUSE BRAIN.

M.J.Eaton,[1]*, K.P.Gudehithlu[1], C.P.Silvia[1], M.Hadjiconstantinou[1,2,3], and N.H.Neff[1,3], Depts of Pharmacology[1], Psychiatry[2] and Neuroscience Program[3], Ohio State University College of Medicine, Columbus, OH 43210.

A 286 bp DNA sequence for mouse-brain aromatic L-amino acid decarboxylase (AAAD) was obtained from a mouse brain cDNA library using oligonucleotide probes prepared from a complete bovine adrenal AAAD sequence. Antisense riboprobes for the bovine adrenal and mouse-brain AAAD were labelled with digoxigenin and 20 μm sections of mouse brain used for non-radioactive in situ hybridization and anti-digoxigenin UTP immunohistochemistry. Brain from mice treated with MPTP, 30 mg/kg ip daily for 7 days, were also probed for AAAD mRNA. Both the full length bovine adrenal and mouse brain AAAD probes stained the cell nuclei known to synthesize dopamine, serotonin and norepinephrine. The substantia nigra, dorsal raphe nucleus, locus coeruleus and olfactory bulb contained the highest concentrations of AAAD mRNA. When MPTP-treated animals were examined, substantia nigra pars compacta had barely detectable staining for AAAD, while both locus coeruleus and dorsal raphe had levels of mRNA unchanged from those found in untreated mice. Ventral tegmental dopaminergic cells retained an intermediate level of AAAD staining. Histaminergic neurons in the hypothalamus and the Purkinje neurons in the cerebellum containing histidine decarboxylase and glutamic acid decarboxylase, respectively were unlabelled by these in situ methods. However, neurons of the deep layers of the frontal cortex, nuclei of the thalamus, and the pyramidal neurons of the hippocampus were moderately or strongly labelled for mouse AAAD mRNA. This specific probe for mouse brain AAAD message may be useful to monitor changes in expression of AAAD in models of Parkinson's disease.

CALCIUM CHANNEL TOXINS II

409.1

EFFECTS OF THE CALCIUM CHANNEL BLOCKER OMEGA-CONOTOXIN ON *IN VIVO* DOPAMINE EFFLUX IN RAT STRIATUM. C.A. Duva, C.D. Blaha* and A.G. Phillips. Dept. Psych., Univ. British Columbia, Vancouver, BC, Canada, V6T 1Z4.

The effects of omega-conotoxin (CTX, fraction GVIA), an N- and L-type voltage-sensitive calcium channel (VSCC) blocker, on basal dopamine (DA) efflux was investigated using *in vivo* electrochemistry (chronoamperometry, 1 s potential pulse/ 30 s). A 30 gauge cannula was positioned 0.5 mm adjacent to a stearate-graphite paste recording electrode and was stereotaxically implanted into the dorsomedial striatum of urethane anesthetized rats. Following at least 1 hr of baseline recordings, injection of CTX (0.1, 1 or 10 pmole/ 1 ul/ 4 min) produced a dose-dependent decrease in basal DA efflux. A maximal decrease in DA efflux was achieved within 10 min of injection of 10 pmole CTX. This decrease was followed by a rebound in DA efflux which increased significantly above preinjection values within 1 hr of CTX injection. Additional CTX (10 pmole) injections during this rebound phase produced decreases in DA efflux that were similar in magnitude and time-course as the first injection. These results provide some of the first *in vivo* evidence indicating that both N- and L-type calcium channels are involved in basal DA transmission and suggests that transient inhibition of these channels may lead to increased DA efflux. These findings are in contrast with *in vitro* studies which demonstrate an irreversible blockade of VSCCs by CTX. The mechanisms responsible for the transient and rebound effects of CTX are unknown at present, but may include a biphasic modulation of VSCCs or increased storage of DA at the presynaptic terminal.

NOREPINEPHRINE (NE) RELEASE FROM CARDIAC ADRENERGIC NERVE TERMINALS: AGE-RELATED DIFFERENCE IN OMEGA-CONOTOXIN INHIBITION. D.L. Snyder, V.J. Aloyo*, M.D. Johnson, and J. Roberts. Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Cardiac synaptosome (SYN) preparations from hearts of 6 and 24 mo old male F344 rats were used to investigate the effect of age on omega-conotoxin (CTX) inhibition of NE release. CTX is a specific N-type Ca^{2+} channel blocking agent. SYN were incubated in ^{3}H-NE, placed in a superfusion system, and then perfused for 30 min with various concentrations of CTX. The SYN were then depolarized with a 2 min pulse of buffer at 75 mM K^+ (concentration which produces maximum release) or 60 mM K^+. The mean fractional release of NE (% of total NE actually released) was significantly reduced in 24 mo old rats when compared to 6 mo old rats (N=3, see table). 6 mo old rats were more sensitive to CTX inhibition and showed a greater percent reduction in NE release at each level of CTX. These results suggesting that the adrenergic nerve terminals of 6 mo old rat hearts contain more CTX sensitive Ca^{2+} channels than at 24 mo agree with our previous finding that SYN from 6 mo old hearts contain more CTX binding sites than SYN from 24 mo old hearts. The loss of Ca^{2+} channels with age may be responsible for the age-related reduction in NE release.

		Mean fractional NE release (% inhibition by CTX)					
[CTX]		0	10 pM	100 pM	1 nM	10 nM	100 nM
6 mo	75 mM K+	4.9	4.5 (8)	3.7 (24)	3.3 (33)	3.3 (33)	2.5 (49)
24 mo	75 mM K+	4.0	4.2 (0)	3.8 (5)	3.6 (10)	3.1 (22)	2.9 (27)
6 mo	60 mM K+	4.8	4.0 (17)	3.4 (29)	2.4 (50)	1.6 (67)	2.0 (58)
24 mo	60 mM K+	4.0	3.2 (20)	3.3 (17)	3.0 (25)	2.3 (42)	2.3 (42)

BLOCK OF MAMMALIAN CALCIUM CHANNELS EXPRESSED IN *XENOPUS* OOCYTES BY ω-AGATOXINS. A. Kondo, J. D. Mills*, and M. E. Adams. Departments of Entomology and Neuroscience, University of California, Riverside, CA 92521.

ω-Agatoxins from *Agelenopsis aperta* spider venom are potent and selective blockers of voltage-activated calcium channels. We are using these toxins as probes in comparative studies of Ca^{2+} channels expressed in *Xenopus* oocytes. Oocytes injected with mRNA prepared from rat heart, whole brain, and cerebellum displayed voltage activated currents through Ca^{2+} channels using Ba^{2+} as a charge carrier. TEA, 4-AP, and niflumic acid were used to block potassium and chloride currents. Oocytes expressing mRNA from heart muscle showed Ba^{2+} currents with kinetics typical of L-type Ca^{2+} channels. Exposure to 100-200 nM ω-Aga-IIIA resulted in 50-90% block of high threshold current, with little or no effect observed on low threshold currents. Expression of mRNA from whole brain resulted in Ba^{2+} currents that were blocked as much as 70% by 200 nM ω-Aga-IIIA, but only 15-25% by 400 nM ω-Aga-IVA. In contrast, oocytes injected with cerebellar mRNA displayed Ba^{2+} currents that were substantially blocked by both ω-Aga-IIIA and ω-Aga-IVA. Based on the selectivity of ω-Aga-IVA, (see Mintz et al., this meeting), these results suggest that P-type channels are relatively more abundant in the cerebellum than in whole brain.

Supported by NIH grant NS24472.

409.4

A NOVEL PEPTIDE NEUROTOXIN SELECTIVELY BLOCKS MYOCARDIAL L-TYPE CALCIUM CURRENT. J.J. McArdle, Y.-F. Xiao, S.P. Aiken*, L.C. Sellin, J.J. Schmidt, and S.A. Weinstein. Dept. Pharmacology & Toxicology, New Jersey Medical School (UMDNJ), Newark, NJ 07103-2714, and Dept. Toxinology, USAMRIID, Frederick, MD 21701-5011.

Peptide I (WTX-I) from the venom of *Trimeresurus wagleri* appears to act presynaptically to interfere with synaptic transmission (Pharm. & Tox. 1992, in press). In order to explore the interaction of WTX-I with ion channels, we examined its effect on L-type Ca^{2+} (I_{Ca}) and transient K^+ (I_{to}) currents, as well Na^+ (I_{Na}) currents recorded from myocytes isolated from the left ventricle of 10-11 week old rats. Ionic currents were recorded with the whole cell configuration of the patch voltage-clamp technique. Bath application of 6 to 20 μM WTX-I had no detectable effect on I_{to} or I_{Na}. In contrast, 2, 4, and 6 μM WTX-I reduced I_{Ca} to 68.4 ± 15.4 % (n=3), 47.7 ± 6.0 % (11), and 10.1 ± 10.1 % (3) of the respective control values. This inhibitory effect on I_{Ca} could not be reversed by application of 5 μM isoproterenol. Recovery occurred after washout of the WTX-I containing solution. These findings suggest that WTX-I selectively blocks L-type Ca^{2+} channels and that stimulation of β-adrenergic receptor-modulated phosphorylation of this channel cannot overcome the blocking effect of WTX-I. Supported by grants from the NIAAA (AA08025) and the American Heart Association (90-G-27).

The cytochemical distribution of ω-Conotoxin binding sites in the Electrosensory Lateral Line Lobe (ELL) of *Apteronotus leptorhynchus*. R.W. Turner* and R. Hawkes
Neuroscience Research Group, Univ. of Calgary, Alberta T2N 4N1

The ω-conotoxin GVIA (ω-CgTX; *Conus geographus*) binds to a subset of high threshold voltage-operated calcium channels (VOCCS). ω-CgTX-binding sites in the ELL were determined using a monoclonal antibody against ω-CgTX (mab anti-ω-CgTX). 500 μm ELL slices maintained alive in cold oxygenated ACSF were exposed to 1nM - 1μM ω-CgTX (20 min), washed (3 X 10 min), and fixed in 4% PARA (2 hrs). 100 μm slices were cut and incubated overnight in mab anti-ω-CgTX (1: 0.66) and processed using the ABC technique and HRP label. The intensity of immunoperoxidase label was variable across a section but consistent in cellular distribution. Omission of ω-CgTX from the first incubation prevented all labelling. Intense staining was observed in spherical cells, but also in somata of polymorphic, granule and pyramidal cells. Pyramidal cell basal dendrites were positive but all apical dendrites beyond ~150 μm were negative. Punctate membrane-associated label was detected on spherical, polymorphic, and granule cell somata, and in association with synaptic contacts on pyramidal cells. Preliminary *in vitro* slice recordings reveal that pyramidal cells are insensitive to ω-CgTX unless exhibiting oscillatory discharge that incorporates synaptic circuitry. These data reveal a localized distribution of physiologically relevant ω-CgTX-binding sites (putative VOCCS) among cell classes of the ELL.

BIOLOGICAL CHARACTERIZATION OF THE NOVEL CALCIUM CHANNEL BLOCKER ω-AGA-IVA IN MAMMALIAN CNS. L.D. Hirning[1*], L.D. Artman[1], N. Alasti[1], D. Phillips[2], R.A. Volkmann[2], N.A. Saccomano[2] and A.L. Mueller[1]. [1]NPS Pharmaceuticals, 420 Chipeta Way, Salt Lake City, UT 84108 and [2]Pfizer Central Research, Pfizer, Inc., Groton, CT 06340.

The venom of the funnel-web spider *Agelenopsis aperta* contains a number of peptides which block voltage-sensitive Ca^{2+} channels (VSCC). Sequential chemical purification of crude peptide fraction AG1 gives rise to a single pure peptide called ω-Aga-IVA which was recently isolated and characterized independently by M. Adams and his colleagues (Nature 355: 827, 1992). ω-Aga-IVA possesses novel inhibitory activity on dihydropyridine (DHP)- and ω-CgTx-insensitive VSCC in a variety of mammalian CNS preparations. First, ω-Aga-IVA blocks transmission at the Schaffer collateral-CA1 pyramidal cell synapse in rat hippocampal slices potently and with high efficacy. Synaptic transmission in this pathway is resistant to blockade by DHPs and is blocked only partially by ω-CgTx. Second, the release of ^{3}H-GABA from hippocampal minces is resistant to blockade by DHPs and ω-CgTx. ω-Aga-IVA blocks GABA release in this system to the same extent as does 100 μM Cd^{2+}. Third, ω-Aga-IVA blocks DHP- and ω-CgTx-resistant current in acutely dissociated rat cerebellar Purkinje cells ("P-channels"). Finally, stimulation of N1E-115 cells in culture with 60 mM KCl produces transient and sustained increases in intracellular Ca^{2+} as measured with fura-2. The transient response is largely DHP-resistant but nearly completely blocked by 100 nM ω-CgTx. ω-Aga-IVA at 100 nM is ineffective, again demonstrating that ω-CgTx and ω-Aga-IVA target different populations of VSCC. ω-Aga-IVA is a unique probe with which to study the function of this novel type of VSCC in the mammalian CNS.

ω-GRAMMOTOXIN SIA: A SPIDER VENOM PEPTIDE INHIBITOR OF ω-CONOTOXIN GVIA-SENSITIVE AND -INSENSITIVE VOLTAGE-SENSITIVE CALCIUM CHANNEL RESPONSES. R. A. Keith*, P. A. DeFeo, M. B. Horn, T. J. Mangano and R. A. Lampe. Dept. of Pharmacology, ICI Americas, Inc., Wilmington, DE 19897.

A purified fraction from *Grammostola spatulata* venom was recently shown to inhibit neuronal voltage-sensitive calcium channel (VSCC) responses that were insensitive to ω-conotoxin GVIA (ω-CgTx), a selective inhibitor of N-type VSCC (Keith et al., Pharmacol. Commun., in press). The present report characterizes further the VSCC profile of this purified fraction, termed ω-grammotoxin SIA (ω-GsTx). ω-GsTx caused a concentration-dependent and near complete inhibition of K^{+}-evoked $^{45}Ca^{++}$ influx in both rat and chick synaptosomes with IC_{50} values ≅ 200 nM. In contrast, ω-CgTx potently inhibited chick synaptosomal $^{45}Ca^{++}$ influx (IC_{50} ≅ 20 nM) but was virtually inactive against rat synaptosomal $^{45}Ca^{++}$ influx (IC_{50} > 10,000 nM). ω-GsTx also caused a concentration-dependent and near complete inhibition of K^{+}-evoked release of ^{3}H-norepinephrine (NE) from rat hippocampal and chick cortical brain slices and K^{+}-evoked release of ^{3}H-D-aspartate from rat hippocampal brain slices (IC_{50} ≅ 150 nM). ω-CgTx caused a potent and complete inhibition of chick brain slice ^{3}H-NE release (IC_{50} ≅ 50 nM), a potent but incomplete inhibition of rat brain slice ^{3}H-NE release (IC_{50} ≅ 5 nM, 60% maximum inhibition), and was virtually inactive against rat brain ^{3}H-D-aspartate release (no effect at 3000 nM). ω-GsTx (750 nM) did not significantly displace ^{125}I-ω-CgTx, ^{3}H-PN 200-110 or ^{3}H-D-888 binding to rat synaptosomal membrane fragments. The results suggest that ω-GsTx is a potent inhibitor of ω-CgTx-sensitive and -insensitive neuronal VSCC by a mechanism that is distinct from previously identified VSCC antagonists.

409.8

ISOLATION AND STRUCTURAL CHARACTERIZATION OF ω-GRAMMOTOXIN SIA, A NOVEL PEPTIDE INHIBITOR OF NEURONAL VOLTAGE-SENSITIVE CALCIUM CHANNELS. R. A. Lampe*, M. M. Lo, M. Davison, M. B. Horn, A. Verticelli, P. A. DeFeo, J. L. Herman and R. A. Keith. Depts. of Pharmacology, Structural Chemistry and Biotechnology, ICI Pharmaceuticals, Wilmington, DE 19897.

ω-Grammotoxin SIA (ω-GsTx), a peptidergic blocker of voltage-sensitive calcium channels (VSCC), was purified from *Grammostola spatula* (tarantula spider) venom by reverse phase HPLC (RP-HPLC). Three RP-HPLC purification steps, using gradient and isocratic elutions from a C-8 Zorbax Rx semi-preparative column, were required to obtain this single, apparently homogeneous, peptidergic species. Biological activity was monitored by determining the inhibition of K^{+}-stimulated influx of $^{45}Ca^{++}$ into rat brain synaptosomes *vs.* lack of inhibition of ^{125}I-ω-conotoxin GVIA binding to rat hippocampal membranes. Fast atom bombardment mass spectrometry (FAB-MS) indicated an average molecular mass of 4110 daltons for the protonated molecular ion. Exposure of the peptidergic entity to reducing agents on the FAB probe led to an increase of 6 amu indicating the presence of 3 disulfide bridges or 6 Cys residues. N-Terminal Edman sequence analysis of the reduced, pyridylethylated peptide was carried out on the intact species and on the COO^{-} terminal fragment following tryptic digestion. Primary sequence data confirms the existence of 6 Cys residues, and 36 residues in total, with a calculated molecular mass of 4109 for the amidated COO- terminal species. Synthetic preparation of ω-GsTx is currently underway to provide undeniable demonstration of the biological profile obtained for the purified peptide. This biological profile includes the blockade of N-, as well as non-L/non-N-type, VSCC responses, with no inhibition of binding of known Ca^{++} channel ligands. Biological data are presented in a companion abstract.

NOVEL CONOPEPTIDE INHIBITORS OF MAMMALIAN PRESYNAPTIC Ca CHANNELS DERIVED FROM cDNA CLONING AND PEPTIDE SYNTHESIS. D. R. Hillyard, V.D. Monje, S. Gaur, L. Nadasdi, G. Miljanich, J. Ramachandran, and B. M. Olivera*
Depts. of Pathology and Biology, U. of Utah, Salt Lake City, UT 84132; Neurex Corp., 3760 Haven Ave., Menlo Park, CA 94025.

The venoms of fish-hunting cone snails contain potent peptide inhibitors of presynaptic neuronal calcium channels. However, previously characterized peptides such as ω-conotoxin GVIA, target only a subset of mammalian CNS Ca channels. We used a molecular biological approach to derive new ω-conopeptides which inhibit an expanded subset of mammalian CNS Ca channels. Oligonucleotide probes directed to codons of conserved amino acids of the Ca channel-targeting conopeptides MVIIA and MVIIB were used to identify cDNAs encoding two new Ca channel ligands. cDNA sequencing was used to guide synthesis of peptides MVIIC and MVIID which inhibit synaptic transmission which is ω-GVIA-resistant. Several ω-GVIA-resistant Ca currents, i.e., depolarization-induced ^{45}Ca uptake in rat synaptosomes, "P" currents in cerebellar Purkinje cells and a subset of ω-GVIA-resistant channels in CA1 hippocampal cells are sensitive to ω-MVIIC. In addition, in several systems, ω-MVIIC inhibits a component of neurotransmitter release that is resistant to ω-GVIA or MVIIA (see abstracts by Gaur *et al.*, and Newcomb and Palma). Accordingly, these new peptides offer important new tools for the study of Ca channel subtypes.

409.10

NEOMYCIN DISPLACEMENT OF [^{125}I]-ω-CONOTOXIN GVI-A BINDING IS NOT UNIFORM ACROSS NEUROANATOMICAL REGIONS: EVIDENCE FROM AUTORADIOGRAPHIC STUDIES. F. Filloux[1*], B.M. Olivera[2] and J.M. McIntosh[3], Depts Neurol[1], Pediatr[1], Biol[2] and Psychiat[3], Univ. Utah, Salt Lake City, UT 84132.

Previous studies have demonstrated that neomycin (NEO) inhibits [^{125}I]-ω-Conotoxin GVI-A (*ω-CgTx) binding to brain membranes suggesting that NEO may block or modulate N-type Ca^{++} channels. Our early observations, however, have indicated that the ability of NEO to displace *ω-CgTx from slide-mounted tissue sections is not uniform across brain regions. This issue has been investigated further. 10μM sagittal slide-mounted tissue sections from rat brain were labeled with *ω-CgTx at 4 concentrations (40, 80, 200 and 500 pM). Adjacent tissue sections were labeled in the presence of 0.1 mM NEO or 250 nM unlabeled ω-CgTx (the latter to define non-specific binding). At each concentration of *ω-CgTx, NEO produced the same asymmetric pattern of regional displacement of radioligand binding; e.g., at 200 pM *ω-CgTx, NEO displacement varied from greatest to least as follows: granule cell layer, cerebellum (94% displacement)> granule cell layer, dentate gyrus (84%)> thalamus (77%)> molecular layer, cerebellum (58%)> neocortex (47%)> substantia nigra reticulata (38%). These results confirm that the displacement of *ω-CgTx by NEO varies considerably across neuroanatomical areas. Such findings may indicate that the combined use of NEO and *ω-CgTx may delineate subtypes of Ca^{++} channels which occur in differing proportions in distinct brain regions.

409.11

CALCIUM CHANNEL ANTAGONISTS [^{125}I]ω-Aga-IIIA AND [^{125}I]ω-CgTx: AN AUTORADIOGRAPHIC COMPARISON OF BINDING SITES IN RAT BRAIN. J.M. McIntosh[1]*, M.E. Adams[2], B.M. Olivera[3] and F. Filloux[4], Departments of Psychiatry[1], Biology[3], Pediatrics[4] and Neurology[4], University of Utah, Salt Lake City, Utah, 84132; and Departments of Entomology and Neuroscience[2], University of California, Riverside, California, 92521.

Specific binding of the calcium channel ligands [^{125}I]ω-agatoxin IIIA (*ω-Aga-IIIA) and [^{125}I]ω-conotoxin GVIA (*ω-CgTx) was compared autoradiographically using sagittal sections from rat brain. Binding patterns for these two ligands were generally similar, but notable differences were detectable particularly in the cerebellum and hippocampus. Specific *ω-Aga-IIIA binding was greatest in the granule cell layers of the cerebellum and of the dentate gyrus. In contrast, binding of *ω-CgTx was most intense in the molecular layers of these structures. 250 nM ω-CgTx inhibits less than 33% of *ω-Aga-IIIA binding while 40 nM ω-Aga-IIIA inhibits greater than 92% of *ω-CgTx binding. The P-type calcium channel antagonist ω-Aga-IVA (40 nM) blocked only 11% of *ω-Aga-IIIA binding and 2% of *ω-CgTx binding. These data suggest that ω-CgTx binding sites are a subset of ω-Aga-IIIA sites and that the combined use of agatoxins and conotoxins may be useful for discriminating between calcium channel subtypes.

409.12

A POLYPEPTIDE FRACTION ISOLATED FROM *CONUS MAGUS* VENOM EXHIBITS NOVEL CALCIUM CHANNEL ACTIVITY IN NEURONAL PREPARATIONS. S.J. Stoehr†, A.B. Giordani‡, S.R. Naisbitt°, J.M. McIntosh°, D.J. Dooley†, B.M. Olivera°, and D.A. Downs*†. Departments of Neuroscience† and Chemistry‡, Parke-Davis, Pharmaceutical Research Div., Warner Lambert, Ann Arbor, MI 48106; Departments of Psychiatry° and Biology°, University of Utah, Salt Lake City, UT 84112.

Natural peptides purified from the venoms of numerous poisonous organisms have become important tools for understanding neuronal ion channels. We have isolated two polypeptides from venom of the marine snail *Conus magus* which interact with L-type Ca^{2+} channels. An aqueous extract from crude venom was tested in a [^{3}H]-isradipine binding assay to assess L-type Ca^{2+} channel affinity. The *C. magus* extract was at least ten times more effective at inhibiting [^{3}H]-isradipine binding to rat neocortical membranes than extracts from eight other *Conus* species (relative IC_{50} = 1/400,000 dilution). We used two reverse phase chromatography steps to isolate the active component. In each step, the inhibitory activity eluted as a single peak (absorbance at 214 nm), resulting in a ~300-fold purification of the material. This material inhibited [^{3}H]-isradipine binding to both neocortical and crude skeletal muscle membranes. Intracerebroventricular injection of this fraction into mice resulted in arched backs and extended extremities, an effect similar to that seen with the L-type Ca^{2+} channel activator Bay K 8644. This fraction also blocked K^+-induced $^{45}Ca^{2+}$ flux into rat brain synaptosomes, indicating a functional interaction with presynaptic Ca^{2+} channels. When the fraction was further purified using reverse phase chromatography with isocratic elution, the fraction separated into two peaks, and both inhibited [^{3}H]-isradipine binding. The polypeptide molecular weights were found to be ~13.7 kDa by electrospray mass spectrophotometry. Sequencing efforts are underway to determine the identity of these polypeptides.

409.13

[^{125}I]-ω-CONOTOXIN MVIIA: A NEW, COMMERCIAL RADIOLIGAND FOR N-TYPE CALCIUM CHANNEL BINDING IN NEURONAL MEMBRANES. J.J. Geer*, S.J. Stoehr, and D.J. Dooley. Department of Neuroscience, Parke Davis, Pharmaceutical Research Div., Warner Lambert, Ann Arbor, MI 48106.

The ω-conotoxins GVIA and MVIIA, isolated from the marine snails *Conus geographus* and *Conus magus*, are important tools for identifying and blocking N-type calcium channels in neuronal preparations. Although [^{125}I]-GVIA is commercially available, its irreversible binding characteristics make true competitive binding studies difficult. We recently tested an experimental preparation of [^{125}I]-MVIIA (Amersham), and compared this ligand to [^{125}I]-GVIA. We report here the methods for and characteristics of [^{125}I]-MVIIA binding. Synthesized MVIIA (Peninsula) was iodinated by Amersham using an enzymatic method. Specific activity of the ligand was ~2000 Ci/mmol (74 TBq/mmol). Binding of [^{125}I]-MVIIA to crude rat neocortical membranes was carried out at 37° C in 0.5 ml buffer (50 mM HEPES-NaOH, 0.1% BSA; pH 7.4) for 30 minutes. Unbound ligand was removed by filtration through GFC filters presoaked in 0.1% polyethylenimine (PEI), followed by two washes with buffer supplemented with 0.2 M NaCl. Saturation analysis gave a K_D of 6 x 10^{-13} M and a B_{max} of 1200 fmoles/mg protein. Binding was linear from 10-800 ng protein using [^{125}I]-MVIIA at 3 pM. These results were comparable to those obtained with [^{125}I]-GVIA (K_D = 0.6 pM; B_{max} = 995 fmol/mg protein, 23°C). The association kinetics of both [^{125}I]-MVIIA and [^{125}I]-GVIA were rapid (MVIIA, $t_{½}$ = 2 min, 37°C, at 3 pM ; GVIA, $t_{½}$ = 4 min, 23°C, at 4 pM). However, the dissociation rates were markedly different. [^{125}I]-MVIIA was readily displaced by excess cold ligand ($t_{½}$ = 1 min). [^{125}I]-GVIA was not significantly displaced by cold GVIA in 4 hours. Commercial availability of this high affinity, reversible radioligand will allow for direct competitive analyses of novel N-type calcium channel modulators.

DISTRIBUTION OF OMEGA CONOTOXIN-SENSITIVE CALCIUM CHANNELS IN THE ADULT RAT BRAIN. R.E. Westenbroek*[1], J.W. Hell[1], S. Dubel[2], T.P. Snutch[2], and W.A. Catterall[1]. [1]Department of Pharmacology, University of Washington, Seattle, WA 98195, and [2]Biotechnology Laboratory and Departments of Zoology and Neuroscience, University of British Columbia, Vancouver, B.C., Canada, V6T1W5.

N-type channels are high-voltage-activated Ca channels which are blocked by ω-conotoxin GVIA (ω-CgTX) and have been implicated in generation of calcium-dependent action potentials and neurotransmitter release. A polyclonal anti-peptide antibody (CNB1) that recognizes the α_1 subunit of an ω-CgTx-sensitive Ca channel immunoprecipitates the high affinity receptor for ω-CgTX but not the dihydropyridine receptor of L-type Ca channels after solubilization from rat forebrain (Dubel et al., Proc. Natl. Acad. Sci. USA, in press). In the present study, CNB1 immunoprecipitated 43% of the total N-type calcium channels labeled with [^{125}I]ω-CgTX. Immunoblotting with CNB1 revealed proteins of 210 and 240 kDa. CNB1 was used in combination with the immunofluorescence and indirect peroxidase-anti-peroxidase techniques to investigate the distribution of N-type Ca channels in rat brain. Ca channels recognized by CNB1 are localized along dendritic processes and on occasional somata. For example, CNB1 immunoreactivity is localized along the full length of apical dendrites of hippocampal pyramidal neurons with little labeling of the somata, while somata of pyramidal cells in the dorsal cortex are frequently labeled and the staining of apical dendrites decreases as distance from the cell body increases. In addition, there is intense punctate staining of structures (possibly synapses) along the dendrites and on occasional cell bodies in the dorsal cortex, subiculum, and cerebellar Purkinje cells. These observations contrast with studies of L-type calcium channels which have been shown to be localized in a narrow zone around the periphery of neuronal somata and in proximal dendrites of projection neurons such as hippocampal pyramidal cells (Ahlijanian et al., Neuron 4:819-832, 1990; Westenbroek et al., Nature 347:281-284, 1990). These results indicate that the ω-CgTX-sensitive Ca channels recognized by CNB1 have a distinct distribution from L-type Ca channels in central neurons which may correlate with distinct functional roles for these channel subtypes.

Components of the electrically evoked increase in intracellular calcium in chick dorsal root ganglion and sympathetic ganglion neurons. Yi Zhou,* and W. D. Branton. Department of Physiology, University of Minnesota, Minneapolis, MN. 55455.

We measured changes in Fluo-3 fluorescence as an indicator of changes in intracellular calcium in primary cultures of chick DRG and sympathetic ganglion neurons. Ca^{++} rises were induced via trains of electrical stimuli delivered thru extracellular electrodes placed in the recording chamber. A 1-2 sec train at 10 hz produced a rapid and reversible rise in internal Ca^{++} in both DRG and sympathetic ganglion cells. The response was prevented by removal of external Ca^{++} and by 200 nM TTX, indicating that it was dependent on calcium influx and on the generation of sodium dependent action potentials. In DRG cells 89% (+/- 2%; n=15) of the Ca^{++} rise was prevented by brief incubation with omega Conotoxin. The block appeared saturated at 1 uM toxin. 10 uM Nitrendipine blocked 13% (+/- 1%; n=7) 1 mM Amiloride blocked 4% (+/- 2%; n=7). This data suggests that the calcium influx in chick DRG cells under these conditions is largely through N type channels. T type channels appear to play a very minor role, since even relatively high concentrations of Amiloride block little of the Ca^{++} increase. These data appear to conflict with recent voltage clamp studies suggesting a significant role for T currents during the action potential. In sympathetic cells, Conotoxin blocked considerably less of the Ca^{++} rise (63% +/- 4%; n= 7). Very preliminary data suggest that Nitrendipine and Amiloride may each block more of the Ca^{++} rise in sympathetic cells relative to their effects in DRG cells. (Supported by NIH R01 GM42829. We particularly thank Stan Thayer for valuable advice and discussion.)

Toxins in *Plectreurys* spider venom are potent blockers of vertebrate calcium channels. E. A.Newman, Yi Zhou, M. S. Rudnick, and W. D. Branton*. Dept. of Physiology, University of Minnesota, Minneapolis, MN 55455.

We prepared a partially purified fraction of *Plectreurys tristes* spider venom for assay on vertebrate calcium channel preparations. Size exclusion on Sephadex G50 and step elution from C18 with 30% and 60% acetonitrile (0.1% TFA) yields a relatively hydrophobic fraction containing peptides with masses of a few thousand daltons. This fraction has been found in various previous assays to be primarily inhibitory. This inhibitory fraction represents approximately a one hundred fold purification from crude venom on the basis of mass, but it still contains many different peaks when analyzed on reverse phase by gradient elution. We assayed this fraction for activity in blocking electrically stimulated rises in internal Ca^{++} in primary cultures of chick dorsal root ganglion (DRG) and sympathetic ganglion neurons. The change in intracellular Ca^{++} induced by a train of brief extracellular voltage pulses was measured as an increase in the fluorescence of the Ca^{++} indicator dye Fluo-3. The inhibitory fraction of the venom blocked 87% (+/- 2%; n=-10) of the fluorescence increase in DRG cells, and 60% (+/- 2%; n=15) of the increase in sympathetic ganglion cells. The block saturated at a 1:1000 or greater dilution of toxin relative to crude venom and was not reversible during the time course of the experiments. This toxin activity is similar to omega Conotoxin and likely represents a potent block at least of N type channels. Preliminary voltage clamp data on DRG cells also show that this fraction blocks Ca^{++} currents. Purification and analysis of specific toxin components are in progress. (Supported by NIH R01 GM42829.)

A NOVEL CALCIUM CHANNEL BLOCKING CONOPEPTIDE, SNX-230 (M-VIIC), REVEALS MULTIPLE COMPONENTS OF NOREPINEPHRINE RELEASE. S. Gaur, L. Nadasdi, J. Bell, J. Ramachandran, and G. Miljanich*. NEUREX Corporation, Menlo Park, CA 94025.

We have synthesized the conopeptide designated SNX-230 corresponding to a novel ω-like conopeptide, M-VIIC, predicted from a c-DNA sequence obtained from a *Conus magus* venom gland expression library (see abstract by Hillyard, et al.). SNX-230 potently (20pM IC50) inhibits about 50% of release of radiolabeled norepinephrine (*NE) from K^+-depolarized rat hippocampal slices. It inhibits the remaining 50% with much lower potency (65nM IC50). In contrast, ω-conopeptide SNX-111 (synthetic M-VIIA from *C. magus* venom) inhibits a maximum of 65% of *NE release and with moderate potency (0.5nM IC50). To understand the relationship of the conopeptide-sensitive components of *NE release, slices were subjected to both peptides simultaneously: SNX-111 at a maximally (65%) effective concentration (100nM) and SNX-230 at a concentration (1nM) at which it exhibits only its high-potency (50%) inhibitory activity. Surprisingly, *inhibition of *NE release was not complete* - being only about 85% complete. One explanation is that there are four conopeptide-sensitive components of *NE release:

	total effect	comp.1 (35%)	comp.2 (20%)	comp.3 (15%)	comp. 4 (30%)
SNX-230, 1μM	100%	+	+	+	+
SNX-230, 1nM	50%		+		+
SNX-111, 100nM	65%	+			+
SNX-230 + SNX-111	85%	+	+		+

Thus, SNX-111 inhibits components 1 and 4 with about the same moderate potency (0.5nM IC50) and SNX-230 inhibits components 2 and 4 with high potency (20pM IC50) and components 1 and 3 with much lower potency (65nM IC50). Since these inhibitory effects are very likely due to blockade of calcium channels, we believe that the conopeptides SNX-111 and SNX-230 will be uniquely useful reagents in elucidating the roles of their calcium channel targets in neuronal function.

CALCIUM CHANNELS: PHYSIOLOGY II

410.1

LOCALIZATION OF CAFFEINE-SENSITIVE AND IP3-SENSITIVE CALCIUM RELEASE CHANNELS TO DISCRETE AREAS OF THE RAT BRAIN. A.H. Sharp*, P.S. McPherson±, C. Aoki#, T.M. Dawson, K.P. Campbell± and S.H. Snyder. Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205, +H.M.I., Univ. of Iowa, Iowa City, IA 52242 and #C.N.S., New York Univ., N. Y., NY 10003

Release of caffeine-sensitive and IP3-sensitive intracellular Ca2+ stores are mediated by distinct proteins identified as ryanodine receptor (RyR) and IP3 receptor (IP3R), respectively. Rises in intracellular Ca2+ can induce release of Ca2+ from the caffeine-sensitive pool via the RyR, a process known as Ca2+-induced Ca2+ release. We have localized caffeine-sensitive and IP3-sensitive Ca2+ release channels in the brain using specific antibodies raised against purified brain RyR and IP3R, respectively. RyR and IP3R were identified in overlapping populations of neurons in widespread areas of the brain but labeling was reciprocal in a number of areas. For example, while IP3R was enriched in cerebellar Purkinje cells and hippocampal CA1 pyramidal cells, RyR was present at relatively low levels in these cells. RyR was most enriched in the dentate gyrus and CA3/4 areas of the hippocampus, where IP3R was present at relatively low levels. In the cortex, RyR was localized to pyramidal neurons, some of which were not labeled by anti-IP3R antibodies. Electron microscopy in the hippocampus revealed the presence of RyR in axons and in dendritic spines receiving asymmetric synapses while IP3R was primarily identified in dendritic membranes forming symmetric synapses. These results suggest that the IP3- and caffeine-sensitive Ca2+ pools have roles in controlling intracellular Ca2+ levels that are in some cases distinct and that in other cases may interact to varying degrees depending on the neuron and on the subcellular compartment within a given neuron. Supported by MH09953 to AHS, DA00074 to SHS, 2-S07-RR07062-26 to CA and Pfizer Fellowship to TMD. KPC is HHMI investigator.

ACTION POTENTIAL-INDUCED ALTERATIONS IN CYTOSOLIC CALCIUM IN FURA-2-LOADED DISSOCIATED BULLFROG SYMPATHETIC NEURONS. T.J. Heppner* and J.F. Fiekers. Dept. Anatomy & Neurobiology, College of Medicine, University of Vermont, Burlington, VT, 05405, U.S.A.

The kinetics of $[Ca^{2+}]_i$ in response to direct electrical stimulation were examined in dissociated neurons from the 9th and 10th sympathetic ganglia of the bullfrog *Rana catesbeiana*. $[Ca^{2+}]_i$ was determined in individual neurons using a ratiometric analysis with fura-2. Simultaneous recording of action potentials and passive electrical properties were recorded with electrophysiological techniques. Basal levels of $[Ca^{2+}]_i$ ranged from 82 nM to 225 nM (n=19). Trains of action potentials (0.1 to 10.0 Hz) were evoked by depolarizing current injection. The rate of rise of $[Ca^{2+}]_i$ was increased in a frequency-dependent manner. At each stimulus frequency, a maximal level of $[Ca^{2+}]_i$ was obtained and maintained during the train. Basal levels were restored following cessation of stimulation. The addition of Co^{2+} (2 mM) to the extracellular solution abolished the stimulation-induced increase in $[Ca^{2+}]_i$. The $[Ca^{2+}]_i$ response to puffer applications of ACh was decreased during train-induced elevations of $[Ca^{2+}]_i$. These results indicate that the origin of $[Ca^{2+}]_i$ during action potential generation is extracellular and that these neurons are capable of buffering large changes in $[Ca^{2+}]_i$ during and following train stimulation. (Supported by NS 27319).

410.3

SPONTANEOUS CALCIUM OSCILLATIONS IN CULTURED RAT CHROMAFFIN CELLS. A.R. Wakade, D.A. Przywara* & T.D. Wakade. Dept. of Pharmacology, Wayne State University, Detroit, MI 48201.

Rat chromaffin cells (RCC) of 8-day-old pups were cultured and used to measure intracellular Ca^{2+} by Indo-1 dye method, to monitor membrane potential using patchclamp technique and to determine catecholamine release by labeling with $[^3H]$NE. Almost all cultured RCC exhibited spontaneous oscillations (OSC) in intracellular free Ca^{2+} ($[Ca^{2+}]_i$). The OSC were random and varied in frequency, duration and magnitude. Neither cadmium, nifedipine, lanthanum, ryanodine, thapsigargin nor tetrodotoxin or tetraethylammonium affected OSC. $CaCl_2$-free Krebs solution plus 0.5 mM EGTA completely blocked OSC and lowered $[Ca^{2+}]_i$ in RCC. Spontaneous release of $[^3H]$NE was reduced by more than 50% when Ca^{2+} was omitted from the external medium. Low temperature (≈5°C) caused maximum and sustained rise in $[Ca^{2+}]_i$. Whole cell current clamp recordings showed that RCC had unstable resting membrane potentials (Em) and spontaneous action potentials (AP) which varied in frequency. Spontaneous AP were depressed by TTX and blocked by TTX plus Ca^{2+}-channel blockers. However, Em continued to fluctuate in the presence of these blockers. We have ruled out the possibility that Ca^{2+} OSC are due to voltage- or receptor-operated Ca^{2+} channels, or release of Ca^{2+} by intracellular mechanisms. Passive influx of Ca^{2+} could generate OSC and initiate exocytosis in RCC.

410.4

$[Ca^{2+}]_i$ RELAXATIONS AND OSCILLATIONS FOLLOWING CHANGES IN VOLTAGE-DEPENDENT Ca^{2+} ENTRY AND Ca^{2+}-INDUCED Ca^{2+} RELEASE IN BULLFROG SYMPATHETIC NEURONS. D.D Friel* and R.W. Tsien, Dept. of Molec. and Cell. Physiol. Stanford Univ., Stanford, CA 94305.

We studied how $[Ca^{2+}]_i$ relaxes after sudden changes in voltage-dependent Ca^{2+} entry, and uptake and release from a caffeine- and ryanodine-sensitive store. High K^+ (30-50 mM) depolarized V_m and caused a steady $[Ca^{2+}]_i$ elevation, while caffeine (1-10 mM) produced a transient $[Ca^{2+}]_i$ rise. Restoring $[K^+]_o$ to 2 mM led to repolarization and a monotonic decline in $[Ca^{2+}]_i$; caffeine removal produced a transient $[Ca^{2+}]_i$ undershoot. Both relaxations are described by the sum of two decaying exponentials with the same τ_{fast} (~3-5 s) and τ_{slow} (~5-10 min) but with different amplitudes. This is consistent with a three-compartment scheme consisting of the external bath, the cytoplasm and an internal store, with pump and leak fluxes between compartments depending linearly on Ca^{2+} concentration, valid for small departures from the steady state. In this scheme, the τ's reflect the dynamical properties of the system (transport rates, relative cytosolic and store volumes) while the amplitudes additionally depend on the initial conditions. To account for $[Ca^{2+}]_i$ dynamics in the presence of caffeine, an internal Ca^{2+}-dependent leak was introduced. The resulting flux equations exhibit periodic solutions resembling $[Ca^{2+}]_i$ oscillations in the presence of caffeine and high K^+ (Friel and Tsien (1992), Neuron 8, 1-20): (1) ↑$[Ca^{2+}]_o$ → ↑ frequency (f); (2) ↑$[caff]_o$ → ↑f and ↓amplitude, and (3) Ca^{2+} removal has phase-dependent effects on $[Ca^{2+}]_i$. Therefore, a three compartment system with linear Ca^{2+} pumps and leaks and a single $[Ca^{2+}]_i$-dependent leak in the internal store predicts $[Ca^{2+}]_i$ oscillations like the observed ones; nonlinear pumps, etc. are not required. This provides a simple and testable model for caffeine-induced $[Ca^{2+}]_i$ oscillations in sympathetic neurons, and may be useful in the study of caffeine- and ryanodine-sensitive $[Ca^{2+}]_i$ oscillations induced by agonists in non-neuronal cells.

410.5

DISTRIBUTION OF CALSEQUESTRIN, RYANODINE AND IP3 RECEPTORS IN THE CHICK CEREBELLUM: A THREE-DIMENSIONAL IMMUNOLOCALIZATION STUDY. M. E. Martone*, V. M. Simpliciano, T. J. Deerinck, J. A. Airey‡, J. L. Sutko‡, and M. H. Ellisman. San Diego Microscopy and Imaging Resource, Dept. of Neurosciences, U.C.S.D., La Jolla, CA, 92093; ‡Pharmacology, Univ. of Nevada, Reno, NV 89557.

Many proteins involved in intracellular calcium regulation in skeletal or smooth muscle, e.g. the IP3 and ryanodine receptors, calsequestrin, Ca++ ATPase, have been found in brain where they are particularly abundant in the endomembrane system of cerebellar Purkinje neurons (Walton et al., *J. Cell. Biol. 113:* 1145, 1991; Villa et al., *J. Cell Biol. 113*: 779, 1991). While the muscle sarcoplasmic reticulum is planar and ordered relative to the sarcomere, the neuronal endomembrane system anastomoses in three dimensions (3D) presenting formidable obstacles to understanding the organization of calcium regulatory components. In the present study, the distribution of immunolabeling for calsequestrin (CS), the IP3 (IP3R) and ryanodine receptor (RR) was examined in chick cerebellum. Labeling for these proteins was determined in E18 to 4 week old chicks using laser-scanning confocal microscopy. Although labeling for all three proteins was extensively distributed within Purkinje cells, a unique pattern was found for each. Labeling for the IP3R was fairly evenly distributed throughout the cell body, dendrites and dendritic spines while labeling for RR and particularly CS was more discontinuous and not found in spines. The discontinuities in CS labeling appeared most prominent in older chicks. Preliminary analyses of double-labeled preparations suggest that the distribution of RR and CS labeling are not identical. In order to determine the structural basis for this difference, we have adapted a cryosection immunolabeling method for 3D studies using thick sections and high voltage electron microscopy. Labeling for IP3R with 5nm gold was achieved through 0.25 um sections, with good fine structure, by using extended incubation times and elevated temperatures. Through the use of single and double-labeling, we expect to resolve how the spatial distribution of these proteins relates to endomembrane system components thus adding important information to our understanding of the mechanisms by which these cells modulate intracellular calcium.

410.6

DETERMINATION OF THE 3-D CHANGES IN INTRACELLULAR Ca^{++} ACTIVITY IN DISSOCIATED RAT HIPPOCAMPAL NEURONES USING RATIOMETRIC CONFOCAL LASER SCANNING MICROSCOPY.

S.D.Jane, H.R.Parri, H.V.Wheal & J.E.Chad*. Dept. of Physiology and Pharmacology, Univ. of Souhampton, SO9 3TU, UK.

The increase in intracellular calcium ion activity (Cai) within neurones is a powerful and potentially dangerous signal, and is subject to a host of control systems. However, conventional investigative techniques have lacked the resolution to determine the true spatial and temporal extent of these changes.

Confocal Laser Scanning Microscopy (CLSM) can resolve cellular morphology to a sub-micron level in three dimensions (3-D), revealing individual synaptic spines. This capability can be harnessed to the determination of changes in intracellular Ca^{++} ion activity within discrete volume elements (voxels), with the use of Ca^{++} sensitive fluorescent dyes. We have used the acetoxymethyl esters (AM) of the calcium-sensitive fluorescent dyes fluo-3 (10μM) and indo-1 (20μM), to load (60min,18°C) viable, dissociated rat hippocampal neurones. Indo-1, requires UV (360nm) excitation optics (argon ion laser), but can be used for ratiometric measurements.

The Cai responses of neurones to elevated K^+ (20mM), caffeine (20mM) and glutamate (50μM), were tested (objective lens Nikon x60 PlanApo, NA 1.4). The experimental design was to record z-series image data under control conditions, in the presence of the stimulus, after wash, in the presence of ionomycin, and finally with ionomycin and extracellular EGTA. The last two conditions give a calibration for maximal (saturated) and minimal Ca^{++} loading of the dye. Caffeine gave the most consistent data, with apparently widespread elevations in Cai (n=20/20 viable cells). Both glutamate and high K^+ also produced increases in Cai but less consistently. We are presently refining our techniques to unequivocally determine the subcellular localisation and extent of the changes in Cai due to different stimuli.

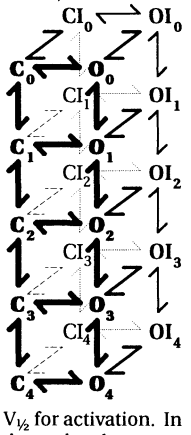
AN ALLOSTERIC MODEL FOR INACTIVATION OF VOLTAGE-DEPENDENT CHANNELS. Stephen W. Jones*. Dept. Physiol. & Biophys., Case Western Reserve Univ., Cleveland, OH 44106.



Activation kinetics of L-type calcium channels can be described based on the Monod-Wyman-Changeux model, with movement of a voltage sensor corresponding to ligand binding, and channel opening corresponding to activation of the protein; the channel opens more readily with more voltage sensors moved (Marks & Jones, *J. Gen. Physiol.* **99**, 367-390, 1992). A model where inactivation is also allosterically coupled to voltage sensor movement can explain (1) voltage-dependent macroscopic inactivation, (2) voltage-*in*dependent microscopic inactivation, (3) strong inactivation at depolarized voltages, but rapid recovery from inactivation at negative voltages, and (4) $V_{½}$ for inactivation more negative than $V_{½}$ for activation. In its simplest form, where inactivation rates depend on how many voltage sensors have moved but *not* on whether the channel is open or closed (or on voltage), the model has 9 free parameters.

410.8

Depolarizing afterpotentials and the T-type calcium current in hippocampal dentate granule neurons: experimental and computer simulation.

T. A. Valiante, L. Zhang, N. Gurevich* and, P. L. Carlen. Playfair Neuroscience Unit, Toronto Western Hospital, M5T 2S8, Departments of Physiology and Medicine (Neurology), Addiction Research Foundation, Bloorview Epilepsy Foundation, University of Toronto, Toronto, Ontario, Canada.

Among intrinsic ionic events, post-spike potentials are known to play an important role in regulating neuronal excitability. In mature dentate granule (DG) neurons, a single action potential is followed by a depolarizing afterpotential (DAP). Ca^{2+}-dependant conductances have been suggested to contribute to the DAP in mature DG neurons and, play a role in post-spike depolarizing afterpotentials in other mammalian CNS neurons. We used whole cell and, perforated patch recording techniques to determine the ionic mechanisms underlying the DAP in hippocampal slices of postnatal day 10-17 rats. DAPs were generated either by antidromic stimulation of the mossy fiber pathway or with brief depolarizing current steps. DAPs display an all or none type of behaviour and, DAP like potentials can be generated in the presence of tetrodotoxin. Of the three types of calcium currents (transient low threshold or T-type; transient high threshold or N-type and, sustained high threshold or L-type) only the T-type calcium current displays strong voltage dependent inactivation, persists when evoked at 2 Hz and, is blocked by Ni^{2+}. That these properties are shared by the DAP, indicates that the T-type calcium current may play a role in the genesis of the DAP in immature DG neurons. From voltage clamp data we characterized the T-type current according to an m^3h Hodgkin-Huxley formulation and incorporated this current into a compartmental model of a DG neuron. Computer simulations of antidromically evoked action potentials indicate that the kinetics of the T-type calcium current are sufficient to generate a DAP like potential if the T-type calcium conductance has both a somatic and dendritic distribution.

THEORETICAL AND EXPERIMENTAL STUDIES OF PANCREATIC ISLET CELL BURST CURRENTS USING A BURST-WAVEFORM VOLTAGE-CLAMP COMMAND. L.S. Satin* and P.D. Smolen. Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA. 23298 and Biomathematics Research Branch, NIDDKD, Bethesda, MD. 20892

We recently suggested that a slowly-inactivating Ca current may act as a burst pacemaker mechanism in pancreatic islet B-cells (Cook, Satin and Hopkins (1991),TINS **14**:411-414). To test this hypothesis, a burst-waveform voltage command (BWC) that mimicked a B-cell burst was used to drive different theoretical models of bursting as well as voltage-clamped insulin-secreting HIT cells. The BWC started from a silent potential of -50 mV and slowly depolarized to a plateau of -30 mV from which spikes to -10 mV commenced. The spiking phase lasted for 7 seconds and was followed by repolarization to the next interburst. To simplify the analysis of Ca current, 20 msec test pulses to +20 mV were superimposed on the BWC at 1 Hz. *Results:* Models that incorporated slow Ca current inactivation predicted slow Ca current decay during the burst-waveform plateau and recovery during the interburst. Application of the same BWC to HIT cells whose Ca current was pharmacologically isolated (Satin and Cook, 1989; Pflugers Archiv **414**:1-10) showed that Ca current initially activated and then slowly inactivated during the BWC, supporting the recent models. In addition, analysis of spike currents suggests that fast inactivation may contribute to spike repolarization. Application of BWC appears to be a powerful new approach for understanding the bursting mechanisms of excitable cells.

ISOLATION OF NOVEL NEURONAL CALCIUM CHANNEL BETA SUBUNITS. E. Massa and M.D. Uhler* Graduate Program in Neuroscience, Mental Health Research Institute and Department of Biochemistry, Mental Health Research Institute, Ann Arbor, MI 48105.

The dihydropyridine-sensitive calcium channels in rabbit skeletal muscle consist of α_1, α_2, β, and γ subunits. The cDNAs of these skeletal muscle subunits have been cloned. The β subunit has been further characterized and shown to have two genes that encode for homologous proteins. β_1 is expressed in skeletal muscle and brain. In contrast, β_2 is expressed in brain, heart and lung. In order to isolate splice variants of the β_2 subunit, we screened a mouse brain cDNA library with a 900 bp DNA fragment corresponding to the first 900 nucleotides of the rabbit skeletal muscle β subunit coding region. Preliminary characterization of the isolated clones suggests that multiple splice variants of the β_2 exist in brain. Sequencing of one clone demonstrated the existence of a previously undescribed splice variant. The predicted amino terminal sequence of this splice variant was found to diverge from the published β_2 subunit sequence at amino acid 17. Initial characterization of the other clones suggests that additional splice variants of the β_1 subunit exist in brain. In the future, coexpression of these novel β_1 subunit splice variants with mouse neuronal α_1 subunits, currently being cloned in our laboratory, will be performed.

410.11

ISOLATION AND CHARACTERIZATION OF THE P-TYPE CALCIUM CHANNEL FROM MAMMALIAN MUSCLE. B. Cherksey*, M. Sugimori and R. Llinás. Dept. Physiol. & Biophys., NYU Med. Ctr. New York, N.Y. 10016

P-type calcium channels, which are specifically blocked by the polyamine channel blocker "synthetic FTX", have been shown, both functionally (Llinas, et al PNAS, 1989) and immunohistochemically(Hillman, et al, PNAS, 1991), to be present in diverse regions of the CNS. However, little is known about their distribution outside of the brain.

The polyamine, 1-arginyl N,N',-Bis(3-aminopropyl)-1,4-butane-diamine, which we have previously termed synthetic FTX(3:4) was coupled to Sepharose 4B CL via a 1,4-Butanediol Diglycidol ether linkage. This affinity gel allowed the extraction of a protein from rat solubilized skeletal muscle homogenate. The functional activity of the resulting protein solution was assessed using the "tip-dip" bilayer technique. The electrical activity was measured in solutions containing: 80 mM BaCl2, 10 mM HEPES, pH 7.4 in the pipette; 120 mM CsCl, 10 mM HEPES, pH 7.4 in the bathe. Single channel activity was recorded under these conditions was characterized by a slope conductance of 15±5 pS. The i-V curves exhibited some rectification. Erev was at +100±20 mV. The channel was rarely open at potentials more negative than -70 mV and opened with increasing frequency as the potential was made more positive. Single channels were blocked by the addition of Cd or Co at concentrations below 100 μM and by both the polyamine blocker synthetic FTX and by natural FTX. Ensemble averages of 60 mV steps from -90 to -30 mV showed that the channel activity did not inactivate during the 200 msec pulse duration.

Analysis of the protein solution isolated using the polyamine affinity gel was performed using SDS Polyacrylamine Gel Electrophorsesis. Under reducing conditions, only a single band (a doublet structure) at a molecular weight of 80±5 kDaltons was seen when gels were silver stained.

The results we have obtained suggest that the protein isolated from mammalian skeletal muscle using an sFTX affinity gel is a P-channel of similar structure and behavior to that found in CNS.

CHARACTERIZATION OF P-TYPE CALCIUM CHANNELS IN CEREBELLAR PURKINJE CELLS. M.M. Usowicz*, M. Sugimori, B. Cherksey & R. Llinás Dept. of Physiology and Biophysics, NYU Medical Center, 550 First Avenue, New York, NY 10016

There is good agreement between the pharmacological profiles of P-type Ca channels in cerebellar Purkinje cells, Ca channels expressed in *Xenopus* oocytes from brain mRNA, and the cloned BI brain Ca channel (see Tsien *et al*, TIPS 12, 349). However, it has been difficult to compare the biophysical properties of these channels, because the currents have not been recorded with the same Ba concentrations. Therefore, we have recorded P-type Ca channel currents carried by Ba ions ranging in concentration from 1mM to 110mM, and also by 2.4mM Ca. Cell-attached patch recordings were made at 22°C from the somata of adult Purkinje cells in thin cerebellar slices of the guinea-pig (Edwards *et al*, Pflugers Archiv 414:600).

The threshold of activation varied linearly with the log of $[Ba]_o$; it was shifted towards positive potentials as $[Ba]_o$ was increased, presumably due to screening of the surface potential by Ba ions. For instance, it was -48mV with 2mM Ba, -41mV with 5mM Ba and -23mV with 40mM Ba. Currents carried by 2.4mM Ca activated at about -41 mV. Moreover, we found little difference in single-channel conductances measured with 10-110mM Ba; channel openings were to three conductance levels of 10pS, 14-16pS and 19-21pS (slope conductances). As $[Ba]_o$ was reduced below 10mM, the unitary currents became progressively smaller and multiple levels could not be resolved. Single-channel currents carried by 2.4mM Ca were barely resolvable.

P-CHANNEL IS RESPONSIBLE FOR HIGH-THRESHOLD DENDRITIC ACTION POTENTIAL IN INFERIOR OLIVE NEURONS, AN FTX STUDY. A. Manfridi*, B. Cherksey, M. Sugimori and R. Llinás. Dept. Physiology and Biophysics, NYU Medical Center, 550 First Avenue, NY, NY 10016.

Inferior olive cells have been shown to exhibit high-threshold and low-threshold calcium spikes (Llinás & Yarom J. Physio. 315:549,1981). The low-threshold spike is generated by a conductance consistent with the presence of T-type voltage-dependent calcium channels. The type of channel resonsible for the high-threshold spike has not been determined. A histochemical study of the distribution of P-channels in the CNS using P-channel specific antibodies indicated that the inferior olivary neurons express P-channels in abundance (Hillman et al. PNAS 88:7076,1991).

Since a polyamine purified from *Agelenopsis Aperta* (FTX) has been shown to block P-channels (Llinás et al. PNAS 86:1689,1989) the effect of HPLC-purified FTX as well as whole venom of *Agelenopsis Aperta* was tested in intracellularly recorded inferior olive neurons in guinea pig brainstem slices. Both of these substances produced a clear block of the high-threshold calcium spiking without affecting either the sodium action potential, the low-threshold calcium spike or calcium-dependent potassium conductance that generates the afterhyperpolarization. By contrast, the large high-threshold calcium dependent action potential and the afterhyperpolarization that follow were blocked. In addition, when the cell was depolarized, repetitive high-frequency sodium-dependent action potentials could be obtained. The results indicate at least two calcium conductances are found in the inferior olive, a T-type conductance responsible for the low-threshold spike and the P-type channel responsible for most of the high-threshold spike. (Supported by NIH grants AG09480 and NS13742)

410.14

IMMUNOLOGIC AND KINETIC CHARACTERIZATION OF A Na^+/Ca^{2+} EXCHANGER IN PRIMARY NEURONAL CELL CULTURES. **G. Hoel*, R. Pal, M. Hurlbert, J. Walsh, and M.L. Michaelis. Dept. Pharmacology and Toxicology, and Center for Biomedical Research, University of Kansas, Lawrence, KS 66045.**

The plasma membrane Na/Ca exchanger is believed to play a role in regulation of Ca fluxes in neurons. We recently reported the development of Ab's against a 36 kDa synaptic membrane protein which immunoprecipitated exchanger activity from solubilized membranes (J. Neurochem. 58:147, 1992). We have now used those Ab's to label primary neurons in culture with avidin-biotin conjugates to peroxidase. The antibodies produced significant labelling of axons, dendrites and cell bodies in neuronal cultures prepared from 18-day embryonic rat brain. Given the substantial amount of Ab labelling of the cells, it was of interest to see whether these cells exhibited Na /Ca exchanger activity with properties similar to those reported for adult brain synaptic membrane preparations. Points of contact between neurons stained quite heavily. Sodium-dependent Ca^{2+} transport was measured in washed homogenates of primary cortical neurons maintained for 3 -6 days in serum-free, defined culture medium. Kinetic determinations of transport activity revealed that Ca^{2+} uptake was linear for at least 30 seconds at 23° C. Uptake was measured across Ca^{2+} concentrations using 20 sec incubations and the kinetic constants were determined to be: K_{act} for Ca = ~ 39 uM and the V_{max} = ~ 0.55 nmol/mg protein/sec. These values are quite close to those reported for other mammalian brain preparations. (Supported by grant AA04732 and MMD Sci. Educ. Partnership).

AFFERENTS TO THE MESOPONTINE CHOLINERGIC NUCLEI FROM THE PERIAQUEDUCTAL GRAY IN THE RAT

T.L. Steininger* and B.H. Wainer, Comm. on Neurobiology, and Dept. Pharm. and Phys. Sci., The University of Chicago, Chicago, IL 60637.

A large body of evidence suggests that the mesopontine cholinergic groups, the pedunculopontine tegmental (PPT) and laterodorsal tegmental (LDT) nuclei, participate in mechanisms of behavioral state control; specifically in arousal and the generation of rapid eye movement sleep. Previous retrograde tracing studies have identified putative afferents to the PPT from numerous regions, including the midbrain and brainstem reticular formation, lateral hypothalamic area, dorsal raphe nucleus, and the periaqueductal gray (PAG), particularly the ventrolateral region (Steininger et al., J. Comp. Neurol., in press). In the present study, we have utilized anterograde tracing with PHA-L combined with choline acetyltransferase immunohistochemistry to examine the PAG innervation of the mesopontine cholinergic neurons. At the light microscopic level, a dense innervation of PHA-L labeled fibers was observed in the region of the PPT and LDT. At higher magnification, numerous putative contacts were observed between anterogradely-labeled boutons and cholinergic neurons. The functional implications of these connections are unclear, but may be involved in mediating the physiological and behavioral correlates of arousal that are features of the 'defense reaction' elicited experimentally by ventrolateral PAG stimulation. (Supported by NS 17661 and MH 09919)

MEDIAL PREFRONTAL CORTEX PROJECTS DIRECTLY TO CHOLINERGIC NEURONS OF THE MESO-PONTINE TEGMENTUM R.S. Revay* and S.J. Grant Depts. of Biological Sciences, Psychology and Program in Neuroscience, University of Delaware, Newark, DE 19716

Stimulation of the medial pre-frontal cortex (MPFC) reliably activates neurons in meso-pontine nuclei including the laterodorsal tegmental nucleus (LDT) and rostral locus coeruleus (rLC). Although anatomical studies report direct projections from the MPFC to the LDT it is not clear if these cortical afferents directly and/or selectively contact the cholinergic neurons in the LDT. In order to resolve this question we used Phaseolus leucoagglutinin (PhaL) injected into the rat MPFC to label afferent fibers, and NADPH-diaphorase histochemistry to identify cholinergic neurons .

Both cholinergic and non-cholinergic neurons in the LDT were contacted by numerous branched and varicose afferent fibers. The fibers were denser at rostral levels and formed a continuous plexus that extended from the LDT to the adjacent dorsal raphe (DR), but avoided the intervening dorsal tegmental nucleus of Gudden. Some fibers swept laterally into the dorsolateral portion of the pedunculo-pontine nucleus. Fibers also extended ventrally into the reticular formation. Laterally, fibers generally spared Barringtons nucleus, but PhaL positive fibers occasionally entered the rLC. Fibers in the LC appeared thicker than fibers in other areas. The relative number of PhaL labeled fibers in the LDT and LC was related to the dorso-ventral positioning of the injection.

This study is consistent with our stimulation and pharmacologic studies suggesting a monosynaptic excitatory amino acid projection from the MPFC to the LDT. Studies combining retrograde tracers with glutamate immunohistochemistry are in progress to verify the cortical transmitter.

411.3

ACTIONS OF CARBACHOL ON SYNAPTIC TRANSMISSION IN THE RAT NUCLEUS RAPHE DORSALIS (DR) IN VITRO. S. Birnstiel*, R.W. McCarley and R.W. Greene. Neuroscience Lab., V.A. Medical Center, Brockton, MA 02401.

The cholinergic agonist carbachol has been shown to induce a REM-sleep like state in vivo, whereas the serotonergic neurons in the DR have been postulated to inhibit REM. In order to investigate possible interactions between cholinergic and serotonergic systems, recordings were obtained from coronal slices of the rat brainstem with the electrical stimulation placed ventrolaterally to the DR.

Carbachol (1-10 μM) depolarized 23 out of 58 cells tested by about 4 mV with no significant change in membrane resistance. Carbachol had no effect on the membrane potential in 30 neurons and caused a hyperpolarization with a decrease in input resistance in 5 cells. The hyperpolarization, but not the depolarization persisted in the presence of TTX. Carbachol (10 μM) decreased the stimulus-evoked biphasic postsynaptic potentials (PSPs; recorded with electrodes filled with 2 M K-Methylsulfate). PSPs remaining in the presence of 50 μM bicuculline as well as those remaining in the presence of 2 mM kynurenate were equally reduced by carbachol. Preliminary results indicate that this action is mediated by muscarinic receptors, since it is blocked by atropine and not mimicked by the nicotinic agonist 1,1-Dimethyl-4-Phenyl-Piperazinium Iodide.

The present results suggest a presynaptic muscarinic inhibiton of evoked excitatory and inhibitory amino-acid mediated neurotransmission in the DR. (Supported by the DFG and NIMH grant MH39683.)

411.4

CHOLINERGIC MESOPONTINE TEGMENTAL NEURONS WITH BILATERAL PROJECTIONS TO THE PONTOMEDULLARY BRAIN STEM: A FLUORESCENT TRIPLE LABELING STUDY IN THE RAT M. Yanagihara*, K. Ito, L. Dauphin, & R. W. McCarley. Lab. Neurosci.,Dept.Psych.,Harvard Med.Sch./VAMC, Brockton Ma 02401.

The descending cholinergic projection from the laterodorsal tegmental (LDT) and pedunculopontine tegmental (PPT) nuclei to the pontomedullary reticular formation is thought to be implicated in the regulation of the rapid-eye-movement (REM) sleep phase. The fluorescent triple labeling methodology combined choline acetyltransferase (ChAT) labeling by fluorescent (AMCA) immunohistochemistry with the use of two different fluorescent retrograde tracers, fluorescein- and rhodamine-conjugated latex beads. The retrograde tracers were injected into the each side of the pontomedullary reticular formation and adjacent structures in 13 rats. In each case, triple-labeled neurons were found in the LDT and PPT nucleus, indicating ChAT immunopositive neurons with bifurcating axons. Overall, there was a contralateral projection in about 22% of all ipsilaterally projecting neurons in the pons and 15% in the medulla for the PPT. Furthermore, for contralaterally projecting PPT neurons, there were ipsilateral branches in 38% in the pons and 22% in the medulla. LDT percentages were less in both cases. Quantitative volumetric measurements indicated that all injections of retrograde label occupied less than 3% of the reticular nuclei; despite this small volume of injection, bilaterally projecting cholinergic neurons constituted 1.1% of PPT cholinergic neurons, and 0.35% of LDT cholinergic neurons. Such bilaterally projecting neurons appear suited for global regulation of excitability throughout the pontomedullary reticular formation and adjacent cholinoceptive structures.

411.5

Carbachol Induced Hyperpolarization of Neurons in the Rat Laterodorsal Tegmental Nucleus *in vitro*. Luebke, J.I.*, McCarley, R.W., & Greene, R. W. Neuroscience Lab, Dept. Psychiatry, Harvard Medical School, Brockton V.A.M.C, Brockton, MA 02401

Intracellular recordings were made from laterodorsal tegmental nucleus neurons in the *in vitro* brainstem slice preparation. Recordings were obtained from 95 cells which had mean input resistances of 160 (+/- 45) MOhms and action potential overshoots of at least 10mV. Virtually all cells, regardless of their cholinergic or non-cholinergic nature, responded to the application of carbachol (1-10 μM) with a membrane hyperpolarization and associated decrease in input resistance. Under voltage clamp conditions this response was shown to be due to an outward current that was strongly inwardly rectifying and had a reversal potential near the equilibrium potential for potassium. The carbachol response was partially blocked by cesium (2 mM) and fully blocked by barium (100 μM)-providing additional evidence for the activation of an inwardly rectifying potassium conductance by carbachol. The carbachol effect was not blocked by low concentrations of the M1 antagonist pirenzipine, indicating that the response was due to the activation of non-M1 acetylcholine receptors.

Supported by the Dept. of Veteran's Affairs and N.I.M.H. grant MH39683.

411.6

NORADRENALINE HYPERPOLARIZES CHOLINERGIC NEURONS IN RAT LATERODORSAL TEGMENTUM *IN VITRO*. J.A. Williams* and P.B. Reiner Kinsmen Laboratory of Neurological Research, Dept. of Psychiatry, University of British Columbia, Vancouver, B.C. Canada, V6T 1Z3.

Inhibition of brainstem cholinergic neurons by noradrenergic neurons of the locus ceruleus has long been suggested as one mechanism of behavioral state control. While there is anatomical evidence for a noradrenergic innervation of cholinergic neurons in the rat laterodorsal tegmentum (LDT), the direct inhibitory influence of noradrenaline upon cholinergic neurons has never been demonstrated. The purpose of the present study was to characterize the effect of noradrenaline upon cholinergic neurons in the rat LDT. Using whole-cell patch clamp recordings in slices, 26 cells were studied during bath application of 50 μM noradrenaline (NA). Cholinergic neurons were positively identified by intracellular labelling with biocytin and subsequent NADPH-diaphorase staining. 93% (13/14) of identified cholinergic neurons hyperpolarized with an increase in conductance in response to noradrenaline. In contrast, non-cholinergic neurons exhibited mixed responses to NA (25% [3/12] hyperpolarized, 33% [4/12] depolarized, 42% [5/12] no response). Bath application of 1 μM idazoxan, an α_2 adrenergic antagonist, blocked the hyperpolarizing effect of NA on cholinergic cells. To test whether the response to NA was a direct effect, some slices were bathed in low Ca^{2+}, high Mg^{2+} ACSF solution. The responses of cholinergic cells to NA in this condition were identical to those in normal ACSF. These results demonstrate for the first time the direct hyperpolarization of cholinergic neurons by NA, and that this is an α_2-mediated effect.

EFFECTS OF SEROTONIN UPON BASAL FOREBRAIN NEURONS *IN VITRO*. Natalia A. Gorelova* and Peter B. Reiner, Kinsmen Laboratory of Neurological Research, Department of Psychiatry, University of British Columbia, Vancouver, BC V6T 1Z3 Canada.

Neurons of the basal forebrain project to the hippocampus and cerebral cortex and are thought to be intimately involved in the control of cortical arousal. Anatomical studies have demonstrated the existence of serotonergic afferents to the basal forebrain. Moreover, there is considerable evidence that serotonergic inputs to the medial septum are involved in generation of some types of hippocampal theta rhythm.

In order to understand the role of serotonergic afferents in control of cortical arousal, we studied the responses of basal forebrain neurons (medial septum, diagonal band) to serotonin using whole-cell patch clamp recordings in an *in vitro* slice preparation. Basal forebrain neurons exhibited heteregenous physiological properties, with a mean resting membrane potential of -52 ± 4.8 mV and input resistance of 350 ± 152 MΩ. In accord with the variable electrophysiological properties of basal forebrain neurons, responses to serotonin also varied. Of twelve cells studied, 6 cells depolarized, 2 cells hyperpolarized and 4 cells showed no response. Current efforts are directed towards correlating transmitter status with responses to serotonin.

NUCLEUS BASALIS STIMULATION ELICITS NEOCORTICAL ACTIVATION AND FACILITATES THALAMOCORTICAL SYNAPTIC TRANSMISSION: INTRACELLULAR AND EXTRACELLULAR RECORDINGS IN RAT AUDITORY CORTEX Raju Metherate* and John H. Ashe Departments of Neuroscience and Psychology, University of California, Riverside CA 92521

Neocortical activation (EEG desynchronization) reflects a state of behavior and cortical information processing. Through largely undetermined cellular mechanisms, the neurotransmitter acetylcholine (ACh) is thought to be involved in neocortical activation. Since nucleus basalis (NB) neurons are a primary source of cortical ACh, these cells may mediate EEG activation. We have examined this hypothesis, and the implications of cortical activation for thalamocortical transmission, by stimulating the NB and the auditory thalamus (medial geniculate, MG) during intracellular and extracellular recordings in the middle to deep layers of auditory cortex in urethane-anesthetized rats.

Electrical or chemical stimulation of the caudal NB desynchronized the local EEG recorded in auditory cortex; this action was blocked by cortical application of the muscarinic receptor antagonist atropine. Simultaneously with its effect on the EEG, NB stimulation elicited depolarization (1-10 mV) of cortical neurons and altered subthreshold membrane potential fluctuations from large amplitude, slow (1-5 Hz) oscillations to low amplitude, fast (25-40 Hz) oscillations. MG stimulation elicited in auditory cortex an afferent volley (peak latency ca. 2 ms) followed at short latency (ca. 3 ms onset, 7 ms peak) by a negative-going field potential, or intracellularly, an excitatory postsynaptic potential (EPSP). NB stimulation did not alter the thalamocortical afferent volley, but facilitated the slope and amplitude of the negative-going field potential via a muscarinic action. NB stimulation also enhanced MG-evoked EPSPs, producing a higher probability of evoked spike discharge.

These data suggest that one function of ACh-mediated neocortical activation is to facilitate thalamocortical transmission.

Ca^{2+}/CALMODULIN KINASE MEDIATES MUSCARINIC BLOCKADE OF $g_{K(Ca)}$ AND ENHANCEMENT OF Ca^{2+} CHANGES IN HIPPOCAMPAL CA3 PYRAMIDAL NEURONS W. Müller#*, J.J. Petrozzino*, L. Griffith*, W. Danho§ and J.A. Connor *Dept. of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley NJ 07110 §Peptide Research Department, Hoffmann-LaRoche, Inc., Roche Research Center, Nutley NJ 07110 #Max-Planck-Institut für biophys. Chemie, W-3400 Göttingen, FRG.

An important intrinsic control of excitability in pyramidal neurons of the hippocampus is represented by adaptation of discharge during constant stimulation and a slow afterhyperpolarization following repetitive discharge. This negative feedback is mediated by Ca^{2+} dependent K-conductances $g_{K(Ca)}$ and is subject to down-modulation by muscarinic, serotonergic and glutamatergic inputs. Muscarinic modulation is of particular interest for its important role in synaptic plasticity and learning. This input uncouples intra-dendritic Ca^{2+} from $g_{K(Ca)}$ activation and thereby potentiates intradendritic Ca accumulations, a factor that possibly underlies facilitation of synaptic plasticity during muscarinic activation.

Using new peptide inhibitors of Ca^{2+}/calmodulin dependent kinase (CaM kinase) and PKC we found that muscarinic modification of $g_{K(Ca)}$ and Ca^{2+}-changes relies on CaM kinase activation, but the converging effects of serotonergic and glutamatergic agonists are mediated either through other kinases or by entirely different processes. We surmise that these in large part separate pathways include also divergent branches that are relevant for distinct functions of these neurotransmitters.

MUSCARINIC AGONISTS AND PHORBOL ESTERS FACILITATE GLUTAMATE-MEDIATED RESPONSES IN RAT AUDITORY CORTEX *IN VITRO*. C.L. Cox*, J.H. Ashe and S. Haeri, Departments of Neuroscience and Psychology, University of California, Riverside, CA 92521.

The actions of muscarinic agonists, methacholine (MCh) and oxotremorine-M (Oxo-M), and the phorbol ester, phorbol 12,13 dibutyrate (PDBu), were tested upon glutamate-mediated membrane depolarizations. Glutamate, iontophoretically applied, (1M, 15-100 nA) produced a membrane depolarization associated with a decrease in membrane resistance. Iontophoretically applied acetylcholine (ACh)(1 M, 25-100 nA) or MCh (1 M, 25-100 nA) produced no or little (<2 mV) change in membrane potential, a slight increase in membrane resistance and a decrease in spike frequency accommodation. However, ACh or MCh facilitated the amplitudes of the glutamate-mediated membrane depolarizations that persisted for several minutes following the offset of the cholinergic agonists. The muscarinic antagonists, atropine (1 μM) and pirenzepine (1 μM), suppressed the facilitation. Oxo-M (100 μM), also produced a lasting facilitation of the glutamate depolarizations. These data suggest that activation of muscarinic receptors can produce a facilitation of glutamate-mediated responses.

Muscarinic receptor activation has been associated with an increase in phosphatidyl inositol turnover and activation of protein kinase C (PKC). We therefore tested the action of a PKC activator, PDBu, upon the glutamate depolarizations. PDBu (50-100μM), depolarized the cortical neurons and also produced a facilitation of the glutamate-mediated membrane depolarizations. The facilitation of the glutamate depolarizations outlasted the membrane depolarization produced by the phorbol ester. Furthermore, the facilitation of the glutamate depolarization persisted during clamping of the membrane potential at pre-drug levels, suggesting the facilitation is independent of the membrane depolarization produced by PDBu.

These data suggest that 1) activation of muscarinic receptors can facilitate the amplitude of glutamate-mediated depolarizations, 2) PKC activation facilitates glutamate-mediated depolarizations and 3) these actions occurs independent of a change in membrane potential suggesting a potential neuromodulatory action Supported by NSF BNS 9008818.

411.11

CHOLINERGIC SLOW SYNAPTIC ACTIONS ON RAT NEOCORTICAL NEURONS *IN VITRO*. J.H. Ashe*, C.L. Cox, R. Metherate and E. Jobst. Depts. of Neuroscience and Psychology, Univ. of Calif., Riverside, CA 92521.

Acetylcholine (ACh), exogenously applied, can produce lasting modifications of functional characteristics of cortical neurons. However, the actions of synaptically released ACh upon neuronal excitability and synaptic transmission in neocortex is not clearly understood. These experiments investigated the action of cholinergic agonists and endogenous ACh upon auditory cortical neurons.

Tetanic stimulation of deep cortical gray matter (10-100 μA; 8-40 pulses, 20-80 Hz) elicited a voltage-dependent long-lasting slow membrane depolarization (tens of seconds to many minutes). The slow depolarization persisted in the presence of amino acid antagonists (DNQX, APV, picrotoxin). Tetanic stimulation also produced voltage dependent 1) decreased spike frequency accommodation, 2) decreased slow afterhyperpolarization and 3) facilitated afterdepolarization. The effects of the tetanic stimulation were mimicked by exogenously applied cholinergic agonists, ACh and methacholine (MCh), enhanced by the anticholinesterase eserine, and attenuated by the muscarinic antagonists atropine or pirenzepine. These data suggest that synaptically released ACh produces multiple voltage-dependent actions via muscarinic receptors.

A subpopulation of neurons has been identified as "rhythmic bursting" neurons due to their low frequency rhythmic (5 Hz) bursting discharge to a depolarizing current pulse. These cells have been histologically identified as layer 5 pyramidal neurons, following biocytin injection. In these cells, tetanic stimulation reduced the number of bursts and increased the number of higher frequency (10-15 Hz) single spike discharge in response to a depolarizing current pulse, independently of membrane depolarization. This effect was enhanced by eserine, blocked by atropine and mimicked by muscarinic agonists, MCh and oxotremorine-M.

These data suggest that synaptically released ACh, acting via muscarinic receptors, can modulate the excitability of neocortical neurons. Modulation of the excitability of these neurons may influence the neurons response to subsequent afferent synaptic information and may serve as a potential mechanism of synaptic plasticity. Supported by NSF BNS 9008818.

411.12

CHOLINERGIC AND NORADRENERGIC MODULATION OF A SLOW OSCILLATION IN CAT NEOCORTICAL CELLS. F. Amzica*, A. Nuñez and M. Steriade, Lab. of Neurophysiology, Laval Univ. Sch. of Med., Quebec, Canada G1K 7P4.

Neocortical cells recorded from cat association areas 5 & 7 display an oscillation around 0.3 Hz, consisting of depolarizing and/or hyperpolarizing sequences, time-locked with a similar EEG rhythm (Steriade et al., this meeting). Here we report the modulation of this novel type of slow neuronal oscillation by shifting the EEG synchronization (high-amplitude and slow waves) to activated patterns. We used intracellular recordings of cortical cells under urethane anesthesia and changed the EEG state by a brief stimulation (pulse-trains at 30 Hz lasting for 1 s) of pedunculopontine tegmental (PPT) and locus coeruleus (LC) nuclei.

In most cells, PPT stimulation induced a depolarization (3-5 mV) associated with tonically increased firing and lasting for 10-20 s. The slow oscillation was blocked for 5-10 s and resumed thereafter. This cellular effect was voltage-dependent, as it could not be obtained at a membrane potential more negative than -85 mV. In some neurons, in which the oscillation mainly consisted of rhythmic hyperpolarizations sculpturing the background firing, PPT stimulation interrupted the oscillation by selectively suppressing the hyperpolarizing episodes. The time-course of the PPT-induced blockage of slow oscillation was similar to that of EEG activation. The PPT effect was suppressed by systemic administration of a muscarinic blocker, scopolamine. LC stimulation produced qualitatively similar effects on cells and EEG activity, but less pronounced and durable. After clonidine administration, the effects of LC stimulation were no longer observed. The similarity between the cholinergic and noradrenergic effects suggests that the major mechanism underlying the blockade of the slow cortical oscillation, and especially of the rhythmic hyperpolarization, is the reduction or suppression of potassium conductances. Supported by MRC of Canada (grant MT-3689).

SERIAL SECTION ANALYSIS OF THE ACETYLCHOLINE (ACh) INNERVATION IN ADULT RAT PARIETAL CORTEX. D. Umbriaco*, K.C. Watkins, L. Descarries, C. Cozzari and B.K. Hartman. CRSN, (Départements de pathologie et de physiologie), Université de Montréal, Montréal, Qué., CANADA; Istituto Biologia Cellulare CNR, Roma (ITALY), and Department of Psychiatry, University of Minnesota, Minneapolis (MN).

We have now completed the electron microscopic examination in serial thin sections of 785 ACh axon terminals (varicosities) from adult rat parietal cortex (Par1), immunostained with monoclonal antibodies against purified rat brain choline acetyltransferase (*Soc. Neurosci. Abstr.* 16: 200, 1990). This material from 4 rats was initially fixed by perfusion of a paraformaldehyde (2.5%)-glutaraldehyde (0.1%) mixture, and processed with the ABC method. 140 varicosities of layer I, 123 of layers II-III; 147 of layer IV; 159 of layer V and 216 of layer VI were photographed from end to end and examined at a final magnification of X 36 000 (average of 11 pictures per varicosity). The mean maximal transverse diameter of these varicosities was similar in every layer (0.49 ± 0.15 μm s.d.). Both large and small varicosities could be observed on the same fibers. In each layer, a relatively small proportion of the varicosities exhibited a synaptic membrane differentiation (9.3% in layer I; 13.8% in II-III; 11.6% in IV; 22% in V; 14.8% in VI), for a I-VI average of 14.5%. These 118 synaptic junctions were almost invariably symmetrical (98.2%). A majority were found on dendritic branches (80.7%), some on spines (22.8%) and none on cell bodies. Junctional and non junctional varicosities were present on the same fibers. There were only 4 varicosities with dual junctions and the 2 asymmetrical junctions were on spines in layers I and II-III. These data indicate that the ACh innervation in every layer of adult rat parietal cortex is mostly non junctional, with a slightly higher proportion of synaptic varicosities in layer V. Identification of receptive elements will be needed to determine the functional targets of such an innervation. [Supported by the FCAR and grants MT-3544 (MRC) and NS 12311].

CHOLINERGIC INNERVATION OF THE HUMAN AMYGDALOID COMPLEX. M. Emre, C. Geula, M-M. Mesulam* Harvard Medical School, Boston, MA 02215

The cholinergic innervation of the human amygdaloid complex was studied using choline acetyltransferase (ChAT) immunohistochemistry. ChAT-positive fibers and varicosities were observed throughout the amygdaloid complex. In parts of the amygdala the density of this cholinergic innervation was higher than in any part of the cerebral cortex. The highest level of ChAT-positive varicosities was seen in the basolateral nucleus and the lateral part of central nucleus. The basomedial, accessory basal and cortical nuclei, the amygdalo-hippocampal and cortico-amygdaloid transition areas and the anterior amygdaloid area showed a lower density of ChAT-positive varicosities and fibers. The lateral nucleus displayed an even lower density of innervation and there were only rare ChAT-positive fibers in the medial nucleus. Although the lateral nucleus displayed a low level of innervation in comparison to the other amygdaloid nuclei, the level of this innervation was approximately equivalent to that of entorhinal cortex, which receives one of the heaviest cholinergic innervations in the cerebral cortex. The pattern of differential staining was maintained throughout the anteroposterior extent of the amygdaloid complex. The distribution of ChAT-positive fibers and varicosities within the various nuclei and their subdivisions was by and large homogenous at a given level except for some patchiness in the central nucleus. The distribution of the cholinergic innervation as studied by ChAT immunohistochemistry was comparable to that observed with AChE histochemistry. These results confirm that, as part of the limbic system, the human amygdaloid complex receives a dense and differentially distributed cholinergic innervation.

411.15

ULTRASTRUCTURAL EVIDENCE FOR DISTINCT CHOLINERGIC AND VIP-ERGIC MODULATION OF INTRACORTICAL BLOOD VESSELS.
A. Chédotal,[1] D. Umbriaco[2], B.K. Hartman[3] and E. Hamel[1]*. [1]Montreal Neurological Institute, McGill Univ., [2]Univ. de Montréal, Montréal, Québec, Canada and [3]Dept. of Psychiatry, Univ. of Minnesota, MN, USA.

Acetylcholine (ACh) and vasoactive intestinal polypeptide (VIP) exert potent vasoactive effects within the cerebral cortex. The relationships of ACh and VIP terminals with cortical microvessels were evaluated at the ultrastructural level after immunocytochemical labeling for choline acetyltransferase (ChAT; MCAT-1C, Cozzari et al., Soc. Neurosci. Abstr. 16: 200, 1990) or VIP (Peninsula). Rats were perfused with 4% paraformaldehyde (PF) and 0.025% glutaraldehyde followed by PF alone. Vibratome sections (60 μm) were immunostained for ChAT or VIP by the ABC method with DAB-nickel as the chromogen. An equal number (> 80) of ChAT and VIP terminals located close (0-3 μm) to blood vessels were photographed and analyzed in single thin sections (Bioquant II). These terminals were respectively located at an average distance of 0.62 $\pm$ 0.05 and 0.75 $\pm$ 0.07 μm from the vessel wall (capillaries or arterioles). Of these, 26% (ChAT) and 20% (VIP) were separated from to the basal lamina by a thin glial leaflet only. Irrespective of the distance, VIP (0.56 $\pm$ 0.05 μm^2) were significantly larger than ChAT terminals (0.34 $\pm$ 0.03 μm^2; $p < 0.001$). Membrane specializations were never observed at the neuro-vascular interface even in serially-sectioned ChAT (n=20) and VIP (n=5) terminals. Together with our previous data showing that 59% of cortical neurons stain for VIP, 28% for ChAT and 13% only colocalize both transmitters, the present results strongly suggest that intracortical vascular functions are primarily influenced by distinct ACh and VIP nerves. Supported by the MRC of Canada.

EXCITATORY AMINO ACIDS: RECEPTORS V

412.1

THE GLUTAMATE RECEPTOR ANTAGONIST NBQX DOES NOT AFFECT ACTIVITY IN NORMAL RATS AND RHESUS MONKEYS.
C. Kearns,[1] Z. Zhang,[1] J.T. Greenamyre[2] and D.M. Gash.*[1] Departments of Neurobiology and Anatomy[1] and Neurology,[2] University of Rochester, Rochester, NY 14642.

NBQX [2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo(f) quinoxaline], a selective antagonist of the AMPA subtype of glutamate receptor, has antiparkinsonian effects in monoamine-depleted rats and MPTP-treated primates (*Ann. Neurol.* 1991; 30:717-723). In the present study, NBQX was administered to normal rats and primates to determine if it produced any apparent side effects. In rats, various doses of NBQX (0, 5, 10, 20, 30 mg/kg; i.p.) were evaluated (n=9/dose). Each rat was tested measuring horizontal activity and stereotypy. There were no apparent side effects in rats treated with 0, 5, 10, 20 mg/kg NBQX. However, there was a slight but significant ($p>0.05$) narcotic effect observed in rats treated with 30 mg/kg NBQX. In the primate testing, 3 normal older (approximately 12-16 years old) female rhesus monkeys were administered doses of 0 and 1 mg/kg (i.m.) NBQX on alternate days. Each primate was subjected to 1 week of testing. Data were gathered by videotaping and computerized cage activity monitoring in which the number of times an animal crossed an infrared beam was recorded. These data were analyzed using a Clinical Rating Scale consisting of 4 measures of parkinsonian features (posture, gait, bradykinesia and balance), 3 measures of drug-related side effects (dyskinesias, vomiting and psychological disturbance) and 1 measure of overall level of activity. There were no apparent NBQX related side effects seen in any of the primates.

Supported by a grant from the Markey Foundation.

412.2

THE EFFECT OF THE SPECIFIC AMPA RECEPTOR ANTAGONIST NBQX UPON LOCAL CEREBRAL GLUCOSE UTILIZATION IN THE RAT.
P.D. Suzdak* and M.J. Sheardown. Novo Nordisk A/S, CNS Division, DK-2760 Maaloev, Denmark.

Excitatory amino acid receptors can be classified by pharmacological and electrophysiological selectivity for the ligands NMDA, AMPA, kainic acid and t-ACPD. The present report characterizes the effect of antagonism of the AMPA receptor, with NBQX, on local cerebral glucose utilization (LCGU). NBQX has been previously shown to have neuroprotective effects. NBQX was administered at doses of 3 to 90 mg/kg i.p. 30 minutes prior to the administration of 50 uCi ^{14}C-2-deoxyglucose i.v. in conscious rats. NBQX (3 - 30 mg/kg) selectively increased LCGU in the lateral hebenula, raphe, superior and inferior colliculus and vestibular nucleus. NBQX at 60 mg/kg decreased LCGU in 47 of the 62 brain regions examined. NBQX at 90 mg/kg decreased LCGU in 60 of the 62 brain areas examined.

NBQX did not increase LCGU in limbic brain areas at any of the doses examined. In fact, NBQX at ≥60 mg/kg decreased LCGU in limbic areas. These data suggest that antagonism of the AMPA receptor in vivo with NBQX results in changes in LCGU different from that previously reported for non-competitive antagonists (i.e. PCP, MK 801), further suggesting that NBQX may not be associated with PCP-like effects.

412.3

KAINATE-INDUCED EPILEPSY LEADS TO AN INCREASE IN GLUTAMATE-STIMULATED PHOSPHOINOSITIDE METABOLISM IN THE HIPPOCAMPUS.
E.Mayat,[1]M.Lerner-Natoli,[1]G.Rondouin and M.Récasens*. INSERM U254,Hôpital St-Charles,[1]INSERM U249 & CNRS UPR 8402, 34000 Montpellier, FRANCE.

Intra-amygdala injections of kainate (KA) ultimately induce status epilepticus associated with neuronal loss in local and distant structures. In the hippocampus, a mossy fiber sprouting occurs in consequence of this seizure-related damage. Since glutamate metabotropic receptors (mGLU-R) may be involved in synaptic plasticity, we examined the agonist-induced inositol phosphate (IP) formation in hippocampal slices of rats subjected to an intra-amygdala KA injection (2.5 nmol in 1 ul). After 24 hours, no significant effect of KA application on IP accumulation was observed. However, 1 week following injection, significant increases of the metabotropic responses mediated by quisqualate (QA), ibotenate (IBO) and trans-aminocyclopentane-dicarboxylate (t-ACPD) were noted in hippocampal slices. In control animals, the IP formation ($\bar{X}\pm$SEM) for buffer, QA, IBO, t-ACPD and carbachol were 2,806±96; 4,145±109; 5,493±14; 7,506±754 and 4,164±757 dpm/mg protein respectively whereas in KA treated animals they were 3,123±629; 11,071±1054; 13,196±2,208; 19,119±1,377 and 5,662±1,119 dpm/mg protein.Significant increases were also obtained 2 and 6 weeks after injection. For carbachol, there was no significant increase at all times except after 6 weeks following KA treatment. This specific dramatic increase of the mGLU-R response in the hippocampus following seizure-related damage suggests that mGLU-R may play a role in the molecular mechanisms leading to brain plastic changes.

NMDA AND KAINATE/AMPA RECEPTOR GENE EXPRESSION IN HIPPOCAMPUS FOLLOWING KAINATE-INDUCED SEIZURES IN MATURE AND IMMATURE RATS.
L.K. Friedman*, D.E. Pellegrini, E.F. Sperber, S.L. Moshe, M.V.L. Bennett, R.S. Zukin. Dept. of Neuroscience, Albert Einstein Coll. of Med. Bronx, NY.

Glutamate receptors (GluR) are thought to play a role in epilepsy. We examined GluR gene expression in adult and 15 d rat brains after induction of status epilepticus by kainate (15 or 4.5 mg/kg i.p.). *In situ* hybridization was used to measure levels of NMDAR1, GluR1, GluR2, and GluR3 mRNAs in coronal sections from control and KA-injected animals 6 to 144 h after seizure onset. In adults, damage to amygdala, entorhinal cortex, and selective thalamic nuclei was evident at 6-12 h, while CA3/4 selective cell loss was not evident until 48 h. Autoradiography of adult brain sections indicated significant increases in GluR2 and GluR3 expression (50-100%) in the dentate gyrus (DG) and subiculum (35%) and a concomitant decrease (40-60%) in CA3/CA4 hippocampal subfields at 24 h. GluR1 expression was unchanged. Emulsion-dipped sections revealed that the observed changes were in mRNA content per neuron. After 12 h adult NMDAR1 mRNA levels were greatly reduced in CA1 (60-80 %) but unchanged in DG suggesting a specific role for genomic expression of glutamate receptor subtypes in seizure activity. In 15 d pups,an age when KA does not induce neurodegeneration in limbic structures, GluR1 and GluR2 dentate mRNA levels were elevated in DG by 50-100% 24 h after seizure onset with no changes in GluR3 mRNA. The three transcripts were unchanged in CA3/CA4. In conclusion, changes in adult mRNA expression occur prior to obvious CA3/4 pyramidal cell loss, but after afferent denervation from limbic structures. There are maturational differences in GluR mRNA expression that may be explained by the presence or absence of associated structural lesions.

CELL-ATTACHED RECORDINGS OF NMDA CHANNELS IN CHRONICALLY EPILEPTIC (KINDLED) NEURONS. G. Köhr*[1] and I. Mody[2]. [1]Center for Molecular Biology, Univ. of Heidelberg, F.R. Germany and [2]Dept. of Neurology & Neurol. Sciences, Stanford Univ. Sch. of Med., Stanford, CA.

Our studies in hippocampal slices and acutely dissociated neurons have shown that kindling-induced epilepsy increases synaptic activation of NMDA receptors, modifies whole-cell NMDA responses and alters the activation/inactivation kinetics of HVA Ca^{2+} currents. We have now examined if long-lasting changes can be detected at the level of single NMDA channels.

Cell-attached recordings were obtained in acutely dissociated control and kindled dentate gyrus granule cells in Mg^{2+}-free medium containing 3 μM glycine using NMDA as an agonist (1, 5 and 10 μM). Single open times and the conductance of single channels were comparable in control and kindled neurons. Kindled channels differed from controls by having a longer burst duration and a higher p_{open} at low NMDA concentrations (1 or 5 μM). Following kindling, the combined effect of the longer burst duration and the higher p_{open} was a 23-fold and a 3.6-fold increase in the charge carried through NMDA channels at 1 and 5 μM NMDA respectively. As a result of a reduced p_{open} at 10 μM NMDA the charge through kindled channels was 57% of that recorded in control cells. On-cell dose-response studies, according to a double-fill method (A. Auerbach, Biophys. J., 60: 660, 1991), were done by allowing NMDA (25 μM) to gradually diffuse to the channels over a period of 15-30 min. These experiments confirmed the higher affinity and augmented desensitization at high NMDA concentrations of kindled channels.

The chronically enhanced NMDA receptor/channel function may result from a covalent modification during kindling; the outcome for neuronal excitability conceivably contributes to epileptogenesis.

CHRONIC ANTIDEPRESSANT TREATMENT DESENSITIZES THE NMDA RECEPTOR COMPLEX. G. Nowak, P. Skolnick* and I.A. Paul. Lab. Neuroscience. NIDDK, NIH, Bethesda, MD 20892.

Functional antagonists at the NMDA receptor complex, such as 1-aminocyclopropanecarboxylic acid (ACPC) and MK-801, possess antidepressant-like activity in animal models (Trullas, R. and Skolnick, P., *Eur. J. Pharmacol.*, 185:1, 1990) and down-regulate ß-adrenoceptors after chronic treatment (Paul, I.A. *et al.*, *Psychopharmacology*, 106:285, 1992). These findings indicate that NMDA receptors may be involved in antidepressant activity. To test this hypothesis, we examined the effect of treatment with ACPC and several "classical" antidepressant drugs on [^{3}H]5,7-dichlorokynurenic acid (DCKA) binding to strychnine-insensitive glycine modulatory sites and on [^{3}H]CGP-39653 binding to glutamate sites in mouse cortex. Chronic, but not acute treatment with ACPC, imipramine and amitriptyline reduced the affinity of glycine to inhibit [^{3}H]5,7-DCKA binding ($p < 0.05$). Chronic citalopram treatment also produced a marginal reduction in the affinity of glycine. [^{3}H]CGP-39653 binding is displaced by glycine with both high ($\approx$70%, $IC_{50} \approx$ 600 nM) and low ($\approx$30%, $IC_{50} \approx$ 3 mM) affinity components. Chronic ACPC and imipramine treatment significantly increased the proportion of low affinity sites ($p < 0.05$) and reduced the proportion of high affinity glycine-displaceable [^{3}H]CGP-39653 binding sites. These data indicate that the NMDA receptor complex may be involved in the neural adaptation produced by chronic antidepressant treatment.

DELAYED PHENCYCLIDINE EFFECTS ON NMDA SENSITIVE ^{3}H-GLUTAMATE BINDING X.-M. Gao,* T.Kakigi, C.A. Tamminga University of Maryland, MPRC, P.O. 21247, Baltimore, MD 21228

Phencyclidine (PCP) is a psychoactive drug which has prolonged psychotomimetic effects in humans, hence has been used as psychosis model. We have previously demonstrated that single doses of PCP in rat produces an initial increase then a prolonged decrease in regional cerebral glucose metabolism (rCMRglu) lasting longer than 24 hours. This effect is prominent in rat limbic structures. Moreover, schizophrenia studies have shown in vivo structural and metabolic changes in limbic structures and postmortem pathologic changes in limbic and paralimbic regions. Therefore, we have begun to explore the neurochemical correlates of this delayed PCP action, especially in the limbic system. Here, we report the 24 hour effect of PCP (8.6 mg/kg) on the NMDA sensitive ^{3}H-glutamate binding sites and on other glutamate receptors. NMDA and AMPA glutamate receptors were quantified according to standard technique, using ^{3}H-glutamate and ^{3}H-AMPA, respectively. Our results show an increase of more than 40% in NMDA binding in limbic structures like hippocampus, and in limbic related neocortex, like dorsolateral frontal, medial prefrontal, and posterior cingulate cortex, 24 hours after a single dose of PCP. This effect is significant in CA1 region of the hippocampus (dorsal: PCP=92.6±22.9, control=64.6±13.9 fmol/mg tissue; ventral: PCP= 86.0±15.5, control=62.8±11.8, Mean±SD, n=6,P<0.05), and dorsolateral prefrontal cortex (PCP=52.0±16.3, control=26.8±5.6, P<0.01). No change in AMPA receptor density was found. These data suggest that the psychotomimetic effects of PCP, particularly of those delayed effects may be mediated by limbic glutamatergic synapses selective for NMDA. These observations may suggest directions of study in schizophrenia.

EFFECTS OF POSTWEANING LEAD (Pb) EXPOSURE ON [^{3}H]DIZOCILPINE (MK-801) BINDING IN RAT BRAIN. S.C.Johnson*[1,2], J.T.Greenamyre[3], and D.A.Cory-Slechta[1]. Environ. Health Sci. Center[1], Program in Neuroscience[2],Dept. of Neurology[3], School of Med. and Dent., Univ. of Rochester, Rochester, NY 14642.

Pb has been shown to affect a number of neurotransmitter systems both in vivo and in vitro. Recently evidence has shown that in vitro Pb acutely inhibits LTP formation and that it inhibits the binding of MK-801, a noncompetitive antagonist of the NMDA subtype of glutamate receptors. However, there is still little data on the effects of long-term in vivo exposure to Pb on the neurochemistry of excitatory amino acid systems. We used quantitative autoradiography to assess [^{3}H]MK-801 binding sites in brains of rats exposed to Pb for 60 days using a Pb exposure regimen known to produce behavioral alterations. Rats were exposed to either 0, 50, or 2000 parts-per-million (ppm) Pb in their drinking water from 21 to 81 days of age. At that time, blood samples were taken for blood lead analysis via anodic stripping voltammetry, and the brain was taken for determination of [^{3}H]MK-801 binding using quantitative autoradiography. Control rats (n=8) had no measurable blood-Pb levels, while the 50 ppm exposure group (n=8) had a mean blood-Pb level of 15 ug/dl and the 2000 ppm exposure group (n=8) had a mean blood-Pb level of 82 ug/dl. Autoradiographic analyses revealed no significant effect of Pb exposure upon MK-801 binding in the striatum in either of the Pb exposure groups compared to controls. In the dentate gyrus of hippocampus, binding in the 50 ppm exposure group was significantly reduced in relation to the control and the 2000 ppm exposure group, whereas binding of the 2000 ppm group was elevated in comparison to both the control and 50 ppm groups. The 50 ppm Pb exposure likewise resulted in a reduction in binding in the CA1 region of hippocampus relative to the 2000 ppm, while the 2000 showed no difference relative to control. These findings suggest that there are significant changes in MK-801 binding in rats chronically exposed to Pb after weaning (day 21) and that the dose-response relationship of Pb exposure and MK-801 binding sites may reflect a U-shaped function. In addition, there are also regional differences in the Pb induced changes in MK-801 binding.ES05017,ES05093.

Interactions of EtOH and Glycine with the NMDA Receptor-Linked Ion Channel Complex in EtOH Withdrawal Seizure-Prone and -Resistant Mice. A. Janowsky*, L. Carter, and J. C. Crabbe, VAMC and Oregon Health Sciences Univ., Portland, OR 97201

We have (re)characterized the assay conditions that are required for equilibrium binding of [^{3}H]MK-801 to the NMDA receptor-linked ion channel complex. Results of our experiments indicate that radioligand binding to a well washed tissue preparation that includes glycine (10μM) and NMDA (10μM) requires 24 hrs to reach equilibrium. In addition, the dose response curve for the glycine-induced increase in the affinity of the binding site is optimal after 24 hrs incubation at 25°C, with Hill coefficients increasing over time.

Under these conditions, EtOH (3 - 100mM) has no effect on the characteristics of radioligand binding, or on the glycine-induced increase in affinity for radioligand binding. In addition, there appears to be no difference in the density of [^{3}H]MK-801 binding sites in cortex or hippocampus of naive EtOH-withdrawal seizure-prone (WSP) and -resistant (WSR) mice, which differ in handling-induced convulsion severity. Acute administration (24 hr inhalation) of EtOH did not alter the density or affinity of binding sites in either mouse line. Thus, under well defined equilibrium binding conditions, EtOH does not directly interact with either the glycine or [^{3}H]MK-801 binding sites on the NMDA receptor-linked ion channel complex. Differences between the effects of EtOH on radioligand binding under equilibrium and non-equilibrium conditions, and on EtOH-induced behaviors will be discussed. *This work was supported by NIAAA and the V.A.*

INCREASED NMDA RECEPTOR FUNCTION IN CEREBELLAR GRANULE CELLS EXPOSED CHRONICALLY TO ETHANOL. **K. Iorio, P.L. Hoffman, B. Tabakoff, K. N. Kumar and E. Michaelis*. Univ. Colorado Hlth. Sci. Ctr., Denver, CO 80220, and Univ. Kansas, Lawrence, KS 66047.**

Acutely, ethanol is a selective inhibitor of the function of NMDA/glutamate receptors. To assess changes in NMDA receptor function after chronic ethanol exposure, we measured NMDA-stimulated increases in intracellular Ca^{2+} in primary cultures of cerebellar granule cells. The cells were obtained from 8-day old rats and exposed in vitro to 100 mM ethanol for two or more days or 20 mM ethanol for three or more days. In the ethanol-treated cells there was an increased maximal response to NMDA (in the presence of glycine) and glycine (in the presence of NMDA), with no change in the EC_{50} value for either compound. There was no change in inhibition of the NMDA response by competitive or non-competitive antagonists or by ethanol added acutely. Chronic ethanol exposure apparently produced an increase in the number of NMDA receptors, with no change in their properties. Western blot analysis of membrane proteins using an antibody raised against the recently-cloned 70 kDa glutamate-binding protein, believed to represent a subunit of an NMDA receptor, revealed a 60% increase in the amount of this protein in cells exposed to 100 mM ethanol for 2 days and a 100% increase for cells exposed for 4 days. These results are compatible with an ethanol-induced increase in synthesis, or decrease in degradation, of the glutamate binding subunit of an NMDA receptor. [Supported by grants AA 9005 and AA 4732 from NIAAA]

GLUTAMATE RECEPTOR SUBUNITS EXPRESSED IN *XENOPUS* OOCYTES DEMONSTRATE DIFFERING SENSITIVITIES TO ETHANOL. J. E. Dildy-Mayfield*, M. L. Robinson, and R. A. Harris. Univ. of CO Hlth. Sci. Ctr. & Denver VAMC, Denver, CO 80262.

Xenopus laevis oocytes were injected with either GluR1, R3, R1+3, R2+3 cRNA or GluR6 cDNA and ethanol's action on minimum and maximum kainate (KA)-induced currents was studied electrophysiologically. In GluR3-injected oocytes, both low (12.5 μM) and high (400 μM) KA responses were inhibited approximately 35 and 50% by 50 and 100 mM ethanol, respectively, with KA responses in GluR1-injected oocytes being slightly less sensitive to inhibition by ethanol. In comparison to GluR1 and R3, maximum KA responses in GluR6 expressing oocytes occurred in the presence of 10 μM KA and were less sensitive to ethanol in that 50 and 100 mM ethanol produced only 15 and 28% inhibition, respectively. Moreover, in GluR6-injected oocytes the ethanol sensitivity was dependent on the KA concentration with minimum KA responses (0.2 μM) being more sensitive to ethanol (e.g., 47% inhibition by 100 mM ethanol) which has also been observed in rat hippocampal or cerebellar mRNA injected oocytes (J. Neurochem. 58: 1569-1572, 1992 and unpublished observations). In addition, when GluR2+3 subunits were co-expressed, low KA responses were more sensitive to ethanol inhibition compared to high KA responses whereas the ethanol sensitivity of low and high KA responses in GluR1+3 expressing oocytes was similar to that of GluR3 alone. Thus, expression of GluR subunits in oocytes provides evidence for homomeric and heteromeric KA channels with differing sensitivities to KA and ethanol. GluR clones were kindly provided by J. Boulter and S. Heinemann and the R6 expression construct was provided by K. Cauley, Salk Institute.

3H-MK801 BINDING IN LONG-SLEEP (LS) AND SHORT-SLEEP (SS) MICE: DIFFERENCES FOUND IN EIGHT BRAIN REGIONS. W.R. Wilson* and A. C. Collins†. School of Pharmacy* and Inst. for Behavioral Genetics†, Univ. of Colorado, Boulder, CO 80309.

Previous studies have shown that LS and SS lines of mice, selectively bred for differences in hypnotic sensitivity to acutely administered ethanol, differ in stimulated glutamate (GLU) release from slices of cortex, striatum and hippocampus. Also, SS whole brain vesicles take up more 3H-GLU and contain more endogenous GLU than LS vesicles. Behavioral tests have shown that hypnotic sensitivity to ethanol is decreased by central administration of NMDA receptor agonists and increased by administration of NMDA receptor antagonists in both LS and SS lines of mice. These findings suggest that differences in NMDA receptors exist in LS and SS lines of mice. NMDA receptors were, therefore examined by measuring 3H-MK801 binding to the NMDA receptor ion channel, under saturating conditions of the agonist GLU, the coagonist glycine and the positive modulator spermidine. Binding was examined in hypothalamus, cerebellum, hindbrain, colliculi, hippocampus, midbrain, striatum and cortex. 3H-MK801 binding differed between the LS and SS lines in cerebellum, hippocampus and striatum. SS mice displayed greater levels of binding in hippocampus and striatum while LS mice displayed greater levels of binding in cerebellum. Binding affinity did not differ between LS and SS mice within a brain region, however, affinities varied between regions, which, suggests heterogeneity of NMDA receptors. The data support the hypothesis that NMDA receptor mediated events may play a role in genetic differences in hypnotic sensitivity to ethanol.
Supported by grants AA-06391 and DA-00116.

EXCITATORY AMINO ACID RECEPTORS IN SCHIZOPHRENIA: SELECTIVE PLASTIC RESPONSES IN THE HIPPOCAMPUS OF SOME SCHIZOPHRENIC INDIVIDUALS. J. Ulas*, L.C. Brunner, L. Nguyen and C.W. Cotman. Irvine Research Unit in Brain Aging, University of California, Irvine, CA 92717, USA.

There is growing evidence for interactions between central dopaminergic and glutamatergic systems. It has been suggested that hyperactivation of the dopaminergic system observed in schizophrenia may be due to a disturbance of the glutamatergic system. In addition, neuroanatomical studies suggest aberrant anatomical changes in the temporal lobe of schizophrenic patients. Since most of the neurons in this brain region utilize glutamate as a neurotransmitter we compared the distribution of NMDA receptors (L-[^{3}H]glutamate and [^{3}H]CPP binding sites) and non-NMDA receptors ([^{3}H]KA and [^{3}H]AMPA binding sites) in the hippocampus and parahippocampal gyrus of schizophrenic and normal, control brains. *In vitro* quantitative autoradiography studies were performed on 4 clinically assessed schizophrenic individuals and 12 age-matched control subjects. Ligand binding experiments did not reveal any changes in levels of L-[^{3}H]glutamate and [^{3}H]CPP binding to NMDA receptors in the schizophrenia *vs* control group. [^{3}H]KA and [^{3}H]AMPA binding levels were also largely maintained. Although there were no striking alterations in binding to NMDA and non-NMDA receptors between the schizophrenic and control groups, an analysis of binding to non-NMDA receptors in individual schizophrenic patients revealed different patterns of receptor changes in various individuals. For example, in one schizophrenic subject, a pronounced 37% increase in [^{3}H]KA binding was found in the outer 2/3 of the dentate gyrus molecular layer. This increase in [^{3}H]KA binding was accompanied by a widening of the zone occupied by KA receptors. In addition, the same individual exhibited a 51% increase in [^{3}H]AMPA binding in the infragranular layer. A similar response of KA and AMPA receptors was noted previously in the hippocampus of some Alzheimer's patients. This suggests that plastic responses, similar to those occuring in Alzheimer's disease, may have a common basis across several disease states.

SUBSTANTIA NIGRA NMDA AND AMPA RECEPTOR LOSSES IN A MOUSE MODEL OF PARKINSON'S DISEASE. U. Wüllner*, O. Isacson, J.B. Penney and A. B. Young Neurology Service, Massachusetts General Hospital, Boston, MA 02114

Exposure to the selective neurotoxin MPTP causes degeneration of mesencephalic dopaminergic neurons projecting to the striatum and parkinsonian symptoms in humans and various animal species. To investigate whether MPTP treatment elicits receptor changes resembling those found in Parkinson's disease we used quantitative receptor autoradiography in a mouse model of Parkinson's disease.

Mice (c57b) were treated with MPTP, 2x40mg/kg sc and sacrificed two and eight weeks after the onset of treatment, respectively. Striatal dopamine terminals measured with [^{3}H]mazindol binding to the dopamine uptake site were reduced to 17% of control at two weeks and to 38% at eight weeks (control: 1.73±0.12 pmol/mg protein, mean±sem; 2wk: 0.29±0.04; 8wk: 0.65±0.07) indicating recovery from the initial lesion. At two weeks, substantia nigra NMDA-sensitive [^{3}H]glutamate binding was reduced to 52% (control: 0.19±0.02; MPTP: 0.10±0.02; $p<0.05$). [^{3}H]AMPA binding was reduced to 76% (control: 0.64±0.07; MPTP: 0.44±0.06; $p<0.05$). No significant changes could be detected at eight weeks.

The decreases in NMDA and AMPA binding could be caused by decreased receptor synthesis in dopaminergic compacta cells or by down-regulation of receptor binding sites in pars reticulata due to increased glutamatergic activity of subthalamic projection neurons. Although, the impairment of the nigrostriatal dopaminergic system may not have been sufficient to elicit changes in subthalamic nucleus neurons. Supported by USPHS grant NS19613

412.15

DEVELOPMENTAL CHANGE OF INHIBITION BY LEAD OF *N*-METHYL-D-ASPARTATE-INDUCED CURRENTS IN CULTURED HIPPOCAMPAL NEURONS. H. Ujihara*, M. Alkondon and E.X. Albuquerque. Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

The ontogeny of the NMDA subtype of glutamatergic receptor/ion channel and developmental changes in inhibition of these currents by lead were studied by examining whole cell currents evoked by NMDA in cultured hippocampal neurons 1-30 days after plating of cells from fetuses obtained from 18-20-days gestation rats. We observed a maturation-dependent increase in conductance, indicating an increased density of NMDA receptors. The whole cell currents evoked by NMDA (10-100 μM) in the presence of glycine (1-100 μM) were composed of a rapidly decaying and a slowly decaying current, the ratio of these currents depending upon glycine concentration. The EC_{50} values for glycine were 1.8 μM and 0.3 μM, for the fast and slow components, respectively. The slow component became more predominant and the fast component less predominant along with cell maturation in culture. Pb^{2+} selectively inhibited NMDA currents recorded from young cultured neurons, exhibiting a noncompetitive antagonism against NMDA and glycine. The fast component, predominant at early states of neuronal development in culture that has the low affinity glycine site, was most affected by Pb^{2+}. These findings on Pb^{2+} actions at the NMDA receptor may explain the selective toxicity of this heavy metal on the immature brain. (Support: USPHS Grants NS25296 & NS05730)

THE SPASTIC HAN-WISTAR RAT AS A MODEL OF GLUTAMATE EXCITOTOXICITY: ELECTROPHYSIOLOGICAL ANALYSIS. R.W. Cohen*, J.E. Margulies, J.B. Watson, N.A. Buchwald, and M.S. Levine. Mental Retardation Res. Center, UCLA School of Medicine, Los Angeles, CA 90024.

Our laboratory has been studying a mutant strain of the Han-Wistar (HW) rat which carries an autosomal, recessive gene resulting in spastic paresis characterized by ataxia, tremor, and hind limb rigidity. Morphologically, starting about 30 days postnatally, progressive cell death occurs in the Purkinje cell layer of the cerebellum and the CA3 layer of the hippocampus. Currently, we are investigating the hypothesis that the cerebellar and hippocampal degeneration may be induced by glutamate (GLU) excitotoxicity. Evidence was first obtained from Xenopus oocytes expressing HW rat glutamate receptors following injection with mRNA from mutant or wildtype (control) cerebellum. Oocytes injected with mutant HW cerebellar mRNA (45-50 days of age) displayed significantly larger current responses to GLU and kainate (KA) than controls. The development of this disorder was studied by comparing the responses of oocytes injected with 30-35, 40-45, and 50-55 day old cerebellar mRNA from mutants or controls. Results indicated that GLU and KA evoked significantly larger inward currents in oocytes injected with mutant cerebellar mRNA after 40 days of age. GLU- and KA-dose response curves were also altered in oocytes injected with mutant mRNA (after 40 days). These curves exhibited reduced EC_{50}s, but displayed similar threshold dosages. To assess in situ electrophysiological alterations, field potentials were recorded in the Purkinje cell layer following stimulation of the molecular layer of mutant or control cerebellar slices. The results showed a 40% increase in the maximum amplitude of the response in the mutant cerebellum. There was no difference in the threshold voltage needed to evoke a response. These findings provide more evidence for abnormal, glutamate neurotransmission in the cerebellum of HW rats which may underlie the cellular degeneration observed in this mutation.

412.17

THE SPASTIC HAN-WISTAR RAT AS A MODEL OF GLUTAMATE EXCITOTOXICITY: MOLECULAR APPROACHES. J.E. Margulies*, R.W. Cohen, M.S. Levine and J.B. Watson. Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

We are studying a mutant strain of Han-Wistar (HW) rat which may provide information about genetically-induced alterations in excitatory amino acid receptor expression. Mutant HW rats carry an autosomal, recessive gene resulting in spastic paresis. Progressive degeneration of Purkinje cells in the cerebellum and CA3 pyramidal cells in the hippocampus occurs in mutant animals beginning around postnatal day 30 (P30), and marked cell loss is observed in both regions by P50. Voltage-clamped Xenopus oocytes injected with mutant HW cerebellar mRNA (50-55 days old) exhibit enhanced current responses to glutamate and kainate relative to oocytes injected with wildtype cerebellar mRNA. These data suggest that changes occur in the functional expression of glutamate receptors at an age corresponding to cerebellar degeneration. These changes may reflect a "mutant" multimeric receptor with enhanced sensitivity to kainate which places the cell at risk for excitotoxicity. To test the hypothesis that the stoichiometry of glutamate receptor subunit assembly is altered in mutant HW rats, expression of glutamate receptor subtype mRNAs (GluR1-5) was determined by Northern and slot blot analyses of cerebellar and hippocampal mRNA. Analysis of RNA from two independent sets of animals revealed a 30% decrease in GluR2 mRNA expression at 30-35 days and an 80% increase in GluR4 mRNA expression at 50-55 days in mutant cerebellum. GluR2 mRNA expression was also decreased by 30% in the hippocampus of 30-35 day old mutants. The cellular basis for the altered GluR2 and GluR4 mRNA expression can be investigated using in situ hybridization histochemistry. The early change in GluR2 mRNA expression in both mutant brain regions showing degeneration suggests that glutamate receptor assembly may be altered in neuronal populations at risk for or undergoing cell death. Conceivably, other untested kainate sensitive receptor subunits (e.g., KA-1, KA-2, GluR6, GluR7) are altered significantly in their expression in degenerating neurons.

GABA RECEPTORS: FUNCTION III

413.1

DEPOLARIZATION OF CULTURED EMBRYONIC RAT SPINAL CORD NEURONS BY GABA-A RECEPTOR ACTIVATION: MAGNITUDE AND IONIC BASIS. A.Kyrozis*, D.B.Reichling and A.B.MacDermott. Dept. Physiology & Cellular Biophysics and Center for Neurobiology and Behavior, Columbia Univ., New York, NY 10032.

GABA-A receptors activate Ca^{2+} entry into cultured spinal cord neurons via voltage-gated Ca^{2+} channels (Wang et al., Neu..Abs. 17:797, 1991). Patch techniques were used to test directly if the activation of the GABA-A receptor depolarizes embryonic dorsal horn neurons and by what ionic mechanism. Membrane voltage responses to 10 uM muscimol, a GABA-A receptor agonist, were recorded in current-clamp mode using perforated patch recording. Pipettes contained (mM): K_2SO_4 75, KCl 10, HEPES 10 and 100 ug/ml gramicidin or amphotericin B. Bath was NaCl-based (Cl^-=159mM). Of 65 neurons tested during the first week in culture, 10 depolarized to between -30 and -40 mV, 26 to between -40 and -50mV and 24 to less positive than -50mV. 5 cells were hyperpolarized. To test the ionic basis of the depolarization, cells with depolarizing responses were identified, the perforated patch electrode was pulled off, then whole cell recording was established using a second pipette to control $[Cl^-]_i$. Lowering $[Cl^-]_e$ to 49mM led to a depolarizing shift of +25 ± 2 mV (mean ± SEM; n=5) in the measured reversal potential. A +30 mV shift is predicted if Cl^- is the only permeating extracellular ion. Reducing $[Na^+]_e$ to 0 or 40 mM led to slightly depolarized reversal potentials (n=3) suggesting that Na^+ is not responsible for the depolarizing responses. These results demonstrate that GABA-A receptor activation can significantly depolarize a high percentage of embryonic cultured dorsal horn neurons and that an anionic conductance is mainly responsible for this effect, possibly due to a high $[Cl^-]_i$. GABA-INDUCED Ca^{2+} TRANSIENTS IN TYPE 1 ASTROCYTES IN PRIMARY CULTURES. Michael Nilsson[1], Peter S. Eriksson[1], Lars Rönnbäck[1,2] and Elisabeth Hansson*[1], Institute of Neurobiology[1] and Department of Neurology[2] University of Göteborg, Göteborg, Sweden.

By using the Ca^{2+}-sensitive indicator fura-2/AM, the cytosolic Ca^{2+} levels $[Ca^{2+}]_i$ were measured in type 1 astrocytes in rat cortical astroglial primary cultures, after stimulation with GABA, muscimol ($GABA_A$-agonist) or baclofen ($GABA_B$-agonist). We report that stimulation of both $GABA_A$ and $GABA_B$ receptors evokes Ca^{2+} transients in type 1 astrocytes. In some cells, the responses after GABA stimulation were blocked to baseline levels after exposure to bicuculline ($GABA_A$-antagonist). In other cells, bicuculline only slightly reduced the GABA-evoked responses, and the addition of phaclofen ($GABA_B$-antagonist) did not amplify this inhibition. However, the muscimol-evoked rises in $[Ca^{2+}]_i$ were completely inhibited after exposure to bicuculline, while the responses after baclofen could only be partly blocked by phaclofen. GABA evoked rises in $[Ca^{2+}]_i$ which alternatively were inhibited (mostly) or persisted in Ca^{2+}-free buffer. The rises in $[Ca^{2+}]_i$ persisted, but were reduced, in Ca^{2+}-free buffer after stimulation with muscimol, but were on the contrary inhibited after baclofen stimulation. The results suggest that type 1 astrocytes in primary culture express GABA receptors which can elevate $[Ca^{2+}]_i$ directly or indirectly via Ca^{2+} channels and/or via release from internal Ca^{2+} stores.

THE EFFECT OF FLUPIRTINE ON CULTURED NEURONS: A PATCH-CLAMP STUDY M. Wienrich*§, T. Weiser§, I. Szelényi† Battelle PR&E§, ASTA Medica AG† Frankfurt/M., Germany

In order to investigate the mechanism of action of Flupirtine, we tested its effect on cultured neurons from rat brain using the "whole-cell" configuration of the patch-clamp technique. Under symmetrical chloride-concentrations, Flupirtine induced a dose-dependent, reversible depolarization. This was suppressed in the presence of bicuculline indicating that Flupirtine has $GABA_A$-agonistic properties. With threshold concentrations of Flupirtine, the GABA-effect was enhanced in an over-additive manner. Experiments performed at voltage-clamped neurons demonstrated, that the action of Flupirtine is dependent on the membrane potential. At potentials more negative than -50 mV, the drug caused a monophasic chloride inward current. At more positive membrane potentials, the application of Flupirtine induced an additional transient outward current. Probing the effect with voltage-jump protocols showed, that this initial current is not carried by chloride, and thus is not mediated via the $GABA_A$-receptor.

COMPARISON OF DIAZEPAM EFFECTS ON FREE CALCIUM LEVELS IN SYNAPTOSOMES AND SYNAPTONEUROSOMES FROM RAT BRAIN. J.V. Martin*, G. Thorp, L.B. LaCorte and H. Lee. Biology Dept., Rutgers Univ., Camden, NJ 08102.

In previous work, stimulatory effects of diazepam (DZP) on free Ca^{2+} were demonstrated using the membrane-permeant acetoxymethyl ester of the fluorescent dye fura-2 (fura-2/AM) in rat brain synaptosomes (Martin *et al.*, 1991, Brain Res. 548:222). As an approach to evaluate the relative presynaptic and postsynaptic contributions to the observed effects of DZP on Ca^{2+} metabolism, we compared the effects of DZP on Ca^{2+} in synaptosomes and synaptoneurosomes from rat brain. A freshly dissected brain (without brainstem or cerebellum) was divided equally as starting material for the two preparations. Synaptosomes were made by the Percoll step gradient method of Dunkley, *et al.* (1988, Brain Res., 441:59) and synaptoneurosomes were made according to Hollingsworth, *et al.* (1985, J.Neurosci. 5:2240). Both preparations were maintained in buffered salt solution in which Na^+ was replaced by isomolar choline (136 mM choline chloride, 5.6 mM KCl, 1.3 mM $MgCl_2$, 11 mM glucose, pH 7.4) and incubated with fura-2/AM for 55 min, followed by extensive washing, so the only fluorescent response was due to fura-2 generated inside the organelles by endogenous esterases. In all cases, depolarization with 45 mM added KCl including 1.2 mM $CaCl_2$ increased the level of cytoplasmic free Ca^{2+}. While DZP increased the levels of synaptosomal Ca^{2+} in a dose-dependent fashion which was synergistic with the effects of depolarization (as before), there was no effect of doses of DZP as high as 100 μM on synaptoneurosomal Ca^{2+}. Since synaptoneurosomal membranes are primarily post-synaptic in origin, these findings support the idea that effects of DZP on Ca^{2+} may be selectively mediated through a presynaptic mechanism. EXCITOTOXIC LESIONS IN NEOSTRIATUM/GLOBUS PALLIDUS CAUSE AN INCREASE IN IRON STAINING AND GLIAL CELL NUMBERS IN GLOBUS PALLIDUS AND SUBSTANTIA NIGRA. S. Sastry, G.W. Arendash, R. Richmond*. Dept. of Biology and Institute for Biomolecular Science, University of South Florida, Tampa, FL 33620.

The substantia nigra (SN) and globus pallidus, two iron-rich brain areas, receive a dense GABAergic innervation. This anatomic relationship suggests that GABA is important in regulating brain iron. Therefore, we investigated the effects of denervation of striatal/pallidal GABA inputs to globus pallidus/SN on iron staining and correlative histology; apomorphine induced rotation behavior was also assessed. Adult male Sprague-Dawley rats were divided into three groups. The first group received four ibotenic acid infusions (5 µg/µl PBS each) throughout the neostriatum and globus pallidus (NG); the second and third groups received two infusions of ibotenic acid each, into either the anterior neostriatum (AN) or the posterior neostriatum/globus pallidus (PG) regions. Animals were sacrificed at 1 month following surgery. Alternate brain sections were stained with thionine or for iron. All lesions were limited to the neostriatum/globus pallidus; NG lesions involved this entire region, whereas AN and PG lesions destroyed either the rostral or caudal halves, respectively. In the NG group, an increase in iron staining and gliosis occurred throughout zona reticularis of the SN (SNr). These changes were accompanied by a decrease in overall volume of the SN. Similar results were obtained for the PG group, with the gliosis in SNr being relatively localized. The AN group showed only a minimal increase in SNr iron staining with a localized gliosis. Also evident in the AN group was a marked gliosis and increased iron staining within globus pallidus. Only NG and PG groups showed substantial ipsilateral rotation through 1 month after lesions. These results indicate that discrete excitotoxic lesions compromising GABAergic innervation to SN and globus pallidus alter iron levels in these areas, supporting a regulatory influence of GABA on brain iron.

EFFECTS OF EXCITATORY AND INHIBITORY NEUROTRANSMITTERS ON WHOLE CELL RECORDINGS IN GUSTATORY ZONE OF NTS. L. Wang, M. S. King* and R. M. Bradley, Dept. of Biologic and Materials Sciences, School of Dentistry, University of Michigan, Ann Arbor, MI 48109.

The gustatory zone of the NTS contains fibers and terminals immunoreactive for substance P (SP) as well as GABA-immunoreactive interneurons. Therefore, SP and GABA may have important influences on rostral NTS neurons. We investigated the effects of these transmitters on neurons in the gustatory zone of the NTS using whole cell recording in slices of the rat medulla. Superfusion of μM concentrations of SP transiently depolarized 54 of 88 neurons (61%) and increased input resistance, while GABA (10^{-3}M) hyperpolarized 105 of 156 neurons (67%) and decreased input resistance. Since they could be elicited when synaptic transmission was blocked, these effects were due to direct postsynaptic action on the recorded neurons. GABA acted on both $GABA_A$ and $GABA_B$ receptors because both muscimol (10^{-3}M; $GABA_A$ agonist) and baclophen (10^{-4}M; $GABA_B$ agonist) mimicked the effects of GABA. In addition, the $GABA_A$ antagonist bicuculline (10^{-4}M) and the $GABA_B$ antagonist phaclophen (10^{-3}M) strongly suppressed the neuronal responses to GABA. Bicuculline also depressed synaptically induced IPSPs evoked by electrical stimulation of the solitary tract. Of 34 neurons tested, 15 (44%) responded to both SP and GABA, suggesting inhibitory and excitatory modulation of single rostral NTS neurons. The integration of these excitatory and inhibitory influences may be important in processing gustatory information. This possibility is currently being investigated through the analysis of inhibitory and excitatory potentials, evoked by electrical stimulation of the solitary tract, in neurons in the gustatory zone of the NTS. [Supported by NIH DC00288].

GABA-INDUCED MEMBRANE CURRENTS IN DISSOCIATED MEDIAL SEPTUM/DIAGONAL BAND (MS/nDB) NEURONS. G.D. Frye* and W.H. Griffith. Dept. of Med. Pharmacol. & Toxicol., Texas A&M Univ. Coll. of Medicine, College Station, TX 77843-1114

Anatomical and electrophysiological data indicate that cells in MS/nDB receive major GABAergic innervation. Virtually all cells in these regions appear to receive GABAergic synaptic contacts. In the present study a significant fraction of spontaneous postsynaptic potentials recorded intracellularly in MS/nBD brain slices were blocked by picrotoxin (30µM). Whole-cell patch clamp recordings in acutely dissociated, adult MS/nDB neurons, identified GABA-induced membrane currents in all cells examined (rats, n=10; Guinea pigs, n=7). Rapid application of GABA (30sec) by a large bore pipette induced concentration-dependent currents from a holding potential of -60mV that reversed near 0mV. Responses to GABA (3µM) showed little desensitization unlike larger responses to GABA (10µM) which swiftly decreased an average of 42.3±1.3% during the application. The effects of combined application of GABA with pentobarbital, midazolam or ethanol are currently being investigated. Supported by AG07805 (WHG); AA06322 and RSDA AA00101 (GDF)

DIRECT ACTIVATION OF THE $GABA_A$ RECEPTOR BY ISOFLURANE AND EVIDENCE FOR SUBUNIT SPECIFICITY. T.G. Hales, N.L. Harrison, S. Glusman* and M.V. Jones. Dept. Anesthesiology, UCLA, LA. CA 90024 and Dept. of Anesthesia and Critical Care, University of Chicago, Chicago, Il 60637.

Intravenous (IV) and volatile general anesthetics (GAs) potentiate neuronal responses to GABA. In addition, IV GAs directly activate $GABA_A$ receptors at anesthetic doses. We have investigated direct activation and modulation of $GABA_A$ receptors by isoflurane (ISO). Whole-cell recordings were made from cultured hippocampal neurons (HPC) from day 20 embryonic rats and immortalized hypothalamic (GT1-7) neurons, using 145 mM CsCl or K-gluconate based electrode solutions. GT1-7 neurons have been shown to contain mRNA for α1, β1 and β3 $GABA_A$ receptor polypeptides, but do not express γ subunits (Hales et al., Mol. Pharm. in press). Bath applied ISO (1-3 MAC 0.51-1.53 mM) modulated currents evoked by GABA (50-100 µM) in HPC and GT1-7 cells, under voltage-clamp. ISO increased the time for half-decay of GABA-evoked currents, in GT1-7 cells (by 299 ± 74% SEM) and HPC (by 152 ± 41%). Bath application of ISO (0.17-3 MAC) to HPC also directly activated an outward current, with K-gluconate in the electrode and 145 mM $[Cl^-]_o$, at -40 mV. Pressure application of ISO (< 4 mM) to HPC activated inward currents at negative potentials, which reversed at +3 ± 1 mV with 145 mM Cl- in the electrode and extracellular solutions. Reducing extracellular $[Cl^-]$ to 30 mM shifted the reversal potential of the ISO activated current to +38 ± 7 mV. GABA responses reversed at similar potentials. Bicuculline methiodide (BMI) (10 µM) and picrotoxin (5 - 10 µM) inhibited ISO-evoked currents by 78 ± 8% and 40 - 80 %, respectively. In the absence of ISO, BMI (20 µM) had no effect on the conductance of HPC. These data are consistent with ISO directly activating the $GABA_A$ receptor. ISO (<4 mM) did not directly activate currents in GT1-7 cells. One explanation for these data is that direct activation of the $GABA_A$ receptor by ISO is subunit specific. $GABA_A$ receptor activation by ISO may require subunit(s) not expressed by GT1-7 cells.

NMDA-RECEPTOR CHANNELS ARE SPECIFIC SOURCES IN THE SUPPRESSION OF $GABA_A$ RECEPTOR FUNCTION BY INTRACELLULAR CALCIUM H. Shi* and A. Stelzer. Dep. of Pharmacology, SUNY Brooklyn, Brooklyn, NY 11203.

Elevation of intracellular calcium $[Ca^{2+}]_i$ leads to a suppression of $GABA_A$ whole-cell currents in acutely dissociated CA1 pyramidal cells (cf. Chen et al., 1990, J. Physiol.). In the same preparation, we examined the contribution of various sources of $[Ca^{2+}]_i$ elevating systems in the regulation of $GABA_A$ receptors. Under whole-cell clamp conditions, voltage activated calcium currents were elicited by voltage commands from -70 to +10 mV followed in short intervals by GABA-induced chloride currents. Alternatively, NMDA currents were elicited by pressure application followed at similar intervals by GABA chloride currents. GABA-mediated outward currents were measured at +10 mV under both experimental conditions. Ca^{2+} influxes through NMDA-receptor channels produced a marked suppression of $GABA_A$ peak-current amplitudes. Recovery from reductions of $GABA_A$ responses generated by Ca^{2+} influxes through NMDA-receptor channels were absent in 47 out of 69 cells and small and incomplete in the rest. Changes of $GABA_A$ responses were not observed when NMDA currents were triggered in the absence of extracellular Ca^{2+}. In addition, voltage-activated calcium currents of any size and interval preceeding GABA currents did not affect $GABA_A$ responses. We assessed the amount of $[Ca^{2+}]_i$ elevations by calculating the sum of integrated individual currents through NMDA and voltage gated channels, resp. Elevations of $[Ca^{2+}]_i$ through NMDA-receptor channels which lead to a significant reduction of $GABA_A$ responses represent only a small fraction (less than 20%) of (ineffective) $[Ca^{2+}]_i$ rises through voltage-activated calcium channels. These data demonstrate that rises of $[Ca^{2+}]_i$ through NMDA receptor channels represent a specific source in the long-term suppression of $GABA_A$-receptor function.

413.10

$[^3H]$Ro15-1788 IS NOT A NONSELECTIVE BENZODIAZEPINE RECEPTOR RADIOLIGAND. P.A. Maguire*, M.F. Davies and G.H. Loew. Molecular Research Institute, Palo Alto, CA 94304.

With the emergence of multiple $GABA_A$ receptor subunit variants and many possible combinations in the brain, it has become a challenge to determine, from receptor binding studies, the number and pharmacological characteristics of the sites present. A major weakness has been the use of fairly nonselective radioligands. Critical to the determination of receptor heterogeneity using curve-fitting programs such as LIGAND, is that the K_d of the radioligand must be determined at each putative site present, as the K_i of each competing ligand is dependent on this value. We have found that $[^3H]$Ro15-1788 is not sufficiently selective to clearly distinguish different receptor types using LIGAND, however, its absolute nonselectivity cannot be assumed. We have been exploring a powerful new method to determine the K_d and receptor density of this ligand in several rat brain regions. This method, a Fourier-derived affinity spectrum analysis (FASA), (Anal. Biochem. 157:221, 1986), transforms receptor binding data (free and bound ligand conc.) into a probability-density function and solves it using Fourier analysis, resulting in an "affinity spectrum" of density as a function of affinity. No assumptions are made as to the number of binding populations. We have used this method to investigate the affinity of $[^3H]$Ro15-1788 at BDZ sites in several tissues, including the rat cerebellum and olfactory bulb. In each tissue, the radioligand binds to multiple sites with K_ds varying 10 to 20-fold. This information will greatly help the analysis of competitive binding data using LIGAND, by the determination of the number of binding sites, and by providing initial estimates for the subsequent calculation. The use of the FASA method, along with data analysis using LIGAND, should enhance our understanding of BDZ binding sites in the rat brain.

413.11

EFFECT OF A BENZODIAZEPINE AGONIST AND INVERSE AGONIST AND ZINC ON GABA-MEDIATED CHLORIDE INFLUX INTO CEREBELLAR AND CORTICAL MICROSACS M.F. Davies*, P.A. Maguire and G.H. Loew. Molecular Research Institute, Palo Alto, CA 94304.

Modulation of GABA-mediated ^{36}Cl influx into microsacs by ligands binding to the benzodiazepine (BDZ) site on $GABA_A$ receptors is a potentially useful discriminant of agonist and inverse agonist actions. To develop reliable conditions for assessing such actions, we have studied the effects of a prototypical agonist flunitrazepam (FLU 1μM) and inverse agonist DMCM (1μM) in rat cerebellar and cortical microsacs. In both tissues, most of GABA mediated ^{36}Cl flux occurred in the first 3 of 5s. Significant enhancement of this effect by FLU and reduction of it by DMCM was achieved in both tissues when the drugs were preincubated with the microsacs with ^{36}Cl and GABA for 3s. The DMCM effect was in part due to a reduction of flux in the nominal absence of GABA. Although reproducible, the effects of these BDZ ligands are modest (<50%), and may be due to not all GABA mediated Cl ion channels being sensitive to BDZs. To approach this problem, we have preformed these studies in the presence of zinc (100μM), known to preferentially inhibit GABA receptors that are insensitive to BDZs because they lack a γ subunit. The presence of Zn substantially reduced GABA (100μM) mediated ^{36}Cl flux in cortex (61±6%) and in cerebellum (51±8%) suggesting a significant proportion of the Cl channels are likely insensitive to BDZs. Under these conditions FLU increased dramatically to 273% from 42% without Zn. These results indicate that optimum conditions for measuring the effects of BDZ agonists and inverse agonists on GABA mediated ^{36}Cl flux involves measuring the effect within 3s of addition of GABA, but with the ligands in prior contact with the GABA receptor. Addition of Zn appears to enhance the effect of these ligands by allowing the measurement of Cl flux only through BDZ sensitive GABA channels.

413.12

BIOCHEMICAL MARKERS OF GABAERGIC AND DOPAMINERGIC TRANSMISSION IN THE CNS OF ROMAN HIGH-AVOIDANCE AND ROMAN LOW-AVOIDANCE RATS.

O. Giorgi*, M. Orlandi, D. Lecca, M.G. Pibiri, M.R. Murgia, A. Fernandez-Teruel (1), R.M. Escorihuela (1), P. Driscoll (2) and M.G. Corda.

Dept. of Exp. Biology, Neurosci. Section, Univ. of Cagliari, Italy. (1) Medical Psychol. Unit, School of Med., Autonomous Univ. of Barcelona, Spain. (2) Verhaltensbiologie Laborder ETHZ, Zurich, Switzerland.

A range of biochemical markers of GABAergic and dopaminergic (DAergic) neurotransmission were examined in the CNS of Roman high-avoidance (RHA/Verh) and Roman low-avoidance (RLA/Verh) rats, two psychogenetically selected lines which differ in their level of emotionality. The stimulatory effect of GABA (10 μM-100 μM) on ^{36}Cl-uptake was reduced in the cerebral cortex of RLA/Verh rats as compared with RHA/Verh rats. In addition, the increase of the GABA-dependent ^{36}Cl- uptake produced by diazepam (1 nM-100 nM) was larger in RLA/Verh rats than in their RHA/Verh counterparts. By contrast, no strain-related changes were detected in ^{3}H-GABA, ^{3}H-Flunitrazepam and ^{35}S-TBPS binding in the cerebral cortex. On the other hand, the density of D1 DA receptors labeled with ^{3}H-SCH 23390 was decreased in the nucleus accumbens of RLA/Verh rats as compared with RHA/Verh rats, whereas the binding parameters of these receptors were not different in the amygdala, prefrontal cortex and striatum of the two strains. It is proposed that these biochemical differences may play a role in the distinct emotional responsiveness and stress reactivity of RHA/Verh and RLA/Verh rats.

413.13

MDL 26479 MODULATES $GABA_A$ RECEPTOR ACTIVATED SINGLE CHANNEL CHLORIDE CURRENT FROM CULTURED RAT HIPPOCAMPAL NEURONS. C.J. ROGERS* and A.M. OGDEN, Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

$GABA_A$ receptor complex chloride current is gated through the integral ion channel by $GABA_A$ receptor activation and modulated via allosteric receptor interactions. MDL 26479, may act via a benzodiazepine-like binding site as an inverse agonist. In vivo, MDL 26479 displaced [^{3}H] Ro 15-1788 binding consistent with a benzodiazepine-like interaction. Extracellular recordings from the hippocampus revealed increased excitability with MDL 26479. [^{3}H]-Hemicholinium-3 binding was increased with MDL 26479 suggesting a benzodiazepine inverse agonist-like action. Behavioral studies indicate MDL 26479 enhances cognition. To determine whether MDL 26479 modulates GABA-activated Cl^- current and the mechanism by which it may do so, we used the single channel patch clamp recording technique. Single channel recordings were obtained from cultured rat hippocampal neurons in response to the pressure application, from 10-25 micron diameter micropipettes, of GABA (2μM) alone or GABA (2μM) plus MDL 26479 (20, 100 or 300nM). Single channel currents were pooled from up to 80 different recordings for each of the different conditions tested.

MDL 26479 modulated GABA-activated Cl^- current in a concentration dependent manner. Total Cl^- current, comparing GABA (2μM) alone versus GABA (2μM) plus MDL 26479 (20nM) was decreased by 38%, decreased by 69% at 100nM, but increased by 134% at 300nM. The mean open duration of the channel for the ~30 pS conductance state was concentration dependent: 2.42 msec, GABA (2μM); 6.1 msec, GABA (2μM) plus MDL 26479 (20nM); 3.34 msec, GABA (2μM) plus MDL 26479 (100nM) and 1.67 msec, for GABA (2μM) plus MDL 26479 (300nM). Further investigations are underway to better understand this concentration dependent response and to determine whether this compound selectively activates specific receptor subunit configurations.

413.14

EFFECTS OF MDL 26,479 ON MUSCIMOL STIMULATED ^{36}CHLORIDE INFLUX INTO BRAIN MEMBRANE VESICLES. J.A. MILLER*, D.L. Braun and P.A. Chmielewski, Marion Merrell Dow Research Institute, Cincinnati, OH, 45215.

The cognition enhancer MDL 26,479 possesses benzodiazepine (BZD) inverse agonist activity. However, MDL 26,479 does not bind to known sites on the $GABA_A$ receptor complex or other receptors. We examined the effects of MDL 26,479 on muscimol stimulated ^{36}Cl influx into brain membrane vesicles. Membranes were prepared by the method of Harris and Allan (Science 228: 1108, 1985).

MDL 26,479 at low (< 100 nM) and high (> 1 μM) concentrations inhibited muscimol stimulated ^{36}Cl influx. At intermediate concentrations (150 nM to 1 μM) MDL 26,479 enhanced the muscimol stimulated ^{36}Cl influx. In contrast the BZD inverse agonists DMCM and β-CCM (10 nM to 10 μM) had only inhibitory effects. When MDL 26,479 was combined with DMCM at concentrations ranging from 10 nM to 10 μM these two were additive in effect even at supramaximal concentrations. In contrast, when β-CCM and DMCM were combined they were additive only at threshold concentrations. The BZD antagonists flumazenil (10 μM) enhanced the inhibitory effect and blocked the stimulating effect of MDL 26,479 on ^{36}Cl flux whereas it antagonized the inhibitory effect of DMCM. These data suggest that MDL 26,479 acts as a combined positive and negative modulator at the $GABA_A$ chloride ion channel at a site which is distinct from the BZD site.

413.15

A COMPARISON OF THE ACTIONS OF THE BENZODIAZEPINE (BZ) PARTIAL AGONIST, Ro16-6028, WITH "FULL AGONIST" BZs ON THE $GABA_A$ RECEPTOR COMPLEX (GRC). D.A. Finn* and K.W. Gee. Dept. Pharmacology, College of Medicine, Univ. of California, Irvine, CA 92717.

Ro16-6028 (Bretazenil) is a relatively new imidazo-diazepinone derivative with a pharmacological profile characteristic of a BZ partial agonist. Ro16-6028 exhibits potent anticonflict and anticonvulsant effects with minimal psychomotor impairment or development of physical dependence. The present study utilized modulation of [^{35}S]*t*-butylbicyclophosphorothionate (TBPS) binding and enhancement of GABA-stimulated ^{36}Cl- (chloride) uptake as measures of GRC function to further assess Ro16-6028's partial agonist profile. Ro16-6028 was the most potent BZ examined, exhibiting an IC_{50} (concentration at which half-maximal inhibition of specific [^{35}S]TBPS binding occurs) of 1.1nM, compared to 21.7nM for diazepam (DZP), 4.3nM for clonazepam (CLON) and 4.7nM for flunitrazepam (FLU). However, Ro16-6028 was less efficacious in that it produced 27% inhibition of specific [^{35}S]TBPS binding, compared to DZP (49%), CLON (34%) or FLU (41%). In the presence of 10μM DZP, Ro16-6028 antagonized the inhibition of [^{35}S]TBPS binding due to DZP alone. These results provide further support that Ro16-6028 is acting as a partial agonist at the BZ receptor in modulating [^{35}S]TBPS binding. (Supported by NIH grants NS25986 and NS24645).

413.16

REDUCTION OF CALCIUM INFLUX BLOCKS HALOTHANE EFFECT ON $^{36}Cl^-$ EFFLUX RATE IN RAT BRAIN CORTICAL SLICES. B. Longoni*, G.C. Demontis and R.W. Olsen. Department of Pharmacology, School of Medicine, University of California, Los Angeles, CA 90024.

Halothane (0.56-1.7 mM) increases muscimol (1-10 μM) stimulated $^{36}Cl^-$ efflux in rat brain cortical slices. This halothane action is accounted for by an increase in [^{3}H]muscimol binding affinity for GABA-A receptors (Longoni and Olsen, 1991 *Abstr. Soc. Neurosci.* 17: 1341). Additionally, following four minutes exposure to muscimol plus halothane, removal of both drugs produces a large increase in $^{36}Cl^-$ efflux lasting for several minutes. Halothane's action on GABA-A receptors has been suggested to involve an increase in intracellular Ca^{2+} (Mody et al., 1991). We find that incubation conditions which reduce intracellular Ca^{2+} prevent the increased $^{36}Cl^-$ flux seen following exposure to and removal of halothane plus muscimol. $CoCl_2$ (200 μM), or Ca^{2+}-free medium, or BAPTA-AM (5 μM, a membrane permeant Ca^{2+} chelator) in the medium, all block the effect. The time course, halothane dose-dependence, and calcium-dependence of this effect will be compared to the direct effects of halothane on GABA-A receptors.

Supported by NIH Grant AA07680 to RWO.

413.17

Bretazenil, unlike CL-218,872 or abecarnil, is a partial agonist in electrophysiological assays of benzodiazepine (BZ) receptor activity.
C. M. Wang* and R. F. Cox, Burroughs Wellcome Co., Research Triangle Park, NC 27709.

Novel BZ receptor ligands have been described as anxiolytic without sedation and myorelaxation. The basis for anxioselectivity is unknown but has been attributed to either "partial" BZ receptor agonism (i.e., low efficacy) or subtype selectivity. We examined the effects of bretazenil (Ro 16-6028, a benzodiazepine), CL-218,872 (a triazolopyridazine) and abecarnil (a β-carboline), all so-called BZ partial agonists, on GABA-Cl channel activity of cultured hippocampal neurons in vitro and on firing rates of substantia nigra pars reticulata (SNR) neurons in vivo.

Clonazepam and diazepam, known BZ receptor agonists, potentiated GABA-Cl channel activity in vitro (EC50s ~0.1 uM) and inhibited SNR firing by up to 90% (ED50s 0.1 and 0.6 mg/kg i.v., respectively). Abecarnil, bretazenil and CL-218872 were all potent in vitro (EC50s 0.1, 0.2 and 0.5 uM, respectively). Abecarnil inhibited SNR firing by 86% at 4 mg/kg i.v. (ED50 0.3 mg/kg) and CL-218,872 by 77% at 8 mg/kg i.v. (ED50 1 mg/kg). The inhibitory effect of bretazenil plateaued at 50% after 4 to 8 mg/kg. Furthermore, bretazenil partially reversed or blocked clonazepam-induced inhibition of SNR firing.

These results suggest that bretazenil is a partial BZ receptor agonist relative to the full agonists diazepam and clonazepam. Both abecarnil and CL-218,872 have high efficacy, and their anxioselective effects may be due to factors other than partial agonism (e.g., BZ receptor subtype selectivity).

GABA CONCENTRATIONS CAN INFLUENCE THE PHARMACOLOGICAL PROFILE OF GABAA RECEPTOR ACTIVATED CURRENTS. G. White*and P. Ross. Neurogen Corp., Branford CT, 06405.

In general, the pharmacological profile of a ligand-gated channel is independent of ligand concentration, within the confines of agonist/agonist or agonist/antagonist interactions which can be predicted from simple pharmacological models. Holland et al. (Mol. Pharm. 39, 1991) reported that effects of some butyrolactones on GABA activated currents depended upon the concentration of GABA employed. This finding represents a significant departure from simple pharmacological models. We report additional evidence that the pharmacological profile of GABAA gated currents can depend upon the concentration of GABA employed. Adult rat dorsal root ganglion (DRG) neurons were isolated and recorded from using the whole-cell variant of the patch-clamp technique as described previously (White, J. Neurophys. 64, 1990). Oocytes were prepared and recorded from in a manner similar to that described by Malherbe et al. (Mol. Brain Res. 8, 1990). In oocytes injected with RNA from adult rat cortex and in DRG neurons, the anesthetic agent trichloroethanol (TCEt, 10 mM) potentiated current amplitudes at 5 μM GABA (835±183%, n=5 and 656±127%,n=5), but not at ~EC50 (100 μM GABA, n=6) concentration of GABA in oocytes (-3±9%, n=5). 5 mM TCEt actually reduced current amplitude by 26±6% (n=6) at concentrations of GABA > EC50 in DRG neurons (100 μM GABA employed, EC50=51 μM, n=17). In addition, 40 sec pre-application of 5 μM GABA often resulted in a reduced potentiation by TCEt, suggesting a time dependent as well as concentration dependent phenomenon. In DRG neurons, current activated by 5 μM GABA was potentiated 144±21% (n=7) in the presence of 25 nM alprazolam, whereas current activated by 50 μM GABA was not potentiated (-6±3%, n=7). A parallel shift in the GABA concentration/response curve should have resulted in a 40% potentiation at 50 μM GABA. A parallel shift in the concentration response curve for GABA in the presence of 25 nM alprazolam was observed in 2 of 2 oocytes examined. We conclude that the pharmacological properties of the GABAA receptor ionophore complex are varied and intricate.

414.1

A *cis* ELEMENT IN THE NEUROPEPTIDE Y GENE MEDIATES STIMULATION BY NERVE GROWTH FACTOR G.L. Yount*, R.A. Maikis and J.D. White. Div. Endocrinology and Dept Neurobiology & Behavior, SUNY Stony Brook, Stony Brook, NY 11794

Neuropeptide Y (NPY) gene expression, in rat PC12 cells, is stimulated by nerve growth factor (NGF) at the level of transcription. To investigate the mechanism by which NGF regulates rat NPY expression, we have transfected PC12 cells with vectors containing parts of the NPY gene promoter linked to a reporter gene in a modified pUC18 plasmid. The first vector contains 702 bp of the NPY 5' flanking sequence that includes a partial consensus AP1 sequence which is completely conserved in the human NPY gene (TGACTGC). A 81 bp deletion subclone of the first vector generated a second vector lacking the putative AP1 binding site. One day after electroporation, the cells were grown in the presence or absence of NGF (75ng/ml) for one day. mRNA levels of the reporter gene, the constitutive gene cyclophilin and the endogenous preproNPY were measured from total RNA. NGF induced a 2.5-fold increase in reporter mRNA levels in PC12 cells transfected with the vector containing the full length promoter region. Identical transfection experiments with the deletion vector demonstrated a loss of NGF stimulation. In all the transfection experiments, NGF treatment induced preproNPY mRNA levels an average of 6-fold above controls while cyclophilin remained unchanged. These data reveal a *cis*-acting element between -176 bp and -95 bp upstream of the transcription start of the rat NPY gene that mediates transcriptional activation seen with NGF treatment.

414.2

TRANSCRIPTIONAL CONTROL OF HIPPOCAMPAL NEUROPEPTIDE Y EXPRESSION. J.B. McCarthy, G.L. Yount, P. Camp, and J.D. White*. Div. Endocrinology and Dept. Neurobiology & Behavior, SUNY Stony Brook, Stony Brook, NY 11794.

Hippocampal neuropeptide Y (NPY) expression is predominatly localized to neurons in the dentate gyrus hilus and stratum oriens. In the current study NPY expression was analyzed following pentylenetetrazole (PTZ) induced seizure. Male Sprague-Dawley rats (200-225gm) were injected ip with 57mg PTZ/kg bw or vehicle. At 3, 6, 12, 18, and 24 hr post injection, animals were terminated and hippocampi removed. Total RNA was isolated from hippocampal extracts and preproNPY mRNA content was measured by nuclease protection analysis. PreproNPY mRNA levels increased 4.5-fold by 6 hr relative to control values, before returning to normal by 24 hr post-injection. *In situ* hybridization analysis of preproNPY mRNA levels in control and 6hr post-PTZ animals revealed that the change in total hippocampal preproNPY mRNA content was due to the apparent induction of NPY expression in dentate gyrus granule cells. Nuclear run-on analysis of control and 6 hr post-PTZ hippocampal extracts demonstrated a 2.5-fold increase in total hipocampal NPY transcription in PTZ-injected animals. The possible requirement for protein synthesis for increased NPY expression was investigated by anisomycin treatment prior to and throughout the 6 hr post-seizure interval. *In situ* hybridization analysis demonstrated a block of preproNPY mRNA induction in granule cells, suggesting a role for prior gene induction in activity-dependent NPY transcriptional activation. Thus, the simplest explanation for these data is that increased neural activity induced by convulsant treatment results in increased NPY transcription in granule cells that may be mediated by one or more cellular immediate early genes.

414.3

SECOND MESSENGER AND RECEPTOR-MEDIATED REGULATION OF SUPERIOR CERVICAL GANGLION NEUROPEPTIDE Y (NPY) EXPRESSION AND SECRETION. V. May* and K.M. Braas. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Superior cervical ganglion (SCG) neurons synthesize and secrete catecholamines and bioactive neuropeptides in response to a variety of stimuli. We have examined key regulators of neuropeptide Y (NPY) expression and secretion in primary rat SCG neuronal cell cultures. Enzymatically dissociated SCG cells from newborn rats were treated with 10 μM cytosine arabinoside to remove nonneuronal cells. Enriched SCG neuronal cells were subsequently cultured in serum-free defined medium containing 32 ng/ml NGF. The basal NPY secretory rate was less than 1% of the cell NPY content/h. To examine the regulation of SCG NPY expression and secretion, SCG neuronal cultures were treated with a variety of second messenger system activators and specific receptor ligands for 0 to 96 h. Dibutyryl cAMP elicited dose-dependent changes in NPY secretion and cell content. Sustained SCG neuronal NPY secretion stimulation of 8- to 10-fold was observed with dibutyryl cAMP treatment; other second messenger system activators, including the calcium ionophore A23187 or phorbol myristate acetate, elicited smaller reponses. Treatment of SCG cultures with pituitary adenylate cyclase activating polypeptide (PACAP) increased NPY secretion over 10-fold, in a dose-dependent manner; approximately 100-fold greater levels of the related peptide, VIP, were required to elicit similar half maximal stimulation of NPY secretion. (Supported by HD-27468 to VM)

414.4

TRANSCRIPTIONAL ACTIVATION OF NEUROPEPTIDE Y (NPY) PRECURSOR GENE BY MEMBRANE DEPOLARIZATION. H. Higuchi*, K. Nakano, A. Iwasa, and N. Miki. Dept. of Pharmacology I, Osaka Univ. Sch. of Med., Osaka 565, Japan.

Gene expression of neuropeptide Y (NPY), an important cotransmitter of catecholaminergic neurons, is regulated by neural activity via transsynaptic control. To investigate how neural activity changes its expression, changes in NPY mRNA abundance and transcriptional activity of the gene were studied in NG108-15 and PC12 cells. In these cells the membrane depolarization stimuli (high potassium and veratridine) increased NPY mRNA abundance time-dependently. The effect of veratridine was blocked completely by tetrodotoxin, while that of potassium was hardly suppressed. Voltage-dependent Ca channel blockers inhibited the increase in NPY gene expression by membrane depolarization completely. Transient assay using the CAT reporter genes containing the rat NPY gene promoter indicated that veratridine stimulates transcriptional activity of NPY gene. These findings suggested that membrane depolarization increases the NPY gene expression through transcriptional activation following Ca entry.

414.5

NEUROPEPTIDE Y EXPRESSION IN TARGET SPECIFIC NEURONS IN THE RAT SUPERIOR CERVICAL GANGLION. A.F. Elshaar*, K. Hentschel, and L.L. Wright, Dept. Anatomy/Neurobiology, BUSM, Boston, MA 02118.

This study was to compare the pattern of neuropeptide Y-like immunoreactivity (NPY-li) in adult and developing rat sympathetic superior cervical ganglion (SCG) neurons projecting to purely vascular targets, and those projecting to "mixed" vascular and glandular targets. Adult and postnatal day 5 (P5), P15, P25 male rats were used. The retrograde tracer Flurogold (FG) was injected into the temporalis muscle or frontal cortex to label SCG neurons projecting to a "purely vascular" target, and into the submandibular gland, to label neurons projecting to a "mixed" end organ. Immunofluorescence was utilized to compare the relative proportions of each population of SCG neurons that contained NPY-li.

Analysis of the results showed that nearly all (98%) of temporalis projecting neurons contain NPY, most (76%) of cerebral blood vessels projecting neurons contain NPY, and few (9%) of submandibular projecting neurons contain NPY. The results were similar at P5, P15, and P25, in that most of the SCG neurons projecting to the cerebral blood vessels and temporalis muscle contained NPY-li, while significantly few of those projecting to the submandibular gland contained NPY-li. From these data, we conclude that the population of neurons projecting to these target organs differ significantly in the percentage of neurons displaying NPY-li in adult and that this pattern is present after the fifth postnatal day of development. This work has been supported by a B.U. GSRA to AFE.

COMPARTMENTALIZATION OF VASOPRESSIN mRNA WITHIN HYPOTHALAMIC MAGNOCELLULAR PERIKARYA AND THEIR PROJECTIONS TO THE MEDIAN EMINENCE: IN SITU HYBRIDIZATION AT THE ULTRASTRUCTURAL LEVEL. A. Trembleau, M. Morales*, and F. E. Bloom, Neuropharmacolgy, The Scripps Res. Inst., La Jolla, CA 92037.

The neuronal localization of vasopressin (VP) mRNA was studied using a digoxigenin-labeled oligonucleotide complementary to nucleotides 908-943 of the VP cDNA. Vibratome sections of rat brain fixed by perfusion with 4% paraformaldehyde and 0.1% glutaraldehyde were permeabilized either by freezing or with triton X-100 and hybridized with the digoxigenin-labeled probe. Following the washing steps, the oligonucleotide was detected using an anti-digoxigenin antibody and the ABC-peroxidase method. The peroxidase was revealed with DAB enhanced with $NiCl_2$, the sections were postfixed with osmium tetroxide and embedded in epoxy resin. This method allowed us to label specifically VP magnocellular neurons of the rat hypothalamus. In addition, its high sensitivity was demonstrated by the labeling of VP neurons of the suprachiasmatic nucleus, where VP mRNA concentration is known to be low. At the electron microscope level, the well preserved morphology allowed for precise subcellular localization of VP mRNA: 1. MAGNOCELLULAR PERIKARYA. In the perikarya, the label was mainly associated with the membrane of the rough endoplasmic reticulum (RER), but not its lumen. This labeling was localized to discrete areas along the RER, suggesting a possible compartmentalization of VP mRNA within the RER. The Golgi apparatus, as well as neurosecretory granules appeared to be devoid of label. 2. AXONAL COMPARTMENT. Some axonal swellings in the median eminence, containing secretory granules, were highly labeled. These positive swellings were more abundant in salt-loaded rats. Some positive swellings were also observed in lactating rats and much more rarely in control animals. Within these swellings, the labeling was diffuse and therefore the precise localization of VP mRNA could not be ascertained. This limitation may be overcome through the use of colloidal gold probes.

414.7

ARGININE VASOPRESSIN (AVP) GENE EXPRESSION IN DISCRETE AREAS OF THE RAT BRAIN FOLLOWING PRE-TREATMENT WITH AVP. **P. Poulin*, P. Szot[1], O.J. Pittman and D.M. Dorsa[1]. Neuroscience Research Group, University of Calgary, Calgary, Alberta, CANADA and [1]GRECC, VA Medical Center, Seattle, WA 98108.**

It has been shown that AVP enhances its own release and enhances (sensitizes) the responses of the rat brain to subsequent AVP exposure. One possible mechanism for these effects may be by AVP-induced alteration in AVP gene expression. The level of cytoplasmic AVP mRNA was quantified autoradiographically by in situ hybridization in discrete areas of male Sprague Dawley rat brain 24 hrs following AVP (100 pmol icv) or vehicle (physiological saline icv) pre-treatment. Following decapitation, brains were frozen and 20 µm sections were hybridized with a ^{35}S-labeled probe for AVP mRNA, emulsion coated, developed and analyzed for the number of labeled cells and/or for densitometry. Preliminary results show that while AVP pre-treatment enhanced the number of hybridization positive cells in the Bed nucleus of the stria terminalis increases from 26 (control) to 35 (AVP pre-treated), the number of AVP mRNA expressing cells in the medial amygdala (16 control; 18 AVP pre-treated) and the paraventricular nucleus (rod .284 control; .283 AVP pre-treated) was not enhanced by AVP pre-treatment. These results suggest that pre-exposure of the rat brain to AVP results in discrete alterations of the expression of AVP message. Studies are now in progress to evaluate AVP mRNA levels in discrete areas of rat brain 1, 3, 6, and 12 hrs following AVP (100 pmol icv) or vehicle (physiological saline) pre-treatment. This work was supported by Savoy Foundation (PP) MRC (QJP) and VA medical center and NS 20311 (PS and DMD).

CCK mRNA EXPRESSION, PRO-CCK PROCESSING AND REGULATED SECRETION OF CCK IMMUNOREACTIVE PEPTIDES BY THREE ENDOCRINE TUMOR CELLS IN CULTURE: A VALID MODEL FOR BRAIN CCK? M.C.Beinfeld*, Dept. Pharm. & Physiol. Sci., St. Louis Univ. School of Medicine, St. Louis MO 63104.

Subclones of three common endocrine cell lines At-T20, rat insulinoma (RIN 5F), and a thyroid medullary carinoma (WE) express a single CCK mRNA species the same size as that found in rat brain. The WE cells contained levels of immunoreactive CCK comparable to rat cerebral cortex (about 4 ng/ mg protein) while the other cells lines contained significantly less CCK. Like the rat brain, they were able to correctly process pro-CCK to a form which co-eluted with CCK 8 on Sephadex and HPLC. All three cell lines secreted CCK 8 as well as some CCK 33, and this secretion was significantly enhanced by cAMP, but not by tumor-promoting phorbol esters.

When transfected with a eukaryotic expression vector containing the rat CCK cDNA behind the CMV promoter, the At-T20 cells expressed about 500 times as much CCK as the wild type. These cells still correctly processed pro-CCK to CCK 8, which suggests that either the expression of the processing enzymes is coordinately regulated with expression of the prohorme or that the enzymes are present in a considerable excess.

In summary, these cells lines appear to be a good model for studying pro-CCK processing in the brain and should facilitate future studies of CCK expression, biosynthesis, processing, and secretion. Supported by NIH 18667.

414.9

HALOPERIDOL-INDUCED NEUROTENSIN GENE EXPRESSION IN STRIATAL NEURONS IS REDUCED BY CHRONIC TREATMENT. K.M. Merchant*, D.J. Dobie and D.M. Dorsa. GRECC, Seattle VA Medical Center; Depts. of Psychiatry & Behavioral Sciences and Pharmacol., Univ. of Washington, Seattle, WA 98195.

Expression of neurotensin/neuromedin N (NT/N) gene in dorsolateral striatal (DLSt) neurons appears to be under the regulation of dopamine D_2 receptors such that acute blockade of D_2 receptors by neuroleptics (e.g., haloperidol) raises the level of NT/N mRNA by 1000%. The present study investigated the responses of this NT system to chronic haloperidol administration, a treatment which has been shown to increase the expression of D_2 receptors. Male Sprague-Dawley rats were treated s.c. with saline or haloperidol (1 mg/kg/day) using osmotic minipumps and sacrificed on day 28. A separate group of rats was treated similarly followed by removal of the pumps on day 28 and was challenged 24 hr later with a single dose of saline or haloperidol. Expression of NT/N mRNA was examined by *in situ* hybridization. Densito-metric analysis of film autoradiograms revealed that NT/N mRNA expression in DLSt was significantly lower in rats which received chronic haloperidol when compared to those which received acute haloperidol following chronic saline treatment. The tolerance in NT/N mRNA expression was not modified by an acute haloperidol challenge to rats chronically treated with haloperidol. It is likely that the decreased sensitivity of DLSt NT neurons to chronic haloperidol reflects a compensatory postsynaptic response to upregulation of D_2 receptors. (Supported by Scottish Rite Schizophrenia Foundation, the VA, and NS 20311)

REGULATION OF SOMATOSTATIN GENE EXPRESSION IN DISSOCIATED CULTURES FROM CEREBRAL CORTEX. G.T.Capone*, and C.B.Choi Dept of Pediatrics, The Kennedy Krieger Institute and Johns Hopkins Medical Institutions, Baltimore MD 21205

Somatostatin (SOM) is a small peptide transmitter/modulator found in the cerebral cortex. The two biologically active forms SOM-14 and SOM-28 are both derived from the same inactive precursor molecule preprosomatostatin (ppSOM). Within the cortex, SOM is localized to a small subset of interneurons and comprise about 2% of the total neuronal population.These neurons have been implicated in the pathogenesis of several neurologic disorders (Alzheimer's disease, Down syndrome, Epilepsy and hypoxic-ischemic encephalopathy).

Previous studies have demonstrated that the ppSOM gene can be regulated by such divergent stimuli as second messengers (cAMP), neurotransmitters (acetlycholine, glutamate) or membrane depolarization. The purpose of our study is to characterize ppSOM gene expression in developing cortical neurons using agents which mimic the effects of cAMP. Primary cultures of dissociated cerebral cortex were made from E15 mouse brain and grown for 7 days in MEM, with 10%FCS/10%HS in 95% air and 5% CO_2 . Cultures were stimulated with N^6-2-O dibutyrl cAMP or 8-Bromo cAMP then total RNA was isolated at 4,8,12 and 24 hours. Changes in ppSOM mRNA abundance was measured using Northern blot analysis. Stimulation with dbcAMP resulted in a (10-fold) increase in ppSOM mRNA by 4 hours and a (>50-fold) increase by 8 hours. When cultures were stimulated with BrcAMP increased ppSOM mRNA was also seen at 4 hours (2-fold), 8 hours (6-fold), 12 hours (9-fold) and 24 hours (7-fold) compared to untreated controls. Our results support previous findings which demonstrate that ppSOM gene expression is regulated via cAMP mediated signal transduction pathways and extend the observation to neurons in the developing cerebral cortex.

REGULATION OF SOMATOSTATIN GENE EXPRESSION BY CALCIUM AND TRIIODOTHYRONINE IN A RAT MEDULLARY THYROID CARCINOMA CELL LINE. L.J. Huffman and C.S. Whisnant*. Dept. of Physiology, West Virginia Univ. Hlth. Sci. Center, Morgantown, WV 26506.

Somatostatin (SRIF), a neuropeptide produced by C cells in the thyroid gland, has been shown to play a role in the modulation of thyroidal function. In the present study, we have assessed whether SRIF gene expression is regulated by calcium or triiodothyronine (T_3). Since cyclic AMP is a known regulator of SRIF gene transcription, we also evaluated the effect of forskolin or a cyclic AMP analog on SRIF production. Rat medullary thyroid carcinoma cells (MTC 6-23) were grown in DMEM and 15% horse serum. For experiments, cells were incubated in DMEM-0.05 mg/ml bacitracin. The media content of SRIF and calcitonin was determined by radioimmunoassay. Northern blot analysis (20 μg total RNA/lane) was used to assess SRIF mRNA levels. Forskolin (10^{-6}M) or the cyclic AMP analog (10^{-3}M) increased SRIF mRNA levels and SRIF in the media after four, eight, and 24 hours of stimulation ($p<.05$ vs control). A four hour exposure to calcium (3mM) was associated with two-fold increases in the media content of calcitonin and SRIF as well as intracellular SRIF mRNA levels ($p<.05$ vs. 0.5 mM calcium). However, T_3 (10^{-10}M; four hours) had no effect on SRIF mRNA level or media content. These results indicate that calcium acts to increase calcitonin release as well as cause increases in both SRIF secretion and steady state SRIF mRNA levels. Since SRIF has been shown to inhibit calcitonin secretion, SRIF may act in an autocrine fashion to limit calcitonin production in response to a calcium challenge. (Supported by WVU Med.Corp. and NIH BRG No.2 S07 RR05433-29).

EVALUATION OF A PUTATIVE CIS-ACTING ELEMENT IN THE 5' UPSTREAM REGION OF THE MURINE POMC GENE. J. F. Bishop* and M. M. Mouradian, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Transcription of the proopiomelanocortin (POMC) gene is inducible by phorbol esters and cAMP. We have previously identified two potential target sites for transacting factors between nucleotides -137 and -106 of the murine POMC gene that are 11 bases apart. One site is homologous to the consensus sequence for AP-1 binding (TCAGCCA) and the other for AP-2 (CCCCCCTCCC). To investigate the potential enhancer activity of this region, we have fused the -137 to -106 sequence upstream to the SV40 promoter in a chloramphenicol acetyltransferase (CAT) expression vector yielding pCAT-POMC-137/106. Transient transfection of AtT-20 cells with this construct revealed two fold induction of CAT expression compared with the enhancer-less vector. Alteration of this construct by point deletion of a single C from the AP-2-like sequence resulted in loss of this enhancer activity. No significant change in CAT expression was seen in response to forskolin and/or TPA treatment in pCAT-POMC-137/106 transfected cells, suggesting that the -137 to -106 region of the POMC gene is not by itself involved in AP-1 or AP-2 mediated transcription. Other factors that interact with this sequence to confer its enhancer activity remain to be explored.

DOPAMINERGIC REGULATION OF TRANSCRIPTIONAL ACTIVITY OF ENKEPHALIN GENE IN RAT BASAL GANGLIA. S. P. Sivam*and A.K. Chaudhary, Department of Pharmacology & Toxicology, Indiana University School of Medicine, 3400 Broadway, Gary IN 46408.

This study examined whether a deficiency of dopamine during neonatal developmental period will induce permanent alterations in the rate of transcription of enkephalin gene. Dopamine deficiency was induced in Sprague-Dawley rat pups, by intracisternal administration of 100 µg of free base of 6-hydroxydopamine (6-OHDA) on the third day after birth. The animals were sacrificed 60 days after the 6-OHDA lesion. Striatal tissues were used for the determination of preproenkephalin (PPE) mRNAs by Northern blot analysis, Met^5-enkephalin (ME) levels by radioimmunoassay and amines and metabolites by HPLC. The rate of transcription of PPE gene was determined by a nuclear run-on assay using nuclei isolated from fresh or frozen tissues; the ^{32}P-labelled run-on transcripts obtained from a run-on transcription reaction were hybridized to a slot-blotted nitrocellulose or nylon membrane containing a plasmid with rat cDNA for PPE. As expected, dopaminergic denervated animals exhibited a severe loss of dopamine (>90% of control), an increase in PPE-mRNA and an increase in ME levels. The rate of transcription of PPE gene as evidenced from the run-on transcription assay was increased in lesioned animals. The increase in the rate of PPE transcription gene coupled with an increase in PPE-mRNA and its translation product ME indicate an enhanced rate of biosynthesis of enkephalin in lesioned animals. The results suggest a crucial role for dopamine in the development and regulation of enkephalin neurons of the basal ganglia. Supported by USPHS grant NS26063.

GLUCOCORTICOIDS POTENTIATE FORSKOLIN STIMULATION OF ENKEPHALIN PRODUCTION IN BRAIN CELL CULTURES. **M. K. McMillian*, H. H. Suh, L. Thai, K. R. Pennypacker, P. M. Hudson and J. S. Hong. LMIN/NIEHS/NIH, MD14-06, Research Triangle Park, NC 27709**

Dexamethasone (DEX, 10^{-7} M) increased [Met^5]enkephalin (ME) secretion from cultured striatal and hippocampal cells 2-fold over basal release after 24 hrs and 4 days exposure, an effect comparable to stimulations with the adenylate cyclase activator forskolin (FSK,10^{-5} M) and the protein kinase C activator phorbol myristate acetate (PMA, 10^{-7} M). DEX strongly potentiated the stimulation by FSK (to > 8-fold over basal) at 4 days, but not after 24 hrs. DEX did not increase the response to PMA or to the Ca^{2+} ionophore ionomycin (10^{-6} M). The potentiation by DEX was mimicked by corticosterone and competitively blocked by the anti-glucocorticoid RU486. Surprisingly, progesterone pretreatment abolished the DEX effect. Stimulated ME release at 4 days reflected synthesis of peptide, being much greater than cell ME content, and increased preproenkephalin (PPE) mRNA was observed in in situ hybridization studies. In hippocampal cultures, PPE mRNA and ME and precursor peptides appeared restricted to a subpopulation of type-1 astrocytes. In striatal cultures, neurons may also contribute to the observed effects of DEX on ME.

414.15

LONG-TERM ACTIVATION OF NICOTINIC RECEPTORS IS REQUIRED FOR STIMULATION OF PROENKEPHALIN (PROENK) GENE EXPRESSION AND FOR LONG-TERM [MET^5]-ENKEPHALIN (ME) SECRETION IN BOVINE ADRENAL MEDULLARY (BAM) CELLS. H.H. Suh*P. M. Hudson, M. K. McMillian, D. Leszczyszyn and J-S. Hong, LMIN/NIEHS/NIH. RTP, NC 27709

We have previously reported that long-term exposure of BAM cells to nicotine increases both the secretion of ME and the expression of proENK gene. In order to elucidate the molecular mechanisms underlying these long-term effects of nicotine, studies were undertaken to determine whether continuous activation of nicotinic receptors is required for both the delayed increase in ME secretion and proENK mRNA. Cholinergic receptor antagonists, hexamethonium (1 mM) and atropine (1 µM), were added to the incubation media at different time points (0.5, 1, 3, 6, 9, 12, and 24 hr) after nicotine treatment and aliquots of incubation medium were taken at each time point for ME determination and the cells were harvested at 24 hr for proENK mRNA measurements. Nicotine (10 µM) stimulated two distinct phases of ME secretion; a short-term rapid phase, followed after 9 hr by a sustained increase in ME release. Hexamethonium and atropine added 0.5 to 6 hr after nicotine treatment significantly inhibited the long-term phase of ME secretion and the expression of the proENK mRNA levels measured after 24 hr of nicotine treatment. Surprisingly, these antagonists were ineffective in blocking the nicotine-induced responses when added 9 hr post-treatment. Nuclear run-on assays showed that the transcriptional rate for proENK mRNA was increased by nicotine for at least 9 hr after drug treatment. Our results suggest that the long-term (at least 6 hr) stimulation of BAM cells with nicotine is required for increases of proENK mRNA and the long-term secretion of ME. The increase in proENK mRNA levels induced by nicotine reflects increased transcription of the proENK gene. Currently, we are comparing these effects of nicotine with effects of this drug on the expression of tyrosine hydroxylase mRNA and the short- and long-term secretion of catecholamines.

414.16

NICOTINE INCREASES [MET^5]ENKEPHALIN (ME) IN RAT ADRENAL MEDULLA AND SPLEEN. **P.M.Hudson*, M.K.McMillian, K.R.Pennypacker and J.S.Hong, LMIN/NIEHS/NIH, MD14-06, Research Triangle Park, NC 27709.**

The promoter region of the preproenkephalin gene contains elements for regulation by a number of transcription factors and second messenger systems. In striatum and glia, cAMP and CREB appear important for regulation. In rat adrenal, there is evidence for AP-1 binding as a primary regulator, and in spleen NFκB has been reported to regulate enkephalin expression. Nicotine stimulates adrenal medulla and sympathetic and parasympathetic ganglia. Chronic nicotine (3mg/kg bidaily) was no more effective than saline injections at increasing adrenal ME, in agreement with reported findings. However, acute repeated nicotine injections (3mg/kg every 30 minutes for 3 hours) produced a significant 2-fold increase relative to saline injections when measured after 2 days. Adrenal medulla AP-1 binding was decreased by nicotine and the decrease was long lasting (12 hrs) after acute repeated injections. Adrenal NFκB binding was increased by nicotine. In spleen, repeated acute nicotine injections also increased ME by about 2-fold after 2 days. Both AP-1 binding and NFκB binding were increased in spleen by nicotine. Our data indicate differential regulation of ME in peripheral tissues by nicotine.

414.17

EFFECT OF NICOTINE ON RELEASE OF CALCITONIN GENE-RELATED PEPTIDE FROM THE RAT TRACHEA

S.JINNO, X.-Y.HUA, A.IWAI* & T.L.YAKSH Dept. of Anesthesiology, Univ. of California, San Diego, CA92093

Calcitonin gene-related peptide (CGRP) exists in the peripheral terminals of sensory C-fibers which innervate the airway. Topical nicotine is known to stimulate there terminals[1]. Given this excitatory effect, the present study assessed whether nicotine could evoke the release of C-afferent CGRP from the rat trachea. The rat trachea (from larynx to carina) was dissected free and incubated in oxygenated Krebs solution kept at 37•C. After 30-min equilibrium time, the trachea was sequentially incubated in tubes containing 2ml of : 1) Krebs (baseline); 2) Krebs + drugs (nicotine or capsaicin); 3) Krebs (post) for 10-min. CGRP levels in each test tube was analyzed by RIA. Nicotine ($5x10^{-6}$ to $5x10^{-5}$M) caused a concentration-dependent increase in the levels of CGRP in the perfusate. Forty minutes after the first exposure to nicotine, a second challenge with nicotine revealed a concentration-dependent desensitization of CGRP release. The releasing effect of capsaicin (10^{-7}M) was unaffected by nicotine desensitization. Pretreatment, however, with capsaicin (10^{-5}M) blocked nicotine (10^{-5}M)-induced peptide release. The result suggests that nicotine activated the peripheral terminals of capsaicin-sensitive primary afferents in the trachea and released CGRP.

PEPTIDES: PHYSIOLOGICAL EFFECTS II

415.1

THE EFFECTS OF REPEATED INTRACEREBRAL ADMINISTRATION OF CORTICOTROPIN-RELEASING FACTOR (CRF) ON THE ELECTROPHYSIOLOGICAL RESPONSE OF THE LOCUS COERULEUS TO SUBSEQUENT CRF OR CLONIDINE. L.H. Conti* and S.L. Foote. Dept. of Psychiatry, School of Medicine, Univ California San Diego, La Jolla, CA 92093.

Male Sprague Dawley rats were handled daily for 1 week following surgical implantation of a guide cannula aimed at the lateral ventricle. For the next 9 days, rats were either handled only, or handled while receiving an infusion (icv) of either CRF (3 ug) or sterile saline once each day. Twenty-four hours after the last infusion, rats were anesthetized with halothane and LC multiple unit activity was recorded. After establishing stable baseline activity, CRF (3 ug in 1 ul) or clonidine (1 ug in 1 ul) was infused into the lateral ventricle. In rats that had received no previous infusions, acute CRF produced a long-lasting increase in LC activity: 15 min post infusion, mean multiple unit activity was 176 % of baseline. However, in rats repeatedly treated with CRF prior to this acute challenge, CRF did not increase multiple unit activity in the LC: mean activity 15 min post infusion was 89 % of baseline. Additionally, in rats repeatedly treated with saline (icv), CRF failed to increase LC activity: mean activity 15 min post infusion was 98 % of baseline. In rats which were repeatedly handled but which received no infusions, CRF resulted in increased LC activity comparable to that seen in naive controls. The inhibitory effect of clonidine on LC activity was also diminished following repeated CRF administration. It is possible that the stress of repeated infusions resulted in repeated release of endogenous CRF which produced a functional decrease in responsivity to exogenous CRF and clonidine. This possibility is currently being investigated.

415.2

CYSTEAMINE PRETREATMENT ENHANCES INHIBITORY ACTION OF SS_{28} IN THE DENTATE GYRUS. T.W.J. Watson*, L. Borg. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

We have previously reported that both SS_{14} and SS_{28} exert an inhibitory action on the evoked ECFP pop spike recorded from the dentate gyrus (DG) and cause direct postsynaptic hyperpolarization of dentate granule cells. These experiments were designed to examine the effects of the somatostatin depleting agent cysteamine on responses to SS_{14}/SS_{28} in DG. 500 μm thick transverse rat hippocampal (HPC) slices were completely submerged and constantly perfused in a recording chamber with oxygenated pH buffered aCSF. Three to four week old Sprague Dawley rats were pretreated with a single injection of 200 mg/kg of cysteamine given 15 to 20 hours prior to preparation of brain slices. All recordings were carried out in 10^{-4} M bicuculline. Cysteamine pretreatment resulted in selective increase in the inhibitory action of SS_{28} on the DG ECFP. Threshold of inhibitory effect was noted at 0.1 μM with complete and reversible supression of evoked activity being observed at concentrations of 3 to 5 μM. Interestingly, inhibitory action of SS_{14} was reduced in the cysteamine pretreated slices. When cysteamine was added to the perfusate (100 μM) a gradual increase in amplitude and number of evoked pop spikes was observed and this increase in activity persisted during the wash. These findings indicate that cysteamine pretreatment results in selective enhancement of the response to SS_{28} with relative down regulation of SS_{14} response and suggests the possibility of a differential effect on receptor subtypes. The increased amplitude and repetitive firing observed during bath application of cysteamine supports the concept that somatostatinergic neurons in the DG play an inhibitory role in controlling the firing of DG granule cells and that loss of these neurons may be involved in the pathophysiology of certain seizure disorders.

415.3

NEUROPROTECTIVE AND LTP-ENHANCIMG EFFECTS OF CHOLECYSTOKININ IN HIPPOCAMPAL SLICES. K.Kawasaki ※ and M.Yasui, Div. of Pharmacol., Shionogi Res. Labs., Shionogi & Co., Ltd., Osaka 553, Japan.

Cholecystokinin octapeptide (CCK-8) is densely distributed in the hippocampus, however its functional significance in this area is still unclear. Here we demonstrate neuroprotective and long-term potentiation (LTP)-enhancing effects of CCK-8. CCK-8 dose-dependently enhanced the magnitude of LTP induced by tetanic stimulation of Schaffer collateral-commissural fibers in the CA1 region of guinea pig hippocampal slices. This enhancing effect was antagonized by concomitant application of a CCK_B-receptor antagonist. Furthermore, desulfated CCK-8 showed a similar action on the LTP. The late negative component of evoked response, which was sensitively reduced by a K^+ channel blocker and by elevation of extracellular [K^+], was reduced by CCK-8. In vitro ischemic insult (hypoxia & hypoglycemia) induced a transient disappearance of evoked response followed by a short hyperexcitable period and a long-lasting dysfunction of CA1 pyramidal neurons in hippocampal slices of stroke-prone spontaneously hypertensive rat. CCK-8 reduced spreading depression-like depolarization and shortened time for the early disappearance of evoked potential as well as that for recovery of population spike. This neuroprotective action was also mediated by CCK_B-receptors. These results suggest that CCK-8 plays a positive role in the memory system and shows neuro-protective effects possibly by closing K^+ channels via breakdown of phosphoinositide in the hippocampus.

415.4

VASOPRESSIN ELICITS A LASTING INCREASE IN EXCITATORY POSTSYNAPTIC POTENTIALS (EPSPs) IN VENTRAL HIPPOCAMPUS NEURONS. I.J.A. Urban and P.J. French Rudolf Magnus Institute, University of Utrecht, The Netherlands. (Spon: ENA)

Vasopressin (VP) is a neuropeptide which is synaptically released in several of brain structures, including the lateral septum (LS) and ventral hippocampus (VH). Small amounts of VP, applied centrally, alter acquisition and extinction of various conditioned behaviors as well as the activity of brain neurons. In LS slices, pM concentrations of VP for hours enhanced EPSPs in LS neurons, without affecting the resting membrane potential (RMP), input resistance (IR) and other properties of these neurons. We used conventional microelectrode (3M KAc) and studied in brain slices the effect of VP on the EPSPs in neurons in the CA1/subiculum region of VH, evoked by stimulation of the stratum radiatum. Application for 15 min with 10^{-10} M VP had little effect on either RMP (before VP: -62.6±7.5 mV; 35 min after VP: -60.7±5.3 mV), IR (before VP: 46.8±6.5 MΩ; 35 min after VP: 49.2±8.7 MΩ) or the threshold for action potential was little changed by VP (before VP: 50.51±3.4 mV; 35 min after VP: 48.7±4.9 mV). In 14 of 20 neurons studied, EPSPs commenced to increase during and after VP application. At 35 min after the peptide application the amplitude of the EPSPs attained on average 137.5% of the control values and remained at this level for the rest of the recording (maxim 2.5 hrs). In the remaining 6 neurons EPSPs either did not changed (n=4) or decreased (n=2) after the VP treatment. Thus, pM concentration of VP can for many hours enhance the efficacy of the excitatory, presumably glutamatergic, transmission on CA1/subiculum neurons of the VH presumably by augmenting the glutamate release and/or the sensitivity of postsynaptic glutamate receptors. This VP effect was presumably different from the short excitatory action on the hippocampus, LS and other brain neurons that required much higher VP concentrations, may be of physiological significance and could be related to the behavioral effects of this neuropeptide.

415.5

EFFECTS OF CEREBROLYSIN ON SYNAPTIC TRANSMISSION IN THE RAT HIPPOCAMPUS. J.M. Wojtowicz, S. Wang and A. Baskys*, Department of Physiology and Clarke Inst. of Psychiatry, Univ. Toronto, Toronto, Ont, M5S 1A8, Canada.

Cerebrolysin (CB) is a brain tissue-derived mixture of polypeptides and amino acids that is widely used in treatment of dementias. To understand how CB exerts its therapeutic actions we applied it acutely to the rat hippocampal slices from 3-5 week old Wistar rats. CB was dissolved in saline and applied to slices for 5-10 minutes. CB inhibited the evoked field potential (FP) responses in the CA1 region of the hippocampus. The threshold of the effect was observed at 2μL/ml and a maximal inhibition at 10-20μL/ml. At 10μL/ml FPs were inhibited by 59% (S.E.=9.5, n=11). In 5 out 11 experiments a long-lasting increase (28%, S.E.=12.7) of FPs followed the inhibition. The effects were not associated with changes in the presynaptic fibre volley or paired pulse facilitation. Addition of 10μM bicuculline did not affect the CB action on FP, suggesting independence of $GABA_A$ receptors. Similar effects were observed in CA3 area of the hippocampus but not in the dentate gyrus where smaller inhibition (16%, S.E.=1.5, n=4) followed by 18.5% increase was noted. Given complex, albeit unknown composition of CB, it appears to have remarkably specific action on synaptic circuits in the hippocampus. Further studies are needed in order to elucidate the active ingredient(s) of CB. Supported by EBEWE, Austria.

MODULATION OF PAIRED-PULSE STIMULATION IN THE RAT HIPPOCAMPAL SLICE BY CHOLECYSTOKININ OR BICUCULLINE. E. Rich-Bennett*, D. Dahl, and B. B. LeCompte III. The University of Texas at Dallas, Richardson, TX 75083.

Cholecystokinin (CCK) is an ubiquitous cortical neuropeptide, and has been found to be colocalized with GABA in the hippocampal dentate gyrus. Paired-pulse stimulation was used to examine the effects of CCK (8S) and bicuculline (BIC, a $GABA_A$ antagonist) on activation of granule cells by selective orthodromic stimulation of the medial (MPP) or lateral (LPP) perforant pathways. An index of paired-pulse inhibition (PPI) or facilitation (PPF) was obtained by an initial control stimulus (S1) followed 10 sec later by paired stimuli ($S2_A$ & $S2_B$) with interpulse intervals (IPI) in the range of 5 to 1000 ms. The indices were determined by the ratio $S2_B/S1$, and were used to obtain paired-pulse response curves. Each pathway condition consisted of a drug-free (ACSF) response curve, followed by a drug response curve obtained during perfusion with either 1 μM CCK-8S or 1 μM BIC.

At the granule cell layer, each pathway possessed similar ACSF response curves: an early PPI (< 40 ms IPI), an intermediate PPF (30-200 ms), and a late PPI (200-1000 ms). With the LPP, BIC attenuated the inhibition of the early PPI, as well as the facilitation of the intermediate PPF, but had little or no effect on the late PPI. CCK-8S had little effect on the early or late PPI, but greatly enhanced the intermediate PPF. With the MPP, BIC attenuated inhibition of both the early and the late PPIs, as well as the intermediate PPF. The results with CCK-8S were similar to those found with the LPP. In contrast to the cell layer, the molecular layer ACSF response curves clearly differentiated the LPP from the MPP: the LPP showed a PPF for 10-1000 ms IPIs, whereas the MPP showed either no change or a slight PPI. Neither BIC nor CCK-8S had a clear effect on the molecular layer responses. (Supported by the Whitehall Foundation.)

ACTIONS OF SOMATOSTATIN ON GABA-ERGIC SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS. Z. Xie* and B. R. Sastry, Neurosci. Lab., Dept. of Pharmacol. & Therap., Univ. of B. C., Vancouver, B. C., Canada, V6T 1Z3.

Since somatostatin (SS) and gamma-aminobutyric acid (GABA) are co-localized in some neurons, the interactions between the actions of SS and GABA-ergic inhibitory postsynaptic potentials (IPSPs) in the CA1 pyramidal neurons of guinea pig hippocampal slices, are investigated. SS (SS-14, 2 μM) induced a hyperpolarization of the CA1 neurons associated with a reduction in the input resistance of the cells (n=16). These effects were not blocked by picrotoxinin (20 μM) (n=24) or phaclofen (1 mM) (n=16). Chelation of intracellular Ca^{2+} (Ca^{2+}_i) with BAPTA (n=6) or inhibition of protein kinase C (PKC) with sphingosine (30 μM) (n=4) had no significant effects on the hyperpolarizing action of SS. The peptide suppressed the $GABA_A$ receptor-mediated fast IPSPs and the $GABA_B$ receptor-mediated slow IPSPs, but had no significant effect on the excitatory postsynaptic potentials (EPSPs) (n=16). SS-induced depression of the IPSPs was not due to the hyperpolarization of the neurons. SS-induced hyperpolarization of the CA1 neurons was greatly reduced in the presence of baclofen (20 μM, n=6), an effect that was not due to the hyperpolarization by baclofen. The presence of QX-314 in the CA1 neurons, prevented the hyperpolarization of the neurons by SS and baclofen (n=12). QX-314 blocked the depressant effect of the peptide on the fast IPSP but not of the depressant effects of baclofen on the EPSP and the fast IPSP (n=12).

These results indicate that SS depresses GABA-ergic IPSP without affecting the GABA receptors. The peptide suppresses the fast IPSP through a QX-314-sensitive postsynaptic mechanism. SS can modulate IPSPs if the peptide receptors and the postsynaptic $GABA_B$ receptors are coupled to the same channels or the peptide and the amino acid act through the same intracellular second messengers. (The authors are grateful to Astra Pharmaceuticals for the gift of QX-314.)

415.8

GALANIN INDUCED ACETYLCHOLINE RELEASE IN THE RAT STRIATUM; POSSIBLE MECHANISMS. A. Pramanik* and S.O. Ögren. Dept. of Histology and Neurobiology, Karolinska Institute, Box 60 400, S-104 01 Stockholm, Sweden.

Galanin (GAL), a biologically active neuropeptide, is widely distributed in the CNS. Available evidences suggest that GAL is an inhibitory modulator of several neurotransmitters at both the pre- and postsynaptic levels. Recently we have for the first time demonstrated that GAL also possesses a facilitatory modulation of acetylcholine (ACh) in the rat striatum (Ögren and Pramanik, Neurosci. Lett. 128 (1991) 253-256).

The effect of GAL on the basal and the muscarinic agonist/antagonist mediated release of ACh was investigated in the enflurane-anaesthetized rats (body wt. 260-280 g) using in vivo microdialysis and HPLC techniques. GAL (3 nmol/10 μl), applied in the lateral ventricle (i.c.v.) or perfused through the microdialysis membrane into the striatum, was found to enhance basal ACh release. The GAL evoked ACh release was completely prevented by bupivacaine (Na^+-channel blocker, 0.25%) when coperfused with GAL. This shows that the effect of GAL depends on neuronal activity and thus is ascribed to action potential-dependent processes. In addition, the putative GAL antagonist M15 (3 nmol/10 μl, i.c.v./intrastriatally) completely blocked the GAL evoked ACh release, suggesting that GAL stimulates the basal ACh release in the rat striatum by a direct action of the peptide on striatal GAL receptors. GAL ((3 nmol/10 μl, i.c.v. or intrastriatally) was able to reverse the oxotremorine (0.3 mg/kg, i.p.) or carbachol (0.1 mM, infusion) induced inihibition of ACh release but did not change the scopolamine (0.25 and 0.5 mg/kg, i.p.) or pirenzepine (1 μM, infusion) stimulated release of ACh. In contrast to the GAL evoked ACh release, the scopolamine (0.25 mg/kg, i.p.) stimulated ACh release was not blocked by M15, indicating that the mechanisms behind GAL and scopolamine evoked striatal ACh release differ. Our data indicate that stimulation of the basal ACh release by GAL in the striatum occurs in striatal interneurons. The implication of this finding for both the peptide functions and how peptide-receptor coregulations may occur in the CNS will be further discussed.

415.9

SYNTHESIS AND EVALUATION OF THE PHYSIOLOGICAL EFFECTS OF HUMAN GALANIN. T.P. Iismaa,* D.G.P. Carey, D.J. Chisholm, I. Ferguson, K.K.Y. Ho, E.W. Kraegen, N.D. Oakes, I.A. Rajkovic and I. Shine. Garvan Institute of Medical Research, St Vincent's Hospital, Darlinghurst 2010, Sydney, Australia.

Human galanin is a 30 amino acid peptide which differs significantly from porcine, bovine and rodent galanin both in regard to sequence in the carboxy-terminal segment of the peptide and in the absence of carboxy-terminal amidation. Synthetic human galanin, prepared using a solid phase peptide synthesiser and purified to homogeneity using high pressure liquid chromatography, was administered to rats and humans in order to assess the biological activity of human galanin. Intravenous bolus administration of synthetic human galanin to conscious rats during glucose infusion increased blood glucose elevation and reduced circulating insulin, consistent with established effects of native galanin in the rat. Synthetic human galanin was infused for 90 min into healthy human volunteers at low and high levels (33 and 132 pmol/kg/min, respectively) for 90 min or saline control (n=8). A 25g intravenous glucose bolus was administered 30 min into the galanin infusion. There was a small drop in systemic blood pressure and an increase in resting heart rate during the infusion. All subjects reported a metallic taste and hypersalivation. No significant effect of human galanin on plasma glucose, serum insulin (basal or stimulated) or C-peptide levels was observed relative to control. Plasma growth hormone levels rose even in the face of a glucose load in both low and high dose infusions. Thus, human galanin is an ineffective β-cell suppressant in humans, compared with rats, but significantly increases growth hormone secretion.

415.10

PASSIVE IMMUNIZATION TO GALANIN ALTERS BIOGENIC AMINE METABOLISM IN MALE RATS. S.M. Gabriel* and P.J. Knott, Dept. Psychiatry, Mount Sinai School of Medicine, New York, NY 10029 and Bronx VA Hospital, Bronx NY 10468.

Galanin is found in biogenic amine-containing neurons. In the present study, male rats were implanted with lateral ventricular cannulae. After surgical recovery, 2μl of preimmune or a specific anti-galanin serum were administered intraventricularly to freely-moving, conscious rats. Animals received two morning injections, 24 hours apart. Hypothalamic tissues were harvested 4 to 6 hours after the second injection for analysis of biogenic amine and metabolite concentrations by HPLC with electrochemical detection. Concentrations of the serotonin metabolite, 5-hydroxy-indol-acetic acid [5HIAA] were significantly elevated 33% and 39% in anti-galanin versus preimmune-treated rats in the medial basal and preoptic hypothalamus, respectively. Concentrations of 5HIAA were unchanged in the paraventricular and supraoptic hypothalamus. Presumably, passive immunization sequesters released peptide. Thus, these data suggest that galanin exerts an ongoing inhibitory influence on serotonergic neurotransmission, perhaps subsequent to increased serotonin release or monoamine oxidase activity. This indicates that a novel biological interaction exists between galanin and serotonin.

415.11

N-Acetyl-Aspartyl-Glutamate Potentiates Inward Currents in Rat Dorsal Lateral Geniculate Nucleus Neurons In Vitro. R.A. Brautigan and D.A. Eagles* Department of Biology, Georgetown University, Washington, DC 20057.

N-acetyl-aspartyl-glutamate (NAAG) is an endogenous dipeptide found in varying concentations throughout the brain and is proposed to have a neurotransmitter or neuromodulatory role in the central nervous system. In the visual system, high concentrations and a calcium-dependent release have been reported (Moffett et al., Brain Res 538:86-94, 1991). Among the highest concentrations noted was that of the dorsal lateral geniculate nucleus (dLGN). Since retinogeniculate transmission is thought to be mediated by glutamate, and NAAG has been reported to activate glutamate receptors, its effect was studied on dLGN neurons in the rat. In vitro slice preparations were used to do whole cell patch clamp electrophysiology on 300 micron thick thalamic slices containing the dLGN.

When NAAG was applied via a pressure pipette (9 mM in ACSF, pH 7.3) positioned upstream from the recording site, cells clamped at the resting membrane potential (typically -68 to -73 mv) exhibited fluxes of inward current (as much as -.14 pA) for varying periods of time before returning to baseline current values. Similar responses were obtained when glutamate (10 mM in ACSF, pH 7.3) was applied in the same manner, suggesting that responses to NAAG were mediated by glutamate receptors. These results suggest a role for NAAG as a neurotransmitter in the dLGN.

PEPTIDES: PHYSIOLOGICAL EFFECTS III

416.1

PARTICIPATION OF ENDOGENOUS NEUROPEPTIDE Y IN THE SUPPRESSION OF BARORECEPTOR REFLEX RESPONSE BY LOCUS COERULEUS IN THE RAT. J.Y.H. Chan*, C.D. Shih and S.H.H. Chan. Dept. of Med. Res., Vet. Gen. Hosp.-Taipei and Inst. of Pharmacol., Natl. Yang-Ming Med. Coll., Taipei, Taiwan, R.O.C.

We evaluated the role of endogenous neuropeptide Y (NPY) in the suppression of baroreceptor reflex (BRR) response by locus coeruleus (LC), using adult, male Sprague-Dawley rats anesthetized with pentobarbital sodium (40 mg/kg, i.p.). Under an electrical stimulation condition (10-s train of 1-ms rectangular pulses, at 10-20 μA and 10-20 Hz) that did not appreciably alter the basal systemic arterial pressure and heart rate, the LC significantly suppressed the BRR responses induced by an intravenous injection of phenylephrine (5 μg/kg). Bilateral microinjection of NPY (4.65 pmol/20 nl), or an antiserum against NPY (1:20, 20 nl), into the nucleus tractus solitarius (NTS), the terminal site of baroreceptor afferents, elicited respectively a reduction in, and an enhancement of, the BRR response. Direct application of the NPY antiserum into the NTS also attenuated the suppressive effect of the LC on the BRR response. Treatments with normal rabbit serum, and heat-inactived NPY or NPY antiserum, on the other hand, were ineffective. These results suggest that neurons in the brain that contain NPY may exert a tonic reduction in the BRR sensitivity. Furthermore, the endogenous NPY may participate in the modulation of the same reflex by the LC. Both these actions may possibly take place at the NTS.

416.2

EFFECT OF NEUROPEPTIDE-Y (NPY) ON BLOOD FLOW IN THE RAT TAIL AND FOOT. M. E. Heath and J. R. Thomas*, Navy Medical Research Institute, Bethesda, MD 20889.

The purpose of this study was to assess the effect of i.v. administered NPY on superficial cutaneous microcirculatory blood flow in the tail and foot (by laser doppler flowmetry), and on total blood flow in the tail (via venous occlusion plethysmography). Male 300 g Long-Evans rats, with jugular catheters, were anesthetized, placed in a tubular plexiglass holder, and allowed to equilibrate for 25-30 min before experiments. NPY, norepinephrine (NE), [Leu^{31}, Pro^{34}]NPY, NPY[13-36] or saline control was administered i.v. following 5 min of baseline data. Increasing doses of NPY, from 16 to 64 ug/kg, induced an immediate, marked, and long lasting decrease in superficial cutaneous microcirculatory blood flow in both foot (max=50%) and tail (max=25%). In contrast, total blood flow in the tail either showed no change or increased (max=25%). In addition, the volume of blood in the tail usually increased in response to NPY, thus suggesting relaxation of and reduced resistance in the larger tail vessels. NE and the specific Y_1 receptor agonist, [Leu^{31}, Pro^{34}]NPY, produced effects on superficial foot and tail blood flow and on total tail blood flow similar to that of NPY, although smaller in magnitude. NPY[13-36], a specific Y_2 receptor agonist, did not appear to modulate blood flow in either the foot or tail. These findings suggest that NPY Y_1 receptors do, and Y_2 receptors do not, participate in the cutaneous microvascular blood flow response of NPY.

416.3

VASCULAR EFFECTS OF SYSTEMIC IMMUNIZATION AGAINST VASOACTIVE INTESTINAL PEPTIDE AND NEUROPEPTIDE Y. M. Michalkiewicz*, L.J. Huffman, M. Dey and G.A. Hedge. Department of Physiology, West Virginia Univ. Hlth. Sci. Ctr., Morgantown, WV 26506

The regulatory peptides, VIP and NPY, are present in autonomic nerve fibers innervating blood vessels. Exogenous VIP exerts vasodilatory effects resulting in a decrease in blood pressure (BP), while NPY has vasoconstrictor effects resulting in increased BP. To study the role of endogenous VIP and NPY in the regulation of BP, we passively immunized rats against these peptides. Anti-VIP serum (AVS-1) and anti-NPY serum (ANS-1) were generated in rabbits against synthetic porcine VIP and NPY, respectively. VIP monoclonal antibody (VIP-1b) was supplied by J.C. Porter (Univ. of Texas). AVS-1 has a B_{max}=4.91 nmol/ml and Kd=0.83 nM for VIP and does not crossreact with any of 17 other peptides tested, including peptide histidine isoleucine. ANS-1 has a B_{max}= 1.99 nmol/ml and Kd=0.47 nM for NPY and does not crossreact significantly with rat peptide YY, rat pancreatic peptide or any of 8 other peptides tested. Arterial BP was continuously measured in anesthetized (ketamine & pentobarbital) Sprague-Dawley rats (males, 220-250g) for 45 minutes beginning 5 min before treatments. BP was not changed after ANS-1 administration (1 ml, iv) when compared to BP in control rats (saline or normal rabbit serum). In contrast, when AVS-1 (1 ml, iv) was given, BP increased (144%, $p<0.01$). Heart rate was not changed. Similarly, VIP-1b (2-10 mg IgG, iv) increased BP in a dose-dependent manner (up to 138%, $p<0.01$). These results suggest that VIP may function as a tonic vasodilator and be involved in the physiological regulation of BP in the rat, whereas the involvement of NPY in the maintenance of normal BP is not evident. (Supported by NSF DCB-8904470).

416.4

DIFFERENTIAL ACTION OF NEUROPEPTIDE Y AND SUBTYPE AGONISTS ON SINGLE UNIT ACTIVITY IN THE PARAVENTRICULAR HYPOTHALAMUS. V.B. Aramakis*, J.H. Ashe, J. Juranek, L.M. Lomeli, A. Taneja & B. G. Stanley. Depts. Neuroscience & Psychology, University of California, Riverside, CA 92521

Hypothalamic neuropeptide Y (NPY) has multiple behavioral and physiological functions and has been shown to produce both increases and decreases in neuronal activity. To determine the possible contributions of NPY receptor subtypes to these responses, the effects on neuronal activity of NPY and the presumed Y1 and Y2 agonists [Pro34]-NPY and C2-NPY were examined. Coronal slices of rat hypothalamus were maintained in vitro and extracellular single unit recordings have been obtained from 39 paraventricular nucleus (PVN) neurons and 7 perifornical area (PFH) neurons. Cells in the PVN had a spontaneous firing rate of 3.2 spikes/sec; spontaneous firing rate for cells in the PFH was 7.8 spikes/sec. In the PVN, microtopical application of NPY and [Pro34]-NPY produced a repeatable decrease (11/16 at 1.5 μM and 6/13 cells at 0.15 μM) on average, to 20% of spontaneous rates. The reduction lasted from 3 to 20 min. Similar responses to NPY were evident in the PFH. In contrast, C2-NPY (0.15 μM) application in the PVN predominantly increased firing rate an average of 79% in 5/9 cells. Excitation lasted an average of 4 min and most cells returned to their baseline firing rates. The present findings suggest that the NPY agonists have differential effects on neuronal discharge rate; perhaps via actions on different NPY receptors. Supported by NSF BNS9008818 and NIH NS24268.

416.5

BI-DIRECTIONAL REGULATION OF INTRACELLULAR CALCIUM CONCENTRATION BY NEUROPEPTIDE Y (NPY) RECEPTOR ACTIVATION IN PC12 CELLS. X. Chen and T.C. Westfall* Dept. Pharmacol. & Physiol. Sci., St. Louis Univ. Sch. of Med., St. Louis, MO 63104

We have previously demonstrated that catecholamine (CA) release from PC12 cells can be modulated by NPY receptor activation through a non-cyclic AMP pathway (Soc. Neurosci. Abstract 17:79.9, 1991). In the present study, we tested the hypothesis that NPY modulates CA release via its action on intracellular Ca^{++} concentration ($[Ca^{++}]_i$) in PC12 cells. PC12 cells were co-cultured with A10 cells (embryonic rat aorta smooth muscle cell) and differentiated with either nerve growth factor (NGF) or dexamethasone (DEX) for 5-7 days. Changes in $[Ca^{++}]_i$ in single PC12 cells were monitored by spectrofluorometry. NPY ($5x10^{-7}$ M) potentiated the K^+-induced increase in $[Ca^{++}]_i$ in the PC12 cells differentiated by NGF or DEX. In contrast, NPY^{13-36} (10^{-7} M and 10^{-6} M), which was shown to inhibit evoked CA release in PC12 cells through activation of Y_2 receptors, attenuated K^+-induced increase in $[Ca^{++}]_i$ in NGF-treated cells. The attenuation by NPY^{13-36} was not observed in DEX-treated cells, which is consistent with our previous results showing that DEX-treated PC12 cells have neither Y_2 binding sites nor Y_2 receptor-mediated modulation of CA release. The attenuation of K^+-evoked increases in $[Ca^{++}]_i$ induced by NPY^{13-36} was dependent on extracellular Ca^{++}, but the potentiation induced by NPY was not. NPY at a concentration of 10^{-7} M showed a potentiation of K^+-evoked increases in $[Ca^{++}]_i$ in Ca^{++}-free buffer, although it had no effect in Ca^{++}-containing buffer. The effect of NPY was attenuated by thapsigargin, an intracellular Ca^{++} depleting agent. PYX-2, a NPY receptor antagonist, significantly blocked NPY- and NPY^{13-36}-induced potentiation and attenuation, respectively. These results suggest that NPY^{13-36} attenuates CA release by inhibiting extracellular Ca^{++} influx through Y_2 receptor activation. (Supported by HL35202 and HL26319).

NEUROPEPTIDE Y MODULATION OF MELATONIN SECRETION FROM RAT PINEALOCYTES. V. Simonneaux*, S. Bichet and P. Pévet. Lab of Neurobiology of Rhythmic and Seasonal Functions, URA-CNRS 1332, 12, rue de l'Université, 67000 Strasbourg, France.

Pineal gland of mammals receives a noradrenergic input indirectly from the retina. The day/night rhythm of norepinerphrine (NE) release to the pineal induces a day/night rhythm of melatonin synthesis and release with high nightime values. Neuropeptide Y (NPY) is co-localized with NE in pineal sympathetic nerve endings. The studies of NPY physiological effect on pineal activity however have brought different results as the techniques used were different: organ culture, in vivo administration, cell culture. The aim of this work was to examine the effect of various concentrations of NPY (0.1 to 100 nM) on melatonin secretion by pinealocytes previously stimulated or not by the ß-adrenergic agonist isoproterenol (ISO). This study was performed on 2 day-old pinealocyte cultures of one month-old rats. NPY alone induces a small stimulation of melatonin secretion. Together with ISO, NPY displays a clear potentiatory effet on melatonin secretion especially at low ISO concentrations. The most efficient concentration of NPY in stimulating pineal activity is 10 nM.

In conclusion, this study demonstrates that NPY stimulates melatonin secretion at a postsynaptic level in the rat pineal gland.

EFFECTS OF LHRH FRAGMENTS ON THE ELECTROPHYSIOLOGICAL PROPERTIES OF CA1 NEURONS IN THE RAT HIPPOCAMPAL SLICE. Y.S. Chen, M. Wong, and R.L. Moss*. Dept. of Physiol., UT Southwestern Med. Center, Dallas, TX 75235.

The decapeptide, luteinizing hormone-releasing hormone (LHRH), exerts both behavioral and electrophysiological actions in extra-pituitary CNS sites. LHRH has been shown to be cleaved into specific LHRH fragments in brain tissue. Ac-$LHRH^{5-10}$, a synthetic fragment without LH-releasing activity, has been demonstrated to facilitate lordosis behavior (Dudley and Moss, 1988) and displace LHRH from its hippocampal membrane receptor (Thompson and Moss, 1992). In contrast, $LHRH^{1-6}$ has no effect on LH-release nor on lordosis. The present study investigated the effects of these LHRH fragments on the electrophysiological properties of CA1 neurons. Intracellular recordings were made from CA1 neurons in the hippocampal slice from ovariectomized female rats. The fragments were applied to neurons by addition to the superfusing medium. Ac-$LHRH^{5-10}$ and LHRH at 10^{-7}M had similar actions on CA1 neurons: a long-duration depolarization associated with increased input resistance, reduction in the slow afterhyperpolarization (AHP), and decrease in accommodation. However, at a concentration of 10^{-8}M, some cells were responsive to LHRH, but not responsive to Ac-$LHRH^{5-10}$, or had a stronger response to LHRH than to Ac-$LHRH^{5-10}$. This suggests that LHRH was a more potent modulator of CA1 neurons than the fragment. This result correlates with the relative binding affinities of LHRH and Ac-$LHRH^{5-10}$ in the hippocampus. $LHRH^{1-6}$ had no effect on CA1 neurons. These data suggest that Ac-$LHRH^{5-10}$, a behaviorally active fragment, might have a modulatory action on hippocampal neurons. Supported by NIH grant MH47418.

VIP INCREASES $[Ca^{++}]_i$ IN RAT PINEALOCYTES BY INCREASING PERMEABILITY ACROSS THE PLASMA MEMBRANE. N.C. Schaad*, J. Vanecek, D.C. Klein and J.T. Russell, Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda MD 20892.

VIP acts on many cell types trough mechanisms which are not fully understood. In the pineal gland, VIP increases cAMP accumulation and N-acetyltransferase (NAT) activity, the rate-controlling step in melatonin synthesis. It is known that stimulation of these parameters by norepinephrine (NE) is strongly dependent upon α_1-adrenergic elevation of $[Ca^{++}]_i$. Accordingly, in this investigation we determined whether $[Ca^{++}]_i$ is also elevated by VIP; this was examined using computer assisted single cell analysis of pinealocytes in primary culture.

VIP (1-100 nM) produces a rapid and sustained increase in $[Ca^{++}]_i$ in more than 85 % of the cells, as does NE. This indicates that both agonists act on the same population of pinealocytes. The VIP-induced increase in $[Ca^{++}]_i$ is absent when $[Ca^{++}]_o$ is less than 1 μM. In contrast, the NE response is reduced to a transient increase in these conditions, suggesting that VIP and NE may act in part trough different mechanisms. The VIP-induced increase in $[Ca^{++}]_i$ is not abolished by classical voltage-gated Ca^{++}-channel inhibitors, such as nicardipine, D-600 and omega-conotoxin. The effect of VIP was mimicked by PACAP 1-28.

These studies indicate that VIP can elevate $[Ca^{++}]_i$ and that it acts by opening plasma membrane channels which are distinct from classical voltage-gated channels.

VIP INFLUENCES ELECTROPHYSIOLOGICAL AND METABOLIC ACTIVITIES IN VIVO. A. BARDEA, R. GLAZER, G. LILING* AND I. GOZES, DEPT. CHEM. PATH. SACKLER MED. SCHOOL, TEL AVIV UNIV. TEL AVIV, ISRAEL.

VASOACTIVE INTESTINAL PEPTIDE (VIP) IS A NEUROMODULATOR, GROWTH REGULATOR AND SECRETAGOGUE FOR NEURONAL SURVIVAL FACTORS (GOZES AND BRENNEMAN, 1989, MOL. NEUROBIOL.3,1). TO MEASURE THE INFLUENCE OF VIP ON METABOLIC AND ELECTROPHYSIOLOGICAL ACTIVITIES IN VIVO, WE HAVE EMPLOYED A MULTIPARAMETER MONITORING SYSTEM LOCATED ON THE SURFACE OF THE BRAIN CORTEX OF THE LIVING RAT (MAYEVSKY ET AL., 1991, SPIE PROC.1431,303). WE MEASURED: LEVELS OF INTRACELLULAR NADH, CONTRACTION AND DILATION OF BLOOD VESSELS, VOLUME OF BLOOD, BLOOD FLOW, EEG, EXTRACELLULAR IONS (CA AND K) AND pH. THESE PARAMETERS WERE MEASURED AFTER STIMULATION WITH KCL WHICH PRODUCES A REGION OF DEPOLARIZATION AS FOLLOWS. THE ELECTROPHYSIOLOGICAL ACTIVITY IS CHARACTERIZED BY SPREADING DEPRESSION (SD) WHICH IS REFLECTED IN DEPRESSED EEG, AND ENHANCED IONIC WAVES INCLUDING HIGH AMPLITUDE K WAVES RESULTING FROM K LEAKS AT THE TIME OF DEPOLARIZATION. THE METABOLIC ACTIVITY IS CHARACTERIZED BY A DECREASE IN THE LEVEL OF NADH, AN INCREASE IN BLOOD FLOW AND IN VASODILATION LEADING TO ATP PRODUCTION NEEDED FOR ENERGY SUPPLY TO THE NA/K PUMP. AFTER INJECTION OF VIP INTO THE LATERAL VENTRICLE OF THE BRAIN (60-1400 ng) MULTIPLE CHANGES WERE OBSERVED IN THE K DEPOLARIZATION REGION, INCLUDING, A REDUCTION IN THE AMPLITUDE OF THE K WAVE AND A PROLONGATION OF THE DEPRESSED EEG. THE DEPOLARIZATION REGION AFTER TREATMENT WITH VIP WAS MORE SENSITIVE AND DISPLAYED A HIGHER WAVE FREQUENCY IN A DOSE DEPENDENT MANNER, IMPLYING A METABOLIC AND ELECTROPHYSIOLOGICAL ACTIVITY FOR VIP. FINALLY, THE PATTERNS OF VIP GENE EXPRESSION IN VIVO SUGGEST RECIPROCAL RELATIONSHIP BETWEEN ELECTROPHYSIOLOGICAL ACTIVITY AND VIP IN THE CORTEX, WHERE VIP GENE ACTIVITY REACHES A PEAK AT THE TIME OF BRAIN MATURATION (GOZES ET AL., 1987, MOL. BRAIN RES. 2,137.) AND IN THE SUPRACHIASMATIC NUCLEUS (THE BIOLOGICAL CLOCK), WHERE OUR RECENT RESULTS SUGGEST VIP AS A PART OF AN ENDOGENOUS OSCILLATOR.

ANTAGONISTIC PROPERTIES OF $CGRP_{8-37}$ ON NEUROCHEMICAL EFFECTS OF HUMAN CALCITONIN GENE-RELATED PEPTIDE. D. MENARD*, A.L. DRUMHELLER, A. FOURNIER, AND F.B. JOLICOEUR Departments of Psychiatry and Pharmacology, Faculty of Medicine, University of Sherbrooke, Sherbrooke, Québec, Canada J1H 5N4 INRS-Santé, Pointe Claire, Qc, Canada

Pre-administration of the C-terminal fragment $hCGRP_{8-37}$ antagonizes some but not all neurobehavioral effects of hCGRP (Menard et al., N.Sc. 1991). In the present study, we investigated the effects of CGRP administered alone or following pre-treatment with $hCGRP_{8-37}$ on brain regional concentrations of norepinephrine, (NE), dopamine (DA), DOPAC, HVA, as well as serotonin (5-HT) and 5-HIAA . Peptides were administered ICV in a dose of 20 µg and , 20 min later, brains were removed and dissected for neurochemical assays No neurochemical changes were found in striatum or septum. However, hCGRP reduced DA and increased HVA concentrations in the nucleus accumbens. Increased concentrations of all amines and metabolites were found in the globus pallidus, amygdala and frontal cortex. In the hippocampus, except for HVA, all neurochemical parameters were elevated by hCGRP . In the hypothalamus, hCGRP significantly increased and decreased DOPAC and HVA respectively without affecting other neurochemical parameters. In the substantia nigra, marked decreases in Da and HVA levels were the only significant changes found. Pre-treatment with $hCGRP_{8-37}$ either significantly attenuated or completely abolished all neurochemical effetcs of hCGRP in the substantia nigra, amygdala , nucleus accumbens and globus pallidus. In the frontal cortex , except for the increase in HVA concentrations, all neurochemical effects were blocked by $hCGRP_{8-37}$. CGRP-induced increases in hioppocampal DOPAC and 5-HIAA concentrations were also not affected by the fragment. Finally , $hCGRP_{8-37}$ did not alter any of the neurochemical actions of hCGRP in the hypothalamus. Together, these results reveal pervasive but heterogeneous neurochemical effects of hCGRP and point to the existence of pharmacologically distinct receptors mediating these effects .Supported by the Medical Research Council of Canada

PHARMACOLOGY OF THE EFFECTS OF BRADYKININ AND SEROTONIN ON THE RELEASE OF CGRP FROM THE RAT TRACHEA

X.-Y. HUA*, S. HEDLEY, S.M. BACK & T.L. YAKSH Dept. of Anesthesiology, Univ. of California, San Diego, CA92093-0818

Depolarization of peripheral terminals of C-fiber afferents in the rat trachea can induce a local release of CGRP. In a previous study, application of bradykinin (BK) into the tracheal perfusate induced a dose-dependent increase in CGRP release, while serotonin (5-HT, 10^{-6}M) with no effect alone, facilitated CGRP release by capsaicin (caps 10^{-6}M)[1]. In the present study, we found that BK ($5x10^{-6}$M)-evoked CGRP release was significantly inhibited by a B2 antagonist: [D-Arg^0, Hyp^3, $Thi^{5,8}$, D-Phe^7]-BK $5x10^{-6}$M or indomethacin 10^{-5}M, but not by a B1 antagonist: [Des-Arg^9, Leu^8]-BK. The facilitatory effect of 5-HT was not markedly affected by 5-HT_1 or 5-HT_2 antagonists: s(-) propranolol or methysergide, but completely blocked by 5-HT_3 receptor antagonist ICS 205-930 10^{-6}M and also by indomethacin 10^{-5}M. PGE_1, E_2, F_{2a} as well as I_2 (10^{-8} to 10^{-6}M) were able to induce CGRP release from the rat trachea. None of them, however, have been found to potentiate caps-evoked peptide release. Thus, BK-induced CGRP release appears mediated by activation of the B2 receptor and subsequent PG formation. The sensitization effect of 5-HT on the releasing function of primary afferent terminal is apparently mediated by a 5-HT_3 receptor and prostanoid synthesis.

ANATOMICAL DELIMITATION OF A NEW ANIMAL MODEL OF DEPRESSION USING CALCITONIN. S. Souad and R. de Beaurepaire*, Laboratoire de Pharmacologie, CHRU Côte de Nacre, 14032 Caen, France.

Calcitonin is a peripheral peptide hormone which has several functional, behavioral, and hormonal effects when injected into the rat cerebral ventricles or into specific brain sites: calcitonin decreases food intake, locomotor activity, intestinal motility, produces sleep disorders, increases cortisol secretion, and inhibits sex hormones secretion and TRH-induced TSH secretion. On the whole, these calcitonin effects mimic the symptoms of the human depressive syndrome. Moreover, the anorectic effect of calcitonin can be reversed by tricyclic antidepressants. We therefore proposed the effects of calcitonin in the animal as a new model of depression. Previous experiments have shown that many of the effects of calcitonin listed above are related to an effect on the paraventricular nucleus of the hypothalamus. Calcitonin has also marked analgesic and hyperthermic effects which are not common symptoms in depression. To clarify possible anatomical grounds for our model, we studied the brain sites involved in the analgesic and hyperthermic effects of calcitonin.

We tested the effects of intracerebral injections of salmon calcitonin (15ng in 0.3µl) on pain sensitivity (hot plate test) and rectal temperature. The results show that the sites involved in calcitonin induced analgesia and hyperthermia are the preoptic area, the dorso-medial and posterior nucleus of the hypothalamus, the arquate nucleus, the centro-medial nucleus of the thalamus, and an area in the internal part of the zona incerta. The ventro-medial and the paraventricular nucleus of the hypothalamus are not involved in calcitonin-induced analgesia and hyperthermia.

We conclude that calcitonin-induced analgesia and hyperthermia can be excluded from our model of depression which may fit more specifically with a selective action of calcitonin on the paraventricular nucleus of the hypothalamus.

DYNORPHIN A (1-17) INDUCED DEPRESSION OF VENTRAL ROOT POTENTIALS IS MEDIATED THROUGH KAPPA OPIATE RECEPTORS. H. Ristic and L. Isaac*. Department of Pharmacology, University of Illinois College of Medicine at Chicago, Chicago, IL 60680.

Intrathecal application of dynorphin A (1-17) (DYN) results in a dose-dependent hindlimb paralysis of 30-60 min duration which may be mediated through kappa opiate receptor interaction. Additionally, repeated injections of DYN at 2 hr intervals results in desensitization to paralysis. Finally, direct application of DYN to the spinal cord results in a dose-dependent depression of the ventral root potentials (VRP) of 30-60 min duration. To investigate this apparent parallelism we determined whether the VRP depression is kappa receptor mediated and whether it is subject to desensitization.

Rats were surgically prepared, under urethane anesthesia, to record VRP monosynaptic and polysynaptic reflexes. The kappa opiate receptor antagonist nor-binaltorphimine (nor-BNI 20nmol) was applied directly to the spinal cord 60 min prior to DYN application and in separate experiments DYN (10nmol) was applied at 2 hr intervals to the spinal cord.

Nor-BNI resulted in a parallel shift of the dose-response curve for DYN-induced depression of the VRP. With nor-BNI the ED_{50} was 8 nmol and with saline it was 4 nmol. Repeated application of DYN resulted in desensitization to depression of the VRP of about 50%.

These data suggest that DYN-induced depression of the VRP is mediated through the kappa opiate receptor. Because both DYN-induced paralysis and depression of the VRP are mediated through kappa receptor interaction they may be causally related. Although the mechanism of these effects remain to be investigated they both involve desensitization. Supported by NSF BNS-8918963 and NIH NS-30295.

COMPARISON OF BEHAVIORAL EFFECTS OF DYNORPHIN A (1-17) WITH DYNORPHIN A (1-13) AFTER INTRATHECAL INJECTION IN THE RAT. **Z-X. Qu, T. J. Marczynski* and L. Isaac Department of Pharmacology, Univ. of Illinois College of Medicine at Chicago, Chicago, IL 60680**

Previously, we reported that dynorphin A (1-13) administered intrathecally (i.t.) to rats resulted in a reversible hindlimb paralysis and an irreversible inhibition of the tail-flick reflex[1,2]. These effects followed a dose-response relationship with identical ED_{50} values.

In the present investigation, we report the influence of dynorphin A (1-17), the peptide configuration of the endogenous substance, on these same behaviors after i.t. injection in rats. Injection of this substance results in a reversible hindlimb paralysis and an irreversible inhibition of the tail-flick reflex. These effects follow a dose-response relationship with an ED_{50} value for paralysis of 7 nmole and a value for inhibition of the tail-flick reflex of 18 nmole whereas the value for the (1-13) configuration is 10 nmole for both behaviors.

With (1-13), paralysis and inhibition of the tail-flick reflex always occur together; on the other hand with (1-17), some animals paralyze while their tail-flick reflex remains intact suggesting that different mechanisms may be involved with the different peptide configurations.

These data demonstrate a fundamental difference between dynorphin A (1-17) and dynorphin A (1-13). In conclusion, it appears that use of the (1-17) peptide to study the physiologic and pathophysiologic role of dynorphin in spinal cord function is preferred over the use of the (1-13) configuration.

EVIDENCE FOR A DIRECT ACTION OF MET-ENKEPHALIN ON GABAergic TERMINALS IN ORGANOTYPIC SLICE CULTURES OF THE RAT HIPPOCAMPUS. J.C. Rekling *. Institute of Neurophysiology, University of Copenhagen, DK-2200 N, Denmark.

Intracellular recordings from pyramidal cells in organotypic slice cultures of the hippocampus were performed with 1 M KCl containing electrodes. Spontaneous EPSPs were blocked by 20 µM NBQX, APV and synaptic transmitter release due to sodium-dependent action potentials was blocked by TTX. Under these circumstances a tonic bombardment of miniature IPSPs were seen. The IPSPs were blocked by 20 µM bicuculline and thus were GABAergic.

Application of 10-20 µM met-enkephalin reduced the frequency of spontaneous IPSPs by up to 50 % and this effect was reversed upon wash for 20 min.

These observations point to the conclusion that pyramidal cells in organotypic cultures of the hippocampus are exposed to tonic GABAergic inhibition, which is not the result of propagating sodium-dependent action potentials, and that this tonic inhibition can be reduced by met-enkephalin through a direct action of met-enkephalin on the presynaptic terminals.

416.16

EVIDENCE THAT PITUITARY ADENYLATE CYCLASE ACTIVATOR PEPTIDE (PACAP) IS A PRESYNAPTIC NEUROTRANSMITTER IN THE BOVINE ADRENAL MEDULLA. J.C. Waymire, V. Hemelt, and D. Marshak*. The Department of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77030.

VIP has been shown to stimulate catecholamine (CA) synthesis in isolated bovine adrenal chromaffin cells. One of the peculiar aspects of this stimulation is the high concentration of peptide (µM) required, as if VIP is mimicking the action of other peptides that act endogenously at lower concentrations. Accordingly, we tested the effect of PACAP, a VIP-like peptide, on the CA synthetic pathway in bovine adrenal chromaffin cells. These studies revealed a potent interaction of either PACAP-27 or PACAP-38. At the short time points, 10 sec to 5 min, CA synthesis is stimulated 4-5 fold with a 1/2 max concentration of 20 nM. Tyrosine hydroxylase (TH), the rate limiting enzyme in CA synthesis, is phosphorylated selectively on serine 40 by both PACAPs. At longer time points, TH mRNA synthesis and levels are elevated, followed by increased TH protein and activity. Morphological studies using perfusion-fixed, intact bovine adrenal medulla showed PACAP-27 immunoreactive axons innervating BAC. Labeled axons and terminals were found throughout the medulla but were particularly dense near the adrenal cortex and around blood vessels. The labeling was unaffected by synthetic 1 µM synthetic VIP but completely abolished by synthetic PACAP-27. These results support the conclusion that PACAP is a presynaptic neurotransmitter in the bovine adrenal medulla and a promising candidate for the endogenous ligand of the "VIP receptor" described previously. Supported by USPHS grants NS11061 & EY06472.

PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP) REGULATION OF AtT-20/D16v CORTICOTROPE CELL FUNCTION. K.M. Braas*, L.M. Konopka[1], C.A. Brandenburg and V. May. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405, and [1]Department of Biological Psychiatry, Hines VA Medical Center, Hines, IL 60141.

The α-amidated hypothalamic peptides, pituitary adenylate cyclase activating polypeptides (PACAP38 and PACAP27), share considerable amino acid homology with vasoactive intestinal peptide; however, the physiological roles of the PACAP peptides remain unclear. PACAP alters the functions of anterior pituitary gonadotropes, somatotropes and a small population of corticotropes. To investigate the roles of PACAP in corticotrope function, we examined PACAP-mediated regulation of ACTH/endorphin secretion and membrane depolarization using AtT-20/D16v mouse pituitary corticotrope cells. The basal secretory rate for AtT-20 cell ACTH was approximately 3% of cellular hormone content/h. Treatment of AtT-20 cells with 100 nM PACAP38 for 3 to 6 h stimulated hormone release approximately 1.5- to 1.8-fold. PACAP27 elicited a similar stimulated secretory response. AtT-20 cells displayed spontaneous action potentials; occasionally these action potentials led to the initiation of sustained depolarizations (SD) (< 3 sec), followed by hyperpolarizations (< 1 sec). The input resistance significantly decreased during the plateau of the depolarizations. 100 nM PACAP38 increased the rate of SD approximately 2-fold, suggesting a possible correlation with increased hormone release. OPIOIDS: ANATOMY AND PHYSIOLOGY I

417.1

THE PENETRATION OF DYNORPHIN1-13 ACROSS THE BLOOD BRAIN BARRIER J.L. Browning*, T.D. Turner, M.A. Widmayer and D.S. Baskin Dept. of Neurosurgery, VAMC Houston and Baylor College of Medicine, Houston, TX 77030.

The opioid peptide dynorphin 1-13 has been shown to increase survival and decrease neurologic deficit and infarct size in a feline model of focal cerebral ischemia (FCI). The ability of ([^{3}H]-pro^{10})-dynorphin1-13 (DYN) to cross the blood brain barrier (BBB) was studied in rats, cats and cats with FCI. The brain uptake index (BUI) as measured by a modified Oldendorf technique showed that the BUI of DYN was not significantly different from sucrose (vascular space reference) in the rat. Peptidase inhibitors had no effect. In contrast, the BUI of DYN in the cat was significantly greater than that of sucrose in hippocampus, cortex and cerebellum. In addition, the BUI of DYN was even greater in cats with FCI, such that the BUI of DYN was significantly greater in hippocampus, cortex, brainstem and hypothalamus. These results suggest that DYN does cross the BBB of cats and may act centrally in ischemia to mediate its neuroprotective action.

417.2

LATERALIZATION OF PROOPIOMELANOCORTIN mRNA CONTENT IN THE RAT MEDIOBASOHYPOTHALAMUS. D.D. Rasmussen*. Dept. of Reprod. Med., Univ. Calif. at San Diego, La Jolla, CA 92093-0802.

We have previously demonstrated that β-endorphin (βEND) content is lateralized in the medial preoptic and caudal arcuate areas of the male rat brain, and that this lateralization is differentially modulated by left *vs* right hemicastration (Neuroendocrinol.Lett. 12:232). We have now initiated a series of studies to further investigate the mechanism of this apparently lateralized control. In this first study we investigated lateralization of proopiomelanocortin (POMC; precursor for βEND biosynthesis) mRNA content in the adult male rat caudal mediobasohypothalamus (MBH). 16 rats were sacrificed at 1400 h and the left and right half-MBHs were removed. Left *vs* right half-MBHs from sets of 2 rats were pooled, and cytoplasmic POMC mRNA contents were quantified by solution hybridization/RNase protection assay. POMC mRNA content was consistently (8/8) greater (20.9±1.2%, $p<0.01$) in the left caudal MBH relative to the right. This difference was similar regardless of whether the results were expressed as pg POMC mRNA, pg POMC mRNA/μg total RNA or fg POMC mRNA/pg cyclophilin (internal reference) mRNA. These results are consistent with our previous demonstration that left caudal MBH βEND content is greater than right, and suggest greater forebrain opiomelanocortinergic activity originating in the left *vs* right MBH. We have previously demonstrated that MBH POMC mRNA content is correlated with MBH tyrosine hydroxylase (TH) mRNA content, suggesting interaction between MBH opiomelanocortinergic and dopaminergic activity (Neuroendocrinology, in press). Consequently we are further investigating whether MBH TH mRNA is also lateralized and whether this lateralization is correlated with that of POMC mRNA.

417.3

TWO DIFFERENT OPIOID CELL GROUPS IN LAMINA X OF RAT LUMBOSACRAL SPINAL CORD. A.P. Nicholas, Z. Xu and T. Hökfelt*. Department of Histology and Neurobiology, Karolinska Institute, Stockholm, 10401, Sweden.

Using a tri-color immunofluoresence technique, the coexistence of enkephalin-like immunoreactivity (ENK-LI) with immunoreactivities for other peptides was examined in neurons of lamina X in the lumbosacral spinal cord of colchicine-treated rats. Briefly, animals were anesthetized, the lumbosacral laminae were removed, the dura mater excised and colchicine soaked gelfoam plugs were placed under the dorsal roots for 1-2 hrs and then removed. After a 48 hr survival time, the animals were perfused with formaldehyde/picric acid and the lumbosaral cords removed, frozen and cut (14 μm) on a cryostat. These sections were incubated overnight in 1:20 mouse anti-ENK, plus either a combination of 1:400 rabbit anti-cholecystokinin (CCK) and 1:200 guinea pig anti-galanin (GAL), or a combination of 1:400 rabbit anti-neurotensin (NT) and 1:400 goat anti-neuropeptide Y (NPY) antisera. Secondary antisera (1:40; Jackson Immuno Research) consisted of a combination of AMCA (blue) conjugated donkey anti-mouse and FITC (green) conjugated donkey anti-rabbit, plus Lissamine Rhodamine (red) conjugated either to goat anti-guinea pig or to donkey anti-goat antibodies. ENK was shown to coexistist with CCK and GAL in almost all large lamina X neurons from L1 to L5, while ENK coexisted with NPY in almost all smaller lamina X neurons from L6 to S2. In this caudal region, a few ENK/NPY/NT cells were also seen, but NT-positive cells were primarily a separate cell group. Thus, the present study showed that in lamina X of the lumbosacral spinal cord, there are at least two major populations of opioid neurons: a rostral group of large ENK cells that are CCK and GAL positive and and caudal group of smaller ENK cells that are primarily NPY (and sometimes NT) positive. Previous studies have shown that CCK/GAL and ENK cells in lamina X of the lumbosacral cord project to higher brain centers and it has been suggested that they are involved with pain transmission.

417.4

ULTRASTRUCTURAL LOCALIZATION OF ENKEPHALIN AND GABA IN RAT SUBFORNICAL ORGAN V.M. Pickel* and J. Chan. Division of Neurobiology, Department of Neurology and Neuroscience, Cornell University Medical Center, New York, N.Y. 10021

We examined the ultrastructural localization of Met^{5}-enkephalin (ME) and GABA in the rat subfornical organ (SFO). ME-like immunoperoxidase labeling was intensely localized to large dense core vesicles (DCVs) in axon terminals. These terminals formed symmetric synapses primarily on unlabeled dendrites and also were seen within perivascular spaces and in the parenchyma adjacent to fenestrated capillaries in the central and caudal portions of the SFO. GABA labeled soma, dendrites and terminals were numerous throughout the SFO. In dually labeled sections, immunoperoxidase labeling for ME was detected in a few terminals forming synapses with cells showing gold silver labeling for GABA, but most of the targets were without detectable immunoreactivity. Other types of associations between ME and GABA included: colocalization within single axon terminals, convergence of separately labeled terminals on common targets, and appositions between separately labeled terminals. Single as well as dually labeled terminals formed symmetric synapses with unlabeled dendrites throughout the SFO. These results suggest that in rat SFO, GABA and opioid peptides may be released from separate, or sometimes the same, axon terminals to inhibit (symmetric junctions) local neurons. Moreover, the release of one or both putative transmitters may be modulated by circulating hormones or axonal associations. The findings suggest that GABA may be involved in the inhibition of renal water, sodium and potassium secretion by opiates at the level of the SFO (Grant support: MH00078, DA04600, HL18974).

417.5

VENTRAL TEGMENTAL AREA NEURONS RECEIVE CONVERGENT GABAERGIC AND ENKEPHALINERGIC INPUT FROM THE SAME AND MORPHOLOGICALLY DISTINCT TERMINALS S.R. Sesack* and V.M. Pickel. Depts. Behavioral Neuroscience, Univ. Pittsburgh, PA 15260 and Neurology & Neuroscience, Cornell Univ. Med. Coll., NY, NY 10021.

We examined the ultrastructural basis for functional interactions between enkephalin (ENK) and γ-aminobutyric acid (GABA) in the rat ventral tegmental area (VTA), using dual immunoperoxidase-gold methods. Immunoreactive terminals were either singly labeled for ENK or GABA, or were dually labeled for both substances. Immunoreactivity for ENK was intensely associated with dense-cored vesicles localized along non-synaptic portions of the plasmalemmal surface, while GABA labeling was primarily associated with small clear vesicles, some of which aggregated at presynaptic specializations. GABA-labeled terminals, with or without ENK-immunoreactivity, formed symmetric synapses on unlabeled dendrites, while singly ENK-labeled terminals formed either symmetric or asymmetric synapses on unlabeled targets. Separately labeled GABA and ENK-immunoreactive terminals frequently converged on common dendrites, or were in direct apposition to one another. These results suggest that GABA and ENK (1) are colocalized in a subset of VTA terminals; (2) are differentially released from distinct vesicle populations, regardless of their co-distribution; and (3) may have opposing actions on common VTA neurons following their release from the same or separate terminals. Our findings suggest multiple sites through which GABA and opioid peptides may interact to modulate the activity of dopaminergic and non-dopaminergic VTA neurons. EXTRACELLULAR NUCLEUS ACCUMBENS DOPAMINE IS INCREASED BY MICROINJECTIONS OF SELECTIVE μ OPIOID ANTAGONISTS INTO THE VENTRAL TEGMENTAL AREA. D. P. Devine*, P. Leone, and R. A. Wise. Ctr. for Stud. Behav. Neurobiol., Dept. Psychol., Concordia Univ., Montreal, Canada H3G 1M8.

We have previously reported that ventral tegmental area (VTA) microinjections of the selective μ opioid receptor agonist DAGO produce increases in extracellular nucleus accumbens (NAS) dopamine (DA), DOPAC, and HVA, assayed with intracranial microdialysis and HPLC with electrochemical detection. Interestingly, VTA microinjections of the selective μ-antagonist CTOP also produce increases in NAS DA and metabolites. The dose-dependence of the CTOP-induced increases in NAS DA and metabolites was evaluated, and the μ-receptor selectivity of the response to CTOP (a substituted somatostatin analogue) was assessed by comparison with the response to a structurally dissimilar μ antagonist, ß-funaltrexamine (ß-FNA: a fumarate methyl ester derivative of naltrexone). VTA microinjections of CTOP in the dose range 0.03 - 3.00 nmoles/μl produced dose-dependent increases in NAS DA and metabolites. VTA ß-FNA (1.0 nmoles/μl) produced increases in NAS DA and metabolites which were roughly equivalent to the increases produced by an equimolar microinjection of CTOP. One possibility is that these effects of CTOP and ß-FNA may be mediated through actions at μ receptors located on GABAergic afferents to the VTA. Release of these afferents from opioid-inhibition could result in increased GABA-mediated inhibition of GABAergic interneurons intrinsic to the VTA. This increased inhibition of GABAergic interneurons would then produce a disinhibition of mesolimbic dopaminergic neurons, resulting in the observed increases in NAS DA and metabolite concentrations. Therefore, under physiological conditions, GABAergic afferents to the VTA and GABAergic interneurons within the VTA may interact in a complex manner to modulate mesolimbic dopaminergic activity.

INTERACTION OF DOPAMINE AND NMDA RECEPTORS IN THE REGULATION OF DYNOPRHIN AND c-FOS/FRA EXPRESSION. D. Bronstein *, H. Ye, W. Q. Zhang, K. Pennypacker, & J.-S. Hong. Lab. Mol. & Integr. Neurosci., Natl. Inst. Environ. Hlth. Sci., Research Triangle Park, NC 27709.

It is well established that, in the striatum, biosynthesis of the opioid peptide dynorphin (Dyn) increases following activation of D1 receptors and decreases following D1 receptor blockade. In the present experiments, we were interested in examining some of the molecular mechanisms which may mediate, or interact with, the dopaminergic regulation of Dyn biosynthesis in the striatum. Repeated treatment (twice daily for 7 days) with the dopaminergic agonist, apomorphine (APO; 5 mg/kg), caused a small but significant increase in Dyn-ir in the striatum; this increase was accompanied by increases in the immediate early gene products, c-fos and/or. fra. Pretreatment of animals with a low dose (.125 mg/kg) of MK-801, a non-competetive antagonist of NMDA receptors, blocked the increases in both Dyn and fos/fra immunoreactivity. In a subsequent experiment, animals received unilateral 6-hydroxydopamine lesions of the substantia nigra (destroying the dopaminergic innervation of Dyn-containing neurons in the striatum) and then were injected repeatedly with APO alone or together with MK-801. APO treatment alone caused a 4-fold increase in Dyn-ir levels as well as an intense stimulation of fos/fra peptide expression in the lesioned striatum. However, in contrast to its effects in intact animals, MK-801 did not appear to have any effect on the APO-induced increase in fos/fra expression in 6-OHDA lesioned rats although it did reverse the increase in Dyn. These data demonstrate that changes in fos/fra expression are sometimes dissociated from Dyn and suggest that other factors in addition to fos/fra may be involved in the nigrostriatal regulation of Dyn expression.

REGULATION OF C-FOS AND 28 K CALBINDIN mRNA IN RAT CEREBELLUM IN RESPONSE TO ACUTE AND CHRONIC MORPHINE. P.S. Tirumalai and R.D. Howells*. Department of Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ 07103

The cellular and biochemical adaptations which underlie the addictive state are poorly understood. Since it is likely that changes in gene expression accompany the development of addiction, we are examining changes in the expression of candidate genes. In this study, the effect of acute and chronic morphine administration on expression of the proto-oncogene transcription factor, c-*fos* and the 28 kDa calcium-binding protein, calbindin, was examined in rat cerebellum and rat brain (minus the cerebellum). Adult male Sprague-Dawley rats were injected with saline or with escalating doses of morphine sulfate twice daily for 15 days. Rats were sacrificed 45 min after the last injection, the cerebellum and remaining brain minus the cerebellum were removed, and total RNA was extracted using the acid guanidinium thiocyanate/phenol chloroform method. RNA levels were quantified by Northern blot analysis. In addition, other rats received a single injection of morphine (10 mg/kg) and were sacrificed after 45 min, 4 hr, or 24 hr later. The effect of naloxone-precipitated withdrawal on gene expression in morphine-addicted rats was also analyzed 45 min after naloxone (1 mg/kg ip). Levels of c-fos mRNA were increased 2.5-fold in cerebellum and brain 45 min after a single dose of morphine compared to saline-injected controls. Calbindin mRNA levels in cerebellum were decreased to 30%-40% control at 45 min and 4 h after a single morphine injection. Tolerance developed to these effects in that levels of c-fos and calbindin were not altered 45 min after morphine injection in morphine-addicted rats. Unlike the cerebellum, calbindin mRNA was increased 3-fold compared to controls 45 min after morphine injection in chronically injected animals in the remainder of the brain. Naloxone-precipitated withdrawal caused a 30% decrease in c-fos levels in the brain minus the cerebellum. Differential effects on c-fos and calbindin gene expression following either acute or chronic morphine administration may be important aspects of the adaptation of the nervous system to morphine. C-FOS INDUCTION AND PROENKEPHALIN (Penk) GENE EXPRESSION CAN BE DISSOCIATED IN RAT ADRENAL (RA). Y.S. Zhu*, S.O. Franklin, M. Brodsky, T. Huang and C.E. Inturrisi. Dept. of Pharmacology, Cornell Univ. Med. College, New York, NY

Increases or decreases in transsynaptic activity in the RA activate c-fos and Penk gene expression in a sequential manner. We investigated whether c-fos induction and Penk gene expression can be dissociated in RA. Increases in transsynaptic activity by a neurogenic stressor [a metrazole (MTZ)-convulsion] produced a sequential elevation of c-fos and preproenkephalin (PPenk) mRNAs in RA. In hypophysectomized RA, the MTZ-induced increase in PPenk mRNA, but not c-fos mRNA was significantly reduced. In normal RA, ACTH treatment blocks the MTZ-induction of c-fos mRNA and Fos protein without a significant effect on the MTZ-induction of PPenk mRNA. Removal of transsynaptic activity by adrenal medullary explantation also produced a sequential induction of c-fos and PPenk mRNAs. The induction by explantation of PPenk mRNA, but not c-fos mRNA was blocked by cycloheximide (2 mg/ml). Forskolin (25 uM) had no effect on the explant-induced increase in c-fos mRNA at 1 hr, but reduced the explant-induced increase in PPenk mRNA at 24 hrs. These results demonstrate that although the Penk gene is an apparent target of Fos, c-fos induction does not always result in Penk gene expression and Penk gene expression can occur in the absence of c-fos induction. MU-OPIOID ENHANCEMENT OF NMDA AND AMPA RESPONSES IN HORIZONTAL VERSUS CORONAL SECTIONS OF RAT LOCUS COERULEUS. S. Oleskevich* and J.T. Williams. The Vollum Institute, Oregon Health Sciences University, Portland, Oregon, 97201.

The μ-opioid receptor agonist DAGO was recently reported to selectively enhance the NMDA component of the glutamate response in spinal trigeminal neurons via activation of protein kinase C (Huang, 1991). We have investigated this modulation by DAGO in locus coeruleus (LC) neurons where μ-opioids elicit inhibitory effects through *augmentation of a K+ conductance. Intracellular voltage clamp* recordings were performed on LC neurons (holding potential -60 mV) in horizontal or coronal brainstem slices. All drugs were applied by superfusion. Following pretreatment with idazoxan (1 μM) and picrotoxin (100 μM), the response to NMDA (30 μM) was increased by DAGO (1 μM) by a factor of 1.9 (-167 ± 12 versus -307 ± 30 pA). This enhancement was observed in horizontal sections of the LC (n=10) but not in coronal sections (n=6; factor of 1.1) nor in horizontal sections treated with 2 mM barium (n=3; factor of 1.1). The specificity of the DAGO-mediated enhancement was tested following application of AMPA (100-300 nM). The AMPA response (125 ± 39 pA) was potentiated by a factor of 2.3 by DAGO (275 ± 68 pA) in horizontal sections (n=4) but not in coronal sections of the LC (n=4; factor of 1.6). Current-voltage relationships from horizontal sections indicate a convergeance of the AMPA and AMPA/DAGO regression lines. A lack of voltage clamp control of the dendritic arborization may explain the enhanced responses to NMDA and AMPA following DAGO application. (Supported by FRSQ and NIH DA04523).

ACTIVATION OF LOCUS COERULEUS DURING CLONIDINE WITHDRAWAL: AN *IN VIVO* VOLTAMMETRIC STUDY. M. Hong*, S. Duggan, B. Milne and K. Jhamandas. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario K7L 3N6

In the locus coeruleus (LC), a major noradrenergic brain center, both α_2-adrenoceptor and opioid agonists inhibit neuronal firing. While it is known that the increase in LC firing during morphine withdrawal is suppressed by α_2-agents such as clonidine, it is not known whether increases in LC activity occur during clonidine withdrawal. To investigate this possibility, LC activity in the rat was measured using differential normal pulse voltammetry (DNPV). Clonidine (10 μg i.c.v.) significantly reduced LC activity to 54.4 ± 3.1% of baseline 45 min following injection. A subsequent injection of yohimbine (0.5 mg/kg i.v.) or the more selective α_2-antagonist atipamezole (0.2 mg/kg i.v.) resulted in a reversal of the depressant effects of clonidine and a significant rebound increase in LC activity: peak increases of 135.0 ± 1.7% above baseline 45 min following yohimbine and 131.6 ± 1.8% above baseline 45 min following atipamezole. Yohimbine, but not atipamezole, produced a significant increase in LC activity in saline treated animals, peak increase 136.6 ± 6.8% above baseline 45 min following yohimbine. These data suggest that activation of LC occurs during acute clonidine withdrawal.

A SODIUM-DEPENDENT COMPONENT OF THE OPIOID-INDUCED OUTWARD CURRENT IN LOCUS COERULEUS (LC) NEURONS

M. Alreja* and G.K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Opioids hyperpolarize LC neurons by opening K^+ channels. However, the opioid-induced current often does not reverse at K^+ reversal potentials in these neurons. We provide evidence to suggest that this is in part due to opioids turning off an additional current - a resting Na^+-dependent conductance.

Bath-applied met-enkephalin (200 μM) produced an outward current at -60 mV in rat LC neurons in brain slices. An 80% substitution of Na^+ in the ACSF by choline/atropine or TRIS produced a persistent outward current (choline - 144.3 ± 18.5 pA, TRIS - 136 ± 25.6 pA, n=12) with a decrease in conductance, indicating the presence of a resting Na^+-dependent current in LC neurons. Both treatments produced ~ 50% decrease in the opioid-induced-outward current and altered its reversal potential, bringing it closer to the K^+ reversal potential. $BaCl_2$ (100 μM), a K^+ channel blocker, also decreased the amplitude of the agonist-induced outward current by about 50% and together with choline or TRIS, it almost completely abolished the outward current, suggesting additivity of the Ba^{2+}- and Na^+-sensitive components of the opioid response.

We conclude that opioids turn off a resting Na^+-dependent conductance in LC neurons, in addition to opening K^+ channels. Since opiates inhibit adenylate cyclase activity in LC neurons, a possible candidate for the Na^+-dependent component of the opioid response is the resting cAMP-induced-Na^+-dependent inward current which drives pacemaker activity in these cells and reverses at ~ -30 mV.

CHRONIC MORPHINE INDUCES A PERSISTENT INCREASE IN RAT STRIATAL CALBINDIN D28K IMMUNOREACTIVITY VIA AN NMDA RECEPTOR-DEPENDENT MECHANISM. M.M. Garcia* and R.E. Harlan, Dept. of Anatomy, Tulane Univ. Medical School, New Orleans, LA 70112.

Calbindin D_{28k} (CD) is an intracellular calcium-binding protein which acts as a Ca^{++} buffer, thus protecting cells from the damaging effects of high intracellular Ca^{++}. As chronic morphine (M) has been reported to cause increased Ca^{++} levels in striatal synaptosomes, we studied its effect on CD immunoreactivity (ir) in rat brain, using immunocytochemistry. In the initial series of experiments, male rats were made M tolerant and dependent by sc implantation of 75 mg M pellets (1/day for 5 days); controls were implanted with vehicle pellets. Using a monoclonal antibody to CD, we found CDir in control brains in the matrix compartment of striatum but not in patches. In the brains of M-treated rats, there was a dramatic increase in CDir in matrix, with the appearance of intense CDir in patches. When M treatment was discontinued, the increased CDir in patches persisted through day 14 post-M. Because striatal patches receive glutamatergic (GLU) input from cortex, we studied the interactions between M and GLU in a second series of experiments using the NMDA antagonist, MK-801. Rats were injected twice daily for 5 days with saline(S)/S, S/M (10 mg/kg), MK (2 mg/kg)/S or MK/M. Levels and patterns of CDir in brains of S/Sand MK/S rats were as found in controls from the previous study, while the S/M CDir resembled the pattern seen in the M-treated brains. CDir in the MK/M brains, however, resembled control patterns, with CDir absent from patches. We suggest that chronic morphine increases glutamatergic transmission in striatum, increasing Ca^{++} and CD levels. These findings are consistent with reports that MK-801 inhibits tolerance to morphine, and provide a possible mechanism for this inhibition. (DA-05411 [MMG] and DA-06194 [REH])

MORPHINE REGULATES EXPRESSION OF JUN FAMILY MEMBERS IN RAT BRAIN. R.E. Harlan, O. Prakash* and M.M. Garcia. Department of Anatomy, Tulane Medical School (REH, MMG) and Division of Research, Ochsner Medical Foundation (OP), New Orleans, LA 70112.

Members of the Jun family of immediate-early genes dimerize with c-fos or fos-related antigens, to form a protein complex which binds to the AP-1 promoter sequence, activating or inhibiting expression of a variety of genes. We have used immunocytochemistry with antibodies to c-Jun (Oncogene Science AB-1 and AB-2) and to Jun-B and Jun-D (gift of R. Bravo) to study the cellular distribution of these proteins, and their regulation by morphine. In untreated rat brains, the four antibodies reveal four distinct distributions, suggesting that they may recognize four Jun family members. The distributions of cells recognized by the c-Jun AB-1, Jun-B and Jun-D antibodies are very similar to recent reports on distributions of cells expressing the c-Jun, Jun-B and Jun-D genes. Since the distribution revealed by the c-Jun AB-2 antibody is strikingly different, with immunostaining of neurons only in the nucleus accumbens, striatum, olfactory tubercle and central nucleus of the amygdala, this antibody may recognize a Jun-related antigen. In the striatum, the AB-2 antibody recognizes neurons in the matrix, leaving patches unstained. Chronic morphine treatment (one 75 mg morphine pellet, sc, daily for 5 days) greatly increased the number of neurons stained by the AB-2 antibody, especially in the patch compartment. Acute (3 hours after 10 mg/kg) or chronic treatment with morphine greatly increased the number of neurons stained with the Jun-B antibody in the nucleus accumbens, striatum and frontal cortex. These results extend previous work demonstrating morphine-regulated induction of immediate-early gene expression (c-fos) in the striatum and further suggest that the activated mu opiate receptor may be coupled to stimulatory as well as inhibitory cellular events. Supported by DA-06194, NS-24148 (REH) and DA-05411 (MMG).

HYPERTHERMIA INDUCED BY INTRAPREOPTIC MICRODIALYSIS OF A SELECTIVE μ OPIOID RECEPTOR AGONIST IN RAT. L. Xin*, E.B. Geller and M.W. Adler. Department of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140.

Previous studies from this and other laboratories have shown that the hyperthermic responses of the rat to opioids are mediated by μ receptors. To investigate the role of the preoptic area (POA) in the hyperthermia, the present study used the selective μ receptor agonist PL-017 (Try-Pro-N-MePhe-D-Pro-NH_2), the μ receptor antagonist CTAP (cyclic D-Phe-Cys-Tyr-Arg-Thr-Pen-Thr-NH_2), the κ receptor antagonist nor-binaltorphimine (nor-BNI) and naloxone (Nal, general opioid antagonist). The drugs were delivered directly into the POA of freely moving male S-D rats through a microdialysis probe, and rectal temperature (Tr) was measured at 21°C ambient and 50% relative humidity. All drugs were dissolved in the pyrogen-free saline (PFS) which had no effect on Tr alone. The efficiency of the probe during perfusion in vitro was 12% (1st h), 23% (2nd h) and 34% (3rd h). Three hours of dialysis of PL-017 (0.2, 1 and 2 μg/μl) at a speed of 1 μl/min induced a dose-related hyperthermia (ΔT± SEM: 0.74±0.21, 1.75±0.26, 1.94±0.35 °C, respectively). One hour of dialysis of PL-017 (1 μg/μl) produced a rise of 1.44 ±0.36 °C in Tr. PFS, Nal (1 μg/μl) and CTAP (1 μg/μl) were each microdialyzed into POA after 1 hour perfusion of PL-017. Nal and CTAP shortened the recovery time course from 180 min to 80 and 60 min, respectively, compared with the 160 min time course seen with the control PFS. In addition, one hour microdialysis of Nal or CTAP before PL-017 prevented the hyperthermia, but nor-BNI did not. The POA microdialysis route produced similar results to those seen after i.c.v. or s.c. administration of opioid, but at lower doses. These data not only support the hypothesis that μ receptors mediate hyperthermia in the rat, but indicate that the POA may be the primary site for opioid-induced temperature responses. (Supported by grant DA 00376 from NIDA)

418.1

ELECTROPHYSIOLOGIC EVIDENCE THAT VENTRAL PALLIDAL (VP) DOPAMINE MODULATES VP RESPONSES TO AMYGDALA STIMULATION. R.J. Maslowski-Cobuzzi* and T.C. Napier. Neurosci. Prog. and Dept. of Pharmacol., Loyola Univ. Chicago, Stritch Sch. of Med., Maywood, IL 60153.

The VP is a dopaminoceptive brain region that also receives amygdala (AMN) efferents. Receptor subtypes involved in dopamine (DA)-mediated VP responses and the effects of DA on AMN inputs to VP are unknown. Thus, the present study determined if VP responses to AMN stimulation could be modulated at the level of the VP by exogenous DA (microlontophoretic application), and/or endogenous DA (stimulation of midbrain dopaminergic regions; mDAr).

Single, spontaneously active VP neurons, recorded *in vivo* from male Sprague-Dawley rats anesthetized with chloral hydrate, were assessed for convergent responses to AMN and mDAr single pulse stimulation. Most VP neurons tested responded to both. Seventy percent of the short latency inhibitory VP responses to activation of the mDAr was attenuated by microiontophoretically applied SCH23390 (D1 DA antagonist), but only 45% were effected by the D2 DA antagonist, sulpiride. Similarly, the D1 DA agonist, SKF38393 suppressed VP activity more often than the D2 agonist, quinpirole (38% vs. 12.5%), and with a greater magnitude (61±7% vs. 30±5%).

AMN-evoked short and long latency inhibitory effects of VP neurons were attenuated by DA within the VP (64% and 80%, respectively), and by prior mDAr stimulation (10 pulse train; 85% and 78%). The results suggest a monosynaptic inhibitory influence on VP neurons by mDAr that often is mediated through D1 DA receptors. DA within the VP and mDAr activation produce a similar modulatory influence on AMN efferents to the VP. Thus, the VP may be an integrative site of limbic (AMN) and motor (mDAr) systems. Work supported by MH45180.

CORTICAL CHOLINE ACETYLTRANSFERASE (ChAT) ACTIVITY IS AFFECTED BY CHRONIC DOPAMINE ANTAGONISM. M.B. Muench*, I. Hanin, G. Battaglia, and T.C. Napier. Dept. Pharmacol. Loyola University Chicago, Maywood, IL 60153.

Pharmacologic and electrophysiologic evidence suggests that the dense population of cortically-projecting cholinergic cells in the ventral pallidum/substantia innominata (VP/SI) is dopaminoceptive. The present study demonstrates the sensitivity of rat basal forebrain cholinergic projection neurons to chronic dopamine (DA) receptor antagonism.

Rats received either SCH23390 (0.25 mg/kg s.c.), sulpiride (12.5 mg/kg s.c.), or vehicle (s.c.) for 21 days. On day 23, the rats were killed and their brains dissected and frozen. D1 and D2 DA receptors in rat basal forebrain tissue homogenates respectively were labeled with [3H]SCH23390 and [3H]spiperone. ChAT activity was measured in basal forebrain terminal regions.

ChAT activity significantly increased in frontal cortex (fCTX) and amygdala (AMYG) following chronic SCH23390 treatment as compared to vehicle controls. No changes occurred in hippocampus (HIPP) or anterior cingulate (AC). In contrast, after chronic sulpiride, ChAT activity significantly decreased in HIPP and significantly increased in AC. ChAT activity in fCTX and AMYG remained unaltered.

Radioligand binding data demonstrated selective upregulation of striatal D1, but not D2, receptors after chronic SCH23390. No changes in D1 sites were observed in septum, globus pallidus or VP/SI homogenates. No significant changes in [3H]spiperone-labeled D2 receptors occurred in any of these tissues following sulpiride; however, this might be a result of the low sulpiride dose used during this experiment.

These results suggest that basal forebrain cholinergic neurons are sensitive to DA and that they are modulated differently by D1 and D2 receptors. (Work supported by MH45180 to T.C.N.)

418.3

MOTORIC ANALYSIS OF DOPAMINE RECEPTOR SUBTYPE ACTIVATION WITHIN THE VENTRAL PALLIDUM AND DORSAL GLOBUS PALLIDUS. T.C.Napier* and F.Rehman. Department of Pharmacology, Loyola University Chicago, Stritch School of Medicine, Maywood, Il., 60153.

Dopamine (DA) projections ascending to forebrain striatal regions are known to mediate a complex repertoire of motor-related behaviors. Recent work demonstrates that pallidal regions also are dopaminoceptive, responding to both D1 and D2 DA receptor activation. Thus, the effect of this input on DA-mediated motor functions, and whether the contribution of the dorsal globus pallidus (dGP) differs from that of the infracommissural ventral pallidum (VP), were examined.

Under pentobarbital anesthesia, male Sprague Dawley rats were implanted bilaterally with guide cannulae to allow ic microinjection of treatments into the dGP and VP. Experimentation began 1 week after surgery, and various motor effects were quantified for 1 hr following ic treatments. Intrapallidal DA (.001 to 100 μg/0.5μl ic) produced a dose-related increase in locomotion and rearing/wall climbing. Quinpirole (QUIN, D2 agonist) elevated these behaviors only when injected into the dGP. In the VP, such effects were mimicked by SKF82958 (SKF, a full D1 agonist). SKF also produced robust "mouthing movements" that remained intact in rats with acute depletions of endogenous DA (in contrast to the other behaviors). Thus, dGP and VP regions contribute a distinct profile to dopaminergic modulation of motoric function. Since the magnitude of the locomotor and rearing/wall climbing measures were less than that observed in these animals with 1mg/kg ip amphetamine, pallidal structures serve as constituents of an engaged system for these behaviors. Whereas, mouthing movements resulting from VP D1 receptor activation, without the involvement of endogenous DA (and thus, D2 receptors) induced a response that was greater than any other treatment assessed, suggesting that VP D1 receptors play a critical role in this behavior. Supported by MH45180.

DO INHIBITORY G-PROTEIN COUPLED RECEPTORS ACTIVATE AN ATP-SENSITIVE POTASSIUM CHANNEL? G.A. Hicks, A.W. Twigg and G. Henderson. (SPON: Brain Research Association) Department of Pharmacology, University of Bristol, Bristol, BS8 1TD, U.K.

The D_2-dopamine receptor is a member of the inhibitory G-protein coupled superfamily of receptors which includes the μ-opioid receptor and the α_2-adrenoceptor. Roeper et al (1990, Pflugers Archiv 416: 473-475) have suggested that activation of D_2 receptors resulted in the opening of ATP-K channels. Using whole cell recording from substantia nigra zona compacta (SNc) neurones in a brain slice we have been unable to demonstrate that the membrane hyperpolarisation produced by dopamine is reversed by the ATP-K channel antagonist glibenclamide (Hicks and Henderson, 1992, Neurosci. Letts. in press). To exclude the possibility that we had washed out an intracellular component necessary for the inhibitory action of glibenclamide we have performed cell attached and conventional extracellular recordings of the firing rates of SNc neurones. Dopamine (30-100μM) inhibited neuronal firing but this effect was not antagonised by glibenclamide (10μM). The electrically evoked neurogenic contractions of the isolated guinea-pig ileum (GPI) and rat vas deferens (RVD) were inhibited by the ATP-K channel activator, lemakalim (0.03-3μM), in a concentration-dependent manner. Glibenclamide reversed the action of lemakalim. The site of action of lemakalim appears to be on the presynaptic nerves because directly evoked contractions of the smooth muscle were unaffected. The inhibition of neurogenic contractions produced by the μ-opioid receptor agonist morphine (10μM; GPI) and the α_2-adrenoceptor agonist clonidine (3nM; RVD) were not reversed by glibenclamide (1-6μM) but were antagonised by naloxone (1μM) and yohimbine (100nM) respectively. We have thus been unable to demonstrate the inhibitory G-protein coupled receptors activate an ATP-K channel on either neuronal somata or terminals.

EXCITATION OF RAT CAUDATE NEURONS BY INDIRECT AND DIRECT ACTING DOPAMINE AGONISTS. D.K.Hyslop,* W.E.Hoffmann and M.F.Piercey, The Upjohn Co., Kalamazoo, MI 49001.

The effects of dopaminergic (DA) drugs were evaluated for effects on neuronal firing rates of DA neurons in the substantia nigra pars compacta (SNPC) and the caudate nucleus (Cd), the major projection area for SNPC DA neurons, in chloral hydrate anesthetized rats. Using dye-filled glass microelectrodes, DA neurons in substantia nigra pars compacta (SNPC, Bunney et al., JPET 155:560, 1973) and caudate neurons were identified by classical electrophysiological/neuroanatomical criteria. Cells were located in central caudate and were selected for spontaneous activity and large positive-negative wave forms (Type II, Life Sci 25:419, 1979). Intravenous injections of the indirect DA agonist, amphetamine (AMPH, 1-3 mg/kg), excited spontaneously active Cd neurons and inhibited SNPC neurons by a HAL-sensitive mechanism. Similarly, quinpirole (QUIN, 0.3-3 mg/kg), a D2 agonist, and APO (3 mg/kg), a D1/D2 agonist, excited spontaneously active Cd neurons by HAL-sensitive mechanisms. However, much lower doses of APO and QUIN were effective in inhibiting SNPC neurons. SKF38393, a D1 agonist, did not alter Cd firing rates or responses to QUIN. The data is consistent with the view that, while AMPH inhibits SNPC neurons by striatonigral feedback pathways, QUIN and APO inhibit SNPC neurons by direct autoreceptor activation.

ELECTROPHYSIOLOGICAL STUDIES OF (-)-STEPHOLIDINE ON SNC AND VTA DA NEURONS.

G.Z. Jin,* B.C. Sun. and X.X. Zheng
Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai 200031, China.

(-)-Stepholidine (SPD) is a novel DA receptor antagonist, but it possesses agonistic action on rotational behavior in the 6-OHDA-lesioned rats. It is presumed that D_1 receptors in the SNR are involved in this agonistic action. The present work attempts to elucidate whether SPD exhibits the antagonistic or agonistic action on extracellular firing recorded from SN and VTA DA neurons in the anesthesized, the reserpinized, and the 6-OHDA-lesioned rats.

It has been shown that SPD had antagonistic effect only to D_2 receptors in the SNC and VTA of anesthetized rats. However SPD was an antagonist both to D_1 and D_2 receptors in the reserpinized rats. Interestingly, SPD had the characteristic of depolarization inactivation in VTA, not in SNC, of the anesthetized rats. This action is the characteristic of atypical neuroleptic. Thus SPD would exist the potential possibility of atypical neuroleptic. Furthermore, when firing was recorded from the SNR in the 6-OHDA-lesioned rats, SPD showed the D_1 agonistic action. This result would be compatible with the rotational behavior.

418.7

DIFFERENTIAL INTERACTION OF DOPAMINERGIC D-1 AND D-2 RECEPTORS WITH GLUTAMATERGIC AND CHOLINERGIC TRANSMISSION IN THE 6-HYDROXYDOPAMINE MODEL OF PARKINSON.

M.Morelli *, S.Fenu, A.Cozzolino, A.Pinna, and G.Di Chiara. Dpt. of Toxicology, University of Cagliari, Cagliari, Italy.

The interaction of dopaminergic D-1 and D-2 agonists with antagonists of N-methyl-D-aspartate (NMDA) or muscarinic receptors, was examined after a unilateral 6-hydroxydopamine lesion of the dopaminergic nigro-striatal system. Blockade of NMDA receptors by MK-801 increased the contralateral rotational behavior induced by the D-1 agonist SKF 38393 and inhibited the rotation induced by the D-2 agonist LY 171555. Blockade of muscarinic receptors by scopolamine, like MK-801, potentiated D-1 mediated contralateral rotation but did not influence D-2 mediated rotation. D-1 dependent activation of the proto-oncogene c-fos in the lesioned caudate-putamen (CPu) was increased after both treatments. 2DG utilization studies evidenced an increased metabolic activity in the entopeduncular nucleus and substantia nigra reticulata after these treatments, indicating that the behavior observed is associated with specific biochemical modifications in the CPu, reflected by functional modifications in striatal afferent areas. The results suggest that administration of NMDA or muscarinic receptor antagonists might improve the therapeutic efficacy of D-1 agonists in the treatment of Parkinson's disease.

ALTERATIONS IN G PROTEIN LEVELS IN 6-OH DOPAMINE LESIONED RATS. E.R. Marcotte, S.K. Gupta, R.K. Mishra*, R. Sullivan, and H. Szechtman. Depts. of Psychiatry and Biomedical Sciences, McMaster University, Hamilton, Ont., Canada, L8N 3Z5.

6-OH dopamine (6-OHDA) is known to selectively destroy nigrostriatal pathways in the brain. In this study, we have investigated the effects of 6-OHDA lesions on G protein levels in the rat striatum. Male Sprague Dawley rats were given unilateral lesions of 6-OHDA and striata were removed from both hemispheres 1, 4, 8, or 16 days post-lesion. Quantitative immunoblotting of western blots, using specific antisera, was used to assess relative levels of $G_S\alpha$, $G_i\alpha$, and $G_o\alpha$ subunits. Both $G_S\alpha$ and $G_i\alpha$ levels were found to be depressed in striata ipsilateral to the lesion relative to non-lesioned striata, and this effect was most pronounced by day 16. Although both $G_S\alpha$ and $G_i\alpha$ levels showed similar patterns of alteration, $G_S\alpha$ levels consistently showed the greatest difference for each day post-lesion, suggesting that alterations in $G_i\alpha$ levels may follow changes in $G_S\alpha$ activity. $G_o\alpha$ levels showed no significant alterations in lesioned relative to unlesioned striata at any day post-lesion. Given that the molecular basis of many human neurodegenerative diseases are not at present well established, we have begun attempts to relate these results to healthy individuals and to the alterations in human neurodegenerative conditions. This work was supported by grants from the Parkinson's Foundation of Canada and NIH.

QUINPIROLE, BUT NOT SKF-38393 INHIBITS STRIATAL NEURONS IN FREELY-MOVING RATS. K.C. HOOPER*, I. M. WHITE, M.E. TAYLOR AND G.V. REBEC. Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Indirect dopamine agonists, such as amphetamine, typically increase motor-related, but suppress nonmotor-related neurons in rat striatum (Haracz et al., Brain Res. 489:365, 1989). In an initial attempt to assess the mechanisms by which dopamine regulates striatal activity, we monitored the effects of quinpirole (LY-171555), a dopamine agonist that has a high affinity for D2 and, especially, D3 receptors, and SKF-38393, a D1 agonist, on single-unit activity in the striatum of awake, behaving, male rats.

Like amphetamine, quinpirole (1.0-5.0 mg/kg sc) alone, or administered 30 minutes after the D1 agonist SKF-38393, inhibited nonmotor-related neurons in the striatum. Unlike amphetamine, quinpirole also inhibited motor-related neurons located in the lateral and central striatum. In medial striatum, however, neurons were particularly sensitive to the animal's state of arousal. After quinpirole, these cells showed complex changes in firing rate that may, in part, reflect behavioral activation induced by the drug. In contrast, SKF-38393 (5mg/kg sc) alone had no effect on the firing rate of striatal neurons. Nor did its effects differ from control when administered 30 minutes after quinpirole. Collectively, these results suggest an important role for D2 and/or D3 receptors in regulation of striatal activity.

SOME STUDIES ON DA D1 & D2 ANTAGONIST-INDUCED CATALEPSY IN RATS. D.M. Jackson[1], J.A. Watson*[2], A. Bengtsson[1] and M Lindgren[1] Astra Arcus AB[1] and Astra Pain Control AB[2], Södertälje 151 54, Sweden.

Catalepsy (C) is produced in rats by either DA depletion or by blocking DA D1 & D2 receptors with antagonists. While C is a useful & predictive model, the measure itself is sensitive to environmental manipulations. In this rat study we investigated the method of testing on SCH23390 (SCH) & raclopride (R)-induced C. C was determined on a steel grid at an angle of 60 +/- 2° & the time each rat spent before moving 1 of its 4 paws determined. 3 experiments are described. 1. 2 methods were used to measure C after antagonist injection. First, the C time for each rat was determined 0.5, 1, 2, 4, 8 & 24 h after injection. Secondly, the C time was measured only once on each rat either 0.5, 1, 2, 4, 8 or 24 h after injection. With the first technique, both SCH & R produced dose dependent C that peaked 2 to 8 h after R & 0.5 to 1 h after SCH, peak time depending on dose. With the second technique, SCH induced C that was similar to that seen after repeated testing. In contrast, R produced weak C when each rat was tested once. 2. Rats were injected with R (60 µmoles/kg). Half were injected 10 min later with saline & the remaining remained untreated. All rats were then tested repeatedly beginning 0.5 h after saline injection for 24 h. The time course curve for C was altered by the saline injection. 3. Rats were given R (60 µmoles/kg) & half handled each 5 min, & half not handled, before determining C 0.5 h through 24 h after injection. Less C was evident in the handled group. It is clear that D1 & D2 induced C depends upon markedly different mechanisms, as proposed earlier. Some form of conditioning, which is extremely sensitive to environmental influences, seems to play a major role in D2,- but not D1, -induced C.

REM SLEEP DEPRIVATION AND DOPAMINE RECEPTOR BINDING IN RAT STRIATUM. A. Hamdi, J.Brock* K. Ross, S Payne, and C. Prasad. Pennington Biomed.Res.Ctr., Baton Rouge, LA, 70808; Dept. Medicine, LSUMC, New Orleans, LA, 70112.

Rats deprived of sleep express facilitation of dopamine-mediated behaviors, but the mechanisms involved are largely unknown. Male rats were divided into 4 groups (N=6 each). Group REMd was deprived of REM sleep for 96 hours using a water-tank procedure; group L/S resided on larger (control) pedestals for 72 hrs, then on small pedestals for 24 hrs; group TC resided on large pedestals for 96 hrs; and group CC remained in the home cage. The striata were analyzed for dopamine D1 and D2 receptor density and affinity using [^{3}H]SCH23390 and [^{3}H]YM-09151-2 as ligands, respectively. Group REMd showed increases in Bmax for D1 and D2, and increased Kd for D2, compared to group TC. Group L/S had increases in Bmax and Kd for D1 and D2, compared to group TC. Group TC showed decreased Bmax for D1 and D2 and decreased Kd for D2, compared to group CC. Thus, stress caused downregulation of both receptor subtypes, whereas REMd had an opposite effect. These data suggest that differences in D1 and D2 receptor binding may be used to distinguish the effects of stress from the specific effects of REMd.

SYNERGISTIC AND ANTAGONIST INTERACTIONS OF DOPAMINE D1 AND D2 AGONISTS: A 2-DEOXYGLUCOSE AUTORADIOGRAPHY STUDY. C.A.Ray, M.Stults, W.E.Hoffmann* and M.F.Piercey, The Upjohn Co., Kalamazoo, MI 49001 and Kalamazoo College, Kalamazoo, MI 49007.

D1 and D2 receptor subtypes are distributed unevenly and independently within the brain. D1 and D2 agonists act synergistically to stimulate behavior (Braun and Chase, Eur. J. Pharmacol. 131:301) and neuronal firing (Carlson et al., Brain Res. 400:205, but see Hyslop et al., this meeting). We have used the 2-deoxyglucose (2DG) autoradiography procedure (Sokoloff et al., J. Neurochem. 28:897) to evaluate the effects of the D1 agonist, SKF38393 (SKF, 20 mg/kg i.v.) and the D2 agonist, quinpirole (QUIN, 1 mg/kg i.v.) in lightly restrained unanesthetized rats. Both drugs stimulated SNPC and SNPR. SKF, but not QUIN, stimulated caudate, VTA, n. basalis, sup col., d horn, and olf., pyriform, and temp. cortex. QUIN, but not SKF, stimulated globus and inhibited AV thalamus. QUIN and SKF synergistically excited SNPC, globus, subthal., cent. amygdala, d and v horn. QUIN inhibited SKF stimulation in sup col., olf. and temp cortex. There were no interactions at other sites. It is concluded that D1, D2 interactions are not uniformly synergistic but vary greatly amongst neuroanatomical structures.

COMPARATIVE STUDIES OF F-18 LABELED BENZAMIDES AND [F-18]N-METHYLSPIPERONE . RH Mach,[1] JG Greenberg,[1] PA Nowak,[1] PH Evora,[1] RL Ehrenkaufer,[2] RR Luedtke,[1] CD Unsworth,[1] K Ivins,[1] S Childers,[2] PB Molinoff,[1] and M Reivich.[1*] [1]Univ. of Pennsylvania and [2]Bowman Gray School of Medicine.

A series of imaging studies using PET were carried out on a baboon comparing the uptake and retention of 2,3-dimethoxy-N-(p-fluorobenzyl)piperidin-4-yl benzamide (MBP) and 2,3-dimethoxy-N-(9-(p-fluorobenzyl)-9-azabicyclo[3.3.1] nonan-3ß-yl benzamide (MABN) with that of N-methylspiperone (NMSP). All three compounds displayed a high accumulation in the basal ganglia (BG) with NMSP exhibiting the slowest rate of washout from the cerebellum (Cb). MBP reached a maximum BG uptake at 40 min post-injection. Washout of MBP after maximal accumulation occurred with a half-life of 140 min. MABN and NMSP did not washout from the BG and a linear increase in the BG:Cb ratio was seen over the three hour data acquisition period. The rapid washout of MABN from the Cb resulted in a BG:Cb ratio twice that of NMSP. A series of in vitro binding studies were conducted in order to determine the selectivity of each analog for D2 vs 5-HT2 and α2 receptors. The radioligands and tissue sources used were: D2, [^{125}I]NCQ-298, rat striatum; 5-HT2, [^{125}I]I-LSD, P11 cells; α2, [^{3}H]Rauwolscine, rat cortex. The results of the in vitro studies indicate MBP and MABN possess a higher 5-HT2:D2 ratio than NMSP. All three analogs possess a low affinity for α2 receptors. The results of these studies suggest that MBP and MABN may be superior to NMSP for PET studies of D2 receptors.

Table (Ki nM)

compound	D2	5-HT2	α2	5-HT2/D2
NMSP	0.118	0.55	3000	4.66
MBP	0.38	1840	3000	4842
MABN	0.028	84	1300	3000

418.14

A NOVEL AND RAPID METHOD FOR ENRICHMENT OF LACTOTROPH CELLS (LC) FROM DISPERSED RAT ANTERIOR PITUITARY (AP). K. Bohmaker*, T. Puza, J. Diamond, J.Y. Lew, M. Schütte[¶], D. Okrongly[¶], M. Goldstein and E. Meller. Dept. of Psychiatry, NYU Medical Center, New York, NY 10016, [¶]Dept. of Biology, CCNY, New York, NY 10031 and [¶]Applied Immune Sciences, Inc., Menlo Park, CA 94025.

The rat AP contains at least 6 different cell types, complicating electrophysiological and pharmacological studies of signal transduction mechanisms regulating the release of hormones. Enriched LC preparations, obtained by density gradient sedimentation or centrifugation, have been used to study dopamine (DA)-regulated second messengers and membrane ion channels involved in prolactin (PRL) release. These methods require specialized equipment and are labor-intensive. A simple and rapid method for LC enrichment is described which yields results comparable to those obtained with other techniques.

An affinity-purified polyclonal Ab to the N-terminal region of the D_2 DA receptor (50 μg/ml in PBS) was covalently attached to MicroCELLector surface-activated 24-well polystyrene plates (Applied Immune Sciences, Menlo Park, CA) by incubation for 1 hr at RT. After washing (PBS) and blockade of nonspecific binding sites with BSA, appx. $1x10^6$ dispersed rat AP cells were added/well and incubated for 1 hr at RT. Non-adherent cells were removed and the wells were washed. After overnight incubation (37°C) and further washing, captured cells were transferred to poly-L-lysine-coated microscope slides or regular culture plates. Captured cells were fairly uniform in size; several days incubation revealed the absence of fibroblasts which normally proliferate extensively. Immunostaining with a rat PRL antiserum by the ABC method showed that about 80% of the cells stained positively, compared to about 20% in non-captured cells, i.e., about 4-fold enrichment. Comparison of functional response in enriched and standard cell preparations will be reported.

418.15

REVERSED RELATIVE EFFICACIES OF QUINPIROLE (QUIN) AND (+)3-PPP AT DOPAMINE (DA) D_2 RECEPTORS (D_2R) IN STRIATUM AND ANTERIOR PITUITARY (AP). E. Meller*, T. Puza, J. Diamond and K. Bohmaker. Dept. Psychiatry, NYU Medical Center, New York, NY 10016.

Previous studies have shown that D_2R on striatal DA nerve terminals and AP lactotrophs mediating, respectively, inhibition of transmitter synthesis and prolactin (PRL) release, both display a similar large receptor reserve (RR) for full agonists. Both effects involve receptor coupling to pertussis toxin (PTX)-sensitive G proteins(s); consequently, the efficiency of receptor/coupling (i.e., RR), is likely to be related to the ability of agonists to induce ternary complex formation. Treatments which reduce the amount of receptor or G protein are therefore expected to reduce the RR.

Treatment of AP cell cultures with 17ß-estradiol (EST; 10 nM, 3 days), recently shown to reduce PTX-sensitive G protein levels in AP, shifted the dose-response curve (DRC) for N-propylnorapomorphine (NPA) to the right 14-fold; receptor inactivation studies with phenoxybenzamine (PBZ; 1 μM, 60 min) showed that EST treatment abolished the RR for NPA. Surprisingly, EST had nearly identical effects on the DRCs for QUIN and (+)3-PPP (4.5-fold shift), although differential effects were expected since (+)3-PPP had been found to be a much weaker agonist than QUIN in striatum. Treatment of cultures with PTX (10 ng/ml, 24 hr) produced shifts in the DRCs for NPA, QUIN and (+)3-PPP which did not correlate with their previously determined relative efficacies; the PTX DRCs were also significantly shallower ($P<.001$). Receptor inactivation expts. revealed that half-maximal response in AP for QUIN and (+)3-PPP required 25.6 and 9.6% receptor occupancy, but 6.2 and 30%, respectively, in striatum. "Promiscuous" coupling of D_2R to different G proteins in the two tissues may underlie the reversal of relative efficacy, as recently predicted (Kenakin and Morgan, Mol. Pharmacol. 1989). Supported by NS 23618.

LOCALIZATION AND BINDING ANALYSIS OF [^{3}H]BTCP: A DOPAMINE UPTAKE SITE ANTAGONIST. M.E. Hunt*, F. Filloux, N. Narang, C. Johnson, and J.K. Wamsley. Neuropsychiatric Research Institute, Fargo, ND 58103 and Western Institute of Neuropsychiatry, Salt Lake City, UT 84108.

The phencyclidine analog, N-[1-(2-benzo(b)-thiophenyl cyclohexyl] piperidine, has recently been made available in tritiated form ([^{3}H]BTCP) from Dupont NEN. Specific binding of [^{3}H]BTCP in striatal tissue was maximized at a pH ranging from 6.8 to 7.0 and a NaCl concentration between 180 and 220 nM. Nonlinear regression analyses of association and dissociation experiments yielded a k_{+1} .0008min^{-1}nM^{-1} and a k_{-1} .023min^{-1}. The calculated k_d is equal to 30.22nM which is in agreement with the k_d derived from nonlinear regression analysis of the saturation isotherm for a single site model. However, two site modeling of the saturation isotherms proved to be significantly better than a one site model and revealed high and low affinity binding sites with k_d's of 1.3nM and 79.7nM respectively. Autoradiographic localization showed high binding in the caudate putamen, nucleus accumbens, and olfactory tubercle.

418.17

DOPAMINE SYNTHESIS, STORAGE, RELEASE AND RECEPTOR CONTENT IN A MESENCEPHALIC CELL LINE. S.P. Han*, K.L. O'Malley, H. Choi,[+] A. Heller[+] and R.D. Todd[#] Depts of Anatomy and Neurobiology and [#]Psychiatry and Genetics, Washington Univ. Sch. of Med., St. Louis, MO 63110 and [+]Dept. of Pharmacological and Physiological Sciences, The Univ. of Chicago, Chicago, IL 60637

An immortalized mouse mesencephalic dopamine (DA) containing cell line (MN9D) has been established by somatic cell fusion techniques (Choi et al., Brain Res., 552:67-76, 1991). This cell line contains DA, NE, and DOPA as well as DA metabolites. These cells show neurite formation, generation of action potentials and sensitivity to MPP^+. MN9D cells express tyrosine hydroxylase mRNA and immunoreactive protein. In the present study we have further characterized the dopaminergic properties of the MN9D cell line. Enzymatic assays show the presence of L-aromatic amino acid decarboxylase activity which can be inhibited by NSD1015, a specific inhibitor of the decarboxylase enzyme. Dense core vesicles are clearly visible under electron microscopy. DA can be released by potassium-induced depolarization in a concentration dependent manner. Differentiation with 1 mM sodium butyrate results in increased cellular DA levels. No D_1-like or D_2-like binding sites were detected in receptor binding assays using [^{3}H] SCH23390 or [^{3}H] spiperone. Furthermore, reverse transcription-polymerase chain reaction assays detect no D_1-like or D_2-like receptor mRNA. Given these findings, the MN9D cell line appears to be a suitable model system for examination of CNS DA neurobiology and a convenient system for studying autoreceptor function by transfection of specific receptor types. Supported by NS29343, MH45019 and MH28942.

ELECTROPHYSIOLOGICAL ACTIVITY MODULATES THE LEVEL OF ENDOGENOUS ADENOSINE IN THE HIPPOCAMPAL SLICE. J.B. Mitchell* and T.V. Dunwiddie. University of Colorado Health Sciences Ctr. and VA Medical Ctr., Denver, CO 80262

Adenosine is a potent inhibitory neuromodulator within the CNS. An increase in adenosine levels accompanies hypoxia, ischemia and seizures, but it is not known if adenosine has a role in normal electrophysiological function. We have found evidence for the activity-dependent release of adenosine from in vitro hippocampal slices maintained under physiological conditions. Bipolar stimulating electrodes were positioned in the Schaffer collateral-commissural fiber layers of areas CA1 and CA3, and test fEPSPs were recorded from a single recording electrode positioned in the stratum radiatum of CA1. A train of conditioning pulses was applied to one stimulating electrode, and then a response evoked by applying a test pulse to the second stimulator. A train of 6 conditioning pulses (100 Hz) beginning 250 ms prior to the test pulse decreased the amplitude of the test fEPSP to 78.6 $\pm$ 1.9 percent of control. Antidromic firing of the CA1 pyramidal cells, evoked by an electrode positioned in the alveus, decreased the amplitude of the test fEPSP to 84.1 $\pm$ 2.6 percent of control. The decrease in fEPSP amplitude induced by either conditioning stimulus could be prevented by superfusion with an adenosine antagonist. When 2 conditioning pulses were used, the decrease in fEPSP amplitude lasted 500 ms and the maximum decrease occured at 250 ms. Superfusion with the adenosine uptake inhibitor, dipyridamole, (50 μM) lengthened the duration of the decrease. These results suggest that endogenous adenosine levels can be increased in response to activation, and that this adenosine can then decrease excitatory neurotransmission in the hippocampus.

NMDA- AND NON-NMDA-EVOKED ADENOSINE RELEASE: DISTINCT PURINERGIC SOURCES AND MECHANISMS OF RELEASE. C.G. Craig* and T.D. White, Dept. of Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7.

Activation of excitatory amino acid receptors releases the inhibitory neuromodulator adenosine from superfused rat cortical slices. Here we investigated the source of adenosine and its mechanism of release. Inhibition of the nucleoside transporter with dipyridamole greatly enhanced adenosine release evoked by glutamate, NMDA, kainate and AMPA. Inhibition of *ecto*-5'-nucleotidase with α,β-methylene ADP and GMP had no effect on either kainate- or AMPA-evoked adenosine release but decreased glutamate- and NMDA-evoked adenosine release by 23% and 68%, respectively. NMDA-evoked adenosine release, but not kainate- or AMPA-evoked release, was Ca^{2+}-dependent. These results indicate that activation of non-NMDA receptors releases adenosine *per se* in a Ca^{2+}-independent manner. In contrast, NMDA receptor activation evokes a Ca^{2+}-dependent release of a nucleotide which is subsequently converted extracellularly to adenosine. Although neither NMDA- nor non-NMDA-evoked adenosine release occurs via the nucleoside transporter, this transporter does appear to be a major route for removal of adenosine from the extracellular space.

419.3

BLOCK OF NMDA-EVOKED ADENOSINE RELEASE BY IBMX IS NOT DUE TO INHIBITION OF PHOSPHODIESTERASE I OR IV. T.D. White* and C.G. Craig. Department of Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7.

Activation of NMDA receptors in rat cortical slices evokes a Ca^{2+}-dependent release of a nucleotide which is then degraded extracellularly to adenosine. To test whether the released nucleotide might be cAMP, we examined the effects of PDE inhibitors on adenosine release. IBMX, a non-selective PDE inhibitor, blocked NMDA-evoked adenosine release but this was not accompanied by enhanced cAMP recovery in the medium. However, it seemed possible that cAMP may be degraded intracellularly to 5'AMP which is then released and converted to adenosine by *ecto*-5'-nucleotidase. PDE I, II and IV have been isolated in the cortex. Inhibitors of Ca^{2+}/calmodulin-dependent PDE I (8-methoxymethyl-IBMX, W-7 and calmidazolium) and cAMP-specific PDE IV (rolipram) did not mimic the effects of IBMX on NMDA-evoked adenosine release. It appears that IBMX decreases the NMDA-evoked release of purines from cortex either by inhibiting PDE II or by acting at a site other than PDE. (Supported by the MRC of Canada)

419.4

HETEROGENEITY OF ADENOSINE TRANSPORTERS AS BASIS FOR CNS-SPECIFIC ADENOSINE TRANSPORT INHIBITORS? J.Deckert*, A.Hennemann, B.Bereznai, W.Gsell, M.Götz J.Fritze, H.Beckmann and P.Riederer. Dept. of Psychiatry, Univ. Würzburg, 87 Würzburg, FRG.

Adenosine transport inhibitors have been suggested for the treatment of neuropsychiatric disorders. Heterogeneity of adenosine transporters has been described with differential sensitivity to dipyridamole (DPR) and nitrobenzylthioinosine (NBI) in the brain of some mammals.

Preparation of crude menbranes from human parietal cortex and (^{3}H)DPR as well as (^{3}H)NBI radioreceptor assays were performed as described.

(^{3}H)DPR and (^{3}H)NBI marked approximately the same number of binding sites with a Bmax of about 1000 fmol/mg protein and Kd`s in the low nanomolar range. They displaced each other completely from their respective binding sites with Ki`s equivalent to their respective Kd`s.

In conclusion, the data obtained so far in human brain makes the development of CNS-specific adenosine transport inhibitors on the basis of DPR- and NBI- sensitive transport unlikely.

419.5

CHARACTERIZATION OF ADENOSINE UPTAKE SITES IN CULTURES OF CHICK EMBRYO RETINAL CELLS. R. Paes-de-Carvalho* and R. Visser. Dep. Neurobiologia, Univ. Fed. Fluminense, Niterói, RJ 24000, Brazil.

The presence of a specific uptake system for adenosine that can be inhibited by nitrobenzylthioinosine (NBI) or dipyridamole (DPR) was previously demonstrated in cultures of chick embryo retinal cells. Here we show that (^{3}H)NBI binds with high affinity to adenosine uptake sites on intact retinal cells. Cultures obtained by dissociation of 8-day-old chick embryo retinas and incubated in BME with 5% fetal calf serum for 6 days at 37°C were washed and incubated in Hanks' with 2-5nM (^{3}H)NBI in the absence or presence of unlabeled NBI (10µM) to determine nonspecific binding. The binding was blocked approximately 70% in the presence of unlabeled NBI or DPR and attained equilibrium after 10 min at 37°C. The addition of NBI or DPR after equilibrium completely displaces specific binding, indicating the binding to surface sites rather than (^{3}H)NBI uptake into cells. The data indicate that adenosine uptake sites labeled with (^{3}H)NBI can be directly studied in living intact retinal cells and that primary cultures of chick embryo retinal cells are excellent models for the study of these sites and their regulation by external factors.

419.6

[^{3}H]ADENOSINE TRANSPORT IN POSTMORTEM HUMAN BRAIN. J.G. Gu*, G. Kala, and J.D. Geiger. Dept. Pharmacology, Univ. of Manitoba, Faculty of Medicine, 770 Bannatyne Avenue, Winnipeg, Manitoba, R3E 0W3

The kinetics of [^{3}H]adenosine transport was characterized in cerebral cortical synaptoneurosomes prepared from postmortem human brain. For this assay, it was determined that the adenosine transport inhibitors dypridamole and dilazep were instantaneously and completely effective in blocking adenosine transport. For 5 sec incubations, two kinetically distinguishable processes were identified; the Kt and Vmax values for high affinity adenosine transport were 89 uM and 0.98 nmol/min/mg protein and for low affinity adenosine transport were 4.5 mM and 15.2 nmol/min/mg protein. With incubation of 1 uM [^{3}H]adenosine, [^{3}H]adenosine accumulation was 0.3 uM at 5 sec and 1.0 uM at 600 s; hence adenosine transport was not a concentrative process. For 5, 15, 30, 60 and 600 sec incubations, 14, 23, 34, 43 and 80% of transported [^{3}H]adenosine was metabolized mainly to its phosphorylated derivatives AMP, ADP, and ATP. The concentration (uM) of total accumulated radiolabeled purines at these times was 0.3, 0.5, 1.0, 1.3 and 5.6, respectively; hence the accumulation of radiolabeled purines was concentrative only when extensive metabolism was present. In the presence of 10 uM EHNA, an adenosine deaminase inhibitor, and 10 uM iodotubercidin, an adenosine kinase inhibitor, metabolism was 14, 14, 16, 14, and 38% of the transported [^{3}H]adenosine and total radiolabeled purine accumulation was 0.3, 0.5, 0.5, 0.7, and 1.8 uM; hence concentrative accumulation of radiolabeled purines can be inhibited by the inhibition of adenosine metabolism. Thus, adenosine transport in human brain synaptoneurosomes is via a facilitated diffusion system that exhibits low affinity for adenosine.

419.7

INHIBITORY ADENOSINE A_1 RECEPTORS EXIST ON MYENTERIC AH/DOGIEL TYPE II NEURONS OF THE SMALL INTESTINE. F.L. Christofi, H.J. Cooke* and J.D. Wood. Dept. of Physiology, Ohio State Univ., Columbus, OH 43210.

Intracellular microelectrodes were used to characterize the adenosine receptors of 102 myenteric neurons. Biocytin was injected from microelectrodes to characterize the morphology of responsive neurons. Superfusion of adenosine, the A_2 agonists 5'-N-ethylcarboxamidoadenosine and CGS 21680 or the A_1 selective agonists N^6- cyclopentyladenosine and 2- chloro-N^6-cyclopentyladenosine (CCPA) evoked an inhibitory response in 93 of 102 AH/type 2 neurons (91.3%). The response consisted of membrane hyperpolarization, associated with a decrease in input resistance, increase in the hyperpolarizing after-potentials, inhibition of spike discharge and a decrease in cell input resistance. The potency profile for inhibition of cell input resistance was CCPA > > CGS 21680 > ADO (N=40); the EC_{50} for CCPA (5.15+2.17 nM) was 1000 fold lower than that of CGS 21680 (5.60 +2.54 μM). This effect was reversible with the A_1 selective antagonist 8-cyclopentyl-1,3-dimethylxanthine (0.10-1.00 μM). Of 30 responsive neurons, 27 neurons (90%) had Dogiel Type II and 3 neurons (10%) had Filamentous morphologies. It is concluded that inhibitory A_1 adenosine receptors exist mainly on myenteric AH/Dogiel Type II neurons.**(Supported by NIH R29 DK44179 to FLC and R01 DK 37238 to JDW).**

419.8

ADENOSINE AND 5-HT INHIBIT SUBSTANCE P RELEASE FROM ENTERIC NERVES THROUGH DISTINCT G PROTEINS. R.M. Broad* and M.A. Cook. Dept of Pharm. & Tox., Univ. of Western Ontario, London, CANADA N6A 5C1.

Evidence suggesting that both adenosine and 5-HT, released from enteric nerves, can function to inhibit the release of excitatory neurotransmitters is well documented. It is possible that both of these compounds cause hyperpolarization of neurons and that transduction may involve G protein coupling. Examination of the *pertussis* toxin-sensitivity of the inhibitory actions of these neuroactive substances was undertaken. A perifused preparation of enzymatically dispersed guinea pig myenteric ganglia was used to examine the inhibitory actions of 5-HT and N^6-cyclopentyl-adenosine (CPA, an A_1-selective adenosine analog) on the $\uparrow[K^+]_o$-evoked release of Substance P-like immunoreactivity (SP-LI). The release of SP-LI was inhibited, in a simple graded manner, by CPA. Incrementing concentrations of 5-HT also inhibited SP-LI release yielding a biphasic concentration-response relationship. The selective A_1 antagonist DPCPX (1μM) abolished the inhibition due to CPA while 5-HT-mediated inhibition was abolished by the 5-HT_{1A}-selective antagonist NAN-190 (10μM). In the presence of DPCPX alone, evoked SP-LI release was enhanced supporting the presence endogenous adenosine. The inhibition mediated by both A_1 and 5-HT_{1A} agonists was insensitive to tetrodotoxin (1μM) implicating a prejunctional locus for both receptors on tachykininergic nerve endings. Pretreatment of ganglia with *pertussis* toxin had no effect on CPA-mediated inhibition while that to 5-HT was abolished. Treatments designed to eliminate the possible influence of adenosine receptor occupancy by endogenous adenosine on binding of PTX to the G proteins did not alter these results. The findings demonstrate directly the presence of functional adenosine A_1 and 5-HT_{1A} receptors on enteric nerve endings, coupled negatively to tachykinin release, and that they are coupled through distinct mechanisms, putatively distinct G proteins, (G_i or G_o). Supported by the Medical Research Council of Canada.

MODULATION OF PITUITARY TRANSCRIPTION FACTOR EXPRESSION BY ADENOSINE A_1 RECEPTOR LIGANDS. M.T.C. Jong, F.B. Tuazon, E.J. Simon*, H.H. Samuels and M.R. Sherman. Depts. of Med. and Pharmacol., New York Univ. Sch. of Med., New York, NY 10016 and Depts. of Biol. Sci. and Chem., Rutgers Univ., Newark, NJ 07102.

Pit-1 (GHF-1) is a pituitary-specific transcription factor that regulates the synthesis of growth hormone (GH) and prolactin. Hormones and other agents regulate Pit-1 synthesis by various mechanisms, including effects on adenylate cyclase (AC). Since AC activity can be decreased or increased by analogs of adenosine (Ado) *via* A_1 or A_2 receptors, respectively, we studied the effects of these ligands on mRNA synthesis under the control of the Pit-1 promotor. GH-producing rat pituitary tumor cells (GH_4C_1) were transiently transfected with a chimeric reporter construct containing part of the 5'-flanking sequence of the Pit-1 gene (-389/+11) linked to the coding sequence for chloramphenicol acetyl transferase (CAT). After 24h, various concentrations of forskolin (Forsk), a direct activator of AC, *R-*N^6-phenylisopropyladenosine (PIA, an A_1 agonist), 8-cyclopentyltheophylline (CPT, an A_1 antagonist) and/or Ado deaminase (ADA) were added. Cells were harvested 24h later and lysates were assayed for CAT activity. ADA altered both the magnitude and dose-dependence of Forsk-stimulated CAT activity, suggesting a role for secreted Ado. In the presence of 2 U/ml ADA, the Forsk concentration giving half-maximal increase in CAT activity was increased 2- to 3-fold, and CAT activity was stimulated 25-fold by 0.5 µM Forsk. PIA (0.1 or 1 µM) consistently *inhibited* the expression of this construct to 40-60% of the basal value in the presence of 0.25 µM Forsk and 2 U/ml ADA. The effect of 0.1 µM PIA was completely blocked by 1 µM CPT. In the absence of ADA, responses to PIA were variable, *e.g.* 10 nM PIA *stimulated* construct expression 2-fold in some experiments. Our results indicate that adenosine should be added to the growing list of neurotransmitters and hormones which regulate pituitary hormone production at the transcriptional level. *(Supported by NIH grant DK16636 and the Cohen Fund)*

ADENOSINE A1 RECEPTOR/G-PROTEIN COUPLING DURING EARLY DEVELOPMENT IN THE RAT. R. Guillet*. Depts. Pediatrics and Psychology, University of Rochester, Rochester NY 14642.

Caffeine, an adenosine receptor antagonist, is commonly administered to human neonates with apnea of prematurity. In an animal model of such exposure, it has been shown that neonatal exposure to caffeine (1) alters the ontogeny of adenosine A1 receptors in certain brain regions, (2) alters developmental sensitivity to adenosine receptor ligands, and (3) alters control of locomotor activity in the developing rat. All of the observed effects have age and/or brain region specificity. Morgan et al. have demonstrated in guinea pigs both a region- and age-specific efficacy of displacement of 3H-CHA (an adenosine receptor agonist) by a guanine nucleotide analogue. This may reflect a region- and age-dependent degree of adenosine A1 receptor/G-protein coupling. To investigate this phenomenon in the developing rat as well as the effect of early caffeine exposure on such development, rats were exposed to 15-20 mg/kg caffeine (p.o.) over postnatal days 2-6. Membranes were prepared from cortex, cerebellum and hippocampus obtained from control (nonhandled and vehicle-exposed) and caffeine-exposed rats on postnatal days 10, 14, 18, 21, and 28. Membranes were incubated with 0.5nM 3H-CHA in the absence and presence of 100µM GTP for 2 hours at room temperature. Specific binding±GTP and % decrease in binding in the presence of GTP were calculated. As demonstrated previously, there was an increase in specific binding as a function of neonatal caffeine exposure in cortex ($p<.02$), but not in cerebellum. There was a trend toward a greater decrease in cortical specific binding in the presence of GTP in neonatally-caffeine exposed rats compared with controls. There was no difference in % decrease in specific binding in the presence of GTP as a function of age in any region examined. These results suggest a regionally-specific alteration in coupling between the adenosine A1 receptor and its associated G-protein as a function of neonatal caffeine exposure, but not as a function of age during the second and third weeks of life in the rat.

MECHANISMS OF ADENOSINE A_1 RECEPTOR-MEDIATED EFFECTS ON CELLULAR PROPERTIES IN RAT VAGAL MOTONEURONS. J.D. Marks*, D.F. Donnelly, and G.G. Haddad. Dept. of Pediatrics, Section of Resp. Med., Yale U. Sch. of Medicine, New Haven, CT 06510.

We have previously shown that specific adenosine A_1 receptor activation in the rat medullary slice preparation decreases vagal motoneuron excitability and increases input resistance (R_N). This decrease in excitability is due in part to an adenosine-mediated increase in afterhyperpolarization (AHP) amplitude. In order to understand better the mechanisms underlying A_1 receptor effects, we recorded intracellularly from vagal motoneurons using a rat brainstem slice preparation before and during subfusion with either adenosine (10 μM-1 mM) or a specific A_1 receptor agonist, cyclopentyladenosine (CPA, 10 μM). Synaptic blockade with either TTX or a perfusate containing high Mg^{++} (10 mM), low Ca^{++} (0.5 mM) blocked the CPA-induced increase in R_N. Blockade of Ca^{++} entry with $CoCl_2$ (2 mM) abolished the AHP increase. In addition, selective K^+ channel blockade with either 4-aminopyridine (4-AP, 1 mM) or apamin (0.5-2.5 nM) failed to block the increase in AHP amplitude. Blockade of native adenosine with 8-cyclopentyltheophylline (0.8 mM) decreased both R_N and AHP amplitude, and increased excitability. Interestingly, no effect was seen with exogenous adenosine itself, unless adenosine uptake had been blocked with dipyridamole 25 μM. We conclude that 1) the adenosine-induced R_N increase, and possibly the AHP increase as well, is due to A_1 receptor actions on presynaptic mechanisms, 2) the ion channel mediating the increase in AHP amplitude is sensitive to cobalt but not 4-AP or apamin, and 3) the adenosine uptake system in the vagal motor nucleus effectively buffers extracellular adenosine.

MDL 102,234: A SELECTIVE ADENOSINE A_1 RECEPTOR ANTAGONIST REFLECTING A NEW BINDING MODE TO THE RECEPTOR. M. Dudley, M. Racke, A.M. Ogden, N. Peet, R. Secrest, R. McDermott. Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

The accepted binding mode for a xanthine within the A_1 receptor superimposes N^1,N^3,N^7 and N^9 of the xanthine with the 4 identical nitrogens of the adenine base. This mode does not overlap the xanthine C-8 nor the adenosine C^6-N positions, the positions which impart potency and selectivity to xanthine-based antagonists and substituted adenosine agonists. With superimposition of N^1,N^3 and N^9 of adenosine and N^9, N^3 and N^1 of the xanthine, the C^6-N and C-8 positions are in close proximity. MDL 102,234 (MDL) [(R)-1,3-dipropyl-8-(1-phenylpropyl)xanthine] is a C-8 substituted xanthine with the same stereochemistry as the C^6-N phenylisopropyl substituent of the A_1-selective agonist R-PIA. MDL 102,234 has K_i values at the adenosine A_1 and A_2 receptors of 3 and 900 nM, respectively. The compound is a very weak phosphodiesterase inhibitor with IC_{50} values against PDE Type III and PDE Type IV of 514 µM and 28.3 µM, respectively. This is 10,000-fold weaker than its potency at the A_1 receptor. In guinea pig atria, the compound antagonizes A_1 agonist-induced negative chronotropic and inotropic responses. MDL at a concentration of 10 µM has no effect on heart rate or developed tension in the tissue. In conclusion, MDL 102,234 is a selective A_1 antagonist and supports the new binding mode of xanthines to the A_1 receptor.

419.13

IN VIVO ACTIVATION OF A1 ADENOSINE RECEPTOR BY CCPA ENHANCES ^{35}S-TBPS BINDING IN THE MOUSE BRAIN. A.Concas*, E. Maciocco, L. Dazzi, G. Santoro, M.P. Mascia, M. Trampus[1], E. Ongini[1] and G. Biggio Dept. of Experimental Biology, Chair of Pharmacology, University of Cagliari and [1]Schering-Plough, Research Laboratories, Comazzo (MI) - Italy

The effect of 2-chloro-N_6-cyclopentyladenosine (CCPA), the most selective A_1 adenosine receptor agonist, was studied on ^{35}S-TBPS binding measured "ex vivo" in the mouse brain. In fact, the increase and decrease of ^{35}S-TBPS binding in the rat and mouse brain homogenate reflect a reduction and an enhancement in the function of the $GABA_A$ receptor-coupled chloride channel, respectively. CCPA (0.5 - 10 mg/kg i.p.), like negative modulators of GABAergic transmission, elicited in 30-60 min a dose-dependent increase of ^{35}S-TBPS binding in the mouse cerebral cortex, hippocampus, striatum, but in the cerebellum. The effect of CCPA lasted for more than 4 hrs. Saturation studies revealed that the effect of CCPA on ^{35}S-TBPS binding was entirely due to an increase in the apparent affinity for TBPS recognition sites with no changes in the Bmax. The effect of CCPA on ^{35}S-TBPS binding was abolished by the concomitant administration of the specific A_1 receptor antagonist DPCPX (3 mg/kg i.p.). Moreover, abecarnil (0.5 mg/kg, i.p.), an anxiolytic and anticonvulsant benzodiazepine receptor ligand, completely abolished the increase of ^{35}S-TBPS binding induced by CCPA. In spite of its capability to reduce the function of GABA-coupled chloride channel, CCPA (1-3 mg/kg) completely antagonized the convulsant activity of pentylentetrazol and isoniazid, two GABA function inhibitors, while failed to antagonize kainic acid and strychnine-induced seizures.

419.14

EFFECTS OF ALCOHOL ON ADENOSINE A_1 AND A_2 RECEPTOR-MEDIATED CHANGES IN ADENYLATE CYCLASE ACTIVITY IN BRAIN MEMBRANES FROM LONG-SLEEP MICE. M.R. Sherman*, F.B. Tuazon, E.N. Shafik and J.J. McArdle. Dept. of Biol. Sci., Rutgers Univ., Newark, NJ 07102; Dept. of Pharmacol. and Toxicol., Univ. of Med. and Dent., Newark, NJ 07103.

Prolonged exposure to alcohol (alc) is known to diminish adenosine receptor-mediated activation of adenylate cyclase (AC) in a cultured neural cell line and in human lymphocytes *(PNAS 83:2105, 1986; PNAS 84:1413, 1987)*. However, definitive evidence for the involvement of a particular receptor subtype has been difficult to obtain. We have addressed this question by assaying AC activity in membranes from various brain regions of mice selectively bred for alc sensitivity (long-sleep mice). Mice were kept on liquid diets ± 3.8% alc for 10d. AC activity (α^{32}P-ATP → ^{32}P-cAMP) in membranes from hippocampus (hip), cortex and striatum was measured in the presence of adenosine deaminase and various concentrations of forskolin (Forsk, a direct activator of AC), *R-N*^{6}-phenylisopropyladenosine (PIA, an A_1 agonist), 8-cyclopentyltheophylline (CPT, an A_1 antagonist) and/or 2-(carboxyethylphenylethylamino)adenosine-5'-carboxamide (CGS21680, an A_2 agonist). We detected no effect of alc on the A_1 receptor-mediated inhibition of AC by PIA in either hip or cortex. In striatal membranes, 1 μM CGS21680 stimulated AC to 140 % of basal activity in the absence of Forsk and the presence of 0.1 or 1 μM CPT (which presumably blocks CGS21680 binding to A_1 receptors), but no effect of alc was detected. Only in freshly prepared cortical membranes was there clear evidence for an effect of alc on A_2 receptors. When cortical membranes from control mice were assayed with 20 nM Forsk and 1 μM CPT, AC activity was increased 2-fold by 1 μM CGS21680 and to a lesser extent by 10 or 100 μM. In membranes from alc-treated mice, no stimulation of AC activity was detected at any tested concentrations of CGS ± CPT. These results demonstrate that 10 days of alc ingestion by alc-sensitive mice abolishes the responsiveness of AC in their cortical membranes to a ligand selective for A_2 but not A_1 adenosine receptors.

EXPRESSION OF ADENOSINE A1 AND A2 RECEPTOR SUBTYPES IN PRIMARY CULTURED NEURONS FROM FETAL RAT FOREBRAIN. J.L. Daval*, F. Nicolas, J. Oillet and V. Koziel. INSERM U.272, 30 rue Lionnois, 54013 NANCY, FRANCE.

The expression of both adenosine A1 and A2 receptors, which are physiologically coupled to adenylate cyclase via G proteins, was investigated by radioligand binding methods in primary cultured neurons isolated from fetal rat forebrain and grown in serum-free medium for 8 days. A1 receptors were labeled by incubating intact neurons in 50 mM Tris-HCl buffer (pH 7.4) for 120 min at 25°C with 2 IU/ml adenosine deaminase and increasing concentrations of (3H)2-chloro-N6-cyclopentyladenosine (CCPA), using cyclohexyladenosine for the determination of non-specific binding. A2 binding sites were analyzed by incubating the cells for 90 min at 25°C with deaminase and (3H)CGS 21680. Non-specific binding was assessed with NECA. Additionally, the presence of adenylate cyclase was tested by analyzing (3H)forskolin specific binding. Each radioligand bound specifically and with high affinity to a single population of sites. Scatchard plots yielded Kd-values of 2.9 nM for (3H)CCPA, 1.7 nM for (3H)CGS 21680 and 33 nM for (3H)forskolin. Maximum numbers of sites were 160±14, 10±3 and 254±23 fmol/mg protein for CCPA, CGS 21680 and forskolin, respectively. The addition of 1 μM G(pp)NHp, a GTP analogue, increased significantly KD-values for both CCPA and CGS 21680, suggesting that receptors are, at least partly, linked to G proteins.

419.16

DEPRESSION OF LOCOMOTOR ACTIVITY BY ACTIVATION OF A_2 RECEPTORS IN THE NUCLEUS ACCUMBENS IN MICE, K. Martens[1], M. Parizon[1], H.J. Normile[1,2] and R.A. Barraco*[1]. Depts. of [1]Physiology and [2]Psychiatry, Wayne State Univ. Sch. of Med., Detroit MI 48207

Adenosine agonists are potent locomotor depressants in rodents- an effect which has been shown to be centrally mediated. In the present study, we examined the locomotor effects of A_1 and A_2 agonists when infused into the nucleus accumbens, a ventral striatal structure which appears to functionally link limbic and motor systems. The selective A_1 agonist N^6-cyclopentyladenosine (CPA), and the selective A_2 agonists 5'-N-ethylcarboxamidoadenosine (NECA) and 2-[4-(2-carboxyethyl)phenethylamino]-5'-N-ethylcarboxamido adenosine (CGS) were injected (0.0002, 0.002, 0.02, 0.2, and 2.0 nmoles per mouse) bilaterally (0.5 ul/side) into the nucleus accumbens through permanent indwelling cannulae in mice. Each of the A_2 agonists, NECA and CGS, significantly suppressed locomotor activity in a dose-dependent fashion, whereas the A_1 agonist, CPA, had no effect on locomotor activity. These findings suggest that selective activation of A_2 receptors in the nucleus accumbens may suppress locomotor activity.

419.17

ADENOSINE-2 RECEPTOR SEQUENCES ON HUMAN CHROMOSOME 22. RA Peterfreund*, M MacCollin, M MacDonald, RH Lekanne Deprez, EC Zwarthoff, J Gusella and JS Fink. Depts. of Anesthesia and Neurology, Mass. Gen. Hosp., Boston, MA 02114, USA and Dept. Pathology, Erasmus U., Rotterdam, The Netherlands

Adenosine-2 receptors (A2Rs) are abundantly expressed in the striatum, suggesting an important role in motor function and extrapyramidal diseases. Complementary DNAs (cDNAs) for the A2R have been isolated from dog (BBRC 173:1169) and rat (Mol Br Res, *in press*). These cDNAs exhibit substantial nucleic acid and amino acid homology in the transmembrane (TM) domains but diverge in their carboxy termini. To further understand the functional significance of sequence divergence at the carboxy terminus of the A2R, we have begun to characterize the human A2R gene.

A panel of somatic cell hybrids containing various human chromosomes on a rodent background was screened with a 540bp fragment of coding sequence from the rat A2R. Hybridization was detected with the chromosome 22 containing cell line. Localization on chromosome 22 proximal to a t(4:22) breakpoint at 22q11 was then established by hybridization with a regional somatic cell hybrid panel. A human chromosome 22 cosmid library was screened with the same probe and two clones were isolated. A restriction fragment from one of the cosmid clones which selectively hybridized to the rat probe was subcloned and sequenced. The predicted amino acid sequence of this fragment was highly homologous to the dog and rat A2Rs (70% overall identity and greater than 90% identity in the transmembrane domains). We conclude that A2R-like sequences homologous to the rat and dog A2R reside on human chromosome 22.

419.18

MOLECULAR CLONING AND CHARACTERIZATION OF A NOVEL ADENOSINE RECEPTOR: THE A3 ADENOSINE RECEPTOR. Q.-Y. Zhou, C. Li, M. E. Olah, J. Williams*, G. Stiles, and O. Civelli. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201 and Department of Medicine, Duke University, Durham, NC 27710.

We have previously reported the selective amplification of several rat striatal cDNA sequences that encode novel G-protein coupled receptors. One of these sequences (R226) exhibited high sequence identities (58%) with the two previously cloned adenosine receptors RDC7 (A1) and RDC8 (A2). A full-length cDNA clone for R226 has been isolated from a rat brain cDNA library. The cDNA clone encodes a protein of 320 amino acids that can be organized into seven transmembrane stretches. When stably expressed in CHO cells, R226 could bind the nonselective adenosine agonist [^{3}H]NECA and A1-selective agonist [^{125}I]APNEA but not A1-selective antagonists [^{3}H]DPCPX and [^{3}H]XAC or the A2-selective agonist ligands [^{3}H]CGS21680 and [^{125}I]PAPA-APEC. Extensive characterization with [^{125}I]APNEA showed that R226 binds [^{125}I]APNEA with Kd of17 nM, which is ten fold lower than typical A1AR, and the specific [^{125}I]APNEA binding could be inhibited by adenosine ligands with a potency order of R-PIA = NECA > S-PIA > adenosine > ATP = ADP but not by antagonists XAC, IBMX and DPCPX. In R226 stably transfected CHO cells, adenosine agonists R-PIA, NECA, and CGS21680 inhibited by 40-50% the forskolin-stimulated cAMP accumulation through a pertussis toxin-sensitive G protein with EC50 of 18±5.6 nM, 23±3.5 nM, and 144±34 nM, respectively. Based on these observations we conclude that R226 encodes an adenosine receptor with non-A1 and non-A2 specificity and thus name it the A3 adenosine receptor. mRNA analyses revealed that the highest expression of R226 was in the testis and low level mRNAs were also found in the lung, kidneys, heart, and some parts of the CNS such as cortex, striatum and olfactory bulb. The high expression level of the A3 receptor in the testis suggests its possible role in reproduction.

420.1

NUCLEOTIDE RECEPTORS IN PHEOCHROMOCYTOMA (PC12) CELLS.
L. de Souza[1], S. Raha[1], A. Lange[2]* and J.K. Reed[3]. Depts of Biochemistry[1], Zoology[2] and Chemistry[3], University of Toronto, Erindale College, Mississauga, Ont. L5L 1C6

The effect of extracellular ATP was studied in PC12 cells, a neurosecretory line that co-releases ATP with catecholamines upon stimulation. We have examined the effects of ATP by monitoring both cytosolic free Ca^{2+} concentrations $[Ca^{2+}]_i$ and inositol phosphate (IP) levels. Micromolar concentrations of ATP evoked a transient increase in $[Ca^{2+}]_i$ as measured with the Ca^{2+}-sensitive dye fura-2. The increase was eliminated by EGTA. UTP and ITP also evoked an increase while GTP and CTP had little effect. A variety of ATP cogeners were screened to identify the purinergic receptor subtype involved. The rank order potency of these analogues is not consistent with either P_{2X} or P_{2Y} purinergic receptors. The effect of ATP on IP levels was determined using ^{3}H-inositol. IP levels increased in response to ATP and other nucleotides such as UTP and ITP, but not GTP. The rank order potency for agonist-induced stimulation of IP production followed closely the rank order potency for the calcium response. We propose that PC12 cells express a P_{2N} nucleotide receptor that is distinct from classical purinergic receptors.

This research was supported by NSERC.

SECOND MESSENGER PATHWAY FOR ATP-EVOKED INCREASES IN INTRACELLULAR Ca^{2+} IN GLIA CULTURED FROM THE DORSAL SPINAL CORD.
M.W. Salter* and J.L. Hicks. Div. Neurosci., Hosp. for Sick Children, and Dept. Physiol., Univ. of Toronto, Ont., Canada, M5G 1X8.

ATP increases intracellular Ca^{2+} in glial cells from the spinal cord and other regions of the CNS by activating P_{2y}-purinergic receptors. Signal transduction mechanisms of this effect of ATP were investigated by measuring $[Ca^{2+}]_i$ in individual cells and delivering agents intracellularly by whole-cell patch clamp electrodes. Glia were studied in primary dissociated cultures prepared from the dorsal spinal cord of E17-E19 rats and grown for 7-14 days. $[Ca^{2+}]_i$ was measured using the fluorescent dye, Fura-2. Cells were loaded with the dye by incubating the cultures with the membrane permeant form, Fura-2 AM (2 μM). The standard intracellular solution used for whole-cell recording contained (in mM): 140 KCl, 1 $MgCl_2$, 10 HEPES, 0.1 EGTA, 0.05 K_5-Fura-2; pH 7.25. ATP (1-5 μM) was applied by pressure (5-20 s pulses) from a pipette located near the cell. ATP was tested before breakthrough into whole-cell mode and caused a rapid, transient increase in $[Ca^{2+}]_i$ in cells studied. Increases in $[Ca^{2+}]_i$ were evoked by ATP for up 30 min after breakthrough when the standard intracellular solution was used. In contrast, when heparin (1 mg/ml), an IP_3-receptor antagonist, was included in the intracellular solution, ATP was found to have no effect on $[Ca^{2+}]_i$ within 5 min following breakthrough. Including the G-protein activator GTPγS (50-500 μM) produced spontaneous increases in $[Ca^{2+}]_i$ and occluded the effect of ATP. GDPβS (100 μM), a G-protein inhibitor, did not affect resting $[Ca^{2+}]_i$ but attenuated the effect of ATP. Also, pretreatment with pertussis toxin (1 μg/ml, 24 hr) had no effect on the responses to ATP. These results indicate that ATP evokes release of Ca^{2+} from IP_3-sensitive stores via P_{2y}-receptors coupled to phospholipase C by a pertussis toxin-insensitive G protein. (Supported by the MRC of Canada and the Nicole Fealdman Memorial Fund.)

ACTIONS OF ATP ON SYNAPTIC TRANSMISSION IN THE MYENTERIC PLEXUS OF THE GUINEA-PIG ILEUM.
K.Morita*, T.Kamiji and Y.Katayama. Department of Autonomic Physiology, Tokyo Medical and Dental Univ., Tokyo, 101 Japan.

Intracellular recordings were made from myenteric neurons *in vitro* to study the actions of ATP applied by superfusion (10 nM-100 µM). ATP showed pre- and postsynaptic actions in a concentration-dependent manner. ATP produced a membrane depolarization associated with an increase in input membrane resistance in S cells and a hyperpolarization accompanied by a fall in input resistance in AH cells; both responses were reversed in polarity near the K^+ equilibrium potential and were markedly reduced or abolished in Ca^{2+} free/high Mg^{2+} solution. These suggest that they may be due to inactivation and activation of Ca-sensitive K conductance, respectively. Furthermore, ATP inhibited both fast and slow EPSPs in S cells and slow EPSPs in AH cells. The inhibitory effects of ATP on the synaptic potentials were observed, when the ATP-induced depolarization and hyperpolarization were nullified with manual clamp method. It should be added that ATP at lower concentration ($\leq$100 nM) did not affect ACh-nicotinic depolarizations but at higher concentration ($\geq$1 µM) augmented the ACh-responses. These results suggest that ATP may inhibit presynaptic release of ACh. Thus, it is concluded that ATP may act pre- or postsynaptically or both and may regulate synaptic transmission in the myenteric plexus. This was supported in part by a Grant-in-Aid from the Ministry of Education, Japan.

Fura-2 Imaging of Calcium mobilization by two different P_{2}-Purinoceptors on Single Rat Parotid Acinar Cells.
L. Tenneti* and B.R. Talamo, Neurosciences Labs, Tufts Med. Sch., Boston,MA.

Receptor-mediated cytosolic Ca^{2+} (Ca_i) regulation is readily studied in the rat parotid acinar cell model, where at least five different neurotransmitter receptors participate in Ca_i elevation. Previously, we observed that extracellular ATP stimulated Ca^{2+} influx without IP_3 formation in cell suspensions, and that the concentration-response curve was biphasic. Fluorescence microscope ratio-imaging methods were used to examine Ca_i responses in perfused, single acinar cells loaded with Fura-2. All cells (93%) which respond to muscarinic and Substance P activation through IP_3-stimulated Ca^{2+} release also respond to ATP. Analysis of the concentration-response curves showed that two responses to ATP can be resolved in most cells. The high affinity response, detectable at 0.1 μM ATP, saturates at 1- 3 μM and rapidly desensitizes in 50% of the cells, fully recovering within about 6 min after washout. At much higher concentrations of ATP (300-600μM), a large, more slowly developing Ca_i rise occurs, which can be blocked by Mg^{2+} as expected for an ATP^{4-}-specific response. The latter response does not desensitize, and is difficult to fully reverse on washout, possibly because a large influx of extracellular Ca^{2+} is handled differently from an equally high Ca_i level produced through muscarinic receptor activation, which is readily and rapidly reversed. Examination of these two Ca^{2+}-mobilizing purinergic receptors as well as PLC-activating receptors reveals the participation of different mechanisms of Ca_i homeostasis in recovery of resting Ca_i levels in individual cells.

420.5

EFFECT OF ATP ON VOLTAGE-SENSITIVE CALCIUM INFLUX AND PROTEIN PHOSPHORYLATION IN SYNAPTOSOMES ISOLATED FROM RAT CEREBRAL CORTEX.
P. Wixom*, T.-F. Mann and A.Y. Sun, Dept. of Pharmacol., Univ. Missouri, Columbia, MO 65212 and Institute of Neurosciences, National Yang Ming Med. College, Taipei, Taiwan.

Adenosine triphosphate (ATP) is co-released from nerve terminals together with neurotransmitters such as acetylcholine. Aside from its action on purinergic receptors, other functional aspects of extracellular ATP are not yet known. Since extracellular ATP has been implicated in the disruption of intracellular Ca^{2+} homeostasis, we examined the effect of ATP on the Ca^{2+} transport system. Results indicated that ATP at 1-2 mM enhanced the voltage-dependent calcium influx (VDCI). The enhancement of VDCI activity was specific for ATP and activity was blocked by ADP and AMP. Furthermore, the slowly hydrolyzable ATP, ATPγ-S, inhibited synaptosomal VDCI significantly, indicating that ATP hydrolysis was involved in ATP-induced enhancement of VDCI. Under similar conditions a 43 kD protein was phosphorylated by an ecto-kinase. The level of phosphorylation of this protein was dependent on exogenous calcium and was dephosphorylated upon depolarization. It is possible that the phosphorylation of the 43 kD protein is functionally linked to the ATP-induced VDCI activity.

420.6

GUANOSINE AND GTP ENHANCE NGF-STIMULATED NEURITE OUTGROWTH IN PC12 CELLS.
John W. Gysbers and Michel P. Rathbone*. Departments of Biomedical Sciences and Medicine, McMaster University Health Sciences Center, Hamilton, Ontario, Canada L8N 3Z5.

Extracellular guanosine or GTP (30-300µM), but not adenosine or ATP (0.3-300 µM) enhanced the neuritogenic effect of NGF in rat pheochromocytoma (PC12) cells. None of these purines induced significant neurite outgrowth in the absence of NGF. The effects of guanosine and GTP were synergistic with that of NGF in increasing the proportion of cells bearing long neurites. Adenosine - receptor agonists such as N^6-cyclopentyladeonsine (CPA), 5'-(N-cyclopropyl)-carboxamidoadenosine (CPCA) or 5'-N- ethylcarboxamideadenosine (NECA), also increased NGF-stimulated neuritogenesis, but to a lesser extent than did guanosine with NGF. High concentrations (1µM) of PACPX (1,3-dipropyl-8-(2-amino-4-chloro)xanthine, a preferential adenosine A_1 receptor antagonist, blocked the synergistic effect of guanosine and NGF. However, adenosine A_2 receptor antagonists DPMX (1,3-dipropyl-7-methylxanthine) or CGS15943 did not inhibit the effects of guanosine plus NGF. Interestingly, guanosine also acted synergistically with NECA (an adenosine A_1/A_2 receptor agonist) to induce significant neurite outgrowth in the absence of NGF, although neither of these compounds alone stimulated significant neurite outgrowth in PC12 cells. These data indicate that guanosine may not act via the purinergic P_1 (A_1 and A_2) receptors to enhance neuritogenesis. Moreover, neither ADPβS and ATP (purinergic P_2 receptor agonists) enhanced neurite outgrowth, indicating that the neuritogenic effects of GTP may not be mediated through classical P_2 purinergic receptors. BOVINE CHROMAFFIN GRANULE MEMBRANES UNDERGO CALCIUM-REGULATED EXOCYTOSIS IN XENOPUS LAEVIS OOCYTES [1]D.L. Scheuner, [2]C.D. Logsdon, and [1]R. W. Holz*, [1]Dept. of Pharmacol., [2]Dept. of Physiology, Univ. of Mich., Ann Arbor, MI 48109-0626.

We have devised a new method that permits the investigation of exogenous secretory vesicle function using bovine chromaffin granules and frog oocytes. Highly purified chromaffin granule membranes were injected into Xenopus laevis oocytes. Exocytosis was detected by the appearance of dopamine-β-hydroxylase (DBH) of the chromaffin granule membrane in the oocyte plasma membrane. The appearance of DBH on the oocyte surface was strongly Ca^{2+}-dependent and was stimulated by co-injection of the chromaffin granule membranes with $InsP_3$ or Ca^{2+}/EGTA buffer (18 μM free Ca^{2+}) or by incubation of the oocytes in medium containing the Ca^{2+} ionophore ionomycin. Similar experiments were performed with a subcellular fraction from cultured chromaffin cells enriched with [^{3}H]norepinephrine-containing chromaffin granules. The Ca^{2+}-dependent appearance of DBH on the oocyte surface correlated with [^{3}H]norepinephrine secretion. Therefore, it is likely that intact chromaffin granules and chromaffin granule membranes undergo exocytosis in the oocyte. This system may allow the study of secretory vesicle membrane constituents required for exocytosis.

GABA PRODUCTION AND RELEASE FROM CELLS PROGRAMMED TO EXPRESS GAD_{65} AND GAD_{67}. A. Sandrasagra[1], C.H.J. Ruppert[1], R.C. Weatherwax[1*], B. Anton[2], C.J. Evans[2], E.S. Schweitzer[3], and A.J. Tobin[1,4,5], Departments of [1]Biology, [2]Psychiatry and Biobehavioral Sciences, [3]Anatomy and Cell Biology, [4]Molecular Biology Institute, and [5]Brain Research Institute, University of California, Los Angeles CA 90024.

GABA is an important signalling molecule in both neuronal and non-neuronal systems, but the mechanisms of GABA production, GABA compartmentalization and GABA release are still obscure. To address these questions directly, we are using a retroviral GAD-cDNA expression system to obtain *in vitro* cell culture models of GABA producing cells that are of neuronal, neuro-endocrine, and pancreatic origin. We have obtained stable clones of PC12, and B65 neuroblastoma cells that express either or both GADs (GAD_{65} and GAD_{67}). These cells produce GAD mRNA(s), enzymatically active GAD, and GABA. In addition we are currently characterizing G418 resistant AtT-20 and RINm5F clones for GAD expression. Experiments that detail the calcium-dependent and calcium-independent release of GABA from the engineered cells are in progress. (Supported by NIH Grants NS23084-07 to E.S.S., and NS22256 to A.J.T.)

SKF 89976A INCREASES EXTRACELLULAR GABA IN RAT DORSOLATERAL STRIATUM IN VIVO. K.L.Drew* and U.Ungerstedt. Dept. Pharmacology, Karolinska Institute, Stockholm, Sweden.

The effects of SKF 89976A, a non-substrate inhibitor of GABA uptake, on extracellular levels of GABA in rat dorsolateral striatum were studied as a prelude to further studies of the role of the GABA transporter in voltage dependent GABA release. Procedures were as described in Drew and Ungerstedt (1991). SKF 89976A (0.02, 0.2 and 2.0 uM) was dissolved in modified Ringer's solution (1.2 mM $CaCl_2$, 0.85 mM $MgCl_2$, 2.7 mM KCl and 148 mM NaCl) and delivered through the probe. The drug dose dependently increased extracellular levels of GABA. SKF 89976A failed however, to significantly decrease veratridine-evoked release of GABA. Bupropion (6.0 uM), an inhibitor of dopamine uptake was also shown to increase extracellular levels of dopamine in rat dorsolateral striatum and to reduce veratridine-evoked release of dopamine. Further studies are required to determine if bupropion interfers with carrier mediated release of dopamine or if an increase in extracellular dopamine and consequent reduction in the frequency of cell firing explains the bupropion-induced inhibition of veratridine-evoked dopamine release.

421.4

EFFECT OF DRUG-INDUCED CHANGES IN THE DISPOSITION AND METABOLISM OF NEUROTRANSMITTER ON THE QUANTITATION OF ^{3}H-SEROTONIN (5HT) RELEASE. P.J. Monroe*, D.L. Smith, B.K. Kradel, D.J. Smith, and P. Blier, Dept. of Anesthesiology, West Virginia University Health Sciences Center, Morgantown, WV 26506 and Department of Psychiatry, McGill University, Montreal, Canada

While evaluating the effect of 2-methylserotonin (2-Me-5HT) on the release of ^{3}H-5HT from rat spinal cord tissue, it was determined that the drug altered the intrasynaptosomal disposition of the neurotransmitter. Superfusion of the tissue with 2-Me-5HT (0.3 - 10 μM) produced a concentration-dependent increase in ^{3}H-5HIAA efflux which occurred without a concomitant elevation in the efflux of ^{3}H-5HT. This effect was blocked by the co-superfusion of an uptake inhibitor, suggesting the drug disrupts intraneuronal storage of neurotransmitter following active uptake. The effect of 2-Me-5HT on ^{3}H-5HIAA efflux was slow in onset. Fifteen minutes was required before changes in ^{3}H-5HIAA efflux could be detected. However, this length of drug exposure is frequently achieved in the course of routine neurotransmitter release assays. Therefore, if total ^{3}H-efflux is quantitated (rather than separated neurotransmitter and metabolite), it is possible that a drug induced increase in ^{3}H-metabolite efflux could be mistakenly associated with an enhancement of depolarization-evoked ^{3}H-neurotransmitter efflux. For example, when calculated using total ^{3}H-efflux, 10 μM 2-Me-5HT caused an apparent 2.2 fold enhancement above the control (no 2-Me-5HT) response to a 15 mM K+ stimulus. On the other hand, when superfusate fractions were analyzed for ^{3}H-5HT and ^{3}H-5HIAA content, K^+-evoked increases in ^{3}H-5HT efflux were comparable in drug treated and control conditions. However, drug-induced increases in ^{3}H-5HIAA efflux were of the same magnitude as those seen from tissues which were not exposed to elevated K^+ concentrations. Thus, these results indicate that the separation of transmitter from metabolites is necessary to ensure that drug-induced changes in the disposition of neurotransmitter do not adversely affect the assessment of radiolabelled neurotransmitter release evoked via depolarization induced mechanisms.

RELEASE OF GLUTAMATE AND ASPARTATE FROM SYNAPTOSOMES OF HIPPOCAMPAL AREA CA1. M. Zhou, C.P. Duncan and J.V. Nadler*, Depts. Neurobiology and Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710.

When stimulated with elevated K^+, slices of hippocampal area CA1 release endogenous glutamate and aspartate in a 5:1 ratio. Release of these amino acids from CA1 slices originates predominantly from the Schaffer collateral-commissural projection and is Ca^{2+}-dependent. Axon terminals of this pathway thus appear to release both glutamate and aspartate. However, studies of neocortical synaptosomes have revealed little evidence of K^+-evoked aspartate release, in contrast to the substantial release evoked from neocortical slices. It has therefore been proposed that aspartate release in slice preparations reflects exchange of intracellular aspartate with released glutamate. This idea was tested by comparing glutamate and aspartate release from CA1 slices and synaptosomes.

Transverse slices of the rat hippocampal formation were prepared, area CA1 (excluding stratum lacunosum-moleculare) was isolated and synaptosomes were prepared by the method of phase partition. Synaptosomes were layered onto moistened filter paper disks and superfused in the same manner as CA1 slices. When superfused for 1 min with 25 μM K^+ or for 2 min with 300 μM 4-aminopyridine, the synaptosomes released both glutamate and aspartate in a Ca^{2+}-dependent manner. The glutamate/aspartate ratio was about 5:1. This result demonstrates that excitatory synaptic terminals can release aspartate, even under conditions where membrane transport of released amino acid is expected to be minimal. (Supported by NIH grant NS 16064.)

KINETIC ANALYSIS OF Na^+-DEPENDENT PROLINE AND GLUTAMATE UPTAKE IN RAT HIPPOCAMPAL FORMATION DURING POSTNATAL DEVELOPMENT. S. M. Cohen* and J. V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Some of the excitatory glutamate pathways in the rat hippocampal formation, including the Schaffer collateral-commissural fibers and the lateral perforant path, take up proline by a high affinity Na^+-dependent process. The role of proline in glutamate transmission is unknown. This study compared the uptakes of proline and glutamate by crude synaptosomal preparations of the hippocampal formation during ontogenesis. Uptake of both amino acids was determined from the same tissue samples.

At all ages studied from 9 d onward, glutamate was taken up by a single high affinity, Na^+-dependent process ($K_T \approx 2$ μM). In contrast, proline was taken up by both high affinity ($K_T \approx 5$ μM) and low affinity ($K_T \approx$ 100-1000 μM) Na^+-dependent processes. High affinity uptake of proline increased 4-fold and high affinity uptake of glutamate increased 2.5-fold between 9 and 15 d after birth. At 15 d postnatal, glutamate uptake had reached adult values and it remained relatively constant afterward. In contrast, proline uptake remained elevated above adult values during the 15-21 d period. These results demonstrate that high affinity uptakes of proline and glutamate, which are co-expressed by many of the same pathways, develop during the same postnatal period. The developmental overshoot in proline uptake suggests that this process may play a more significant role in synaptic physiology during adolescence in the rat than during adulthood. (Supported by NIH grant NS 16064.)

EFFECTS OF ACUTE AND CHRONIC INSULIN TREATMENT ON NOREPINEPHRINE (NE) UPTAKE AND NE TRANSPORTERS IN RAT BRAIN AND PC-12 CELLS. D. Figlewicz Lattemann*, P. Szot, P.A. Israel, and C. Payne. Depts. of Psych. and Med., U. Washington, Seattle, WA 98195 and VA Medical Center, Seattle, WA 98108.

Previous work from this laboratory has led to the suggestion that some insulin (INS) receptors in the CNS may be located presynaptically on noradrenergic neurons. To test whether insulin may serve as a neuromodulator for NE neurons, we measured 3H-NE uptake into hypothalamic slices, and into the rat pheochromocytoma PC-12 cells. Acute INS treatment significantly inhibited 2-min NE uptake into hypothalamic slices and PC-12 cells over a concentration range of 0.1--10 nM, in good agreement with the Kd of the insulin receptor (-31±15% and -29±4% inhibition, respectively, with 10 nM insulin). Chronic INS treatment (96 hr) of partially serum-deprived PC-12 cells also resulted in significant inhibition of 3H-NE uptake (-45±9% inhibition with 10 nM insulin). Chronic third ventricular INS infusion *in vivo* resulted in a significant decrease of NE transporter mRNA levels vs. vehicle-treated controls (grain area=3598±716 vs 9782±592). Together, these results suggest that INS may play a physiologic role in the acute and chronic regulation of synaptic NE concentrations via modulation of its re-uptake within certain populations of NE neurons in the CNS.

R75231 IS AN IRREVERSIBLE INHIBITOR OF [^{3}H]NITROBENZYLTHIOINOSINE BINDING TO THE NUCLEOSIDE TRANSPORTER OF RABBIT CNS CORTICAL SYNAPTOSOMES. K.W.Jones*, and J.R.Hammond. Dept. of Pharmacology and Toxicology, University of Western Ontario, London, Ontario, Canada, N6A 5B8.

The nucleoside adenosine has a wide range of physiological effects including modulation of CNS neuronal activity. Adenosine effects are terminated primarily by uptake, via the nucleoside transporter, from the extracellular milieu into the cell. Inhibitors of the nucleoside transporter are able to increase extracellular adenosine levels, and thereby potentiate the effects of endogenously released adenosine.

R75231, a mioflazine derivative, has been reported to be unique as a extremely long-lasting, tightly-binding inhibitor of nucleoside transport (Van Belle and Janssen, Nucleosides and Nucleotides, **10**:975, 1991). We have examined the nature of R75231 interaction with the nucleoside transporter in rabbit CNS cortical synaptosomes, using [^{3}H]nitrobenzylthioinosine ([^{3}H]NBMPR) as a specific probe. Synaptosomes were incubated in the absence and presence of 4nM R75231 or 4nM nitrobenzylthioguanosine (NBTGR) for 45 min, after which, an aliquot of each was removed for analysis of [^{3}H]NBMPR (0.4nM) binding. The remaining synaptosomes were washed (10 min centrifugation at 40 000*g*, resuspension in ≈50 vol., 30 min incubation at room temperature) and the assay repeated. The inhibition of [^{3}H]NBMPR binding by NBTGR (≈70%) was eliminated after 2 washes, whereas the inhibition of [^{3}H]NBMPR binding by R75231 after 5 washes (≈85%) was not significantly different from that observed before washing, nor did inclusion of either 10mM adenosine or 10μM nitrobenzylthioguanosine in the wash procedure induce the dissociation of R75231. Saturation analysis of [^{3}H]NBMPR binding to synaptosomes showed that R75231 caused a decrease in B_{max} and an increase in K_D (ie. mixed inhibition). These results are consistent with a model in which R75231 binds irreversibly to membrane components associated with the nucleoside transporter.

EFFECT OF CHOLINE ON BASAL ACETYLCHOLINE RELEASE *IN VIVO*. D.L.Marshall, M.D.Greaney[1], A.Erfurth and R.J.Wurtman. Dept. of Brain & Cogn. Sci., M.I.T, Cambridge MA 02139, [1]ESA, Bedford, MA 01730.

Acetylcholine (ACh) formation in brain neurons depends on choline (Ch) levels, because of the high K_M of choline acetyltransferase for this substrate. Using microdialysis, Farber *et al.* (1992) observed a slight increase in basal ACh release in anesthetised rats after intraperitoneal (i/p) Ch, using a high dialysate neostigmine concentration (10^{-5}M) to allow detection of the small amount of ACh present. This may have influenced ACh synthesis by depriving the neuron of a Ch source, thus making it more sensitive to exogenous Ch, or by causing excessive activation of presynaptic M_1 receptors, thus reducing ACh synthesis. To reduce such artefacts we examined ACh release using *low* neostigmine concentrations and a sensitive new ESA HPLC system for ACh. The effects of i/p Ch (120mg/kg) or saline on striatal ACh release were determined in anesthetised rats, using high (10^{-5}M) and low ($5x10^{-8}$M) neostigmine concentrations. With 10^{-5}M neostigmine, basal ACh release was unaffected one hour after Ch (n=6) or saline (n=4). However, with $5x10^{-8}$M neostigmine, ACh levels were significantly increased by 50±22% (mean±S.E.M.; n=6; $p<0.05$) one hour after Ch, but not changed (-6±11%; n=4) by saline. These initial data show that the ability of Ch to enhance basal ACh release is greater using low neostigmine concentrations.

MICRODIALYSIS WITH HYPERTONIC NaCl CAUSES CENTRAL RELEASE OF AMINO ACIDS AND DOPAMINE, T.Horn, L.Bauce, R.Landgraf and Q.J.Pittman*; Section of Biosciences, Univ.of Leipzig, Germany & Neuroscience Research Group, Univ. of Calgary, Canada.

Recent studies have shown that the neuropeptides arginine vasopressin (AVP) and oxytocin (OXT) are released within the supraoptic (SON) and paraventricular (PVN) nuclei of the hypothalamus in response to microdialysis of these nuclei with hypertonic perfusion media. These results suggest an inherent osmosensitivity of SON and PVN neurons. In order to investigate whether the observed release of these peptides is a unique phenomenon, several brain regions were examined for the release of amino acids or dopamine in response to hyperosmotic stimulation. Urethane-anaesthetized male Sprague-Dawley rats were perfused with five ion solution using chronically implanted U-shaped microdialysis probes (3 mm total length, 6 kDa cut off). Samples were collected at 30 min intervals and analyzed by HPLC.

In all perfusion areas, including the SON, PVN, dorsal hippocampus (DH) and striatum, concentrations of aspartate, glutamate, serine, glutamine, glycine, taurine and GABA were significantly increased during perfusion with hypertonic NaCl. This release was found to be dose dependent in the DH and striatum when tested with ion solution containing 0.25, 0.5 or 1M NaCl. In addition dopamine levels in striatal perfusates was significantly increased during hyperosmotic stimulation (1M NaCl). These results indicate that hyperosmotic stimulation with high NaCl affects the release of several neurotransmitters and is not specific for AVP and OXT. Furthermore, release of amino acids and dopamine may influence local release of neuropeptides and play a role in the previously described "rebound" release of AVP.

AMPHIPHILIC WEAK BASES INCREASE EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS OF FREELY MOVING RATS IN A NON-EXOCYTIC DOSE-DEPENDENT MANNER. E. Pothos*[1], D. Sulzer[2], S. Rayport[2] and B.G. Hoebel[1]. [1]Dept. of Psychology, Princeton Univ., Princeton, NJ 08544 and [2]Dept. of Psychiatry, Columbia Univ., Dept. Neuropathology, NYS Psychiatric Inst., New York, NY 10032.

As amphiphilic weakbases, amphetamine (AMPH) and phencyclidine (PCP) may release dopamine (DA) by reducing synaptic vesicle proton gradients, thereby discharging vesicular DA into the cytosol and, via the DA transporter (Sulzer et al., this meeting), into the extracellular space. Local infusion of either AMPH or PCP increases extracellular DA in the nucleus accumbens (NAC) of freely moving rats (Br. Res. Bull. 19:623, 1987; Life Sci. 42:1713, 1988) and abolishes pH gradients in cultured DA neurons (Neuron 5:797, 1990). To show that weak base action mediates psychostimulant-like synaptic DA elevation in vivo, we infused ammonium chloride (NH_4Cl), benzylamine ($C_6H_5CH_2NH_2$) and methylamine (CH_3NH_2) into the NAC of freely moving rats by reverse dailysis over 30 minutes. All compounds increased extracellular DA in a dose-dependent manner (n=6 for 25, 50, 75 and 100mM; $p<.05$). DOPAC and HVA levels increased significantly during ammonium or methylamine infusions ($p<.05$); in contrast, DOPAC output decreased significantly ($p<.05$), but HVA output did not change during benzylamine infusions. The addition of 15uM TTX in physiological Ringer's or 1mM verapamil in CA^{2+}-free Ringer's reduced DA and metabolite basal levels but failed to attenuate the weak base-induced DA increase or the increase in metabolites. These results suggest that (a) amphiphilic weak bases not known as drugs of abuse mimic the effects of AMPH or PCP in vivo, (b) their mechanism of action involves non-exocytic DA release, and (c) benzylamine like AMPH, but not like ammonium or methylamine, seems to act as a DA transporter substrate and/or monoamine oxidase inhibitor.

ELECTROGENIC TRANSPORT OF GABA BY HORIZONTAL CELLS OF THE CATFISH RETINA. J. Cammack and E. A. Schwartz*, Dept. Pharmacological & Physiological Science, University of Chicago, Chicago, IL 60637.

GABA transport has two roles in synaptic transmission. GABA is removed from the extracellular space when a cell is hyperpolarized, and released into the extracellular space when a cell is depolarized[1]. Membrane voltage plays an essential role in regulating influx and efflux. We have investigated the electrophsyiology of GABA transport in solitary horizontal cells whose membrane voltage was controlled with a whole-cell voltage clamp. Two GABA-activated currents were identified. A GABA-activated Cl^- curent could be blocked with 0.5 mM picrotoxin. Current produced by GABA transport was voltage dependent, and was blocked by the GABA uptake inhibitors nipecotic acid and NNC-711. Transport currents produced by influx and efflux were observed. The dependence of each component on monovalent cations and anions was determined. The electrical properties of GABA transport can be compared to the properties of glutamate transport previously characterized in retinal Müller cells[2].

DELAYED INCREASE OF EXTRACELLULAR ARGININE (ARG), THE NITRIC OXIDE (NO) PRECURSOR, FOLLOWING ELECTRICAL WHITE MATTER STIMULATION IN RAT CEREBELLAR SLICES. C. Hansel[1], A. Batchelor[2], M. Cuenod*[1] J. Garthwaite[2], T. Knöpfel[1] and K.Q. Do[1]. [1]Brain Res. Inst., Univ. of Zürich, Switzerland ; [2]Dept. of Physiology, Univ. of Liverpool, U.K.

Amino acid levels were measured in perfusates from L-shaped rat cerebellar slices installed in a Krebs-filled three-compartment system following electrical white matter stimulation. The lateral compartments housed white matter and a cortical section containing parallel fibres respectively, whereas the central compartment housed cortical structures at the point of bending. This arrangement allows electrical stimulation while the perfusion medium passing the central chamber can be collected for amino acid analysis with HPLC. Following a 2-minutes stimulation period of either 2 Hz (n=6) or 5 Hz (n=5) Arg levels were significantly rised above levels already present in the Krebs-solution (6.62±1.75 pmol/min respectively 7.31±2.66 pmol/ min). Arg is the precursor of NO, a neuronal messenger in the brain, which is synthesized by NO synthase. Since Arg and the NO synthase are located in different cell types it can be suggested that Arg passes through the extracellular space in order to replenish the precursor pool for NO synthesis.

422.2

IN VIVO MICRODIALYSIS OF NITRIC OXIDE-DEPENDENT cGMP EFFLUX IN THE RAT CEREBELLAR CORTEX. D. Luo*, E. Leung and S.R. Vincent. Kinsmen Laboratory of Neurological Sciences, Department of Psychiatry, The University of British Columbia, Vancouver, B.C. Canada.

Nitric oxide activates soluble guanylyl cyclase causing a transient increase in cGMP levels in target cells. We have found using intracerebral microdialysis that nitric oxide also mediates an increase in the extracellular levels of cGMP. Rats were implanted with a transverse microdialysis probe in the cerebellar cortex, which was perfused two days later with an artificial CSF at 5 µl/min. Samples were collected and assayed for cGMP by radioimmunoassay. Perfusion at ultra-slow flow rates gave an approximation for the basal extracellular cGMP concentration of 4 nM. Inhibition of cerebellar phosphodiesterase activity with IBMX in the dialysate doubled the levels of cGMP. Pharmacological activation of the climbing fiber input to the cerebellum, with systemic harmaline, produced a rapid, 12-fold increase in the extracellular levels of cGMP. This was dose-dependently attenuated by prior administration of various inhibitors of nitric oxide synthase, either systemically, or via the microdialysis probe. Blockade of sodium channels with TTX, or removal of calcium from the microdialysate also blocked the harmaline-induced increase in cGMP. Inhibition of soluble guanylyl cyclase, with methylene blue or LY83583 in the perfusion solution, also inhibited the cGMP increase. These treatments also decreased the basal levels of cGMP. These results indicate that activation of the climbing fiber synapses in the cerebellar cortex stimulates the production of NO which in turn causes a large increase in the extracellular levels of cGMP. The efflux of cGMP may serve to decrease intracellular cGMP levels. It may also indicate a role for cGMP as an intercellular messenger.

422.3

NITRIC OXIDE SYNTHASE-CONTAINING CELLS IN THE CEREBRAL CORTEX OF RATS R.J. Weinberg*[1], I.G. Valtschanoff[1], V.N. Kharazia[1], M. Nakane[2], H.H.H.W. Schmidt[3] and A. Rustioni[1] [1]Dept. Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599; [2]Dept. Vascular Research, Abbott Labs, Abbott Park, IL 60064; and [3]Dept. Pharmacology, Northwestern U., Chicago, IL 60611.

We have employed histochemistry for NADPH diaphorase and immunohistochemistry using antibodies prepared against neuronal nitric oxide synthase (NOS-1) to reveal neurons and fibers in the rat cortex likely to synthesize nitric oxide. Nembutal-anesthetized animals were perfused with mixed aldehydes; Vibratome sections 20-100 µm thick were stained for NOS. The distribution of NOS-stained cells was plotted; detailed drawings showing their morphology were made with camera lucida. Particular attention was focused on sensorimotor cortex.

NOS-positive neurons comprised about 0.5% of neurons in SmI. They were densest in layers 2, 3 and 6 and in the subcortical white matter. Stained neurons were morphologically heterogeneous, but did not include typical pyramidal neurons. Most had aspiny dendrites and axons branching close to the soma. Stained axons had predominantly radial orientation. Boutons were visible throughout the cortex, densest in layers 4 and 6. The morphological impression that NOS-positive neurons are local circuit neurons was supported by double-label experiments in which injections of CTB-gold or WGA-HRP were placed in contralateral cortex, thalamus, caudoputamen or spinal cord. In all cases, retrogradely labeled neurons and NOS-positive ones belonged to separate populations. In tangential sections through the barrel field NOS-positive neurons and dendrites were confined to the septa between barrels. Preembedding and postembedding immunocytochemistry in combination with NADPH diaphorase histochemistry demonstrated that a large fraction of NOS-positive somata also contained GABA.

NITRIC OXIDE GENERATION RELEASES [^{3}H]-NOREPINEPHRINE FROM HIPPOCAMPAL SLICES. K.M. Johnson* and G. Lonart, *Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77555-1031.*

Nitric oxide (NO), a diffusible second messenger, has been suggested to potentiate neurotransmitter release. Cross-chopped hippocampal slices (300 X 300 µm) were prepared from male Sprague-Dawley rats, washed and incubated with [^{3}H]-norepinephrine ([^{3}H]-NE) for 30 min in Krebs- bicarbonate buffer, containing 10 µM pargyline and saturated with O_2/CO_2 (95:5). Efflux of [^{3}H]-NE was determined and the data are expressed as fractional release. Hydroxylamine (3-300 µM), which is known to generate NO subsequent to cellular metabolism, induced a concentration dependent increase in the basal [^{3}H]-NE release. The EC_{50} value was about 30 µM and 100 µM hydroxylamine produced a maximal 10-fold increase in the basal [^{3}H]-NE release. 10 µM hydroxylamine increased basal [^{3}H]-NE release about 2-fold. Since NO stimulates the activity of guanylate cyclase, we tested the effect of methylene blue, a inhibitor of this enzyme. 3 µM methylene blue alone induced a steady 2-fold increase in the basal [^{3}H]-NE release and significantly potentiated the response to 10 µM hydroxylamine. 20 min pretreatment with 3 µM or 10 µM hydroxylamine did not significantly influence NMDA (300 µM) stimulated [^{3}H]-NE release, while higher concentrations had inhibitory effects. Ongoing experiments are being carried out to characterize the mechanism underlying the effects of hydroxylamine and methylene blue in this preparation. Supported by DA-02073.

AN NMDA/NITRIC OXIDE PATHWAY MEDIATES LIGHT RESPONSIVENESS BY THE SUPRACHIASMATIC NUCLEUS. S. Amir*, CSBN, Concordia University, Montreal, Quebec, Canada.

The messenger molecule nitric oxide (NO) is produced in brain on stimulation of N-methyl-D-aspartate (NMDA) receptors, and receptors for NMDA have been implicated in the transmission of light to the hypothalamic suprachiasmatic nucleus (SCN), site of a circadian pacemaker. We assessed the involvement of the NMDA/NO pathway in SCN responsiveness to light by blocking NMDA receptors or NO production in the SCN and evaluating the effect on heart rate during photic stimulation in dark-adapted urethane-anaesthetized rats. Photic stimulation (300 Lux, 3 min) caused a rapid increase in heart rate (Δ = 37.3±4.4 bpm, n=8). This effect was blocked by prior infusion of a competitive NMDA antagonist (CPP, 20 nmol) in the SCN (Δ = 12.9±1.6 bpm, n=8, p<0.01). Infusion 2 mm dorsal to the SCN had no effect, suggesting a role for NMDA receptors specific to the SCN. Infusing a competitive blocker of NO synthesis, N^G-nitro-L-arginine methyl ester (L-NAME; 40 nmol) in the SCN, but not 2 mm dorsal to the SCN, blocked the rise in heart rate in response to light (Δ = 16.1±1.8 bpm, n=16, p<0.01). This effect was selective and stereospecific: addition of L-arginine (80 nmol), which competes with L-NAME for the substrate site on the NO-generating enzyme, reversed the effect of L-NAME (Δ = 42.1±4.9 bpm, n=8), and infusion of an inactive isomer of L-NAME, D-NAME (40 nmol), had no effect (Δ = 38.8±5.4 bpm, n=12). The ability of light to stimulate heart rate and of infusion of a competitive NMDA antagonist or a competitive blocker of NO production in the SCN region to inhibit this effect suggests a functional link between activation of an NMDA/NO pathway and SCN light responsiveness.

EVIDENCE THAT NITRIC OXIDE (NO) MEDIATES THE CYCLIC GMP RESPONSE TO SYNAPTIC ACTIVITY IN THE RAT SUPERIOR CERVICAL GANGLION (SCG). Marion L. Hughes[1], Hong Sheng[2], Ferid Murad[2], and Clark A. Briggs[1]*. [1]Neuroscience Research and [2]Signal Transduction, Abbott Laboratories, Abbott Park , IL 60064.

Preganglionic stimulation increases cyclic GMP levels in the SCG. It is not known what neurotransmitter mediates this response. However, exogenous nitroprusside and azide, which liberate NO, also have been shown to stimulate cyclic GMP synthesis (Volle & Quenzer 1983). We investigated whether NO is the physiological mediator of the cyclic GMP response to preganglionic stimulation.

Paired SCG were isolated and superfused *in vitro* at ambient temperature (21-23°C) with oxygenated Locke's solution containing 0.3 mM 3-isobutyl-1-methyl-xanthine. Various drugs were applied for a period of 75-85 minutes before stimulation. In each pair, one SCG served as a non-stimulated control and the other received a preganglionic stimulation of 10 Hz for 30 sec. Cyclic GMP was determined by radioimmunoassay.

Upon stimulation, cyclic GMP levels increased 8-fold and this response was Ca^{2+} dependent. The NO synthase inhibitor, N^G-nitro-L-arginine (L-NNA), inhibited the cyclic GMP response in a concentration dependent manner which was partially reversed by the NO synthase substrate, L-arginine (1 mM). L-NNA (10 µM) blocked the response and this effect was stereoselective because D-NNA (10 µM) showed no inhibition. Additionally, the cyclic GMP response was inhibited 65% by 10 µM oxyhæmoglobin. Thus, it appears that NO or a similar substance mediates, in an extracellular fashion, the cyclic GMP response to synaptic activity in the rat SCG.

TRANSCRIPTION OF THE BRAIN NITRIC OXIDE SYNTHASE GENE IN NEURAL CELL CULTURES. D.Minc-Golomb & J.P.Schwartz*. Clinical Neuroscience Br., NINDS, NIH, Bethesda, MD 20892.

Nitric oxide synthase (NOS) generates the second messenger nitric oxide from arginine. The brain NOS has been cloned and found in highest density in the cerebellum and accessory olfactory bulb. We now present data on the expression of the NOS gene in cerebellar granule cells (CGCs), prepared from postnatal day 8 rat pups, after 10 days in culture. Using specific oligonucleotide primers to the brain NOS gene, reverse transcription of CGC RNA followed by polymerase chain reaction (RT-PCR) produced a 366 bp fragment, the expected size. Identity was confirmed by hybridization of a blot containing the electrophoresed product with a full-length cDNA probe for NOS, followed by high stringency washes (0.1XSSC-65°), which showed a positive signal for the same 366bp band. NOS activity was also detected in CGCs, by measuring conversion of arginine to citrulline, thus showing that CGCs express the brain NOS. Preliminary results suggest that type 1 astrocytes also express brain NOS mRNA and activity. These culture systems are being used to assess the modulation of NOS in cerebellar neural cells both in physiological and neurotoxic conditions.

CARBON MONOXIDE AS A PHYSIOLOGICAL MESSENGER INDICATED BY HEME OXYGENASE LOCALIZATIONS AND CYCLIC GMP REGULATION. David J. Hirsch*, A. Verma, C. Glatt, G. Ronnett and S.H. Snyder. Dept of Neuroscience, Johns Hopkins School of Medicine, Baltimore, MD, 21205.

Abundant evidence indicates that nitric oxide(NO) is a major physiologic molecule, accounting for endothelial derived relaxing factor(EDRF) of blood vessels, the turmoricidal and bactericidal actions of macrophages, and serving as a putative neurotransmitter in the central and peripheral nervous system. The notion that a normally noxious gas such as NO might serve as a physiologic messenger raises the possibility that other gases might have similar functions. One such candidate might be carbon monoxide. Carbon monoxide(CO) is endogenously generated by the enzyme heme oxygenase. Heme oxygenase(HO), in concert with cytochrome P450 reductase, catalyzes the conversion of heme into biliverdin with the concomitant release of CO. We thought that this CO could function in an analogous manner to NO. The brain has been previously reported to have high levels of HO. We localized HO2, the constitutive form of this enzyme, by *in situ* hybridization. Highest densities of HO2 mRNA are evident in the olfactory neurons of the olfactory epithelium as well as the olfactory neuronal layer of the olfactory bulb along with the granule cells in the bulb. We also observed discreet localizations in the cerebellum, hippocampus, pontine nucleus, olfactory tubercle, and habenulae. To investigate the physiological role of CO we utilized a primary culture of olfactory neurons which expressed HO2 at high levels as revealed by the *in situ* localizations. These neurons have very high levels of cGMP which could be potently blocked by hemoglobin but were insensitive to inhibitors of nitric oxide synthase(NOS). When zinc protoporphyrin-9 (Zn PP-9) which is a potent inhibitor of HO was added to the cultures, cGMP levels plummeted These findings suggest that CO might be a messenger molecule similar to NO

G_{OLF} EXPRESSION IN THE BRAIN: MOLECULAR CLONING, *IN SITU* HYBRIDIZATION AND IMMUNOHISTOCHEMISTRY.

L.A. Williams*, C.D. Hodson, T.P. Snutch & S.R. Vincent. Dept. Psychiatry & Biotechnology Lab., Univ. of British Columbia, Vancouver, B.C. Canada.

Striatal neurons express high adenylyl cyclase activity and large amounts of a stimulatory G protein, but very low levels of Gsα mRNA. We have previously presented evidence suggesting that the novel stimulatory G protein Golf is expressed in the basal ganglia. In support of this hypothesis, we have now used synthetic oligonucleotides, derived from the published Golf cDNA sequence, to identify and characterize four independent cDNAs from a rat brain cDNA library. These code for a protein of 381 amino acids with a predicted molecular mass of 44.3 kD, whose sequence is identical to the Golf sequence originally derived from a rat olfactory epithelium library, except for one conservative amino acid substitution. Thus Golf is expressed in rat brain. To determine the cellular localization of Golf in the brain *in situ* hybridization and immunohistochemistry were used. Golf mRNA was expressed in neurons in the striatum, nucleus accumbens and olfactory tubercle. For the immunohistochemical localization of Golf, rabbits were immunized with a synthetic peptide corresponding to amino acids 73-87 of Golf, conjugated to KLH. This yielded an antibody that upon affinity-purification, specifically labelled a striatal protein of about 46 kD in Western blots. In immunohistochemical studies, this antibody selectively stained many neurons within the striatum, nucleus accumbens and olfactory tubercle. In addition, stained fibers were seen leaving the striatum, and forming terminal networks in the globus pallidus, entopeduncular nucleus and substantia nigra pars reticulata. In conclusion, striatal projection neurons express a novel stimulatory G protein, Golf, which may couple the D1 receptors in these neurons to adenylyl cyclase.

CHARACTERIZATION OF THE HIGH-AFFINITY FORSKOLIN BINDING SITE IN THE RAT STRIATUM. S.R. Vincent* and B. Dhillon. Kinsmen Laboratory of Neurological Sciences, Department of Psychiatry, The University of British Columbia, Vancouver, B.C., Canada, V6T 1W5.

The diterpene forskolin is a potent activator of adenylyl cyclase. We have characterized the high-affinity binding site for [^{3}H]-forskolin in the rat striatum using quantitative autoradiography. Saturation analysis revealed a single high-affinity binding site with a Kd of 26 nM and a Bmax of 694 fmole/mg tissue. Lesion studies indicate that these binding sites are largely present on striatal neurons, including the striato-nigral, medium-spiny, projection neurons which contain D1 dopamine receptors. The abilities of various forskolin analogues to displace high-affinity [^{3}H]-forskolin binding correlated well with their effectiveness in activating adenylyl cyclase. The density and affinity of the striatal binding sites were decreased if Mg^{2+} was absent from the incubation medium. This is consistent with the hypothesis that binding of forskolin to adenylyl cyclase involves an interaction with a stimulatory G protein. However, pretreatment of rats with SCH-23390, which blocks D1 dopamine receptors, and should therefore largely reduce the ability of endogenous dopamine to activate stimulatory G proteins in striatal neurons, had no effect on forskolin binding. Similarly, pretreatment with the atypical neuroleptic clozapine, a potent inhibitor of dopamine-stimulated adenylyl cyclase, was without effect on high-affinity forskolin binding in the striatum. These data suggest that endogenous D1 receptor activation does not account for the very high levels of forskolin binding present in the striatum.

P_{2Y} PURINOCEPTOR-MEDIATED PHOSPHOINOSITIDE TURNOVER, Ca^{2+} INFLUX AND HOMOLOGOUS DESENSITIZATION IN C_6-GLIOMA. W.W. Lin* and D.-M. Chuang[1]. Dept. of Pharmacology, National Taiwan Univ. Taipei, Taiwan and [1]Biological Psychiatry Branch, NIMH, MD 20892.

In response to ATP, C_6-glioma cells accumulated inositol phosphates and elevated $[Ca^{2+}]_i$ dose-dependently with an EC_{50} of 60 μM and 10 μM, respectively. For stimulation of phosphoinositide (PI) turnover, the rank order of potency of adenine nucleotides was ATP>ADP>ADPβS >>AMP, adenosine, α,β-MeATP, β,γ-MeATP. ATP-stimulated PI metabolism was found to be partially dependent on $[Na^+]_o$ and $[Ca^{2+}]_o$, but resistant to tetrodotoxin, amiloride, ouabain and inorganic Ca^{2+} blockers. In Ca^{2+}-free medium, ATP caused only a transient increase in $[Ca^{2+}]_i$ as opposed to a sustained $[Ca^{2+}]_i$ increase in normal medium. The ATP-induced elevation of $[Ca^{2+}]_i$ was resistant to Na^+ depletion, verapamil and nisoldipine, but was attenuated by La^{3+}. The ATP-induced PI hydrolysis showed homologous desensitization following agonist prestimulation and was unaffected by PKC inhibitors (staurosporine, H-7) and depletion of PKC activity. On the contrary, the inhibition caused by PMA or octylindolactam V was inhibited by staurosporine, H-7 and polymyxin B. Our results suggest that P_{2Y} purinoceptors are coupled to PI turnover and Ca^{2+} influx in C_6-glioma and its desensitization does not involve PKC activation.

422.12

FACTORS INFLUENCING THE EFFECT OF CALRETININ ON PHOSPHORYLATION OF A 39 kDa MITOCHONDRIAL PROTEIN FROM RAT BRAIN. **L. Winsky* and D.M. Jacobowitz. Lab. of Clin. Sci., NIMH, Bethesda, MD**

The calcium binding protein calretinin (CR, 100 to 1000 nM) produced a significant reduction in the phosphorylation of a 39 kDa band in mitochondrial membranes. This 39 kDa band was maximally phosphorylated within 15 sec while the inhibition by calretinin was most apparent after 2 min. Both the phosphorylation of the 39 kDa protein and inhibition by calretinin were pH dependent. The 39 kDa band was phosphorylated in the presence of 5 mM EDTA and a stimulation was observed in the presence of Mg^{2+} (4.5 or 10 mM) or 4.5 mM Mn^{2+}, Ni^{2+}, Ca^{2+} or Co^{2+}. The inhibitory effect of calretinin was enhanced in the presence of Mg^{2+}, Co^{2+} and $Ni^{2+}$and was attenuated by 5 mM EDTA. Zn^{2+} (4.5 mM) inhibited both the phosphorylation of the 39 kDa band and the inhibition of phosphorylation produced by calretinin. Calretinin also produced a slight inhibition in the phosphorylation of a 42 kDa band in the presence of 4.5 mM Ni^{2+}, or Co^{2+}. This band was tentatively identified as the alpha subunit of pyruvate dehydrogenase based on immunoblots and comigration with purified phosphoenzyme. These results suggest a possible functional role of calretinin in modifying mitochondrial enzyme activity through effects on protein phosphorylation.

422.13

MOBILIZATION OF INTRACELLULAR CALCIUM IN CULTURED GLIA CELLS FROM THE RAT NEURAL LOBE BY VASOPRESSIN CAN BE INHIBITED BY OPIOID PEPTIDES. C.J.C. Boersma*, F.W. van Leeuwen, W.G. O'Brien[1], G.J. Law[1], W.T. Mason[1] and J.R. Bicknell[1] Netherlands Institute for Brain Research, Amsterdam, the Netherlands. and [1]Department of Neuroendocrinology, AFRC, Babraham, Cambridge, U.K. (Spon: ENA)

Evidence is accumulating that the resident astrocytes (pituicytes) in the neural lobe of pituitary are involved in the regulation of the release of neurohormones (oxytocin and vasopressin) into the circulation. Pituicytes possess opioid binding sites and the modulatory actions of opioids on neurosecretion have been extensively studied. Using real time quantitative fluorescence microscopy and ratiometric imaging (Miracal, Applied Imaging, Santa Clara, USA) we measured changes in free intracellular calcium $(Ca^{2+})_i$ levels in FURA-2 loaded pituicytes in culture in response to administration of Dynorphin 1-17 (DYN 1-17) and/or AVP.

Hatton et al. (Brain Res., in press) have previously demonstrated that administration of 10 nM AVP results in a large transient mobilisation of Ca^{2+} which can be blocked by V_1-antagonists. We have now shown that preincubation with DYN 1-17 both delays and decreases the $(Ca^{2+})_i$ response to AVP, effects which can be blocked by Naloxone. DYN 1-17 by itself does not affect basal $(Ca^{2+})_i$ levels. The present results show that opioid receptors are present on pituicytes and are coupled to a second messenger pathway by which they can affect Ca^{2+} mobilising effects of other neuropeptides, such as AVP. Phosphoinositides (PI) are likely candidates for this pathway as AVP application activates PI turnover.

THE EFFECT OF GUANINE NUCLEOTIDES ON [^{3}H]-IDAZOXAN BINDING SITES IN HUMAN AND GUINEA-PIG CEREBRAL CORTEX. J.F.Hussain, V.G.Wilson and D.A.Kendall. SPON: Brain Research Association. Dept. Physiology and Pharmacology, University of Nottingham Medical School, Nottingham NG7 2UH, U.K.

Idazoxan is an imidazoline compound which binds to both α_2-adrenoceptor and non-adrenoceptor imidazoline binding sites (NAIBS) in a variety of tissues and species. We have examined the potential interaction of NAIBS with G-proteins, investigating whether GTP alters [^{3}H]-idazoxan binding to human and guinea-pig cortical membranes in the presence and absence of α_2-adrenoceptor blockade.

Membranes were incubated with 1-2 nM [^{3}H]-idazoxan in Tris HCl buffer (pH 7.4) for 60-90 mins at 25°C in a total volume of 0.5 ml. Non-specific binding was defined by 10 μM cirazoline; bound radioligand was recovered by rapid vacuum filtration and quantified by liquid scintillation spectrometry.

The selective α-antagonists rauwolscine and corynanthine were used to identify [^{3}H]-idazoxan binding to NAIBS. A concentration of 10 μM rauwolscine was used to block [^{3}H]-idazoxan binding to α_2-adrenoceptors. Of the total binding sites labelled by [^{3}H]-idazoxan, 40 % in the human cortex and 30% in the guinea-pig cortex were NAIBS. Saturation curves were then constructed using increasing concentrations of [^{3}H]-idazoxan in the presence and absence of 10 μM rauwolscine and 300 μM GTP. The B_{max} values in the presence of GTP were significantly less than those without GTP, regardless of α_2-adrenoceptor blockade.

These results suggest that NAIBS may activate an intracellular mechanism via interaction with GTP-binding proteins and that idazoxan may be acting as an agonist at these sites.

JF Hussain is a SERC CASE student in conjunction with Syntex (UK).

PURIFICATION AND CHARACTERIZATION OF BOVINE FOREBRAIN CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II M. Tanji*, R. Horwitz & J. C. Waymire, Department of Neurobiology & Anatomy, University of Texas Medical School., Houston, TX 77030.

Calcium/calmodulin-dependent protein kinase II (Ca^{2+}/CaM kinase), is an abundant brain protein proposed to mediate Ca^{2+}-regulated signal transduction in neuronal tissue. The enzyme purified from rat brain is reported to exists as isoenzymes (M_r 550,000 & 615,000) that vary in their relative ratio of three subunits, M_r 50,000, 58,000, and 60,000.

In this study we have purified Ca^{2+}/CaM kinase from bovine forebrain. The tissue was frozen in liquid N_2 within 5 min of the animals death. The purification revealed two isoenzymes with apparent Ca^{2+}/CaM kinase properties based on the phosphorylation of a known Ca^{2+}/CaM kinase substrate peptide (MHRQETVD). The two isoenzymes have similar purification characteristics, subunit composition, and physical properties. Native gradient-gel electrophoresis provided an estimated M_r of 560,000 for the major isoenzyme and 870,000 for the minor isoenzyme. The autophosphorylated subunits of the major kinase have apparent M_r of 72,000 and 59,000 while those of the minor kinase are M_r 72,000 and 53,000. Both bovine kinases bind calmodulin. The major kinase weakly cross-reacts with monoclonal anti-rat Ca^{2+}/CaM kinase IgG in a spot blot assay while the minor kinase dose not cross-react at all. Western blotting technique using polyclonal anti-rat kinase IgG shows that a M_r 72,000 subunit of bovine kinase cross-reacts with the antibody. These results suggested that although the two isoenzymes of bovine kinase are similar to rat Ca^{2+}/CaM kinase, their are several important differences between the rat and bovine enzymes. MULTIPLE MECHANISMS OF SLOW SYNAPTIC EXCITATION IN MYENTERIC NEURONS. P. P. Bertrand*, J. J. Galligan. Dept. Pharmacol./Toxicol., Michigan State University, MI 48824.

Conventional single electrode voltage clamp recordings were made in vitro from individual myenteric neurons of guinea pig ileum; (holding potential -70 mV). Drugs were applied by superfusion or by pressure ejection from a micropipette; sEPSCs were elicited by focal stimulation of interganglionic nerve tracts (500 ms, 40 V, 20 Hz). Myenteric neurons fell into two categories, S-cells (receiving fast nicotinic input) or AH-cells (spike afterhyperpolarization > 1 s). Superfused forskolin (.01-3 μM) produced an inward current in S and AH cells (EC_{50}, 80 and 200 nM respectively). IBMX (25 μM) produced a similar current in AH, but not S cells (n=5). IBMX potentiated submaximal responses to forskolin (< 100 nM) but did not affect maximal doses of forskolin (1-3 μM) or substance P (SP) (0.1-0.3 μM). In 75% of cells (n=59), forskolin-induced currents were associated with a decreased conductance (g_M) (max. current: 230 pA/S, 283 pA/AH). SP or the NK-3 agonist senktide (.01-.3 μM) produced a transient (1-1.5 min.) inward current with an initial decrease in g_M, and a later increase in g_M (max. late current: 423 pA/S, 530 pA/AH). Nerve stimulation produced an inward current that reversed near E_K within the first 5 seconds, and a secondary current with an unclear g_M change (max. late current: 200 pA/S, 304 pA/AH). Reversal potentials were determined for forskolin (-111 mV), SP (early: -98 mV, late: -9 mV) and the sEPSC (early: -80 mV). Forskolin (1 μM) occluded the sEPSC by 50%/S and 57%/AH as did SP (100 nM)(98%/S, 85%/AH). Forskolin did not occlude the peak late current from pressure applied senktide (3 μM), but preferentially occluded the early g_M decrease. These data suggest that increases in cAMP induced by forskolin can only mimic part of the conductance change seen during the sEPSC. It is possible that one or more transmitters with multiple transduction pathways and ionic mechanisms mediate the sEPSC. (Supported grant DK 40210)

IDENTIFICATION OF SIGMA RECEPTORS AND THEIR POTENTIAL ROLE IN ARACHIDONIC ACID RELEASE IN RAT CEREBELLAR GRANULE CELLS. J.B. Starr and L.L. Werling*. Dept. Pharmacology, The George Washington University Medical Ctr., Washington, D.C. 20037.

The sigma receptor has been well characterized in terms of ligands that bind to it, but its functional significance has remained elusive. The goals of this study were to 1) identify its presence in neonatal rat cerebellar granule cells in culture and 2) to test its potential role in the arachidonic acid (AA) cascade in these cells.

Cerebella of eight-day-old neonatal rats were dissected and chopped into pieces. Cells were mechanically and enzymatically dissociated, subjected to differential centrifugation, resuspended and plated on poly-D-lysine coated dishes. Cultures were treated with 10 μM cytosine arabinofuranocide to prohibit growth of non-neuronal cells. Cells were allowed to develop for at least eight days in culture (DIC) before use in any assay.

Sigma receptors were identified by the specific binding of 2 nM [^{3}H]haloperidol in the presence of spiperone to prohibit labeling of dopamine receptors. The sensitivity of [^{3}H]haloperidol binding to a variety of competing ligands supported identification of the receptors labeled as sigma. A 10 μM concentration of the sigma-selective agonist (+)pentazocine inhibited approximately 40-50% of specific binding. The binding of [^{3}H]haloperidol and its competition by (+)pentazocine was stable over a period of 3 days (8-11 DIC). This interval was chosen for second messenger studies.

Cells in culture were incubated with 1 μCi/dish [^{3}H]arachidonic acid ([^{3}H]AA) overnight, then washed to remove residual, unaccumulated labeled eicosanoid. The release of [^{3}H]AA was stimulated by 50 μM NMDA, resulting in the release of approximately 0.5% of total accumulated [^{3}H]AA. About 30% of stimulated release could be inhibited by 10 μM (+)pentazocine.

Collectively, these findings provide the first evidence that sigma receptors reside on cerebellar granule cells, and that they may be involved in the regulation of the release of arachidonic acid in these cells. This is the first direct association of sigma receptors with this metabotropic second messenger system.

422.18

ARACHIDONIC ACID METABOLISM MAY INVOLVE VOLTAGE-SENSITIVE COMPONENTS IN ACUTELY DISSOCIATED EMBRYONIC CHICK SPINAL CORD CELLS. K.S. Madden*, A. Prasad, S.V. Smith, and G.D. Lange. Laboratory of Neurophysiology and Instrumentation and Computer Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD 20892

Prostaglandin E_2 and most other types of eicosanoids are metabolites of arachidonic acid (AA) formed by multi-factorial enzymatic pathways with components distributed throughout cell membranes and the cytosol. The pathways can be blocked at particular branch points by exposing preparations to various inhibitors of AA metabolism. We studied the effects of several of these inhibitors on the steady-state membrane potential of individual chick cells using two different electrophysiological approaches. Flow cytometry coupled with a voltage-sensitive oxonol dye monitored the effects of bath applications on populations of cells in suspension. Conventional whole cell patch techniques for intracellular voltage recordings measured the effects of superfusing single plated cells that were not stained with the oxonol dye. We found that four molecularly different agents, indomethacin, ETYA (5,8,11,14-eicosatetraynoic acid), BW755C and NDGA (nordihydroguiaretic acid) decreased the intensity of oxonol signal and hyperpolarized cells at concentrations known to block oxygenase activity. Subsequent exposure to PGE_2 did not counteract these effects unless preparations were first depolarized by elevating extracellular potassium ion concentrations. Then, the PGE_2 increased the hyperpolarization elicited by the drugs. These findings support the possibility that PGE_2 acts through an intracellular mechanism which is normally protected by electrical and chemical gradients opposing its net influx. These gradients would also promote its net efflux after *de novo* synthesis.

INTRASTRIATAL FORSKOLIN INCREASES NEURONAL PREPROENKEPHALIN AND PREPRODYNORPHIN mRNA IN RATS. J.N. Simpson*, S.R. Childers†, and J.F. McGinty. Dept. Anat. and Cell Bio., School of Medicine., East Carolina Univ., Greenville, NC 27858-4354, †Dept. Physiol. and Pharm., Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27103.

This experiment utilized in situ hybridization histochemistry (ISHH) to examine the effects of intrastriatal forskolin on pro-opioid and c-fos gene expression in the rat striatum. Bilateral 21 G guide cannulae were implanted above the striata of rats. Alza 1003D mini-osmotic pumps (pumping rate of 1 µl/h) were loaded with 500 µM, 1 mM, or 10 mM forskolin dissolved in 70% dimethyl sulfoxide (DMSO) solution with 0.1% pontamine sky blue dye (PSB). PSB was included to examine the extent of drug diffusion. As controls, other pumps were loaded with only the 70% DMSO / 0.1% PSB solution. Tubing was used to attach the pumps to 26 G injection cannulae. The pumps with attached injection cannulae were placed in sterile saline at 37°C overnight to fill the tubing and injection cannulae with solution. Four to seven days after guide cannulae implantation, two pumps were implanted subcutaneously in each rat and the attached injection cannulae were inserted through the guide cannulae and cemented in place. The brains were removed after 24 h of continuous infusion. The right hemispheres were quickly frozen for ISHH and the striato-accumbens were immediately dissected out of the left hemispheres for adenylate cyclase assays. ISHH for preproenkephalin, preprodynorphin, and c-fos was performed using ^{35}S-dATP labeled oligos on 12 µm sections taken through the infusion area. Infusion of forskolin for 24 h caused some tissue damage around the infusion area. However, forskolin increased preproenkephalin and preprodynorphin mRNA in neurons around the damaged area in a dose-dependent manner as compared to controls. The area of increased mRNA correlated positively with the distribution of PSB. There did not appear to be any forksolin-stimulated induction of c-fos mRNA in these rats. Digital image analysis of this tissue is currently underway. Initial results of adenylate cyclase assays on 10 mM forskolin-infused striatal tissue indicates a 2 - 3 fold forskolin-induced increase in cyclase activity. These results indicate that continuous in vivo activation of the adenylate cyclase cascade induces expression of the pro-opioid peptide genes in striatal neurons. Supported by DA 05470 (JNS), DA 02904 (SRC), and DA 03982 (JFM).

REGULATION OF SUBSTANCE P RECEPTOR SYSTEM IN THE SPINAL CORD BY NALTREXONE. O.J. Igwe*, Division of Pharmacology, Schools of Pharmacy & Medicine, UMKC, Kansas City, MO 64108.

Substance P-immunoreactive (SP-ir) and opioid peptide-ir nerve terminals interact in the regulation of nociceptive pathway in the spinal cord as two opposing systems. Opiate antagonist, naltrexone (NALT), increases opioid peptides and upregulates opioid receptors in the CNS. Recent evidence strongly suggests that SP system is also regulated by opioid peptides. Here, NALT was used to examine the functional link between SP receptor system and the activation of opioid receptors in the spinal cord by chronic blockade. Under ether anesthesia, male Sprague-Dawley rats were implanted SubQ with Alzet® miniosmotic pumps, filled with either NALT HCl (70 mg/ml) or vehicle (control), for 7 days. Animals were sacrificed on day 8, spinal cord rapidly removed, and used to determine SP and inositol-1,4,5-trisphosphate (IP_3) tissue contents, and to examine the regulation of their specific receptors using in vitro binding assays. SP and IP_3 levels in the spinal cord were significantly increased by 53% and 34%, respectively, over controls. Using [^{125}I] Bolton Hunter SP and [^{3}H]IP_3 as ligands, the affinities (K_d) for SP and IP_3 were unaffected by chronic NALT treatment. However, the density (B_{max}) of IP_3 receptors, increased by 120% over control, while the B_{max} for SP receptors remained unchanged. The data suggest that IP_3 production, coupled to functional SP receptor activation, and IP_3 receptors, which mediate IP_3-induced alterations in intracellular Ca^{2+} flux, are increased in the spinal cord by chronic blockade of opioid receptors. Supported by UMKC-FRG and USPHS grant AR 41606.

ESTROGEN DESENSITIZES HYPOTHALAMIC ß-ADRENOCEPTORS WITHOUT ALTERING RECEPTOR DENSITY OR ANTAGONIST BINDING AFFINITY. S. Ungar* and A.M. Etgen. Depts. Psychiat. & Neurosci., Albert Einstein Coll. Med., Bronx, NY 10461

We have shown previously that, in membranes prepared from female rat hypothalamus and preoptic area, estrogen desensitizes ß-adrenergic receptor stimulation of adenylate cyclase without modifying G protein stimulation of the enzyme. The current experiments examined the possibility that estrogen modulates receptor function through changes in either receptor density or binding affinity. We examined receptor binding affinity and density using the high specific activity radiolabeled antagonist [^{125}I]Iodocyanopindolol (^{125}ICYP) in membranes prepared from combined hypothalamus-preoptic area of ovariectomized (OVX) and OVX, estrogen-primed rats. OVX rats received oil vehicle or 2 µg of estradiol benzoate 48 and 24 h prior to sacrifice. Scatchard analysis of saturation binding experiments revealed a single class of binding sites with Kd in the range of 30-50 pM and Bmax in the range of 30-40 fmol/mg protein. Estrogen had no effect on either the Kd or Bmax of ^{125}ICYP binding in hypothalamic-preoptic area membranes. Saturation experiments carried out in cortical membranes also showed no measurable effect of estrogen on ß antagonist binding affinity or receptor density. These data suggest that estrogen-dependent uncoupling of ß-adrenergic receptor from adenylate cyclase is not contingent on hormonal modulation of receptor density or antagonist binding affinity. Agonist affinity studies are currently underway to determine if estrogen regulates the coupling of ß-adrenergic receptors to adenylate cyclase by modulation of agonist binding.

EFFECTS OF THE AMINOSTEROID U-73122 ON NEUROTENSIN OR MUSCARINIC RECEPTOR MEDIATED CGMP FORMATION AND PPI HYDROLYSIS IN N1E-115 CELLS. M. Yamada, Mi. Yamada and E. Richelson.* Mayo Foundation, Jacksonville, FL 32224.

The aminosteroid, U-73122 (1-{6-{[17ß-3-methoxyestra-1,3,5(10)-trien-17-yl]amino}hexyl}-1H-pyrrole-2,5-dione) reportedly inhibits muscarinic receptor sequestration and polyphosphoinositide (PPI) hydrolysis in SK-N-SH human neuroblastoma cells. Like the muscarinic receptor, the neurotensin receptor couples to cyclic guanosine 3',5'-monophosphate (cGMP) synthesis and PPI hydrolysis. For this study, we examined the effects of U-73122 on neurotensin or muscarinic receptor mediated cGMP formation and PPI hydrolysis in murine neuroblastoma clone N1E-115. Both cGMP formation and PPI hydrolysis stimulated with 10 nM neurotensin or 1 mM carbamylcholine (a muscarinic receptor agonist) were inhibited dose dependently after incubation with U-73122 (dissolved in DMSO, 1% final) at 37°C for 15 min. Maximum inhibition occurred with 10 µM U-73122. We showed before that 10 µM U-73122 inhibits neurotensin receptor down-regulation in N1E-115 cells. Molecular mechanisms underlying these phenomena are unknown. However, our results suggest that U-73122 inhibits the down-regulation, cGMP formation, and PPI hydrolysis in many other receptors that couple with these responses (Supported by Mayo Foundation and USPHS grant MH27692).

DEPOLARIZATION CHANGES THE EXPRESSION OF NEUROPEPTIDES AND CATECHOLAMINES IN THE CHICK SYMPATHOADRENAL SYSTEM. G. Maynard-Salgado* and J. E. García-Arrarás. Biology Department, University of Puerto Rico, Río Piedras, PR 00931.

The sympathoadrenal system is characterized by the expression of catecholamines (CA) and several neuropeptides. Electrical activity, elicited by the presynaptic fibers, influence the survival, maintenance and phenotypic expression of the sympathoadrenal cells. We are using adrenal gland and sympathetic neuronal cultures from 11 day chick embryos to study the effect of depolarization on CA and neuropeptides, enkephalin (ENK), neuropeptide Y (NPY) and somatostatin (SS) expression. Histochemical studies demonstrate that, as occurs in vivo, CA, ENK-, NPY- and SS-like immunoreactivity are expressed by sympathoadrenal cell cultures. Radioimmunoassays for ENK and NPY show that their expression is enhanced in both cell cultures upon depolarization by 30 mM K^+ or veratridine (10 µM). SS levels, on the contrary, are lowered or do not change. These effects can be mimicked by the Ca^{+2} channel agonist (±) Bay K 8644 (1 µM) but not by the adenylate cyclase activator forskolin (10 µM), suggesting the involvement of Ca^{+2} but not cAMP on the depolarization effect. CA levels are also affected by high K^+ depolarization; exposure to 30 mM K^+ cause a lowering in epinephrine and norepinephrine levels in adrenal cells, as quantified using high performance liquid chromatography . However, no changes are observed in norepinephrine levels in sympathetic neuron cultures. Our results show that electrical activity modulates the expression of neuropeptides and CA in the avian sympathoadrenal system in vitro and suggest that a similar effect might occur in vivo.

REGULATION OF CALCITONIN GENE-RELATED PEPTIDE mRNA IN PRIMARY CULTURES OF DORSAL ROOT GANGLIA NEURONS. M.D. Christensen,* D.J. DiPette, K.N. Westlund and S.C. Supowit. Depts. of Int. Med., Marine Biomed. Inst., Human Biol. Chem. & Genetics, Univ. of Texas Med. Br., Galveston, TX 77550

Calcitonin gene-related peptide (CGRP) is produced by the alternative processing of the calcitonin/CGRP gene primary transcript. CGRP is a potent vasodilatory neuropeptide and has been implicated in regulation of cardiovascular function. Neuroendocrine and behavioral effects of centrally administered CGRP also suggest that this neuropeptide may play an important role in CNS function, however, very little is known about the factors and mechanisms that modulate neuronal CGRP synthesis and release. We have therefore begun to use primary cultures of dorsal root ganglia (DRG) neurons to identify the factors that modulate CGRP mRNA levels. DRG were chosen because this is the site of neuronal cell bodies known to produce abundant CGRP levels and to send axons peripherally to periadventitial tissue and centrally to spinal cord. It has been previously documented that isolated DRG neurons produce CGRP and that levels of both CGRP mRNA and protein are positively regulated by NGF. Using Northern blot analysis and immunocytochemical staining we have confirmed that DRG neurons contain immunoreactive CGRP and CGRP mRNA. Preliminary results indicate that treatment (20h) of isolated neurons with either forskolin (10uM) or phorbol 12-myristate 13-acetate (PMA; 20µM) in absence of NGF also increase CGRP mRNA levels. These results suggest that regulatory agents which act through protein kinase A and protein kinase C signal transduction pathways may modulate neuronal CGRP expression.

IDENTIFICATION AND CHARACTERIZATION OF A NOVEL GTP-BINDING PROTEIN IN BOVINE HIPPOCAMPAL MEMBRANES. J. Zhu, M.L. Toews, R.G. MacDonald and T.D. Hexum.*, Depts. of Pharmacology and Biochemistry, Univ. Nebraska Med. Ctr., Omaha, NE 68198-6260

A novel GTP-binding protein with an apparent molecular weight of 55 kDa was identified in purified membranes from bovine hippocampus. [α-^{32}P]GTP was covalently linked to GTP-binding proteins by incubating membranes in buffer for 3 min at 32° followed by exposure to UV light for 5 min at 3°. The reaction was stopped by removal of the light source and dilution in cold buffer. The 55 kDa protein was the most prominently labeled species under these conditions. Labeling could be moderately promoted by neuropeptide Y (NPY) but greatly enhanced by the C-terminal fragments, NPY(18-36) and NPY(20-36), in a concentration-dependent manner. The labeling was sensitive to inhibition by GTP-γ-S and GDP but not ATP. [α-^{32}P]ATP labeled a 53 kDa protein which did not increase after the addition of any of the peptides and was sensitive to inhibition by ATP but not GTP-γ-S. Labeling of membrane proteins by both nucleotides was strictly dependent on UV irradiation. Photoaffinity-labeling of the 55 kDa protein was facilitated, in a dose-dependent fashion, by dithiothreitol but was inhibited by pretreatment with N-ethylmaleimide. Western-blot analysis showed that an antibody against a consensus sequence of G-protein alpha subunits recognized a protein band co-migrating with the band that was photoaffinity-labeled. Thus, a novel GTP-binding protein exists in bovine hippocampus which may mediate an NPY effect in brain. (Supported by NS26479 and the Amer. Heart Assoc., Neb. Affil.)

G PROTEIN INVOLVEMENT IN COCAINE SENSITIZATION. C.D. Striplin* and P.W. Kalivas. Department of VCAPP, Washington State University, Pullman, WA. 99164-6520.

Behavioral sensitization is associated with a significant increase in dopamine neurotransmission in the nucleus accumbens (NA); while the neurochemical initiation of behavioral sensitization is thought to occur in the ventral tegmental area (VTA). A role for G proteins has been hypothesized since daily cocaine (30 mg/kg X 10 days) has been shown to decrease the levels of Gi and Go proteins. Also five daily injections of 15 or 30 mg/kg cocaine was shown to decrease the level of in vitro pertussis toxin ribosylation 1-6 hours after the last injection and a significant correlation has been found between the level of behavioral sensitization observed at 15 mg/kg and pertussis toxin ribosylation in the VTA . To determine if the G protein changes were transient or long-lasting, rats were sensitized to cocaine for 5 days and then given a final challenge of cocaine 14 days later. Rats were killed at 1hour after the final injection and G proteins were analyzed in the VTA, NA, substantia nigra, striatum and prefrontal cortex by Western blot analysis. The levels of Go, Gs, and Gi2 did not show any significant change in any of the brain areas tested. However, a significant decrease in Gi1 levels was observed in the NA in chronic cocaine treated animals given an acute cocaine challenge (85.5%) and chronic cocaine treated animals given an acute saline challenge (89.2%). These data indicate that G proteins in the VTA may play a role in the initiation of sensitization while long-term sensitization is associated with G protein changes in the NA.

CANNABINOID RECEPTOR-COUPLED G-PROTEIN ACTIVITIES IN CEREBELLAR MEMBRANES. M.A. Pacheco* and S.R. Childers. Dept. Neuroscience, University of Florida Sch. of Med., Gainesville, FL 32610. Dept. Phys./Pharm., Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27157.

Cannabinoid (Cn) receptors inhibit adenylyl cyclase (AC) and stimulate low K_m GTPase in cerebellar membranes. The AC inhibition is markedly reduced in cerebellar but not striatal membranes from Staggerer and Weaver mutant mice deficient in cerebellar granule cells, thus suggesting that these receptors are localized to granule cells. Studies of Na^+ effects on Cn receptor-coupled G-protein activities showed that Na^+ decreased specific binding of the Cn agonist ^{3}H-WIN 55212 in both cerebellar and striatal membranes, while Cn inhibition of AC in cerebellar membranes was maximal in the absence of Na^+. However in striatal membranes, AC inhibition was minimal in the absence of Na^+ and maximal at 50 mM Na^+. Cn agonists stimulated low K_m GTPase by 75-90% with potencies parallel to Cn-inhibted AC. Cn and $GABA_B$ stimulated GTPase was additive while corresponding agonist inhibition of AC was not additive. Na^+ dependence of Cn-stimulated GTPase in cerebellar and striatal membranes paralleled AC inhibition in these membranes: Na^+ decreased Cn-stimulated GTPase in cerebellar membranes, but in striatal membranes Cn-stimulated GTPase was maximal at 50 mM Na^+ with less than half that activity at without Na^+. These data suggest that in cerebellum Na^+ is not required for Cn-inhibited AC or Cn-stimulated GTPase activity.

THE FUNCTION AND QUANTITY OF GTP BINDING PROTEINS IN POST-MORTEM BRAIN OF ALCOHOLISM. H. Ozawa*[1], Y. Katamura[1], E. Hashimoto[1], S. Hatta[2], T. Saito[1], L. Frolich[3], N. Takahata[1] , P. Riederer[3]. Dept. of [1]Neuropsychiatry and [2]Pharmacology, Sapporo Medical College, Sapporo 060, Japan, [3]Dept. of Psychiatry, Wurzburg University, D-8700 Wurzburg , Germany.

Our and other lab suggested that ethanol may have direct effects on GTP (G) binding proteins, particularly stimulatory G protein (Gsα). The chronic exposures of ethanol in animal or peripheral tissues from alcoholism provides a reduction of Gs-mediated adenylate cyclase and the amount of Gsα . Taken together with these evidences ,alcoholism may be associated with the abnormality of postreceptor signaling system. The present study examines the function and quantity of G proteins in membrane preparation from several regions (frontal, parietal ,temporal, occipital cortex) in postmortem brain obtained from alcoholism (N=5) and aged and postmortem delay time matched control (N=5). G proteins (Gsα ,Giα ,Goα ,Gqα , beta subunit) were identified by Western blotting with polyclonal antibody (RM/1, AS/7, GC/2,QL,SW/1,respectively). The quantitative immunoblotting showed that immunoreactivity of high molecular weight Gsα in temporal cortex was significantly decreased (30% , $p<0.05$) in alcoholism compared with control. Additionally functional photoaffinity GTP [azidoanilido GTP(AAGTP)] labeling to Gsα was decreased in frontal and parietal cortex in alcoholism even though no alteration of the immunoreactivity. These results indicate that disturbances of G protein mediated signal transduction may be involved in the pathophysiology of alcoholism.

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: STRESS—DEVELOPMENTAL ASPECTS

423.1

Reversible Depletions of 5-Hydroxytryptamine in the Neo-Natal Rat Exaggerates Stress Responses in Adulthood. J.W.Smythe[1]*, C.M.McCormick[1], S.Bhatnagar[1], J.R.Seckl[2] and M.J.Meaney[1], Dept. Psychiatry, McGill Univ. Montreal, Canada, and [2]Dept. Medicine, Univ. Edinburgh, Scotland.

5-Hydroxytryptamine (5-HT) systems subserve both neurotransmitter and neurotrophic functions in the rat. Recent data showed that 5-HT can regulate the density of glucocorticoid receptors (GCr) in fetal hippocampal cell cultures. Elevated GCr levels are associated with enhanced negative-feedback control of the hypothalamic-pituitary-adrenal axis (HPA). We examined the effects of perinatal 5-HT depletions on stress responses of the adult rat in order to assess the trophic action of 5-HT on HPA function.

Neonatal rats were injected with PCPA or vehicle (VEH) on alternate days, up to day 8. Plasma corticosterone (B) was measured in response to 20 min restraint stress in adulthood.

Although basal levels of B were the same for both groups, PCPA-treated rats hypersecreted B upon termination of stress and at 20 + 60 min post-stress. By 120 min post-stress both groups had returned to basal levels.

These results indicate that 5-HT can regulate HPA function, presumably by some trophic action. We are currently investigating the specific brain locations and nature of this regulation.

423.2

CHANGES IN PLASMA ACTH, CORTICOSTERONE, CBG, AND HIPPOCAMPAL GLUCOCORTICOID RECEPTOR OCCUPANCY IN RAT PUPS FOLLOWING MATERNAL SEPARATION AND/OR ETHER STRESS. Shakti Sharma*, V. Viau, S. LaRocque and M.J. Meaney, Douglas Hos. Res. Ctr., Depts of Psychiatry, and Neurology and Neurosurgery, McGill Univ, Montreal, Canada H4H 1R3

Plasma ACTH and corticosterone (B) responses to stress are often reduced in the neonatal rat. However, plasma cortiosteroid-binding globulin (CBG) levels of the neonate are substantially decreased, which might enhance the biological significance of existing glucocorticoid levels. We examined this question by estimating hippocampal glucocorticoid receptor (GR) occupancy in Day 6, Day 15, and adult animals under basal and stressful conditions. The results showed that: 1) Plasma ACTH levels were elevated in Day 6 animals in response to acute exposure to ether, maternal separation, and maternal separation + ether, however, ACTH responses were substantially lower than in Day 15 or adult animals. 2) Plasma total B levels followed a similar pattern; most noteworthy was the potent glucocorticoid response in Day 15 animals to the combination of maternal separation + ether. 3) Plasma CBG levels in Day 6 animals were extremely low (<3% adult values); by Day 15 CBG levels were about 25% of adult levels. Interestingly, maternal separation was associated with a substantial decrease in plasma CBG levels. 4) Hippocampal GR occupancy was similar at all ages under both basal and stress conditions. The only noteable exception occurred during maternal separation in Day 15 animals, where hippocampal GR occupancy was higher than that observed at any time in either Day 6 or adult animals. This finding is likely related to the decrease in plasma CBG that occurs following separation of Day 15 pups from the dam. Thus, despite the differences in plasma B levels, GR occupancy was generally comparable across all ages either under basal conditions, or following stress. These receptor data underscore the importance of developmental changes in plasma CBG levels.

423.3

DEVELOPMENTAL MANIPULATIONS DIFFERENTIALLY AFFECT HPA AXIS OF MALE AND FEMALE RATS. C.M. McCormick*, J.W. Smythe, S. Sharma, & M.J. Meaney, McGill University, Dept. of Psychiatry, Douglas Hospital Research Centre, Montreal, CANADA H4H 1R3.

Hypothalamic-pituitary-adrenal (HPA) function was investigated in adult animals in relation to both prenatal stress (PS: 20 min restraint of mothers on days 15-19 post-conception) and neonatal handling (H: separation from mothers for 15 min daily during first 10 days of life). Blood samples were drawn from catheters prior, during, and following 20 min restraint. PS females showed elevated levels of ACTH and corticosterone (B) during and following stress compared to NS females. No marked differences in B, ACTH, or corticosteroid binding globulin (CBG) were observed between PS and NS males. Despite similar basal levels of B, PS females showed elevated levels of CBG compared to NS females, which may account for their increased HPA response to stress. PS was associated with increased glucocorticoid receptor (GR) levels in the frontal cortex (FC) in females, decreased levels in FC of males, and increased levels in septum (SPT) of males. PS was not associated with GR levels in hippocampus (HPC), hypothalamus (HYPO), and amygdala (AMG). In contrast, neonatal handling (H) was associated with a reduced HPA response to stress in both males and females. H animals showed increased levels of GR in HPC (both sexes) and FC (males only), and decreased GR levels in SPT (males only) compared to non-H animals. H was not associated with GR levels in HYPO or AMG. Across experimental groups, when sex differences were observed, they were in the direction of higher GR levels in females than in males.

The results reflect sex differences in the effects of early environmental events on (1) HPA response to stress, and (2) GR levels in brain regions implicated in HPA regulation, and (3) plasma levels of CBG.

423.4

CENTRAL GLUCOCORTICOID RECEPTORS AND IMMUNE FUNCTION IN CHRONICALLY COLD STRESSED HANDLED AND NON-HANDLED RATS. S. Bhatnagar*, N. Shanks & M.J. Meaney, Douglas Hospital Research Center, Depts. of Psychiatry and Neurology & Neurosurgery, McGill University, Monteal, Quebec, Canada H4H 1R3.

Neonatally handled (H) animals secrete less corticosterone (B) and adrenocorticotropin (ACTH) in response to acute stress than their non-handled (NH) counterparts. Additionally, H animals have increased concentrations of Type II glucocorticoid receptors in the hippocampus and frontal cortex, structures known to be involved in feedback inhibition of HPA activation. We have previously shown that when chronically cold stressed H and NH animals (H CHR and NH CHR, respectively; 4h at 4 ° C a day for 21 days) are exposed to a novel stressor (20 min of restraint), NH CHR exhibit delayed recovery such that by 120 min following termination of the strss, plasma B does not return to baseline. We examined Type II glucocorticoid receptor concentrations in hippocampus, frontal cortex, hypothalamus and pituitary in these animals. Chronic stress does not alter Type II concentrations in any of these areas such that hippocampal glucocorticoid receptor density in both H CTL and H CHR is greater than in NH groups. The effects of chronic cold stress on immune function was examined in H CTL and NH CTL, H CTL and NH CTL animals exposed to one 4 h period of acute cold stress (4 ° C) 92 h after inoculation with sheep red blood cells, and in H CHR and NH CHR re-exposed to cold stress (4 ° C) 92 h after inoculation. We found that H CTL and NH CTL animals did not differ in their plaque forming cell (PFC) response or serum anitbody titers. A single exposure to cold strss reduced the PFC response equally in both H CTL and NH CTL. However, when H CHR and NH CHR were re-exposed to cold stress, immune responsiveness was reduced even further in NH CHR compared to NH CTL, whereas H CHR did not differ from H CTL or NH CTL exposed to one period of cold stress. These data suggest that early environmental experience may modulate adaptation to chronic stress and influence predisposition to stress-related pathologies.

423.5

PLASMA CORTICOSTERONE IS SIGNIFICANTLY INCREASED BY COLD STRESS IN THREE DAY-OLD NEONATAL RATS. S.-J. Yi*, L. Schultz, T.Z. Baram, Div. of Neurology, Childrens Hospital Los Angeles, Los Angeles, CA 90027

The hypothalamic-pituitary-adrenal axis underlies the hormonal stress response. The responsiveness of the neonatal hypothalamic-pituitary-adrenal axis to stress has been thought to be impaired ("stress hyporesponsive period"). We studied the response of neonatal rats to cold stress by measuring plasma corticosterone levels.

Rats aged 3 to 17 days were placed in compartmentalized plastic cages in a cold room (4^0C) for 20 to 60 min. Trunk blood was collected 5 min, 20 min, 1 hour, 4 hours and 28 hours after the onset of cold stress for plasma corticosterone measurement by RIA. Littermate control rats were kept under "stress free" conditions.

Animals exposed to cold stress showed a marked increase in plasma corticosterone starting on the third postnatal day, compared to non-stressed controls. We are currently studying the response of plasma ACTH and CRH-mRNA abundance in the paraventricular nucleus to cold stress during the first postnatal week.

423.6

POSTNATAL HANDLING ALTERS GLUCOCORTICOID FEEDBACK REGULATION OF HYPOTHALAMIC-PITUITARY-ADRENAL FUNCTION. D.S.L. MacIntosh*, V. Viau, S. Sharma, P.M. Plotsky and M.J. Meaney. Douglas Hosp. Res. Ctr., McGill Univ, Montreal H4H 1R3 and Peptide Biology, Salk Institute, La Jolla CA 92138.

Postnatal handling of rat pups is known to permanently alter hypothalamic-pituitary-adrenal (HPA) responses to a wide variety of stressors and negtaive feedback sensitivity to circulating glucocorticoids. In the present studies, we found that H animals show lower levels of plasma ACTH in response to both restraint and ether stress. However, H and NH did not differ in glucocorticoid fast feedback: Administration of 30 µg/kg corticosterone (B) immediately prior to restraint stress significantly dampened the subsequent increase in plasma ACTH levels to the same extent in H and NH animals. H and NH animals adrenalectomized (ADX) 5 days prior to testing did not differ in plasma ACTH responses to restraint stress, demonstrating that the differences between the groups is dependent upon the presence of circulating B. However, the handling effect was apparent in ADX animals provided with a low level of B replacement (50% B pellets producing plasma B levels of ~5 µg/dl). H/ADX + B rats showed lower levels of plasma ACTH both during and following restraint stress than did H/ADX animals. In contrast, there were no differences in plasma ACTH levels between NH/ADX and NH/ADX + B animals. Thus, a low level of B replacement was able to restore the difference between H and NH animals in plasma ACTH responses to stress. This finding shows that the differences between H and NH animals in HPA responses to stress can occur independent of stress-induced elevations in plasma B levels. Finally, we found that resting-state levels of corticotropin-releasing factor (CRF) and arginine vasopressin (AVP) in median eminence were significantly higher in NH animals compared with H animals. Taken together, these findings suggest that H and NH animals differ in delayed negative-feedback, that this difference occurs in response to low levels of B and is reflected in differential rates of CRF and AVP synthesis.

423.7

EARLY, POSTNATAL EXPERIENCE ALTERS HYPOTHALAMIC CORTICOTROPIN-RELEASING FACTOR (CRF) mRNA, MEDIAN EMINENCE CRF CONTENT AND STRESS-INDUCED RELEASE IN ADULT RATS. Michael J. Meaney* and Paul M. Plotsky. Douglas Hospital Res. Ctr., McGill Univ., Montreal H4H 1R3, Canada and Peptide Biology Lab., The Salk Inst., La Jolla, CA 92037.

The early studies of Levine, Denenberg and others have shown that early handling permantently alters hypothalamic-pituitary-adrenal responses to stress. Nevertheless, despite the long history of the neonatal handling paradigm and its importance for the study of the environmental regulation of development, we know rather little about the mechanisms that underly differences in HPA activity between handled (H) and nonhandled (NH) animals, and less about the effects of other forms of alterations in early rearing environment on the development of the HPA axis. In these studies, rat pups 2-14 days of age were exposed daily to handling (15 min of separation from mother and home cage), maternal separation (MS; 180 min of separation), or were left entirely undisturbed (nonhandled; NH). As adults, MS rats showed increased hypothalamic corticotropin-releasing factor (CRF) mRNA levels compared with NH rats, while CRF mRNA levels in H rats were significantly lower than either MS or NH animals. Hypothalamic CRF content under basal conditions followed exactly the same pattern. A 20-min period of restraint stress produced significant CRF depletion in all groups, although the percentage of depletion was significantly lower in H animals compared with either MS or NH animals. Restraint stress produced significantly higher increases in plasma corticosterone in MS and NH animals than in H animals. These data reflect the importance of early environmental factors in regulating the development of the hypothalamic CRF system and the responsiveness of the hypothalamic-pituitary-adrenal axis to stress.

424.1

PLASTICITY OF ß-ADRENOCEPTORS ON SPLENOCYTES FROM YOUNG AND OLD F344 RATS FOLLOWING ACUTE CHEMICAL SYMPATHECTOMY. S.M. Breneman*, D.L. Bellinger, K.S. Madden, A. Tong, J. Housel, S.Y. Felten, and D.L. Felten. Department of Neurobiology & Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

ß-adrenoceptor (ßAR) density on splenocytes was examined in 3- and 21-month-old (mo) male F344 rats between 1 and 56 days (D) after chemical sympathectomy (SympX) with 6-hydroxydopamine. In splenocytes from 3-mo SympX rats, ß-adrenoceptor density was not significantly different from nontreated or vehicle-treated controls at D1-3 post-treatment, but progressively increased through D10, and then declined from D10 through D56. ßAR density at D56 still was slightly elevated compared with both control groups. The initial rise in ßAR density suggests an upregulation of receptors in response to NA denervation of the spleen. The subsequent progressive decline closely parallels the time course of reinnervation of NA nerve fibers into the spleen. ßAR density on splenocytes from nontreated and vehicle-treated 21-mo rats was significantly higher compared with that seen in 3-mo rats (approximately 780-900 and 475-525, respectively). Vehicle-treated 3- and 21-mo animals possessed a slightly higher density of ßAR on splenocytes than did nontreated age-matched controls. In splenocytes from 21-mo SympX rats, a progressive decline in ßAR density was observed between D1 and D3, followed by a progressive rise in ßAR density through D56. At D56 the density of ßAR on splenocytes from denervated 21-mo rats was not significantly different from vehicle-treated controls. These findings indicate that regulation of ßAR density on splenocytes following acute denervation is impaired with age; upregulation of ßAR in response to denervation was not observed, only a slow progressive increase in the receptor density that closely parallels the reinnervation of the spleen in 21-mo rats. The initial decline in ßAR following SympX in 21-mo rats may result from a decrease in the ability to metabolize norepinephrine released from damaged sympathetic nerves. 424.2

PRESENCE AND AVAILABILITY OF VIP IN PRIMARY AND SECONDARY LYMPHOID ORGANS. D.L. Bellinger*, D.J. Earnest, M. Gallagher, and D.L. Felten. Department of Neurobiology & Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

A large body of pharmacological and immunological data indicate that vasoactive intestinal peptide (VIP) acts as a neurotransmitter with cells of the immune system as targets. VIP receptors have been found on human and murine T and B lymphocytes. In functional studies, VIP inhibits mitogen-induced proliferation of lymphocytes from murine Peyer's patches and spleen, inhibits natural killer cell activity, alters antibody production, and promotes vasodilatation of vascular beds during local inflammatory responses. VIP receptors on T lymphocytes mediate their migration into gut-associated lymphoid tissue (GALT) and mesenteric lymph nodes (MLNs). While a few immunocytochemical (ICC) studies have reported VIP-positive (+) nerves in thymus, LNs and GALT, the presence and availability of VIP in lymphoid organs has not been examined thoroughly. We examined VIP innervation of primary and secondary lymphoid organs using ICC for localization of VIP and radioimmunoassay (RIA) for neurochemical measurement of VIP. A sparse density of VIP+ fibers was present in the thymus, residing exclusively in the capsule and intralobular septa, often in close proximity to mast cells. VIP+ nerves were most abundant in MLNs. These fibers coursed along the vasculature in internodal regions of the cortex, and to a lesser extent into the surrounding parenchyma and along medullary cords. No innervation was observed in the popliteal LNs (PLNs) or in the spleen. RIA for neurochemial measurement of VIP demonstrated high levels on MLNs (1.58 picograms/milligram tissue wet weight), and very low VIP content in thymus. VIP was not detectable in bone marrow, PLNs or spleen. Collectively these findings support the presence and abundant VIP innervation of MLNs and sparse VIP innervation of thymus. Supported by 1 R29 MH47783, R37 MH42076, and Markey Foundation Center. Award.

424.3

PLASTICITY OF NORADRENERGIC NERVES IN SPLEENS FROM AGED F344 RATS FOLLOWING CHEMICAL SYMPATHECTOMY. K.S. Madden*, D.L. Bellinger, A. Tong, J. Housel, N.L. Costello, C. Richardson, S.Y. Felten, and D.L. Felten. Department of Neurobiology & Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

The time course and pattern of noradrenergic (NA) nerve ingrowth into the spleen following acute chemical sympathectomy with 6-hydroxydopamine (6-OHDA) was examined in 3- and 21-month (mo)-old male F344 rats using glyoxylic acid fluorescence histochemistry and neurochemical measurement of norepinephrine (NE). In spleens from 3-mo-old rats, NA nerve ingrowth occurred along the splenic artery and entered the hilus (1-5 days, D1-5), extended into the hilar region (D5-10), and then proceeded into regions distal from the hilus (D21-56), suggesting orderly ingrowth from the hilus to distal regions. NA nerves reinnervated the same compartments seen in vehicle controls, but nerve fiber density in these compartments differed based on distance from the hilus and time after denervation. By D56 post-lesion, regions distal from the hilus had fewer NA nerves than vehicle controls, suggesting that reinnervation does not restore nerve density identical to that of vehicle controls. In contrast, splenic NE concentration at D56 post-lesion returned to vehicle control values, suggesting that functional restoration of NA nerves in the spleen may involve metabolic and receptor compensation for the lack of complete fiber regrowth into regions of white pulp distal from the hilus. In spleens from 21-mo-old rats NA nerves still were capable of ingrowth into the spleen following denervation; however, the initial ingrowth was delayed until D15 after the last dose, ingrowth occurred over a slower time course, and the density of NA nerves returning to the spleen was reduced at D56 compared with all other young and old treatment groups. Splenic NE levels at D56 post-lesion also were significantly lower than in 21-mo-old vehicle controls, suggesting that plasticity of NA innervation is compromised with age. Supported by 1 R29 MH47783, R37 MH42076, and Markey Foundation Center. Award.

424.4

MORPHINE-INDUCED ALTERATIONS OF IMMUNE STATUS: EVIDENCE FOR ß-ADRENERGIC RECEPTOR INVOLVEMENT. Karamarie Fecho,* Donald T. Lysle & Linda A. Dykstra. Department of Psychology & Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

There is evidence suggesting that morphine's immunomodulatory effects are mediated through the central nervous system. For example, the systemic administration of morphine, but not of N-methylmorphine, has been found to produce a naltrexone-reversible suppression of splenic NK cell activity. However, little is known about how the activation of central opiate receptors by morphine translates into peripheral immune alterations. The purpose of the present experiments was to investigate the involvement of the ß-adrenergic system as one possible mediator of morphine's effects.

Prior to a subcutaneous (s.c.) injection of either 15 mg/kg morphine or saline, male Lewis rats (N=180) were administered either the nonselective ß-adrenergic receptor antagonist nadolol, the selective $ß_1$-adrenergic receptor antagonist atenolol or the selective $ß_2$-adrenergic receptor antagonist ICI-118,551 in doses of 0, 0.125, 0.5, 2.0 or 8.0 mg/kg, s.c. All three antagonists dose-dependently attenuated the suppressive effects of morphine on the proliferative responses of splenic lymphocytes to Con-A, PHA, LPS and Iono/PMA. In contrast, none of the antagonists exhibited any effect on the morphine-induced suppression of the proliferative responses of blood lymphocytes to Con-A or PHA; likewise, there was no antagonism of the suppression of splenic NK cell activity produced by morphine. Although the immunosuppressive effects of morphine appear to involve multiple mechanisms, these data clearly implicate the ß-adrenergic system.

PAVLOVIAN CONDITIONING OF MORPHINE-INDUCED IMMUNE ALTERATIONS: EVIDENCE FOR OPIOID RECEPTOR INVOLVEMENT Mary E. Coussons*, Linda A. Dykstra, and Donald T. Lysle, Departments of Psychology and Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3270

Our prior work has shown that morphine's immunomodulatory effects can become conditioned to environmental stimuli that predict drug administration. These alterations include conditioned changes in natural killer cell activity, interleukin-2 production, and mitogen-stimulated lymphocyte proliferation. The present studies were aimed at determining the involvement of opioid receptor activity in the establishment and expression of morphine-induced conditioned immune alterations. During the training phase, Lewis rats received two conditioning sessions during which a subcutaneous injection of 15 mg/kg morphine sulfate was paired with exposure to a distinctive environment. On the test day, animals were reexposed to the distinctive alone prior to sacrifice. Saline or naltrexone (0.3, 1.0, 3.0, or 10.0 mg/kg) was administered either prior to training or to test. Administration of naltrexone prior to training resulted in attenuation of the conditioned immune alterations, whereas naltrexone administration prior to testing had no effect. Taken together, these studies show that opioid receptor activity is involved in the establishment, but not the expression, of conditioned morphine-induced immune alterations. MODULATION OF ANTIBODY PRODUCTION AND ANTIGEN-INDUCED PROLIFERATION BY A CONDITIONED AVERSIVE STIMULUS. Elizabeth H. Bennett, Lynn Perez, Maureen E. Bronson* and Donald T. Lysle, Department of Psychology & Curriculum in Neurobiology, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina 27599.

Our research program is designed to characterize the immunomodulatory effect of a conditioned aversive stimulus (CS) in rats. The present study examined the effect of presentation of the CS on the proliferative response of lymphocytes to the T-dependent antigen, keyhole limpet hemocyanin (KLH) and the production of specific antibody to KLH. The results showed that presentations of the CS on days 0, 2, and 4 following immunization had no effect on the proliferative response to KLH in either spleen or lymph node lymphocytes. Furthermore, presentation of the CS on those days had no significant effect on antibody production. In contrast, presentations of CS on days 10, 12, and 14 following immunization induced a significant suppression of the KLH-induced proliferative response of lymph node lymphocytes, but not splenic lymphocytes, and a reduction in serum antibody levels to KLH. These findings indicate that a conditioned aversive stimulus can modulate the immune response to specific antigen, and that the effect is dependent upon the temporal relationship between antigen administration and presentation of the CS. (Supported by MH46284.)

CHARACTERIZATION OF OPIOID RECEPTOR INVOLVEMENT IN PAVLOVIAN CONDITIONED IMMUNE ALTERATIONS. Lynn Perez and Donald T. Lysle*, Department of Psychology & Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

Previous work from our laboratory has shown that naltrexone can antagonize alterations in immune status induced by presentation of a conditioned aversive stimulus (CS). The present studies were designed to further this investigation by determining the specific opioid receptor subtype involved in conditioned immune alterations. ß-funaltrexamine (ß-FNA), a highly selective μ opioid-receptor antagonist, was administered (0, 5.0, and 25.0 mg/kg, s.c.) 24 hours prior to exposure to the CS. Alterations of immune status were determined by in-vitro assessment of natural killer cell (NK) activity, lymphocyte proliferation induced by Con-A, PHA, LPS, and ionomycin/PMA, and production of interleukin-2 (IL-2). ß-FNA antagonized the CS-induced suppression of NK activity, but did not attenuate the suppression of lymphocyte proliferation or IL-2 production. In a subsequent study, naltrindole, a selective δ opioid-receptor antagonist, was administered (0, 0.1, 1.0, 10.0, and 30.0 mg/kg, s.c.) prior to exposure to the CS. The results showed that naltrindole had no effect on the CS-induced alterations of immune status. To further characterize opioid receptor involvement in conditioned immune alterations, additional studies will investigate the role of kappa opioid receptors using nor-binaltorphimine, a k-selective antagonist. Collectively, the results of these studies provide an extensive analysis of the involvement of opioid receptor subtypes in conditioned immune alterations. (Supported by MH46284.)

CATECHOLAMINE MODULATION OF LYMPHOCYTE MIGRATION AND HOMING TO LYMPHOID TISSUES. S. L. Carlson*, Dept. of Anatomy & Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084

Catecholamines from the sympathetic nervous system have been shown to modulate many *in vivo* assays of immune function. In part, this may result from modulation of the migration patterns of lymphocytes into lymphoid tissues, producing different ratios of T-cell subsets or B-cells and subsequent alterations in immune responses. To test this hypothesis, peripheral lymph node lymphocytes from male C3H/HeN mice were obtained and labelled with fluorescent supravital dyes such as CFSE and the CellTracker dyes (Molecular Probes). Some of the cells were treated with isoproterenol (Iso, 1μM) for 15 min to stimulate the ß-adrenergic receptor, whereas control cells were not exposed to Iso. The cells (10-20 x 10^6) were infused into the tail vein of recipient mice, and allowed to circulate for various lengths of time. Tissues were either frozen for histological analysis or prepared for cell sorter (FACS) analysis of the number of fluorescent cells that migrated into each tissue. After 30 minutes migration, the labelled cells were distributed predominantly in the red pulp and marginal zones of the spleen, with some cells beginning to migrate into the white pulp. The distribution of Iso-treated and control cells appeared to be essentially the same. In peripheral and mesenteric lymph nodes, labelled cells were found throughout, again with the Iso-treated and control cells having a similar distribution. An increase in the number of Iso-treated cells that migrated to the peripheral lymph nodes has been noted, but additional experiments are needed to determine if a significant change will be found. In addition, other time points are being examined, as is the effect of NE and EPI stimulation on lymphocyte migration. (Supported by R29 MH48644-01)

TYPE I AND II ADRENAL STEROID RECEPTOR AGONISTS HAVE SELECTIVE EFFECTS ON PERIPHERAL BLOOD IMMUNE CELLS IN THE RAT. A.H.Miller*, R.L.Spencer, J.Hasset, C.H.Kim, A.Husain, B.S. McEwen, M.Stein. Mt Sinai Med Ctr, 1 Gustave L. Levy Pl., NY, NY 10029; Rockefeller Univ,1230 York Ave., NY, NY 10021.

Administration of adrenal steroids is classically associated with increases in neutrophils and decreases in lymphocytes and monocytes in the peripheral blood. Although immune cells possess two types of adrenal steroid receptors, type I (mineralocorticoid) and type II (glucocorticoid), it is unknown which receptor subtype is involved in these various adrenal steroid effects. To examine this issue, male rats were treated with selective receptor agonists for 7 days via osmotic minipumps, and the number and percentage of immune cells in the peripheral blood was determined. For each receptor agonist (aldosterone for the type I receptor, RU28362 for the type II receptor), five groups of rats (300g) were studied (n=5 per group); sham adrenalectomy (ADX), 7-day ADX, 7-day ADX+1ug/hr, 7-day ADX+4ug/hr and 7-day ADX+10ug/hr. Whereas ADX alone had no effect on the total white blood cell (WBC) count, both aldosterone and RU28362 resulted in a significantly decreased WBC count. While aldosterone decreased the number of neutrophils, lymphocytes, and monocytes; RU28362 decreased lymphocytes and monocytes but was associated with a significant increase in neutrophils. As for lymphocyte subsets, RU28362 had the greatest inhibitory effect on T helper cells and B cells, while aldosterone was associated primarily with decreases in T cells and NK cells. These results suggest that the two adrenal steroid receptor agonists have different effects on peripheral blood immune cells in the rat. Since selective activation of adrenal steroid receptor subtypes can occur under physiologic conditions, these differences allow for complex and varied effects of adrenal steroids on immune cells under basal hormone conditions and following stress. EFFECTS OF ENDOTOXIN ON THE INDUCTION OF C-FOS PROTEIN IN THE BRAIN, PLASMA LEVELS OF CORTICOSTERONE, AND NOREPINEPHRINE AND VIP LEVELS IN THE SPLEEN OF THE RAT. C. Y Vriend*, W. Wan, L. Janz, J. M. Sorvillo^, A.H. Greenberg and D.M. Nance. Departments of Pathology, Psychology, and Institute of Cell Biology, University of Manitoba, Winnipeg, MB., R3E 0W3, Canada and ^Oncogene Sci., Inc., Uniondale, NY, 11553.

Lipopolysaccharide (LPS), an endotoxin associated with gram-negative bacteria, is a potent activator of the immune system. We have tested the effects of ICV infusions of LPS (10 ng) or Ringer's solution on the induction of the proto-oncogene protein c-fos in the brain as well as plasma levels of corticosterone and splenic concentrations of norepinephrine (NE) and VIP. The c-fos was visualized by ICC procedures with a polyclonal antibody to c-fos (1/200, Oncogene Sci.) and the PAP technique. At 3 hr post-ICV infusion of LPS, we observed numerous labeled neurons focused in the paraventricular nucleus (PVN) of the hypothalamus and the A2 region of the brain stem. Corticosterone levels as well as splenic NE and VIP levels were all elevated 3 hr post-ICV LPS, relative to Ringer's solution. In additional studies, we examined the time course for the induction of c-fos labeled neurons in the brain following IP injections of LPS as well as establish a dose response curve for c-fos labeling in the PVN vs IP dose of LPS. Labeled cells first appeared in the PVN 1 hr following IP injection (100 µg), increased further at 2 and 3 hr post-injection and then returned to control levels at later intervals. The dose response curve for IP LPS vs the number of c-fos labeled neurons in the PVN showed a few labeled cells detectable at a dose of 4.0 µg, but the number and staining intensity of labeled neurons increased up to a dose of 100 µg, with no further increase in the number of labeled neurons at higher doses. In contrast to ICV injections, we observed additional labeled cells in the supraoptic nucleus (SON), arcuate nucleus and the A1 regions of the brain stem at IP doses of 40 µg and higher. These results indicate selective and differential effect of central and peripheral LPS on the induction of c-fos protein in hypothalamic and brain stem nuclei. The concurrent changes in corticosterone level and splenic neurotransmitter levels produced by ICV LPS suggest that the endocrine and autonomic nervous systems are primary targets for these activational effects of endotoxin. Supported by MRC, MHRC and HSCRF.

EFFECTS OF LIPOPOLYSACCHARIDE ON OXYTOCIN RELEASE AND ON LOSS OF LOW-AFFINITY THYMIC OXYTOCIN RECEPTOR SITES. J. D. Caldwell*, C. H. Walker, C. A. Pedersen, L. Li, and G. A. Mason. BDRC and Dept. of Psychiatry, Univ. of North Carolina, Chapel Hill, NC 27599-7250

We have previously demonstrated that estrogen increases the affinity of thymic oxytocin (OXT) receptors. This study tested whether an E. coli lipopolysaccharide (LPS) challenge would alter OXT immunoreactive levels or thymic OXT receptors in ovariectomized (OVXed) rats given 5 μg estradiol benzoate (EB) once daily for three days or oil vehicle. On the fourth day rats received iv infusions of 150 μg/kg LPS or saline vehicle 90 min. before decapitation. LPS resulted in a significant increase in blood OXT levels only in estrogen-treated animals. The thymus, MPOA, PVN, septa and pituitaries showed no significant changes in OXT levels with these treatments, although OXT levels in the PVN were correlated with blood levels, while MPOA levels correlated with pituitary levels. Computerized analyses of data from competition binding experiments in which 0.2 to 200 nM OXT were incubated with 0.2 nM ^{125}I-OTA indicated that thymuses from oil-saline treated OVXed matched a two-site model significantly better than a one-site model; demonstrating both high- (Ki = 0.39 $\pm$ .08) and low-affinity (Ki = 9.3 $\pm$ 3.9) OTA binding sites. The EB-saline, oil-LPS and EB-LPS treated animals demonstrated one-site models with only high-affinity sites (Kis were 0.58, 0.42 and 0.42 respectively). In several in vitro experiments 100 nM OXT or 40 μg LPS added to homogenates of thymuses from OVXed oil-saline vehicle treated animals also resulted in the loss of the low-affinity sites (one-site model with Ki = 0.46 for both). OXT release after an immune challenge is estrogen-dependent while LPS directly affects the thymus by eliminating a population of low-affinity OXT receptors.

HYPOTHALAMIC NEURAL SUBSTRATES CONTRIBUTING TO PROLACTIN (PRL) BUT NOT CORTICOSTERONE (CORT) RELEASE AFTER ENDOTOXIN INJECTION. J.M. Dong, L.T. Chen, R.A. Menzies*, J.M. Oliver, B. Muffly and C.P. Phelps . Depts. of Anatomy and Psychiatry and Behavioral Medicine, Coll. Med., Univ. South Florida, Tampa, FL 33612

Amino acids capable of producing excitation and subsequent small axon-sparing lesions are used as neuroendocrine research tools. Studies of brain regulation of Prl and adrenal hormone release after systemic N-Methyl-D,L,-Aspartic Acid (NMA) administration have demonstrated differing thresholds for the modulation of individual pituitary hormones. The prominent role of Prl and Cort in the modulation of immune function coupled with the possibility that these hormones may also have a differential release in response to immune challenge prompted the following experiments. Male rats received atrial cannulas for blood samples (bs, Oday, AM and PM) before bilateral injections of either artificial CSF (aCSF) or NMA (0.6M in 0.1 and 0.15µl aCSF) at 2 sites in the anterior hypothalamic area (AHA). At 3 and 7d post NMA rats received 1 or 1.5 mg/100g. E. coli endotoxin (Endotx) or saline per cannulas after bs at 0hr(AM) and again at 0.5, 1, 3, 6 and 24 hr post endotoxin. Cort and Prl were assayed by RIA. Endo treatment of control rats resulted in 8X max increase (from basal) in plasma Cort at 0.5 hr and a 5X max increase in Prl at 1.0 hr which returned to baseline at 3 hr. Injection of either aCSF alone or NMA into AHA 7d prior to Endo did not prevent plasma cort increases seen in controls. However, both injection of aCSF alone or with NMA resulted in a respective, progressive reduction in Prl release after Endo, so that NMA rats resembled control rats receiving saline. In summary an increase in Prl and Cort release after Endo occurs with the change the latter occurring sooner and lasting longer. Cort release after endotx is not hampered after progressive damage to the AHA after injection of NMA, whereas Prl release was blocked by small (0.1mm^3) lesions. Supported by MH46808.

ENDOTOXIN CHALLENGE IN THREE-DAY-OLD RAT PUPS: HYPOTHALAMIC-PITUITARY-ADRENAL ACTIVATION AND DEVELOPMENTAL CONSEQUENCES N. Shanks* & M.J. Meaney. Douglas Hospital Research Centre, Dept. of Psychiatry, McGill University, Montreal, Quebec.H4H 1R3 CANADA

Antigenic challenge with endotoxin (ENDO) is known to activate the hypothalamic-pituitary-adrenal axis (HPA) in adult animals. Recent data have implicated IL-1ß and corticotropin releasing hormone (CRH) as potential mechanisms responsible for HPA activation during the acute phase response to antigenic challenge. However, relatively little is known about HPA and immune interactions during development and whether neonatal immune challenge alters endocrine functioning as an adult. A series of studies were performed assessing the HPA response to *salmonella enteritidis* endotoxin challenge in three-day-old rat pups. It was observed that ENDO at a dose of 0.05mg/kg (ip) provoked marked elevations in both plasma adrenocorticotrophic hormone (ACTH) and corticosterone (CORT), while only slightly altering blood glucose levels. HPA activation peaked between 3 to 4 hours following ENDO administration in both male and female rat pups. However, a marked sex difference was evident with respect to both the dynamics and magnitude of the HPA response. The magnitude of both the CORT and ACTH responses to ENDO were both greater and occurred earlier in female rat pups relative to males, however, hormone levels returned to basal values within 24 hrs in both sexes. Median eminence CRH content decreased 2-4hrs following ENDO in both male and female rat pups, suggesting that the activation of the HPA axis was mediated by ENDO stimulated CRH release. Studies are presently underway to investigate interactions between CRF and IL-1ß in the neonate, and assessing the longterm consequences ENDO challenge during development on HPA function and its relation to gender.

The Role of Immune Cells in Suppression of EAE Induced by CSF-Infused MBP. C.J. Harling-Berg*, R.A. Sobel, P.M. Knopf, and H.F. Cserr. Physiol. Sec., Brown Univ., Providence, RI 02912 and Dept. of Pathology, Mass. General Hospital, Boston, MA 02114

Pretreatment with a single infusion of guinea pig myelin basic protein (MBP; 90 μg in 9μl) into the CSF of Lewis rats suppresses clinical EAE following an EAE challenge (J. Neuroimmunol., 35:45, 1991). The role of immune cells in this suppression was evaluated by: 1) examining CNS tissues in suppressed rats and 2) determining if immune cells from suppressed rats can transfer suppression. Seven days post-infusion, MBP-pretreated rats were either challenged for EAE (75 μg MBP in CFA s.c) or their spleen (SC) and cervical lymph node cells (LNC) were transferred i.v. (SC 2.0-6.0 X 10^8; LNC 1.9-3.4 X 10^8) to naive recipients who were then challenged for EAE. Sixteen days after EAE challenge, 6 MBP-pretreated rats had fewer CNS inflammatory foci than did 5 non-pretreated controls (167 $\pm$ 35 vs 238 $\pm$ 96, $P<0.05$, Smirnov test). Transferred immune cells, with or without prior Con A stimulation (1.5 μg/ml; 40 h) did not suppress clinical signs in EAE-challenged recipients (mean maximal scores: SC [n=11] 3.7 $\pm$ 1.4; LNC [n=9], 3.2 $\pm$ 1.7; control [n=13] 3.1 $\pm$ 1.6). These results suggest that suppression of clinical EAE by CSF-infused MBP correlates with a reduced amount of CNS inflammation and that this suppression does not appear to be mediated by a transferrable immune cell. (NIH GM 08206, NS 26773, NS 11050, and the RI Foundation)

BRAIN AND LYMPHOID CELLS BETA-ENDORPHIN AND SUBSTANCE P IN EXPERIMENTAL ALLERGIC ENCEPHALYTIS (EAE). J. Veljic, P. Sacerdote*, G. Monastra^ and A.E. Panerai Dept. Pharmacology, School of Medicine, University of Milano, 20129, Milano; ^Fidia Res. Labs, 35031, Abano Terme, Italy.

Evidence is rapidly cumulating that neuropeptides participate in the modulation of immune responses acting both in the central nervous system, and with autocrine, paracrine or endocrine mechanisms. We measured beta-endorphin (BE) and substance P (SP) concentrations in discrete brain areas and draining lympho nodes cells (LC) of Lewis (EAE sensitive) and Brown Norway (EAE fully resistant) rats before and every other day after treatment with guinea pig spinal cord homogenates (GP) or bovine serum albumin (BSA), together with Freund adjuvant and Bordetella Pertussis. At the same time intervals, also tumor necrosis factor (TNF_α) release from splenocytes was measured. In Lewis rats BE increased after GP or BSA in all the brain areas studied, peaked on days 12/14 and declined by day 21. Increases were significantly higher after GP than BSA. A minor increase with the same time pattern was also present in Brown Norway rats. SP concentrations showed a reverse pattern, with nadir on day 12/14. In LC, BE concentrations increased on day 6 after immunization with GP or BSA and returned to normal values thereafter. TNF_α release from splenocytes increased significantly on days 10 and 12 only in Lewis rats. No correlation was found with clinical scores of the disease, but chronic treatment with the opiate receptor antagonist naltrexone starting on the day of immunization aggravated the clinical scores. The data presented are consistent with an inhibitory role for BE on the immune system and on the development of EAE.

424.16

TRANSACTIVATION OF NEUROPEPTIDE GENE EXPRESSION BY HTLV-1 TAX IS DEPENDENT UPON ENKCRE-2/AP-1 BINDING ELEMENT. K. G. Low*, G. M. Daniels†, M. J. Comb and M.H. Melner†. Laboratory of Molecular Neurobiology, Massachusetts General Hospital, Charlestown, MA 02129. †Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Human T-cell leukemia virus type 1 (HTLV-1) is responsible for adult T-cell leukemia. Transactivation of viral and cellular genes by HTLV-1 is dependent upon interactions between a viral *tax* protein and cellular transcription factors. In transactivation assays using human Jurkat T-lymphocytes, Tax transactivates basal expression of proenkephalin (PENK) and proopiomelanocortin (POMC) genes 3- and 4-fold respectively. Treatment with 7 μg/ml concanavalin A, 500 μM cpt-cAMP or 10 ng/ml TPA enhanced Tax-dependent transactivation of PENK gene transcription between 40- to 70-fold. Deletion analysis of the human PENK gene promoter suggests that a region between -104 to -86 (relative to the start site of transcription initiation), which contains two consensus cAMP-responsive elements (CREs), mediates Tax-dependent trans-activation of PENK gene transcription. Further deletion analysis of this region identifies ENKCRE-2 (-92 to -86)(also a consensus AP-1 binding element) as responsible for mediating the Tax-dependent transactivation. Transactivation assays with CAT reporter constructs comprising multiple copies of ENKCRE-1 and/or ENKCRE-2 confirms that ENKCRE-2 but not ENKCRE-1 is responsible for mediating the effects of Tax. These results implicate an involvement of members of the AP-1 family of transcription factor proteins in mediating the transactivation of PENK gene transcription by Tax during HTLV-1 leukemogenesis.

MORPHOLOGICICAL CHANGES IN THE HIPPOCAMPUS OF THE CONGENITALLY ATHYMIC (nu /nu) MOUSE. K.C. Prasad, *G.O. Gaufo*, J.A. Reyes, and M.C. Diamond*. Department of Integrative Biology and *Group in Endocrinology*, University of California, Berkeley, CA 94720

Preliminary data in our laboratory show morphological differences in the hippocampus of 120-day old, female homozygous nude (nu /nu) and balb/c (balb/c/balb/c) mice. Measurements of thionine stained sections of the hippocampus corresponding to CA1 and CA2 + CA4 were taken from nude (N=13) and balb/c (N=9) mice.

Our results indicate that the hippocampus in both the right and left hemispheres of the brain was significantly thinner in the nude than in balb/c mice. In the right hemisphere, the CA1 hippocampal region was thinner by 5.4% ($p<0.03$) and the CA2 + CA4 region thinner by 17.6% ($p<0.02$) in the nude mouse compared to the balb/c. In the left hemisphere, the CA1 region was thinner by 5.1% ($p<0.02$) and the CA2 +CA4 region thinner by 11.4% ($p<0.05$) in the nude compared to the balb/c mouse.

We are continuing to investigate cerebral cortical and hippocampal morphology in female nude and balb/c mice with the addition of the heterozygous nude (nu/balb/c) mice as a control. Our purpose is to gain insight on regulatory hormones or factors that may be involved in mediating the deficiencies observed in brain morphology. We are approaching this problem by grafting thymic and/or pituitary tissue in 3-week old, female homozygous nude mice. Using radioimmunoassay, we will obtain serum levels of prolactin, the primary hormone released from extrapituitary graft, corticosterone, and thyroid hormones (T4 and T3). In addition, we will observe changes in CD4 and CD8 lymphocyte population using fluoroscence-activated cell sorter (FACS) in the different experimental groups.

MITOGEN-STIMULATED SPLENOCYTES ENHANCE EPINEPHRINE (E) RELEASE FROM CHROMAFFIN CELLS S.B.Jones, M.Weber, H. Mathews, J.A. McNulty* and Z. Wang. Loyola University Medical Center, Maywood, IL. 60153.

Enhancement of peripheral catecholamine release from nerve terminals and the adrenal medulla has been suggested to occur during septic shock using whole-animal experiments. Since mononuclear cytokine expression is an important response to sepsis, the present study tested possible neuroendocrine-immune-interactions in vitro by examining the effect of mitogen-stimulated mononuclear cells on catecholamine secretion from chromaffin cells. Chromaffin cells, isolated from bovine adrenals with collagenase digestion, were maintained in 2 cm^2 wells 4-5 days with DMEM and F12 with 10% FCS in 5% CO_2 at 37 C (0.6 x 10^6 cells/well, 1.0 ml). Splenocytes were isolated from bovine spleen and cultured in RPMI with 10%FCS (1.5x10^6 cells/ml) and stimulated with 0.5% phytohemagglutinin (PHA). After 24 hrs. PHA-conditioned media (PHA+) was isolated and frozen. In secretion experiments chromaffin cell growth media was replaced with conditioned (or control) media and E release was measured at variable times. After removal of PHA+ (or control) media, cells underwent nicotinic stimulation (3μM Dimethylphenylpiperazinium) for 10 min. E released was measured and E remaining in cells was determined. Secretion is % of initial E content. After 90 min with PHA+ media, E secretion increased to 19.1$\pm$0.5% of total ($P<0.05$ vs other treatments) compared to 5.2$\pm$0.3% for PHA-extract, 3.3$\pm$0.8% for media + PHA, and 3.7$\pm$0.5% for media alone (N= 4 chromaffin cell preparations). E secretion was 25% by 210 min with PHA+. E release was dose-dependent. Nicotinic stimulation resulted in 5.6$\pm$0.6% release in E after 90 min with PHA+ ($P<0.05$ vs all other treatments) compared to 3.1$\pm$0.3% for PHA-, 2.7$\pm$0.2% for media + PHA and 2.4$\pm$0.4% for media alone (N=4 chromaffin cell preparations). Enhanced nicotinic secretion was also dose-dependent. The results support the concept that sympathetic response to sepsis is in part due to peripheral modulation of catecholamine secretion. (Supported by the Bane Foundation)

NEURONAL-GLIAL INTERACTIONS: CONDITIONED MEDIUM FROM DEVELOPING GLIA INFLUENCES LHRH NEURON MORPHOLOGY, PROLIFERATION AND SECRETION

F. Gallo*, R. Avola, A. Costa and B. Marchetti. Depts of Pharmacology and Biochemistry, Medical School, University of Catania, 95125 Catania, Italy.

Astrocytes are involved in differentiation , migration and maturation of neurons and establishment of appropriate axonal connections. The immortalized hypothalamic neuronal cell line (GT1-1 subclone) recently developed by genetically targeting the expression of the simian virus-40 large T-antigen in the LHRH neurons (Mellon et al. 1990, Neuron 5: 1-10), was used in the present study to address the question of whether products released by glial cells during development might influence LHRH neuronal activity. For this end, an experimental design in which maturing astroglial cells, in the absence or the presence of growth factors, were maintained in culture and the effect of the conditioned medium (CM) assessed on proliferation and secretion of LHRH neuronal cells. Results of this study show that treatment of GT1-1 cell line with CM from astroglial cell cultures at different stages of differentiation and maturation promotes marked changes in the morphology, proliferative and secretory capacities of the LHRH neuron. At early stages of differentiation and in the absence of growth factors, glial cells release inhibitory signals which produce a 50% inhibition of GT1-1 cell proliferation and a 5-fold decrease of basal LHRH output. At later stages of differentiation , a 2-fold stimulation of proliferation and 70% increase in basal LHRH release were observed, suggesting that paracrine communications between LHRH neurons and glial cells might participate in dynamic regulation of LHRH activity.

EFFECT OF IONIZING RADIATION ON RAT'S HIPPOCAMPAL NOREPINEPHRINE RELEASE.

S. B. Kandasamy*, S. Blakely, T. K. Dalton and A. H. Harris. Behavioral Sciences Department, Armed Forces Radiobiology Research Institute, Bethesda, MD 20889-5145.

The purpose of this study was to examine the effect of ionizing radiation on hippocampal norepinephrine (NE) release in vitro, stimulated by KCl 0.5 h, 24 h, 48 h, 72 h after irradiation/sham exposure. Rats were irradiated using a ^{60}Co source. The levels of NE were measured by HPLC coupled to electrochemical detection. There was no significant change in NE release between irradiated and nonirradiated rats when the hippocampal NE was determined after 0.5 h irradiation (5-30 Gy at 10 Gy/min) or sham exposure. However, there was a significant decrease in NE release 48 h, and 72 h after irradiation (10 Gy at 10 Gy/min). Pretreating rats with 3-10 μg/kg of recombinant human interleukin-1β (rhIL-1β) or 3-10 μg/kg of corticotropin releasing factor (CRF) administered IP 1 h before sham irradiation enhanced hippocampal NE release and the same treatment prevented the radiation-induced decrease in NE release 48 h after irradiation. These results suggest that ionizing radiation induces decrease in hippocampal NE release 24 h, 48 h, and 72 h after exposure and pretreatment with rhIL-1β or CRF prevents the decrease.

424.21

TIME COURSE OF CENTRAL VARIATIONS OF 5HT AND DA METABOLISM ASSOCIATED WITH A PRIMARY IMMUNE RESPONSE TO SHEEP RED BLOOD CELLS.

A.M. Gardier*[1], S. Kachaner[1], C. Bohuon[2], C. Jacquot[1] and M. Pallardy[2]. [1]Dept. Pharmacol., [2]Dept. Toxicol., Fac. Pharmacie, Chatenay-Malabry 92296, France.

Antigenic challenge is known to influence hypothalamic norepinephrine activity. In the present study, we have investigated the changes of central dopamine (DA) and serotonin (5-HT) activities at 2, 4, 8, 24, 48 and 96 hr following immunization with sheep red blood cell (SRBC) i.v. A plaque forming cell assay was performed at 96 hr which corresponds to the peak of the production of specific antibodies in Fischer 344 male rats. Major central changes were only evident 8 hr after the primary immune response to SRBC. At this time, striatal DOPAC (+43%) and DA (+17%) levels were significantly increased. 24 hr after SRBC inoculation, hypothalamic DA (+30%), 5-HIAA (+16%) and 5-HT (+19%) levels were significantly increased. 48 hr after SRBC inoculation, cortical DOPAC (-24%) and 5-HIAA (-10%) levels were significantly decreased. 96 hr after SRBC inoculation, hypothalamic 5-HT (-14%) and tryptophan (-10%) levels were significantly reduced, but cortical 5-HT (+11%) and 5-HIAA (+14%) levels were increased. In contrast, no changes occurred in the hippocampus and striatum at 96 hr following primary immunization. Thus, peripheral activation of the immune system induced opposite effects on central 5-HT metabolism at 96 hr, i.e., when the splenic immune response is maximal. These data suggest that further *in vivo* microdialysis studies comparing hypothalamic and cortical 5-HT release should be of particular interest.

NEURAL-IMMUNE INTERACTIONS: INTERLEUKIN-1

425.1

BRAIN INTERLEUKIN-1 (IL-1) ENHANCES NOCICEPTION IN THE RAT.

T. Hori*, T. Oka and S. Aou. Dept. of Physiology, Kyushu University Fac. of Med., Fukuoka 812, Japan.

IL-1 has been shown to play a role in local inflammatory and immune mediated diseases, which are associated with local pain. IL-1β, when given systemically or locally, produces hyperalgesia in rats and rabbits. This hyperalgesia is generally thought to be mediated through increased PGE2, but a prostaglandin-independent mechanism is also pointed out. On the other hand, brain astrocytes and microglia are also known to synthesize IL-1, and such brain-derived IL-1 produces a variety of CNS-mediated responses such as fever.

To determine whether brain IL-1 affects nociceptive function, we investigated the effects of human recombinant IL-1β (rhIL-1β) on nociception in male Wistar rats. The paw lick latency on a hot plate (50±0.5 ℃) was measured before and after LCV injection of rhIL-1β (1pg-1μg/kg). LCV injection of rhIL-1β (1-100pg/kg) dose-dependently reduced the paw lick latency. The hyperalgesic action started 5min after the injection, reached a maximum at 30min and was still observed at 60min. This effect was antagonized by pretreatment with either an IL-1 receptor antagonist, αMSH or salicylate, but not by α helical CRF. An electrophysiological study performed in urethane (1.2g/kg) anesthetized rats revealed that responses of neurons in the spinal trigeminal nucleus to nociceptive stimuli were enhanced by LCV rhIL-1β (10-100pg/kg) with similar time courses as that of the paw lick latency responses. This enhanced responses of nociceptive neurons was also attenuated by αMSH. The results suggest that brain IL-1β induces hyperalgesia through an activation of arachidonate metabolism, but not by that of CRF system.

425.2

INTERLEUKIN-1 DID NOT INDUCE ANALGESIA IN THE RAT HOT-PLATE OR COLD WATER TAIL-FLICK TESTS.

Jill U. Adams, Jeanine L. Bussiere*, Ellen B. Geller and Martin W. Adler, Dept. of Pharmacol., Temple Univ. Sch. of Med., Phila., PA 19140.

There are a few reports in the literature that interleukin-1 (IL-1) induces analgesia (Nakamura *et al.*, Eur.J.Pharmacol.149:49,1988; Bianchi *et al.*, Brain Res.546:139,1991). The present study sought to characterize the analgesic effects of centrally administered IL-1 in rats. In the hot-plate test (HP), latency to a rear paw lick or a four-footed jump off a 55°C surface was measured; in the cold water tail-flick test (CWT), latency to tail withdrawal from a ~3°C liquid was timed. Core body temperature was also monitored with a rectal thermistor. After baseline readings, human recombinant IL-1ß (125-2000 U) was injected in 5 μl phosphate-buffered saline with 0.1% bovine serum albumin, and post-drug measures were recorded at intervals from 5-180 min. In the HP, no dose of IL-1 induced greater than 6.1 (±4.4) % maximum possible analgesia (%MPA) at any time point. Similarly, in the CWT, 7.3 (±2.8) %MPA was the largest result. However, dose-related increases in body temperature were observed, with a 1.7 (±0.15) °C rise 120 min after 1000 U IL-1. Since IL-1 alone did not induce analgesia, we tested its capacity to potentiate morphine analgesia. Morphine (5.0 and 10 μg, icv) induced analgesia in the CWT (35.1 and 84.1 %MPA); however, there was no significant effect of IL-1 on morphine-induced analgesia. In summary, we failed to find an analgesic effect of IL-1, alone or in combination with morphine, at doses which clearly had a physiological effect; this is in contrast to the reports cited above.

SYSTEMIC ADMINISTRATION OF INTERLEUKIN-1ß RESULTS IN INCREASED LEVELS OF NGFI-B mRNA IN THE ENDOCRINE HYPOTHALAMUS AND ITS MEDULLARY AFFERENTS. Anders Ericsson, D.G. Amaral* and P.E. Sawchenko. The Salk Institute for Biological Studies, La Jolla, CA 92037.

NGFI-B, a protein related to the steroid receptor superfamily, is rapidly and transiently synthesized in neurons and PC 12 cells in response to a number of physiological and pharmacological stimuli. In the present study we have analysed the distribution of NGFI-B mRNA in rat brain at varying intervals following intravenous (iv) injection of interleukin-1ß (IL-1ß) or vehicle alone. Constitutively high levels of NGFI-B mRNA expression were localized primarily to telencephalic structures of both unperturbed and vehichle-injected rats; in the hypothalamus, only the suprachiasmatic nucleus displayed detectable basal levels of NGFI-B expression. In contrast, iv injection of IL-1ß (1.87 µg/kg) resulted in an apparent induction of NGFI-B mRNA in the magnocellular and parvocellular divisions of the paraventricular nucleus (PVN) as well as in the supraoptic (SON) nucleus, with peak levels seen at 1 hr postinjection. Specific, though less marked, increases of NGFI-B mRNA were also detected in a number of cell groups that provide afferent projections to the neurosecretory hypothalamus, including the caudal part of the nucleus of the solitary tract, the rostral and caudal parts of the ventrolateral medulla, the lateral division of the bed nucleus of the stria terminalis, and the central nucleus of the amygdala. Ablation methods were used to assess the potential role of ascending projections in mediating IL-1ß effects on the NGFI-B mRNA in the hypothalamus. Discrete unilateral knife cuts at medullary levels that resulted in a marked depletion of the catecholaminergic innervation of the PVN and SON on the ipsilateral side, also virtually eliminated the hypothalamic NGFI-B mRNA responses on the lesioned side to systemic administration of IL-1ß. These data are congruent with the temporal and spatial patterns of *c-fos* expression that we have observed following iv injection of IL-1, and suggest that the integrity of ascending afferents is necessary for the functional activation of multiple neurosecretory cell types commonly seen in response to systemic cytokine challenges.

425.4

INTERLEUKIN-1 (IL-1) INDUCED EXPRESSION OF INTERCELLULAR ADHESION MOLECULE-1 (ICAM-1) IS ANTAGONIZED BY A SOLUBLE IL-1 RECEPTOR. L. Imeri°*, M.R. Opp, L. Hong and J.M. Krueger. Department of Physiology and Biophysics, University of Tennessee, Memphis TN 38163 and °Institute of Human Physiol. II, University of Milan, Milan, Italy.

Intercellular adhesion molecule-1 (ICAM-1) is a cell surface glycoprotein of the immunoglobulin superfamily. It is a specific ligand for lymphocyte function-associated antigen-1. These two molecules are involved in the control of lymphocyte migration. ICAM-1 expression is induced by certain cytokines including IL-1ß. In the present study the effects of a recombinant human soluble IL-1 receptor (sIL-1r) on IL-1ß induced expression of ICAM-1 in a human glioblastoma cell line (HTB 16) were evaluated. Cells were incubated for 4 days with various concentrations of recombinant human IL-1ß (0.1/1/10/100/1000 pg/ml) in the absence or presence of the sIL-1r (1 and 10 µg/ml). An ELISA test was used to quantitate ICAM-1 expression. IL-1ß induced ICAM-1 expression in a dose-related manner. Both doses of sIL-1r significantly attenuated IL-1ß induced expression of ICAM-1; the higher dose was more effective. The present findings suggest that sIL-1r can act as an antagonist to IL-1.

sIL-1r was a generous gift from Immunex (Seattle, WA). LI was partially supported by ARIN (Associazione Italiana per la Ricerca Neurologica). Supported in part by NS25378.

POSSIBLE INVOLVEMENT OF INTERLEUKIN-1β IN NEURONAL CELL DEATH AFTER TRANSIENT FOREBRAIN ISCHEMIA. M. Minami, K. Yabuuchi, S. Katsumata, Y. Tomozawa, Y. Kuraishi* and M. Satoh. Dept. of Pharmacol., Fac. of Pharm. Sci., Kyoto Univ., Kyoto 606, Japan.

The expression of interleukin-1β (IL-1β) mRNA in the hippocampus and other brain regions (cerebral cortex, striatum and thalamus) was examined after transient forebrain ischemia using male Wistar rats. IL-1β mRNA was not detected in these regions of sham-operated rats. IL-1β mRNA was induced after transient forebrain ischemia. The induction of IL-1β mRNA had a few peaks, that is, peaks were observed at 30 and 240 min in the four regions examined and an additional peak was observed at 90 min in the striatum.

In addition, the effect of intracerebroventriculer injection of IL-1β on neuronal cell death after transient forebrain ischemia was examined in the hippocampus. Seven days after 10 min of ischemia, the number of neurons in the hippocampal CA1 region of saline-injected rats was decreased to 20-30% but the number of neurons in the hippocampal CA3 region did not change, compared with non-treated rats. Injection of IL-1β (30 ng/rat) during the ischemic insult potentiated the neuronal cell death. The numbers of neurons in the CA1 and CA3 regions decreased to 10-20% and 30-40% of non-treated control rats, respectively.

These results suggest that IL-1β might be produced in the brain after transient forebrain ischemia and was involved in neuronal cell death.

425.6

HYPOTHALAMIC AND HIPPOCAMPAL MONOAMINE ALTERATIONS AFTER PERIPHERAL INTERLEUKIN-1, -2 OR -6 ADMINISTRATION IN MICE. S. Zalcman*, J. Green-Johnson, L. Murray, D. Dyck, H. Anisman and A. Greenberg. Manitoba Institute of Cell Biology, Winnipeg, MB, Canada R3E 0V9.

Central monoamines vary during the course of the immune response to sheep red blood cells. Inasmuch as IL-1 has been shown to induce similar amine variations, we assessed the neurochemical consequences of IL-1 in parallel with the cytokines IL-2 and IL-6, which are released during an ongoing immune response. BALB/c mice received an injection of either recombinant human (rHu)IL-1ß, rHuIL-2 or rHuIL-6 (0.2 ug, ip) and 2 hr later were sacrificed and brains removed for HPLC determinations. IL-1ß increased hypothalamic and dorsal hippocampal MHPG/NE ratios by increasing the utilization and reducing the content of NE in these regions. These effects, however, were evident in about half of the subjects. In contrast, IL-2 enhanced hypothalamic MHPG/NE ratios by profoundly increasing MHPG accumulation without altering NE levels. IL-2 did not appreciably alter hippocampal NE activity and IL-6 did not alter NE activity in either region. Moreover, IL-1ß and IL-6 markedly enhanced accumulation of the serotonin metabolite, 5HIAA in the dorsal hippocampus.

The cytokines differentially influenced plasma corticosterone (CORT). Whereas IL-1ß greatly elevated CORT, IL-2 and IL-6 did not appreciably alter CORT levels. These latter observations coupled with the cytokine-induced NE alterations in the hypothalamus suggest that the IL-1ß induced CORT increases were independent of hypothalamic NE turnover. DIFFERENTIAL MODULATION OF DISCHARGE PATTERN IN SYMPATHETIC OUTFLOWS TO THE KIDNEY AND THE BROWN ADIPOSE TISSUE BY INTERLEUKIN 1ß IN CONSCIOUS RATS. H.Kannan[1]*, C-K.Su[3], H.Tanaka[1], Y.Ueta[1], C.Y.Chai[3], Y.Hayashida[2] and H.Yamashita[1]- Dept. Physiol[1]., and Dept. Systems Physiol[2]., Univ. Occup. Environ. Health, Yahatanishiku, Kitakyushu, 807 Japan, and Institute of Biomedical Sciences[3], Academia Sinica, Taipei 115, Republic of China.

We have reported that either i.v. or i.c.v. administration of interleukin 1ß(IL-1ß) elicited an increase in renal sympathetic nerve activity(RSNA) accompanied with increases in blood pressure, heart rate and body temperature in conscious rats (Kannan et al., Soc. Neurosci. Abstr. 17: 1198,1991). The present study was conducted to examine the effects of i.v. injection of IL-1ß on discharge pattern in sympathetic nerves innervating the interscapular brown adipose tissue(IBAT), and compare them with those of RSNA in conscious rats. The IBAT sympathetic nerve activity was increased by IL-1ß with an increase in large grouped discharges synchronous with the cardiac cycle. In contrast, small amplitude activity unrelated to the cardiac cycle increased in RSNA, while large amplitude grouped discharges decreased. Plasma noradrenaline concentration increased in conscious rats after i.v. injection of IL-1ß. The responses were abolished by pretreatment of indomethacin. The results suggest that IL-1ß activates systemic sympathetic outflow via prostaglandins , and modulates the discharge patterns in regional different manner.

425.8

INTERLEUKIN-1 RECEPTOR AND ANTAGONIST IN THE RAT HYPOTHALAMUS AND PITUITARY. M. Schultzberg*, T. Bartfai, J. Bristulf, S. Nobel, A. Simoncsits and S. Tingsborg. Clinical Research Center, Karolinska Institute, Huddinge Hospital and Dept. of Biochem, Stockholm Univ., Stockholm, Sweden.

The cytokine interleukin-1 (IL-1) has been shown to stimulate release of hypothalamic and pituitary hormones, notably with resulting increase in corticosterone production. The present studies investigate the possible occurrence of the endogenous IL-1 receptor antagonist (IL-1ra) in the rat central nervous system, and further analyze the finding of IL-1 receptor (IL-1R) in the rat pituitary gland. Antisera against synthetic peptides of the human monocyte IL-1ra and murine lymphocyte IL-1R were used in immunohistochemistry, and polymerase chain reaction (PCR) technique was used to detect IL-1R and IL-1ra mRNA. In addition to the intense immunoreaction in the cells of the intermediate lobe of the pituitary seen with antisera to the second loop of the extracellular domain of the IL-1R protein, recent bleedings of these antisera stained varicose nerve terminals in the neural lobe. An even denser network was stained with an antiserum to IL-1ra, whereas the cells of the intermediate lobe were negative. In the hypothalamus both IL-1R and IL-1ra immunoreactive neurons were seen in the paraventricular (PVN) and supraoptic nuclei and in nerve terminals in the median eminence. PCR analysis confirmed the synthesis of IL-1ra in the hypothalamus. These findings indicate that IL-1R and IL-1ra may be synthesized in PVN neurons projecting to the neural lobe. Experiments are carried out to verify this, to identify which population(s) of PVN neurons the two proteins occur in, and their functional regulation. This work was supported by grants from the Swedish MRC and Clas Groschinsky's Minnesfond.

MEASUREMENT OF INTERLEUKIN-1 BETA (IL-1β) IN RODENT BRAIN-ENDOCRINE-IMMUNE TISSUES USING A MODIFIED SANDWICH ELISA. S. G. Culp*, R. C. Newton, T. Takao and E. B. De Souza. CNS Diseases Research & Inflammatory Diseases Research, The Du Pont Merck Pharmaceutical Co., Wilmington, DE 19880.

We have developed a modified sandwich ELISA to detect the cytokine IL-1β in mouse and rat tissues and fluids that utilizes a specific rabbit immunoglobulin (Ig) and a polyclonal antibody to the IL-1β peptide. ELISA sensitivity was ~ 1 pg, the inter- and intra-assay variabilities were < 6% CV, and the range was 1 - 2,000 pg. The ELISA detects both mouse and rat IL-1β, exhibits a lower reactivity to human IL-1β and a human IL-1β clone extended by three amino acids, and shows no cross-reactivity to human IL-1α, human and rat IL-1 receptor antagonist, human tumor necrosis factor α, somatostatin, vasoactive intestinal peptide, and a variety of unrelated peptides. Commercially available ELISA amplification kits did not alter the sensitivity but did increase the resolution at the lower peptide concentrations. IL-1β levels in normal mouse were 7.09 ± 1.65 pg/mg tissue in spleen and 0.36 ± 0.17 pg/mg tissue in testis; IL-1β levels were detectable in plasma, hypothalamus and hippocampus. Robust increases in IL-1β tissue levels were observed in mouse spleen and testis (6 and 15 fold respectively) six hours after injection of lipopolysacharide (LPS) (1 mg/kg, i.p.). Similar, albeit smaller changes, were observed in rat spleen and testis six hours after LPS injection (2 mg/kg; i.p.). In summary, we have developed a sensitive and specific ELISA for detection of rat or mouse IL-1β. This assay should allow the further investigation of the role of IL-1 in regulating brain-endocrine-immune interactions.

SPECIES DIFFERENCES IN INTERLEUKIN-1 RECEPTORS IN THE BRAIN-ENDOCRINE-IMMUNE AXIS. T. Takao* and E. B. De Souza, CNS Diseases Research, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880

Previous studies utilizing ^{125}I-recombinant human interleukin-1α (^{125}I-IL-1α), ^{125}I-IL-1β and ^{125}I-IL-1 receptor antagonist have identified high affinity binding sites for IL-1 in the mouse brain and endocrine tissues with characteristics of Type I receptors in T lymphocytes. In a preliminary study, there were dramatic species differences in the level of ^{125}I-IL-1α binding with high levels of binding present in mouse and rabbit tissues (hippocampus, spleen and testis), while ^{125}I-IL-1α binding to rat and guinea pig tissues was not detectable. In the present study, we further characterized IL-1 binding in mouse and rat tissues and selective immune cell lines. Utilizing 100 pM or 600 pM ^{125}I-IL-1α, moderate to high levels of specific binding were observed in EL-4 6.1 cells (representative of Type I IL-1 receptors) and in mouse tissues, however, no specific ^{125}IL-1α binding was present in Raji cells (representative of Type II IL-1 receptors) and in rat tissues. On the other hand, utilizing 600 pM ^{125}I-IL-1β as a ligand, high specific IL-1 binding was shown in EL-4 6.1 and Raji cells and moderate binding was evident in mouse tissues, whereas specific ^{125}I-IL-1β binding to rat tissues was barely within the range of sensitivity of the assay. These data demonstrate that under optimal conditions for labeling Type I or Type II IL-1 receptors, no specific binding is observed in rat tissues suggesting the presence of novel IL-1 receptor(s) in rat tissues.

425.11

CYCLIC AMP-DEPENDENT MODULATION OF INTERLEUKIN-1 RECEPTORS IN THE MOUSE AtT-20 PITUITARY TUMOR CELL LINE. E. B. De Souza*, D. E. Tracey and T. Takao, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880 (E.B.D.S. and T.T.) and The Upjohn Company, Kalamazoo, MI 49007 (D.E.T.)

The cytokine interleukin-1 (IL-1) has a variety of effects in brain involving induction of fever, alteration of slow-wave sleep and alteration of neuroendocrine activity. Previous studies utilizing ^{125}I-recombinant human interleukin-1α (^{125}I-IL-1α) have identified high affinity binding sites for IL-1 in brain and endocrine tissues and in mouse AtT-20 pituitary tumor cells with characteristics of Type I receptors in T lymphocytes. Recently, an upregulation of IL-1 receptors in mouse AtT-20 cells following treatment with corticotropin-releasing factor (CRF) has been demonstrated. In the present study, we utilized various secretagogues to further determine the modulation of IL-1 receptors in mouse AtT-20 pituitary tumor cell culture. CRF, isoproterenol (ISO) and forskolin (FSK) increased ^{125}I-IL-1α binding in a dose-dependent manner in mouse AtT-20 cells; in preliminary studies dexamethasone (DEX; 10^{-7}M) and somatostatin (SMS; 10^{-7}M) did not alter ^{125}I-IL-1α binding. Treatment of CRF (10^{-7}M) + FSK (10^{-5}M) and CRF (10^{-7}M) + ISO (10^{-7}M) showed the synergistic increases in ^{125}I-IL-1α binding, while CRF (10^{-7}M) + DEX (10^{-7}M) and CRF (10^{-7}M) + SMS (10^{-7}M) has no synergistic effects. These data demonstrating effects of agents (CRF, ISO, FSK) that stimulate cAMP production in AtT-20 cells on upregulation of IL-1 receptors suggest the importance of this second messenger in modulating IL-1 receptors.

CARDIOVASCULAR REGULATION: LOWER BRAINSTEM I

426.1

PHYSIOLOGICAL MECHANISMS BY WHICH CENTRAL APPLICATION OF ENDOTHELIN-1 (ET-1) REDUCES CARDIAC OUTPUT (CO). T. R. LaHann*, G. Hematillake and G. Daniell. Dept. Pharm. Sci., Idaho State University, Pocatello, ID 83209

CO in the anesthetized rat is dramatically reduced 5-7 minutes after local application of pmole amounts of ET-1 to the ventral surface of the medulla (VSM). VSM application of vehicle or other pressor agents failed to mimic ET-1's effect on CO, suggesting that the drop in CO was a specific effect of ET-1 and not related to changes in medullary perfusion. Changes in CO might reflect changes in heart rate (HR), afterload, preload or cardiac contractility. Studies were undertaken to determine how VSM application of ET-1 affected each of these parameters. HR and total peripheral resistance (a measure of afterload) were little changed following VSM application of ET-1. Marked decreases in peak stroke output and left ventricular dP/dt after VSM application of ET-1 suggest a decrease in cardiac contractility. Left ventricular end-diastolic pressure and central venous pressure showed little change following VSM application of ET-1. These data are consistent with the hypothesis that central application of ET-1 decreases CO by causing a sustained decrease in cardiac contractility.

426.2

CENTRAL CARDIOVASCULAR EFFECTS OF JOINING PEPTIDE. T.Hamakubo, M.Yoshida, T.Watanabe[1], K.Nakajima[1], R.Mosqueda-Garcia, T.Inagami*, Departments of Biochemistry and Pharmacology, Vanderbilt University, Nashville, TN 37232; Peptide Institute[1], Osaka, Japan

Joining peptide (JP), one of the major products of proopiomelanocortin, is present in the hypothalamus and the pituitary. The biological relevance of this peptide, however, has not been identified. In the present study we characterized the central hemodynamic effects of JP. Rat JP C-terminal amide form (rJP) and bovine JP (bJP) were synthesized according to the deduced amino acid sequence. Wistar-Kyoto (WKY) and spontaneously hypertensive rats (SHR) were anesthetized with urethane and blood pressure (BP) and heart rate (HR) were recorded intraarterially. The animals were placed in a stereotaxic frame and the dorsal surface of the medulla was exposed through a limited occipital craniotomy. In a group of animals, a catheter was placed into the cisterna magna for intracisternal administration of either rJP or bJP (10-50nmols/5μl). In a different group of rats, a glass micropipette was positioned in the nucleus of the solitary tract (NTS) for microinjection of rJP (20 pmoles/30 nl). Intracisternal injections of rJP in SHR increased mean BP and HR in a dose dependent manner. Maximal effects were seen at 50 nmols (22±2 mmHg and 36±10 bpm, n=6). Whereas similar effects were observed with bJP, intravenous administration of either peptide had no effect. In WKY, rJP or bJP were less potent to increase BP and HR. Microinjection of rJP into the caudal region of NTS increased BP by 15±2 mmHg and HR by 37±5 bpm (n=9). Maximal changes in BP occurred at 5 min and recovered within 20 min. The maximal HR response occurred 6 min after microinjection. In 2 of 9 rats the pressor effect was preceded by hypotension and bradycardia. These results suggest that JP is a neuropeptide with important central cardiovascular effects in hypertensive animals.

426.3

AREA POSTREMA STIMULATION INHIBITS RENAL SYMPATHETIC DISCHARGE IN THE ANESTHETIZED RAT. R.B. Felder,* A.L. Pence, L.F. Hayward, College of Medicine, University of Iowa, Iowa City, IA 52242.

Area postrema neurons respond to circulating neurohumoral substances and may play an important role in cardiovascular regulation. We examined the effects of area postrema (AP) stimulation on mean arterial pressure (MAP), heart rate (HR) and renal sympathetic nerve activity (RSNA) in 8 urethane anesthetized Sprague Dawley rats with aortic and carotid sinus nerves sectioned. AP was stimulated at low intensity (40 uA, 0.2 ms, 40 Hz) in the midline along its rostral-caudal axis. Penetrations were separated by .2 mm. Stimulation was carried out on the surface of AP and at .2 mm increments to a depth of .8 mm. Stimulation at the surface (n=9) or at .2 mm depth (n=1) decreased sympathetic discharge (164±10.4 to 138.5±10.2 imp/sec; mean±SE; $p<0.05$) without affecting blood pressure or heart rate. At .2 mm depth (n=8) stimulation elicited significant ($p<0.05$) reductions in blood pressure (100±6 to 90±6 mmHg) and renal nerve activity (155±11 to 109±13 imp/sec). There was no change in heart rate. Similar effects were observed at sites .2 mm lateral to midline. Ventral to .2 mm, a pressor response was usually elicited and became more pronounced at deeper stimulation sites. Prominent depressor responses were also observed at deeper sites. Thus, the predominant effect of selectively stimulating AP neurons is a modest reduction in MAP and RSNA. These findings support a sympathoinhibitory influence of area postrema on cardiovascular reflex control.

426.4

AFFERENT NEURONS TO THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) IN THE RAT: RELATIONSHIP WITH CALBINDIN-D-28K IMMUNOREACTIVITY. A.R. Granata* and H. T. Chang† Departments of Pharmacology*, Anatomy and Neurobiology†, The University of Tennessee, Memphis, College of Medicine, Memphis, TN 38163

RVLM is an important center for cardiovascular control. Although many RVLM neurons express immunoreactivity for calbindin D-28k (CaBP), a Vitamin D-dependent calcium binding protein, the relationships between CaBP and the afferent neurons that project to RVLM, and that between CaBP and the RVLM adrenergic neurons have remained unclear. In this study, FluoroGold (FG) was injected into RVLM to retrogradely label neurons that project to the RVLM, and CaBP+ neurons were revealed by Texas Red immunofluorescence. Many FG labeled neurons were found in the brain, including regions that contain many CaBP+ neurons: the ipsilateral medio-caudal nucleus of the tractus solitarius, the medial vestibular nucleus, the contralateral RVLM, the central gray, the lateral parabrachial nucleus, the paraventricular nucleus of the hypothalamus, the posterior and the lateral hypothalamus, the substantia innominata, and the central amygdala. Only a minority of FG labeled neurons in these regions were CaBP+. On the other hand, the FG labeled neurons in many of these regions were found in close association with terminal fields immunoreactive for phenylethanolamine N-methyl transferase (PNMT), the synthetic enzyme for adrenaline. Our results indicate that while CaBP is not a major marker protein in neurons that project to the RVLM, CaBP+ neurons are found in terminal field of adrenergic fibers, and may be a marker for neurons that are targets of RVLM adrenergic neurons.

426.5

ROLE OF THE CAUDAL VENTROLATERAL MEDULLA IN REFLEX PRESSOR RESPONSES. I.C. Solomon, A.M. Motekaitis, J.R. Haselton*, and M.P. Kaufman. University of California, Div. of Cardiovascular Med., Davis, CA 95616

Previous studies have shown that the ventrolateral medulla plays a role in the central pathway of the reflex increase in arterial pressure evoked by static muscular contraction, peripheral nerve stimulation, and hypoxia. The role of the caudal ventrolateral medulla (CVLM) in these reflex arcs is not clearly defined. We therefore examined the role of the CVLM in these reflex arcs controlling arterial pressure in chloralose anesthetized cats. Increases in MAP were evoked by three stimuli: static muscular contraction elicited by ventral root stimulation (CONT), electrical stimulation of the sciatic nerve (ScN), and hypoxia (HYP). These changes were compared before and after bilateral microinjection of a broad spectrum glutamate antagonist, kynurenic acid (KYN) (100 mM, 50 nl), into the CVLM. We tested the hypothesis that bilateral microinjection of KYN into the CVLM potentiates the reflex pressor responses to the three stimuli used. The reflex increase in MAP produced by these stimuli were potentiated within 20-30 min following bilateral microinjections of KYN into the CVLM at sites 1.5 mm caudal to 0.8 mm rostral to obex. The reflex increase in MAP either returned to control levels (n=8) or remained augmented (n=10). In two cats, microinjections of KYN into sites very caudal to obex (> 2 mm) elicited either no effect or an attenuation of the reflex increase in MAP. These findings suggest that the reflex arc increasing MAP evoked by static muscular contraction, sciatic nerve stimulation, and hypoxia can be potentiated by blockade of glutamatergic receptors located in the CVLM.

VAGAL AND SPINAL MODULATION OF VENTROLATERAL MEDULLA NEURONAL RESPONSES TO RENAL STIMULI. M.A. Vizzard*, A. Standish and W.S. Ammons. Department of Physiology, Thomas Jefferson University, Philadelphia, PA 19107.

Recent experiments from this laboratory demonstrated that cells within the ventrolateral medulla of the cat respond to electrical stimulation of renal nerves and to activation of renal mechanoreceptors and chemoreceptors. The purpose of this study was to determine if these responses are mediated by spinal or vagal afferent pathways. The effect of bilateral cervical vagotomy on spontaneous activity, responses to renal nerve, somatic field and renal receptor stimulation of cells within the ventrolateral medulla was determined. Experiments were performed on 31 alpha-chloralose anesthetized and paralyzed cats (2.5-4.7kg). Bilateral cervical vagotomy decreased the evoked responses of 14/19 cells to electrical stimulation of renal nerves from 3.6±0.6 spikes/s to 2.4±0.4 spikes/s ($p<0.05$). Vagotomy decreased spontaneous activity of 8/14 cells from 5.5±1.8 impulses/s to 0.6±0.0 impulses/s ($p<0.05$), increased spontaneous activity of two cells and did not affect four cells. Bilateral cervical vagotomy increased the evoked response of 5 cells to electrical stimulation of renal nerves from 3.0±0.1 spikes/s to 4.8±1.2 spikes/s ($p<0.05$). Spontaneous activity of each cell also increased from 1.4±0.9 impulses/s to 3.9±0.9 impulses/s ($p<0.05$). Bilateral vagotomy never abolished cell responses to renal nerve stimulation. Five cells (26.3%) were responsive to renal artery occlusion; 1 cell was also responsive to ureteral occlusion. Vagotomy did not alter the responses. The response to renal nerve stimulation for 9 of 9 cells was completely abolished after spinal cord transection. Following spinal cord transection, the spontaneous activity of 7 cells was not significantly affected. Somatic field classification of each cell was unaltered and cell responses to somatic stimulation above the transection level were comparable or greater. The results of these experiments have demonstrated that renal afferent information to the ventrolateral medulla is conveyed via the spinal cord. In addition, the results are consistent with a tonic modulatory effect of the vagus nerve on ventrolateral medulla cell responses to renal stimuli.

SUPRAMEDULLARY INPUTS TO CARDIOVASCULAR NEURONS OF ROSTRAL VENTROLATERAL MEDULLA IN RATS. S.K. Agarwal+ and F.R. Calaresu* Dept. of Physiology, Univ. of Western Ontario, London, Ontario, Canada N6A 5C1 and +Playfair Neurosci. Unit, Toronto Hospital, Toronto, Ontario, Canada M5T 2S8

As neuroanatomical and stimulation studies suggest that neurons in the rostral ventrolateral medulla (RVLM) receive and integrate multiple inputs from supramedullary regions of the brain, experiments were done to test the hypothesis that selective activation of cell bodies in the lateral parabrachial nucleus (LPBN), locus coeruleus (LC) and lateral hypothalamic area (LHA) could excite or inhibit the discharge of neurons in the RVLM. We therefore recorded extracellular activity from RVLM units in urethane anaesthetized rats and monitored the changes in firing frequency of these neurons during chemical stimulation of one of LPBN, LC and LHA. Thirtytwo neurons were classified as cardiovascular neurons because their activity was inhibited by baroreceptor activation (1-3 µg phenylephrine i.v.) and displayed a cardiac cycle related rhythmicity. Chemical stimulation with glutamate of arterial pressor sites in the LPBN increased the firing rate (40.3 ± 1.3 %) of 11 (100 %) cardiovascular neurons. Activation of cell bodies in arterial depressor sites in the LC inhibited the firing frequency (59.1 ± 7.1 %) of 10 (91 %) cardiovascular neurons and excited one unit. Activation of cell bodies in arterial depressor sites in the LHA inhibited the discharge rate (25.4 ± 4.7 %) of 6 (60 %) cardiovascular neurons, excited one unit and did not alter the rate of the remaining 3 units. These results provide direct evidence for convergence of excitatory and inhibitory inputs from neurons located in the LPBN, LC and LHA to cardiovascular neurons in the RVLM.

PARRALLEL AND INDEPENDANT PROCESSING OF SYMPATHETIC BARO- AND CHEMOREFLEXES IN THE MEDULLA OBLONGATA. N. Koshiya*, D. Huangfu and P.G. Guyenet. Dpt. of Pharmacology, University of Virginia, Charlottesville, Va 22908.

Splanchnic sympathetic nerve discharge (SND), phrenic nerve activity (PND) and putative vasomotor sympathetic premotor neurons of the rostral ventrolateral medulla (RVL PMNs) were recorded in urethan- anesthetized vagotomized rats without aortic baroreceptor afferents. Carotid chemoreceptor stimulation (CCSt) with brief N_2 inhalation increased SND by 101 ± 7%, raised MAP and increased the discharge rate of RVL premotor neurons by 46 ± 12% (N=32, range 50% inhibition to 200% activation). During chemoreceptor activation, SND and most RVL neurons displayed pronounced post- inpiratory rhythmicity. These experiments confirm that convergence between peripheral chemoreceptor and baroreceptor inputs to the central network responsible for SND generation occurs at or prior to the RVL premotor neuronal stage. Bilateral microinjection of kynurenic acid (Kyn, 5 nmol in 100 nl) into RVL blocked the sympathetic chemoreflex but left the sympathetic baroreflex intact (N=6). Conversely, bilateral microinjection of Kyn into the caudal ventrolateral medulla at obex level (CVL) blocked the baroreflex but left the sympathetic chemoreflex intact (N=5). These injections also left intact the oscillatory nature of the sympathoactivation produced by CCSt.

The effect of Kyn injection into CVL is attributed to blockade of the baroreceptor input to propriomedullary GABAergic cells of CVL with projections to RVL. These CVL cells are likely to be the last medullary relay of the sympathetic baroreflex before the premotor neuronal stage. Thus, the experiments suggest that the sympathetic chemoreflex and baroreflex utilize two separate and largely independant channels in the medulla until the RVL premotor neuronal stage where algebraic synaptic summation of the two inputs probably occurs.

INVESTIGATION INTO THE ROLE OF GLYCINE IN THE PRESSOR RESPONSE TO N-METHYL-D-ASPARTIC ACID (NMDA) INJECTED INTO THE SUBRETROFACIAL NUCLEUS (SRFN). B.Badio and P.J.Gatti*. Dept. Pharmacol., Howard Univ. Coll. of Med., Washington, D.C. 20059.

Recently, it has been shown that there is a glycine binding site associated with the NMDA receptor which facilitates NMDA responses. This site is insensitive to the classical glycine antagonist strychnine. We have shown that NMDA produces a pressor response when injected into the SRFN of the medulla. In this study, we have examined whether blockade of these glycine sites would affect the pressor response to NMDA injected into the SRFN. Adult cats (N=7) were anesthetized with alpha-chloralose 70mg/kg i.v. and a femoral artery was cannulated to measure arterial blood pressure (ABP). The animal was artificially ventilated with room air and the ventral surface of the medulla was exposed. Drugs (50nl) were microinjected into the SRFN of the medulla using glass micropipettes. Stimulation of SRFN with 1mM (N=3) and 10mM (N=4) NMDA produced an increase in ABP of 46±6.6 and 74±6.1 mmHg, respectively. This response could be repeated with no significant change in magnitude. HA-966, an antagonist of the glycine site on the NMDA receptor, was then microinjected into the SRFN and it had no effect on ABP per se. However, after HA-966, the pressor response to NMDA (1 and 10mM) was significantly attenuated to 10±6.9 and 42±6.7 mmHg respectively ($p<0.05$, Student's paired t-test). These data show the importance of the glycine site on the NMDA receptor in the NMDA-induced pressor response in the SRFN.Supported by AHA/NCA.

Effects of Serotonin on Ionic Currents of Nodose Neurons Co-Cultured with Cardiac Myocytes. **M. Hay* and D. L. Kunze. Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.** The effects of serotonin (5-HT) on the cardiopulmonary baroreflex function have been well established however the mechanisms of this action are not fully known. The primary afferent neurons for this reflex are found in the nodose ganglia. The purpose of the present study was to determine the effects of 5-HT on ionic currents recorded from peripheral sensory neurons in the nodose ganglia. One-day old rat nodose neurons were dissociated and plated onto a preformed monolayer of neonatal cardiac myocytes. These neurons were allowed to develop for 2-3 days by which time they appeared to form connections with the spontaneously contracting cardiocytes. Whole cell currents were recorded in response to 200 msec depolarizing voltage steps from a -80 mV holding potential. Initial whole-cell recordings revealed that microejection of 5-HT (200μM) onto nodose neurons results in a decrease in the net outward current when recorded in a physiological bath solution.. The basis for this decrease was determined by isolation of individual ionic currents. Whole-cell inward Ca^{2+} currents were recorded in pipette solution consisting of (in mM) CsCl, 124; EGTA, 2.2; $CaCl_2$, 0.2; $MgCl_2$, 2; and HEPES, 5 and bath solutions of $CaCl_2$, 2.0; Glucose, 10;, and HEPES, 10. Microejections of 5-HT resulted in a 20.7% increase in the peak Ca^{2+} current with no observable effect on threshold voltage or current inactivation. This effect was reversible and repeatable within a given cell. Serotonin also resulted in a moderate decrease in the outward K^+ current. These results suggest the effects of 5-HT may be due, in part, to an increase of the Ca^{2+} current in the sensory neurons of the nodose ganglia. Supported by Grant # HL-36840.

Three Different Potassium Channels Recorded from Cultured Nodose Ganglia Neurons. **D. L. Kunze* and M. Hay. Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.** Presynaptic modulation of potassium (K^+) channel activity has been suggested be involved in the modulation of neurotransmitter release from presynaptic nerve terminals. The purpose of this study was to investigate the properties of the different potassium channels in the peripheral sensory neurons of the nodose ganglia. One-day rat nodose ganglia were dissociated with trypsin and plated on coated coverslips. All recordings were obtained following 1-2 days in culture. Whole cell K^+ currents were recorded in response to 200 msec depolarizing voltage steps from a holding potential of -80mV. Pipette solution consisted of (in mM) KAsp, 145; EGTA, 1.0; $MgCl_2$, 0.5; and HEPES, 10. Bath solution consisted of NMDGCl, 137;, KCl, 5.4; $MgCl_2$, 1.0; Glucose, 10; HEPES, 10. All nodose neurons exhibited a delayed, outwardly rectifying K^+ current that was significantly reduced by extracellular tetraethylammonium (30-50 mM). Approximately 15% of these neurons also exhibited a faster, transient K^+ current which inactivated upon depolarization. This A type K^+ current activated at approximately -35 mV and was blocked by microejected 4-AP. Additional studies in perforated patch whole-cell recordings revealed that microejection of 5mM extracellular Ca^{2+} resulted in a marked increase in the total outward K^+ current. To identify the channels underlying this effect we recorded single channel currents in the inside out patch configuration. Two different channels showed increased open probability when intracellular calcium was raised from 10 nM to 10 uM. The first channel had a slope conductance of approximately 20 pS. A second channel had a slope conductance of 100 pS with a reversal potential near E_k. These data suggest that this channel may be involved in the facilitatory effects of Ca^{2+} on outward K^+ currents in the nodose ganglia. Supported by HL-36840.

ELECTROPHYSIOLOGICAL EFFECTS OF A 5-HT_2 AGONIST IN THE NUCLEUS TRACTUS SOLITARIUS. **Peter D. Feldman* and Dale K. Paulson. Dept. of Pharmacology, LSU Medical Center, New Orleans, LA 70112.**

Autoradiographic evidence indicates the presence of low densities of 5-HT_2 binding sites in the nucleus tractus solitarius (**nTS**) of the rat (Appel, et al., '90, JPET 255: 843). In view of our recent finding of both excitatory and inhibitory effects of exogenously-applied serotonin on the electrophysiological activity of nTS neurons (The Physiologist 34: 242, 1991), we sought to examine the effect on nTS neuronal activity of a putatively 5-HT_2-selective agonist, α-methyl-5-hydroxytryptamine (**α-Me-5-HT**). Extracellular single unit recordings were made of spontaneous nTS neuronal activity in isolated, superfused slices of the rat medulla. A total of 16 neurons were studied. Ten of the 16 neurons responded to α-Me-5-HT (0.25, 0.5, 1.0, 2.5, 5.0 μM) with depressions of firing rate that were roughly concentration-dependent. In contrast, another 3 of the 16 neurons responded with an increase of firing rate, while the remaining 3 neurons did not respond to α-Me-5-HT at concentrations up to the micromolar range. Analysis of the concentration-dependence of the increases and decreases of activity appears to indicate that the threshold for the excitatory effects of α-Me-5-HT occurred at a lower concentration than that for the inhibitory effects. Further studies involving selective and non-selective serotonergic antagonists are under way to determine the 5-HT receptor subtype(s) mediating these divergent effects of α-Me-5-HT. (Supported by NIH Grant NS-29458).

SUBCORTICAL SOMATOSENSORY PATHWAYS: LEMNISCAL AND SPINOTHALAMIC

DOUBLE LEBELING OF RAT SPINAL NEURONS PROJECTING TO BOTH SOLITARY TRACT AND DORSAL COLUMN NUCLEI. G.W.LU* and Z.MENG. Dept. of Neurobiology, Captial Institute of Medicine, Beijing 100054, China.

Physiological evidence has been presented for spinal doral horn neurons (SDHN) with branched axons terminating in both the solitary tract and dorsal column nuclei (Lu G.W. et al:Science in China,34:171-183,1991). The present study is aimed at doubly labeling the cells of origin of the double projection SDHN with fluorescent substances.

Propidium (PI) was injected within left solitary tract nucleus (STN) of Wistar rats anesthetized with pentobarbital.Bisbenzimide (Bb) was injected ipsilaterally within the dorsal column nucleus (DCN) 48 hours later.After an additional 8-10 hours of survival, the rats were sacrificed and perfused under deep anesthesia. The spinal cords were sectioned and viewed on a fluoresent microsope.

A total of 282 retrogradely labeled SDHN was found in the left lumbosacral dorsal horn of 10 rats.Of them,51 cells (18%) were doubly labeled by both PI and Bb. One hundred and twenty (42%) cells were labeled by PI only;and 111 (39%) were labeled only by Bb. The PI and Bb labeled cells were triangle or spindle in form and 20-30um in size. These cells were found primarily in segments L4-L5 and mainly in the laminae III-V.

These findings indicate morphologically the existence of SDHN with branched axons ipsilaterally projecting to both the STN and DCN. These neurons were named spino-solitary tract-dorsal column postsynaptic (SST-DCPS) neurons and thought to play an important role in convergence and processing of viscero-somatic inputs.

CYTOCHROME-OXIDASE (CO) STAINING OF THE CUNEATE NUCLEUS IN THE RAT REVEALS A MODIFIABLE SOMATOTOPIC MAP. D.P. Crockett*, S. Maslany, S.L. Harris and M.D. Egger. Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854-5635.

Within a rostrocaudally limited region in the middle of the cuneate nucleus (CN), distinctive blotches of intense CO-activity were observed. The CO-staining was maximally differentiated approximately 0.3 - 0.7 mm caudal to the obex, which is located within the previously defined *middle region* (approximately 0.2 - 0.9 mm caudal to the obex) that receives a disproportionately large share of primary afferent terminations (Maslany et al., *Neurosci. Lett.*, in press). No CO-blotches were observed anywhere else in the dorsal column nuclei. Transganglionic labelling (WGA-HRP) demonstrated that several of the CO-blotches in the CN are precisely related to the terminal projection fields of primary afferents from the skin of the forepaws. In contrast, control observations demonstrated that 1) the cytoarchitecture (Nissl-stained sections), 2) the dendritoarchitecture (distribution of microtubule-associated protein 2 (MAP2)) and 3) the organization of retrogradely labelled cuneothalamic cells did **NOT** correspond to the topographical organization of the CO-blotches. Postnatal (up to 11 days postpartum) forepaw deafferentation or removal disrupted the CO-staining pattern in the adult CN.

427.3

DIFFERENTIAL DISTRIBUTION OF CALCIUM-BINDING PROTEINS IN THE DORSAL COLUMN NUCLEI AND SPINAL CORD IN THE RAT. S. Maslany*, D.P. Crockett and M.D. Egger. Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854-5635.

The distribution of the calcium-binding proteins, calbindin D28k (CaBP) and parvalbumin (PV), were examined in the dorsal column nuclei and spinal cord in the rat by an avidin-biotin peroxidase method. In the cuneate nucleus (CN), both CaBP-immunoreactive (CaBP-IR) and PV-immunoreactive (PV-IR) cells were found throughout the entire rostrocaudal axis, though PV-IR cells were more numerous. However, the density of the PV-IR cells was greatest in the previously defined *middle region* (approximately 0.2 - 0.9 mm caudal to the obex) that receives a disproportionately large share of primary afferent terminations (Maslany et al., *Neurosci. Lett.*, in press) and is similar to the known distribution of thalamic projection cells. The distribution of the CaBP-IR cells appeared uniform throughout the CN. In the gracile nucleus, where the PV-IR cells were also more numerous, the density of both the PV- and CaBP-IR cells was greatest just caudal to the obex. In the spinal cord, PV-IR cells were found in Rexed's laminae II-III, but not in lamina I, while CaBP-IR cells were found in laminae I-II. A few PV-IR and CaBP-IR cells were observed in the ventral horn. While many PV-IR fibers was found in the gracile tract (GT) in the lumbar region, few PV-IR fibers were detected in the GT in the cervical region, suggesting that a large proportion of PV-IR fibers may be proprioceptive in origin.

427.4

THE LOW-AFFINITY RECEPTOR FOR NERVE GROWTH FACTOR IS DIFFERENTIALLY DISTRIBUTED WITHIN THE DORSAL COLUMN NUCLEI OF THE RAT. D.R. Foschini*, D.P. Crockett and M.D. Egger. Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854-5635.

Nerve growth factor is known to support the survival of many neural-crest-derived primary sensory neurons. We immunocytochemically localized the low-affinity receptor (p75) for nerve growth factor (NGFR) within the dorsal column nuclei of the rat, using a monoclonal antibody (192-IgG; 0.6 - 5.0 μg/ml) and the biotin-avidin method. At the light-microscopic level, most staining appeared to be associated with axons and their terminals. While the gracile nucleus stained intensely and uniformly, within the cuneate nucleus (CN), the most intense NGFR-like immunoreactivity was concentrated in the previously defined *middle region* (approximately 0.2 - 0.9 mm caudal to the obex) that receives a disproportionately large share of primary afferent terminations (Maslany et al., *Neurosci. Lett.*, in press). Within this middle region of the CN, the staining was often patchy, reminiscent of the cytochrome oxidase blotches also observed in this region (Crockett et al., 1992). This pattern of NGFR-like immunoreactivity in the CN was disrupted, and the intensity decreased, in adult rats which had had one forepaw removed perinatally (PD1 - PD6).

427.5

DIFFERENTIAL BRAINSTEM TERMINATIONS OF EXTRINSIC VERSUS INTRINSIC MUSCLE SPINDLE AFFERENTS IN THE MONKEY. C. L. Martin-Elkins*and C. J. Vierck. Department of Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610.

The intrinsic hand muscles, including the lumbricals and the interosseous muscles, appear to play a critical role in fine, coordinated movements of the fingers while the extrinsic hand muscles, located in the forearm, may be more important in gross, powerful movements. Differential effects of dorsal column lesions on these two types of hand movements prompted a comparison of the pattern of central terminations from muscle spindle afferents of intrinsic versus extrinsic muscles of the hand. We have injected cholera toxin conjugated to horseradish peroxidase (CT-HRP) into a variety of intrinsic hand muscles and the superficial digitorum profundus muscle in the forelimb. Prelimary results suggest that the terminal patterns of extrinsic muscle spindle afferents are distinct from those of intrinsic muscle afferents which are not restricted to the triangularis portion of the main cuneate nucleus and the external cuneate nucleus in the brainstem as muscle spindle afferents of extrinsic muscle terminals appear to be. Supported by NS-17474 and NS-07261.

EFFECTS OF A DORSAL COLUMN LESION ON SOMATOSENSORY EVOKED POTENTIALS IN PRIMATES. J.C. Makous*, R.F. Friedman and C.J. Vierck,Jr. Department of Neuroscience, University of Florida School of Medicine, Gainesville, FL 32610.

Previous work has shown that an intact dorsal column (DC) pathway is necessary for normal frequency and duration discriminations. This study addressed the issue of temporal coding in the absence of dorsal columns through evoked potential recordings. Gross potentials were recorded from both awake and anesthetized macaques in response to non-noxious electrocutaneous and mechanical stimulation of the foot at various frequencies. Recordings of compound action potentials from the white matter tracts of the spinal cord in anesthetized macaques indicate that anterolateral, dorsolateral and DC pathways respond reliably at frequencies of up to 10 Hz. However, epidural awake recordings over primary somatosensory cortex indicate that a chronic lesion of the DC results in a greater than 70% reduction in the amplitude of the evoked potential at 1.5 Hz, whereas at 10 Hz the potential can not be distinguished from the noise. These results are consistent with the idea that the DC is important for temporal discriminations made at frequencies of 10 Hz or greater.

427.7

OVERLAYING OF NERVE-RELATED AND SOMATOTOPIC ORGANIZATION IN THE CUNEATE NUCLEUS OF PRIMATES. S.K. Rasey and J.T. Wall*. Department of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Sensory fibers from individual fingers, palmar pads, and other somatotopic divisions of the hand terminate in rod-like clusters in the cuneate nucleus. The hand innervation territories of the median, ulnar, and radial nerves do not always coincide with the borders of the somatotopic divisions. How are sensory fiber terminations of these nerves organized in the cuneate nucleus? Afferent terminal labeling was reconstructed in the cuneate nucleus of squirrel monkeys following wrist-level nerve injections of horseradish peroxidase conjugates. The termination field of each nerve is elongated rostrocaudally, and spans multiple somatotopic clusters in the mediolateral and dorsoventral dimensions. Label density varies within the field from "core" regions containing dense, continuous label to "fringe" regions containing lower density label. These nerve-related termination patterns presumably contribute to subcortical substrates of nerve dominance columns in the cortical hand map, and provide images of the presynaptic neuropil which loses normal sensory signals after injury of a hand nerve. Supported by NS21105.

ULTRASTRUCTURAL CHARACTERIZATION OF SYNAPTIC TERMINALS IN THE RAT CUNEATE NUCLEUS

S.De Biasi*, L.Vitellaro-Zuccarello, P.Bernardi
Dip Fisiologia e Biochimica Generali, Milano, Italy.

In six adult rats WGA-HRP was injected in dorsal root ganglia to label primary afferent terminals (PATs), or in the cervical spinal cord (6 days after unilateral cervical rhizotomy and lesion of the dorsal quadrant at T1) to label post-synaptic dorsal column terminals in the cuneate nucleus. The anterograde tracer was revealed by TMB histochemistry. Post-embedding immunogold staining was then performed on thin sections, using antisera for GABA and for glutamate. PATs are large (mean area= 3.14 μm^2, n= 177), contain many mitochondria and small round vesicles. They are GABA-; some are glutamate +; in the plane of the section they contact two or more dendrites of various caliber, and receive synapses from small boutons, some GABA+. Terminals containing HRP reaction product after injection of the tracer in the spinal cord are small (mean area=1.34 μm^2, n= 185) and contact a single thin dendrite or a cell body. They may be GABA+, or glutamate+ or negative for either antiserum. GABA+ terminals are the smallest of the three types (mean area= 0.9 μm^2, n= 288), and, besides contacting dendrites and cell bodies, they are often involved in complex synaptic arrangements with other terminals. (NIH NS 27827 and MURST 40%)

ULTRASTRUCTURAL INVESTIGATION ON THE DORSAL THALAMUS OF GUINEA PIG

R. Spreafico*, C. Frassoni, M. De Curtis and S. DeBiasi°
Dip. Neurofisiol. Ist. Neurologico "C.Besta", Milano; °Dip Fisiologia e Biochimica Generali, Milano, Italy.

Recent anatomical investigations provided evidence that GABAergic neurons are present in some thalamic nuclei of the guinea pig (Asanuma, 1991). Aim of the present study was to investigate the intrinsic synaptic organization of selected thalamic nuclei such as the ventrobasal complex (VB) and the ventrolateral nucleus (VL), characterized respectively by the presence or absence of GABAergic neurons. Adult guinea pigs were perfused under anesthesia with 2.5% glutaraldehyde and 0.5% paraformaldehyde. Vibratome sections from the thalamus were either processed for immunohistochemical detection of GABA or osmicated and wafer-embedded in Epoxy plastic for ultrastructural investigation. LM confirms that GABA+ neurons are present in VB but not in VL. At EM, several complex synaptic arrangements, similar to those found in the cat, are observed in VB, whereas VL contains only simple axo-dendritic and axo-somatic synapses, as in the rat. The differences in the intrinsic synaptic organization between the two examined nuclei are also confirmed by post-embedding GABA immunogold labeling. (NIH NS 27827)

ULTRASTRUCTURAL EXAMINATION OF THE ISOLATED GUINEA PIG BRAIN PERFUSED *IN VITRO*

M. de Curtis*, P. Arcelli, S. DeBiasi(§), R. Spreafico Dip. Neurofisiologia, Ist. Nazionale Neurologico, Milano, Italy and (§) Dip. Fisiologia e Biochimica Generale, Università di Milano, Italy.

The present work investigates at electron microscopic level the preservation of different areas of the adult isolated guinea pig brain maintained *in vitro* by arterial perfusion (de Curtis et al.1991: Hippocampus 1, 341). After characterization of the electrophysiological viability of the preparation via extracellular field potential recordings, the brains were fixed at different times after isolation (one to seven hours) with a mixed aldehyde solution (4% paraformaldehyde and 0.1 % glutaraldehyde in PB, pH 7.2) perfused through the cannula inserted in the vertebral artery. Samples of neocortex, thalamus and hippocampus were trimmed out from 100 um coronal sections, were osmicated and embedded in Epon Spur resin. Semithin and ultrathin sections were then cut, observed at LM and EM respectively and compared to control samples obtained from deeply anesthetized animals directely perfused with the same fixative through the aorta. In all regions explored the tissue was well preserved during the early hours after dissection and showed only minimal and localized alterations after longer incubation times. Cells shape (somatic and dendritic), mielyn sheaths, cytoplasmatic membranes and synaptic clefts in the thalamus and superficial layers of the neocortex showed no major alterations after several hours. Different degrees of extracellular vacuolization (probably due to swelling) and cell damage (membrane shrinkage, cytoplasm vacuolization, darkly stained dendrites, etc.,) were observed in the hippocampus and in the deep neocortical layers after five hours of perfusion. These anatomical evidences add new data to the demonstration of the long-term preservetion of the isolated *in vitro* brain.

MEDIAL LEMNISCAL TERMINALS IN *M. FASCICULARIS* : 3-DIMENSIONAL COMPUTER-ASSISTED RECONSTRUCTIONS OF SYNAPTIC RELATIONSHIPS.

Henry J. Ralston, III and Diane Daly Ralston.
Department of Anatomy and the W.M. Keck Foundation Center for Integrative Neuroscience, University of California, San Francisco, California, 94143

Medial lemniscal afferents (ML) to the somatosensory thalamus of *M.fascicularis* have been labeled by the anterograde axonal transport of wheatgerm agglutinin-horseradish peroxidase (WGA-HRP) following injection of the tracer into the dorsal column nuclei of anaesthetized animals. The tissue was prepared for post-embedding GABA immunocytochemistry and studied by electron microscopy. Computer-assisted reconstruction analysis of serial thin sections was utilized to determine the nature of the morphology of the ML terminals, the distribution and spatial organization of the projections to the dendritic arbors of thalamocortical relay cells (TCR's) and GABAergic local circuit neurons (LCN's) and the 3-dimensional features of the synaptic relationships. ML terminals form axodendritic contacts upon the proximal dendritic arbors of TCR cells, usually terminating on the first 100µm of their dendrites. In addition, the ML terminals synapse upon the GABAergic dendritic shafts and appendages of LCN's. Counts of contacts of ML afferents upon thalamic neurons demonstrate that more than 90% of the ML terminals contact GABAergic profiles in addition to TCR dendrites. In contrast, the synaptic terminals of STT afferents (STT - adjacent poster) form simple axo-dendritic synapses upon TCR dendrites but are rarely seen to contact GABAergic profiles. 3-D reconstruction analysis of ML profiles reveals that they form eleborate synaptic arrays with multiple GABAergic dendrites and dendritic appendages of LCN's, the latter in turn, synapsing upon the same element of the TCR dendrite as does the ML terminal. A given TCR dendritic segment receives ML (and no STT) afferent terminals. We conclude that the ML synaptic input upon TCR cells also elicits substantial GABAergic feed-forward modulation of the ML synaptic effect. This support the hypothesis that the transfer of non-noxious information by primate thalamic neurons is markedly influenced by GABAergic LCN processing, in contrast to the lack of GABAergic modulation of noxious information. Supported by NS-23347.

SPINOTHALAMIC TRACT TERMINALS IN *M. FASCICULARIS*: 3-DIMENSIONAL COMPUTER-ASSISTED RECONSTRUCTIONS OF SYNAPTIC RELATIONSHIPS.

Diane Daly Ralston* and Henry J. Ralston, III,
Department of Anatomy and the W.M. Keck Foundation Center for Integrative Neuroscience, University of California, San Francisco, California 94143.

Spinal afferents (STT) to the somatosensory thalamus of *M.fascicularis* have been labeled by the anterograde axonal transport of wheatgerm agglutinin-horseradish peroxidase (WGA-HRP), following injection of the tracer into the spinal cord of anaesthetized animals. The tissue was prepared for post-embedding GABA immunocytochemistry and studied by electron microscopy. Computer-assisted reconstruction analysis of serial thin sections was utilized to determine the nature of the morphology of the STT terminals, the distribution and spatial organization of projections to the dendritic arbors of thalamocortical relay cells (TCR's) and GABAergic local circuit neurons (LCN's) and the three dimensional features of these synaptic relationships. STT terminals form axodendritic contacts upon the proximal dendritic arbors of TCR cells, terminating on the first 100µm of their dendrites. STT terminals are rarely seen to contact the GABAergic dendritic shafts or appendages of LCN's. Counts of contacts of STT afferents upon thalamic neurons demonstrate that more than 85% contact the TCR's without interacting with GABAergic profiles. In contrast, the synaptic terminals of medial lemniscal afferents (ML - adjacent poster) form elaborate synaptic interactions with GABAergic profiles and TCR dendrites, suggesting a major role for GABAergic modulation of medial lemniscal projections to primate thalamic neurons. 3-D reconstruction analysis of the STT profiles confirms the finding that they primarily form simple axodendritic contacts with TCR cells. A given TCR cell dendritic segment receives only STT (and no ML) afferent terminals. We conclude that the STT synaptic input upon TCR cells is not subject to GABAergic modulation. This supports the hypothesis that the transfer of noxious information by primate thalamic neurons is less influenced by GABAergic LCN processing than is non-noxious information. IMMUNOCYTOCHEMICAL COMPARTMENTS IN THE LEMNISCAL AND SPINOTHALAMIC PATHWAYS IN MONKEY BRAINSTEM.

E. Rausell*, G. Huntley, T. Hashikawa and E.G. Jones.
Dept. of Morphology, University Autonoma of Madrid, Spain; Dept. of Neurobiology, Mount Sinai School of Medicine, New York; Neural Systems Laboratory, RIKEN, Japan; and Dept. of Anatomy and Neurobiology, University of California, Irvine, USA.

Cytochrome oxidase (CO) staining reveals a histochemical parcellation of the principal trigeminal (PrV) and dorsal column nuclei (DCN) in monkeys (Noriega and Wall, Brain Res.,565:188,1992). CO-rich and CO-weak compartments, also defined by immunoreactivity for calcium binding proteins parvalbumin (PV) and 28kd- calbindin (CB) respectively, are also present in the thalamic ventral posterior nucleus (Rausell and Jones, J Neurosci.,11:210,1991). Lemniscal and spinothalamic fibers terminate preferentially in these compartments. Compartmentalization based on CO- and immunocytochemical staining is also a common feature of relay nuclei at other levels of lemniscal and spinothalamic systems.

In *M. fasciculatis* and *M. fuscata* CO-rich compartments in PrV are made up of clusters of neurons that show PV immunoreactivity and stain with SMI-32, an antibody to nonphosphorylated neurofilament protein. PV and SMI-32-positive axons also leave the nucleus. CB immunoreactivity occurs in the lateral periphery of PrV and in other CO-weak regions that alternate with the CO-rich zones. CB immunoreactive neurons are more numerous in the dorsal part of PrV, and no CB axons are observed. DCN show similar CO, PV and SMI-32 staining patterns but few CB neurons are present. PV and SMI-32 staining are present in the medial lemniscus. In the spinal trigeminal nucleus, CO staining is weaker overall and absent in the dorsal-most portion. PV and SMI-32 staining are confined to the CO-positive and CB staining to the CO-negative regions.

MODELLING SPINDLE-LIKE OSCILLATION IN THALAMOCORTICAL NEURONES.

T.I. Tóth* and V. Crunelli.
Dept. of Physiology, Univ. Wales Coll. Cardiff, Cardiff CF1 1SS, U.K.

Recent experimental studies have shown that thalamocortical neurones are capable of displaying a variety of oscillatory states that do not require synaptic currents (Leresche et al., 1991). The pacemaker oscillation (i.e. low-frequency oscillation associated with high-frequency bursts of action potentials) has successfully been reproduced by models (McCormick et al., 1992; Tóth and Crunelli, 1992) based on the properties of a low threshold Ca^{++} current, I_T and an inward Na^+/K^+ current, I_h that were identified in voltage clamp experiments.

Using the same set of system parameters, however, it has not been possible to reproduce the spindle-like oscillation (SLO), a type of activity where low-frequency oscillation occurs intermittently every 5-25 sec. Our model has been extended by taking into account that an increase in intracellular $[Ca^{++}]$ is known to shift the activation curve of I_h, towards more positive potentials. Thus we have been able to obtain an oscillatory behaviour that closely resembles SLO and to mimic some of the qualitative properties of SLO observed in vitro.

We conclude therefore that I_T, I_h, and the leakage current, I_L are sufficient to describe SLO but the dependence of I_h on the intracellular $[Ca^{++}]$ must be taken into account when dealing with this oscillatory state.

427.15

THE CHARACTERIZATION OF THE INPUT FROM THE NUCLEUS RETICULARIS THALAMI TO THE VENTRO-BASAL THALAMUS OF THE RAT. J.P. Turner* and V. Crunelli. Dept. Physiology, Univ. Wales, Coll. Cardiff, Cardiff, CF1 1SS, U.K.

The GABA containing cells in the thalamus consist of local circuit neurones and those of the nucleus reticularis thalami (NRT), which project to most thalamic nuclei. In the rat ventro-basal complex (VB), local circuit neurones make up $<0.5\%$ of the total neuronal number. When recording intracellularly from VB thalamo-cortical cells in a slice preparation containing rat VB and NRT, single shock, low-frequency stimulation of the NRT resulted in an EPSP (due to activation of cortico-fugal fibres passing through the NRT) and a hyperpolarization. The co-application of 20μM CNQX and 100μM DL-AP5 blocked the EPSP to reveal a fast IPSP, which had a time to peak of 10-30msec, reversed at -70mV, and was blocked by bicuculline (10-50μM). A slow IPSP (time to peak of 200-300 msec), sensitive to the $GABA_B$ antagonist CGP 35348 (100-300μM), was also observed. In the presence of this antagonist, at membrane potentials in the -55 to -65mV range, the decay of the $GABA_A$ IPSP was able to evoke a low-threshold Ca^{2+} potential, indicating that $GABA_A$ receptors may underlie sleep spindle activity in the thalamus. We conclude that the input from the NRT to the VB is mediated via both $GABA_A$ and $GABA_B$ receptors.

PAIN MODULATION: SPINAL I

428.1

THE EFFECTS OF MICROINJECTIONS OF SEROTONIN ON DORSAL HORN NEURONS IN THE CAT. **A.R.Evans* and R.W.Blair, Dept. Physiol. & Biophysics, Univ. Okla. Health Sci. Ctr., Oklahoma City, OK. 73190.**

Serotonin (5-HT) is known to be a neurotransmitter in descending pathways. The purpose of this study was to determine the effects of 5-HT on feline dorsal horn neurons. Three cats were anesthetized with sodium pentobarbital (35 mg/kg). Extracellular potentials were recorded from 7 dorsal horn neurons in the thoracic spinal cord (T_2-T_3). The axons of 3 of the cells were antidromically activated from the medial reticular formation. Seven barrelled glass micropipettes were used to pressure eject (100 msec, 50 psi) small volumes (65 pL) of 3 concentrations (10 μM, 100 μM, 1mM) of 5-HT (pH 7.3), vehicle (phosphate buffered saline, pH 7.4), and 1 mM D-L-homocysteic acid (DLH; pH 7.3). Microinjections of 5-HT increased the spontaneous activity of all 7 cells and the change occurred within 1 sec. The mean changes in activity for 10 μM, 100 μM and 1 mM 5-HT were -0.8, 2.7 and 10.5 spikes/s, respectively. The excitatory responses to 1 mM 5-HT were significantly different from the responses to 10 μM and 100 μM 5-HT. There was no difference in the change in spontaneous activity between the 2 lower concentrations of 5-HT. Five cells were tested for responses to 1 mM DLH; 4 were excited and 1 had no effect. No responses to vehicle were found. Using the pressure ejection technique, 5-HT has been found to excite dorsal horn neurons, some of which are spinoreticular tract neurons. (supported by NIH grant HL29618 and OCAST grant HR9-089).

428.2

MODULATION OF SEROTONIN (5-HT) RELEASE FROM SPINAL CORD TISSUE BY OPIOIDS AND KETAMINE. B.K. Kradel, E.H. Stullken, Jr.*, D.L. Smith, P.J. Monroe, D.J. Smith. Dept. of Anesthesiology, WVU Health Sciences Center., Morgantown WV 26506

Antinociception from some intrathecally administered drugs appears to be mediated in part by spinal serotonergic processes (Pain 12: 57,82; Eur.J.Pharm. 160: 211,89 & 194: 167,91; Neuropharm. 28: 1047,89). In this study, several opioids and ketamine (each in a concentration of 1 μM) were evaluated for their ability to alter the release of ^{3}H-5-HT from superfused rat spinal cord tissue. Using synaptosomes, it was found that neither ß-endorphin nor [D-Pen^{2,5}] enkephalin (DPDPE) affected basal or evoked release (15mM K^+) of ^{3}H-5-HT. These results expand an earlier report (Neuropharm. 25: 261,86) demonstrating that ketamine, morphine and ethylketocyclazocine (EKC) were also ineffective in this preparation, and provide further evidence that these drugs do not release 5-HT directly from spinal serotonergic terminals. On the other hand, when a spinal cord slice preparation was used (neuronal connectivity is less compromised), 5-HT efflux was modified by some of these agents. Ketamine, DPDPE and Tyr-D-Ala-Gly-MePhe-Gly-ol (DAMGO) enhanced the K^+-evoked release of total ^{3}H to 153 ± 13, 190 ± 18 and 178 ± 26 % of control, respectively. In contrast, EKC and U50,488 reduced K^+-evoked release to 63 ± 14 and 63 ± 13 %, respectively. No changes were resolved with either morphine (70 ± 22) or ß-endorphin (115 ± 14 %). Thus, these drugs appear to affect neuronal processes that converge on spinal serotonergic terminals. Interestingly, the effect of the various agents on 5-HT release was not always consistent with what would be proposed from the antinociceptive studies that have implicated 5-HT in their local spinal actions.

428.3

RELEASE OF ADENOSINE FROM THE SPINAL CORD BY 5-HYDROXYTRYPTAMINE (5-HT) AGONISTS: CHARACTERIZATION OF RECEPTOR SUBTYPES. J. Sawynok*, D. Leeson, A. Reid, G. Doak and T. White. Dept. Pharmacology, Dalhousie University, Halifax, NS B3H 4H7.

Release of adenosine by 5-HT may mediate a component of the spinal antinociceptive action of 5-HT (Brain Res. 426: 346, 1988). In this study, the 5-HT receptor subtypes involved in adenosine release were characterized using behavioral and neurochemical approaches. 8-Phenyltheophylline, a methylxanthine adenosine receptor antagonist, reduced spinal antinociception by 5-HT and CGS 12066B (5-HT_{1B} agonist) but not TFMPP (5-HT_{1C} agonist) or DOI (5-HT_2 agonist) in the hot plate test. In neurochemical experiments, 5-HT, CGS 12066B, TFMPP and DOI (but not 8-OH-DPAT, a 5-HT_{1A} agonist, or 2-Me-5-HT, a 5-HT_3 agonist) induced release of adenosine from dorsal spinal cord synaptosomes. In all cases, the adenosine originated from released nucleotide rather than as adenosine per se, as release was reduced by inhibition of 5'-nucleotidase activity. Release of adenosine by 5-HT and CGS 12066B was Ca^{2+}-dependent, while that induced by TFMPP and DOI was not. Release of adenosine from the spinal cord appears to be due to activation of a 5-HT_{1B} receptor subtype; the Ca^{2+}-dependent component of release appears to contribute to behavioral effects of 5-HT agonists. (*Supported by MRC Canada*)

428.4

DESIPRAMINE REDUCES NMDA-INDUCED NOCICEPTIVE BEHAVIOUR MEDIATED THROUGH THE SPINAL 5HT_{1A} RECEPTOR. N.Mjellem, A.Lund and K.Hole*. Departement of Physiology, University of Bergen, N-5009 Bergen, Norway.

The mechanism of the antinociceptive effect of desipramine (DMI) is unclear. It is generally accepted that excitatory amino acids (EAA) act as neurotransmitters in primary nociceptive fibers, and in vitro studies have shown that tricyclic antidepressants may influence the NMDA receptor complex.

The modulatory effect of DMI on the nociceptive behaviour induced by intrathecal (i.th.) NMDA (0.4 nmol, 7µl) was studied in mice. DMI was administered either i.th. (7µg, 7µl) 5 min prior to administration of NMDA, intraperitoneally (i.p.) (10 mg/kg) 90 min prior to NMDA, or in the drinking water during 3 weeks. The nociceptive behaviour (biting and scratching) produced by i.th. NMDA was significantly reduced when the animals were pretreated with DMI, either acutely or chronically.

The 5HT_{1A} agonist 8-OH-DPAT inhibits NMDA-induced behaviour. A functional upregulation of the 5HT_{1A} receptor was found after chronic administration of DMI. We therefore investigated if blocking of the 5HT_{1A} receptor would reduce the effects of DMI.

A selective 5HT_{1A} antagonist, NAN-190 Hydrobromide (10 µg), was injected i.th. 5 min prior to NMDA in animals pretreated with DMI. The 5HT_{1A} antagonist reversed the reduction of NMDA-induced behaviour produced by DMI.

These findings indicate that both acute and chronic administration of DMI reduce the NMDA-induced nociceptive behaviour, and that this may be mediated at least partly through the 5HT_{1A} receptor in the spinal cord.

428.5

DIFFERENTIAL EFFECTS OF 5-HT AND NE UPTAKE BLOCKADE ON OPIOID RECEPTOR SUBTYPE SELECTIVE ANALGESIA. D. Paul* and A.R. Fowler. Department of Pharmacology, Lousiana State University Medical Center, New Orleans, LA 70112.

Selective stimulation of mu_1, mu_2, delta, $kappa_1$ or $kappa_3$ opioid receptors produces analgesia through neuroanatomically and neuropharmacologically distinct mechanisms. Blockade of 5-HT or NE uptake potentiates morphine analgeia. To determine whether selective 5-HT and NE uptake blockade will potentiate analgesia produced through each of the opioid receptor subtypes, we assesed the analgesic effects of morphine, i.c.v. DAMGO (mu_1), i.t. DAMGO (mu_2), i.c.v. and i.t. DPDPE (delta), U50,488H ($kappa_1$), and nalorphine ($kappa_3$) in mice treated with zimelidine (10 mg/kg), desipramine (5 mg/kg) or saline using the tail-flick assay. Zimelidine produced a leftward shift in the dose-response curves for morphine, i.t. DAMGO (5-fold), and U50,488 (2-fold). Desipramine produced a lefward shift in the dose-response curves for morphine and i.t. DPDPE (2-fold). These results indicate that a 5-HT may modulate mu_2 and κ_1 analgesia, whereas NE may modulate spinal delta analgesia.

428.6

SPINAL 5HT1B BUT NOT 5HT1A RECEPTOR SUBTYPES DEPRESS RESPONSES OF DORSAL HORN CELLS TO CUTANEOUS NOXIOUS THERMAL STIMULATION IN THE RAT. Z. Ali, G. Wu, S. Barasi, S. R. Williams and V. Crunelli.* Dept. of Physiology, U.W.C.C., Cardiff. U.K. CF1 1SS.

Intrathecally applied 5HT1B agonists depress and 5HT1A agonists facilitate spinal nociceptive reflexes. To further investigate the actions of 5HT1A and 1B agonists we combined the intrathecal route of drug delivery with extracellular recordings from single lumbar dorsal horn neurons responding to noxious thermal stimulation.

Male Wistar rats were anaesthetised with halothane. Responses in all neurons were depressed by the 5HT1-like agonist 5-CT (0.3nmol., n=6; 3nmol., n=2) and antagonised by cyanopindolol (50nmol., n=4). TFMPP (300nmol.), a 5HT1B agonist, reduced responses in 6 of 7 neurons. However, in 2 of 4 cells 8-OH DPAT (150nmol.), a 5HT1A agonist, increased nociceptive responses.

These data suggest the antinociceptive actions of intrathecally applied 5HT1B agonists in behavioural tests may be mediated by a reduction in responses of dorsal horn neurons to noxious thermal stimuli. In contrast, facilitation of spinal reflexes by 5HT1A agonists may be mediated by increased responses of dorsal horn neurons.

428.7

NOCICEPTION MEDIATED BY THE ACTIVATION OF POLYMODAL NOCICEPTORS MAY BE SELECTIVELY ATTENUATED BY SEROTONIN$_{1A}$ AGONISTS. V. Pirec,* D.C. Yeomans, H.K. Proudfit. Dept. of Pharmacology, Univ. of Illinois College of Medicine at Chicago, Chicago, IL 60612

Experiments were designed to determine whether different rates of noxious skin heating activate different types of nociceptors and if the antinociceptive effects of 5-HT$_{1a}$ agonists are dependant on the nature of the thermal stimulus used for nociceptive testing.

The first group of experiments was designed to determine whether high and low rates of thermal stimulation activated different nociceptor types. Capsaicin was topically applied on the skin of rat's hindpaw to sensitize polymodal nociceptors. Capsaicin sensitized nociceptive responses to low (0.6°C/sec), but not to high (6.5°C/sec) heating rates. As capsaicin selectively sensitizes polymodal nociceptors, low heating rates appear to preferentially activate polymodal nociceptors.

The second group of experiments was designed to determine whether 5-HT$_{1a}$ agonists would selectively reduce nociceptive responses produced by low heating rates. Intrathecal administration of the 5-HT$_{1a}$ selective agonists 8-OH-DPAT and buspirone, in both capsaicin sensitized and non-sensitized rats, produced significant antinociception only when low rates of skin heating were used. These antinociceptive effects of 5-HT$_{1a}$ agonists were significantly attenuated by intrathecal injection of the 5-HT$_{1a}$ antagonists spiroxatrine or NAN-190.

These results indicate that 5-HT$_{1a}$ receptors in the spinal cord selectively modulate the nociception that is mediated by polymodal nociceptors that are activated by low rates of skin heating. (Supported by USPHS Grant DA03980 from the National Institute on Drug Abuse).

INTRATHECAL (I.T.) METHOXAMINE POTENTIATES DEXMEDETOMIDINE SPINAL ANTINOCICEPTION IN THE RAT: EVIDENCE OF A ROLE FOR α_1-ADRENOCEPTORS AND ENDOGENOUS OPIOIDS. C.W. Loomis, K.D. Arunachalam, D. Vyas* and B. Milne, School of Pharmacy, Memorial University, St. John's, Nfld, Canada, A1B 3V6

I.t. α-agonists induce selective antinociception (ANT) in animals via spinal α_2-adrenoceptors. The role of spinal α_1-adrenoceptors is less clear. The objectives of this study were to determine: 1) if i.t. methoxamine (MX; α_1-agonist) potentiates ANT induced by i.t. dexmedetomidine (DX; α_2-agonist) in the rat; and 2) if endogenous spinal Met-Enk is involved in this interaction. Male, Sprague-Dawley rats (250-400 g) were implanted with i.t. catheters. Rats whose baseline responses and motor function were normal were used in the tail-flick and paw pressure withdrawal tests. All drugs were given i.t. The addition of a fixed (10 µg) threshold (<10% MPE) dose of MX to DX yielded an 8-fold leftward shift of the DX dose-response curve (DRC). MX potentiation of DX was: not due to a prolonged duration of DX action; and was significantly antagonized by each of the following i.t. pretreatments: prazosin (10 µg), Wyeth 27127 (0.5 µg), naloxone (30 µg), or antiserum to Met-Enk (but not by antiserum preabsorbed with Met-Enk). Pretreatment with i.t. SCH 32615 (NEP inhibitor) shifted the MX+DX DRC to the left 6-fold compared to vehicle pretreated rats but had little effect on the DX DRC (no effect on MX). Light microscopy of spinal cords from rats given MX+DX (twice daily for 3 days) revealed no inflammation, haemorrhage or necrosis, and no changes in substance P- or CGRP-like IR compared to vehicle controls. The data indicate that the MX potentiates DX spinal ANT without neurotoxicity. The effect appears to be mediated, at least in part, by spinal Met-Enk, consistent with the known ANT interaction between opioid- and α_2-agonists. (Supported by MRC Canada)

428.9

ALPHA-2-ADRENOCEPTOR AGONIST MEDETOMIDINE IS HIGHLY EFFECTIVE FOR SUPPRESSION OF FORMALIN-INDUCED IMMEDIATE EARLY-GENES IN SPINAL BUT NOT IN THALAMIC NEURONS. A.Pertovaara*, T.Herdegen[2], R.Bravo[3] and M.Zimmermann[2]. Dept.Physiol.Univ. Helsinki, Finland, [2]II.Physiol.Inst.Univ.Heidelberg, Germany and [3]Bristol-Myers Squibb Res.Inst.,Princeton,NJ, USA

The expression of c-JUN, JUN B, c-FOS, FOS B and KROX-24 proteins were used to study the antinociceptive effect of ip administered medetomidine (MED), a selective alpha-2-adrenoceptor agonist, in the rat CNS. Proteins were detected by immunocytochemistry. MED (100 or 300 ug/kg) was injected 12 min before the injection of formalin (FOR; 5% 50 ul) in the plantar skin of the hindfoot. The rats were killed and perfused 90 min later. Atipamezole (ATI; 1.5 mg/kg ip) was used to reverse the effects of MED.

FOR induced expression of all studied proteins in the spinal dorsal horn ipsilaterally, and in the medial thalamus. Both MED doses strongly (80-90%) suppressed the expression of all proteins in spinal but not in thalamic neurons. ATI completely reversed the effect of MED.

Thus, the expression of immediate-early gene (IEG) encoded proteins is under powerful control of alpha-2-adrenoceptors in spinal but not in thalamic neurons. These IEG data dissociate from recent behavioral and electrophysiological findings (Pertovaara et al. Neurosci.1991.44.705) indicating that in the thalamus also the low but at the spinal level only the high MED dose produced antinociception. Supported by DFG

428.10

REINFORCEMENT OF SPINAL NORADRENERGIC NEUROTRANSMISSION INDUCES ANTINOCICEPTION IN THE RAT TAIL FLICK TEST - ONE ADDITIONAL MODE OF ACTION OF THE CENTRAL ANALGESIC TRAMADOL. W.S. Reimann*, H. Schlütz and F. Schneider. Dept. Pharmacology, Grünenthal GmbH, W-5100 Aachen, FRG.

Tramadol has low affinity for opioid receptors and shows norepinephrine (NE) and serotonin uptake inhibition in standard assays. We tested whether NE uptake blockade occurred at spinal sites and whether it can effect antinociception. Slices of the rat dorsal spinal cord were preincubated with ^{3}H-NE then superfused and stimulated electrically twice. Tramadol enhanced the stimulation-evoked overflow of tritium, starting at 1 μM, qualitatively similar to the NE uptake inhibitor desipramine (DMI). The effects were mainly due to the (-)-enantiomer of tramadol. When uptake sites were blocked by DMI, tramadol was virtually ineffective, suggesting NE uptake inhibition is responsible for tramadol's effects. I.t. injection site of 12 μg tramadol at the lumbar produced antinociception in the rat tail-flick test; both enantiomers were roughly equally potent. Antinociception was also observed with i.t. DMI, starting with 6 μg. Effects of DMI and tramadol were antagonized by i.p. injection of 1 mg/kg yohimbine. The results from in vitro and in vivo experiments provide evidence that tramadol reinforces NE neurotransmission at the spinal site and that this mode of action in addition to opioid-like activity is involved in spinal antinociception.

428.11

CENTRAL ACTION OF SYSTEMIC LIDOCAINE MEDIATED BY GLYCINE SPINAL RECEPTORS: AN IONTOPHORETIC STUDY IN RATS. G.Biella and M.L.Sotgiu.*Dept.Physiopathol.and Therapy of Pain, Milan University, and I.F.C.N.-C.N.R. Milan, ITALY.

Some antinociceptive properties displayed by systemic lidocaine (lido) result from centrally played effects.In the effort to identify the central target of lido, single neurons in the spinal cord dorsal horn of anesthetized rats were recorded. The microejection of various drugs was used as explorative tool. Concurrent recording to iontophoretic and micropressure ejections of drug solutions (glutamic acid 100mM, strychnine sulphate 1mM, glycine 10mM) were performed. Non- and noxious stimuli were delivered to somatotopically competent areas of the lumbar cord and wide dynamic range neurons (WDR) were selected. Intravenous lido inhibited, for 15-25 min, the excitatory response induced by centrally iontophoresized glutamate (27.3 ± 1.3 to 4.7 ± 0.9 spikes/s). During the inhibitory period,the iontophoretic ejection of strychnine partially counteracted the lido inhibitory effects (4.7 ± 0.9 to 22.0 ± 1.1 spikes/s). Systemic lido had no effect on concurrent glutamate and strychnine ejection; micropressurized lido showed no influence on the excitatory response of the recorded neurons. Strychnine effects were evident also in the case of glycine inhibitions of glutamate induced excitations. We suggest that some of the central effects of lido act upon spinal glycine strychnine-sensitive receptors, possibly by glycine residue bearing metabolites of lido itself.

428.12

MUSCARINIC CHOLINERGIC SPINAL ANTINOCICEPTION. E.T. Iwamoto*, L. Marion, N.W. Pedigo, and R.D. Guarino. Department of Pharmacology, University of Kentucky College of Medicine, Lexington, KY 40536

Intrathecal (i.t.) administration of the muscarinic cholinergic agonist, (+)-*cis*-methyldioxolane (CD), into the lumbar spinal cord of male Sprague-Dawley rats produced antinociception as assessed by the 52° C hot-plate and tail-flick (7 sec control latency) assays. I.t. CD induced antinociception within 5 min for up to 3 hr without altering four other motor reflexes. The median effective i.t. dose of CD was ~10 nmol in both antinociceptive assays. Tissue content of CD 30 min after an i.t. injection of 37.5 nmol ^{3}H-CD was estimated at 1 μM. The antinociception induced by 37.5 nmol of CD was antagonized by 5 min i.t. pretreatment with pirenzepine or methoctramine at IC50 doses of approximately 1 and 7 nmol, respectively. Five min i.t. pretreatment with 20 nmol LY-53857, 25 nmol S-(-)-zacopride, or 25 nmol idazoxan (doses which were inactive alone) each partially antagonized 37.5 nmol CD antinociception, whereas buffer, mecamylamine or naloxone had no effect. CD inhibited ^{3}H-QNB binding in spinal cord homogenates with μmolar affinity. The data suggest that i.t. CD antinociception may be mediated via M1 and/or M2 muscarinic, 5-HT2 and/or 5-HT3 serotonergic, and/or α2 adrenergic lumbar spinal receptor sites. (Supported in part by NS 28847 and KTRB.)

428.13

MULTIPLE SPINAL MEDIATORS IN NICOTINE ANTINOCICEPTION. D. T. Rogers* and E. T. Iwamoto, Dept. of Pharmacol., Univ. of Kentucky Coll. of Med., Lexington, KY 40536.

The antinociceptive effects of s.c. nicotine were evaluated in male Sprague-Dawley rats using the hot-plate and tail-flick tests. Nicotine (0.125, 0.25, 0.375, or 0.5 mg/kg s.c.) produced a dose-related inhibition of nociception in both tests. No significant alteration of other motor reflexes was observed with 0.375 mg/kg s.c. nicotine. The effect of 0.1 μmol of various receptor antagonists intrathecally administered 12 minutes before 0.375 mg/kg s.c. nicotine was examined. The order of potency for inhibition of nicotine antinociception in the hot-plate test for 0.1 μmol antagonists was: methysergide ≥ scopolamine > yohimbine > mecamylamine> idazoxan > atropine > naloxone = 0. In the tail-flick test, the order of potency for inhibition of nicotine antinociception was: scopolamine > methysergide > atropine > idazoxan > yohimbine > mecamylamine > naloxone = 0. These data suggest that the antinociceptive effects of s.c. nicotine are mediated via a number of sites in the spinal cord, including noradrenergic, serotonergic, and muscarinic cholinergic. Spinal nicotinic and opioid receptors appear to have less of an involvement. (Supported by NS 28847 and the KTRB.)

428.14

THE EFFECTS OF AGING ON SPINAL DAMPGO-INDUCED ANTINOCICEPTION. T. Crisp*, J.L. Stafinsky, M. Uram and V.C. Perni. Department of Pharmacology, N.E. Ohio Univs. Coll. of Med., Rootstown, OH 44272.

This study investigated the effects of aging on the antinociceptive efficacy of the μ opiate agonist DAMPGO. Young, mature and aged Fischer 344 rats (6, 16 and 26 months old, respectively) were injected intrathecally (i.t.) with various doses of DAMPGO. Opiate-induced changes in tail-flick latency (TFL) and hot plate latency (HPL) were recorded 5, 15, 30, 60 and 120 min post-injection. The results demonstrated that DAMPGO dose-dependently elevated TFL and HPL in each of the three age cohorts. When the tail-flick test was used as the nociceptive measure, the potency ratio of DAMPGO was significantly different between the 16 and 26 month old rats. No significant age-related differences were observed in the potency ratio for DAMPGO when the hot plate was used as the nociceptive test. Thus, while higher i.t. doses of DAMPGO are apparently needed to produce antinociception in older rats, the μ opioid receptor site continues to mediate spinal DAMPGO-induced antinociception throughout the life span of the rat.

428.15

SELECTIVE INHIBITION OF NOCICEPTIVE RESPONSES OF SPINAL DORSAL HORN UNITS BY COCAINE. J.A. Kiritsy-Roy*, P.J. Danneman, B. Shyu, T.J. Morrow, and K.L. Casey. Depts. of Neurol. and Physiol., Univ. of Michigan and VAMC, Ann Arbor, MI 48105.

Cocaine produces a dopaminergic dose dependent antinociceptive effect in the rat hot plate and formalin tests (Lin et al., Brain Res. 479:306, 1989). To investigate spinal mechanisms mediating the antinociceptive action of cocaine, the inhibitory effect of cocaine on the responses of spinal dorsal horn (SDH) neurons to several natural somatic stimuli was determined in anesthetized rats. Units in the SDH at T13-L1 with receptive fields (RFs) on the ipsilateral hindpaw were identified by their responses to non-noxious (tap) or noxious (pinch) stimulation. SDH units at L2-L3 with RFs on the tail increased firing rate in response to stimulation with an infrared CO_2 laser at intensities that produced a brisk tail flick response in the awake animal (10 W, 45 msec pulses). Stimulation induced unit firing rate was determined before and after intravenous administration of cocaine. Cocaine inhibited the responses of 11 units to noxious pinch of the ipsilateral hindpaw and of 7 units to laser stimulation of the tail. This effect of cocaine was dose related in the range of 0.1 to 3.1 mg/kg iv. Units that responded only to non-noxious stimulation of the hindpaw were not inhibited by the same doses of cocaine. Cocaine failed to attenuate unit firing in response to noxious stimulation of the hindpaw in rats with complete spinal cord transection at the upper thoracic level. These results indicate that cocaine produces a selective reduction of *noxious* somatic input at the level of the SDH. The effect of spinalization suggests that cocaine antinociception is mediated at least in part via supraspinal descending inhibitory pathways. EFFECTS OF INTRATHECALLY INJECTED NON-PEPTIDE SUBSTANCE P ANTAGONIST CP-96,345 ON NOCICEPTION IN RATS Y.I. Garces[1], S.F. Rabito[2], R. Minshall[2], R.S. Cohen*[1] and J. Sagen[1]. Departments of Anatomy and Cell Biology[1] and Anesthesiology[2], University of Illinois College of Medicine, Chicago, IL 60612.

Substance P (SP) may mediate nociceptive transmission via the NK-1 receptor in the spinal cord. Studies in this field have been limited by the lack of specific antagonists. A recently developed non-peptide SP antagonist, CP-96,345, is specific for the NK-1 receptor. The purpose of this study was to assess the effects of this antagonist on nociception. Nociception was determined using tail flick, paw pinch and hot plate tests in rats. The rats received intrathecal injections of various doses of CP-96,345 and pain sensitivity was assessed at several time intervals up to two hours following injection. In addition, the ability of CP-96,345 to inhibit SP-induced biting and scratching was assessed. Results from analgesiometric testing indicated that doses up to 240 μg had no significant effect on either tail flick latency or paw pinch threshold. Hot plate latency was only elevated by high dose of the antagonist. In addition, the SP antagonist failed to inhibit the SP induced biting and scratching. The intrathecal injection of CP-96,345 produced a dose-related decrease in tail skin temperature which could be mediated by the NK-1 receptor. Preliminary binding studies using ^{125}I-SP were also performed. Assessment of the ability of CP-96,345 to inhibit the binding of ^{125}I-SP to the rat spinal cord and rat salivary tissue indicated that CP-96,345 and SP behave similarly at the NK-1 receptor. The results of this study suggest that, while CP-96,345 binds the SP site at the NK-1 receptor in the spinal cord, this receptor is most likely not involved in mediating some types of acute pain at the spinal cord level. Evaluation of the Effect of Nitric Oxide on the Release of iCGRP from the Dorsal Horn of the Spinal Cord in Rats.

M.G. Garry*, H.E. Geier, and K.M. Hargreaves, Univ. of Minnesota, Dept. of Restorative Sciences, and Dept. of Pharmacology, Minneapolis, MN.

Nitric oxide (NO) is a labile gas, previously known to be produced by bacteria. More recently NO has been localized to macrophages, endothelium, and to neurons where it stimulates the formation of cyclic GMP. It has been proposed that NO plays a role in peripheral nociceptive mechanisms (Brain Res. 531:342, 1990). We have previously shown that enhanced capsaicin-evoked *in vitro* release of iCGRP from the dorsal horn may serve as a biochemical marker for hyperalgesia during inflammation (Brain Res., in press). Whether NO plays a role in the processing of nociceptive information at the level of the spinal cord, however, has not been evaluated. Therefore, the goal of this study was to evaluate the effect of NO on the *in vitro* release of iCGRP from certain primary afferent neurons in the dorsal horn of rats. Spinal cords from male Holtzman rats (175-199g) were ejected by hydraulic extrusion. The dorsal horn of the lumbar enlargement was isolated and chopped into 200μ cubes and placed into chambers which were superfused with oxygenated Krebs (pH 7.4) for 51 min. Following this period, one group of chambers (n=3) was superfused for 21 min with 1mM sodium nitroprusside (a liberator of NO) after which the chambers were superfused with capsaicin (10μM) for 6 min to selectively depolarize certain primary afferent neurons in the preparation. Another group (n=3), which was superfused with capsaicin but not with nitroprusside served as the control. The amount of iCGRP in each fraction was assessed by radioimmunoassay. Our results indicate that NO enhances capsaicin-evoked release of iCGRP from the dorsal horn. Preliminary results indicate that there is a significant increase in the capsaicin-evoked release of iCGRP occurs following pretreatment with nitroprusside when compared to controls (5638±511 vs. 2149±736 fmol/gm tissue/6 min, respectively [$p<0.05$]). In contrast, basal release of iCGRP was unchanged following nitroprusside. These results suggest that NO may play a role in the processing of nociceptive information at the level of the spinal cord.

REGULATION OF TACHYKININ RECEPTOR mRNA EXPRESSION IN RAT DORSAL HORN DURING NOCICEPTION. K. E. McCarson* and J. E. Krause. Dept of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

The tachykinin peptides substance P (SP) and neurokinin B (NKB) are both contained in the dorsal horn of the spinal cord. SP is contained in both primary afferent and intrinsic neurons and has been shown to be a mediator of nociception, whereas NKB appears to produce antinociception when applied to the dorsal horn. Binding sites for both peptides exist in the dorsal horn. We used the formalin test as a model of nociception to examine changes in steady state levels of SP, SP receptor (SPR) and NKB receptor (NKBR) mRNA in the dorsal horn of the rat during formalin-induced nociception. Rats were injected s.c. with 100μl of 5% formalin in the plantar aspect of the right hind paw. Sham injected animals served as controls. Either 2 or 6 hr after formalin injection, the rats were decapitated, the spinal cords removed, and RNA extracted from the lumbar dorsal horns. Control tissues were removed 2 hr after sham injection. Solution hybridization-nuclease protection assays were used to quantitate SPR and NKBR mRNA levels and Northern blot analysis was used to quantitate total SP-encoding mRNA levels. SPR mRNA levels were increased by 80% 2 hr after formalin injection and NKBR mRNA levels were increased by 50% 6 hr after injection. Dorsal horn SP mRNA levels were not altered. From these studies we suggest that acute alterations in tachykinin receptor systems occur during formalin-induced nociception.

ACTIVITY OF SPINAL DORSAL HORN NEURONS FOLLOWING UV-INDUCED HYPERALGESIA IN THE RAT. **L. Urban,* A. Dray, E.A. Campbell, M.N. Perkins and I. Patel, Sandoz Institute for Medical Research, 5 Gower Place London, WC1E 6BN, UK.**

Activation of nociceptors during peripheral inflammation or neuropathy increases excitability of spinal wide dynamic range (WDR) neurones. We have characterised the activity of WDR cells during the thermal and mechanical hyperalgesia induced by UV irradiation in the rat (Perkins et al This Meeting).

Female Wistar rats with UV-induced hyperalgesia of the glabrous skin of one hind paw were anaesthetised (urethane, 1 g/kg) and an L2-4 laminectomy performed. Activity of spinal WDR cells was recorded extracellularly in response to stimulation of their peripheral receptive fields by noxious heat (52°C) and pinch in a) control animals, b) 1-3 and 5-7 days after UV treatment.

There was an increase in the proportion of spontaneously active cells in hyperalgesic animals (control, 15% n=39; days 1-3, 47% n=19; days 5-7, 20% n=20). The duration of the response and the total number of action potentials evoked by a thermal stimulus was significantly increased in UV treated animals. In addition, the threshold for noxious heat activation was decreased in the hyperalgesic groups (control, 51.8±1.1°C, n=8; days 1-3, 46.5±1.1°C, n=11; days 5-7, 47.1±0.8°C, n=8) and there was an expansion of the receptive fields of WDR cells.

These data show a lowering of the nociceptive heat threshold and hyper-excitability of spinal WDR cells following UV-irradiation of their receptive fields. These changes may underlie the behavioural hyperalgesia seen in this model.

429.2

USE OF FOS-LIKE IMMUNOREACTIVITY TO STUDY THE EFFECTS OF ANALGESIC COMPOUNDS IN SPINAL CORD NEURONS OF POLYARTHRTIC RATS. C. Abbadie and J.-M. Besson*. INSERM U161 and EPHE, 2 rue d'Alésia, 75014 Paris, France.

We have recently shown that during the development of adjuvant-induced arthritis (AIA) in the rat, the number of Fos-like immunoreactive (FLI) neurons in lumbar spinal cord was maximal 3 weeks after induction of the disease, which is the acute phase of hyperalgesia. Moreover, the number of FLI neurons induced by repeated pressure to the ankle was greater in arthritic animals than in healthy ones. In non-stimulated arthritic rats, FLI neurons were mainly present in the neck (laminae V-VI) of the dorsal horn and in the ventral horn of L3-L5, whereas following stimulation they were numerous in the superficial laminae. Thus, this model was used to gauge the effects of various analgesic compounds.

1. We administered morphine or naloxone in non-stimulated arthritic and in stimulated arthritic animals before ankle stimulation. In non-stimulated arthritic rats, morphine (1-9 mg/kg i.v.) or naloxone (1-3 mg/kg i.v.) induced no change in the FLI present in lumbar spinal neurons. But in stimulated arthritic animals, pretreatment with morphine at 0.5 or 1 mg/kg reduced by more than 50% the number of FLI neurons in the superficial laminae and at 3 mg/kg quite abolished the labeling, whereas in the neck of the dorsal horn and in the ventral horn the decrease of FLI was about 55% at 3 mg/kg i.v. This decrease was reversed by naloxone. Pretreatment with naloxone alone (1mg/kg i.v.) did not change FLI.

2. A 2 week chronic treatment with aspirin or acetaminophen (respectively 300 and 500 mg/kg/day) clearly reduced FLI when administered at the same time as the inoculation of AIA, while there was no clear effect when administered 2-3 weeks after the inoculation.

These results question the sensitivity of FLI to test minor analgesic compounds.

429.3

MONOARTHRITIS INDUCES COMPLEX CHANGES IN μ, δ AND k OPIOID BINDING SITES IN THE SUPERFICIAL DORSAL HORN OF THE RAT SPINAL CORD. M-C. Lombard*, D. Besse, J. Weil-Fugazza, S.H. Butler and J-M. Besson, INSERM, U. 161 and EPHE, 2 rue d'Alésia 75014 Paris, France.

Recently, a model of monoarthritis was described in the rat after inoculation by Freund's adjuvant of the tibio-tarsal joint of one hindlimb. Clinical signs of arthritis are visible from 2 to at least 6 weeks post-inoculation (PI). Our aim was to study the regulation of μ, δ and k opioid binding sites in the superficial layers (laminae I-II) of the lumbar and cervical enlargements of the spinal cord 2, 4 and 6 weeks PI. Using quantitative autoradiography and highly selective opioid ligands, we have shown complex changes in binding for the 3 types of sites. They mainly consist of 1) a bilateral increase in [^{3}H]DAMGO and [^{3}H]pCl-DPDPE specific binding at 2 weeks PI when behavioral contralateral hypoalgesia but no significant ipsilateral change in nociceptive threshold (Randall-Sellito) are measured, 2) a bilateral return to control values for [^{3}H]DAMGO and [^{3}H]pCl-DPDPE specific binding and a decrease in [^{3}H]U.69593 specific binding at 4 weeks PI, concomitantly with behavioral contralateral return to control nociceptive threshold and ipsilateral hyperalgesia. These changes are limited to the lumbar level. At 6 weeks PI, there is a bilateral increase in [^{3}H]pCl-DPDPE specific binding at both lumbar and cervical levels. Our results suggest that, following probable local changes in endogenous opioid peptides, which need to be investigated in the present model, the 3 types of opioid binding sites are differentially involved in the development of the pathological process. These data contrast with the lack of significant modification in μ, δ and k opioid binding classically reported at various levels of the spinal cord in polyarthritic rats at 3 weeks PI and verified for 2, 4 and 6 weeks PI in the present study.

THE ROLE OF ACUTE ACTIVATION OF SPINAL NEURONS IN TONIC PAIN AND EDEMA DEVELOPMENT AFTER FORMALIN-INDUCED TISSUE INJURY. A. Cowan* and H. Wheeler-Aceto. Dept. of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140.

Behavioral and electrophysiological studies of the biphasic response to formalin (F) in rats suggest that neuronal changes associated with the early phase may be required for full expression of the tonic nociceptive response. Here, saline (20 μl) or lidocaine (L, 20 μl, 1%) was injected i.th. into 70-90 g male SD rats at either -10 min or +10 min after F (50 μl, 5% into the right hind paw; n=6). F-induced flinching behavior (Fig a) and paw volume (Fig b) were recorded. I.th. L affects hind limb function and increases 50°C hot-water foot-flick latency only transiently (~ 15 min), but when it is given before F significant and prolonged depression of both phases of the flinching response occurs. In contrast, post-F L attenuates late phase for only slightly longer than it increases foot-flick latencies, after which flinching gradually returns to control levels. Although pre-F L initially retards development of edema, at 2-3 h edema rapidly reaches control levels. Post-F L had no effect. These data suggest that, if immediately after F the barrage of primary afferent firing impinging on spinal neurons surpasses a given threshold, then central changes necessary for full expression of the tonic response are initiated. These changes may also be associated with the development of inflammation as well as pain-related behaviors. Since brief protection of spinal neurons significantly reduces the tonic response, our findings support the use of local anesthetics to preempt the development of functional neuronal changes in response to tissue injury. (DA03945 & DA07237)

DORSAL HORN NEURONS SERVING THE LOW BACK: ACTIVATION BY SYMPATHETIC STIMULATION. R.G. Gillette, R.C. Kramis, and W.J. Roberts*, Dept. of Neurosurg. & R.S. Dow Neurol. Sciences Inst., Good Samaritan Hospital & Medical Center, Portland, OR

Most somatosensory neurons in the extreme lateral dorsal horn of L4/5 in cats have receptive fields in the lumbar region and/or hip and proximal hindleg. Many are **hyperconvergent** WDRs which receive input from all or most of the following tissues: paraspinal muscles, facet joint capsules, vertebral periost, spinal dura, disc, hip and proximal leg muscles, and skin. Such neurons are likely to subserve low back pain.

Clinical reports indicate that sympathetic blocks reduce low back pain in some patients, suggesting a causal sympathetic role. We therefore tested somatosensory neurons in the lateral lumbar spinal cord for responding to electrical stimulation of the lumbar sympathetic trunk. Single unit recordings were made from L4/5 in adult pentobarbital anesthetized cats.

Of 82 neurons with cutaneous and/or deep receptive fields in the lumbar region, 70% were responsive to sympathetic stimulation (SS). Excitatory responses to SS were differentiable into; a) short-latency, entrained responses; and b) longer-latency, non-entrained responses. The former were resistant to systemic alpha-adrenergic antagonists and are thought to result from activation of afferent fibers in the sympathetic trunk, some of which may innervate paraspinal tissues. The non-entrained responses were attenuated by alpha antagonists and are thought to result from direct or indirect sympathetic activation of afferents. The results indicate that both somatosensory afferent and sympathetic efferent activity in the lumbar sympathetic trunk can contribute to low back pain.

429.6

GALANIN-MEDIATED INHIBITION OF NOCICEPTION: ENHANCED ROLE AFTER NERVE INJURY. **Z. Wiesenfeld-Hallin[1], X.-J. Xu*,[1], V.M.K. Verge[2], Ü. Langel[3], K. Bedecs[3], T. Hökfelt[2] and T. Bartfai[3]. Depts. of [1]Clin. Neurophysiol., Karolinska Institute, Huddinge, [2]Histology and Neurobiology, Karolinska Institute, and [3]Biochemistry, University of Stockholm, Stockholm, Sweden.**

We have studied electrophysiologically and behaviorally the endogenous role of the neuropeptide galanin (GAL) in spinal nociceptive mechanisms in rats with intact and sectioned sciatic nerves with M-35 [GAL(1-13)-bradykinin(2-9)-amide], a newly developed high affinity GAL receptor antagonist.

I.t. M-35 potentiated the facilitation of the flexor reflex by conditioning stimulation (CS) of C-afferents in rats with intact and sectioned sciatic nerves, an effect that was strongly enhanced after axotomy. In a behavioral study, i.t. infusion of M-35 on the lumbar enlargement via an osmotic minipump for 10 days after axotomy dramatically increased the incidence and severity of self-mutilation (autotomy), a behavioral sign of neuropathic pain. I.t. infusion of the GAL antagonist did not prevent the increase in GAL mRNA in sensory neurons after axotomy.

GAL synthesis is dramatically up-regulated in primary sensory afferents after axotomy. The present results demonstrate that endogenous GAL plays an inhibitory role in the mediation of spinal cord excitability and this function of GAL is remarkably enhanced after peripheral nerve injury. From behavioral and electrophysiological data it is suggested that GAL or GAL receptor agonists may be useful in treating neuropathic pain.

APPLICATION OF TRANS-ACPD OR PHORBOL ESTERS BY MICRODIALYSIS MODIFIES THE BACKGROUND ACTIVITY AND THE RESPONSES OF PRIMATE STT NEURONS TO SENSORY STIMULI AND TO EXCITATORY AMINO ACIDS. P.M. Dougherty*, J. Palecek, V. Paleckova, J. Ragland, and W.D. Willis, Department of Neuroscience and Anatomy, 200 University Blvd., University of Texas Medical Branch, Galveston, Texas 77550-2772.

We explored the effects of two second messenger systems, the inositol phosphate cascade (activated by trans-ACPD) and the protein kinase C pathway (activated by phorbol tri-acetate, TPA) on the responses of STT cells to cutaneous and chemical stimuli. The experiments were conducted in 5 young adult monkeys (*Macaca fascicularis*). STT neurons were identifed by antidromic activation and recorded using a carbon filament electrode in the center of a multibarrel array, the outer barrels of which contained excitatory amino acids (EAA's). The responses of the STT cells to cutaneous stimulation (BRUSH, PRESS and PINCH) and to iontophoretically released EAA's were recorded. Either ACPD or TPA was then infused for one hour by microdialysis and the responses to the sensory and chemical stimuli were again recorded. Both ACPD and TPA resulted in an initial increase followed by a prolonged decrease in background activity. After the spontaneous activity had become reduced, initially, TPA and ACPD produced a decrease in the responses to the mechanical stimuli. However, following a washout period of one to two hours the responses to the mechanical stimuli, particularly BRUSH and PRESS, doubled. Variable changes were observed in the responses to the EAA's. These results suggest that activation of either the inositol phosphate cascade or the protein kinase C pathway may enhance the reponses of primate STT cells. This work was supported by grants NS09743, NS11255, NS08660, and an unrestricted grant from the Bristol-Myers Squibb Corp.

429.8

NEUROKININ RECEPTOR ANTAGONISTS MODIFY THE RESPONSES OF PRIMATE STT NEURONS TO CUTANEOUS STIMULI. W.D. Willis*, J. Palecek, V. Paleckova, J. Ragland, and P.M. Dougherty, Department of Neuroscience and Anatomy, 200 University Blvd., University of Texas Medical Branch, Galveston, Texas 77550-2772.

The effects of neurokinin receptor antagonists on the responses of STT neurons to cutaneous sensory stimuli were studied. Nine experiments were performed on anesthetized young adult monkeys (*Macaca fascicularis*). STT neurons were identified by antidromic activation and recorded using a carbon filament microelectrode in the center of a multibarrel array, the outer barrels of which were used to release excitatory amino acids (EAA's) or neurokinin receptor agonists into the vicinity of the cells under study by iontophoresis. The responses of the STT cells to cutaneous stimuli (BRUSH, PRESS and PINCH; heat and cold; and intradermal injection of capsaicin, i.d. CAP) and to EAA's were recorded before and then after a one-hour infusion of NK-1 antagonists (CP96345, 0.1mM, GR82338, 0.05 mM). CP96345 was used on 15 cells and resulted in reduced responses to noxious PINCH, heat and i.d. CAP. In addition, CP96345 prevented the development of sensitization of STT cells which normally follows CAP. The inactive isomer CP96344 had no effects in ten neurons. The results using GR82337 are still preliminary; however, this compound also appears to modify the responses of at least some STT neurons to sensory stimuli in a manner very similar to CP96345. In conclusion, our results support the contention that neurokinin-1 receptors participate in nociceptive transmission to STT neurons and in the generation of sensitization of the responses of STT neurons that may underlie the development of hyperalgesia. This work was supported by NIH grants NS09743, NS11255, National Service Award NS08660, and an unrestricted grant from the Bristol-Myers Squibb Corp.

EFFECTS OF SYSTEMIC MORPHINE ON LAMINA I NEURONS IN THE CAT. L.P. Serrano* and A.D. Craig. Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013

The action of morphine on lamina I spinothalamic tract (STT) cells, which form half of the STT, has not been determined. Previous work demonstrated that morphine enhances the activity of "cold"-sensitive lamina I STT cells. This study further tests the hypothesis that morphine's actions are organized in a functionally significant manner by examining its effects on nociceptive lamina I cells. Units recorded with tungsten microelectrodes in L7 in barbiturate-anesthetized cats were characterized with natural stimuli and with antidromic activation from the thalamic lamina I termination sites identified earlier with PHA-L. Quantitative heat and pressure stimuli were used to measure the effects of increasing doses of systemic morphine (0.1-2 mg/kg iv) on the responses of 10 nociceptive lamina I cells (6 STT, 3 non-STT, 1 unclassifiable) that had receptive fields on the ventral hindpaw. All cells had graded sensitivity to noxious heat. Morphine inhibited the responses of 9 cells (mean=45% of control), including all 6 STT cells, 7 in a dose-dependent manner. One non-STT lamina I cell was not inhibited and 2/3 non-STT cells were enhanced by low doses (145%). Morphine in higher doses suppressed the responses of 2 non-STT WDR neurons to heat but not to pinch. Naloxone reversed the effects in 7/8 cells. These observations are consistent with the concept that lamina I STT cells form an integral component of the central representation of pain, since all such cells were inhibited by morphine. However, these results also suggest that non-STT lamina I neurons are differentially responsive to morphine, which supports the hypothesis that opiatergic modulation of lamina I neurons is functionally organized. 429.10

RELEASE OF AMINO ACIDS AND PGE_2 INTO THE SPINAL CORD OF LIGHTLY ANESTHETIZED RATS DURING DEVELOPMENT OF AN EXPERIMENTAL ARTHRITIS: ENHANCEMENT OF C-FIBER EVOKED RELEASE. L.S. Sorkin*, UCSD, Anesth. Res. Lab., La Jolla, CA 92093

Glutamate (Glu) and other amino acids (AA) are thought to participate at the spinal level in the development of hyperalgesia associated with tissue inflammation. Prostaglandins also contribute to inflammatory pain, but until recently were thought to be involved only in the periphery. The present study measures the spinal release of AAs and PGE_2 in response to C-fiber stimulation of the sciatic nerve in normal animals and potentiation of that release after acute joint inflammation initiated by intra-articular injection with kaolin/carrageenan.

Extracellular concentrations of AAs and PGE_2 were measured from the dorsal spinal cords of rats lightly anesthetized with halothane. Half-hour consecutive samples were obtained via microdialysis and assayed by HPLC with UV detection and RIA, respectively. C-fiber intensity (200*minimum motor threshold) stimulation of the sciatic nerve elicited release of Glu and glycine, but not aspartate, taurine or PGE_2. C-fiber stimulation 4 hrs after initiation of the inflammation elicited release of Glu and glycine as well as aspartate, taurine and PGE_2. This release was superimposed upon elevated extracellular concentrations of Glu, glycine, taurine and PGE_2 induced by the inflammation.

These results are consistent with the hypothesis that spinal release of excitatory AAs and prostanoids participate in the generation of arthritis pain. Enhanced stimulus evoked release of some of these substances may mediate the hyperalgesia that occurs during inflammation.

INTRATHECAL ADMINISTRATION OF EXCITATORY AMINO ACID RECEPTOR ANTAGONISTS SELECTIVELY ATTENUATES CARRAGEENAN-INDUCED BEHAVIORAL HYPERALGESIA. G.M. Williams*, K. Ren, J.L.K. Hylden, M.A. Ruda and R. Dubner, NAB, NIDR, NIH, Bethesda, MD 20892.

Dizocilpine maleate (MK-801), a non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist, has been shown to reduce thermal hyperalgesia in rats with hindpaw inflammation. Other excitatory amino acid (EAA) receptor antagonists were examined to further elucidate the involvement of NMDA receptors in the behavioral hyperalgesia associated with inflammation. Hyperalgesia, assessed by paw withdrawal latency (PWL) to a heat stimulus, was induced by a single injection of carrageenan (CARRA) (6.0 mg) into the hindpaw of rats. The effects of NMDA receptors were examined by intrathecal (I.T.) injection of the EAA receptor antagonists: (±)-2-amino-5-phosphono-pentanoic acid (AP-5), (±)-3-(2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP), MK-801, ketamine hydrochloride (KETA), 7-chlorokynurenic acid (7-CK), and 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). Whereas PWLs of non-injected paws and those of naive rats were not significantly affected, PWLs of injected paws were dose-dependently elevated. The rank order of potency of these agents to reduce hyperalgesia was: MK-801 ≥ AP-5 ≥ CPP = 7-CK = KETA >> CNQX > 0. In contrast, I.T. injection of the opioid receptor agonist, [D-Ala^2,$MePhe^4$,$Gly\text{-}ol^5$] enkephalin (DAMGO, μ-selective) produced antinociception in both injected and non-injected paws. DAMGO was about 66 times more potent than MK-801. The dose-dependent effects of various NMDA receptor antagonists provide additional evidence that NMDA receptors are involved in CARRA-induced thermal hyperalgesia.

429.12

DIFFERENTIAL ROLES OF NMDA AND NON-NMDA RECEPTOR ACTIVATION IN INDUCTION AND MAINTENANCE OF THERMAL HYPERALGESIA IN RATS WITH PAINFUL PERIPHERAL MONONEUROPATHY D.J. Mayer[1]*, J. Mao[1], R.L. Hayes[2], J. Lu[1] and D.D. Price[1]. [1]Dept. of Anesthesiology, Medical College of Virginia, Richmond, Virginia 23298, [2]Division of Neurosurgery, University of Texas, Houston, Texas 77030

Excitatory amino acid (EAA) receptor activation within the spinal cord has been implicated in neuropathic pain following nerve injury. Using a rat model of painful peripheral mononeuropathy (Bennett and Xie, Pain, 1988, 33:87), we compared the effects of intrathecal treatment with NMDA receptor antagonists (MK801 or HA966) and a non-NMDA receptor antagonist (CNQX) on induction and maintenance of thermal hyperalgesia induced by chronic constrictive injury (CCI) of the ligated sciatic nerve. Four daily single treatments with 20 nmol HA966 or CNQX beginning 15 min prior to nerve ligation (pre-injury treatment) reliably reduced thermal hyperalgesia in CCI rats on days 3, 5, 7, and 10 after nerve ligation. Thermal hyperalgesia also was reduced in CCI rats receiving a single post-injury treatment with HA966 (20 or 80 nmol) or MK 801 (5 or 20 nmol) on Day 3 after nerve ligation when thermal hyperalgesia was well developed. In contrast, a single post-injury CNQX (20 or 80 nmol) treatment failed to reduce thermal hyperalgesia or to potentiate effects of HA966 or MK 801 on thermal hyperalgesia. Moreover, multiple post-injury CNQX treatments utilizing the same dose regimen as employed for the pre-injury treatment attenuated thermal hyperalgesia only when the treatment began 1 or 24 hrs (but not 72 hrs) after nerve ligation. The results suggest that NMDA and non-NMDA receptor activation may have differential roles in induction and maintenance of thermal hyperalgesia following constrictive nerve injury and that mechanisms underlying post-injury neuropathic pain may be associated with EAA-mediated central alterations.

NMDA RECEPTOR-MEDIATED BIPHASIC EFFECTS ON THERMAL NOCICEPTIVE SPINAL TRANSMISSION. R. Kolhekar,* S.T. Meller and G.F. Gebhart. Dept. of Pharmacology, The University of Iowa, Iowa City, IA, 52242

NMDA (1 fmol-1 nmol) was administered through an 8.5 cm intrathecal (i.t.) catheter to the lumbar spinal cord of awake Sprague-Dawley rats. Changes in tail-flick (TF) latency in response to noxious heat were monitored 0.5, 1, 2, 5 and 10 min post-drug. Lesser doses of NMDA (100 fmol-10 pmol) produced a dose-dependent facilitation of the TF reflex (maximal at 0.5-1 min) while greater doses (0.25 nmol-1 nmol) inhibited the TF reflex (maximal at 2-5 min), and also produced a caudally-directed scratching and biting behavior and vocalizations (CBSV). Maximal facilitation was produced by 10 pmol NMDA while maximal inhibition and CBSV was produced by 1 nmol NMDA. Pre-treatment with D-APV (1 fmol-1 pmol, i.t.), which produced no change in baseline TF latency, blocked all NMDA-produced effects in a dose-dependent manner (100 fmol D-APV produced maximal blockade for about 40 min). D-serine (10 pmol-1 μmol, i.t.), but not L-serine (10 pmol-1 μmol, i.t.) or glycine (10 pmol-10 μmol, i.t.), produced a dose-dependent facilitation of the TF reflex which was comparable to the facilitation produced by NMDA (10 pmol); the facilitatory effects of NMDA and D-serine were blocked by 7-chlorokynurenic acid (10 fmol-10 pmol, i.t.). The NMDA-produced biphasic effects on TF latency, but not the CBSV were similar in lightly pentobarbital-anesthetized rats. Reversible spinalization at T_8-T_{10} by cold-block in lightly anesthetized rats completely abolished the inhibition of the TF reflex produced by 1 nmol NMDA while the facilitation produced by 10 pmol NMDA remained unchanged.

In summary, these data suggest that while NMDA-produced facilitation of the TF reflex may be a local phenomenon, inhibition of the TF reflex and CBSV may be produced by activation of ascending pathways that in turn engage a descending inhibitory pathway to produce inhibition of the TF reflex.

429.14

HYPERESTHESIA INDUCED BY SPINAL GLUTAMATE AND NK-1 TACHYKININ RECEPTORS IS REDUCED BY INTRATHECAL NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDs). A.B. Malmberg and T. L. Yaksh*, Dept. of Anesthesiology, UCSD, La Jolla, CA 92093-0818

Spinal administration of NSAIDs can significantly diminish the second phase, behavior induced by subcutaneous injection of formalin in the paw. Based on the growing appreciation of the involvement of excitatory amino acids (EAA) and substance P in the initiation of a facilitatory state of spinal processing, as observed in the phase 2 of the formalin test, we injected NMDA, AMPA and substance P directly into the spinal canal. Intrathecal injection of NMDA (7 nmol), AMPA (1 nmol) and substance P (7 nmol) each resulted in a dose dependent decrease in the latency of the response evoked by a thermal stimulus applied to the hind paw. The selective antagonists MK-801 (29 nmol), CNQX (27 nmol) and CP96,345 (330 nmol), respectively, given 10 min before the agonists, blocked the observed thermal hyperesthesia for the respective agonists. Importantly, injection of the antagonists 10 min after the agonists failed to block the decreased paw withdrawal. To assess the potential role of prostanoids released by the spinal activation of the respective receptors, we examined the effects of several NSAIDs on the evoked thermal hyperesthesia. We found that acetylsalicylic acid (100 nmol), ketorolac (27 nmol) and S(+)ibuprofen (27 nmol) resulted in a complete reversal of the induced thermal hyperesthesia. Importantly, the intrathecal NSAIDs were equally effective in reducing the thermal hyperesthesia whether administered before or after the agonists. Additionally, the inactive stereoisomer R(-)ibuprofen failed to show any effect at doses 10 times higher than the active isomer S(+)ibuprofen. This emphasizes that the NSAIDs action were mediated by an effect upon cyclooxygenase. These data provide evidence that activation of spinal glutamate and NK-1 receptors results, at least in part, in local generation and release of prostanoids, which mediate a spinal facilitation of the animal's response to noxious stimuli. 429.15

EFFECTS OF INTRATHECAL PROSTAGLANDINS ON BEHAVIORAL RESPONSES TO NON-NOXIOUS AND NOXIOUS STIMULI. M.Kaneko[1], Y. Saito*[1], Y.Kirihara[1], J.G.Collins[2] and Y.Kosaka.[1] Dept. of Anesth., [1]Shimane Med.Univ., Izumo, 693 Japan and [2]Sch.of Med., Yale Univ., New Haven, CT 06511

Prostaglandins(PGs) influence the development of hyperalgesia in the periphery. However, centrally their role is not yet well defined. This experiment was designed to investigate the influences of intrathecally administered PGE_1 and $PGF_{2\alpha}$ on behavioral responses to non-noxious, and noxious somatic and visceral stimuli in rats.

Intrathecal catheter was implanted at the level of L2-L3 in rat. The tail flick (TF) test and colorectal distension (CD) test were employed to measure the responses to noxious somatic and visceral stimuli, respectively. Agitation score (AS) to mechanical pressure produced by three kinds of Semmes-Weinstein monofilaments (SWMs) ranging 0.08 g to 2.35 g was measured to assess the hypersensitive state to non-noxious stimulus. After measuring baseline value measurements were repeated for 3 hours after intrathecal injection of 500 ng of PGE_1, 100 ng of $PGF_{2\alpha}$ or saline. ASs were also evaluated for 2 days after administration.

PGE_1 produced a significant decrease for 20 min in both TF latency and CD threshold compared to intrathecal saline which caused no changes. $PGF_{2\alpha}$ produced a slight decrease in CD threshold but no significant change in TF latency. ASs produced by 2.35 g SWM were significantly increased following administration of both PGE_1 and $PGF_{2\alpha}$ and the effects lasted for at least 2 days, while in the saline group there were no significant changes in ASs produced by any of SWM. This result suggests that PGs may act on hyperalgesic processing in the spinal cord.

430.1

Handedness is Predicted by Cerebral Blood Flow Asymmetry. R.A. Stea*, N.M. Szeverenyi, S.H. Manglos, J. Brueggemann, F.D. Thomas, A.V. Apkarian. Depts. of Neurosurgery and Radiology, SUNY-HSC, Syracuse, NY 13210.

Handedness and speech are highly lateralized in the human cerebral cortex. However, earlier imaging studies have not shown consistent correlations between handedness and regional cerebral blood flow (rCBF) hemispheric asymmetries. In this study, left versus right parietal lobe activity in 6 subjects was evaluated and used to predict handedness. Handedness was determined by a manual dexterity test and Annett's questionnaire. Blood flow studies were done by Single Photon Emission Computed Tomography (SPECT) with the retainable tracer ^{99m}Tc-HMPAO. Baseline studies were done with the subject's right hand immersed in neutral temperature water (control condition for the pain study, see below). Data was analyzed by the region of interest method; parietal lobe was directly localized from the patient's co-registered MRI scan. Five subjects had one SPECT scan; one subject had four.

Hemispheric Asymmetry in parietal lobe activity was predictive of handedness in all subjects; greater parietal activity was contralateral to the dominant hand. In four right handed subjects, left parietal activity was greater than right parietal activity (mean: 5.4%). In one mixed-handed subject, left and right activity were equal. In the left handed subject, the right parietal activity was greater by 5.0%. In the right handed subject with four scans (normalized), the left versus right differences were consistent across studies and significant by student's t-test (p=0.01). The results suggest that handedness correlates with parietal cortical activity.

This study is part of a larger ongoing investigation of the cortical representation of pain. In some of the above subjects, thermal pain was induced in either the hand or the foot in order to reveal the nociceptive somatotopy in the cortex. These results will be presented at the conference.

430.2

RESPONSES IN THE RAT TO NOXIOUS COLORECTAL DISTENSION IN THE PRESENCE OF ACETIC ACID. M. Burton* and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242.

The mechanisms of visceral pain have recently been a major focus of investigation. Distension of hollow organs has been reported to be noxious. Clinically, there is usually some pathology associated with pain from visceral organs; however, this has not been extensively studied in animals. Therefore, the aim of this study was to determine the effects of acetic acid irritation on the responses to noxious colorectal distension (CRD).

Pressor and motor (EMG) responses to CRD (80 mmHg, 20 sec, 3 min apart) were examined in unanesthetized, chronically instrumented, male Sprague-Dawley rats before and 6 and 24 hours after 1 ml intracolonic 5% acetic acid (or vehicle). The colons of a separate group of rats were examined 4, 6, 8 or 24 hours after 1 ml intracolonic acetic acid for evidence of leukocyte infiltration. Acetic acid did not produce any change in resting mean arterial pressure (MAP), or in the ΔMAP in response to CRD at any time tested. In contrast, the magnitude of both baseline EMG and ΔEMG produced by CRD were significantly increased at 6 and 24 hours after acetic acid, as noted in the table. Acetic acid had no effect on the number of leukocytes in colonic tissue at any time tested.

These results suggest that irritation, but not inflammation, of the colon produced by acetic acid results in an increase in the magnitude of nociceptive responses to CRD.

	control	6 hr	24 hr
Baseline EMG (%)	100	170 ± 66	255 ± 99
ΔEMG (%)	100	187 ± 49	216 ± 34

EFFECTS OF PARADOXICAL SLEEP (PS) DEPRIVATION ON PAIN-RELATED BEHAVIORS AND NEUROGENIC INFLAMMATION IN RATS. C.A. Landis*. Dept. of Physiological Nursing, University of Washington, Seattle, WA, 98195.

PS deprivation (PSD) is known to increase central nervous system excitability and behavioral activation. PSD rats show a reduction both in the threshold for reflex withdrawal to noxious stimuli and in antinociceptive responses to opiates. Increased excitability of somatic sensory nerves could facilitate mechanisms of peripheral and/or central sensitization to noxious stimuli.

Compared to baseline, after 96 h of PSD by the small platform method, 5 μl of mustard oil (50% in 95% ethanol) applied to the dorsum of one hind paw produced a quantifiable increase in pain-related behaviors. This same solution produced an increase in Evans blue extravasation in 4mm skin biopsies from the dorsum of the left hind paw in PSD rats, compared both to large platform and to normal control rats. Ethanol applied to the contralateral paw was without effect in all rats. These observations suggest neurogenic inflammatory mechanisms contribute to heightened pain sensitivity in PSD rats. EFFECTS OF MANIPULATING INTRACELLULAR CALCIUM ION CONCENTRATION USING VOLTAGE SENSITIVE CALCIUM CHANNEL BLOCKERS AND DANTROLENE SODIUM ON PERSISTENT HINDLIMB FLEXION IN SPINALIZED RATS. M.F. Anderson* and J.T. Earnhardt Department of Psychiatry, St. Elizabeth's Hospital of Boston, Boston, MA 02135 & Department of Pharmacology, University of New England, Biddeford, ME 04005.

Stimulation (2mA, 7ms, 100Hz, 60min) across the musculature of the upper hindlimb in the spinalized rat produces a persistent hindlimb flexion. Previously, we have shown that NMDA receptor antagonists interfere with the induction of this flexion. Given NMDA receptor stimulation indirectly may activate voltage sensitive calcium L-channels, the dose response of pretreatment with nimodipine, nifedipine and diltiazem on induction of a persistent hindlimb flexion was explored.

Following spinalization of adult Long Evans rats under halothane anesthesia, animals were pretreated with one dose of a particular test agent (nimodipine: 0.03, 0.1, 0.3, and 1.0mg/kg, i.p., nifedipine: 0.1, 0.3, 1.0, and 3.0mg/kg, i.p., diltiazem: 0.03, 0.1, 0.3, and 1.0mg/kg, i.p.) and wound clips were applied to the musculature of the right upper hindlimb. After a 30min waiting period, current (2mA, 7ms, 100 Hz, 1 hr) was delivered across the clips. In all groups, flexion was reduced in a dose dependent manner. Since 1) the systemic administration of calcium L-channel blockers may promote skeletal muscle relaxation and 2) NMDA receptor activation may effect release of intraneuronal calcium ion stores, the dose response of pretreatment with dantrolene sodium which theorectically inhibits the release of both skeletal muscle and neuronal calcium ion stores was studied. Following the above protocol, dantrolene sodium (0.1, 0.3, 1.0, and 3.0mg/kg, i.p.) pretreatment reduced poststimulation flexion in a dose dependent manner. These data suggest that induction of a persistent hindlimb flexion in the spinalized rat depends on both adequate 1)neuronal and skeletal muscle intracellular calcium ion levels and 2) activation of skeletal muscle afferents.(Support: Mead Johnson & St.Elizabeth's)

THE CENTRAL DELAY OF THE LASER-ACTIVATED RAT TAIL FLICK REFLEX. P.J. Danneman, J.A. Kiritsy-Roy , T.J. Morrow, M. Mata* and K.L. Casey. Unit for Lab. Animal Med. and Depts. of Neurol. and Physiol., Univ. of Michigan and VAMC, Ann Arbor, MI 48105.

Latency of the rat tail flick reflex is dependent upon: 1) nociceptor activation; 2) afferent conduction to the dorsal horn (DH); 3) central delay; and 4) conduction to and activation of tail muscles. Knowledge of the central delay of the rat tail flick reflex would provide a framework in which to evaluate the temporal constraints on neuronal modulation of this reflex. Using a CO_2 infrared laser (10 W, 45 msec) to produce synchronous activation of tail nociceptors, we measured tail flick latency in awake rats (N=9). Shifts in reflex latency from two points of stimulation on the tail provided an estimate of conduction velocity in the afferent limb of the reflex (0.8 ± 0.1 m/s), indicating that the response is mediated by C-fibers. Animals were then anesthetized with pentobarbital (55 mg/kg), and multiple unit activity and evoked potentials (EPs) were recorded from lamina I DH at L2-L3 during stimulation of the tail using laser or high intensity electrical stimulation (10 mA, 1 msec). Unit activity or EPs elicited by either stimulus consisted of two distinct components, corresponding to activation of A-δ and C-fibers. The difference in latency between laser and electrical evoked activity indicated that an average of 64 ± 7 msec is required for laser activation of nociceptors in the tail. Electrical stimulation of the ventral horn (VH) produced a tail flick response with a latency of 4 msec. Average central delay, calculated as the difference between total tail flick reflex latency and the time required for nociceptor activation, afferent conduction to the DH and efferent conduction from VH, was 72 ± 10 msec. Thus, any pain-activated intrinsic analgesia system must exert its modulatory influence during this interval in order to alter tail flick reflex latency. ENDOGENOUS ANTI-ANALGESIA: EFFECTS OF AMYGDALA, DORSAL RAPHE & SPINAL LESIONS. L.R. Watkins*, E.P. Wiertelak, K. Mooney-Heiberger, R. Grahn & S.F. Maier. Dept. Psychology, University of Colorado at Boulder, Boulder, CO 80309.

We have shown that rats can learn to activate neural circuitry that blocks opiate analgesias (Wiertelak et al., Science, 1992). Using classical conditioning procedures, "danger" signals (cues predicting shock) come to elicit conditioned analgesia & "safety" signals (a light cue predicting that shock will NOT occur for some period) come to elicit conditioned anti-analgesia.

To begin defining anti-analgesia circuitry, we tested the effect of lesions of central nucleus of the amygdala (CeA; bilateral), dorsal raphe nucleus (DRN) & spinal dorsolateral funiculus (DLF; bilateral), vs. sham controls. Each of these areas has been previously implicated in fear &/or analgesia.

After surgery, rats received training to contextual "danger" signals & the discrete light "safety" signal (see Wiertelak et al., Science, 1992). Tail flick (TF) latencies were recorded during each of the 4 days of conditioning to assess the effect of the various lesions on acquisition of conditioned analgesia & anti-analgesia. Conditioned analgesia was then extinguished across 4 days. All rats were injected with morphine the next day to test whether any lesion would prevent reversal of morphine analgesia by the safety signal.

The results were as follows. CeA lesions (a) blocked development of conditioned analgesia, yet (b) did NOT block safety signal reversal of 5 mg/kg s.c. morphine analgesia. Similarly, DLF lesions (a) blocked development of conditioned analgesia, yet (b) did NOT block safety signal reversal of intrathecal morphine analgesia. In contrast, DRN lesions (a) did NOT block development of conditioned analgesia yet (b) prevented reversal by the safety signal of both conditioned analgesia & 5 mg/kg s.c. morphine analgesia. Taken together, these data provide strong evidence that anti-analgesia is mediated by neural circuitry distinct from that previously defined for analgesia systems. INTERNAL AVERSIVE STIMULI ELICIT ACUTE & CONDITIONED HYPERALGESIA. E.P. Wiertelak*, K. Mooney-Heiberger, W. Van Wyhe, G.R. FitzPatrick II, S.F. Maier & L.R. Watkins. Department of Psychology, University of Colorado, Boulder, CO 80309.

Hypoalgesia aversive to external stimuli promotes effective defense/escape behaviors. Perhaps, then, the adaptive response to aversive internal stimuli is hyperalgesia, to promote recuperative behaviors.

An emetic agent (0.15 M lithium chloride [LiCl] i.p.) was used to produce an aversive internal state (illness). Indeed, LiCl produced profound hyperalgesia (tail flick), compared to controls. This appeared specific for nociception, as reactivity to non-painful stimuli (vonFrey hairs) was unchanged. LiCl-induced hyperalgesia involves activation of a centrifugal pathway since it is blocked by spinal transection. Further, this effect appears to be mediated by cholecystokinin (CCK) since it is abolished by proglumide (0.4 mg/kg s.c.), a CCK antagonist. Paradoxically, 7 mg/kg naltrexone produced profound analgesia in LiCl injected rats, but not in vehicle controls.

Since illness clearly could produce hyperalgesia, could hyperalgesia be conditioned to cues associated with illness? To address this question, 2 groups were tested using a taste aversion paradigm. The first received saccharine paired with LiCl. The second (control) received equal numbers of LiCl & saccharine exposures, but in an unpaired fashion. On test day, all rats received saccharine. The rats that previously had saccharine paired with LiCl showed profound hyperalgesia, compared to controls. Conditioned hyperalgesia was again abolished by proglumide, indicating a role of CCK. Again, paradoxically, naltrexone produced profound analgesia in the rats that previously had saccharine paired with LiCl.

These data clearly demonstrate that conditioned effects on pain sensitivity are bidirectional. External danger cues can produce analgesia. The present data demonstrate that aversive internal stimuli can produce hyperalgesia as can learned cues that signal such events. 430.8

CONTROLLABLE, BUT NOT UNCONTROLLABLE SHOCK ELICITS AN ANTINOCICEPTION IN SPINALIZED RATS. C.W. Parker III., P.A. Illich, J.W. Grau & M.W. Meagher*. Dept. of Psychology, Texas A&M Univ. College Station, TX 77843.

Prior work has shown that exposure to inescapable shock produces both short- and long-term analgesia. These effects are not observed in rats that experienced the same amount of shock, but can control its termination. It has been generally assumed that such effects are mediated by forebrain systems. However, we have recently shown that other antinociceptive phenomena thought to involve forebrain systems can be obtained in spinalized subjects. Here, we assess whether having control influences nociception in spinalized subjects. A day after rats received a spinal transection at T2, they were placed in restraining tubes and tested for baseline levels of nociception. Nociceptive thresholds were defined as the shock intensity needed to produce a leg flexion. Subjects were then given a 30 min training session in which they received 1.0mA footshocks. Subjects were run in pairs. One rat could terminate the shock by flexing its leg (Exp). The other rat received the same shock irrespective of leg position (Yok). Exp, but not Yok subjects spent increasingly more time with their legs in a flexed position. Interestingly, after training, Exp subjects exhibited an increase in nociceptive threshold (antinociception), while Yok subjects showed a decrease in nociceptive threshold(hyperalgesia) ($p < .01$). The results suggest that controllability influences nociception in spinalized rats.

430.9

MILD SHOCK PRODUCES AN UNCONDITIONED, NALTREXONE-INSENSITIVE INCREASE IN REACTIVITY ON THE VOCALIZATION MAGNITUDE AND THRESHOLD TESTS. P.A. Illich*, C. W. Parker III., K.D. Burks, & J.W. Grau. Dept. of Psychology, Texas A&M Univ. College Station, TX 77843.

Prior work suggests that an aversive event can produce either an increase (hyperalgesia) or decrease(hypoalgesia) in pain reactivity. Although stress-induced hypoalgesia has been extensively examined both at the behavioral and neural levels, relatively little is known about stress-induced hyperalgesia. Here, we first establish a paradigm that produces a robust increase in responding to pain. Subjects experienced either mild shock (3, 0.75-s, 1.0mA) or nothing, and were then given a single test shock (0.75-s, 1.0mA). Previously shocked subjects vocalized more to the test shock relative to unshocked controls. A second set of subjects were treated the same except that vocalization threshold rather than magnitude was assessed. Shocked subjects exhibited a substantial decrease in vocalization threshold (hyperreactivity) that decayed over time (Experiment 2), irrespective of whether they remained in the shock-context (Experiment 3). Experiment 4 showed that this effect was naltrexone (14 mg/kg) insensitive. The results suggest that mild shock can produce an unconditioned, naltrexone-independent, increase in responding on the shock-induced vocalization and vocalization threshold tests. We are currently exploring the neural mechanisms that underlie this effect. Supported by BRSG 2S07RR07090 to J.W.G.

EFFECTS OF CAPSAICIN DERIVATIVES ON TAIL-FLICK REFLEX,NEURAL CONDUCTION AND CONTENT OF SUBSTANCE P. J.H.Lee*1, S.S. Lee2, J.S.Kim1, and K.N.Kim1. Department of Physiology, Seoul National University, School of Dentistryl and School of Pharmacy2, Seoul, Korea, 110-460.

This experiments was performed to compare the effects of capsaicin and its new derivatives on the tail-flick and jaw opening reflex evoked by noxious stimuli and content of substanceP in spinal dorsal horn and trigeminal sensory nucleus. Tail-flick reflex was tested by hot water immersion method in rat after subcutaneous injection of capsaicin, paradol, shogaol and demethoxy-NE(DM-NE). Neural conduction of peripheral nerve was determined in saphenous nerve. Saphenous nerve was exposed and action potential was evoked by noxious electrical stimulation. Capsaicin and its derivatives were dissolved in vehicle and applied to saphenous nerve between stimulating and recording site for 30 minutes. Amplitude and conduction velocity of action potential was compared before and after application of drugs. SubstanceP of spinal cord and trigeminal sensory nucleus was determined by radioimmunoassay. Capsaicin inhibited neural conduction of mainly C-fiber but paradol and shogaol had inhibitory effect on both A- and C-fiber. Capsaicin and DM-NE significantly increased latent period of tail-flick reflex at first day after injection. Capsaicin decreased the substance P in spinal dorsal horn and caudal part of trigeminal sensory nucleus.

430.11

A COMPARISON OF NOCICEPTIVE RESPONSES USING TWO METHODS OF HOT-PLATE MEASUREMENTS: ABSOLUTE TEMPERATURE THRESHOLD VERSUS REFLEX LATENCY. Przemyslaw Marek[1]*, Anthony L. Vaccarino[2], Bogdan Sadowski[3] and John C. Liebeskind[1], [1] Dept. of Psychology, UCLA, CA 90024, [2]Dept. of Psychology, University of New Orleans, LA 70148 and [3]Institute of Genetics and Animal Breeding, Jastrzebiec, Poland.

Mice bred for high (HA) and low (LA) stress-induced analgesia display dramatic differences in baseline hot-plate latencies. Interpretation of baseline sensitivity in the hot-plate test, however, is confounded by the stressful nature of this test and it is unclear whether such differences are due to stress-induced analgesia (produced by the test itself) or due to differences in tonic pain inhibition. We have recently developed a method of measuring hot-plate pain sensitivity which reduces the stressful component. HA and LA mice were habituated for 20 minutes to a hot-plate maintained at $37\pm1^{o}C$. The temperature of the hot-plate was then gradually increased and the temperature to hind-paw lick was recorded. No differences were found in baseline temperature threshold between HA and LA mice. In contrast, HA mice showed higher baseline responses than LA mice when the conventional hot-plate test was used (i.e. plate maintained at $56\pm1^{o}C$). Morphine produced a dose-dependent analgesia in both tests. These results suggest that this method of measuring absolute tempurature threshold may provide an alternative method of assessing pain sensitivity, which greatly reduces the confounding effects of stress. Supported by NIH Grant NS07628 and an Unrestricted Pain Research Grant from the Bristol-Myers Squibb Company.

EXPOSURE TO A HEAT STRESSOR INDUCES AN OPIOID CONDITIONED HYPOALGESIA IN RATS TESTED FOR NOCICEPTION TO FORMALIN. H. Foo* and R.F. Westbrook. School of Psychology, Univ. of N.S.W. Sydney, Australia.

Rats exposed to a heated floor in a distinctive environment (E1) and subsequently tested there on that floor are hypoalgesic. This conditioned hypoalgesia is naloxone irreversible and not cross-tolerant with morphine. However, morphine-tolerant rats come to acquire the conditioned hypoalgesia and naloxone given in combination with the initial exposure to the heated floor enhances the acquisition of the conditioned hypoalgesia.

The present study examined whether these hypoalgesic effects are observed when a chronic pain measure is used to assess nociception. Rats exposed to a heat stressor in E1 were hypoalgesic when subsequently tested there for pain sensitivity to formalin. This conditioned hypoalgesia was naloxone-reversible and cross-tolerant with morphine. The unconditioned hypoalgesia induced by formalin was also naloxone-reversible and cross-tolerant with morphine. These results, thus, suggest that the nature of the conditioned hypoalgesia associated with pre-exposure to a heat stressor might depend upon the type of pain elicited on test. Although acquisition of the conditioned hypoalgesia was facilitated by pairing exposure to the heated floor with naloxone, morphine-tolerant rats were hyperalgesic in the formalin test. However, morphine-tolerant rats were just as hypoalgesic as morphine-naive ones when tested with the opioid in the formalin test. Thus, the capacity of morphine tolerance to block the acquisition of conditioned hypoalgesia appears to be independent of opioid pain mechanisms.

430.13

NOCICEPTIVE RESPONSES TO HIGH AND LOW RATES OF FOOT SKIN HEATING IN RATS MAY BE MEDIATED BY DIFFERENT NOCICEPTORS.
D.C. Yeomans*, V. Pirec, and H.K. Proudfit. Department of Pharmacology, U.I.C., Chicago, IL 60612.

The selective actions of capsaicin or morphine to increase or decrease nociceptive responses mediated by polymodal nociceptors were used to test the hypothesis that heating the dorsal hairy surface of the hindpaw at low rates elicits withdrawal responses evoked by polymodal nociceptor activation, whereas high rates of heating evoke responses mediated by other nociceptors. Capsaicin was applied topically to the hairy foot skin of rats to selectively sensitize polymodal nociceptors. Capsaicin reduced the latency of the reflexive withdrawal response evoked by low heating rates, but not by high heating rates. In addition, the skin temperature at which the response to low heating rates occurred was reduced from 46 to 41°C, but the temperature at which the response to high heating rates occurred (51°C) was not affected.

Responses mediated by the activation of C polymodal nociceptors have been demonstrated to be preferentially attenuated by low doses of systemic morphine (Cooper et al., Pain, 24:93-116, 1986). In the present experiments, low doses of morphine (0.01 to 1.0 mg/kg i.p.) selectively attenuated nociceptive responses to low heating rates in normal rats, and to an even greater extent after capsaicin treatment. The same doses of morphine did not attenuate nociceptive responses to high heating rates in either normal rats or those with capsaicin sensitized skin. Higher doses of morphine (2.0 to 10.0 mg/kg i.p.) attenuated responses to both types of stimulation. These results support the conclusion that low rates of heating elicit responses elicited by the activation of polymodal nociceptors. In addition, the potency of analgesic drugs, determined using thermal methods, may depend on the rate of skin heating. Supported by USPHS Grants DA03980 (HKP) and DA05406 (DCY).

C-FIBER CONDITIONING CAUSES FACILITATION OF TOUCH-EVOKED RESPONSES IN RAT FLEXOR MOTONEURONS IN VIVO
L.G. Sivilotti* and C.J. Woolf, Anatomy Dept., University College London, Gower St., London WC1E 6BT, U.K.

Touch-evoked pain, mediated by Aβ fibers, can be produced in humans following C-fiber activation by intradermal capsaicin (Torebjörk et al. (1992), J.Physiol., 448, 765). In the rat, pharmacological blockade of inhibition in the spinal cord results in touch-evoked agitation (Yaksh (1989), Pain, 37, 117). We set out to examine the effects of C-fiber conditioning and central disinhibition on flexor motoneuron responses in the decerebrate spinal rat. The response of hamstring motoneurons to noxious and non-noxious stimuli applied to the receptive field was tested. In control conditions tactile or Aβ stimulation caused little or no activity. Responses to repeated standardized touches of the hindpaw or electrical activation of Aβ afferents were greatly enhanced after C-fibers were activated either by cutaneous application of mustard oil or by conditioning the sural nerve (1 Hz, 20 s; +1118 ± 248 and +279 ± 48%, respectively). A similar facilitation of touch-evoked responses was observed following a subconvulsant dose (3 μg) of strychnine or bicuculline i.t. (+1042 ± 499 and + 1239 ± 377%, respectively). These changes were associated with a decrease in the mechanical threshold of the flexor reflex and an increase in the response to noxious stimuli. Sural conditioning at Aβ strength (1-10 Hz, 20 s) had no effect. These results suggest that C-fiber induced central sensitization results in allodynia as well as hyperalgesia and that disinhibition may be involved.

RETINA AND PHOTORECEPTORS: AMACRINE, GANGLION AND GLIAL CELLS

431.1

SYNAPTIC ORGANIZATION OF DOPAMINERGIC AMACRINE CELLS IN THE LARVAL TIGER SALAMANDER RETINA.
P.A. Glazebrook, K.R. Fry* and C.B. Watt. Alice R. McPherson Laboratory of Retina Research, Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX. 77380.

Immunocytochemistry of tyrosine hydroxylase (TH) was used to visualize tiger salamander dopaminergic amacrine cells. The avidin-biotin immunoperoxidase method was used to immunostain TH immunoreactive cells in vibratome-prepared sections that were routinely processed for ultrastructural examination. TH-positive somas exhibited an evenly distributed peroxidase reaction product throughout their cytoplasm. Their nuclei were generally unstained and possessed indented nuclear membranes. TH-positive processes were generally stained throughout and were characterized by an occasional dense-core vesicle in addition to a generally homogeneous population of small round clear synaptic vesicles. They formed conventional synaptic contacts that were characterized by symmetrical synaptic membrane densities.

A total of 112 synaptic relationships were observed in the inner plexiform layer that involved TH immunoreactive processes. TH-positive processes were presynaptic to amacrine cell processes (33.0%) and to processes that lacked synaptic vesicles (26.8%). Synapses onto amacrine cell processes were observed only in sublayer 1. Synaptic contacts onto processes that lacked synaptic vesicles were observed primarily in sublayer 1 (93.4%), but also in sublayers 3 (3.3%) and 5 (3.3%). As postsynaptic elements, they received synaptic input from both amacrine (39.3%) and bipolar (0.9%) cells. Bipolar input was observed only in sublayer 1, while amacrine cell input was found in sublayers 1 (59.1%), 3 (25.0%) and 5 (15.9%). Supported by grants from the NIH (EYO5622) and the Retina Research Foundation (Houston).

COEXISTING RELATIONSHIPS OF SUBSTANCE P-AMACRINE CELLS IN THE LARVAL TIGER SALAMANDER RETINA.
C.B. Watt*, V.J. Florack and R.B. Walker. Alice R. McPherson Laboratory of Retina Research, Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX. 77380.

Substance P (SP) immunocytochemistry was combined with either immunocytochemistry of gamma-aminobutyric acid (GABA) or autoradiography of high-affinity GABA uptake to examine for the presence of GABA in SP-amacrine cells of the larval tiger salamander retina. Three thousand SP-like immunoreactive cells were visualized in double-label preparations. Double-label analyses revealed two populations of SP-amacrine cells that express each marker of GABA activity. The majority of these cells were situated in the innermost cell row of the inner plexiform layer and were designated as Type 1 amacrine cells. The other population was displaced to the ganglion cell layer. No SP immunoreactive Type 2 amacrine cells co-labelled for markers of GABA activity. Approximately 10% of SP-amacrine cells in the amacrine and ganglion cell layers co-labelled for markers of GABAergic activity. Double-labelled cells accounted for less than 1% of GABA-labelled cells observed in these layers. SP immunocytochemistry was combined with autoradiography of glycine high-affinity uptake to examine for the presence of glycine in SP-amacrine cells of the tiger salamander retina. Preliminary results reveal that approximately 90% of SP-cells exhibit high-affinity accumulation of glycine.

This study was supported by grants from the NIH (EYO5622) and the Retina Research Foundation (Houston).

INTRACELLULAR RECORDING, STAINING WITH BIOCYTIN AND IMMUNOHISTOCHEMISTRY OF AMACRINE CELL NETWORKS IN CARP RETINA.
J.C. Goddard[1], E.M. Fitzgerald[1]*, U.D. Behrens[2], H.-J. Wagner[2] and M.B.A Djamgoz[1]. [1]Dept. of Biology, Imperial College, London, SW7 2BB, UK; [2]Inst. Anatomy and Cell Biology, Philipps University of Marburg, D-355 Marburg, FRG.

Correlation of electrophysiological, morphological, neurochemical characteristics and connectivity of neurones is important for understanding the functional organization of neuronal systems. The amacrine cell of the carp retina has been chosen to show how the above characteristics can be brought together in a model system. Amacrine cells were electrophysiological recorded and then injected with a solution of 4% biocytin in 0.5 M KCl.

Biocytin diffused through gap junctions and often up to 25 coupled amacrine cells were observed from a 2 min injection at 1-10 nA. From the analysis of the stained networks, it appeared that not all coupled amacrine cells were morphologically the same. Some cell groups were cryosectioned and processed for GABA immunohistochemistry. Several cells generating on-off transient responses have yielded positive results. However, it was not clear whether all coupled cells within a network were GABAergic. Present research is further analysing the morphological and neurochemical characteristics of amacrine cell networks.

431.4

MORPHOLOGIES AND MOSAICS OF AXON-BEARING AMACRINE CELLS IN THE RABBIT RETINA: A NEUROBIOTIN TRACER-COUPLING STUDY.
L.L. Wright and D.I. Vaney*. Vision, Touch and Hearing Research Centre, University of Queensland, Brisbane 4072, Australia.

Many types of retinal amacrine cells show homologous coupling when injected with the biotinylated tracers, biocytin or Neurobiotin, thus revealing their somatic array (Vaney, 1991). Moreover, these small tracers are readily transported along the thin processes that characterize "axon-bearing" amacrine cells: visualization of these long processes is greatly aided by photochromic intensification of the DAB reaction product in the presence of tetrazolium salts (Vaney, 1992). We have thus used Neurobiotin injections of microscopically identified cells in the superfused rabbit retina to characterize the complete morphology and the somatic mosaic of several types of low density, axon-bearing amacrine cells. They include the long-range cell (LR; Vaney et al., 1988), the type 1 and type 2 catecholamine-accumulating cells (CA1 & CA2; Tauchi et al., 1990), the type 1 NADPH-diaphorase cell (ND1; Sagar, 1990), the interstitial amacrine cell (PA1; Famiglietti, 1992a), and the presumptive somatostatin cell (PA2; Famiglietti, 1992b). Whereas the LR, ND1 and PA1 cells showed strong homologous coupling, the PA2 and CA1 cells were only weakly coupled, and the CA2 cell showed no coupling. The LR and PA1 cells showed homologous coupling to somata located in either the inner nuclear, inner plexiform or ganglion cell layers. Both the LR and ND1 cells also showed heterologous coupling to other types of presumptive amacrine cells. The distal processes of the LR cells and the axons of the ND1 cells could be traced for up to 5 mm from the soma: this greatly exceeds the extent of other retinal interneurons that have been intracellularly labelled by previous methods.

COMPARISON OF RETINAL GANGLION CELL MORPHOLOGY IN NORMAL AND TRANSGENIC MICROPHTHALMIC MICE. **S.D. Schlussman and S.C. Sharma*** Depts. Cell Biol. and Anatomy and Opthalmology, New York Medical College, Valhalla, N.Y. 10595.

Genetic ablation of gamma-2 crystallin expressing cells leads to a microphthalmic phenotype. We have previously demonstrated a decreased density of neurons in the Ganglion Cell Layer in transgenic microphthalmic mice as compared to controls. This observation prompted a consideration of the morphology of RGC in microphthalmic retinae. HRP labelled RGC were analyzed in normal and transgenic microphthalmic mice on the basis of 1) soma diameter, 2) dendritic field diameter and 3) dendritic morphology. The diameter of RGC somata in normal CD-1 mice ranged from a low of 3.0 μm to a high of 22.4 μm with an average of 13.1 ± 3.9 μm. The dendritic field diameters of normal RGC ranged from a low of 11.168 μm to a high of 145.6 μm and had an average of 70.7 ± 27.96 μm. Transgenic microphthalmic RGC somata ranged in size from 10.24 μm to 26.3 μm and had an average of 16.3 ± 3.8 μm. The dendritic field diameters in these animals ranged from a low of 63.7 μm to a high of 234.9 μm and had an average of 136.8 ± 50.0 μm. These correspond to an average increase of approximately 24% and 93% respectively. These data indicate that RGC dendritic fields are capable of altering their morphology in response to changes in their local environment. Supported by NEI 01426

431.6

SPATIO-TEMPORAL RESPONSE PROFILES OF CAT RETINAL W-CELLS M.H. Rowe* and J.F. Cox, Neurobiology Program, Ohio Univ., Athens, OH 45701.

We have used a one dimensional version of the reverse correlation procedure of Jones and Palmer (J. Neurophysiol., 58: 1187-1211, 1987) to examine the spatio-temporal (ST) response profiles of cat retinal W-cells and compare them to those of X- and Y-cells. The stimuli consist of stationary bright or dark bars which are presented for a fixed duration, typically 50 msec, at one of 16 positions spanning the entire receptive field along one spatial dimension. A series of stimuli are presented successively with no interstimulus interval, and both the position and contrast (bright or dark) of each stimulus are varied randomly. The times of occurrence of all action potentials occurring during the presentation sequence are recorded and the reverse correlation procedure quantifies the relationship between the time of occurrence of each spike and the position, contrast and time of onset of each stimulus in the sequence. The resulting ST profiles thus represent one dimension of space and one of time, and provide an estimate of the cell's spatio-temporal impulse response. Most tonic W-cells have ST profiles similar to those of X- or Y-cells, i.e. a spatial center-surround organization at short latencies, which is space-time inseparable due principally to the longer latency of the surround response. Some phasic W-cells also conform to this pattern, but some have profiles that are much simpler, consisting of a single central zone, not flanked in space or time by an antagonistic region, while others have much more complicated profiles, often with central zones which are bimodal in the space domain, flanked by antagonistic regions that are offset in both space and time. Supported by NIH EY08038.

CHARACTERIZATION OF LIGHT-EVOKED NMDA RECEPTOR-MEDIATED INPUT TO GANGLION CELLS IN DARK-ADAPTED RETINAS. J. S. Diamond and D. R. Copenhagen*. Bioengineering Graduate Group, Departments of Physiology and Ophthalmology, University of California, San Francisco, CA 94143.

Light-evoked excitatory synaptic input to ganglion cells has been shown to be mediated by both NMDA and AMPA-type glutamate receptors (Mittman et al. (1990) *J. Physiol.* **428:** 175).

We have used standard whole-cell patch clamp techniques in the tiger salamander retinal slice preparation to investigate the time course and magnitude of the light-evoked glutamate receptor-mediated inputs to ganglion cells in dark-adapted retinas. In voltage-clamp recordings, the reversible effect of D-2-amino-7-phosphonoheptanoate (AP7), a competitive NMDA antagonist, on the response to a two-second flash of light was greatest at -40 mV, a potential at which NMDA-mediated current is thought to be near maximal; the AP7 effect was least at -90 mV, where the NMDA receptor channel is blocked by external Mg^{2+} (1 mM). The relative strength of the NMDA-mediated input with respect to the AMPA input was determined by taking the ratio of the light response at -40 mV to that at -90 mV. AP7 (30 μM) caused as much as a five-fold reduction in this ratio.

Mittman et al. showed that cells in light-adapted preparations displayed a relatively fast response to light and that the excitatory inputs could be distinguished temporally, because the NMDA input had a much slower time course (time to peak = 100 msec) than the AMPA input (time to peak = 28 msec). In dark-adapted retinas the ganglion cell response to dim light had a much slower time course (time to peak ≈ 500 msec). When AP7 was applied, the magnitude of the light-evoked current at -40 mV decreased, but no significant change in time course was seen. Neither the magnitude nor the time course of the dim flash responses at -90 mV was affected by AP7. Consequently, there is considerably more temporal overlap of the AMPA- and NMDA-mediated light responses in dark-adapted than in light-adapted retinas. Any nonlinear interactions between the AMPA and NMDA conductances would, therefore, be enhanced under dark-adapted conditions.

CHANGES IN THE MORPHOLOGY AND SURVIVAL OF THE CELLS OF THE GANGLION CELL LAYER OF THE RETINA FOLLOWING CORTICAL LESIONS AND OPTIC NERVE SECTION IN THE FERRET. T.J. DROLSUM AND E.H. POLLEY*. Dept. of Anatomy & Cell Biology, Univ. of Ill., Chicago, Ill. 60612.

The morphological responses of retinal ganglion cells (RGCs) to axonal section and loss of postsynaptic targets was studied in 13 male ferrets (Mustela putorius furo). Experiments included: 1) ablation of the visual cortex (with retrograde degeneration of cells in the lateral geniculate nucleus (LGN); 2) a lesion of LGN (to include projecting optic nerve terminals); and 3) intracranial section of one optic nerve. Survival times ranged from 5 mos. to 1 yr. Retinal flatmounts were embedded in glycol methacrylate, sectioned en face at 5 microns, and stained with 0.1% Thionin. An unbiased counting frame (Gundersen et al., 1988) was used to measure cell density and cell size distributions from serial sections of the RGC population in a defined area, 2.5 mm. temporal to the optic disc. In addition, changes in the frequency distribution of surviving small, medium and large RGCs were obtained from a larger population of RGCs with the aid of a digitizing computer program by Sigma Scan (Jandel). Only those cells demonstrating a nucleus, nucleolus, and Nissl material were included in the study.

Data analysis indicates that there is a decreased frequency in the numbers of medium sized cells among the RGCs surviving a lesion of visual cortex. While the frequency of the large cells in the RGC layer remained unchanged, the relative numbers of the small cells increased. Following lesions of the LGN or after transection of the optic nerve, the frequency distribution of both large and medium sized cells decreased while that of the small cells increased. The latter procedures also resulted in a marked decrease in the overall cell density in the RGC layer, whereas cell density remained unchanged following the cortical lesions.

These results suggest that the retrograde transneuronal effects of visual cortical lesions on retinal ganglion cells is limited to a modification of normal soma size of the medium sized cells. This is in contrast to the degenerative effects of a lesion to optic nerve terminals or optic nerve fibers which broadens the retrograde effects to include a degeneration and shrinkage of large, medium and small RGCs. We believe that the cortical lesion demonstrates a dependency of a subset of RGCs on an intact postsynaptic target for specific maintenance of soma size. The retrograde degenerative effects of lesion of the optic nerve axon or its terminals demonstrates a dependency of the RGCs that is associated with the integrity of these processes.

Circuitry of Midget Ganglion Cells In Primate Fovea Distinguishes Two Classes of Cone. D.J. Calkins, K. Klug[1], S.J. Schein[1], Y. Tsukamoto[2]*, P. Sterling. U. of Penn., Phila., Pa 19104, [1]UCLA, 90024, [2]Hyogo Col. Med., 663 Japan.

Middle (M) and long wavelength sensitive (L) cones, which together constitute about 90% of the foveal cone population, can be distinguished from short wavelength sensitive (S) cones by differences in immunoreactivity to antigenic markers, dye uptake, and ultrastructure. However, M and L cones have not so far been distinguished from each other. Consequently, neither their relative numbers nor their circuitry have been determined. We reasoned that if the synaptic circuits that link each cone to its pair of midget ganglion cells (on- and off-) differ for M and L cones, then by reconstructing these connections we might distinguish the two classes. In electron micrographs of serial sections, we identified, for a small patch of cones (outer segments at 1.5° nasal), the pair of midget bipolar cells to which each cone connected and also the corresponding pair of midget ganglion cells. For one set of cones (N=17), the number (mean ± s.d.) of synaptic outputs (ribbons) per midget bipolar cell was 29 ± 2, and the number of inputs (at ribbons) per midget ganglion cell was 15 ± 2. For another set of cones (N=9), the number of synaptic outputs per midget bipolar cell was 51 ± 3, and the number of inputs per midget ganglion cell was 26 ± 3. Thus, in the parametric space defined by this circuitry, the cone array was partitioned into two distinct groups. The ratio of the two classes was 1.9, and within the patch studied they were completely interspersed. Psychophysical results[1] suggest that the ratio of L to M cones is about 2, so conceivably the two classes identified here represent, respectively, L and M cones. Supported by EY08124.
We thank P. Masarachia, A. Meyers, and L. Chukoskie for their help.

HYPEROSMOTIC ACTIVATION OF TRANSMITTER RELEASE FROM PRESYNAPTIC TERMINALS ONTO RETINAL GANGLION CELLS. W. Yu and R. F. Miller*. Department of Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

We studied neurotransmission from 2nd order neurons to ganglion cells, using micro hyperosmotic stimulation (μHS) to activate transmitter release from presynaptic terminals in the inner plexiform layer. These experiments were carried out in a perfused retinal slice preparation of the tiger salamander, using direct visualization under an upright binocular microscope. A micropipette, filled with hyperosmotic sucrose (0.5 M + Ringer) was placed in the IPL and whole-cell recordings were obtained from single ganglion cells. Single cells were studied under current and voltage-clamp conditions, and many cells were stained with 5 and 6 carboxyfluoroscein added to the whole-cell pipette and visualized with fluorescence microscopy.

Brief positive pressure pulses (0.5-2 bar), applied to the sucrose pipette, activated a postsynaptic response in ganglion cells which was graded in magnitude, based on the duration of the pressure pulse. Voltage-clamp analysis and pharmacological studies indicate that the μHS response usually consists of both excitatory and inhibitory components. When the inhibitory components are blocked with picrotoxin (100 μM/strychnine (10 μM)), the postsynaptic current can be studied as a relatively pure excitatory postsynaptic event which typically consists of NMDA and non-NMDA contributions based on the use of dAP7, an NMDA receptor antagonist and NBQX (2,3 Dihydroxy-6-nitro-7-sulfamoylbenzo (F) quinoxaline), a non-NMDA receptor antagonist. This approach permits the analysis of relative NMDA/non-NMDA contributions into identified cell types and at different spatial positions along the soma-dendritic tree. Supported by NIH grants RO1 NEI-07376 and NS-17763 awarded to RFM.

STRUCTURE AND FUNCTION OF GANGLION CELLS PROJECTING TO THE CAT'S GENICULATE WING: AN *IN VITRO* STUDY. M. Pu, T. Pan and D.M. Berson*. Div. Biology & Medicine, Brown Univ., Providence, RI, 02912

The cat's geniculate wing (retinorecipient zone of the pulvinar) is thought to receive its retinal input from a single morphological class of presumed W-cells termed epsilon cells (Leventhal, et al., JCN 194:'80; Rodieck and Watanabe, Neurosci. Abst. 12:'86). We labeled wing-projecting cells by retrograde transport of fluorescent beads and studied their morphology and physiology in vitro. Intracellular staining with Lucifer Yellow and biocytin showed that nearly all of these cells (147/150; 98%) had the medium-sized somas (17-32 μm dia., mean 24 μm) and large, simple, radiate dendritic fields typical of epsilon cells. Dendritic-field diameters increased with eccentricity in the central retina (200-400 μm near the a.c.; 500-800 μm at 3 mm eccentricity) but exhibited little further increase more peripherally (500-1000 μm). Many dendritic profiles were elliptical with long axes pointing toward the a.c. Dendrites stratified narrowly in the inner IPL. Axons were as thick as any among presumed W-cells and similar to those of beta cells (~ 1 μm dia.). The morphology of these epsilon cells closely matches that of a wide-field type prominent among cells we have labeled by retrograde transport from the medial interlaminar nucleus (Neurosci. Abstr. 17:'91).

Epsilon-cell anatomy suggests certain physiological traits: large receptive field (large dendritic profile); ON-center (inner IPL ramification); tonic subtype of W-cell (thick axon, large soma, and uncrossed projections from temporal retina). We have begun testing these hypotheses by recording extracellularly from identified wing-projecting cells in a flattened superfused eyecup preparation. To date, all cells in our small sample (n=5) had the predicted large ON-center, OFF-surround receptive fields and tonic light responses.

IMAGING OF LABELLED RETINAL GANGLION CELLS IN THE LIVING MAMMALIAN EYE. R.W. Rodieck*, B. Lia, & P. Kuthan. Department of Ophthalmology, RJ-10, University of Washington, Seattle WA 98195.

At present, it is difficult to correlate the ganglion cell types distinguished by function with those distinguished in terms of morphology and central projections. However, straightforward techniques *are* available to:
1. determine functional properties by means of extracellular recording from ganglion cells *in vivo*, and 2. determine morphology and central destinations, by means of a retrograde label and intracellular injection (e.g. HRP, Neurobiotin) of ganglion cells *in vitro*. We have developed an approach that combines these two techniques with *in vivo* imaging so as to allow the receptive-field properties, dendritic morphology, and central destinations of individual ganglion cells to be characterized.

Near-infrared fluorescent microspheres ('Crimson', Molecular Probes) are used as the retrograde label, in order to preserve rod sensitivity. Labelled ganglion cells are visualized by what is, in effect, an epifluorescence ophthalmoscope. This device makes use of a barrier filter, a 135 mm imaging lens, and a CCD array cooled to -45° C in order to allow the slow collection of the image of the ganglion-cell layer, using a relatively dim, monochromatic excitation beam. Spatial resolution is 2 µm/pixel; intensity resolution is 12 bit (0.025%). Image quality is good, with contrast between labelled cells and background as large as 3:1. Images may be saved on disk. Tungsten-in-glass recording electrodes with Crimson microspheres in the tip can be advanced onto selected labelled cells, and the apparatus swung out of the way in order to investigate receptive-field properties. Later, the same cells can be located and intracellularly injected via the *in vitro* technique. Supported in part by NIH grants EY02923 and EY01730, and by the E.K. Bishop Foundation.

NEURAL CIRCUITRY OF FOVEAL GANGLION CELLS IN THE HUMAN RETINA. Helga Kolb* and Jill Crooks, Physiology Dept., University of Utah, Salt Lake City, U.S.A.

While the relationship of midget bipolar cells and midget ganglion cells is well established (Kolb and DeKorver, '91) little is known of the synaptic circuitry involving amacrine cells to ganglion cells in the primate fovea. Thus in this study we have concentrated on understanding the neurochemical signature of the input amacrine cells to ganglion cells using techniques of postembedding immuncytochemistry for GABA and glycine on EM serial sections.

Both midget and parasol ganglion cells and their respective input bipolar cells have been included in the analysis. GABAergic amacrine cells provided about 27% of the amacrine input to ON-center ganglion cell dendrites while glycinergic amacrines provided only 6% of the synapses. OFF-center cells received about the same proportion of GABAergic synapses (23%) as ON-center cells but a higher proportion of glycinergic synapses (23%). 50 to 60% of the amacrine synapses to all types of ganglion cells were of unknown neurotransmitter species.

GABAergic amacrine cell synapses upon bipolar axon terminals formed about 50% of all the amacrine input for both ON-center and OFF-center variety. Only in a minority of cases was the same GABAergic amacrine postsynaptic to the bipolar presynaptic upon the ganglion cell dendrite. In contrast, GABAergic amacrine cells were frequently reciprocal upon the bipolar cell without making a synapse upon the ganglion cell. There is evidently a complex synaptic circuitry concerning bipolar/ganglion/amacrine interactions even to construct the most "simple" foveal ganglion cell receptive fields. (Supported by grant EY03323)

EXCITATORY SYNAPTIC INPUTS TO SALAMANDER RETINAL GANGLION CELLS ARE MODULATED BY POLYAMINES AND GLYCINE. Peter D. Lukasiewicz* & Carmelo Romano. Department of Ophthalmology & Visual Science, Washington Univ. Sch. of Med, St. Louis, MO 63110.

Recent biochemical and electrophysiological studies have shown that both polyamines and glycine can enhance the activity of the NMDA receptor. This work was undertaken to determine if polyamines and glycine can modulate the strength of the excitatory synaptic inputs to retinal ganglion cells.

Excitatory synaptic currents were recorded from ganglion cells in the tiger salamander retinal slice preparation using whole-cell patch recording. Synaptic inputs were elicited by puffing K^+ onto the dendrites of bipolar cells presynaptic to the ganglion cell. The NMDA component of the input was isolated by including 1-5μM CNQX, 1μM strychnine and 100 μM picrotoxin in the bath. We investigated whether or not a polyamine site was associated with NMDA receptors on ganglion cells using the polyamine inverse agonist diaminodecane (DA10). DA10, at 10-50 μM, reversibly reduced the amplitude of the NMDA component of the synaptic input. The competitive polyamine antagonist diethylenetriamine reversed the suppressive action of DA10, consistent with DA10 acting specifically at the polyamine site. These results suggest that polyamines can modulate excitatory synaptic inputs to ganglion cells.

We used the glycine modulatory site antagonist 7-Cl-kynurenate to determine if glycine could modulate the NMDA component of synaptic input. 7-Cl-kynurenate (20 μM) reversibly reduced the puff-elicited NMDA component of the synaptic input to ganglion cells. These results suggest that a glycine site associated with the NMDA receptor complex on ganglion cells can modulate the strength of their excitatory synaptic inputs.

EFFECTS OF VASOACTIVE INTESTINAL PEPTIDE ON GANGLION CELLS IN THE RABBIT RETINA. Ralph J. Jensen.* Southern College of Optometry, Memphis, TN 38104.

The putative neurotransmitter vasoactive intestinal peptide (VIP) has been shown to be present in a population of amacrine cells. Like the neurotransmitter dopamine, VIP stimulates adenylate cyclase activity in the rabbit retina. In the present study, I examined the effects of bath-applied VIP on ganglion cells recorded extracellularly in a superfused, rabbit retinal preparation.

Most OFF-center and ON-center ganglion cells responded with an increase in spontaneous activity when VIP was applied to the retina. The light responses of these cells to spots and annuli were however only minimally affected. When applied to retinas bathed with the dopamine antagonist (+)-SCH 23390, VIP enhanced the light responses of most OFF-center ganglion cells. VIP brought out both the center and surround responses that were reduced by (+)-SCH 23390. The effects of (+)-SCH 23390 on ON-center ganglion cells were not reversed by VIP. It is proposed that VIP counteracts the effects of (+)-SCH 23390 on OFF-center ganglion cells by stimulating adenylate cyclase activity in dopamine-receptive cells of the retina (Supported by NIH grant EY07318).

Prenatal Development of Neuropeptide Y Immunoreactivity in the Ganglion Cell Layer of the Cat Retina Jeffrey J. Hutsler* and Leo M. Chalupa, Psychology Department and the Center for Neurobiology, University of California, Davis.

Previously we have shown that immunoreactivity for neuropeptide Y (NPY-IR) identifies a subgroup of gamma type ganglion cells in the adult cat retina which project to the superior colliculus (Hutsler et al., 1991). In the adult, these cells (approximately 2,000 per retina) are clustered along the horizontal streak with the highest density at the area centralis. Amacrine cells within the inner nuclear layer (INL) are also NPY-IR in the adult cat, and these are distributed in a regular array across the entire retinal surface (Hutsler et al., in preparation). We have now examined the development of NPY-IR in these two population of cells. At embryonic day (E) 38 NPY-IR profiles are not present within the GCL or the INL. By E46 such cells appear in a densely packed region of the central retina within the GCL, and by E50 NPY-IR cells within the GCL have extended out to the retinal periphery. At this age their overall distribution is similar to that seen in the adult. NPY-IR cells within the INL do not appear until E50, when they are largely confined to the central retina. About one week later the NPY-IR amacrine cells are first seen in the periphery, with the overall population characterized by a regularly spaced array. During fetal development the number of cells that are NPY-IR was not found to be appreciably greater than in the adult retina. These results indicate that NPY-IR can be utilized during prenatal development to identify specific populations of amacrine and ganglion cells in the cat retina . (Supported by EY03991 from the NEI.)

RETINAL GANGLION CELLS ARE NOT FRACTAL IN THE BOX COUNTING MEASURE. J. Panico and P. Sterling*, Dept. of Neuroscience, Univ. Penn., Phila., PA 19104.

Fractal geometry can be used to characterize patterns that are statistically self-similar, i.e., for which pieces of the pattern, when magnified, resemble the whole. The degree of fractalness is measured by the degree of self-similarity over a certain range of scales. Many physical systems which have been modelled with fractal geometry display a high degree of self-similarity over at least 3 decades of scale. Though retinal ganglion cells also appear fractal, their reported self-similarity spans at most 1 decade of scale and has not been rigorously evaluated.

Images of HRP-filled retinal ganglion cells (from this and other labs) were digitized, then "skeletonized", and overlaid with a square grid of mesh size d. The number of boxes intersected by the skeleton was counted. In a plot of log(#boxes intersected) vs. log(d), fractalness is assessed by the degree of linearity over a designated portion of the abscissa. As a control, "box counting" was applied to patterns generated to express self-similarity over specified range of scales. Also, we manipulated the spatial struture of neural and control skeletons according to various randomizing algorithms and observed the effects on the log-log plots.

The log-log plots for the controls have linear regions spanning more than one decade of scale. However, plots for the neural patterns have no significant linear portion; instead they are truly sigmoidal: not fractal. We then established an operational criterion: we designated a pattern "fractal" if arbitrarily deforming the pattern made its log-log plot less linear. The plots for control patterns lost most of their linearity, but the plots for neural patterns were unaltered by the deformation. Thus we conclude that, in the box counting measure, ganglion cells are not measurably fractal. Supported by EY08124.

RAB3A IS EXPRESSED IN THE PRIMARY VISUAL SYSTEM. K.L. Moya*, O. Stettler, A. Zahraoui, L. DiGiamberardino and B. Tavitian. INSERM U334 and CNRS URA 1285, C.E.A., S.F.H.J., Orsay and INSERM U248, Paris, France.

Rab3A is a small GTP-binding synaptic vesicle protein preferentially expressed in the brain and implicated in exocytosis. Our previous studies have shown that rab3A is present in specific neuronal circuits, expressed in a subset of neurons in the brain and is developmentally regulated. In the normal adult rat brain, the superficial layers of the superior colliculus (SC) show considerable rab3A immunoreactivity. Excitotoxic lesions of primary visual cortex, while diminishing rab3A in the dorsal lateral geniculate nucleus (LGNd), did not appear to affect the SC. These experiments suggested that the corticogeniculate projection from layer 6 contained considerable rab3A, whereas the descending corticotectal projection from neurons in layer 5 did not account for the observed staining in the SC. This raised the possibility that rab3A is synthesized in other neurons that project to the SC such as retinal ganglion cells which send a massive input to the tectum.

We used in situ hybridization of the retina and immunohistochemistry of the midbrain after eye enucleation to assess whether rab3A was synthesized in retinal ganglion cells and if their terminals in the SC contained this protein. In the retina, silver grains were observed over the nuclei of retinal ganglion cells after hybridization with a labeled 30-mer oligonucleotide that was derived from the hypervariable C-terminal coding region and specific for rab3A mRNA. Immunohistochemical studies showed that rab3A was reduced in the superficial layers of the contralateral SC 6 (N=2) and 14 (N=2) days after unilateral eye enucleation. In addition, immunoreactivity was also reduced in the contralateral pretectal nucleus, however, there were no obvious changes in the LGNd.

These results show that rab3A is expressed in retinal ganglion cells and localized to their terminals in the SC. The presence of this small G protein in the primary visual pathway suggests that rab3A can participate in the transmission of visual information.

TRANS-ACPD EVOKES INCREASES IN INTRACELLULAR FREE CALCIUM CONCENTRATION IN ISOLATED RETINAL GLIAL (MULLER) CELLS S.A. Keirstead* and R. F. Miller. Department of Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

Electrophysiological studies have demonstrated that retinal glial (Muller) cells do not respond to application of ionotropic glutamate receptor agonists (NMDA, quisqualatic acid, kainic acid). Rather, these cells respond only to application of glutamate with an inward current generated by an electrogenic glutamate uptake mechanism (Henshel and Miller, 1986, Soc. Neurosci. Abstr. 12: 169; Brew and Attwell, 1987, Nature 327: 707-709). The calcium imaging studies that we report here revealed that the metabotropic gluatamate receptor agonist 1S,3R-1-aminocyclopentane-1,3-dicarboxylic acid (trans-ACPD) evokes increases the intracellular free calcium concentration ($[Ca^{2+}]_i$) of isolated Muller cells .

Muller cells were acutely isolated from the retina of the larval tiger salamander and were loaded with the calcium sensitive dye Fura-2 AM. A commercially available imaging system was used to observe changes in $[Ca^{2+}]_i$ evoked by bath application of trans-ACPD (50-200 uM) in calcium-free Amphibian Ringer (2mM EGTA). Nine of eleven Muller cells tested responded to the application of this glutamate agonist with an increase in $[Ca^{2+}]_i$. In six of the responsive cells the increase in $[Ca^{2+}]_i$ ocurred later in the endfoot region of the cell. In one cell the $[Ca^{2+}]_i$ the region of the nucleus was lower at rest than that in the other regions of the cell, and the response to trans-ACPD in the nucleus occured later than the other regions, and was of a larger amplitude. Further experiments include the pharmacological characterization of these responses to determine if they are due to specific activation of the metabotropic glutamate receptor and if glutamate itself also evokes increases in $[Ca^{2+}]_i$ in Muller cells. Supported by NIH grant EY03014 to R.F. M.

TRYPAN BLUE STAINING ON RETINAL GANGLION CELL OF RAT INSULTED IN EXPERIMENTAL HIGH INTRAOCULAR PRESSURE. Z.H. Liu, Q.L. Liu, D.H. Lu, J.Z.Shuai and X.G. Luo*. Dept. of Neurobiology, Hunan Medical University, Changsha, Hunan 410078, P.R.C.

We have continued the study on damaged retinal ganglion cell (RGC) resulting from ischemia-reperfusion (I/R) in experimental high intraocular pressure. The experimental high intraocular model was used as before (Liu at el., Soc. Neurosci. Abst. 17:1567 '91). In 10 albino rats, two eyes of each rat were enucleated and fresh whole-mounted retinae were prepared for dye-exclusion test. Trypan blue (TB) was used as a marker to determine the viablity of RGC and was applied according to the method of Taylor and Hunt (Brit. J. Ophthal. 65:815 '81). The nucleus and perikaryon of RGC, which lost its viablity, were full of TB substance. For statistics, the stained RGCs within the four quadrants of each retina was counted at a microscopic magnification of 200-fold with the help of fixing a scored reticle on the slide. The area of whole retina and its four quadrants were digitalized respectively with an image analysis system (PC VISION Plus). The data were analyzed for statistical significance utilizing Student's t-test by Macintosh computer. As comparing these two kinds of retinae, far more RGCs of the I/R retina were stainable than those of the SI (simple ischemia) retina ($p<0.001$). The results indicated that the disintegration of RGCs occurred predominatly since the artificial pressure has been removed. The increased permeablity of membrane of RGCs may be related to the attack of the free radical produced in the reperfusing periods as reported by us. Supported by NSFC 3870621 to Z.H..Liu.

SUBCORTICAL VISUAL PATHWAYS: CORTICO-TECTAL, ACCESSORY OPTIC SYSTEM, CENTRIFUGALS

432.1

OCCIPITOTEMPORAL AND PARAHIPPOCAMPAL GYRUS PROJECTIONS TO THE BASIS PONTIS IN RHESUS MONKEY. *J.D. Schmahmann,*D.N. Pandya, Massachusetts General Hospital, Boston, MA, and ENRM Veterans Hospital, Bedford, MA 02130.*

We used tritiated amino acids to study projections to the basilar pons from parastriate cortices in thirteen rhesus monkeys to determine how connectional and functional heterogeneity of these regions are reflected in corticopontine circuitry. Labelled fibers travelled with those from other parasensory associative cortices as they arched over the dome of the lateral geniculate nucleus and entered the cerebral peduncle. Pontine projections were derived from area 19 at the medial convexity, from the dorsal part of the prelunate gyrus, and from the caudal part of the parahippocampal gyrus (area TF). No pontine projections arose from the ventral prelunate gyrus or from the inferotemporal region. Terminations in the pons were observed in the dorsolateral and lateral nuclei, and the lateral part of the peripeduncular nucleus. Medial convexity injections produced more extensive rostrocaudal labelling, as well as terminations in the extreme dorsolateral nucleus. Dorsal prelunate injections had additional terminations in the ventral pontine nucleus. Posterior parahippocampal gyrus injections had discrete label in the lateral and dorsolateral nuclei. These results suggest that the dorsal visual stream communicates with the pons whereas the ventral visual stream does not. The posterior parahippocampal gyrus implicated in visual spatial memory also sends efferents to the pons. These anatomical results have implications for cerebellar function. (Supported in part by NIH 16841 and the Veterans Administration).

432.2

CORTICOSTRIATAL AND CORTICOTECTAL PROJECTIONS FROM THE VISUAL CORTICAL AREA 17, 18 OR 18a IN THE RAT: AN ANTEROGRADE TRACING STUDY Masahiro Serizawa, Kaeko Hoshino and Masao Norita* Dept. Anatomy, Niigata Univ. Sch of Med., Niigata 951, Japan

The neurons in the deep laminae of the superior colliculus (SC) send descending efferents to a variety of regions of brainstem and spinal cord involved in orienting the eyes, head and limbs indicative of important role of the collicular neurons for "visually guided orientation behavior." In an attempt to detail the corticostriatal and corticotectal projections from the visual cortex in the rat, we injected the tracers such as biocytin or WGA-HRP into visual cortex of Long Evans rat and observed the terminal distributions of the cortical efferents. After injection of the tracer into area 17, numerous labeled axons and terminals were observed in the superficial laminae of SC. In this case, only a few, if any, labelings were found in the caudate putamen. On the other hand, when the tracer was injected into area 18a, a number of labelings were found in the dorsocaudal region of caudate putamen as well as in the deep laminae of SC. Following the tracer injection into area 18, some labelings were observed in the dorsocaudal region of caudate putamen as well as in the deep laminae of SC. The present results suggested that these corticofugal projections from area 18a are important in controlling the visually guided orientation behavior as those found in the cat's corticostriatal and corticotectal projections from the lateral suprasylvian visual area (Norita et al., Neuroscience Res. 10: 149-155, 1991).

432.3

CORTICAL DEACTIVATION DISRUPTS MULTISENSORY INTEGRATION. L.K. Wilkinson[1]*, M.A. Meredith[2], and B.E. Stein[3]. Departments of Psychology[1], Anatomy[2], and Physiology[3], Medical College of Virginia, Richmond, VA, 23298

The cortex of the anterior ectosylvian sulcus (AES) contains unimodal visual, somatosensory and auditory neurons whose projections converge, along with those from lateral suprasylvian cortex (LS), on multisensory superior colliculus (SC) neurons. These SC neurons are believed to play important roles in attentive and orientation behaviors. In the present experiments we sought to determine the effect of reversibly deactivating these cortices on such behavior. The testing apparatus consisted of a semi-circular array of paired LEDs and speakers at 15° intervals. Two cats were trained to approach a near-threshold visual stimulus, regardless of location, for a food reward. The auditory stimulus was presented at the same site as the visual stimulus, or 45° lateral or medial to that site. In normative testing, animals showed a multiplicative enhancement of their responses to visual stimuli when an auditory stimulus was presented spatially coincident with the visual stimulus. Conversely, they showed dramatic inhibition of responses to the visual stimulus when the auditory stimulus was 45° disparate to it. During testing, a cortical area (either AES, LS, AI/AII, or striate cortex) was deactivated with lidocaine through indwelling cannulae. Deactivation of AES disrupted multisensory enhancement and multisensory depression at all eccentricities tested. However, deactivation of the other cortical areas tested, and/or saline controls in AES, had no influence on these multisensory processes.

432.4

RESPONSE PROPERTIES OF CORTICOTECTAL NEURONS IN THE LATERAL SUPRASYLVIAN CORTEX OF CAT.

T. Niida, B.E. Stein, and J.G. McHaffie*. Department of Physiology, Medical College of Virginia, Richmond, VA, 23298.

Because the projections from lateral suprasylvian cortex (LS) to the superior colliculus (SC) and striatum (ST) originate primarily from non-overlapping populations of corticofugal neurons (Norita *et al. Neurosci. Res.* **10**:149-155, 1991), it has been suggested that the information they process is also quite different. The present experiment represents a first step in examining this possibility. Forty-three neurons that could be antidromically-activated from the SC, but not from the ST, have been studied thus far in halothane anesthetized, paralyzed cats. Twenty-four of these were located in the medial bank of LS and 19 in the lateral bank. Most corticotectal neurons were binocular (95%) and dominated by the contralateral eye (93%). They generally exhibited spatial summation (77%) and surround inhibition (79%), responded well to flow field vectors (71%), had wide variations in velocity selectivity, and showed obvious direction selectivity (84%), with the majority (81%) preferring centrifugal movements. Comparatively few (5%) exhibited orientation selectivity. These data are consistent with the disruption of many of these same characteristics in SC neurons during deactivation of LS (Ogasawara *et al. J. Neurophysiol.* **52**:1226-1255, 1984) and underscores their corticotectal origin. Supported by NEI grant EY05554.

432.5

CORTICOSTRIATAL AND CORTICOTECTAL PROJECTIONS FROM THE FRONTAL EYE FIELDS OF THE CAT.

C.M. Thomson*, B.E. Stein and J.G. McHaffie. Department of Physiology, Medical College of Virginia, Richmond, VA, 23298

The relationships between the frontal eye fields (FEF) and the striatum (ST) of the cat are poorly understood. The present experiments were an attempt to determine how regions surrounding the presylvian and cruciate sulci, known to send projections to the superior colliculus (SC), project to the ST. Injections of WGA-HRP made into both cortical regions resulted in dense label in the ST and the SC. In the ST, anterograde labeling was found bilaterally (with a ipsilateral predominance) in the caudal part of the head of the caudate nucleus (AP +17.5 to +14.0); only presylvian injections resulted in the labeling in the putamen, where it was restricted to the caudal aspect. Presylvian injections resulted in label distributed dorsally whereas cruciate injections produced label ventromedially. These same cortical injections also resulted in label restricted to the deep laminae of the ipsilateral SC. After injections of WGA-HRP into ST, numerous labeled corticostriatal neurons were observed. In the presylvian, they were found in lamina III and the upper aspects of lamina V while in the cruciate, they were located in lamina III, upper aspects of lamina V, and lamina VI. In both regions, corticotectal neurons were found only in lamina V. These data are consistent with the idea that, in addition to a direct influence on deep laminae SC neurons, the FEF may modulate tectospinal neurons indirectly via the ST and substantia nigra. Supported by NEI grant EY05554.

432.6

DEACTIVATION OF UNIMODAL CORTICES ALTERS THE PROPERTIES OF MULTISENSORY NEURONS IN CAT SUPERIOR COLLICULUS. M.T. Wallace[1]*, L.K. Wilkinson[2], M.A. Meredith[3], and B.E. Stein[1]. Depts of Physiol[1], Psychol[2] & Anatomy[3]. Medical College of Virginia, Richmond, VA, 23298

Visual, auditory and somatosensory inputs from anterior ectosylvian (AES) and lateral suprasylvian (LS) cortices converge onto multisensory superior colliculus (SC) neurons (Wallace et al., 1991). In this study we sought to determine how these corticotectal inputs influence the response properties of SC neurons. Reversible deactivation (cooling) of a single modality-specific cortical region (i.e., SIV-somatosensory, Field AES-auditory, AEV and LS-visual) was found to depress the corresponding unimodal response of a multisensory SC neuron (e.g., cooling SIV depressed somatosensory responses of a visual-somatosensory neuron). In many cases this deactivation also resulted in a proportional decrease in the integrative product produced by presenting two different sensory stimuli simultaneously. However, in certain instances deactivating a single cortical region altered multisensory integration in SC neurons in ways not readily predictable from its influences on unimodal responses. For example, in some neurons deactivation of SIV decreased visual-somatosensory integration to a far greater extent than that expected based on the slight depression of the unimodal somatosensory response. In at least one case a seemingly paradoxical effect was observed when multiple cortices (i.e., LS, AEV and SIV) were deactivated simultaneously: unimodal visual and somatosensory responses were depressed, but the magnitude of the multisensory interaction was dramatically increased (from 84 to 495%). This is likely due to the principle of 'inverse effectiveness', wherein the combination of weakly effective unimodal stimuli produce disproportionally high enhancements of one another's effect on SC activity. These data demonstrate the importance of the different unimodal cortices in maintaining the integrity of multisensory integration in the SC. Supported by NIH grants NS 08902 and NS 22543

"Extrastriate" Visual Pathways in the Pigeon: Descending Projections upon the Optic Tectum. Harvey J. Karten*, Kevin Cox and Toru Shimizu. Dept. Neurosciences, University of California San Diego, La Jolla, CA 92093 and Dept. Psychology, University of South Florida, Tampa, FL 33620

Two major visual pathways to the forebrain have been identified in birds: 1) A tectofugal pathway, the retino-tecto-rotundo-ecto system similar to the extrastriate pathways through inferior pulvinar of mammals; and 2) A retino-thalamo-wulst pathway, similar to the geniculostriate system of mammals.

Two major descending pathways from telencephalon upon the optic tectum in pigeon have been identified. These arise from: a) The wulst, (Karten et al., 1973, Reiner and Karten, 1982), and b) the archistriatum (Zeier and Karten, 1971), a purported target of the rotundo-ectostriatal pathway. Cholera toxin B (CTb) was used to identify the locus of origin within the archistriatum of projections upon the tectum, and to then characterize the pattern of termination of these projections within the tectum.

Telencephalic Origins of Tectal Afferents: Following injections of CTb limited to the optic tectum, without spread to underlying ventricle or subtectal nuclei, retrogradely labeled cells in the telencephalon were confined to two regions: a) A sharply restricted zone within the ventrolateral portion of the archistriatum intermedium (Aivl); and, b) The hyperstriatum accessorium of the wulst, and adjacent lateral corticoid region.

Projections of the Archistriatum upon the Optic Tectum: Injection of CTb in the Aivl resulted in axonal labeling in the tractus occipito-mesencephalicus with terminations in Layers 10-13 of the ipsilateral optic tectum. Projections of the wulst terminate in more superficial laminae of the tectum.

The pattern of differential distribution of wulst vs. archistriatal projections resembles the differential pattern of projections of corticocollicular connections in mammals arising from the striate vs. extrastriate cortices, respectively.

WHOLE-FIELD MOTION SENSITIVITY OF SINGLE UNITS IN THE LARGE-CELLED PRETECTAL NUCLEUS LENTIFORMIS MESENCEPHALI (nLM) IN RANA PIPIENS Z. Li* and K. V. Fite, Neuroscience and Behavior Program, University of Massachusetts, Amherst MA 01003

The large-celled pretectal nucleus lentiformis mesencephali (nLM) is considered to be essential for horizontal optokinetic nystagmus in frogs. Although the relationship between directionally specific pretectal neurons and horizontal optokinetic nystagmus has been demonstrated in various vertebrates, the significance of velocity sensitive neurons in nLM needs clarification. The present study consists of a single-unit analysis of nLM using a large-field (100 x 100°), random dot patterned stimulus. This stimulus was presented for 4 directions and 4 velocities (0.4-40°/s) of movement centered on the receptive field of the unit.

All units localized in nLM were spontaneously active, and sensitive to "off" changes in ambient illumination. A majority (more than 2/3's) of the recorded units showed velocity sensitivity. These response profiles could be categorized into three types: (1) Units responding in the lower range (0.4-10°/s) of stimulus velocity, which increase in response when the stimulus velocity increases. (2) units responding in the lower range (0.4-10°/s) of stimulus velocity, which decrease in response when the stimulus velocity increases. (3) Units showing a nearly linear increase in response when stimulus velocity increased from 0.4 to 40° /s. Approximately one-third of the units could be classified as directional, and no response bias for horizontal or temporal-to-nasal motion was observed. (supported by NSF grant BNS 8819870 to K.V.F.)

LINEARITY AND DYNAMICS OF THE RETINAL SLIP CODE IN TURTLE ACCESSORY OPTIC SYSTEM NEURONS. A.F. Rosenberg* and M. Ariel, Dept. of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260, USA.

The basal optic nucleus (BON), the major retinal recipient area of the reptilian accessory optic system, contains direction-sensitive (DS) cells that respond to full-field, textured visual stimuli. It is thought that these neurons provide a retinal slip signal that drives the optokinetic reflex. The purpose of this study was to quantitatively investigate how retinal slip is encoded in these neurons using linear system theory.

Single unit responses of BON neurons were characterized using whole-field visual stimuli projected directly onto retinas of isolated turtle brains. Direction-tuning curves were obtained either by using constant velocity stimulation (linear sweeps) along several polar axes or by presenting a constant speed stimulus that moved along a circular path (circular sweeps). The hypothesis that stimulus velocity is encoded along a single linear axis was first tested by fitting direction-tuning curves to cosines. Second, the direction-tuning derived from circular sweeps was compared to the sum of responses of two orthogonally oriented stimuli, each of which followed a linear path with sinusoidally modulated velocity (sinusoidal sweeps). Finally, linear sweeps were applied along the axis with maximal DS modulation at different speeds to directly test the cosine rule. The tuning of these cells obeys a cosine rule to a first approximation, with the addition of a non-DS component.

To assess the dynamic responses of BON neurons, sinusoidal sweeps were applied along the axis with maximal DS modulation at several frequencies. The resulting discharge rates were fit to rectified sinusoids to determine gain and phase. Strong sinusoidal modulation persisted at frequencies to 1 Hz with peak speeds below 15°/s.

BON neurons exhibit DS responses at a broad range of stimulus velocities, yet the range of movement for which these cells exhibit somewhat linear responses seems to be restricted to slow velocities.

432.10

VISUAL INPUTS TO THE TURTLE CEREBELLAR CORTEX STUDIED *IN VITRO*. M. Ariel* and T. X. Fan, Department of Behavioral Neuroscience. University of Pittsburgh, Pittsburgh, PA 15260.

Single units were recorded extracellularly in the cerebellar cortex (Cb) from an isolated turtle brain preparation during visual stimuli and current pulses to the basal optic nucleus (BON). Only a small fraction of isolated units responded to visual stimuli. They were all direction-sensitive (DS), driven only by the contralateral eye and found below the Purkinje cell layer. The most effective stimulus was a moving check pattern imaged onto the retina from a computer-generated video monitor. A unit's spike frequency in the preferred direction increased as a function of stimulus velocity until about 10 °/s, but was DS up to 100 °/sec.

The cellular identity of the visual units was analyzed based on their location in Cb, their spike waveform and by their responses to single current pulses (30-150 μA) to the BON. Of the 15 units driven by BON stimulation, 6 units followed high frequency stimulation at a fixed short latencies. Such responses were also recorded following a transection in the frontal plane just caudal to the Cb peduncles. Although this lesion presumably removes climbing fiber input from the inferior olivary nuclei, the visual and electrical response properties in Cb were unaffected. Thus, it appears that at least some of the visually responsive units in the granule layer are recordings from mossy fibers originating in the BON.

The properties of these units to visual and BON stimulation indicate that they relay retinal slip information directly from BON to Cb. As the BON receives direct input from DS retinal ganglion cells, these results thus provide electrophysiological evidence of the bisynaptic retinocerebellar pathway described anatomically by Reiner and Karten in 1978. The possible role of these units in oculomotor control is discussed.

432.11

CENTRIFUGAL PROJECTIONS TO THE RETINA IN THE TURTLE *Pseudemys scripta elegans*. D. Zhang and W.D. Eldred*. Dept. of Biology, Boston University, Boston, MA 02215

The existence of centrifugal or efferent fibers to the retina from the brain has been demonstrated in many vertebrate species, including the turtle. However, little detailed information is known regarding the number of cells involved and the location of the cells in the brain which give rise to these centrifugal fibers. To investigate this question, we used intraocular injections of cholera toxin B to retrogradely label the cell bodies in the brain which project to the eye. The labeled cell bodies in the brain were visualized using an antibody directed against cholera toxin B. Approximately 40 centrifugal cell bodies were found on each side of the brain. The locations of these neurons were not confined to specific nuclei within the brain. The majority of cell bodies were concentrated in the nucleus of isthmi parvocellularis. This nucleus is homologous to the isthmo-optic nucleus in birds, which also gives rise to centrifugal fibers to the retina. Additional cells were observed in the nucleus reticularis isthmi, the lateral lemniscus, and in the lateral wing of the dorsal raphe nucleus in the reticular formation of the mesencephalon. The localization of these cell bodies within the brain will provide the basis for future studies of their role in visual processing. This research supported by EY04785 to WDE.

432.12

THE MORPHOLOGY OF PRESUMPTIVE CENTRIFUGAL TERMINALS IN RETINAE OF PIGEON (*Columba livia*) AND CHICK (*Gallus gallus*) . W. Woodson*, A. Brzozowska-Prechtl, K. Cox, and H.J. Karten, Dept. of Neurosciences, University of California, San Diego, 92093.

Woodson et. al. (Soc. Neurosci Abstr.('90) 16: 1313)reported three distinct morphological types of presumptive centrifugal terminals (pTs) in the pigeon retina. Subsequent investigations revealed that: (i) the isthmo-optic nucleus (ION) proper and the ectopic cells each give rise to different types of centrifugal pT endings; (ii) high density areas were observed in the inferior and mid-temporal to nasal retina and on both sides of the pecten; (iii) overlap of different types of centrifugal pTs was observed in all portions of the retina.

The distribution and morphology of centrifugal endings of 21 day old chicks were examined following injections of 1% cholera toxin B into ION and the surrounding tegmentum. As in pigeons, centrifugals are found mainly in the inferior retina. One type has a thin axon with small varicosities (~ 1 to 4 μm in diameter) arborizing over a wide area of the retina. The main differences between chicks and pigeons included: (i) the presence of a centrifugal fiber having a thick axon arborizing with one large and compact bulbous ending (~ 10 μm in diameter) consisting of 5-10 smaller varicosities (~ 1 μm in diameter); (ii) the presence of two types of arborizations in the contralateral retina, and only the thin widely arborizing type in the ipsilateral retina. The results suggest a transient developmental stage or a species difference in the morphology of centrifugal pT arborizations. Moreover, we suggest that the thin and widely arborizing ipsilateral centrifugal projections in the chick retina arise from the ectopic cell region.

TECTAL VISUAL RESPONSES ARE MODULATED BY ISTHMIC NEURONS IN PIGEONS. Y.-C. Wang*, S.-R. Wang and B.J. Frost. Departments of Physiology and Psychology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Anatomical studies in pigeons have shown that both nucleus isthmi parvocellularis (Ipc) and nucleus isthmi magnocellularis (Imc) receive input from, and feedback to, the optic tectum. However, the functional effects of these neural circuits on the tectal cells are still unknown. The present study evaluates the roles of Ipc and Imc in modulating the visual response properties of tectal neurons. In Ketamine/Rompun anaesthetized pigeons, Ipc or Imc was reversibly blocked by lidocaine (2%, 5–9 nl) or excited by NMDA (50 mM, 5–9 nl) while stimulating tectal neurons (n=165) with moving visual stimuli. Single cell recordings showed that 80% of the tectal neurons were almost totally inhibited after injection of lidocaine into the region of Imc having receptive fields (RFs) overlapping the tectal RFs. However, 68% of the tectal neurons were unchanged when the same drug was applied to Ipc under the same conditions. In contrast, adminstration of NMDA into Ipc dramatically reduced the response of 71% of tectal cells, while NMDA applied to Imc had no effect. These feedback effects are tightly related to the topographic relation between RFs in nucleus isthmi (Ipc and Imc) and optic tectum. Removal of Imc–tectal feedback loop (lidocaine) or excitation of Ipc–tectal pathway (NMDA) significantly reduced the excitability of tectal neurons whose RFs were located within the isthmic RFs, otherwise, there was no effect. These results suggest that the subdivisions of nucleus isthmi (Ipc and Imc) play a differential feedback role in modulation of visual processing in the avian optic tectum. LOCAL MECHANISMS OF CORTICAL DIRECTION SELECTIVITY: GABA-INACTIVATION COMBINED WITH INJECTIONS OF [^{3}H]-NIPECOTIC ACID.
J. M. Crook*, Z. F. Kisvárday and U. T. Eysel. Dept. of Neurophysiology, Medical Faculty, Ruhr University of Bochum, W-4630 Bochum, Germany.

Iontophoresis of GABA was used to inactivate iso-orientation sites or cross-orientation sites at a horizontal distance of 400–700μm from single cells recorded in cat area 18, and the effects on direction selectivity studied. During iso-orientation inactivation, 71% of 51 cells showed a significant (>0.2) change in the directionality index [DI: (response to preferred direction − response to nonpreferred direction)/(response to preferred direction − spontaneous activity)], with a mean change of 0.58. When the inactivation site showed strong direction bias (DI>0.5), the effects were predictable in the sense that remote inactivation caused a change in a cell's response to the direction of motion that was closest to the preferred direction at the inactivation site: *viz.* an increase or a decrease in response to the cell's preferred direction (due presumably to the loss of iso-orientation inhibition or excitation, respectively), or an increase in response to the nonpreferred direction. In the latter case, pressure injections of [^{3}H]-nipecotic acid were sometimes made at the recording site in order to retrogradely label inhibitory interneurones. The histological reconstructions revealed the presence of labelled cells in the vicinity of the inactivation site, thus demonstrating an anatomical substrate for the effect on direction selectivity in terms of the loss of inhibition between cells with opposite preferred directions. During cross-orientation inactivation, a significant change in DI was seen in only 18% of 68 cells, and was always accompanied by an increase in response to non-optimal orientations. These effects were probably due to the loss of a cross-orientation inhibitory input which contributes mainly to orientation tuning. Overall, iso-orientation inactivation had a significantly greater effect on direction selectivity than did cross-orientation inactivation (mean change in DI 0.43 and 0.14; P <0.001). The results thus emphasize the importance of local iso-orientation interactions in the generation of cortical direction selectivity, with cross-orientation inhibition playing a relatively small but significant role.

433.2

NEURAL CORRELATES OF THE MOTION AFTEREFFECT: THE TIME COURSE OF DIRECTION-SELECTIVE ADAPTATION.
D.E. Giaschi*, S.G. Marlin, R.M. Douglas and M.S. Cynader. Depart. of Ophthalmology, University of British Columbia, Vancouver, BC, Canada.

Following prolonged viewing of a moving pattern, a stationary pattern appears to drift in the opposite direction. This is the well-known motion aftereffect, and it probably results from adaptation of direction-selective neurons in the visual cortex. We used single-unit recording techniques to investigate the time course of direction-selective adaptation in simple and complex cells in the striate cortex of anesthetized cat. Adaptation to prolonged unidirectional visual stimulation and subsequent recovery of responsiveness were compared in the adapted and non-adapted directions for each neuron. Following adaptation in either the preferred or the non-preferred direction, all neurons were less responsive to motion in both the adapted and the non-adapted direction. For complex cells adapted in their preferred direction, the time course of adaptation was exponential with a fast time constant of 3s in both directions. The time course of recovery was also exponential with time constants of 6s and 9s in the adapted and non-adapted directions respectively. An overshoot of the response was observed in the non-adapted direction. Simple cells showed a similar adaptation and recovery in the non-adapted direction, but the change in responsiveness in the adapted direction was characterized by a fast (3s) initial drop followed by a slow (23s) gradual decline. Similarly, the recovery was characterized by a fast (6s) initial rise followed by a slow (200s) gradual increase in responsiveness. For adaptation in the non-preferred direction, there was less adaptation overall, and no overshoot of the response in the non-adapted direction during recovery. The time constants of adaptation and recovery were 5s and 3s respectively for both simple and complex cells and for adapted and non-adapted directions. Thus, there appears to be a fast general process underlying adaptation in cortical neurons. An additional slow direction-selective process is revealed when simple cells are adapted in the preferred direction. We suggest that this latter type of adaptation is a key feature underlying the perceptual motion aftereffect.

433.3

ADAPTATION OF POST-SYNAPTIC POTENTIALS (PSPs) IN RAT VISUAL CORTEX,
P. G. Finlayson*, S. Marlin and M. Cynader, Dept. Ophthal., Univ. of British Columbia, Vancouver, B.C. V5Z-3N9.

Adaptation to repeated patterned electrical stimulation was recorded intracellularly in cortical tissue slices. PSPs, often monosynaptic, were evoked by short trains (3-5 stimuli at 100 Hz) of electrical stimuli to the slice. Control and recovery responses were to stimulus trains separated by 10s intervals. All neurons recorded exhibited an exponential decrease (tau: 6 - 30s) in PSP amplitude and area with stimulus trains presented at short (0.3s) intervals for 30 to 120 s. The recovery of adapted responses was exponential (tau:10s - 8 min). Cortical cells recorded extracellularly *in vivo* show similar time constants of adaptation with moving stripes. Cells initially depolarized 5-10 mV at the start of adaptation, and repolarized often to or below resting potentials. Input resistance initially decreased with the membrane depolarization and increased as the size of the PSPs decreased and the membrane repolarized. Input resistance often continued to increase during the recovery period. These effects were also observed with KCl recording electrodes. Adaptation of PSPs was observed whether stimuli evoked spikes or only PSPs. Adaptation was not affected by hyperpolarizing or depolarizing the cell. Repetitively activating action potentials in the cell with intracellular current pulses did not result in adaptation of PSPs. Adaptation in cortical cells is not dependent on cell firing or due to $GABA_A$ (Cl-dependent) inhibition, or spike adaptation. These results show that the most likely mechanisms of adaptation in cortical cells are presynaptic, involving changes in transmitter release. Post-synaptic post-adaptation changes may also occur.

RESPONSES OF SIMPLE CELLS IN CAT'S AREA 17 TO MOVING TEXTURE PATTERNS: COMPARISON WITH COMPLEX CELLS.
C. Casanova*. Dept. of Surgery-Ophthalmology and Dept. of Physiology and Biophysics, Fac. of Medicine, University of Sherbrooke, Canada, J1H 5N4.

There is still some controversy surrounding the responsiveness of simple cells in the cat's striate cortex to moving random dot patterns. Initial reports of Hammond and colleagues (e.g Hammond and McKay, Exp. Brain Res. 1977) indicated that all complex cells respond vigorously to visual noise while simple cells are virtually unresponsive to the same stimulus. This clear distinction between cells has been challenged in subsequent studies (e.g. Skottun et al., J. Neurophysiol. 1988) which reported that the noise could also drive simple cells. The present study re-examined this issue.

Experiments were performed with anesthetized and paralyzed normal adult cats. Receptive fields in area 17 were first characterized with drifting sine-wave gratings. Under computer control, the direction of a random texture field (Julesz's type, 256x256 of density) was varied over 360° in 12 steps. Each condition was randomly interleaved. The 2D Fourier power spectrum showed that all frequencies have the same expected amount of power.

We recorded from 55 complex cells. 32 units responded vigorously to moving visual noise with sustained discharges (mean direction bandwidth of 39 deg). A few cells (11) could simply not be activated by the pattern. Out of the 38 simple cells recorded, a total of 18 responded well to the motion of the texture. Most responses were not as sustained as those of complex cells, nor as robust. Rather, they consisted of multiple peaks while responses of a few cells showed some periodicity. These results support the notion that the two types of cells in area 17 respond to moving texture patterns.

RELATION OF LINEAR SPATIAL AND TEMPORAL PROPERTIES TO DIRECTION SELECTIVITY IN VISUAL CORTEX NEURONS.
C.L.Baker (Jr.)* McGill Vision Research Centre, Montreal, PQ Canada H3A 1A1.

The "reverse correlation" method was used to analyze responses of simple cells in cat visual cortex (A17 and A18) to ternary white noise stimuli (Emerson *et al*, J.Neurophysiol. 58: 33, 1987). To insure adequate spatial resolution, stimuli were scaled in relation to the period of a given neuron's optimal spatial frequency.

In contour plots of first-order spatiotemporal correlograms, positive and negative "islands" were clearly resolved, corresponding to classical ON and OFF-responding zones spatially and to biphasic responses temporally. Typically there were prominent asymmetries in the degree to which adjacent zones were biphasic or monophasic (ie, transient or sustained). In some cases these regions were weakly spatiotemporally oriented, especially at reduced spatial resolution.

Power spectra derived from these correlograms were narrowband for spatial and temporal frequency, and directionally biased. The magnitude and direction of this bias were in general poor predictors of measured direction selectivity to drifting sinewave gratings, suggesting an important role of nonlinear mechanisms.

Supported by Canadian MRC grant (MA-9685).

433.6

ILLUSORY SHIFTS OF THE FOCUS OF EXPANSION IN OPTIC FLOW FIELDS.
C. J. Duffy* and R. H. Wurtz. Lab. of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

While moving through the visual environment, we see an optic flow field having a radial pattern of motion emanating from a focus of expansion (FOE). When we make a smooth pursuit eye movement during self-movement, reafferent planar motion from eye rotation is combined with the radial motion to displace our retinal image of the FOE. This complicates the task of interpreting optic flow field information about our direction of self-movement.

We studied human perception of optic flow fields by asking 14 observers to indicate the location of FOE in computer generated simulations of optic flow fields projected onto a tangent screen covering 100° X 100° of their central visual field. All of our subjects accurately judged the position of FOE displaced along the horizontal meridian. When we used an artificial optic flow stimulus in which we overlapped radial motion having a centered FOE with horizontal planar motion, our observers experienced an illusory shift of the FOE. The illusory shift of the FOE was always in the direction of the overlapping planar motion; the magnitude of the shift increased with increasing planar motion speed, and decreased with increasing radial motion speed. The illusory shift of the FOE persisted when the observer was free to make eye movements, required to fixate a stationary target, or required to pursue a moving target.

We suggest that the illusory shift of the FOE occurs because the planar motion is interpreted as a reafferent signal indicating a smooth pursuit eye movement. This signal might trigger an attempt to compensate for the expected effects of eye movements on the retinal image of the optic flow field by shifting the perceived FOE. This is consistent with a two stage, parallel processing model of optic flow field analysis, and with the response properties of neurons found in the medial superior temporal area (MST) of monkey cerebral cortex.

433.7

OCULOMOTOR RESPONSES TO PERCEPTUALLY COHERENT AND NON-COHERENT PLAIDS. KR Dobkins*, GR Stoner and TD Albright, The Salk Institute, La Jolla, CA 92037.

When two moving gratings are superimposed, they can be perceived as either a single coherently moving "plaid pattern" or as two component gratings sliding non-coherently across one another. Since visual motion signals are known to exert a strong influence over oculomotor activity, we sought to determine whether there is correspondence between involuntary eye movements elicited by moving plaids and judgments of motion coherency. Specifically, we asked whether direction and speed of eye motion in human subjects were independent of perceptual coherence or, alternatively, approximated component motion when non-coherence was reported and pattern motion when coherence was reported.

Plaid patterns were constructed using two heterochromatic (red/green) sinusoidal gratings oriented 67.5° apart. Motion of the plaid was produced by moving only *one* of the two gratings. Unlike conventional plaids constructed from two moving components, coherent and non-coherent percepts elicited by these novel plaids are each associated with a single direction of motion. Non-coherence is characterized by perceived motion in the direction of the single moving component. By contrast, coherence is associated with perceived motion along the axis of the stationary component. Plaid stimuli were 22° diameter and positioned at the center of gaze.

We used color asymmetries to manipulate perceptual coherence of moving plaid patterns and we recorded accompanying oculomotor activity. Individual gratings within the plaid contained either + (red brighter) or - (green brighter) luminance contrast. When the two heterochromatic gratings contained "symmetric" (+/+ or -/-) luminance contrasts, coherent motion was perceived. When the gratings contained "asymmetric" (+/-) luminance contrasts, non-coherent motion was perceived.

When the plaids were perceived as moving coherently, eye movements were relatively fast and closer to the coherent direction. Conversely, when non-coherent motion was perceived, eye movements were relatively slow and closer to the component direction. These results suggest that the neural mechanisms underlying perceptual motion coherency also participate in the generation of eye movements.

433.8

AREA MST REPRESENTS ABSTRACT FEATURES OF MOTION FOR A BROAD RANGE OF STIMULI. B. J. Geesaman and R. A. Andersen*. Department of Brain & Cognitive Sciences, MIT, MA 02139.

It has been suggested that area MST of the macaque monkey has a role in processing optical flow information relevant to determining direction of observer heading. It may, as well, be important in the perception of object motion. We are interested in determining the diversity of stimulus types over which these cells can extract information about motion; e.g. expansion, contraction, rotation, etc.

To test the response of MST cells to different motion patterns, we recorded from 50 cells in the awake behaving monkey. We probed the receptive fields of these cells with different classes of stimuli and constructed tuning curves for each class based on the responses. Each class contained either 20 degree or 40 degree stimuli that covered 8 equally distributed directions in "spiral space". Spiral space is defined such that 0 degrees in this space represents a stimulus with a velocity vector field consistent with pure expansion, 180 degrees is pure contraction, 90 degrees is counter-clockwise rotation, and 270 degrees is clockwise rotation. This is a continuous space; therefore, a stimulus lying between these cardinal orientations would have elements of two types of motion and perceptually appear as a spiral. The different classes of stimuli included moving random dot patterns (44 out of 50 cells responded), a single solid square (46/50 cells), an outline of a square (8/9 cells), and a square aperture moving relative to an underlying stationary pattern of equally spaced diagonal lines (6/8 cells). Interestingly, although the magnitude of response often varied between classes, for those cells that responded strongly to different classes of stimuli, the orientation and shape of the tuning curves were similar for a given cell. Thus, many cells ignored the differences in spatial structure between the stimuli and were selective for the type of motion. In conclusion, MST is able to extract information about motion type for a range of stimuli, making it an appropriate candidate for analysis of object motion, as well as motion introduced by observer translation.

433.9

LESIONS OF LATERAL SUPRASYLVIAN CORTEX IN THE CAT REVEAL DEFICITS IN THE PERCEPTION OF GLOBAL MOTION. K. K. Rudolph* and T. Pasternak, Center for Visual Science and Department of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14627.

High incidence of directional selectivity and large receptive fields make neurons in the lateral suprasylvian (LS) cortex of the cat well-suited for the analysis of visual motion. We examined the role of LS cortex in the integration of local motion signals into a global percept. We placed bilateral ibotenic acid lesions in LS cortex and used dynamic random-dot targets to test the discrimination of motion direction. The targets consisted of dots that were displaced with a constant step size in directions chosen at random from a specified distribution. When the range of the distribution of such displays is limited to about 300 deg, the entire display appears to move in the direction of the mean.

LS lesions produced deficits in the discrimination of opposite directions for large (1 deg) but not small (0.15 deg) step sizes. The spatial limit for the task (Dmax) was also substantially decreased. These results suggest that there is a change in spatial scale of residual motion mechanisms in the absence of LS cortex. Postoperative motion thresholds were also affected by the addition of dots moving in random directions (directional noise), even at small step sizes. Thus, LS lesions affected the integration of local motion signals in the presence of directional noise. Finally, cats with LS lesions showed a two-fold loss in accuracy in discrimination of small direction differences.

These results provide further evidence for the role of LS cortex in processing visual motion. However, observed deficits were relatively limited: cats with LS lesions were still able to perform tasks requiring integration of local motion signals. Thus, it is likely that the mechanisms underlying these discriminations are not limited to LS neurons. Rather, LS cortex may be only one component of a larger motion network. It is of interest that the effects of LS lesions bear striking similarity to those recently reported after MT/MST lesions in the monkey (Pasternak et al., Neurosci. Abstr. 17, 1991).

A MATHEMATICAL MODEL FOR THE SELF-ORGANIZATION OF DIRECTION COLUMNS IN AREA MT. S. Tanaka,* H. Shinbata and M. Miyashita. Fundamental Res. Labs. NEC, Tsukuba, Ibaraki 305, Japan.

Computer simulations were conducted to study which neural connections give rise to modular structures in the middle temporal area (MT) of monkeys. These simulations were based on our thermodynamic model for the activity-dependent self-organization of neural networks. All presynaptic cells regarded as V1 and/or V2 cells were assumed to be direction-selective. Direction selectivity of MT cells in response to moving visual stimuli and the related modular structures in MT were successfully reproduced. The simulated results showed that singular lines with respect to preferred directions of afferent fiber terminals emerge in the postsynaptic layer. The topological arrangement of preferred directions of afferent inputs was found to determine the direction selectivity of postsynaptic cells. That is, pan-directional cells appeared at the ends of the singular lines, while bi-directional cells were along the length of the lines, although all presynaptic cells were assumed to be direction-selective. Both the frequency distribution of changes in the preferred direction between adjacent cells and the distribution according to the value of the directionality index closely agreed with those observed in physiological experiments. In the absence of intracortical inhibition, all postsynaptic cells tended to be pan-directional cells. This suggests that intracortical inhibition in area MT as well as inputs from directional cells in area V1 and/or V2 are necessary for the generation of the direction selectivity characteristic of MT.

MOTION DETECTION AND IDENTIFICATION FOR LUMINANCE AND CHROMATIC STIMULI

Karl R. Gegenfurtner* (1), Michael J. Hawken and Daniel C. Kiper(1)
Howard Hughes Medical Institute (1), Center for Neural Science, New York University, New York 10003.

We have measured thresholds for detection and identification of a vertically oriented sinewave grating vignetted by a two-dimensional spatial Gaussian window. The stimulus appeared as a contrast-reversing grating to the left or to the right of fixation on the horizontal meridian and then moved either towards or away from the fovea. The temporal frequency of the contrast reversing and drifting gratings were identical. The color of the grating was modulated along different directions in color space around an equal energy white, thus leading to different input contrasts for the L- and M- cones. This allowed us to measure complete detection and identification contours in cone contrast space (Stromeyer, Eskew, Ryu & Kronauer, ARVO 1991).

We find that contrast sensitivity is particularly impaired for stimuli having no L-cone contrast. When considering the mechanisms that mediate motion detection and identification, we find that under certain spatio-temporal conditions contrast sensitivity is determined by a mechanism primarily stimulated by the L-cones.

These results are compared to behavioral and physiological data in macaque monkeys.

SPATIAL SUMMATION OF MOVEMENT AFTEREFFECTS AND ITS MODIFICATION BY EYE PURSUIT MOVEMENTS

O.-J. Grüsser*, E. Fredericksen, W. van de Grind and E. Verstraten
Dept. Comp. Physiology, Rijksuniversiteit Utrecht, The Netherlands, and Dept. Physiology, Freie Universität, Berlin 33, Germany.

A random dot pattern (RDP), generated on a computer screen and moving across the foveal and parafoveal retina (stimulation field 6-8 degrees, 30 s stimulation period), evokes a movement aftereffect (MAE) in the direction opposite to the RDP movement direction for both viewing condition: (a) fixation and (b) eye pursuit movements (head fixed, 0.25 - 8.0 deg/s).

When simultaneously two RDPs ("transparencies") are moved perpendicularly to each other across the stimulation field, two moving patterns are seen, but only one rather uniform MAE is evoked (Verstraaten et al. ,1990). Its direction D is in between the MAE directions expected for each of the two moving RDPs. D depends on the angular velocities of the two RDPs and on the stimulus conditions (a) or (b). A sensitivity-weighted vector summation predicts the outcome for stimulus condition (a). When, however, with stimulus condition (b) one of the moving RDPs is pursued, D is determined by "retinal" stimulation and by efference copy mechanisms.

It is concluded that the "weighted vector summation" of the MAE may be attributed to cortical areas (MST, FST ?), where gaze movement signals interact with retinal movement signals. Thus MAE depends on the "perceived visual movement". Only with the restricted stimulus condition (a) MAE depends merely on the activation of the retinotopically organized parts of the visual system.(O.-J.G. was supported by a F.C.Donders-professorship, University of Utrecht).

ORGANIZATION OF GABAERGIC NEURONS AND AXON TERMINALS IN CAT PRIMARY AUDITORY CORTEX (AI). J. J. Prieto* and J. A. Winer. Division of Neurobiology, Department of Molecular and Cell Biology, University of California, Berkeley, California 94720-2097.

We (i) identified the GABAergic cell types, (ii) counted the proportion of GABAergic neurons in AI, and (iii) analyzed the density of GABAergic terminals in the neuropil. The neurons were studied in adult animals in 25 µm-thick sections. The number and proportion of GABAergic cells were determined in 1 µm-thick plastic sections, counterstained with toluidine blue, in 500 µm-wide samples at systematic intervals.

The proportion of GABAergic neurons (24.6%) resembled the values in other neocortical areas; the laminar differences were also similar. However, GABAergic neurons were not homogeneously distributed, and changed along the dorsoventral axis: more lay in the central part of AI, where physiological studies find the most sharply tuned neurons.

The types of GABAergic cells include: horizontal cells (layers I and VI), extraverted multipolar cells (layer II), bitufted cells (layers II-IV), small (layers I-VI), medium-sized (layers I-VI), and large (layers II-VI) multipolar neurons, bipolar cells (layers II-VI), inverted pyramidal cells (layers V-VI), and large ovoid neurons (layer VI).

There were more puncta in the neuropil in the supragranular than in the infragranular layers, especially in layer Ia. They were variable in size, with the largest in layers III and IV, and the finest in layer I. Many of the biggest GABAergic puncta end near the somata and primary dendrites of immunopositive large multipolar neurons in layers II to VI; in layers II, V and VI these terminals are rare in the neuropil. Thus, a specific circuit for the axosomatic inhibition of these neurons may be independent of the pattern in the neuropil.

Supported by United States Public Health Service Grant RO1 NS16832-13, and by a personal fellowship (J.J.P.) from the Ministerio de Educación y Ciencia (Spain). We thank D.T. Larue for technical assistance and Drs. E. Mugnaini, D.E. Schmechel and R. J. Wenthold for the antisera.

EXPRESSION OF AMPA-SELECTIVE GLUTAMATE RECEPTOR SUBUNIT mRNAs IS RELATED TO SYNAPTIC POPULATIONS IN THE RAT COCHLEAR NUCLEUS. C. Hunter*, T. Yu, and R. J. Wenthold. Lab. of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

We have previously used *in situ* hybridization histochemistry to localize AMPA-selective glutamate receptor (GluR) subunit mRNAs in morphologically defined cell types in the rat cochlear nucleus. Selective antisense oligonucleotides to GluR1-4, 45 nucleotides in length (see Keinanen et al., Science 249:556-560, 1990) and their sense controls were hybridized to tissue sections and the sections processed for autoradiography. Three main patterns of GluR subunit expression were identified with antisense probes: All four GluR subunits were expressed in cartwheel/stellate neurons of the dorsal cochlear nucleus, which receive excitatory input from cochlear nucleus granule cells; GluR2, 3, and 4 subunits were expressed in globular, spherical, fusiform and round cell types, which receive excitatory input from the ipsilateral auditory nerve; GluR2 and 4 subunits were expressed in granule cells, with, as yet, unidentified excitatory inputs. Quantitative analyses in addition, showed that the level of GluR3 expression, as measured by grain density, is heterogeneous within one or two cell types. Thus GluR1-4 expression is likely related to the presynaptic input to these cells.

We now further examine the role of presynaptic input on GluR1-4 subunit expression in neurons: 1) following 7-day and 21-day lesions of the auditory nerve in the adult rat, eliminating ipsilateral, excitatory input to the cochlear nucleus and 2) during postnatal development during the period of synaptogenesis in the cochlear nucleus.

434.3

SALICYLATE INDUCED SHIFTS IN INTENSITY THRESHOLDS AT VARYING FREQUENCIES IN ADOLESCENT RATS. J.F. Brennan[1]*, C.A. Brown[1] and P.J. Jastreboff[2]. [1]Dept Psychology, Univ of Massachusetts/Boston, MA 02125 and [2]Dept Surgery, Univ of Maryland Sch Med., Baltimore, MD 21201.

25 day old pigmented rats were trained in a 2-way shuttle box to avoid a footshock signalled by 5 s tonal presentations of 10 kHz, 62 dBC. Reliable avoidance levels were obtained by the end of the 2nd training day of 150 trials. Changes in auditory intensity thresholds were tested at 23 different frequencies (1-16 kHz) that were presented in counterbalanced order across testing days and subjects. 2 hrs prior to each of 5 successive extinction sessions, groups of 6 pups received either saline injections or salicylate injections of either 200- or 300-mg/kg. For each frequency series initial probes began at 62 dB and decreased in 5 dB units until an error (i.e., response latency greater than 10 s) was recorded, at which time the series increased in 2.5 dB units until a correct response (i.e., latency less than 10 s), followed by a decrease in units of 1 dB. Salicylate injections induced threshold increases at a broad range of frequencies, and were not as selective as induced threshold deficits reported in adults. (NIH DC00299).

A DUAL SYNAPTIC SYSTEM REVEALED IN RAT AUDITORY THALAMUS IN VITRO. B. HU* *Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada. K1Y 4E9*

The ventral (MGv) and dorsal (MGd) divisions of the rat medial geniculate body (MGB) represent the "principal" and "association" thalamic auditory systems respectively. They transmit the auditory signals arising from the inferior colliculus (IC) to the cortex in a parallel manner. The present study examined the synaptic properties of the two systems in response to IC input. Thalamic explants retaining the entire lateral surface of the MGB and IC brachium (ICB) were continuously superfused via artificial CSF at 32–34°C. Single current pulse was used to stimulate ICB and the evoked responses were recorded from MGv (n=75) and MGd (n=98) regions. Extracellularly, most MGv cells responded with a single spike at a short, consistent latency (9.4±4.3 ms). In contrast, MGd neurons responded primarily with a brief high-frequency burst (10–27 ms; 300–420 Hz), whose latency shifts from 8 to 94 ms depending upon the intensity of input. The MGd bursting response was reversibly blocked by bath application of nickel (100–250 µM) or APV (50 µM) but was unaffected by bicuculline (100 µM) or phaclofen (60 µM). The evoked responses in both regions were totally and reversibly blocked by TTX and by co-application of DNQX (30 µM) and APV (50 µM). Intracellular recordings showed that the ICB-evoked bursting responses in MGd, but not in MGv neurons were mediated by a low-threshold spike (LTS), whose activation latency shifts widely (12 to 100 ms). Failure of LTS revealed (up to 100 ms) an underneath slow EPSP, which could be antagonized by APV and ketamine in a dose-dependent manner. These data suggest that distinct synaptic signalling processes occur in MGv and MGd systems. Supported by OMHF and MRC.

434.5

HOMOGENEOUS DISTRIBUTION OF GABA NEURONS ACROSS CAT PRIMARY AUDITORY CORTEX. S. H. C. Hendry* Dept. of Anatomy & Neurobiology, University of California, Irvine, CA 92717.

The primary auditory area (AI) of cat cerebral cortex contains a map of the cochlea, with each sound frequency represented as a band of dorsoventrally oriented cells (isofrequency bands). In cat AI, callosal afferents are unevenly distributed and terminate in broad anteroposteriorly oriented zones that intersect isofrequency bands. These callosally innervated zones are physiologically distinct from acallosal zones in ways suggestive of inhibitory influences that are greater within the latter. To determine if the physiological differences are correlated with differences in elements intrinsic to AI, GABA immunoreactive neurons were examined for evidence of an uneven distribution of inhibitory interneurons across AI. Stereological methods were applied to determine the numerical density and proportion of GABA immunoreactive somata in 1 µm-thick sections through 5 hemispheres of 3 normal cats. Mean values of 21,400-22,800 GABA neurons underlying 1 mm^2 of cortex, which make up 20.4-21.8% of the total neuronal population was calculated for AI. Values for individual layers varied with the greatest density of GABA neurons in layers III and IV and greatest proportion in layer I. Those values for AI, in general, and for individual layers did not vary significantly either dorsoventrally across AI (parallel to isofrequency bands) or anteroposteriorly (perpendicular to the bands). These data suggest that regional variations in the total population of GABA neurons do not exist across AI and, thus, cannot account for physiological differences in this area. Evidence for variations in GABA neuronal subpopulations is currently under investigation. Supported by DC 00450.

UNILATERAL KAINIC ACID LESIONS OF THE LATERAL LEMNISCUS: EFFECTS ON INTERAURAL INTENSITY DIFFERENCE FUNCTIONS RECORDED FROM SINGLE NEURONS IN INFERIOR COLLICULUS. L. Li* and J.B. Kelly. Laboratory of Sensory Neuroscience, Psychology Department, Carleton University, Ottawa, Ontario K1S 5B6.

Recent anatomical and physiological data suggest that the dorsal nucleus of the lateral lemniscus (DNLL) plays a role in binaural processing in the auditory system. The neurons in DNLL are largely GABAergic and give rise to substantial projections to the contralateral DNLL and inferior colliculus (Shneiderman, Oliver and Henkel, 1988). Kainic acid lesions of DNLL alter evoked responses recorded from the rat's auditory cortex by reducing the extent of binaural suppression in the hemisphere contralateral to the lesion site (Glenn and Kelly, 1991). The present study was undertaken to determine the effects of kainic acid lesions of the lateral lemniscus on single neuron responses recorded from the central nucleus of the inferior colliculus of the rat. Lesions were made by local injection of kainic acid into the lateral lemniscus through a glass pipette. After a recovery period of at least two weeks, recordings were made from the inferior colliculus with glass microelectrodes. Tone pulses were delivered separately to the two ears through a sealed sound system. Results show that unilateral destruction of the intermediate nucleus of the lateral lemniscus has little or no effect on interaural intensity difference functions recorded from ipsilateral or contralateral inferior colliculus. After unilateral DNLL lesions, binaural responses were still present in both left and right inferior colliculus, but there was a tendency toward a reduced slope of interaural intensity difference functions contralateral to the lesion. (Supported by NSERC.)

LONG-TERM EFFECTS OF COCHLEAR AND MIDDLE EAR LESIONS ON SYNAPTIC TRANSMITTER RELEASE IN THE COCHLEAR NUCLEUS. C.G. Benson* and S.J. Potashner. Department of Anatomy, University of Connecticut Health Center, Farmington, CT, 06030.

To determine if cochlear activity affects the regulation of synaptic function in the cochlear nucleus (CN), we measured the effects of unilateral cochlear ablation and unilateral ossicular disarticulation on the activity of glutamatergic or aspartatergic and glycinergic synaptic endings in the CN of adult guinea pigs. Guinea pigs were anesthetized and either the left cochlea was destroyed mechanically or the left middle ear ossicles were disarticulated. Two days, 8 weeks or 16 weeks after surgery, the uptake and release of ^{3}H-D-aspartate (^{3}H-D-ASP) and ^{14}C-glycine were measured bilaterally in dissected segments of the CN, in vitro. Two days and 8 weeks after cochlear ablation, ^{3}H-D-ASP uptake and release were reduced ipsilaterally in all segments. However, by 16 weeks after the lesion these measures had recovered and were no longer significantly different from controls. There were no significant changes in the uptake and release of ^{14}C-glycine in the CN after cochlear ablation. Sixteen weeks after unilateral ossicular disarticulation there were significant decreases in the uptake and release of ^{3}H-D-ASP bilaterally in the CN. These findings suggest that chronic changes in cochlear activity can lead to changes in synaptic release in the CN. (Supported by DC00199 from NIH NIDCD).

434.8

RELEASE OF D-ASPARTATE, GABA, AND GLYCINE FROM GUINEA PIG BRAIN STEM AUDITORY NUCLEI. S.K. Suneja, J. Gross, C.G. Benson and S.J. Potashner*. Dept. of Anatomy, University of Connecticut Health Center, Farmington, CT, 06030.

Evidence suggests that glutamate, aspartate, GABA, and glycine may be transmitters in the cochlear nucleus. In this study, we measured the release of ^{3}H-D-aspartate, ^{14}C-GABA and ^{14}C-glycine from several other brain stem auditory nuclei to determine if they too might contain synaptic endings that use these amino acids as transmitters. After excision, the brain stem was cut transversely into 500 μm sections from which auditory nuclei were punched. The accuracy of punching was confirmed by histological analysis. Punches were incubated with ^{3}H-D-aspartate and ^{14}C-GABA or ^{14}C-glycine before the release of radioactivity was assessed in a superfusion system. Electrical stimulation evoked the Ca^{2+}-dependent release of D-aspartate from each punched nucleus, namely the LSO, MSO, MNTB, VNLL, and the central nucleus of the IC (ICc). Ca^{2+}-dependent release of GABA was observed from the MNTB, VNLL, and ICc while release of glycine was observed from the LSO and MSO. These findings are consistent with the hypothesis that these nuclei contain glutamatergic or aspartatergic synaptic endings. They also suggest that some of these nuclei may contain GABAergic and glycinergic synaptic endings. (Supported by DC00199 from NIH-NIDCD)

434.9

PLASTICITY OF CALBINDIN IMMUNOREACTIVITY IN THE MATURE GERBIL SUPERIOR OLIVARY COMPLEX WITH ALTERED AUDITORY EXPERIENCE M.D. McGinn[1]*, I.R. Schwartz[2], and P.R. Eager[2] [1]Dept. of Otolaryngology, UC-Davis, Davis, CA 95616 and [2]Sect. of Otolaryngology, Yale University School of Medicine, New Haven, CT 06510 U.S.A.

Calbindin D-28k immunoreactivity (CaBP+) showed consistent and distinctly different patterns in the MNTB and LSO which varied with auditory experience. Animals were colony reared(COL), exposed to 3 wks of intermittent (30 min on/off) high (HF)(80dB) or low frequency (LF)(74dB) noise, or to low sound (LIG)(ear canal ligation).

The MNTB showed the most intense CaBP+ cells in all conditions. HF animals showed the largest number and most intense CaBP+ cells and the fewest light CaBP+ cells. LF animals had a greater proportion of light CaBP+ cells; COL animals were similar. LIG animals showed the highest proportion of light CaBP+ cells.

The LSO showed the greatest variation with the different treatment conditions. HF animals showed a densely stained neuropil in the medial limb. Moderately stained cells were found throughout, but some cells in the medial limb were darker. LF animals showed many moderately stained cells in the lateral limb, but fewer in the medial limb. Medial limb CaBP+ cells stained more darkly, but less intensely than in HF animals. The medial limb neuropil stained more densely than the lateral limb, but less darkly than in HF animals. LIG animals showed many lightly stained cells throughout the LSO in a uniformly stained neuropil comparable in intensity to that in the medial limb of LF animals.

PLASTICITY OF CALCIUM BINDING PROTEIN AND GABA IMMUNOREACTIVITY IN THE ADULT GERBIL COCHLEAR NUCLEUS WITH ALTERED AUDITORY EXPERIENCE I.R. Schwartz[1]*, P.R. Eager[1] and M.D. McGinn[2], [1]Sect. of Otolaryngology, Yale University School of Medicine, New Haven, CT 06510 and [2]Dept. of Otolaryngology, UC-Davis, Davis, CA 95616 U.S.A.

Calbindin D-28k (CaBP+), parvalbumin (PV+) and GABA (GABA+) immunoreactivity showed patterns in the cochlear nucleus (CN) which varied with auditory experience. Animals were colony reared (COL), exposed to 3 weeks of intermittent (30 min on/off) high (HF)(80dB) or low frequency (LF)(74dB) noise, or to low sound (LIG)(ear canal ligation). LF animals showed large numbers of intensely stained GABA+ puncta in the DCN and PVCN which were not seen in HF, LIG or COL animals. The intensity and number of CaBP+ dendrites in the DCN molecular layer decreased from LIG to HF to LF animals. COL & LF animals were similar. In octopus cell regions the darkest CaBP+ somata were in HF. The greatest extent of dendritic staining was in LIG animals which also showed the greatest number and size of CaBP+ puncta. PV+ somata in the DCN molecular layer decreased in intensity from HF, to LF to LIG. Changes in CaBP+ and PV+ in the CN were less marked than the changes observed elsewhere in the auditory brainstem. In the superior colliculus LF animals showed an almost complete absence of PV+ stained cells and dendrites compared to HF animals.

The observations are consistent with the hypothesis that a strongly driven auditory system protects neurons from overstimulation by an upregulation of inhibitory inputs.

QUANTITATIVE EVIDENCE THAT COCHLEAR ROOT NEURONS ARE NOT CHOLINERGIC. W.Yao and D.A.Godfrey*. Dept. of Otolaryngology, Med. Col. of Ohio, Toledo, OH 43699.

Cochlear root neurons (CRN) are distinct morphologically from globular bushy cells in rodent auditory nerve root (Merchan et al, 1988). CRN do not immunoreact for glycine or GABA (Osen et al, 1991). Our preparations have shown immunoreactivity of CRN for choline aceytltransferase (ChAT) which, despite their very weak histochemical reaction for acetylcholinesterase, suggests that they might be cholinergic. To provide evidence concerning this, we used a radiometric assay to measure ChAT activities (μmol/kg/min) both of samples containing CRN and of adjacent samples not containing CRN from 5 rats. Mean ($\pm$SD)(# samples) ChAT activity of CRN-containing samples was $35 \pm 20(9)$, while that of the non-CRN samples was $31 \pm 18(13)$. By measuring proportions of the samples occupied by CRN cytoplasm, we estimated the ChAT activity of CRN to be $229 \pm 406(9)$. By contrast, the ChAT activity for samples of the facial nucleus, which contains cholinergic motoneurons, was $4823 \pm 1184(5)$, and that for samples of the facial motor root was $6074 \pm 1397(4)$. Thus, CRN are not likely to be cholinergic. However, the presence of ChAT activity in some samples suggests that they might receive some cholinergic innervation. (Supported by NIH grant DC00172)

EFFECTS OF CHOLINERGIC AGONISTS AND ANTAGONISTS ON SPONTANEOUS ACTIVITY OF RAT DORSAL COCHLEAR NUCLEUS NEURONS: IN VITRO STUDIES. K. Chen[1], H. J. Waller[2]* and D. A. Godfrey[1], Depts. of Otolaryngology[1] and Neurological Surgery[2], Medical College of Ohio, Toledo, OH 43699.

Extracellular recordings from rat brain stem slices tested the effects of bath application of cholinergic agonists and antagonists on cochlear nucleus neuronal activity. Recordings were made from 54 neurons in 30 slices from 28 rats. Of neurons tested, 89% showed increased firing rates in response to 10 μM carbachol (mean increase = 249%, n=18), 63% showed increased firing to 10 μM muscarine (mean increase = 529%, n=35); and 50% showed increased firing to 200 μM nicotine (mean increase =103%, n=12). Only 3% and 25% of the neurons showed decreased firing to muscarine and nicotine, respectively. The excitatory effect of carbachol was eliminated by atropine (1 μM, n=3), but not by d-tubocurarine (2 μM, n=2). Excitatory effects of muscarine were blocked by 1 μM atropine (n=6), but not by selective antagonists of muscarinic receptor subtypes: pirenzepine (1-5 μM, M_1 receptor, n=3), gallamine (10-20 μM, M_2 receptor, n=3) or p-fluorohexahydro-siladifenidol (1-2 μM, M_3 recepter, n=2). We also found that 40% of the neurons tested showed an excitatory response to 50-100 μM serotonin (mean increase = 190%, n=20); 60% were unaffected. (Supported by NIH grant DC00172).

435.1

CHARACTERIZATION OF PRINCIPAL NEURONS IN THE RAT MEDIAL NUCLEUS OF THE TRAPEZOID BODY BY INTRACELLULAR RECORDING AND LABELING. I. Sommer, K. Lingenhöhl*, and E. Friauf. Dept. Animal Physiology, Univ. Tübingen, 7400 Tübingen, Germany.

Neurons of the medial nucleus of the trapezoid body (MNTB) are classically thought to function as a relay station in the ascending auditory system, transmitting information from the contralateral cochlear nucleus to neurons in the lateral superior olive and thereby inhibiting those. We have analyzed the physiological and morphological characteristics of MNTB neurons by means of intracellular recordings *in vivo* and subsequent intracellular injection of HRP. MNTB neurons responded in a primary-like fashion to tone pulses presented to the contralateral ear. Their spontaneous activity was high (>100 Hz), indicating that they may massively inhibit their target neurons. HRP-injection identified that we recorded from principal MNTB neurons; those with higher best frequency were located more medially than those with lower best frequency, thus demonstrating the tonotopic organization of the MNTB (lateral-to-medial from low-to-high). The morphological analysis revealed a complex system of axon collaterals and projections to several ipsilateral brainstem nuclei. Each MNTB principal neuron projected to the LSO and the superior paraolivary nucleus (SPN). Axon collaterals and terminals in the lateral nucleus of the trapezoid body, the medial olivary nucleus, and the ventral and dorsal nucleus of the lateral lemniscus were also present, although not always. Axon terminals could be located perisomatically or in the neuropil. The location of these terminals within the LSO and the SPN correlated with the MNTB neurons' best frequency and indicates that the LSO and the SPN are likely to be tonotopically organized (both lateral-to-medial from low-to-high). The divergent projection patterns of MNTB principal neurons suggest that these neurons are likely to play a complex role both in the ascending and descending auditory system. Supported by the DFG (Fr 772/1-2).

435.2

AUDITORY CORTICOGENICULATE PROJECTIONS IN THE CAT: LAMINAR ORIGINS AND AREAL ORGANIZATION. D.T. Larue*, B.A. Peterson, and J.A. Winer. Division of Neurobiology, Department of Molecular and Cell Biology, University of California, Berkeley, CA 94720-2097.

The corticothalamic system comprises a massive descending projection whose organization and functional role in sensory processing is obscure. We studied the auditory corticogeniculate cells of origin using retrograde tracing methods. Our goal was to define which cortical areas and which cell layers within them project to particular subdivisions of the auditory thalamus. Wheat germ agglutinin-horseradish peroxidase was injected stereotaxically into different subdivisions of the medial geniculate body in adult cats and processed with tetramethylbenzidine.

At least ten different cortical fields project onto the medial geniculate body. They include primary (AI) and secondary (AII) auditory cortex, anterior auditory field (AAF), suprasylvian fringe (SF), insular (Ins), temporal (Te), and perirhinal (Pr) cortex, and posterior ectosylvian (EP), posterior (P) and ventroposterior (VP) auditory fields. Each geniculate subdivision receives a projection from a unique constellation of these cortical areas. Injections in the ventral division labeled cells in AI, AAF, P, and VP, and since the injections also involved the ventrolateral part, which is considered part of the non-lemniscal pathway, labeling was also seen in SF, EP and AII. Injections of the dorsal and caudal dorsal divisions revealed heavy projections from AII, Te, ventral Ep (including area VP) and a lighter input from Ins. In contrast, a smaller injection in the suprageniculate nucleus labeled many neurons in SF, Ins, dorsal EP, and a smaller number in AII, distinguishing it from other parts of the dorsal division. Injections of the medial division produced robust cortical labeling in AAF,Te, and Pr, and lighter labeling in VP, AI and AII, while involvement of suprageniculate in these injections produced labeling in SF and Ins.

The cortical layers of origin typically had a single pattern: a continuous band of cells was labeled in layers VI and Vb, with a discontinuous line of large layer Va cells separated from the deeper Vb cells by a gap without labeling. An exception to this pattern occured in the perirhinal cortex, which was labeled in every case. Injections involving the medial division produced the three-layered pattern described above (layer VI, Vb, and Va). The projection to all other thalamic divisions involved layer VI exclusively.

These findings suggest that, like the thalamocortical projection system, the descending corticothalamic projection is segregated into parallel pathways involving both tonotopic and non-tonotopically organized regions, and that multiple cortical inputs converge onto individual thalamic nuclei. Supported by U.S.P.H.S. grant RO1 NS16832-13.

435.3

PARALLEL PATHWAYS IN THE AUDITORY FOREBRAIN: AFFERENT AND EFFERENT CONNECTIONS OF THE MEDIAL GENICULATE BODY. B.A. Peterson* and J.A. Winer. Division of Neurobiology, Department of Molecular and Cell Biology, University of California, Berkeley, CA 94720-2097.

Studies of the auditory thalamocortical system suggest that more than one pathway ascends to the cortex. To study this question, we injected wheat germ agglutin-horseradish peroxidase into various parts of the cat auditory thalamus to determine how many patterns exist.

A different pattern of connections was defined for each subdivision of the auditory thalamus with the midbrain, cerebral cortex, and subcortical forebrain. Some findings are common to each case. Thus, (i) the thalamic reticular nucleus projects to all parts of the medial geniculate body; (ii) each thalamic injection labels terminals in a different set of cortical fields; (iii) the origins of corticothalamic projections are more widespread than are the thalamocortical terminals; and (iv) corticothalamic projections have multiple laminar origins.

Each division of the auditory thalamus has a unique set of connections. Thus, the ventral division projects to layers III and IV in primary auditory cortex (AI), and to the anterior, posterior and ventroposterior auditory fields. It receives input from the thalamic reticular nucleus and from one or more subregions of the inferior colliculus.

The medial division has a different pattern of connectivity. It projects to layer I in every auditory cortical field, to the perirhinal cortex, and upon the amygdala and striatum as well. It receives projections from the superior colliculus, the thalamic reticular nucleus, and parts of the inferior colliculus outside the central nucleus.

The suprageniculate nucleus projects to layers I, III, and IV of non-primary auditory fields, including the insular, suprasylvian fringe, and dorsal posterior ectosylvian areas. It projects also to layer I in perirhinal cortex and to the amygdala and striatum. Its afferents arise from the superior colliculus mainly, with only modest input from the inferior colliculus.

A different pattern of thalamic connections involves the caudal nucleus of the dorsal division, which projects heavily to AII and temporal field, and less so to posterior ectosylvian and insular fields. Thalamic axons terminate predominantly in layers III and IV, with light input to layer I in perirhinal cortex, and moderate input to the infragranular layers of the temporal cortex. The major brain stem inputs arise from the dorsal cortex and lateral nucleus of the inferior colliculus. Surprisingly, it did not project to the amygdala or striatum.

These findings suggest that each part of the medial geniculate body has a specific constellation of midbrain and forebrain connections that must be related to their functional organization.

INTRINSIC CONNECTIONS OF NEURONS IN THE COCHLEAR NUCLEAR COMPLEX OF MICE IN SLICES. S. Zhang*, D. Oertel. Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53706.

Synaptic potentials, spontaneous and evoked by electrical or chemical stimuli at various sites of the cochlear nuclei, were recorded intracellularly from 41 biocytin-labeled neurons: 6 tuberculoventral, 5 giant, 8 cartwheel, 1 superficial stellate, and 21 fusiform cells. Neuronal connections were deduced from temporal patterns, maps of synaptic inputs and the morphology of neurons.

Cartwheel, superficial stellate, and fusiform cells received spontaneous EPSPs. These same cells responded to electrical and chemical stimulation of the surface of the ventral cochlear nucleus (VCN) with EPSPs. Shocks evoked slowly rising EPSPs after 7 msec. The EPSPs probably reflected granule cell input.

Tuberculoventral neurons were excited by shocks to the auditory nerve with early and later EPSPs that were often suprathreshold. Mapping of excitatory afferents suggested that T stellate cells of the VCN were the source of polysynaptic EPSPs. IPSPs were occasionally recorded; these could have arisen from D stellate or other tuberculoventral neurons.

Giant cells responded to shocks of the auditory nerve with a monosynaptic EPSP that was usually cut short by two sequential IPSPs. Chemical stimulation of the VCN evoked EPSPs and IPSPs from widespread regions. The IPSPs could have arisen from tuberculoventral cells; EPSPs from auditory nerve fibers and T stellate or granule cells.

Fusiform cells receive spontaneous, bursty, IPSPs that are blocked by strychnine. Spontaneous IPSPs are often preceded by slowly rising EPSPs suggesting that a common source, probably granule cells, drive fusiform cells and inhibitory interneurons. The latencies and bursting patterns of spontaneous and late driven IPSPs match firing patterns of cartwheel cells. Fusiform cells also have early IPSPs that may arise from tuberculoventral cells.

REPRESENTATION OF PINNA-PRODUCED SPECTRAL NOTCHES IN DORSAL COCHLEAR NUCLEUS (DCN). E.D. Young*, G.A. Spirou, and J.J. Rice, Center for Hearing Sciences, Johns Hopkins School of Medicine, Baltimore, MD 21205.

The pinnae produce sound localization cues by modifying the spectra of acoustic stimuli in a way that depends on sound-source direction. In cats, the pinnae produce prominent notches (spectral minima) in the sound at the eardrum at frequencies >8 kHz; these notches provide information about both stimulus azimuth and elevation. Here, we describe responses of DCN neurons to stimuli containing such notches. Extracellular single-unit recordings were made in decerebrate cats; the stimuli were broadband noise electronically filtered with previously-measured pinna transfer functions, so as to simulate free-field spectra at the eardrum. The stimuli were scaled in frequency so as to move the center frequency of notches relative to a unit's best frequency (BF). In some DCN units, the only effect of changing notch frequency is to elevate threshold when the notch is centered on BF. This response probably reflects loss of effective stimulus energy when the notch is centered over the unit's tuning curve plus some effect of lateral inhibition; it is the type of response seen in all ventral cochlear nucleus neurons. In some DCN type III and type IV units, a sharp excitation-inhibition-excitation sequence is seen as the notch is swept past the unit's BF. Such responses have not been seen to date in units with BFs<8 kHz; at these frequencies, pinna transfer functions do not contain notches. These results suggest a role for the DCN in processing of complex, biologically relevant spectral features of stimuli, including features related to sound localization. Supported by grants from NIDCD.

FUNCTIONAL ORGANIZATION OF ACOUSTIC AND VOCALIZATION AREAS OF THE BAT CENTRAL NERVOUS SYSTEM REVEALED BY HIGH RESOLUTION AUTORADIOGRAPHIC IMAGING OF ^{3}H-2-DEOXYGLUCOSE UPTAKE. G.E. Duncan*, W.E. Stumpf, and O.W. Henson. Dept. of Cell Biology and Anatomy, Univ. North Carolina, Chapel Hill, NC 27599

Brain activity patterns associated with the generation and processing of echolocation signals in the bat Pteronotus p. parnellii were studied by high resolution autoradiographic imaging of ^{3}H-2-deoxyglucose (2-DG) uptake. Bats were injected i.p. with 2-DG and restrained in a foam holder or allowed to fly in the laboratory. Bats were killed 20 min after the injection of 2-DG. In the flying bats, marked alterations in patterns of 2-DG uptake occurred in brainstem and forebrain regions. Regions activated during flight included the nucleus ambiguous, inferior colliculus, superior colliculus, medial geniculate, auditory cortex, stratum lacunosum molecular of the hippocampus, anterior cingulate cortex, claustrum, and frontal cortex. The results help to define the functional organization of brain regions involved in vocalization and processing of biosonar signals.

435.7

CYTOARCHITECTURE AND HISTOCHEMICAL ORGANIZATION OF ODONTOCETE WHALE AUDITORY BRAINSTEM. W.E. O'Neill[1], M.L. Zettel[1], and S.N. Haber[2]. Depts. of Physiology[1] and Neurobiology and Anatomy[2], Univ. of Rochester School of Medicine, Rochester, NY 14642.

Relatively little is known about the anatomy of the central auditory systems of echolocating whales. We studied the brainstem of the beluga whale and bottlenose dolphin. Sections stained with cresylviolet, acetylcholinesterase (AchE), and antibodies to Calbindin D-28k (cabp) and parvalbumin (pv) were examined to localize and characterize the structures of the auditory brainstem. Comparisons were made to material from bats, rodents, human and non-human primates.

In the beluga whale, an extremely large (5 mm diameter) auditory nerve leads into a large cochlear nucleus (CN). Many cabp(+) and pv(+) cells were scattered throughout the anteroventral CN. Cells in the prominent lateral superior olive were cabp(-) and pv(+), as in other mammals. The medial nucleus of the trapezoid body (MNTB) was both cabp and pv positive. Medial to and apparently associated with the MNTB, there is an unusual dorsoventrally oriented, sickle-shaped sheet of cells, embedded in a band of AchE(+) fibers. These cells may belong to the medial olivocochlear bundle system.

Although the general features are consistent with those in other mammals, certain aspects appear unique to the whale, and may reflect adaptations to echolocation in an aquatic environment.

435.8

DORSAL NUCLEUS OF THE LATERAL LEMNISCUS: ORGANIZATION OF SOME LEMNISCAL AFFERENTS IN THE INFERIOR COLLICULUS OF THE FERRET. C. K. Henkel.*Dept. of Neurobiology and Anatomy, Bowman Gray Sch. of Med., Winston-Salem, NC 27157.

The dorsal nucleus of the lateral lemniscus (DNLL) projects bilaterally to the inferior colliculus. The crossed projection was studied in adult ferret using PHA-L as an axonally transported marker. Most axons crossed to the contralateral side under the periaqueductal gray in the dorsal tegmental commissure of Probst. In cases with injections that involved either the nucleus sagulum or rostral tegmental areas, labeled fibers were seen crossing to the contralateral side in the commissure of the inferior colliculus. The latter fibers typically ended in the rostral pole of the inferior colliculus, superficial layers of the dorsal cortex or ascended into the superior colliculus and were not further studied. Fibers that crossed in the dorsal tegmental commissure approached the contralateral DNLL where they frequently gave off collateral branches. What appeared to be primary axonal branches in the subcollicular tegmentum gave rise to multiple, secondary branches that ascended into the central nucleus of the inferior colliculus with each secondary branch being reduced in size and giving rise to a larger number of tertiary varicose branches. Short side branches ended in small clusters of boutons. Small injections labeled a thin lamina of fibers on the contralateral side that extended from ventrolateral to dorsomedial through the central nucleus and into the deeper layers of the dorsal cortex. The laminae were 90-160 μm in thickness. Axonal branches diverged and distributed branches and endings over 1000 μm rostral-caudally in the laminae. Some axons entered the laminae from a rostral perspective and coursed caudally while others entered caudally and coursed rostrally. Injection sites of only 100-200 μm segment of DNLL labeled axons that diverged over the full expanse of the laminae. Single axons that were reconstructed could be traced over much of the laminae as well.

Supported in part by NIH grant DC00813.

435.9

PARVALBUMIN IMMUNOCYTOCHEMISTRY DELINEATES PRIMARY AUDITORY NEOCORTEX. C.B. Smelser and N.T. McMullen*. Department of Anatomy, University of Arizona College of Medicine, Tucson, AZ 85724.

Electrophysiological and anatomical studies of rabbit auditory neocortex have revealed a large primary field (AI) characterized by a distinct cytoarchitecture: a cell-dense lamina III/IV and a broad cell-sparse lamina V. We report that monoclonal antibodies to parvalbumin (PV), a calcium-binding protein present in GABA-ergic local circuit neurons, precisely delineate the cytoarchitectonically defined AI. PV immunocytochemistry (PVi; SWANT, 1:10K) was performed on 100 um thick sections obtained from young rabbits. Serial coronal sections through the entire temporal pole were processed and every third section was Nissl stained with methylene blue. PVi yields an extraordinary Golgi-like dendritic (and, in some cases, axonal) labeling of nonpyramidal cells in all cortical layers. The dorsal boundary of AI is demarcated by an abrupt increase in the number of PV-positive nonpyramidal cells and dense terminal labeling within lamina III/IV. Lamina II and upper parts of III are populated by nonpyramidal cells with small somata and less often, large cells of the bitufted, bipolar and stellate variety. Lamina III/IV is characterized by a dense population of large spine-free nonpyramidal cells with bitufted dendritic domains and tangentially-oriented local axonal plexi. Basket-type axonal terminals outline pyramidal cell somata and contribute to the dense terminal labeling within III/IV. Cell-sparse lamina V contains large nonpyramidal cells remarkable for their tangentially oriented dendritic fields. Lamina VI can be partitioned into sublamina VIa and VIb. Lightly labeled pyramidal neurons compose VIa while a diverse population of nonpyramidal cells occupy VIb. The ventral border of AI stands in stark contrast to the near absence of PV labeling in perirhinal cortex (Supported by NIH, Deafness Research and Whitehall Foundations).

435.10

DIFFERENTIAL CORTICAL PROJECTIONS FROM SUBNUCLEI OF MONKEY MEDIAL GENICULATE COMPLEX REVEALED BY ANTEROGRADE TRANSPORT OF PHA-L. T. Hashikawa*, H. Ojima and E. G. Jones. Laboratory for Neural Systems, F.R.P., RIKEN, Wako 351-01, Japan, and Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Cortical auditory fields have been shown to receive their thalamic afferents from specific subdivisions of the medial geniculate body (MGB). In the present study, in order to examine how fibers originating from each MGB subdivision contribute to these projections, *Phaseolus vulgaris* leucoagglutinin (PHA-L) was iontophoretically injected under physiological control in limited regions of the MGB in Japanese monkeys, *Macaca fuscata*.

Fibers from the *ventral nucleus* formed several terminal plexuses in a patch-like fashion in the primary auditory cortex (AI), mainly in middle cortical layers. When measured in tangential sections, each patch was 500 - 1000 μm in width. A main patch was surrounded by "satellite" patches and the distance between the patches from center to center was about 1000 μm. Fibers from the *dorsal nuclei* also formed terminal patches in the same layers in cortical areas surrounding AI. Their principal projection was not to AI. Size of the main patches was twice as wide as those in AI, even with smaller injections. Fibers from the *magnocellular nucleus* had rather few terminal branches in middle cortical layers as well as in layer I, but they innervated extremely wide areas, both in AI and surrounding auditory areas by means of collaterals of single axons. Formation of discontinuous terminal patches suggests the presence of unitary modular structures in the auditory cortices based on thalamocortical connections.

435.11

TERMINAL MORPHOLOGY AND LAMINAR ORIGINS OF DUAL CORTICOTHALAMIC SYSTEMS IN CAT PRIMARY AUDITORY CORTEX. H. OJIMA* and E.G. JONES. Neural Systems Laboratory, Frontier Research Program, RIKEN, 351-01 JAPAN.

Dual terminal patterns of auditory corticothalamic fibers and their differential laminar origins were investigated with the anterograde tracers, PHA-L and biocytin, in the cat. Cats (n=8) anesthetized with Nembutal (40 mg/kg) were used. A tracer-filled electrode was introduced into the cortex while monitoring field potentials in response to single square waves applied to an earphone.

Injections of PHA-L into nearly the entire depth of AI resulted in staining of fibers with large or small boutons in the medial geniculate body (MGB). Fibers ending in large boutons were found preferentially in the dorsal and medial divisions, while most with small boutons were in the ventral division, with a smaller number in the dorsal and medial divisions. Large boutons formed clusters resembling bunches of grapes.

Injections of biocytin involving layer V without layer VI always stained fibers with large boutons which were localized in areas corresponding to those revealed by PHA-L. In contrast, localized injections solely into layer VI stained no large boutons but always demonstrated a significant number of small boutons in the ventral division and occasionally in other divisions of the MGB.

The present findings accord with previous findings that neuronal populations projecting to the MGB are separated in superficial layer V and layer VI and provide evidence that their terminal endings and patterns are also different in the MGB.

435.12

RELATIONSHIP BETWEEN NEURONAL BIRTHDATES AND THE LATERALITY OF THE PROJECTIONS IN THE RAT LATERAL SUPERIOR OLIVE. M.Kudo*, Y.Kitao, S.Okoyama and T.Moriizumi. Dept. of Anatomy, Sch. of Medicine, Kanazawa University, Kanazawa 920, JAPAN.

The crossed and the uncrossed projections from the lateral superior olive (LSO) to the inferior colliculus (IC) are distinct in all respects. The correlation between birthdates of the LSO neurons and the laterality of their projections was studied in the rat by double-labeling techniques using 5-bromodeoxyuridine (BrdU), the thymidine analogue, and Fluoro-Gold (FG), a retrograde fluorescent tracer. BrdU was given to a pregnant rat on each day throughout the LSO generation period (E12-E16). In the progeny rats as adults, FG was injected into the IC unilaterally to differentiate the crossed and the uncrossed projection neurons. The results indicate that the crossed projection neurons were mainly produced on day E13, whereas the uncrossed projection neurons generated between days E14 and E16 with peak production on day E16. Thus, one of the factors initiating the target laterality of the projections is the temporal order of neurogenesis.

435.13

INFERIOR COLLICULUS PROJECTIONS TO THE MEDIAL GENICULATE BODY: A STUDY OF THE ANATOMICAL BASIS OF COMBINATION-SENSITIVE NEURONS IN THE MUSTACHED BAT Jeffrey J. Wenstrup*. Dept. of Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

This study used dual anterograde tracers to examine projections to the medial geniculate body (MGB) from regions of the central nucleus of the inferior colliculus (ICC) analyzing different harmonic elements of the mustached bat's biosonar signal. The goal was to investigate whether direct converging input from ICC can provide the anatomical basis for combination-sensitive neurons known to exist in parts of the MGB. Multiple deposits of WGA-HRP were placed at physiologically-identified sites in ICC tuned to 26-30 kHz, while multiple deposits of biocytin were placed at ICC sites tuned either to 51-57 kHz or 60-62 kHz.

ICC regions tuned to 26-30 kHz projected to a set of targets nearer the margins of MGB. These included the suprageniculate nucleus, medial division, lateral part of the ventral division, and dorsal and superficial dorsal nuclei. Small patches of label were also found occasionally within the central part of MGB, but these were inconsistent and of low intensity.

ICC regions tuned to 60-62 kHz or 51-57 kHz each projected strongly to parts of MGB believed to contain combination-sensitive neurons. Thus, 60-62 kHz regions projected to the medial part of the ventral division and to the adjacent dorsal nucleus, while 51-57 kHz regions projected more rostrally to the dorsal nucleus and to the medial division. These major target zones did not overlap significantly with 26-30 kHz projections.

A working hypothesis is that direct projections from 26-30 kHz representations in ICC are insufficient to account for combination-sensitive neurons in MGB. (Supported by USPHS grant DC00937.)

PROJECTIONS TO THE COCHLEAR NUCLEUS FROM PRINCIPAL CELLS IN THE MEDIAL NUCLEUS OF THE TRAPEZOID BODY. B. R. Schofield* and N. B. Cant. Dept. of Neurobiology, Duke Univ. Medical Center., Durham, NC 27710

The superior olivary complex is a major source of descending projections to the cochlear nuclei (CN). In guinea pigs, a large percentage of the olivary cells that project to the CN are located in the medial nucleus of the trapezoid body (MNTB). We have used fluorescent tracers (Fluoro-Gold, Fluoro-Ruby [tetramethyl rhodamine-dextran] and Fast Blue) to determine whether MNTB principal cells, which are post-synaptic to the large synaptic terminals known as calyces of Held, contribute to this projection.

Injection of one of the tracers into the CN labels cells in the ipsilateral MNTB and calyces of Held in the contralateral MNTB. By injecting different tracers into the CN on each side, we could examine each MNTB for retrograde transport from the ipsilateral side and anterograde transport from the contralateral side. In every case, some of the labelled cells were enveloped by a labelled calyx of Held, identifying them as principal cells. It is unclear whether the remaining labelled cells were non-principal cells or were principal cells whose afferent calyx was unlabelled.

Our study demonstrates a projection from one CN to the contralateral CN via the calyces of Held and MNTB principal cells.

Supported by NIH grants RO1 DC00135 and F32 DC00005.

LEFT HEMISPHERE SPECIALIZATION FOR AUDITORY DISCRIMINATION IN MALE AND FEMALE RATS R.H. Fitch*, C. Brown, and P. Tallal. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102

Left-hemisphere lateralization for language processing, as well as for the discrimination of species-typical calls in monkeys and mice, may derive from underlying specialization of the left hemisphere for processing rapidly changing acoustic information. In support of this hypothesis we now report findings of a right-ear advantage for discriminating 2-tone sequences in rats. Adult rats were trained in a modified operant conditioning paradigm, culminating in a testing phase where one of four 2-tone sequences was presented to the right or left ear (alternating in blocks). White noise was simultaneously presented to the contra-lateral ear. Subjects were required to identify their target via a Go-No Go response paradigm. Results from 2 studies showed that male rats were significantly better at identifying their target with the right as compared to the left ear (Study 1, $p<.01$;$df=1,8$; Study 2, $p<.001$;$df=1,8$). Since sex differences in lateralization have been reported for a variety of functions including language, adult female rats were also tested in Study 2. There were no sex differences in overall discrimination. Females, like males, showed a pattern of better discrimination with the right ear, but this effect was much weaker as evidenced by a near-significant interaction between response type, ear, and sex ($p<.09$; $df=1,13$). Implications of these findings for the role of early hormonal exposure in the development of language lateralization, and sex differences in the incidence of language disorders, will be addressed.

SYNAPTIC CONNECTIONS MADE BY THE SUPERIOR OLIVARY COMPLEX (SOC) IN THE INFERIOR COLLICULUS (IC). AN EM AUTORADIOGRAPHIC STUDY. Gretchen E. Beckius and Douglas L. Oliver*, Dept. of Anatomy, Univ. of Connecticut Health Center, Farmington, Ct 06030

We made injections of 3H-leucine and wheat germ-HRP into either the lateral (LSO) or medial superior olives (MSO) of the adult cat. The nuclei were located by stereotaxic coordinates and by their responses to binaural tones. EM autoradiographs from the IC were prepared with Ilford L4 emulsion and exposed 4-66 wk. ***Axonal endings from the contralateral LSO*** usually contain round synaptic vesicles and make asymmetric synapses (RA endings) in the IC. However, one third have pleomorphic synaptic vesicles and make symmetrical contacts (PS endings). ***Endings from the ipsilateral LSO*** are more numerous and varied. About half of this projection to the IC is PS endings; 45% are RA endings; and 5% are unusual with pleomorphic vesicles and asymmetrical contacts (PA endings). ***Endings from ipsilateral MSO*** are invariably RA endings in the IC.

Overall, endings from the SOC represent the largest source of RA endings for the IC. The MSO and LSO projections make up 33% and 26% of all the presumed excitatory inputs to the ipsilateral IC, but the projection from the contralateral LSO represents only 17%. The bilateral LSO projections account for 38% of the presumed inhibitory PS endings.

These data support the concept that synaptic domains are distinct functional zones where different types of inputs are segregated in the IC. The sum of all RA endings from cochlear nucleus and superior olive exceeds 130% of the RA endings in IC. In addition, PS endings from dorsal nucleus of the lateral lemniscus and LSO total 76% of all PS endings in IC. The surplus of RA endings suggests that some excitatory inputs to the central nucleus are mutually exclusive and do not overlap on the same postsynaptic neurons.

CHEMICAL SENSES: PATHWAYS—GUSTATION

436.1

EXCITOTOXIC PARABRACHIAL NUCLEUS LESIONS DISRUPT CONDITIONED TASTE AVERSION, CONDITIONED ODOR AVERSION, AND SODIUM APPETITE IN RATS. G. Scalera*, P.S. Grigson, T. Shimura, S. Reilly, and R. Norgren. College of Medicine, Penn State Univ., Hershey, PA 17033

Previous studies have demonstrated that electrolytic lesions in the parabrachial nuclei (PBN) disrupt both conditioned taste aversions and salt appetite in rats. In order to assess the contributions of neurons and fibers of passage to these effects, we made electrophysiologically guided bilateral injections of ibotenic acid into the PBN of 10 rats (IBO, 0.2 ul; 20 ug/ul). Six other rats received the same volume of vehicle in the PBN (PBS, pH=7.4) and 8 animals served as non-surgical controls. Following overnight fluid deprivation, rats were given 15 min access to 0.3 M alanine and immediately injected ip with LiCl (1.5 mEq/kg, 0.15 M). Three alanine-LiCl pairings were spaced 3 days apart. All non-lesioned rats rejected alanine following a single pairing with LiCl. Even after 3 pairings, however, the IBO rats failed to reject alanine. Subsequently, these rats were acutely sodium depleted with furosemide (7.0 mg, sc) and given simultaneous access to 0.5 M NaCl and water. The IBO rats failed to increase intake of NaCl, while the other groups consumed at least 3 times control levels. In a second set of rats, using a higher concentration of LiCl (0.3 M), IBO lesions of the PBN prevented acquisition of both an alanine taste aversion and an almond odor aversion. Finally, the lesioned rats exhibited an apparent lack of neophobia in 2 situations -- when first presented with alanine and when put on a novel, Na-free diet.

CODING OF TASTE INTENSITY IN THE HAMSTER SOLITARY NUCLEUS. H. J. Duncan* and D. V. Smith. Dept. Otolaryngology-Head and Neck Surgery, Univ. Cincinnati Coll. Med., Cincinnati OH 45267-0528.

In order to examine the contributions of Na^+, H^+ and Cl^- receptor mechanisms to the responsiveness of cells in the nucleus of the solitary tract (NST), we have determined concentration-response functions for a wide array of chemical stimuli. This array includes 8 sodium salts, 2 lithium salts, 5 non-sodium salts, 5 acids, 5 sweet-tasting stimuli, and 5 bitter-tasting stimuli. We recorded multiunit activity from the NST evoked by anterior tongue stimulation with five or more concentrations of each tastant. The peak of the integrated multiunit response to a 10 sec test stimulus was measured; these values were expressed as proportions of the peak response to a 0.032M NaCl standard. The slopes of the concentration-response functions derived in this way varied with respect to taste quality and chemical composition. In particular, the slopes for some salts were more steep than for NaCl, some were less steep, yet many stimuli were similarly effective at 0.032M. The data for salts are well described by power functions and the slopes for these functions are similar to those from human psychophysical studies on the anterior tongue. Equally effective concentrations are chosen from these functions for single unit studies; the matching concentrations (M) for stimuli determined to date are: NaCl=0.032, $NaNO_3$=0.032, Na_2SO_4=0.023, Na-acetate=0.044, LiCl=0.028, KCl=0.11, NH_4Cl=0.032, citric acid=0.0026, tartaric acid=0.0018, Na-saccharin=0.0014, dextrose=0.73, sucrose=0.028, quinine-HCl=0.032 and urea=1.73.

A PATCH-CLAMP ANALYSIS OF NEUROKININ RECEPTOR ACTIVATION IN THE GUSTATORY PORTION OF THE SOLITARY NUCLEUS. H. Liu, M. Behbehani, S. Chandler* and D. V. Smith. Depts. Physiology and Otolaryngology, Univ. Cincinnati Coll. Med., Cincinnati, OH 45267

In previous experiments, we have shown that substance P (SP) can excite many neurons in the gustatory portion of the nucleus of the solitary tract (NST) of the hamster. Using whole cell patch-clamp techniques in an *in vitro* slice preparation, we have examined the effects of SP on the membrane properties of cells in the rostral hamster NST. Recordings were made from 21 cells with stable resting membrane potentials (mean = 55 ± 5 mv sd). Most of the cells fired repetitive action potentials with a mean spike overshoot of 64.7 ± 7 mv. Short application of the neurokinin receptor agonist SP depolarized 13 neurons with a mean depolarization of 4.5 mv that lasted for 1 - 2 min; in 10 cells this depolarization was accompanied by a decrease in conductance and an increase in spontaneous activity. Another 3 cells were hyperpolarized 4 - 6 mv with an increase in membrane conductance and a decrease in spontaneous firing. The remaining 5 cells were not affected by SP. In the presence of TTX, the depolarizing effect of SP was not abolished by perfusion of the slices with high Mg^{++}/low Ca^{++} PSS, indicating a direct postsynaptic action of SP. The effect of SP was blocked by its antagonist ([D-Pro^2, D-$Trp^{7,9}$] substance P) in 6 cells. Current/voltage curves indicated a conductance decrease during the depolarization with a reversal potential of the SP-dependent current close to the K^+ equilibrium potential. We conclude that activation of neurokinin receptors decreases K^+ conductance, leading to membrane depolarization, which may interact with gustatory afferent processing.

RAT TASTERS AND NON-TASTERS REVEALED IN NEURAL ACTIVITY. B.K.Giza*, T.R.Scott & L.Zhang, U.Delaware, Newark DE 19716

Preferences for the bittersweet taste of NaSaccharin (Sac) in rats may be related to the distribution of PROP sensitivity, as it is in humans. Do differences in NTS taste-evoked activity mediate these preferences? We offered rats water and 0.03M Sac, then selected those who consumed >75% Sac (S) or >75% water (W). We recorded the activity of 56 cells from S- and 43 from W-rats in response to 13 stimuli. Activity in the two groups was similar for sugars but greater for all other stimuli in W-rats. **Thus water-preferring animals were not insensitive to sweet stimuli, but rather hypersensitive to non-sweets.** We divided the cells of each group into three clusters: sugar-, sodium- and acid-oriented. Sugar and sodium cells showed few differences between S- and W-rats. Rather the greater responsiveness of W-rats was most evident among acid cells. Therefore, **hypersensitivity to non-sweet tastes in W-rats was carried primarily by cells whose activity is associated with aversive chemicals.** The activity profile evoked by Sac was similar to those of sugars in S-rats, but more like those of non-sweet stimuli in W-rats. In humans, the sweetness of Sac does not differ between tasters and non-tasters of PROP, but bitter sensitivity is greater in the former group. It is the exaggeration of Sac's bitterness that leads to its rejection by PROP tasters. A corresponding situation would seem to obtain in rats.

PARABRACHIAL GUSTATORY LESIONS IMPAIR TASTE-GUIDED QUININE AVOIDANCE IN RATS. A.C. Spector*. Dept. of Psychology, University of Florida, Gainesville, FL 32611.

Rats with lesions centered in the gustatory zone of the parabrachial nuclei (PBN) are able to respond to sucrose in a concentration-dependent manner, but this responsiveness is blunted. This study examined the extent to which PBN lesions alter taste-guided avoidance of an aversive taste stimulus, quinine. Water-deprived rats were tested, in a specially-designed gustometer, for their licking responses to water and 7 concentrations of quinine hydrochloride (0.003 mM - 3.0 mM) during repeated 10 sec trials. Water rinses preceded each stimulus trial and testing occurred over three 40 min sessions. Next, six deeply anesthetized rats received electrophysiologically-guided bilateral electrolytic lesions of the gustatory zone of the PBN. Two lesions were placed on each side, one at the ventral border of the taste area (60 uA, 20 s) and one 200-300 um more dorsal (40 uA, 20 s). A second group (n = 13) received similar lesions, but the current and time were doubled. Eight rats served as surgical controls. After recovery rats were retested for quinine responsiveness. In all groups, licking to quinine significantly decreased as a function of concentration both before and after surgery. There was a slight rightward shift in the concentration-response curve of about 0.10 $\log_{10}$ units after surgery in the control group. The lower current-induced lesions shifted the curve about 0.5 $\log_{10}$ units to the right and the higher current-induced lesions caused a more substantial shift of about 1.0 $\log_{10}$ unit. Histological analysis is in progress to determine the relationship between the degree of behavioral impairment and the cytoarchitectural lesion parameters. These results suggest that rats with PBN lesions are not completely ageusic to quinine. These lesions, however, markedly attenuate taste-guided avoidance responses. Supported by PHS grant DC-00161.

THE PARABRACHIAL NUCLEUS AND INCENTIVE CONTRAST IN RATS. P.S. Grigson, S. Reilly*, A.C. Spector^, and R. Norgren. College of Medicine, Penn State Univ., Hershey, PA 17033 and Dept. Psychology^, Univ. Florida, Gainesville, FL 32611

Rats with bilateral electrophysiologically guided lesions of the parabrachial nuclei (PBN) and surgical controls were food deprived and divided into two groups. One group received 5-min daily access to 0.1 M sucrose for 14 days. The other received similar access to 1.0 M sucrose for the first 10 days and then was shifted to 0.1 M sucrose for the remaining 4 days. Prior to the shift, the lesioned rats consumed less of both solutions than the sham animals. Nevertheless, both groups licked the stronger solution with shorter latencies, at higher rates, and with shorter interburst intervals than they did the weaker stimulus. Following the concentration shift, the sham rats demonstrated contrast on three measures, i.e., they made fewer licks and initiated more bursts that were of shorter duration than did the unshifted controls. The lesioned rats failed to demonstrate a contrast effect on any measure; their licking simply dropped to the level of the lesioned, but unshifted rats. Although motor impairments might account for the differences in preshift licking rates between the lesioned and the sham groups, the data indicated that the incentive value of the stimuli was not eliminated, because the rats with PBN damage did respond more for the stronger than for the weaker sucrose. The absence of a contrast effect in the lesioned animals, however, indicates that the PBN damage disrupted the comparison process that typically occurs when rats are shifted from a more preferred to a less preferred solution. GUSTATORY FUNCTION AFTER LESIONS OF THE ROSTRAL NUCLEUS OF THE SOLITARY TRACT IN RATS. T. Shimura, P.S. Grigson*, and R. Norgren. Dept. Behavioral Science, College of Medicine, Penn State Univ., Hershey, PA 17033

In an automated gustometer, 12 rats generated concentration-response functions for 8 sapid chemicals and capsaicin. When water deprived, the rats progressively decreased their licking of citric acid, $MgCl_2$, NH_4Cl, quinine HCl, and capsaicin. When replete, they increased their licking of sucrose and polycose and decreased intake of NaCl and monosodium glutamate. Six of these animals and 3 additional, inexperienced rats had electrophysiologically guided lesions centered on taste neurons in the nucleus of the solitary tract (NST); 4 others (3 exp., 1 inexp.) served as controls. Subsequently, all animals were retested using the same stimuli under the same conditions. Control animals were unchanged, but the lesioned rats exhibited consistent deficits in responding to sapid stimuli. Licking of 1.0 M sucrose did not differ from water. The normally aversive substances reduced intake only about half as much as before surgery. Intake of capsaicin was not influenced by the NST lesions. In a second experiment, 3 presentations of 0.3 M alanine were paired with injections of LiCl (1.5 mEq/kg, 0.15 M). Both the lesioned and the control rats learned to avoid the alanine. Thus, rats with NST lesions show a marked impairment of gustatory preference and aversion, but still can use taste cues for learned aversions. With lesions in the parabrachial nuclei, the second central taste relay, rats exhibit only moderate changes in gustatory preference, but cannot learn a taste aversion. SALT DEPRIVATION ALTERS TASTE RESPONSES IN THE NUCLEUS OF THE SOLITARY TRACT OF BEHAVING RATS. K. Nakamura and R. Norgren*. Dept. Electronics and Informatics, Toyama Prefectural Univ., Toyama, Japan 939-03 and Dept. Beh. Sci., Col. of Med., Penn State Univ., Hershey, PA 17033

Single neurons were isolated from the nucleus of the solitary tract of awake, behaving rats before (n=41), during (n=58), and after (n=12) they were placed on a sodium-free diet. Fluid stimuli (50 ul) were delivered via intraoral cannulae. During sodium deprivation, taste responses generally were reduced. Spontaneous activity increased by an average of 42%, while responses to water dropped by 28%. Mean response to NaCl decreased 47%; to sucrose, 59%; to citric acid, 32%; and to quinine HCl, 16%. Nevertheless, the response profiles of the neurons to 4 standard stimuli were not changed by the dietary conditions. In the replete condition, 61% of the activity elicited by NaCl occurred in Na-best cells; 33% in sucrose-best neurons. In the depleted state, the figures were 60% and 26%, respectively. At higher stimulus concentrations, however, the relative responsiveness was altered by sodium deprivation. When the animals were sodium replete, in sucrose-best neurons, 1.0 M NaCl elicited only 60% as much activity as that produced by 0.3 M sucrose. When depleted, the response to strong salt was 101% that of sucrose. Similarly, for Na-best neurons, the response to 1.0 M sucrose was only 38% of that to the 0.1 M NaCl standard in the replete condition, but rose to 71% when the rats were sodium deprived. Although the sample was small, these ratios appeared to revert toward previous values when sodium was added back to the diet. Supported by PHS grants DC-00240, MH-43787, MH-00653.

CYCLIC SPONTANEOUS ACTIVITY IN TASTE-RESPONSIVE UNITS IN THE NUCLEUS OF THE SOLITARY TRACT IN THE RAT. Scott Monroe* and Patricia M. Di Lorenzo. Dept. of Psychology, P.O. Box 6000, SUNY at Binghamton, Binghamton, NY 13902-6000.

Recent studies have shown that some taste-responsive units in the parabrachial pons (PbN), the second relay in the central taste pathway in the rat, show non-random, cyclic variations in spontaneous firing rate. The present study examined spontaneous activity in taste-responsive units in the nucleus of the solitary tract (NTS), the first relay in the central taste pathway, in the urethane-anesthetized rat. Initially, responses to representatives of the four basic taste stimuli were recorded followed by 15 min of spontaneous activity. Spontaneous activity (5 sec bins) was examined for cyclic characteristics using a Fourier analysis. Linear trends were removed prior to spectral analysis. Spontaneous activity was classified as cyclic if a peak in the activity spectrum exceeded the 95% confidence limits of the spectral estimates of random data. Preliminary results show that 4 of 12 taste-responsive units showed significant cyclic spontaneous activity. These units showed single peaks in the spectral analysis ranging from .11 - 4.43 cycles/min, with a median of .18 cycles/min. Ten of the NTS units were recorded simultaneously with taste-responsive PbN units and in five of those pairs one unit showed cyclicity where the other did not. This suggests that the occurrence of cyclicity of spontaneous rate may be independent in the NTS and PbN. In contrast to the PbN units, spontaneous firing rates in NTS units were not suppressed following taste stimulation.

THE EFFECTS OF A CTA ON GUSTATORY EVOKED ACTIVITY IN THE RAT NTS REMAIN AFTER BEHAVIORAL EXTINCTION. L.J. Nolan* and T.R. Scott, Dept. of Psychology, University of Delaware, Newark, DE 19716.

Chang and Scott (1984) reported modification of gustatory evoked activity in the rat NTS as a consequence of a CTA. We investigated whether this modification would be lost with the complete behavioral extinction of the aversion. Rats were conditioned to avoid .0025M sodium saccharin (CS) by pairing its taste three times with i.p. LiCl. The aversion was then extinguished over a period of weeks by daily presentations of the CS when the rats were 23-hour fluid deprived. A control group received saline injections. After rats consumed the CS at pre-illness levels, responses of single units in the NTS were recorded to the CS plus an array of 12 stimuli. The stimulus space from the control group presented a typical distribution of chemicals, with the CS among the sugars. In the CTA-extinguished group, the CS shifted decisively away from the sugars towards salt and quinine. This change in location of the CS was similar to that reported in rats with intact CTAs. Therefore, the effect of an intense aversion to the taste system remains even after the rat has regained full acceptance of the CS. This vestige of the initial conditioning may account for the ease with which relearning occurs following extinction.

436.11

LOCATION OF POSTERIOR TONGUE-RESPONSIVE GUSTATORY ACTIVITY WITHIN THE NUCLEUS OF THE SOLITARY TRACT. C.B. Halsell*, J.B. Travers and S.P. Travers. Dept. of Oral Biology, The Ohio State University, Columbus, OH 43210.

The posterior lingual taste buds located within the foliate (FOL) and circumvallate (CV) papillae account for the majority of tongue taste buds in the rat (46% and 35%, respectively). However, there is a paucity of data on central processing of taste-responses arising from the posterior tongue, especially the CV. In the present study, in rat, the location of neurons responsive to specific CV and FOL stimulation were mapped within the nucleus of the solitary tract (NST) using standard extracellular recording techniques. Both posterior taste responses extended from the anterior tongue taste area to about the level where the NST meets the 4th ventricle, with a trend for CV responses to extend caudal to FOL responses. In most cases, CV and FOL taste responses were recorded in the same electrode track, with FOL responses located dorsal to CV responses. Tactile responses from these two fields were co-extensive with taste responsive sites, but were more widespread. All multiunit sites and four single units responsive to specific CV stimulation had similar response profiles: 0.01M HCl > quaternary mixture > 0.003M quinine•HCl, with no response to 0.3M NaCl and 0.01M Na saccharin. This central response profile is more specific than glossopharyngeal nerve response profiles previously described, but is in agreement with the robust responsiveness of this nerve to acids and alkaloids. DISTRIBUTION OF TASTE-RESPONSIVE NEURONS IN THE HAMSTER SOLITARY NUCLEUS. A.P. Knox*, L.D. Savoy, T.P. Hettinger and M.E. Frank. Department of BioStructure and Function, Univ. of Connecticut Health Center, Farmington, CT 06030.

The distribution of taste-responsive neurons in the rostral solitary nucleus (SN) was studied in anesthetized hamsters (*Mesocricetus auratus*). The anterior tongue was isolated in a flow chamber and seven taste stimuli (0.03M NH_4Cl, 0.01M citric acid, 0.1M glycine, 0.1M KCl, 0.03M Na acetate, 0.03M NaCl, 0.1M sucrose) applied. Extracellular recordings from SN neurons were made with glass microelectrodes (1-8 MΩ) filled with 4% HRP in 0.5 M KCl and 0.05 M Tris buffer. Units were recorded on a VCR and played back through a window discriminator for data analysis. Successful recording sites were marked by ionophoresis of HRP, which filled stellate and elongate cells. Perfused brainstems were cut in 40μm frozen sections in the transverse, parasagittal or horizontal plane. The SN is prominent and can be reconstructed from sections in any plane. Sections were processed for HRP, counterstained and the taste-responsive area containing small, densely packed cells was mapped. A high percentage of cells in this area responded to one or more stimulus. Rates as high as 100 spikes/s were obtained to sucrose. Responses in the rostral SN may be stimulus selective at any one multiunit site. Single units, however, could display disparate responses at contiguous sites. These data argue that taste responsiveness of neurons may have a "modular" organization that selects for basic taste stimuli. This work was supported by NIH grant DC 00853.

436.13

TRANSGANGLIONIC DEGENERATION IN THE GUSTATORY SYSTEM. S.T. McGlathery and M.C. Whitehead*. Department of Surgery, Division of Anatomy, UCSD, La Jolla, CA 92093

Peripheral taste nerves are prone to damage in humans and have been experimentally altered in animal studies of the deafferented gustatory system. It is not known whether peripheral nerve damage in the mammalian taste system results in degeneration of central axonal endings as in other sensory systems (e.g. trigeminal, vestibular, auditory). In this study, using 11 Golden hamsters, the right chorda tympani was severed in the middle ear. In 8 cases a toxin, Formocresol, was applied to the nerve stump. The animals survived for 2-15 days. The brains were sectioned and stained for degenerating axons and endings using the Fink-Heimer method. In all cases there was evidence of degenerating axons in the rostral nucleus of the solitary tract. Degeneration was concentrated in the chorda tympani terminal field. In animals treated with both the nerve-cut and Formocresol the degeneration was dense, especially at 11-13 days. In cases where the chorda tympani had merely been severed, degeneration was less robust but relatively heavy at 11 days and observable as early as two days after nerve-cut. The degeneration observed after Formocresol treatment could result from the death of geniculate ganglion cells. However, degeneration after simple nerve cut is best explained as transganglionic, not necessarily requiring cell death. The present findings suggest that damaging peripheral taste nerves can profoundly disrupt the synaptology of the NST. Altered synaptology could relate to the dysgeusia or other taste phenomena of central origin reported for some patients after taste nerve damage (e.g. in middle ear or oral surgery). (Supported by NIH Grant DC00452).

CONSUMPTION AND LICK ANALYSIS OF SACCHARIN-ETHANOL COCKTAILS IN RATS LACKING GUSTATORY CORTEX. C.C. Horn*, S.A. Bailey, J.C. Mitchell, and S.W. Kiefer. Department of Psychology, Kansas State University, Manhattan, KS 66506.

Research on alcohol ingestion has customarily employed water-alcohol mixtures, but in the real world alcohol is often flavored with another pleasant tastant, often something sweet. Alcohol-saccharin mixtures were used in the present study to achieve a degree of external validity. Gustatory cortex lesion (n=6), control lesion (n=4), and normal rats (n=5) were given 30 min lick analysis tests; volume consumed was measured at the end of each session. Solutions of saccharin (.006 M) and alcohol-saccharin mixtures (3%, 6%, 9%, and 12%, v/v) were presented in ascending and descending orders, one solution each day. Contrary to previous findings with water-alcohol mixtures [Kiefer et al., Alcohol, 4, 1987] rats lacking gustatory cortex did not consume more alcohol-saccharin at any concentration compared to controls. Preliminary analysis of lick rate also revealed no significant differences between groups. It is suggested that the synergy of saccharin and alcohol contributes to the lack of differences. There were significant differences across concentrations for all groups, e. g., rats consumed more saccharin and 3% alcohol-saccharin than other concentrations.

436.15

INCREASED SODIUM CHLORIDE PALATABILITY IN RATS LACKING GUSTATORY CORTEX. S.A. Bailey*, S.W. Kiefer, and S.L. Rock. Department of Psychology, Kansas State University, Manhattan, KS 66506-5302.

It has been reported that rats lacking gustatory cortex (GC) consumed significantly more sodium chloride (NaCl) solution over a range of concentrations than did control rats during simple preference tests (Braun et al., 1982). Whether this pattern of consumption could be attributed to palatability, postingestive effects, or some other mechanism could not be delineated using intake as a measure. The present study, which employed taste reactivity as a dependent variable, compared GC rats (n=7) to control rats (n=7) across four NaCl concentrations (0.1M, 0.3M, 0.6M, 1.0M). Each of four daily fluid presentations (given randomly) consisted of videotaping orofacial reactivity to the intraoral delivery of NaCl solution (1 ml/min) for 1 min. The tapes were individually scored for ingestive and aversive reactivity. The data indicated that GC rats produced significantly more ingestive reactivity than control rats. There were no significant group differences on aversive reactivity. The increase in ingestive responding by GC rats may be the basis for the increased consumption of NaCl shown previously.

LOCALIZATION OF STRIATAL EXCITATORY AMINO ACID BINDING SITE SUBTYPES TO STRIATONIGRAL PROJECTION NEURONS . S. J. Tallaksen-Greene[1]*, R. G. Wiley[2] and R. L. Albin[1]. [1]Dept. of Neurology, U. of MI., Ann Arbor, MI 48109. and [2]Depts. of Neurology and Pharmacology, DVAMC and Vanderbilt Univ., Nashville, TN 37212.

Autoradiographic studies have identified high levels of excitatory amino acid (EAA) binding site subtypes in striatum. However, the localization of EAA receptor subtypes to specific populations of striatal projection neurons has not been determined. We used quantitative autoradiography to examine the cellular localization of NMDA, AMPA, metabotropic and kainate EAA binding sites in the striatum following selective lesion of striatonigral projection neurons. Degeneration of striatonigral neurons was induced unilaterally by injection of the suicide transport toxin, volkensin (0.5-0.8 ng in PBS), into the left substantia nigra. Following a survival period of 12 days, we observed a reduction of all EAA binding site subtypes in the striatum ipsilateral to the injected nigra. Striatal NMDA binding sites were reduced approximately 50%. The other EAA binding site subtypes exhibited more modest reductions; up to 18% for AMPA, 27% for metabotropic and 15% for kainate.

These results indicate that there are NMDA, AMPA, metabotropic and kainate binding sites on striatonigral projection neurons and suggest that the NMDA subtype may be selectively enriched on striatonigral neurons. Supported by NS01300, NS19613, NS07222 and the Hereditary Disease Foundation.

437.2

HALOPERIDOL-INDUCED MORPHOLOGICAL CHANGES IN STRIATUM ARE MEDIATED VIA GLUTAMATE SYNAPSES. C. K. Meshul*, R.K. Stallbaumer, B. Taylor and A. Janowsky. V.A. Medical Center and The Oregon Health Sciences Univ., Portland, OR 97201.

We have shown that 14d treatment with haloperidol (0.5 mg/kg/d, s.c.) causes a signficant increase in the percentage of synapses associated with a perforated postsynaptic density (i.e. perforated synapses)(Meshul *et al*, 1992). Based on the size of the presynaptic terminal, we hypothesized that the perforated synapse was not dopaminergic but could be glutamatergic. Co-administration of haloperidol and MK-801 (0.3 mg/kg/d, s.c.), an NMDA non-competitive antagonist, for 14d prevented the haloperidol-induced increase in striatal perforated synapses, but had no effect on the increase in density of dopamine D-2 receptors. Since this glutamate antagonist could be having its effect outside the striatum, MK-801 (10 nmole/0.5 ul/d) was injected directly into the caudate, followed 30 min later by systemic haloperidol administration or saline for 14d. The haloperidol-induced increase in striatal perforated synapses was reduced following pre-treatment with intrastriatal MK-801. Surprisingly, intracaudate injection of MK-801 alone caused a significant increase in the percentage of perforated synapses compared to the saline control. This suggests that blockade of the NMDA channel within the striatum could allow activation of other glutamate receptors, which may then play a role in the appearance of perforated synapses. In order to demonstrate whether the perforated synapse contains glutamate, post-embedding immuno-gold electron microscopy was carried out. Glutamate antibody (Arnel, Brooklyn, NY, diluted 1:400,000 + 1 mM aspartate) was localized within presynaptic terminals associated with perforated postsynaptic densities. Supported by the Dept. of Veterans Affairs and NIAAA.

TENASCIN AND ASTROCYTES IN THE STRIATUM OF PROGRESSIVE GRADES OF HUNTINGTON'S DISEASE. D. Steindler, T. O'Brien*, M. Gates, K. Harrington, E. Laywell, A. Reiner, and A. Faissner. Dept. of Anatomy & Neurobiol., Univ. of TN, Memphis; Dept. of Neurobiol., Univ. of Heidelberg.

Various neuron types may be at risk during the course of Huntington's Disease (HD). Glial cells have not been extensively studied during the course of neurodegeneration within the structure most involved in the disease process, the caudate-putamen (or neostriatum). Since the astrocyte could be a cell at risk, or even associated with the primary gene defect, we examined two markers that have been shown to be specific for astrocyte "reactivity," (glial fibrillary acidic protein, GFAP), and development, (tenascin, a constituent of the extracellular matrix that is developmentally regulated in the neostriatum and other structures, and also expressed early in CNS injury).

Immunocytochemistry for GFAP and tenascin, using well-characterized mono- and polyclonal antibodies, was carried out on presymptomatic, and Grades 2& 3 HD striatum (using the grading scale of Vonsattel). Our studies have revealed that astrocytes show changes in the presymptomatic HD tissue, and that their reactivity, distribution, and expression of tenascin and GFAP mirrors the degenerative process through the caudate and putamen as the disease progresses. In particular, we have found that GFAP and tenascin are upregulated in the HD striatum, and distributed in a patchy manner that may either represent striosomes or a matrix subcompartment. In presymptomatic tissue, GFAP and tenascin patchy staining is light, as compared to Grades 2 & 3. By Grade 3, the tenascin and GFAP immunostaining in the caudate and putamen is dense and pervasive. In Grades 2 & 3, GFAP staining is associated with classical reactive astrocytes, but in the presymptomatic tissue the GFAP labels what resemble immature astrocytes. Thus, astrocytes exhibit morphological and biochemical changes early in HD that may be associated with the onset of disease. Supported by the Hereditary Disease Foundation.

COMPARISON OF THE DOPAMINE EFFECTS ON GABA NEURONS IN THE MEDIAL FRONTAL CORTEX AND THE STRIATUM OF THE RAT. S. Rétaux, N. Kayadjanian, P. Vernier, J. Caboche, M. Mavridis, J. P.Bourgeois*, M.J. Besson and J. Penit-Soria. Lab. Neurochimie-Anatomie, IDN-UPMC, CNRS URA 1488, 75005 Paris; Lab. Neurobiol. Cell. Mol. CNRS UPR 23, 91198 Gif-sur-Yvette, Lab. Biol. Mol., Inst. Pasteur, CNRS URA 1284, 75005 Paris

Previous *in vitro* electrophysiological studies have shown that DA increased the spontaneous firing of GABA interneurons in the medial frontal cortex (MFC). This activation could be involved in the inhibition of the firing rate of pyramidal cells observed *in vivo* following DA neuron stimulation of the ventral tegmental area (VTA). The DA control of MFC GABA interneurons was further investigated by studying the spontaneous 3H-GABA release on MFC slices. Three D2 agonists (quinpirole, RU 24926 and lisuride) dose dependently enhanced 3H-GABA release. These effects were antagonized by the classical D2 antagonist : sulpiride. Endogenous DA released by amphetamine also increased the release of 3H-GABA through a D2 receptor activation. A permissive effect of D1 agonist was observed on the D2-mediated increase of 3H-GABA release. The D2 activatory effect observed on GABA interneurons of the MFC contrasted with the D2 inhibitory effect observed on the spontaneous 3H-GABA release in the striatum.

Finally, DA regulated the levels of mRNA encoding one of the isoforms of glutamic acid decarboxylase (GAD67). In situ hybridization studies showed that the electrolytic lesion of VTA neurons decreased GAD67-mRNA expression in the MFC. At the opposite, a 6-OHDA lesion of DA nigral neurons enhanced GAD67-mRNA levels in the striatum, an effect which can be reproduced by a chronic treatment with sulpiride and haloperidol. SCOPOLAMINE ATTENUATES HALOPERIDOL-INDUCED C-FOS EXPRESSION IN THE BRAIN. N. Guo,* G.S. Robertson and H.C. Fibiger, Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, 2255 Wesbrook Mall, Vancouver, B.C. Canada, V6T 1Z3.

Haloperidol increases the the expression of Fos in some parts of the central nervous system. Haloperidol also induces catalepsy in rodents and extrapyramidal side effects in humans, both of which are reduced by muscarinic receptor antagonists. In order to gain insight into the neurochemical and neuroanatomical substrates of haloperidol-induced catalepsy we examined the effects of the muscarinic receptor antagonist scopolamine on haloperidol-induced c-fos expression in the striatum, nucleus accumbens, and lateral septal nucleus. Male Wistar rats received subcutaneous injections of scopolamine (2.5mg/kg), or vehicle (1mg/kg) 30 minutes before haloperidol (2mg/kg). The rats were perfused 2 hours after the injection. Immunohistochemical staining was performed on brain sections (30μm) to visualize Fos protein. At a dose that reduced the cataleptic effect of haloperidol, scopolamine decreased the neuroleptic-induced Fos expression in the striatum. Striatal cholinergic neurons are known to be interneurons that express D2 receptors and innervate striatal medium spiny neurons. The finding that scopolamine attenuates haloperidol-induced increases in striatal c-fos expression raises the possibility that these increases are mediated indirectly by the ability of this neuroleptic to increase ACh release which in turn acts on muscarinic receptors located on striato-pallidal neurons.

METABOLIC EFFECTS OF CONTINUOUS L-DOPA INFUSION IN RATS WITH UNILATERAL SUBSTANTIA NIGRA LESIONS. C.A. Hubbard, J.P. Bennett, and J.M. Trugman* Dept. of Neurology, Univ. of Virginia, Charlottesville, VA 22908

We used the 2-deoxyglucose (2-DG) method of measuring regional cerebral glucose utilization (RCGU) to study the effects of continuous L-dopa infusion in rats with unilateral 6-hydroxydopamine nigral lesions. Rats were implanted with osmotic minipumps (Alzet) delivering 100, 800, or 1200 mg/kg/day L-dopa and 25 mg/kg/d benserazide and were studied 20-22 h later. Rats receiving L-dopa, 100 mg/kg/d, rotated 0-1 turns/min; rats receiving 800-1200 mg/kg/d rotated 3-7 turns/min. Compared to lesioned controls, administration of L-dopa, 100 mg/kg/d, increased 2-DG uptake in the subthalamic nucleus (up 40%) and mildly increased RCGU in the entopeduncular nucleus (EP) and substantia nigra pars reticulata (SNr; up 30%). At this dose, an asymmetrical RCGU response on the denervated and nondenervated sides of the brain was not seen. These metabolic effects are comparable to those elicited by acute administration of a selective D2 agonist. Infusion of L-dopa, 800-1200 mg/kg/d, decreased 2-DG uptake in the lateral habenula (down 30%) and markedly increased 2-DG uptake in the EP and SNr (up 70-100%) ipsilateral to the lesion, resulting in prominent metabolic asymmetry. Increased RCGU in the EP and SNr of this magnitude has been shown previously to be mediated by D1 receptor stimulation. We conclude that continuous infusion of L-dopa at 100 mg/kg/d produces metabolic effects consistent with selective D2 stimulation whereas infusion at 800-1200 mg/kg/d elicits metabolic effects consistent with both D1 and D2 receptor stimulation.

PROGRESSION OF CEREBRAL METABOLIC CHANGES IN MPTP-INDUCED HEMIPARKINSONISM IN MONKEYS. E. Palombo[1], KS Banckiewicz[2], IJ Kopin[2], L. Sokoloff[2,*] and LJ Porrino[3], [1]NIMH, Bethesda, MD 20892; [2]NINDS, Bethesda, MD 20892; [3]Bowman Gray School of Medicine, Winston-Salem, NC 27157.

Local rates of glucose utilization (LCGU) were determined in 6 hemiparkinsonian monkeys, either 6-10 weeks (short-term, n=3) or 16 to 26 weeks (long-term, n=3) after a unilateral intracarotid infusion of MPTP. Four additional monkeys served as normal controls. MPTP-treament resulted in similar clinical signs of hemiparkinsonism, e.g. unilateral bradykinesia and rigidity that were apparent in all 6 treated monkeys.

In the short-term group, significant side-to-side asymmetries were restricted to the substantia nigra compacta (SNpc) medialis and to the zona incerta (ZI). Additional smaller differences were seen in the external globus pallidus (GPe) and subthalamic nucleus (STN).

In the long-term group, LCGU decreases in the SNpc medialis were similar (-31 short-term vs -34% long-term). Changes in the GPe (+30 vs +55%), STN (-14 vs -20%), and ZI (+9 vs +18%) were far more pronounced. In addition, LCGU was increased in the dorsolateral caudate (+18%), all parts of the putamen (+ 22%), and pedunculopontine nucleus (+19%) ipsilateral to the lesion. Furthermore, bilateral reductions were present in the ventral tegmental tegmental area as compared to controls; bilateral increases were also present in the pars oralis of ventrolateral thalamus and in the supplementary motor area.

Within the time frame of this study, the pattern of LCGU changes in the basal ganglia and associated structures becomes more complex as the length of time after SNpc denervation increases. This suggests that pathophysiological events in the brain progress in spite of a relatively stable clinical syndrome.

THE GLUTAMATE AGONIST QUINOLINIC ACID REGULATES THE EXPRESSION OF *NGFI-A*-LIKE IMMUNOREACTIVITY IN STRIATAL NEURONS. S. Berretta[1]*, J. Mildbrandt[2], G. Evan[3] and A.M. Graybiel[1]. [1]MIT E25-618, Cambridge, MA 02139 USA; [2]Washington University School of Medicine, St Louis, MO 63110 USA; [3]Imperial Cancer Res. Fund, London UK

NGFI-A (*egr-1, zif/268, krox-24*), an immediate-early gene of the zinc finger family, is constitutively expressed at low levels in neurons of the caudoputamen (CP) and therefore in principal could be either up- or down-regulated by neurotransmitters in the striatum. Evidence for such regulation has already been obtained for monoamines: dopamine indirect agonists induce marked increases in expression of *NGFI-A* mRNA in striatal neurons. We investigated the effects of glutamate, the major neurotransmitter in cortical afferents to the CP. We injected the glutamate NMDA receptor agonist quinolinic acid, or vehicle (CSF), intrastriatally in adult male rats and tested for the expression of NGFI-A by immunohistochemistry with two polyclonal antisera. On the side of the injection of quinolinic acid, NGFI-A immunostaining in the CP was markedly increased compared to that on the uninjected (or vehicle injected) side, except around the injection site, where staining was sharply decreased. These effects were blocked by pretreatment with the glutamate NMDA receptor antagonist MK801 (3 mg/kg). In a CSF control mild NGFI-A-induction occurred. In both treated and non-treated CP, we characterized NGFI-A-positive striatal neurons by double immunostaining. Most if not all of the neurons expressing NGFI-A were DARPP-32-positive. This suggests that striatal neurons expressing constitutive or induced NGFI-A bear D1-like dopamine receptors. Many neurons positive for NGFI-A also expressed immunodetectable enkephalin, which is contained in GABAergic medium spiny striatal neurons projecting to the globus pallidus. Striatal interneurons expressing parvalbumin, putative GABAergic striatal interneurons, were not NGFI-A positive. Supported by The National Parkinson Foundation and NIH Javits RO1 NS25529.

EFFECTS OF CHRONIC CLOZAPINE TREATMENT ON INDUCTION OF FOS-LIKE PROTEINS IN THE STRIATUM. N. Hiroi* and A. M. Graybiel, Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

We have previously reported that acute injections of the atypical antipsychotic drug clozapine (CLZ) induced Fos-like immunoreactivity (FLI) in neurons of the nucleus accumbens and caudoputamen acutely (by 2 hrs) in a dose-dependent manner (Hiroi et al. Soc. Neurosci. Abstr., 1991). We have now compared the effects of acute CLZ treatment with the effects of chronic (8 days) CLZ treatment. Groups of rats received one of the following treatments: chronic CLZ followed by acute CLZ (CC), chronic CLZ followed by acute vehicle(CV), chronic vehicle followed by acute CLZ (VC), and chronic vehicle followed by acute vehicle (VV). Rats received 8 days of injections of CLZ (20 mg/kg, i.p.) or vehicle, and on the 9th day they received acute injections of CLZ (20 mg/kg, i.p.) or vehicle 2 hours before perfusion. Brain sections were immunostained with polyclonal Fos antiserum (Oncogene Science, Inc.) or with a monoclonal Fos antibody (Dr. F. R. Sharp). With the polyclonal Fos immunostaining, the CC and VC groups both showed abundant FLI in the nucleus accumbens and caudoputamen. When assessed with the monoclonal Fos antibody, the VC group showed FLI mostly in the dorsomedial nucleus accumbens, but the CC group showed no FLI in either the nucleus accumbens or the caudoputamen. These results suggest that 1) chronic treatment with CLZ changes the genomic responses of nucleus accumbens neurons to acute doses of CLZ and 2) these changes may reflect regulation of Fos-like antigens recognized by the monoclonal Fos antibody but not other Fos-related antigens recognized by the polyclonal Fos antiserum. (Supported by the Human Frontier Science Program and Javits Award NIH. We thank Dr. F. R. Sharp for a Fos monoclonal antibody and Sandoz Pharmaceutical for a gift of clozapine).

LOCAL INJECTION OF DOPAMINERGIC AND MUSCARINIC AGONISTS MODULATE STRIATAL PEPTIDE GENE EXPRESSION. L.K. Nisenbaum*, S.T. Kitai, and C.R. Gerfen, Dept. of Anatomy and Neurobiology, University of Tennessee, Memphis, Memphis, TN, and Lab of Cell Biology, NIMH, Bethesda, MD.

The antagonistic balance between acetylcholine (ACh) and dopamine (DA) within the striatum has long been recognized to be important in the functional activity of the basal ganglia. In order to investigate how ACh and DA influence the output of striatal projection neurons, we have examined the regulation of neuropeptide gene expression by dopaminergic and muscarinic agonists. Lesions of the nigrostriatal dopaminergic pathway have previously been shown to result in an increase in the expression of enkephalin mRNA in striatopallidal projection neurons, while the level of dynorphin mRNA remains unchanged in striatonigral cells. Systemic application of D-1 and D-2 agonists further modifies the expression of dynorphin and enkephalin mRNA in the striatum of lesioned rats. In order to test whether the action of these drugs are mediated locally within the striatum, SKF-38393, a D-1 agonist, was injected directly into the striatum or lateral ventricle (icv) of 6-OHDA lesioned rats. *In situ* hybridization histochemistry was used to measure the expression of dynorphin and enkephalin mRNA. Injection of 5 μg SKF-38393 directly into the striatum produced a local increase in dynorphin mRNA surrounding the injection site. Likewise, 5-10 μg SKF-38393 administered icv produced a 100% increase in dynorphin mRNA within the dorsal medial striatum adjacent to the ventricle. Next, the effect of a muscarinic agonist on striatal gene expression in 6-OHDA lesioned rats was examined. Injection of pilocarpine (120 μg) icv resulted in a further 25% increase in enkephalin mRNA above the lesion-induced level in striatal neurons within the dorsal medial region adjacent to the ventricle. Together, these data suggest that the effects of both D-1 and muscarinic agonists on peptide expression are mediated locally within the striatum. Further, this raises the possibility that DA and ACh may interact locally to modulate peptide gene expression of striatal projection neurons. *Supported by USPHS grant NS20702 and the Human Frontiers Program.*

437.11

TIME COURSE OF ALTERATIONS IN SUBSTANCE P, DYNORPHIN, ENKEPHALIN AND *c-FOS* GENE EXPRESSION IN STRIATAL NEURONS DURING CHRONIC COCAINE TREATMENT.

H. Steiner* and C. R. Gerfen. Lab. of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892.

Projection neurons of the striatum differ in the expression of neuropeptides: striatonigral neurons mainly express substance P and dynorphin, whereas striatopallidal neurons express enkephalin. Dopamine modulates the levels of these peptides. We examined with *in situ* hybridization histochemistry short-term and long-term changes in gene expression of these peptides, as well as of the immediate-early gene *c-fos*, during chronic treatment with the indirect dopaminergic agonist cocaine (30 mg/kg, i.p., twice daily). Thirty minutes after acute application of cocaine, mRNA levels of substance P and *c-fos* are significantly increased, mostly in dorsal striatal regions. By day 3 of the chronic treatment, the cocaine-induced increase in mRNA levels is significantly reduced (as compared to the levels at the beginning of the treatment), and remains reduced thereafter, in most regions. Conversely, mRNA levels of dynorphin and enkephalin are unchanged 30 min after the acute cocaine application, but are significantly increased on treatment day 2, also predominantly in dorsal regions, and remain elevated in some regions after a longer treatment. These results show that chronic cocaine treatment produces different temporal and regional patterns of alterations in gene expression in striatonigral and striatopallidal neurons.

437.12

MORPHOLOGICAL SEQUELAE OF SUICIDE TRANSPORT LESIONS OF THE SUBSTANTIA NIGRA OR GLOBUS PALLIDUS ON SUBSETS OF NEOSTRIATAL NEURONS.

R.C. Roberts*[1], M.B. Harrison[2], S.M.N. Francis[1], G.F. Wooten[2] and R.G. Wiley[3]. Maryland Psychiatric Research Center[1], Univ. of Maryland, Baltimore, MD 21228, Univ. of Virginia[2], Charlottesville, VA 22908 and DVAMC Vanderbilt Univ.[3], Nashville, TN 37212.

Suicide transport agents produce retrograde degeneration of neurons projecting to an injection site. In the basal ganglia these toxins have been shown to produce selective lesions of the striatopallidal and striatonigral pathways based on receptor binding and neuropeptide mRNA studies. In the present immunohistochemical study, the neostriata of adult rats were examined 10 days after an injection of volkensin into the substantia nigra (SN) (n=5) or an injection of OX-7 saporin into the globus pallidus (GP) (n=5). Adjacent sections were processed for 1) Nissl stain to study the density of all neurons and large interneurons, 2) NADPH-diaphorase (-d) histochemistry, to mark medium-sized interneurons, 3) enkephalin (ENK) immunocytochemistry (ICC), to label striatopallidal neurons, or 4) substance P (SUB P) ICC to label striatonigral neurons. Analyses of Nissl stained sections revealed that the striata ipsilateral to the lesions appeared healthy and did not exhibit shrinkage or gliosis; however, a moderate decrease in cell density was detected by quantitation (12-14% loss). The densities of large neurons and NADPH-d labeled neurons in the ipsilateral striata were unchanged after GP lesions and showed a slight decrease (7-8%) after SN lesions. After GP lesions the density of ENK labeled cells (21% loss) decreased more than that of SUB P labeled cells (16% loss). Conversly, after SN lesions, the density of SUB P labeled cells (26% loss) decreased more than that of ENK labeled cells (20% loss). These data suggest that interneurons are relatively spared and that projection neurons may be differentially affected after GP and SN lesions. Supported by DRIF, U. of MD (RCR) & NS01454 (MBH).

IMMUNOHISTOCHEMICAL LOCALIZATION OF 3-HYDROXYANTHRANILIC ACID OXYGENASE (3HAO) AND KYNURENINE AMINOTRANSFERASE IN ASTROCYTES IN THE RAT SUBSTANTIA NIGRA.

R. Schwarcz*, F. Du, K.E. McCarthy, E. Okuno and R.C. Roberts. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Endogenous excitotoxins, such as quinolinic acid (QUIN), may be involved in the pathogenesis of several brain disorders. Kynurenic acid (KYNA), an endogenous antagonist of excitatory amino acid receptors, has neuroprotective and anticonvulsant properties. The immunocytochemical localization of 3-hydroxyanthranilic acid oxygenase (3HAO) and kynurenine aminotransferase (KAT), the biosynthetic enzymes of QUIN and KYNA, respectively, was examined in the adult rat substantia nigra, pars compacta (SNpc). At the light microscopic level, KAT- and 3HAO-immunoreactivity (-i) were present in glia in a robust and homogeneous pattern in both the nucleus and cytoplasm. At the ultrastructural level, both 3HAO-i and KAT-i were present in astrocytic processes surrounding capillaries. 3HAO-i was abundant throughout the neuropil in fine calibre glial processes which often encircled synaptic profiles, both asymmetric (excitatory) and symmetric (inhibitory). KAT-i was also present in astrocytic processes, but usually of larger calibre than those labeled by 3HAO antibodies. KAT-i glial processes abutted, rather than surrounded, both symmetric and asymmetric synapses. Thus, astrocytic QUIN and KYNA appear to be in a position to modulate excitatory amino acid receptor function in the SNpc. Supported by USPHS grants NS28236 and MH44211 and a HDSA fellowship (to F.D.).

Acute nicotine injections induce c-fos expression mostly in nondopaminergic neurons of the ventral tegmental area (VTA).

Ying Pang, Hideo Kiba, H. Gould* and A. Jayaraman. Dept. of Neurology LSU Sch. of Med., New Orleans, LA 70112.

Induction of c-fos gene is considered to be an immediate and early response in the cascade of molecular events that ultimately lead to long-term alterations in gene expression in neurons. The psychomotor stimulant and positive reinforcing effects of nicotine have been speculated to be mediated by the dopaminergic neurons of VTA. To identify the precise subsets of VTA neurons that mediate the nicotinergic effects, the pattern of expression of c-fos gene was mapped using immunocytochemical methods.

Acute nicotine injections (0.3-1.4 mg/kg;s.c) resulted in a prominent Fos-like immunoreactivity (Fos-Li) in the interpeduncular nucleus, medial terminal nucleus of the accessory optic tract and also prominently in the caudal linear subnucleus of VTA. The neurons of other VTA subnuclei, viz., the rostral linear, paranigralis, nucleus parabrachialis pigmentosus, and nucleus interfascicularis did not contain any cells with Fos-Li. Mecamylamine abolished Fos-Li in neurons of VTA, superficial layers of superior colliculus, periaqueductal gray areas and the interpeduncular nucleus.

These results suggest that acute nicotine injections induce c-fos expression mostly in nondopaminergic neurons of the ventral tegmental area.

Supported by Smokeless Tobacco Research Council.

GABA-ergic interneurons of the striatum express D2 receptor mRNA: a double-labelling study with digoxigenin- and radiolabeled-RNA probes.

Y. Qin, E. Robbins, F.Baldino.* and M-F Chesselet. Cephalon, Inc., and Dept of Pharmacol. U. of Penn., Philadelphia, PA 19104.

We have previously hypothesized that those striatal neurons expressing very high levels of a 67 kD isoform of glutamic acid decarboxylase (GAD67) mRNA are interneurons (Chesselet and Robbins, 1989). To further test this hypothesis, striatal sections were hybridized simulataneously with a digoxigenin-labelled RNA probe for GAD67 and a ^{35}S-RNA probe for parvalbumin, a calcium binding protein present in striatal GABA-ergic interneurons (Cowan et al. '90; Kita et al. '90). The majority of neurons densely labelled for GAD mRNA also expressed parvalbumin mRNA, confirming that they are interneurons. Previous studies have shown that dopamine depletion selectively decreased GAD67 mRNA levels in the densely labelled cells (Soghomonian et al. Brain Res. 1992). Further double-labelling experiments revealed the presence of mRNA for dopamine D2, but not D1 receptors in these neurons, suggesting that the D2 receptor subytpe may be involved in the effects of dopamine on striatal GABA-ergic interneurons. Supported by PHS grant MH-448894. We thank A.J. Tobin (UCLA) and M. Berchtold (Zurich) for the cDNAs.

437.16

STRIATAL SUBREGIONS ARE DIFFERENTIALLY VULNERABLE TO THE NEUROTOXIC EFFECTS OF METHAMPHETAMINE.

A.J. Eisch*, F.B. Weihmuller, S.J. O'Dell, J.F. Marshall. Department of Psychobiology, University of California at Irvine, Irvine, CA 92717-4550.

The processes underlying dopaminergic neurotoxicity produced by chronic administration of methamphetamine [m-AMPH] are incompletely understood. Insights into m-AMPH's cytotoxic mechanisms may be gained by assessing the effect a neurotoxic regimen of m-AMPH has on subpopulations of dopaminergic striatal projections. Using measures of dopamine content and [^{3}H]mazindol-labeled dopamine transport sites (visualized with quantitative autoradiography), we report differential vulnerability of striatal regions of rats given m-AMPH one week earlier (4 injections (s.c.), each 4 mg/kg, 2 hrs apart). Three rostrocaudal levels of the striatum were sampled (anterior, middle and posterior), and several regions were examined at each level (e.g. dorsal, lateral, ventral and medial regions; nucleus accumbens at the anterior level). Treatment with m-AMPH resulted in a significant decrease in [^{3}H]mazindol binding at both the anterior and middle levels, with the ventral and medial subregions exhibiting greater reduction than the dorsal striatum or the nucleus accumbens. Parallel to the heterogeneous reduction of striatal [^{3}H]mazindol binding by m-AMPH, striatal dopamine content depletion at the anterior level was most severe in the ventral region. The results encourage attempts to identify factors within the ventral-medial caudate nucleus that make it more susceptible to m-AMPH's neurotoxic effects as compared to the adjacent nucleus accumbens and the dorsal caudate nucleus.

438.1

PERCEPTION OF DURATIONS OF KINESTHETIC STIMULI IN CEREBELLAR PATIENTS. J.S. Lou, S.E. Grill,M. Hallett*, Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892.

Coordinated movement depends upon precise temporal control of muscle activation. Persons with cerebellar disorders have difficulty with such movements as well as in discrimination of durations of auditory and visual stimuli. We have compared the ability to perceive durations of *kinesthetic* stimuli of seven patients with cerebellar disorders (without clinical evidence for peripheral neuropathy) to that of six normal controls.

Subjects were seated with their right forearm resting on a table midway between pronation and supination, the wrist rigidly fixed, and the index finger placed securely in a finger holder attached to a computer-controlled torque motor. This allowed imposition of controlled changes in joint angle about the metacarpal-phalangeal joint. A trial consisted of presentation of a pair of joint angle steps two seconds apart, of different durations but the same magnitude (about one degree). Each pair of stimuli, consisted of a standard 150 msec or 250 msec duration step and a variable duration step ranging from 50 msec to 250 msec when the standard was 150 ms long, and between 150 and 350 ms when the standard was 250 ms long. Stimuli were presented in random order. Subjects were instructed to report which stimulus was longer, by replying "one" or "two". The session continued until each pairing of stimuli was presented ten times.

There were striking differences in the ability to distinguish the durations of stimuli between normal subjects and cerebellar patients (Chi-square, p<.0001). For example, normal subjects were able to distinguish a 150 ms stimulus from one of 110 msec duration with only a 17% error rate, while cerebellar patients did not perform better than chance (making errors 48% of the time).

Impaired resolution of durations of kinesthetic stimuli by motor centers may contribute to deficits in coordinated movements in persons with cerebellar disorders.

438.2

PERFORMANCE OF RATS ON A PERCEPTUAL TIMING TASK FOLLOWING CEREBELLAR LESIONS. J.V. Baldo and R. Ivry*. University of California, Berkeley, CA 94720.

In previous research, we have found that patients with cerebellar lesions are impaired on motor and perceptual tasks that require precise timing. The present study used an animal model to investigate the role of the cerebellum in perceptual timing. Rats were trained on a two-choice discrimination task in which the duration of a visual stimulus was either 300 or 750ms. Probe stimuli of intermediate durations were also presented without reward. Animals received either sham lesions or bilateral electrolytic lesions targeted at the lateral cerebellar nuclei. Preliminary results indicate: 1)the lesions have minimal effect on overall response rate; 2)the experimental and control animals perform similarly on the endpoint stimuli; and 3)the experimental animals are less consistent in their judgements of probe stimuli (difficult discriminations). The observed deficit is not large and may be transient. Further experiments and analyses with this paradigm should help clairfy the role of the cerebellum in time perception.

438.3

CEREBELLECTOMY DOES NOT ELIMINATE THE BEHAVIORAL SUPERSENSITIVITY OF THE GENETICALLY DYSTONIC RAT TO SEROTONERGIC AGONISTS. V.L. Michela*, J.F. Lorden, and K. Vanwanderham. Dept. Psych., Univ. of Alabama at Birmingham, Birmingham, AL 35294.

In normal rats there is a decline in sensitivity to serotonergic (5-HT) agonists during the second postnatal week. During this period, the genetically dystonic *(dt)* rat, an animal model of inherited movement disorder, exhibits enhanced behavioral sensitivity to both quipazine and 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) (Michela, et al., 1990; Wieland and Lucki, 1991). Since this is also the period during which the motor syndrome of the *dt* rat appears, the enhanced sensitivity may be a secondary consequence of the movement disorder per se. To test this hypothesis, the behavioral effects of 5-HT agonists were examined in intact and cerebellectomized *dt* and normal rats at 16-25 days of age. Earlier studies indicated that the output of the cerebellum is abnormal in *dt* rats, and it has recently been found that cerebellectomy (CBX) eliminates the expression of the motor syndrome. Despite the improvement in locomotor ability observed after CBX in the *dt* rats, 8-OH-DPAT produced a characteristic dose-dependent behavioral syndrome in all groups, and the enhanced sensitivity of the *dt* rats was maintained when compared to normal littermates. Thus, the behavioral sensitivity of the *dt* rats is not secondary to their movement disorder. Since experimentally-induced damage to the olivo-cerebellar system in normal rats also increases sensitivity to 5-HT agonists (Wieland, et al., 1990), the cerebellum may normally exert an inhibitory effect on the 5-HT syndrome that is absent in the *dt* rats. EFFECT OF CEREBELLECTOMY ON THE MOTOR SYNDROME OF THE GENETICALLY DYSTONIC RAT. M.S. LeDoux,* J.F. Lorden and J.M. Ervin. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

The dystonic(*dt*) rat is an autosomal recessive mutant with a motor syndrome that resembles generalized dystonia seen in humans. In the absence of intervention, motor function in the *dt* rat deteriorates, resulting in death by postnatal day 35. Glucose utilization studies and electrophysiological recordings have demonstrated abnormal neuronal activity in the deep cerebellar nuclei of the *dt* rat. To test the hypothesis that abnormal cerebellar output is responsible for the *dt* motor syndrome, total cerebellectomies, including ablation of the cerebellar nuclei, were performed on *dt* and normal rats at 15 and 20 days of age. As a control for non-specific lesion effects, a separate group of 15-day-old *dt* rats received bilateral kainic acid lesions of the entopeduncular nucleus.

Rats underwent behavioral testing just prior to surgery and again three days later. Separate groups of age-matched normal and *dt* rats served as unoperated controls. Behavioral testing included the determination of righting reflex times, locomotor and climbing ability. In addition, the severity of the motor syndrome was evaluated.

The *dt* rat demonstrated an immediate and permanent improvement in motor function and a marked decrease in abnormal motor signs after cerebellectomy. Cerebellectomy allows the *dt* rat to survive into adulthood and mate successfully. Interruption of basal ganglia output failed to improve the condition of the *dt* rats. These findings suggest that cerebellar output is critical to the expression of motor signs in the rat disease. (Supported by BNS 90-10187 and the Dystonia Med. Res. Fdn.)

THE EYE OPENING TIME, AS A FACTOR ACCELERATING MATURATION OF CEREBELLAR PURKINJE CELLS IN THE KITTENS. R.Grigorian* and E.Prigarina.I.M.Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Science , 194223, St.Petersburg, Russia.

In experiments performed on two age groups of anaesthetized kittens:(i)blind kittens (3-5 days after birth) and (ii) one week after eye opening (15-17days),the activity of identified cerebellar Purkinje cells (PC) was studied. In blind kittens the cerebellar PC discharges represented by low frequency complex(CS) and simple spikes (SS), namely 0.37 - 0.04 and 3.05-0.37 imp/s, respectively were recorded.A week after the eye opening (15 -17 days) the frequency of CS and SS in PC discharge was increased approximately on three fold, reaching 0.76 - 0.07 and 8.77 + 1,1 imp/s, respectively, i.e. the velocity of the increase of PC discharge frequency before or after eye opening is expressed as 1:3. In blind kittens the cerebellar PC in response to stimulation of n.ishiadici was ,as rule, silent dispite the superthreshold stimulus was applied, whereas PC of(ii)group kittens responded even on the threshold stimuli by CS discharge followed by inhibitory pause (IP). In this case the duration of IP was longer compared with that seen in background active Purkinje cells.

ALTERATIONS IN THE PHYSIOLOGY OF THE ROSTRAL DORSAL ACCESSORY OLIVE (rDAO) ACROSS HORMONE STATES. Sheryl S. Smith*. Dept. of Anatomy, Inst. of Neurosci., Hahnemann Univ., Phila., PA 19102-1192.

Ongoing studies in this laboratory have characterized the olivo-cerebellar circuitry across hormone (estrous) cycles. Limb response to changes in treadmill speed and negotiation of hurdles is most accurate and timely on estrus following endogenous increases in estradiol and progesterone, relative to diestrus (lower hormone levels). One mechanism by which limb coordination might be improved is via alterations in the error detection mechanism at the level of the rDAO (Gellman et al, 1985), i.e., via selective sensory gating of input to this structure during non-movement (unexpected stimulus) versus movement (expected stimulus). Additionally, synchronization of olivary activity is thought to facilitate rapid alternations in limb movement. Both parameters were tested in female rats chronically implanted with arrays of microwires (50 μ dia.) to record simultaneously from 3-8 individual neurons within the rDAO across the estrous cycle during intermittent treadmill locomotion. In some cases, cutaneous afferents to the rDAO were activated using 2 Hz stimulation of the forepaw. Increased amplitude (by 50%) of olivary response to forepaw stimulation during non-movement was observed on estrus vs. diestrus values. In contrast, estrus was associated with a greater decrease (by 30%) in olivary response during movement relative to diestrus values (n = 12, 3 rats). These results suggest that increased sensitivity of error detection mechanisms at the level of the rDAO accompanies estrous-enhanced limb coordination. In addition, use of cross-correlation analysis revealed synchronized discharge of olivary neurons recorded simultaneously on estrus, but not on diestrus (n = 6 in 2 rats, over 3 consecutive estrous cycles). In sum, estrous hormones may produce significant alterations in the physiology of the olivary network which correlate with improvements in both spatial and temporal aspects of trajectory of the distal limbs. TOPOGRAPHY OF SACCADIC EYE MOVEMENTS IN THE CEREBELLAR VERMIS OF THE RABBIT EVOKED BY MICROSTIMULATION. M. Godschalk*, J. van der Burg and B. van Duin. Dept. of Anatomy, Erasmus University Rotterdam, Rotterdam, The Netherlands.

In the oculomotor vermis in monkeys, consisting of parts of the cerebellar lobules VI and VII, saccades can be evoked with low intensity microstimulation (Noda and Fujikado, J. Neurophysiol, 1987). The direction of saccades is ipsilateral, with an upward component in the more rostral part of the oculomotor vermis, gradually changing to downward when going caudally. In rabbits, eye movements have been evoked with microstimulation in other parts of the cerebellum, but not the vermis.

Rabbits were prepared, under full anesthesia, for recording microstimulation-evoked eye movements. Scleral search coils were implanted under the conjunctiva in both eyes and a recording chamber was placed over the cerebellar vermis. After full recovery, penetrations were made in the vermis, searching for eye movements with a 200ms train of biphasic .2ms pulses at 330Hz and a maximum current of 60μA. When eye movements were observed, the current was lowered to assess the threshold. At the end of the experimental period, localization of the stimulation sites was verified by histological analysis.

In parts of lobules VI and VII, saccadic eye movements were evoked by currents ranging between 4 and 60μA. The movements were horizontal with no apparent vertical component. In a strip of approximately 4mm width on either side of the vermal midline, the cortex could be divided in two equal longitudinal zones. In the medial zone saccades were directed ipsilaterally, in the lateral zone contralaterally. Thus the topography of saccadic eye movements in the cerebellar vermis in of rabbits is unlike that of monkeys.

Neuronal activity in lateral cerebellar cortex (lobulus simplex) of cats, related to visual stimuli at rest and during locomotion. D.E. Marple-Horvat, J.M. Criado and D.M. Armstrong, SPON: Brain Research Association. Department of Physiology, School of Medical Sciences, University Walk, Bristol BS8 1TD

One of the major pathways from visual areas of cerebral cortex to motor cortex travels via the pontine nuclei to the cerebellar cortex. The great size of this projection suggests that it plays an important part in the visual guidance of movement, a conclusion that is supported by the devastating effect of cerebellar lesions on visually guided limb movements. We have therefore used full-field flash stimulation to probe for visual input to cerebellar Purkinje cells in cats stationary on a rest platform. Our recording chamber was placed over a region of cerebellar cortex (lobulus simplex, 5-7mm from midline) from which visual evoked potentials to flash stimulation have been recorded by others in anaesthetised cats. Of 16 cells tested, 12 responded to flash. Onset latencies were short, *circa* 25ms. Ten cells increased their simple spike discharge, peaking 40-50ms after flash. Since these neurones provide a highly convergent projection to the target cells in the deep cerebellar nuclei we have pooled these responses in a combined discharge histogram of all 12 cells, in which the visual event is signalled with exceptional clarity (peak z=15.8). Three of these cells were recorded whilst the cats walked on a horizontal ladder. Two rungs can be made to move up or down (6 cm) at two different times during the cat's approach. The 3 cells all gave early responses to rung movement with discharge peaking around 45-75ms. In one cell the response when the cat was close to the rung (2 steps, 40 cm away) was larger, 9.1 spikes per trial, than the response (6.2 spikes) when the cat was further away (3 steps, 60 cm). The magnitude of both responses exceeded the discharge evoked by flash (1.9 spikes), which was a more intense but behaviourally irrelevant stimulus. This cell appeared to have complex properties in which the behavioural significance of visual inputs is important (cf trained rhesus monkeys, Marple-Horvat and Stein 1990).

OPTICAL IMAGING OF RESPONSES TO ELECTRICAL AND NATURAL FACE STIMULATION IN THE RAT CEREBELLAR CORTEX. G. Chen, S.A. Elias and T.J. Ebner*. Departments of Neurosurgery and Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

Afferent responses to the cerebellar cortex have been characterized as a "fractured mosaic". In this study optical recordings with a voltage sensitive dye were used to evaluate the spatial patterns of activity evoked by afferent input. In anesthetized rats (ketamine/xylazine), the exposed cerebellar cortex was stained with RH795 for 2 hours. Using epifluorescence optics, Crus I and II were imaged with a Photometrics CCD system (14 bit A/D, 516 x 384 pixels). A saline filled chamber was used to control brain movement. Stimulation of the face consisted of either discrete bipolar electrical stimulation or "natural" stimulation by a Ling vibrator controlled probe. The basic experimental paradigm consisted of subtracting "background" images without stimulation from a corresponding "stimulus" image during which the face input was delivered. For both types of inputs optical signals could be obtained, characterized by patches of activity. Although small ($\sim$ 0.1% $\Delta F/F$) the responses were reproducible up to several hours. In several animals a "sagittal" organization to the patches was evident. In some animals the optical signal was distributed more widely across the entire folium. Field potential recordings revealed a close spatial correspondence with the optical signals. Consistent with a granule cell layer origin the optical signals were recorded at depths of 400-500μ. These results show that optical signals in the cerebellar cortex can be obtained with not only electrical but more physiological afferent inputs. (Supported by NIH grants NS-27210 and NS-18338).

ACTIVITY OF DENTATE NEURONS DURING SEQUENTIAL MOVEMENTS. H. Mushiake* and P.L. Strick. Research Service, VAMC and Depts. of Neurosurgery & Physiology, SUNY-HSC, Syracuse, NY 13210.

We recorded neurons in the dentate nucleus of the cerebellum while a monkey performed sequential pointing movements under two task conditions. The monkey faced a panel with 5 touch pads and placed his right hand on a hold key in front of him. In the Remembered Sequence Task (SEQ task), LEDs over 3 touch pads were illuminated in a pseudo-random sequence as an instruction to the monkey. After an instructed delay period, an auditory 'Go' signal told the monkey to release the hold key and press the touch pads according to the instructed sequence. In the Tracking Task (TRAC task), the monkey was required to press 3 touch pads immediately after the LED over each of them was illuminated. The two tasks were performed in blocks of 40 trials. We recorded from over 100 dentate neurons that displayed changes in activity during the reaction time period between the 'Go' signal and the release of the hold key. Approximately 40% of these neurons were classified *task dependent* because they displayed enhanced or exclusive changes in activity during the reaction time period for 1 of the 2 tasks. About 75% of these neurons displayed task dependence for the TRAC task and the remainder displayed task dependence for the SEQ task. In general, task dependent neurons were spatially separate from those that were task independent. Our observations suggest that the organization of the dentate is functionally heterogeneous. INFLUENCE OF ARTERIAL PRESSURE ON PURKINJE CELL ACTIVITY. L. T. Robertson*. Dept. Biological Structure and Function, School of Dentistry, Oreg. Health Sci. Univ., Portland, OR 97201-3097

We have shown that a significant proportion of Purkinje cells in lobule V have complex spikes elicited by stimulation of the vagal and renal afferent nerves. This study tested the hypothesis that the simple and complex spikes of Purkinje cells are modulated by changes in arterial pressure and by input from baroreceptors. We measured changes in spontaneous and peripherally-elicited simple and complex spike activity during pharmacologically-induced decreases in arterial pressure and during electrical stimulation of the buffer nerves in the decerebrate cat preparation (i.e., in absence of a hypothalamic-pituitary response to blood pressure changes). In about a third of the Purkinje cells tested, a nitroprusside-induced decrease in blood pressure resulted in a 75 to 90% reduction in simple spike activity. An arterial pressure decrease of 30 mmHg or more was required for the reduction in simple spike activity to occur. The reduction in activity involved both peripheral elicited and spontaneous simple spikes, but did not involve the complex spikes. The reduced simple activity often persisted for several minutes after the arterial pressure had returned to baseline. The prolonged reduction of simple spike activity may reflect a long-term response by the visceral receptors to the decrease in pressure. An increase in arterial pressure, induced by the administration of phenylephrine, affected the spontaneous activity in only a few cells, some of which had a 25% increase in simple spikes and some had a 40% reduction in simple spike, but did not affect the complex spikes. The relation between decreased blood pressure and reduced simple spike activity supports a cerebellar role in cardiovascular regulation.

IN VIVO INTRACELLULAR RECORDING OF PURKINJE CELL RESPONSES TO UPPER LIP STIMULATION IN CRUS IIA OF THE RAT CEREBELLUM. D. Jaeger* and J.M. Bower. Div. of Biology 216-76, California Institute of Technology, Pasadena, CA 91125

Earlier work in our group has shown that a brief tactile stimulus delivered to the lip of a rat can lead to prolonged increases in firing frequency of Purkinje cells in Crus IIA of the cerebellar cortex (Thompson and Bower, Soc. Neurosci. Abstr. 17, 552.8). Findings from intracellular recordings in the slice indicate that the ionic conductances of individual Purkinje cells are capable of generating prolonged depolarizations and increases of firing frequency in response to brief bursts of granule cell input (Jaeger and Bower, Soc. Neurosci. Abstr. 17, 552.10). In the present study we investigated the relevance of prolonged depolarizations in the generation of responses to sensory stimulation with the aid of intracellular recordings *in vivo*.

When inhibitory input to Purkinje cells was blocked locally with bicuculline, electrical stimulation of the upper lip lead to prolonged depolarizations in all recorded Purkinje cells located in the ipsilateral upper lip patch of crus IIA. Simultaneous extracellular recordings in the granule cell layer in close proximity to the recorded Purkinje cells showed a close correlation between discharge bursts in the granule cell layer and the rising phase of prolonged depolarizations in Purkinje cells. The depolarizations in Purkinje cells far outlasted granule cell bursts, however. These findings indicate that bursts of granule cell activity are sufficient to trigger prolonged depolarizations in Purkinje cells *in vivo* with concomitant increases of spike rate. Prolonged depolarizations may therefore provide an intracellular mechanism for lengthening the response to a brief sensory stimulus. Overlying inhibitory circuits are likely to create a sharpened spatial pattern of excitatory responses.

CONTRIBUTION OF THE OLIVOCEREBELLAR SYSTEM TO THE INITIATION OF THE CONDITIONNED ARM MOVEMENT IN MONKEY. J-P. Pellerin*, M-T. Parent and Y. Lamarre. Centre de Recherche en Sciences Neurologiques, Université de Montréal, Montréal (Qc), Canada, H3C 3J7.

Climbing fiber responses (CFR) were recorded in the lateral hemisphere of the cerebellum of a monkey trained to perform both flexion and extension of the elbow in response to conditionned stimuli randomly presented. Differences in the CFR frequency were found in relation to the initiation of the movement depending on whether the monkey moves in response to the presentation of the external stimuli (triggered movement) or performs a self-initiated movement. With triggered movements CFR increase about 100 ms before the onset of movement. With self-initiated movements, this response is very small or even absent in this period. In another experimental condition, the monkey is rewarded only when movements are initiated during a second cue presented at a fixed delay after the 'go' signal. In this 'time constraint' condition, CFR increase significativelv when the velocity exceed 220 degrees/second and when the corresponding reaction time (RT) is between 250 and 275 ms. These relationships are not shown when the monkey does not have to use a precise timing. The link between CFR, velocity and RT is stronger in time constraint task. We would like to suggest that CF are activated in relation to their own oscillatory rhythm. In a time contraint task, repetitive external stimuli may induce a change in the spontaneous rhythm of the CF and allow synchronization of CFR especially when the cue is delivered in phase with the imposed rhythm. These factors would have much less influence on self-initiated movement. Finally when a precise timing is required by the delivery of a second cue, CF are best activated and related to the kinematic parameters of the movement. These results suggest that olivocerebellar inputs induce synchronized activity in the cerebellum allowing a more efficient control of movement initiation.

RESPONSES OF PURKINJE CELLS TO HINDLIMB JOINT ROTATION IN THE CAT. C. Gray, V. Perciavalle* and R. Poppele Dept of Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

To determine the relationship between the response patterns of cerebellar cortical neurons and their locations in the cerebellum, we recorded from Purkinje cells in the anterior and posterior lobes during small amplitude passive rotations of the hind foot in barbiturate anesthetized cats. The 109 responsive cells were located in lobules I through IX between 1.4 and 4.2 mm lateral from the midline. 87% of the responsive cells were located in anterior lobules II and III and posterior lobules VII and VIII. 67% of the cells in the anterior and 79% of those in the posterior responded to both flexion and extension stimuli, the remainder responded to only one direction of rotation.

Response to a movement depended on a cell's location. Cells in the lateral parts of both lobes (3-4.2 mm) were excited at short latency (13-18 ms) by rotation in either direction. Medial cells generally exhibited longer latencies (25-28 ms) and longer response durations. In the posterior lobe they tended to respond identically to flexion and extension while in the anterior lobe those which were excited by movement in one direction were usually inhibited by the other.

The results suggest the possibility of a functional mapping of movement within the spinocerebellum.

TRANSCRANIAL MAGNETIC STIMULATION OVER THE CEREBELLUM CAN DECREASE THE EXCITABILITY OF CONTRALATERAL MOTOR CORTEX IN MAN. K J Werhahn, B-U Meyer, JC Rothwell*, PD Thompson, BL Day and CD Marsden. MRC Human Movement & Balance Unit, Institute of Neurology, London WC1N 3BG, UK.

Ugawa et al (1991) reported that high voltage electric stimulation over the cerebellum could decrease the excitability of motor cortex at conditioning-test intervals of 5-12ms. The present experiments show that the same results can be obtained with much less discomfort to the subject using focal transcranial magnetic stimulation over the cerebellum.

With ethical committee approval, we recorded EMG responses from surface electrodes over the right hand muscles of five relaxed normal subjects following magnetic stimulation over the left motor cortex. These test stimuli were conditioned in random trials by a second magnetic stimulus given through a figure-of-eight coil (7cm loop diameter) placed over the right cerebellum and oriented so that the maximum current induced in the head flowed in the lateral to medial direction. With this arrangement, cortically-evoked test responses could be suppressed at conditioning-test intervals of 8-15ms. The effect was reduced if the conditioning coil was moved 2cm away from its optimal position, or if the direction of the stimulating current was reversed. We suggest that the cerebellar stimulus was producing suppression of motor cortical rather than spinal cord mechanisms since test responses evoked in active muscle by a small anodal electric stimulus over the motor cortex were not affected by a cerebellar conditioning shock. We conclude that both high voltage electric and transcranial magnetic conditioning stimuli may be capable of activating the cerebellum in man. The onset of the effect on cortical excitability is about 3ms longer with magnetic than with electrical conditioning stimuli. This may be due to activation of different neuronal elements in the cerebellum by the two forms of stimulation.

VESTIBULAR SYSTEM: BEHAVIORAL RESPONSES

439.1

NEURAL NETWORK MODEL FOR INTEGRATION IN THE VESTIBULO-OCULAR REFLEX. C.Y. Lee and J.H. Anderson*. Otolaryngology Dept., Univ. of Minn., Mpls., MN 55455.

A number of models for velocity storage and integration of eye velocity signals have been proposed which use positive feedback to integrate signals related to head velocity or retinal slip. Some of their limitations include a sensitivity to small changes in network or single unit parameters and a restricted number of units or a lack of variability related to the physiology of the vestibulo-ocular reflex (VOR). The aim of the present work was to study the properties of a bilateral network which included several different types of units representing brainstem neurons and could simulate the dynamic characteristics of the VOR over a large frequency range. For the initial work on the horizontal VOR twenty six units were used: sixteen representing the vestibular nuclei, eight representing brainstem and cerebellar structures, and two representing the horizontal ocular motoneurons. There were four inputs (representing two types of vestibular afferents) from the two horizontal semicircular canals. Each unit had a sigmoid input-output function and some constraints were put on the projection of the output from a given unit and on the sign of the connections between units. Since the intent was not to simulate physiological learning mechanisms, the method of Williams and Zipser and a non-linear optimization algorithm were used to train the network by adjusting the weights of the connections and the parameters of the sigmoid functions. After fewer than one thousand iterations whereby the weights were adjusted, the network learned to approximate the desired motoneuron output due to a sudden change in head position over 2 sec with an rms error of less than 1%. The dynamic range was extended by increasing the training time and adjusting the sigmoid function for individual units. The network was robust to perturbations in the connection weights and removal of a unit and predicted the response to other head movements. (Supported by NIH (DC00110) and Minn. Supercomputer Institute.)

VERTICAL AXIS PITCH VESTIBULOOCULAR REFLEX DURING LOW AND HIGH VELOCITY SINUSOIDAL ROTATION. S.A. Rude*, S.C. Brettler, J.F. Baker. Northwestern U, Chicago, IL 60611

Vertical vestibulo-ocular reflex (VOR) in cats tested in the 90° rolled position (vertical axis pitch) is less accurately compensatory than in the upright position (horizontal axis pitch). This inaccuracy could be related to a predominance of upward direction slow phase eye movements during low frequency rotations. Last year we reported a steady upward drift of the eyes in darkness in the absence of any rotation when the cat was in the 90° rolled position. Representing the drift as a velocity offset term allowed satisfactory sinusoidal fits to eye velocity during 2°/sec 0.01 Hz sinusoidal pitch rotation about the vertical axis. We are now testing vertical axis pitch VOR in darkness using electromagnetic search coils during 2-64°/s peak velocity oscillations at 0.01 Hz.

Sinusoidal functions with a positive offset term did not provide satisfactory fits to eye velocity during 0.01 Hz rotations above ~8°/sec. While higher head velocities resulted in greater downward slow phase velocities, the increase was not as great as would be predicted by the sum of drift and sinusoidal terms. Average peak upward slow phase eye velocity at 64°/sec head velocity was 43±14°/sec and average peak downward eye velocity was 9±6°/sec. Waveforms of slow phase eye velocities in response to high head velocities were markedly asymmetrical. Upward eye velocities rose steadily to the peak, while downward eye velocities appeared to saturate at a value near zero. These results suggest that in the 90° rolled position, upward but not downward slow phase vertical VOR is improved by a velocity storage mechanism as proposed by Matsuo and Cohen (Exp Brain Res 53:197, 1984). Supported by EY06485, EY07342, DC01559.

439.3

OPTOKINETIC-VESTIBULAR INTERACTION IN PATIENTS WITH INCREASED VESTIBULO-OCULAR REFLEX (VOR) GAIN. R.W. Baloh* and J. Demer Reed Neurological Research Center, UCLA Sch of Med, Los Angeles, CA 90024-1769

We studied optokinetic nystagmus (OKN) and visual-vestibular interaction in 5 patients with markedly elevated VOR gain (approximately 2 x normal over the frequency range of 0.01 - 1.6 Hz). Their lesions were localized to the cerebellum on clinical examination and on magnetic resonance imaging (MRI). All had impaired smooth pursuit and decreased initial slow phase velocity (SPV) of OKN. OKN SPV gradually built up over 25-35 sec reaching normal values for low stimulus velocities (≤ 30 deg/sec). The initial SPV of optokinetic after-nystagmus (OKAN) was increased but the rate of decay of OKAN was normal. Fixation-suppression of the VOR was equally impaired whether the patients fixated on a surrounding optokinetic drum, or a light-emitting diode (LED) in the dark, or imagined an LED in the dark. These findings can be explained by a model that includes a velocity storage element and a variable gain element shared by the vestibular and optokinetic systems. Cerebellar lesions do not affect velocity storage but change the output of the variable gain element.

439.4

VESTIBULAR HABITUATION AND HUMAN REHABILITATION. H. Cohen*, C. Hatfield, M. Kane, L. Miller. Dept. of Otorhinolaryngology, Baylor College of Medicine, Houston, TX 77030, Program in Occupational Therapy, Medical College of Ohio, Toledo, OH 43699, Detroit Receiving Hospital, Detroit, MI 48201

Repeated vestibular stimulation causes habituation of velocity storage in normal primates. Unilateral lesions reduce velocity storage but do not abolish it. Patients with unilateral peripheral vestibular lesions have vestibuloocular reflex phase leads when tested with sinusoids, suggesting that compensation may involve habituation of velocity storage.

We tested patients with unilateral peripheral vestibular lesions before and after receiving 12 biweekly therapy sessions involving repetitive vestibular stimuli. Subjects who had decreased vertigo and disequilibrium also had increased phase leads at low frequencies but not high frequencies. Therefore clinical compensation may involve low frequency habituation.

CHORNOBYL VERTIGO: THE COMPARISON OF THE ACUTE AND CHRONIC FORMS. K.F.Trinus* BCA Foundation. Lukianivsky Str.27,Apt.47, Kiev UKRAINA 252071

197 Chornobyl clean-uppers were studied in 1986 during the works in the accident zone and 53 persons from the stuff of the Chornobyl station were studied in 1991. We used anamnesis, and traditional clinical tests: Uemura's, Fucuda's - stepping and wrighting, - indicating and tracking tests. In both groups the complaints were dominating over objective signs, provided by the test described. The most prominent features for both groups were complaints for vertigo attacks, which troubled several times per month, lasted minutes and hours, were provoked or strongly augmented by head movements and accompanied with nausea and vomiting. In chronic patients the headaches, tinnitus, phobias, cardiac pains and losses of consciousness were also added. If in the group of 1986 mostly the minor signs were recorded in the 1991 group there were medially expressed signs of the vestibular dysfunction. The most significant for both groups were the data of the Uemura's test. The data obtained with Fucuda's were well expressed in the 1986 group and almost insignificant in the 1991 group. The tacking and indicating tests data appeared to become significant in persons with distinctly expressed function changes. The comparison of the Chornobyl vertigo with the drop attacks, Meniere's disease, vestibular neuronitis, supratentorial lesion, - shown that it had some prominent features, which were not common to the pathologies compared.

PERCEIVED PASSIVE BODY VELOCITY AND ACTIVE MOTOR HAND VELOCITY INTERACT WITH TEMPORAL FREQUENCY

M. Aisen,[1,2] E. Katz,[1] C. Oman,[3] M. Gizzi[4]
[1]Neurol. & Neurosci., Cornell University Med. College, New York, NY, [2]Burke Rehab. Ctr, White Plains NY, [3]Aero. & Astro. , MIT, Cambridge, MA, [4]Neurol., Mt. Sinai School of Med., New York, NY.

The motion profile is a plot of object location as a function of time. For an object moving back and forth at constant speed the motion profile has a triangular waveform, with slope and amplitude that represent object velocity and path length respectively. Increments in the period of this waveform, motion profile temporal frequency (MPTF), result in increases in perceived tactile (Katz et al., 1990) and visual (Katz et al. 1991) velocity, even when actual velocity is held constant. Here we studied MPTF in the vestibular and motor systems.

VESTIBULAR: Four velocities and four angular path lengths served to define 14 rotational stimuli. Subjects discriminated the faster of two stimuli in a 2AFC paradigm. While on average they discriminated velocity correctly, 68% of the times if stimuli were of identical paths (slower stimulus had lower MPTF), when stimuli-pair had identical velocities, the shorter (higher MPTF) was judged faster ($p<.05$).

MOTOR: Subjects were asked to move their right hand back and forth on an horizontal surface for a trial lasting about 30 sec. in darkness. At the beginning of each trial the subjects were instructed to move their hand faster than in the preceding trial. The data indicate that increases in velocity in successive trials was accompanied by reduction in path length and thus increasing MPTF.

These findings indicate MPTF interaction with perceived velocity in the vestibular and motor systems.

439.7

PHYSIOLOGICAL RESPONSES TO MOTION SICKNESS DURING SUDDEN-STOP VISUOVESTIBULAR STIMULATION. B. D. Lawson*, P. DiZio, N. S. Blaustein, J. Ventura, and J. R. Lackner. Ashton Graybiel Spatial Orientation Laboratory, Brandeis Univ., Waltham, MA. 02254. We studied how motion sickness (MS), anxiety (ANX), experience with the stimulus (EXP) and physical fitness (FIT) relate to heart rate (HR), blood pressure (BP), respiration rate (RESP) and electrogastrogram (EGG) during nauseogenic stimulation. Subjects (n=14) rotated at 270 deg/sec for 30 sec, then stopped suddenly and opened their eyes. During a 30 sec rest, they reported on MS and ANX. This procedure was repeated for 10 min while physiological responses were monitored. 10 min baseline and recovery periods were included. ANOVA's were performed on 4 time periods: baseline, early and late stimulation, and recovery. MS increased during stimulation (Friedman $X^2 \geq 22.5$, $p<.001$). HR and BP rose ($F \geq 8.0$, $p<.0001$), RESP fell ($F=3.9$, $p=.02$) and EGG did not change. Physiological measures did not distinguish high, medium and low MS groups. Subjects were ranked by MS, ANX, EXP, FIT and peak physiological response. MS correlated with RESP (.57). ANX correlated with HR (.50), BP (.60 dias.) and RESP (.54). EXP correlated with HR (-.47) and RESP (-.64), as did FIT with BP (-.68 sys and -.59 dias). (All 1-tailed $p \leq .05$.) Thus, the physiological responses elicited were not strongly related to MS severity, nor to MS per se, since ANX, EXP, and FIT also correlated to physiological response.

OBJECTIVE ASSESSMENT OF VESTIBULAR DYSFUNCTION B Segal*, G Fuoco, R Sweet[1] & A Zeitouni. Dept Otolaryngol, Jewish Gen. Hosp, [1]Montreal Gen Hosp & McGill U, Montreal, Canada H3T1E2

When assessing vestibular dysfunction, clinicians often rely more on subjective information (e.g., patient history) than on objective data (e.g., caloric test). As a result, vestibular dysfunction is usually characterized by gross descriptive classifications. We compared these broad classifications with objective measures of passive vestibular gaze stabilization, and of torso self-movement.

10 dizzy patients were examined in the clinic, and their overall vestibular dysfunction was classified (5-level rating: none, slight, moderate, etc). Then, passive gaze stabilization was characterized as the seated subject was turned, during brief darkness periods, while looking at a wall target. Next, active head-torso movement was evaluated while the standing subject made maximal-velocity, but "comfortable", ≈60° turns. 11 normals served as controls.

We found that only ≈60% of patients exhibited more gaze error, and slower torso movements, than normals. However, when gaze error was plotted against torso velocity, all abnormally-rated patients separated from the normals. Also, as a patient's rating became more abnormal, tendencies for gaze error to increase, and torso movements to slow, progressively widened this separation. Thus test results were closely related to the clinical ratings, perhaps because both vestibulo-ocular and -postural capabilities were assessed, the latter probably reflecting compensation to existing pathology. THE EFFECTS OF SPACEFLIGHT ON EYE-HEAD COORDINATION DURING LOCOMOTION. J. J. Bloomberg[1], W. P. Huebner*[2], M. F. Reschke[1], B. T. Peters[2]. [1]Space Biomedical Research Institute, NASA Johnson Space Center, Houston, TX, 77058 and [2]KRUG Life Sciences, Houston, TX. 77058

Exposure to the microgravity conditions of spaceflight are believed to induce adaptive sensory-motor modification that enable appropriate body movement in this unique environment. However, such adaptive changes in sensory-motor function may be inappropriate after return to a terrestrial 1-G environment leading to gait instability and oscillopsia during locomotion.

The aim of the present study is to characterize the effects of microgravity exposure on eye-head coordination during postflight terrestrial locomotion. Astronaut subjects walked (6.4 km/h) on a motorized treadmill while visually fixating on a centrally placed earth-fixed target positioned 30 cm from the head. Tests were conducted 10 days prior to launch and 2-4 hours after landing. A video-based motion analyzing system was used to measure head and body movement while standard DC-electrooculographic methods were used to record eye movements.

Preliminary results indicate that head stability during locomotion decreases immediately following spaceflight. In addition, during locomotion, the phase relationship between vertical head translations and the corresponding compensatory vertical eye movements is altered after prolonged exposure to microgravity. These results suggest that exposure to microgravity indeed causes adaptive modification of motor programs responsible for coordinated eye and head movement during locomotion.

439.10

VESTIBULAR COMPENSATION IN UNILATERAL AND BILATERAL LABYRINTHECTOMIZED RATS. J.D. Porter, S. Vrochopoulos and M.E. Meyer*. Dept. of Psychology, Univ. of Fla., Gainesville, FL 32611.

Unilateral loss of a labyrinth results in abnormalities involving the vestibulo-ocular and vestibulo-motor reflexes as well as postural asymmetry. Over time these symptoms diminish in a process known as vestibular compensation. It is known that neither the vestibular receptors nor Scarpa's ganglion regenerate following labyrinthectomy therefore, the mechanism behind this functional recovery is unknown. The reflexive abnormalities following bilateral labyrinthectomy are not well classified. This experiment focused on various locomotor and behavioral deficits observed at various time periods following unilateral and bilateral labyrinthectomy. On postoperative day 2,7,14,28,56,112 and 196, the animals were placed into a circular enclosure which allowed for unrestricted movement and videotaped for a period of 15 minutes. Their behaviors were scored from the tapes and placed into several categories: rearing, circling & pivoting, and horizontal activity. Both unilateral and bilateral rats displayed an initial inability to rear, circling & pivoting behavior and hyperactivity. However, there were differences in the magnitude and rate of vestibular compensation in the unilateral and bilateral labyrinthectomized rats. The unilateral rats recovered the ability to rear by day 56, circling & pivoting behavior was no longer present by day 28. The unilateral group remained hyperactive in relation to controls until day 112. The bilateral rats did not recover the ability to rear and remained hyperactive over the 196 days. Circling & pivoting behaviors in the bilateral group subsided by day 28.

MORPHOLOGY OF DEVELOPING HYPOGLOSSAL MOTONEURONS STUDIED IN SLICE PREPARATIONS OF THE RAT BRAINSTEM. F.He*, P.A.Núñez-Abades and W.E.Cameron. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, PA 15260.

Between week 1 and 2 of postnatal life, there is a dramatic decrease in mean input resistance (R_{in}) of hypoglossal (presumptive genioglossal) motoneurons. One explanation for this decrease in R_{in} could be a doubling of total membrane surface area (A_n). We have quantitated the three-dimensional morphology of 35 genioglossal motoneurons at four different ages that have been labeled by intracellular injection of neurobiotin in rat brainstem slices.

Age (days)	A_n (um^2)	Area of Influence (um^2)	# terminals
1-2	15,707±3,086	126,705± 42,217	25± 7
5-6	14,529±2,023	176,537± 70,839	21± 5
13-15	14,468±2,361	147,647± 50,065	14± 4
19-30	26,669±4,374	302,982±112,623	24± 6

There was no increase in A_n between 5-6 and 13-15 days; therefore, we must propose another mechanisms to explain the decrease in R_{in}. However, the dendritic tree was not static during this period; there was a decrease in the mean number of terminals and the surface encompassing those terminals. This reduction resulted from a loss of 7th and 8th order branches while there was an increase in mean segment length at the 2nd and 3rd order branches.

POSTNATAL CHANGES IN SPECIFIC MEMBRANE RESISTANCE OF RAT BRAINSTEM MOTONEURONS. P.A.Núñez-Abades*, J.M.Spielmann and W.E.Cameron. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, PA 15260.

The mean input resistance (R_{in}) of developing hypoglossal motoneurons undergoes a dramatic decrease between the first and second weeks of postnatal life. This alteration in membrane property could result from the growth of the cell membrane and/or a decrease in the specific membrane resistance (R_m). We have shown in these motoneurons that mean total area of membrane surface area (A_n) remains constant throughout this time period (see He et al). Thus, we set out to estimate the changes in R_m in these developing neurons. Intracellular recordings were made in hypoglossal (presumptive genioglossal) motoneurons from *in vitro* slices of the rat brainstem at various postnatal ages. R_{in} and membrane time constants were measured before the cells were labeled by intracellular injection of neurobiotin. R_m was estimated for each cell (n=21) using an equation derived by Rall (1975). No difference was found between the mean R_m measured at 1-2 days (7116 Ωcm^2) and 5-6 days (7489 Ωcm^2) while there was a 47% decrease in the mean between 5-6 and 13-15 days (3968 Ωcm^2). After the decrease at 2 weeks, the mean R_m rose to 6192 Ωcm^2 at 19-30 days as mean A_n expanded by 78% yielding only a modest decrease in R_{in}. We propose that the transient decrease in R_m results from i) an increase in number of leak channels in the postsynaptic cell and/or ii) an increase in the number of presynaptic inputs onto these neurons. These results suggest that there is a critical period during postnatal development when hypoglossal motoneurons are less excitable.

DYE-, TRACER- AND ELECTRICAL COUPLING IN DEVELOPING HYPOGLOSSAL MOTONEURONS OF THE RAT. W.E.Cameron*, E.Mazza, P.A.Núñez-Abades and J.M.Spielmann. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, PA 15260.

Coupling among developing mammalian motoneurons was studied using *in vitro* brainstem slices from rats ages 1-30 days postnatal. The motoneurons were labeled by intramuscular injection of dextran-rhodamine into the posterior tongue at least one day prior to the experiment. Intracellular recording and/or labeling were obtained from a total of 194 hypoglossal motoneurons in three different age groups. In animals less than 9 days old, 6 of 41 cells (16.2%) injected with Lucifer Yellow showed evidence of *dye-coupling* while 18 of 51 cells (35%) injected with neurobiotin showed evidence of *tracer-coupling*. There was no difference in frequency of dye-coupling between animals at 1-2 days vs. 3-8 days while the frequency of tracer-coupling decreased from 40% (12/30) at 1-2 days to 29% (6/21) at 3-8 days. On average, dye-coupling occurred between two motoneurons whereas tracer-coupling was found among three motoneurons. In animals older than 10 days, there was no evidence of dye-coupling and only one instance of tracer-coupling in 52 motoneurons examined. Evidence of a short latency depolarization (SLD), indicative of *electrical coupling*, was found in 43% (3/7) at 1-2 days and in 42% (14/33) at 3-8 days. There were no SLDs found in animals older than 10 days. We conclude that among developing hypoglossal motoneurons, i) coupling is only transiently expressed and, ii) tracer-coupling provides a better estimate of the frequency of electrical coupling than does dye-coupling.

CHANGES IN MEMBRANE PROPERTIES OF DEVELOPING RAT PHRENIC MOTONEURONS STUDIED *IN VITRO*. J.M.Spielmann*, F.He and W.E.Cameron. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, PA.

Previous *in vivo* studies (J Neurophysiol 65:671,1991) on developing phrenic motoneurons of the cat suggests a dramatic change in membrane during postnatal development. We developed an *in vitro* slice preparation of the rat cervical spinal cord to investigate in greater depth the time course and nature of these changes. Phrenic motoneurons of neonatal rats were retrogradely labeled following an injection of dextran-rhodamine into multiple sites in the sternocostal diaphragm. Horizontal slices (300 μm thick) were prepared from animals in one of four postnatal age groups: 1-3, 6-9, 14-15 and 19-28 days. Intracellular recording and labeling with neurobiotin were made in the phrenic motor nucleus as delineated by rhodamine fluorescence. Mean input resistance (R_{in}) of these neurons was significantly lower at 6-9 days (30.2 MΩ) than at 1-3 days (45.6 MΩ) or 19-28 days (43.4 MΩ) and not different than the mean at 14-15 days (39.4 MΩ). The decrease in R_{in} was not due to an increase in total membrane surface area. Mean surface area of these neurons actually decreased from 20,019 μm^2 (1-3 days) to 15,887 μm^2 (6-9 days) before expanding to 33,772 μm^2 (19-28 days). Estimates of specific membrane resistance (R_m) revealed a transient decline from 10,302 Ωcm^2 (1-3 days) to 2,873 Ωcm^2 (6-9 days); this value increased again in the older groups. In addition, we found a significant increase in the slope of the current-frequency plot from 22 Hz/nA (1-3 and 6-9 days) to 61 Hz/nA at 14-15 days that was followed by a subsequent decrease 24 Hz/nA in the oldest group. Similar to hypoglossal motoneurons (see Núñez-Abades et al), there is a transient decrease in R_m in developing phrenic motoneurons of the rat.

FAST MOTOR UNITS IN RAT GASTROCNEMIUS SHOWING EXTREMES IN FATIGUE RESISTANCE DO NOT DIFFER IN MOTONEURONE PROPERTIES: PAIRED OBSERVATIONS FROM SINGLE EXPERIMENTS. P. Gardiner.* Physical Activity Sciences, University of Montréal, Montréal, Québec, Canada H3C 3J7.

Differences in motoneurone (MN) membrane properties among motor unit types might be masked when grouped data from several experiments are analyzed. We consequently examined gastrocnemius motor units, paired from single experiments, that differed in type according to fatigue resistance and speed. Tibial MN of anesthetized Sprague-Dawley rats were impaled during in situ experiments using conventional microelectrode techniques, and gastrocnemius motor units were identified from their contractile response to MN current injection. Type slow (S) units had twitch half-relaxation times (Rt1/2) > 28 ms, were completely fatigue resistant, and demonstrated no force sag at 25 Hz stimulation. In fast fatigue-resistant (FR) and fast fatigue-sensitive (FF) motor unit pairs, twitch Rt1/2 were longer, twitches were weaker, and axon conduction velocities were faster, for FR. No differences in MN afterhyperpolarization (AHP) time-course or amplitude, in rheobase, or input resistance, were found between FF and FR. S units had lowest rheobase, highest input resistance, highest AHP amplitude and longest AHP 1/2 decay time, but not always the lowest axon conduction velocity, when compared to F units from the same experiments. Results show that MN properties, while showing distinct differences between fast and slow motor units, do not vary systematically among fast motor units which differ in fatigue resistance, in rat gastrocnemius.

MUSCLE-SPECIFIC DISTRIBUTION OF SNB MOTONEURONS IN THE MONGOLIAN GERBIL. L. Abelson* and C. Ulibarri. School of Veterinary Medicine, University of California, Davis, CA 95616 & Dept of Veterinary & Comparative Anatomy, Physiology, and Pharmacology, College of Veterinary Medicine, Washington State University, Pullman, WA 99164-6520.

In the Mongolian gerbil the spinal nucleus of the bulbocavernosus (SNB) is a pool of about 200 androgen-sensitive motoneurons located above the central canal in lamina X. The gerbil SNB innervates three perineal muscles; the bulbocavernosus (BC), levator ani (LA), and anal sphincter (AS). We determined *1)* the percentage of motoneurons that innervates each muscle and *2)* the muscle-specific distribution of motoneurons within the SNB motor column.

Male gerbils (n=10) were castrated and implanted with Silastic capsules containing testosterone propionate (10 mm). One week later the BC, LA, and AS were injected with 10-20 μl of 4% dextran (Molecular Probes, Inc) conjugated to Rhodamine, FITC, or Cascade blue. Each muscle was injected with only one type of dextran. After ten days, gerbils were anesthetized and aldehyde perfused. The spinal cords and perineal muscles were removed, sectioned at 50 μm and then examined with fluorescence microscopy for visualization of labelled-dextran in both transverse (n=6) and longitudinal (n=4) sections. Only spinal cords from gerbils with injections discretely localized in each muscle were analyzed.

The majority of SNB motoneurons innervate the BC (around 75%). About 16% innervate the LA, and approximately 10% innervate the AS. No doubly-labelled motoneurons were identified. BC-projecting motoneurons were found equally distributed throughout the SNB motor column, whereas LA- and AS-projecting motoneurons were primarily found in the more lumbar portion of the SNB pool. These findings indicate that there is a reversed somatotopic representation within the SNB motor column. Supported by BNS-9112097 to CU.

MORPHOLOGY OF EXTERNAL URETHRAL SPHINCTER MOTONEURONS AND LOCALIZATION OF PUTATIVE SPHINCTER INTERNEURONS IN THE RAT SPINAL CORD. W.F. Collins, III*, D. Alspaugh, W. Hu, and J.T. Erichsen. Department of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794.

Spinal bladder/sphincter reflexes are: important for urinary continence, inhibited by supraspinal centers during micturition, and involved in spinal cord injury induced bladder/sphincter dyssynergia. However, little is known about the anatomical organization of these spinal reflexes.

In the present study, the dendritic morphology of external urethral sphincter (EUS) motoneurons and the distribution of putative EUS interneurons were examined using the retrograde tracer, cholera toxin B subunit (CTB), and the retrograde transneuronal tracer, wheat germ agglutinin (WGA), respectively. Adult male and female Sprague-Dawley rats were anesthetized, and either CTB (1%) or WGA (1%) was injected (0.5-3.0μl) into the EUS muscle. After a survival time of 2-5 days, spinal cords were removed and processed immunohistochemically to visualize labeled motoneurons and putative interneurons.

CTB-labeled EUS motoneuron somata were located in the ipsilateral dorsolateral (DL) nucleus. Three major dendritic projections of these EUS motoneurons were observed: (1) rostrocaudally oriented dendrites projecting throughout the DL nucleus, (2) dorsolaterally oriented dendrites projecting into the lateral funiculus, and (3) medially oriented dendrites projecting toward the dorsomedial nucleus. WGA-labeled putative interneurons were localized to the ipsilateral L5 and L6 ventral horn dorsomedial to the DL nucleus.

THE ONTOGENESIS OF CORTICOBULBAR PROJECTIONS AND THE VIRTUAL ABSENCE OF CORTICOSPINAL CONNECTIONS IN THE OPOSSUM, *MONODELPHIS DOMESTICA*. T. Cabana*, C. Desrosiers and A. Nadeau. Sciences biologiques, Université de Montréal, C.P. 6128, Succ. "A", Montréal, QC, Canada, H3C 3J7.

In the *Didelphis* opossum, the corticospinal tract develops postnatally (Cabana & Martin, J. Comp. Neurol., 251:1986), and, as in other mammals, decussates at the medullary-spinal junction. We wished to use that model to study properties of the extracellular matrix at the decussation, but had to turn to the more amenable *Monodelphis* opossum. We had to repeat tracing the tract in order to determine the timetable of its growth and decussation. We herein report on those projections traced anterogradely with WGA-HRP. The sequence of corticobulbar innervation matches that reported for *Didelphis*, except for a few days of precedence in *Monodelphis*. A major difference between the two species is the virtual absence of spinal projections in *Monodelphis*. After crossing at the pyramidal decussation, few cortical axons grow into the white matter of the cord, and even less into the gray matter. *Monodelphis* demonstrates at least as good motor ability as *Didelphis*, whose corticospinal neurons are estimated to be 4 times more numerous, or as the rat, in whom they are 8 times more numerous (Nudo & Masterton, J. Comp. Neurol., 296:1990). *Monodelphis* has indeed the least developed corticospinal tract of all mammals studied. The quasi-absence of corticospinal connections in *Monodelphis* is not a total surprise, in the view of the absence of tactile placing in that species (Cassidy *et al.*, Soc. Neurosci. Abst. 146.1, 1990), and it raises questions about the function of the pyramidal tract in mammals. Supported by NSERC.

440.9

AGED-LIKE ELECTRICAL PROPERTIES INDUCED BY ACRYLAMIDE IN TRIGEMINAL MOTONEURONS OF THE AWAKE CAT. C. Weiss,* S.S. Chirwa, J.K. Engelhardt, F.R. Morales, and M.H. Chase. Dept. of Physiology, Dept. of Anatomy and Cell Biology, and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA. 90024

The effects of age on the electrical properties of motoneurons (MNs) include decreased conduction velocity (CV), increased input resistance (Rin), and an increase in the membrane time constant (Tm) (J. Neurophysiol. 58:180, 1987; 61:194, 1989). The mechanisms underlying the above age-related changes are not known. We sought to model some of these changes using acrylamide, a neurotoxin, in brainstem MNs of the awake adult cat (methods in J. Neurophysiol. 44: 349, 1980). Jaw closer MNs were impaled with glass micropipettes (3M KCl, 5-10 MΩ) and their electrical properties were determined. Masseter MNs were also antidromically activated to evaluate their CV. Following the collection of these control data, administration of acrylamide began (10mg/Kg/day, i.p.). After one week, data collection resumed and continued for approximately one month while the cats continued to receive the drug. Only cells with action potentials (AP) ≥55 mV were analyzed (12 control cells, 25 acrylamide cells). Comparisons between control and treated cells were made with one tailed t-tests (α=0.05). Significant changes occurred in the onset latency of the antidromically activated AP (13.6% increase) and in Rin (40% increase). The Tm increased by 33% (p=.055). There were no significant changes in the amplitude of the AP or the duration of the afterhyperpolarization. While it is not known if acrylamide affects the same mechanisms as the aging process, this drug may provide a method for assessing contributing factors to the electrophysiological changes that are observed in aged MNs. Supported by AG04307 & NS09999.

SYMPATHETIC PREGANGLIONIC NEURONS IN NEONATAL RAT BRAINSTEM-SPINAL CORD *IN VITRO*. C.T. Schulteis*, A. Lev-Tov & J.L. Feldman. Systems Neurobiology Lab., Dept. of Physiological Science, UCLA, Los Angeles, CA, 90024-1527.

Sympathetic preganglionic neurons (SPNs) were characterized using extracellular and sharp-electrode intracellular recordings from *in vitro* brainstem-spinal cord and hemisected spinal cord preparations of neonatal rats. Extracellular recordings from the T1-T5 segments of 3-5 day old rats, revealed spontaneous activity of single units in the intermediolateral cell column (IML). The firing frequency of units varied between 0.5-4 Hz at 27°C. Dye injection showed that the recordings were confined within the intermediolateral and intercalated nuclei. Sharp-electrode intracellular recordings from the T1-T6 segments of hemisected spinal cord preparations isolated from 8-14 days old rats, revealed high impedance (30-50 MΩ) low rheobase (0.02-0.04 nA) neurons located in the IML region. Neurons could be activated antidromically and orthodromically by stimulation of the ventral and dorsal roots respectively. Antidromic activation produced long duration, high amplitude action potentials, followed by delayed depolarization. Orthodromic activation evoked long latency polysynaptic potentials. Based on these criteria, these IML neurons were classified as SPNs. All the presumed SPNs exhibited spontaneous activity at variable frequencies, which could be modulated by shifting membrane polarization. One SPN exhibited clear pacemaker-like activity characterized by short (1-5 spikes at 0.5-10 Hz) repetitive bursts with 5-7s interburst intervals. Our findings suggest that intrinsic properties of SPNs may contribute to generation of the sympathetic tone and its modulation under different physiological conditions. Supported by NIH Grant NS 28805. CTS is supported by an NSF graduate fellowship.

HEAD AND TRUNK DYNAMICS OF YOUNG AND ELDERLY ADULTS DURING GAIT. R.L. Cromwell*, and E.A. Keshner. Dept. of Kinesiology, Univ. of IL at Urbana-Champaign, Dept. of Physical Therapy, Univ. of IL at Chicago. *Supported by grant DC01125.*

Changes in gait with age have produced a more cautious and stable pattern (Winter et al., Phys Ther, 1990). Mechanisms underlying these changes may be found in intersegmental relations. This study recorded the angular velocities of the head and trunk, and step cadence in four young adults (YA) and one elderly (ELD) subject during self-paced normal, slow, and fast walking. Neck velocity was calculated as the difference between head and trunk velocities. For the purpose of analysis, cadences were categorized as 95-120 steps/min for normal, <95 steps/min as slow and >120 steps/min as fast. (Normal cadences for the ELD subject fell within the slow range.) Predominant frequencies of both the head and trunk velocity responses ranged from 1.2-2.3 Hz over all conditions for YA. Head frequencies ranged from 0.08-0.4 Hz, whereas trunk frequencies remained in 1.2-2.0 Hz range for all conditions. Thus the 1:1 head to trunk frequency ratio found in YA was not maintained in the ELD subject. A time domain analysis of velocity revealed that the slow and normal ELD gait was similar to the YA slow gait in that the head, neck, and trunk velocity responses were in phase. A compensatory response was seen in the head, neck, and trunk of the YA normal and fast conditions; trunk flexion occurred with head and neck extension. In the ELD subject however, the fast cadence resulted in an uncoupling of the head, neck, and trunk where peak velocities of each segment occurred independently of the other segments. These data suggest that the ELD subject focused her control on keeping the head stable in order to better utilize vision. The coordinated phasing and the unity ratio of head to trunk in the YA implies that the upper body is controlled as a coordinative structure. Uncoupling of these segments in the ELD subject show a decrease in the ability to control these segments as a unit.

SHIFTING DYNAMICS OF THE HEAD AND NECK. B.W. Peterson*, E.A. Keshner, and R. Cromwell. Dept. of Physiology, Northwestern Univ. Med. School and Dept. of Physical Therapy, Univ. of IL at Chicago, Chicago, IL 60611. *Supported by grants NS22490 and DC01125.*

Rotations about the vertical and horizontal axes have revealed well delineated operating frequencies for mechanisms that control stability of the head (Keshner et al., Soc. Neurosci. Abstr., 1988, 1991). Here we explored how to independently manipulate these mechanisms through differing instructions and weights added to the head. Head velocity and neck EMG responses were recorded in 7 seated subjects receiving pitch rotations in the dark about a horizontal, bitemporal axis with a random sum-of-sines stimulus having 5 frequencies ranging from 0.35 to 3.05 Hz. Subjects were instructed to: 1) voluntarily stabilize the head with and 2) without vision, 3) perform mental arithmetic (MA) to minimize voluntary intervention, 4) simply relax the head, and 5) hold the neck stiff. The first 3 conditions were done with and without a 4.55 kg weight on the head. Voluntary stabilization of the head, seen below 1 Hz, was strong in the first two conditions with and without weights to the head, and was suppressed when the neck was held stiff. Greatly increased neck muscle EMG gains when stiffening suggested that subjects were locking the head to the trunk rather than compensating for the trunk rotations. Reflex stabilization of the head was strong throughout, with the stiffening, relax, and MA conditions exhibiting improved stability at frequencies above 1 Hz. Rising gains and large phase shifts at frequencies above 3 Hz indicated the beginning of head resonance (the mechanical contribution to stability) in the relax and MA conditions. With voluntary stabilization, particularly when the head was weighted, stabilizing gains decreased and phases became more variable above 2 Hz. More consistent compensatory responses were seen in the stiffening condition at the highest frequencies, but increasing neck muscle activation in other conditions implied that neural components continued to exert a compensatory effect.

441.3

THE CONTRIBUTION OF MOTOR UNIT RECRUITMENT TO SURFACE EMG DIRECTION DEPENDENCE. L.E. Miller *, M. Theeuwen, C. Doorenbosch, C.C.A.M. Gielen. Dept. Med. Physics, Univ. of Nijmegen, 6525 EZ Nijmegen, The Netherlands.

We have studied the direction dependence of mean rectified surface EMG and motor unit recruitment while isometric forces were applied at the wrist. Previous studies have shown that recruitment thresholds of motor units for forces in various directions can be fitted by a single straight line or by several line segments (van Zuylen et al., J. Neurophysiol. 60, 1988). In a number of muscles, several sub-populations of motor units have been found, each with different motor unit recruitment characteristics (ter Haar Romeny et al., Exp. Neurol. vol. 85, 1984). Similarly, surface EMG for forces in various directions may be fit by a circle for many muscles (Miller et al. Exp. Brain Res. Series, 22, 1992) , while for some muscles, more complex interpolating functions were required (Flanders and Soechting, J. Neurophysiol., 1990). The aim of our study was to examine the relation between motor-unit activity and surface EMG.

Recruitment contributes primarily to EMG amplitude, while rate modulation affects its spectrum. The effect on the direction dependence of EMG, of these parameters and the inhomogeneous distribution of motor units, has not been tested directly. We have simultaneously measured surface EMG and intra-muscular motor unit activity from several arm muscles while human subjects exerted isometric force in many directions within a horizontal plane. In most cases, the EMG directional dependence could be fit with a circle, and that of motor unit recruitment by a straight line. The orientation of the EMG response was generally consistent with that of the motor units. The few cases of disparity between EMG and motor unit orientation may be explained by sub-populations of motor units within a given muscle, each having a different orientation.

441.4

KINESTHETIC COORDINATION OF MOVEMENT SEQUENCES: COMPARISON OF ACTIVE *VS.* PASSIVE MOVEMENTS. L. Bevan* and P. Cordo. R. S. Dow Neurological Sciences Institute, Good Samaritan Hospital & Medical Center, Portland, OR 97209.

In previous studies of passive elbow rotations, we have shown that the nervous system uses kinesthetic input to coordinate sequential joint rotations during movement sequences. To test the hypothesis that voluntary movement sequences are similarly coordinated, we have compared the errors in target attainment using a movement sequence that begins with either a passive, or an active joint rotation.

Subjects were asked to perform a movement sequence similar to "frisbee" throwing–they opened their right hand when they perceived that their elbow had rotated through a prescribed target angle. In half the trials we passively rotated the elbow at variable velocities. In the remaining half of the trials, subjects actively rotated their elbow at velocities within the range used in the passive trials. The arm and the target location were screened from the subject's view, and information about the target and the elbow rotation was presented on a graphics screen. To also test the effect of visual information on target attainment, subjects were given three types of visual feedback in separate blocks of trials: 1) continuous visual representation of the relative location of their arm with respect to the target, and knowledge of results, 2) knowledge of results only, or 3) no information.

The results suggest that the similarity between kinesthetic coordination of passive *vs.* active movement sequences is dependent on the visual information available. When visual information about the ongoing movement is not available, passive and active movement sequences are kinesthetically coordinated in a similar way.

SINGLE-TRIAL ESTIMATION OF THE MECHANICAL PROPERTIES OF THE ELBOW JOINT DURING A MOTION TRACKING TASK. Y. Xu, J.M. Hollerbach* and I.W. Hunter. Department of Biomedical Engineering, McGill University, Montreal, Quebec, Canada H3A 2B4.

To determine the time-varying dynamic stiffness parameters (inertia, viscosity, stiffness) of the elbow joint during movement, an ensemble averaging method must ordinarily be used (Bennett et al., Exp.Brain Res., 1992)). Because of the many trials needed in ensemble methods and the difficulties in aligning the movements, more recently we have been investigating how well time-varying dynamic stiffness parameters may be inferred from a single movement trial. To this end, we have proposed a tracking method based on exponentially weightedleast squares (Xu et al., Proc. 13th EMBS Conf., 1991,pp. 2020-2021). The dynamic stiffness parameters must vary slowly for the tracking method to work properly, and movements must necessarily be slow. We have found that subjects have some difficulty in making smooth slow motions, when the only constraint or aid is an endpoint target, and the lack of smoothness could be adversely affecting the estimations. In the present studies, we seek to improve trajectory smoothness by a mechanical aid: an artificial elbow joint and forearm which subjects are to track. In the experiments, the artificial forearm is placed next to and parallel to the subject's arm, and the subject is instructed to track a point on the artificial forearm at the wrist level. The target movement spans 60 degrees in the vertical plane, beginning from a vertical forearm position and then extending. The movement is very slow, 12 deg/s. There are five phases in each trial, three posturephases divided by two movement phases. Pseudorandom binary force perturbations are applied to the wrist by an airjet system (Xu et al.,IEEE Trans. Biomedical Eng., 38, 1991, pp.~1111-1122), and we record force, wrist position and target position. Our results indicate that the stiffness parameter is lower during movement phases than that in posture phases. The inertial and damping parameters do not have linear trends. This research is supported by the Medical Research Council of Canada.

Neck Muscle Motor Evoked Potentials (MEPs) Elicited by Transcranial Magnetic Motor Cortex Stimulation

G.J. Grubwieser, D.S. Stokic, A.A. Leis, M.R. Dimitrijevic*
Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston Tx 77030

MEPs following transcranial magnetic motor cortex stimulation through a 9 cm coil centered over the Cz (10-20 EEG placement system) were recorded from the sternocleidomastoid (SCM), the splenius capitis (SC), the upper trapezius (UT) and deltoid muscles of four healthy adult male volunteers. Surface electrodes were used to record MEPs during relaxation, voluntary head rotation and antero- to lateral flexion.

MEPs in the neck muscles occurred with latencies of 10.5 $\pm$ 0.94 ms in the SCM, 10.2 $\pm$ 1.05 ms in the SC, 11.6 $\pm$ 0.98 in the UT and 13.1 $\pm$ 0.63 ms in the deltoid. There are at least two different, responses recordable from the SCM in which a later response is seen with a latency of around 60 ms. The amplitude of the early response in the SCM was increased during volitional lateral flexion to the to the side ipsilateral to the recorded muscle. Also, all muscles showed increased early MEPs during voluntary contraction. Our findings show that short latency MEPs can be recorded in neck muscles. They also suggest that motor control for movement can modify MEP amplitudes in neck muscles.

EFFECTS OF RADIAL NERVE STIMULATION AND ANAESTHESIA ON INDEX FINGER MOVEMENT CONTROL. W.G. Darling*, K.J. Cole, S. Ellison, C. Steyers. Dept. of Exercise Science, University of Iowa, Iowa City, IA 52242.

The role of cutaneous and joint afferents in index finger movement control has received little study, although reports from patients undergoing surgery indicate that finger kinaesthesia is strongly affected by hand anaesthesia (Moberg 1983, Brain 106:1). We have studied the EMGs and kinematics of isolated 3-joint index finger movements during non-noxious radial nerve stimulation and anaesthesia of the index finger to determine whether control of its motion is affected by altered cutaneous and joint afferent sensations.

EMGs were recorded using indwelling hooked wire electrodes inserted into 4-6 muscles of the index finger in 10 subjects. Movements were recorded optoelectronically with infrared emitting diodes placed over the base of the 2nd metacarpal and the centers of the 3 joints. Subjects performed 4 different types of discrete motions (with vision permitted) that involved flexion or extension of all 3 joints and flexion or extension at the interphalangeal (IP) joints while the metacarpophalangeal (MP) joint was voluntary held in a flexed position. Kinematic data showed no consistent changes in movements as a result of radial nerve stimulation (train of 6 pulses at 30 Hz beginning near movement onset), however anaesthesia of the index caused decrements in movement velocities and amplitudes. EMG analysis indicated increased cocontraction of antagonists during anaesthesia and some effects on muscle activity as a result of radial nerve stimulation. Thus, these data suggest that cutaneous and joint afferent information play a relatively small role in index finger movement control in comparison to central programs and, possibly, muscle proprioceptive sensations at least when vision is allowed.

VISUAL PROPRIOCEPTION IN AGING: EFFECTS OF INAPPROPRIATE CUES ON POSTURE. H. Sveistrup* and M.H. Woollacott, Exercise and Movement Science, University of Oregon, Eugene OR 97403

The ability to regulate posture is a function of the detection and integration of inputs from the somatosensory, visual, and vestibular systems, and activation of appropriate muscle responses to correct body sway. The challenge of maintaining balance increases when information from two or more systems is in conflict, eg. when standing in a train while the adjacent train begins to move. Visual field motion is perceived as self motion and conflicts with the somatosensory and vestibular information indicating stability. The ability to reweight the input strength from the visual system to the somatosensory/vestibular systems is required. It is possible that a loss of this ability is observed in some older adults.

We recorded the response of normal young adults (YA: aged 20-29) and normal older adults (OA: aged 65+) to visual perturbations. Subjects stood inside a "moveable room" consisting of a front wall, two side walls and a ceiling which moved TOWARD or AWAY (60 cm) from the subject. Sway was recorded via video through a one-way mirror. Surface electromyograms (EMG) were recorded from the gastrocnemius (G), tibialis anterior (TA), hamstrings (H), quadriceps (Q), trunk extensors (TE) and abdominals (A). Following an AWAY movement of the room, the perceived sway would indicate a backward fall and the corresponding EMG correction would be to activate the TA, Q, and A muscles to pull the body back to vertical.

Minimal sway was recorded in both groups. However, in the AWAY condition, the OA subjects activated the TA, Q, and A muscles more frequently than the YA. A similar increase in frequency of activation of the postural muscles has also been observed in children (aged 5 months to 6 years). The increased frequency of response may reflect a loss of sensory integration ability with aging.

VECTORIAL COMBINATION OF CONTROL MODULES IN THE FROG'S SPINAL CORD. FA Mussa-Ivaldi, SF Giszter and E Bizzi*. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

In recent experiments on the spinalized frog (Bizzi, Mussa-Ivaldi and Giszter, Science, 253, 1991)we have found that the focal microstimulation of a site in the premotor layers in the lumbar grey matter results in a field of forces acting on the frog's ankle and converging to a single equilibrium position. These experiments suggested that the interneuronal circuits in the spinal cord are organised into a set of control modules that "store" a few limb postures in the form of convergent force fields acting on the limb's end-point. The goal of this investigation is to understand how such postural modules can be combined by the CNS for generating and representing a wider repertoire of motor behaviors including but not limited to a large number of postures. In a theoretical study we have found that the vector summation of the convergent force fields generated by a set of control modules is a powerful mechanism for generating and combining a variety of control patterns. The most crucial issue regarding this computational framework is whether or not the fields generated by each spinal module are actually combined by the CNS according to a principle as simple as vectorial summation. To address this issue we have considered the force fields evoked by the microstimulation of two distinct sites in the spinal cord. First, we considered the fields elicited by the stimulation of each site, separately. Then, we compared the vector sum of these two fields with the field obtained by stimulating the two sites simultaneously Our current evidence indicates that the simultaneous activation of two interneuronal sites generates a field of forces that corresponds to the vector sum of the fields generated by the stimulation of each site. However, we also found that the simultaneous stimulation of two sites within the afferent fibers may result in a field that differs significantly from the vector summation of the fields obtained at each site. For example, we have observed "winner-take-all" responses to double stimulation of afferent systems. These results suggest the vector superposition of the motor output is a specific feature implemented by the interneuronal circuits in the frog's spinal cord.

A COMMON MOVEMENT PROFILE IS PRESERVED BY EMG CHANGES UNDER DIFFERENT GRAVITATIONAL LOADS. N. Virji-Babul, S.H. Brown* and J.D. Cooke. Dept. of Physical Therapy, University of Western Ontario, London, Ontario, Canada N6G 1H1

In many single joint movements in the horizontal plane a triphasic pattern of muscle activation is observed. Little is known, however, about the pattern of muscle activation producing movements in the vertical plane. We examined the kinematics and muscle activation patterns during movements made in the vertical plane. Subjects made elbow flexion (against gravity) and extension (with gravity) movements of different amplitudes (5-40 deg) during a visual step-tracking task.

Movement durations and peak velocities increased with movement amplitude. In addition, all movements, regardless of gravitational loads (i.e. flexion and extension) had time symmetric velocity profiles. However, changes were observed in the muscle activation patterns. Movements with gravity were initiated by an agonist burst followed by overlapping antagonist and second agonist bursts. In movements against gravity the initial agonist and antagonist bursts occurred simultaneously.

These findings suggest that the EMG pattern is modified in order to preserve a common temporal structure for movements made under different gravitational loads.

SENSING THE PHYSICAL DYNAMICS IN RHYTHMIC MOVEMENTS. N. G. Hatsopoulos, W. H. Warren, Jr., and J. N. Sanes*. Dept. of Cog. & Ling. Sciences and Center for Neural Science, Brown Univ., Providence, RI 02912.

We present evidence for the view that the motor system takes advantage of the physical dynamics of the limb system during rhythmic movements. In particular, we tested the hypothesis that subjects choose a preferred rate of forearm swinging which corresponds to the resonant frequency of the physical system.

Human subjects were asked to oscillate their forearms in the vertical plane at their preferred frequencies under conditions of added mass and external spring loading. They were also asked to oscillate at frequencies above and below the preferred frequencies by synchronizing their movements to a metronome. These trials were performed in order to generate a phase transfer function under each loading condition which relates the phase between the displacement of the forearm and the torque generated by the biceps and triceps as a function of frequency. This phase transfer function was used to estimate the resonant frequency and to compute the stiffness of the joint (Viviani et al., J. Phys., Paris, 72, 45-58, 1976).

The results demonstrate that the preferred frequency corresponds to the resonant frequency of the muscle-limb system under each condition, a strategy that minimizes energy expenditure. This agrees with other studies which suggest but do not directly show that the preferred rate of oscillation corresponds to the natural frequency of the pendular limb and elastic joint (Kugler & Turvey, 1987; Holt et al., Hum. Mov. Sci., 9, 1990). We also show that the internal joint stiffness remains relatively constant across added mass conditions but is modulated so as to match the impedance of the external springs, a strategy that maximizes the elastic energy stored in the joint (Goldfield et al., subm. for pub., 1992; Hogan, IEEE TAC, 29, 681-90, 1984). These findings imply that the central nervous system can sense and tune the physical dynamics of the body and environment in order to optimize its performance. The results also provide insights as to how the central nervous system may solve the degrees of freedom problem.

CONVERGENCE OF EXCITATORY INPUTS FROM THE CENTRAL GRAY MATTER VOCAL CENTER AND INFERIOR COLLICULUS TO A SINGLE RETICULAR NEURON IN THE RAT Y. YAJIMA*, and Y. HAYASHI Dept. of Physiology Hyogo College of Med., Nishinomiya, Hyogo 663, Japan

Two distinct phases of vocal communication behavior in animals, sound production and sound hearing, are assumed to be integrated in the brain. Present study was conducted to know an interface mechanism for sound communication in rat brain stem. Under Ether anesthesia a bipolar electrode was implanted stereotaxically into the ipsilateral central gray matter(PAG) vocal center using audible vocal sound yielded by pulse train stimulation as a guide. Under alpha-chloralose urethane anesthesia the other electrode was placed in the contralateral inferior colliculus(IC) on the basis of auditory field potentials evoked by acoustic stimuli presented at an either ear. A grass micropippet filled with Fast green dye was introduced into the midline dorsal medulla to search for neurons activated by electrical stimulation of PAG and /or IC. Sixty-four reticular neurons sampled so far responded exclusively to PAG and 37 to IC stimulation(Non-convergent cells). Seventeen reticular neurons, on the other hand, were activated by electrical stimulation of both PAG and IC (Convergent cells). In many convergent cells, responses to PAG stimulation were augmented remarkably when PAG stimulation was preceded approximately by 5 msec to IC electrical stimulation or by 20 msec to noise burst stimulation, indicating the presence of modulatory convergence onto a single reticular cell. Histological verification revealed that most of convergent and non-convergent neurons were found in the ventromedial part of medulla.

HUMAN FORCE CONTROL: MODELLING AND DATA. J.R. Flanagan* and A.M. Wing. MRC Applied Psychology Unit, Cambridge, UK. CB2 2EF.

Models of force control should be able to account for the both the mean form and the variability of force trajectories. Whereas a number of studies have focused on the former, little attention has been given to the pattern of variation of the force-time function. In this study, we examine the mean and variability of force trajectories produced by squeezing a force transducer between the thumb and index finger. The amplitude, duration, initial force level, and direction (loading, unloading) of the force were varied. Step changes in force and force pulses were recorded.

These data are used to test and extend the Parallel Force Unit Model of Ulrich and Wing (1991, Psych. Rev., 98, 268-294). In PFUM, force buildup and decline reflects the summation of a large number of force units with variable onset times. The number and duration of the force units are controlled. This model accounts reasonably well for the mean form and variability of brief force pulses. In this report, we assess the ability of PFUM to account for force trajectories under a range of conditions. The model is elaborated to include antagonist "muscles" and additional motor unit-like properties.

A model based on the equilibrium point hypothesis of motor control (Feldman, 1986, J. Mot. Behav., 18, 17-54) is also presented. According to this hypothesis, central commands regulate force by specifying the equilibrium position of the limb and the level of co-contraction of opposing muscles. Simulations are used to assess the form of central commands underlying force generation. In addition, we examine how variation in these commands are related to variability in observed force trajectories. The equilibrium point model proposes a uniform account of unrestrained and isometric movements.

Finally, these two models of force control are not mutually exclusive and we consider how they may be related.

MODULATION OF SOLEUS H-REFLEX DURING HEAD-BODY TILTS IN MAN. N. Paquet* and C.W.Y. Hui-Chan. School of Physical and Occupational Therapy, McGill University, Montreal, Canada H3G 1Y5.

In a previous study, we found that the soleus H-reflex amplitude increased in a sinusoidal manner with ***static*** changes in forward or backward head-body tilts, in 11 of 13 subjects (Chan and Kearney, *Neurosc. Lett.* 33:333-338, 1982). The purpose of the present investigation was to determine whether soleus H-reflex was modulated in a similar or opposite manner during ***dynamic*** forward head-body tilts.

Eleven young normal subjects stood blindfolded, and were fixed on a tilting apparatus with neck collar and appropriate straps. Sudden forward head-body tilts of 20° were applied through an axis co-linear with the ankle joints. The mean peak acceleration was constant at about 0.7 g, as measured with a linear accelerometer mounted on a dental bite. Ten H-reflexes were elicited at five intervals ranging between 30 and 250 ms after the onset of head acceleration. Only the trials in which (1) the M response was within ±10% of the control amplitude, and (2) the soleus EMG activity was at a constant low level prior to tilt onset, were kept for analysis.

The main finding is that in the majority (8 of 11) of subjects, the soleus H-reflex was inhibited ($p<0.05$) by a mean of 24% (range = 5 to 53% of control H) at 150-250 ms after tilt-onset. In the remaining subjects, the tilt had no effect on the H-reflex amplitude in 2 subjects, and was facilitated by 30% at 110-200 ms after tilt-onset in one subject. These results appeared to reflect real changes, because two subjects tested on different occasions showed a similar (inhibitory) response pattern.

Our results indicate that the effect of dynamic head-body tilts on soleus H-reflex is opposite to that of static tilts, at least in a majority of subjects. Among other possible causes, the opposite modulation may reflect a difference in the stimulus given to the vestibular apparatus under the two tilting conditions, i.e. a transient acceleration during the dynamic tilt, and a change in the orientation of the gravity vector during the static tilt.

This project was supported by McGill University and an MRC studentship for N.Paquet.

MODIFICATIONS IN THE SPEED-INSENSITIVE STRATEGY FOR MOVEMENTS REQUIRING LOW LEVELS OF FORCE. D. M. Corcos*, G. L. Gottlieb, C. -H. Chen. University of Illinois at Chicago, Chicago, IL, 60608 and Rush Medical Center, Chicago, IL 60612.

The dual strategy hypothesis of motor control suggests that human elbow movements performed over different distances and against different inertial loads are controlled by excitation pulses to agonist motoneuron pools that are modulated in width (Gottlieb, Corcos and Agarwal, 1989). The antagonist muscle is delayed for longer movements and movements against larger loads. In addition, there is less myoelectric activity for longer movements than for shorter movements. The work of Hoffman and Strick (1990) suggests that wrist movements performed over short distances are controlled by a combination of height and width modulation and that the antagonist is not delayed for longer movements. To investigate this discrepancy, seven subjects performed movements over seven different distances that encompassed the range of movement distances employed in both sets of previous experiments. Position, acceleration and EMGs from flexor and extensor muscles were measured. In addition, velocity and impulse were calculated. The findings revealed that the myoelectric, kinematic and kinetic variables for the shorter movements at the elbow joint do not rise at the same rate as longer movements and that the antagonist is scaled with distance for the shorter movements but not for the longer movements. The relationship between antagonist EMG and impulse can be improved for the longer movements by including a term corresponding to a viscous force in the calculation of impulse.

These findings and the work of Hoffman and Strick (1990) suggest that short movements, which require brief pulses of force, are generated by pulses of excitation that have reached a minimum width. The only way to perform these movements is by using lower levels of intensity than are used for longer movements. As such, the dual strategy hypothesis has been reformulated so that when movements of short distance and/or with very light loads are generated, intensity is reduced when distance or load reaches very low levels.

441.16

THE INFERIOR OLIVARY NEURON AS AN ERROR DETECTOR IN THE MOVEMENT DISORDER INDUCED BY INTRACEREBROVENTRICULAR INJECTION OF PROPIDIUM IODIDE IN THE RAT. S. Chen and Z.-C. Peng (SPON: EBBS). Institute of Anatomy, University of Verona, Italy.

Intracerebroventricular (ICV) injection of propidium iodide (PI) in the rat results in a movement disorder characterized by nystagmus, ataxia and shaking (Borges et al., Science 228, 346, 1985; Chen and Su, Brain Res 483, 379, 1989) and induces *c*-Fos expression in discrete brain areas, including the inferior olivary complex and cerebellar nuclei (Chen and Bentivoglio, Soc Neurosci Abstr 17, 864, 1991). In the present study, in order to investigate whether the *c*-Fos expression is induced directly by ICV injection of PI or indirectly by the subsequent movement disorder, we studied the *c*-Fos expression induced by ICV injection of PI under urethane anesthesia, in which the animals do not show any movement disorder. PI (10 µl, 0.1% in saline) was injected under urethane anesthesia (1.2 g/kg, i.p.) into the lateral ventricle through a previously implanted cannula. The animals were sacrificed 3 hrs after the PI injection. *C*-Fos immunoreactivity was distributed in the cerebellar nuclei as in the cases in which PI was injected without anesthesia. However, in contrast to the latter cases, in the inferior olivary complex only a few neurons in the medial nucleus were *c*-Fos immunoreactive. In the control cases injected with saline no *c*-Fos immunoreactitvity was observed in the cerebellar nuclei or in the inferior olivary complex. The present data, together with our previous findings, suggest that after the ICV injection of PI the activation of inferior olivary neurons results from the subsequent movement disorder, whereas the cerebellar nuclei are directly activated by PI administration. This supports the hypothesis that the inferior olivary neuron functions as an error detector or 'teacher' in motor control.

PROPRIOCEPTIVE AND VESTIBULAR INPUTS TO NEURONS OF THE CENTRAL CERVICAL NUCLEUS IN THE RAT
B. Ragnarson, L.B. Popova, G.N. Orlovsky and G. Grant* Department of Anatomy, Karolinska Institutet, Box 60 400, S-104 01 Stockholm, Sweden.

Activity of neurons in the central cervical nucleus (CCN) of the rat was recorded extracellularly in decerebrate, immobilized animals. Neurons were identified by their antidromic response to electrical stimulation of the contralateral superior cerebellar peduncule.

Stimulation of the ipsilateral dorsal neck muscles (m. biventer cervicis [MBC] and m. splenius [MS]) by a single electric pulse evoked a short-latency (1.0–3.0 ms) response in the majority of CCN neurons. The response was usually followed by a period of inhibition of the resting discharge of CCN neurons lasting for about 30 ms. Stimulation of the contralateral MBC and MS usually produced only inhibition of the resting discharge (lasting up to 30 ms), though in a few cells a short-latency excitation was also observed. Mechanically induced stretching of these muscles resulted in an up to 100% increase in tonic activity, comprising a static component during prolonged stretching and usually also a dynamic component with greater increase of discharge in the beginning of the stretch and inhibition at the end.

Stimulation of vestibular receptors by roll tilt of the animal (±20°) resulted in modulation of the discharge of CCN neurons. When sinusoidal movements (0.5–1Hz) were applied, neurons exhibited a maximal activity either at the maximal contralateral deflection (contralateral ear down, in relation to a neuron) or during transition from the ipsilateral (ipsilateral ear down) to the contralateral position. Usually, neurons also showed a static response, i.e. their tonic activity at continuously maintained contralateral tilt was 30–40% higher than at ipsilateral tilt.

It can thus be concluded that the CCN of the rat is a center of integration of afferent signals of two different modalities (proprioceptive and vestibular), as it was found earlier in experiments in the cat (Hirai et al. 1979). We have also found that the CCN responds not only to dynamic but also to static vestibular stimuli. Neurons of the CCN transmit to the cerebellum information about various aspects of head movement, as well as about maintained orientation of the head in space and in relation to the body.

Compliant Motion During Surface Following by the Human Arm
J. McIntyre* and J. Droulez. Laboratoire de Physiologie Neurosensorielle du CNRS 15 rue de l'Ecole de Médecine, 75006 Paris, France

Our goal is to understand what strategies are used by the CNS to control forces during movement when in contact with a surface. We have adapted the classic robotics task of "peg in hole" to study this form of movement experimentally. Subjects grasped a joystick with two degrees of freedom and used movements of the arm and wrist to control the movement of a "peg" on a video screen. Motors attached to the joystick were used to simulate the forces of contact between the peg and a flat, rigid surface. The subject was required to slide the peg along the surface withan applied normal force until the peg fell into the hole.

We considered two hypotheses about the control algorithm used to accomplish this task. In the first, called *passive compliance*, the CNS commands the position of the limb, specifying a nominal trajectory for the endpoint based on *a priori* knowledge of the surface. To generate a force, a *virtual* trajectory that passes inside the suface is commanded. This, coupled with a compliant endpoint impedance, results in a movement along the surface with an applied normal force. In contrast we considered an *active compliance* model, in which the normal force is measured continuously during the movement, and compared with a reference, to generate a movement step which maintains the desired value.

For an unexpected change in suface orientation, the virtual position control model predicts ans increesease in force for upward tilt, while the active force control model predicts a constant force output. Subjects executed the task using a contact force of 5 to 10 Newtons. In all subjects tested so far (n=4) the normal force averaged over the entire sliding movement increased for upward tilts of the surface, and decreased for downward tilts, as compared to nominal horizontal movements. The force does not, however, continue to increase throughout the trial. These results suggest that for short time scales the system acts as a passive compliance, but that over longer time intervals force information may be used to modify the virtual trajectory.

Acknowlegements: The joystick was developed by Y. Matsakis, MEDES. This work was support by the Human Frontiers Science Program, the CNES and Matra.

ASSOCIATION BETWEEN RHYTHMICAL AND DISCRETE COMPONENTS OF MOVEMENTS. S.V. Adamovich, M.F. Levin, D.J.Ostry* and A.G. Feldman. Inst. for Problems of Information Transmission, Acad. of Sci., Moscow 101447, Russia; McGill Univ., Centre de Recherche, Inst. de réadaptation de Montréal, Inst. de génie biomédical, Univ. de Montréal, Montreal, Canada H3S 2J4.

Single-joint discrete movements are likely produced by monotonic shifts in the equilibrium point (EP) of the system. On the other hand, oscillatory shifts of EP may underlie rhythmical movements. We tested the hypothesis that the two types of control signals can be superimposed to produce both movements simultaneously (Feldman 1980). Subjects performed fast rhythmical elbow flexion and extension movements about a target position indicated by a light on a horizontal surface. When the target position was shifted by 60°, the subjects made a fast movement to the new target while continuing the oscillation. In other experiments, subjects made isolated discrete movements from one target position to the other. Arm position was recorded on a Watsmart system, and velocity and acceleration were calculated. EMG signals were recorded from two elbow flexors and two elbow extensors. The onset of discrete movement was associated with a deflection in the EMG signal and used as a synchronisation point for averaging of kinematic and EMG data. After averaging, the rhythmical component of the movement was eliminated and the residual discrete component was comparable to the isolated discrete movement made to the same target position. Fast discrete movements arose at any phase of the rhythmical movement, although some phases were preferred. Discrete movements performed in combination with rhythmical ones displayed multi-phasic EMG patterns and kinematics similar to those associated with isolated discrete movements. The data is consistent with the hypothesis of superposition of control signals underlying discrete and rhythmical movements when they are performed simultaneously. However, the discrete component obtained by averaging displays a greater number of terminal oscillations and EMG bursts indicating that there is an interdependency of the two motor components at the executive biomechanical level. (Supported by NSERC Canada).

THROWING IN THREE DIMENSIONS. J. Hore*, S. Watts and D. Tweed. Dept. of Physiology, Univ. of Western Ontario, London, Canada, N6A 5C1

What are the rules by which skilled multijoint movements in 3 dimensions are controlled? Which factors determine speed and which determine accuracy? As a start to answering these questions we studied the kinematics of overarm throwing. Simultaneous 3-D rotations of the hand, forearm, upper arm and clavicle were recorded at 500 Hz using search coils as 6 subjects sat with fixed trunk and threw balls.

Results: 1. When throwing at targets in different directions, the orientation of the hand at the moment of ball release remained relatively constant with respect to gravity, i.e. the hand was oriented approximately as if mounted on a Fick gimbal, as was the case for pointing movements. 2. Accuracy did not depend on hand orientation at the moment of release nor on the timing of release relative to any kinematic parameter. The reason, revealed by photography and hand translation reconstructed from search coil signals, was that the hand path in space to the point of release was approximately straight, and so the variation in the timing and location of the release point along the straight path made little difference to the direction of the ball's flight. 3. Tight linear relations, which held for all throwing speeds, were found between the angular positions in space of adjacent limb segments, i.e. the straight hand path, which could geometrically have been produced by many different patterns of joint motion, was always generated the same way, and faster throws were achieved by running the same joint motions faster.

PERCEPTION OF VISCOSITY: SENSORY THRESHOLDS. L.A. Jones*[1] and I.W. Hunter[2], School of Physical & Occupat. Therapy[1] and Dept. Biomed. Eng.[2], McGill University, 3654 Drummond St., Montreal, Canada H3G 1Y5.

Sensory thresholds have been calculated for a number of different aspects of the human proprioceptive system including limb position, movement, force, and stiffness. Most of this research has focussed on differential thresholds, that is, the amount a stimulus must be incremented or decremented in order for the subject to discriminate that two stimuli differ. For the proprioceptive system, there is a remarkable consistency in the differential thresholds measured for position, movement and force with the values varying between 6% and 10%. In contrast, subjects are much less consistent in discriminating changes in stiffness, for which the threshold is 23% (Jones & Hunter, 1990).

The objective of the present experiment was to extend these findings to an analysis of the sensitivity of human subjects to changes in viscosity. This was measured using the matching procedure in which eleven subjects adjusted the viscosity of a servo–controlled linear motor connected to their left arm (via a foot pedal containing an angular position transducer) until it was perceived to be the same as that of the motor connected to their right arm. The servo–system was under computer (IBM 320) control and force and position were recorded from each motor via the computer's A/Ds. The viscosities ranged from 2 N.s/m to 1024 N.s/m, and there were 8 repetitions of each of the 10 viscosities.

The matching function obtained for viscosity was linear, with a very small deviation from linearity at the lowest viscosity (i.e. 2 N.s/m).The differential thresholds calculated for viscosity ranged from 83% at the lowest viscosity to 26% at the highest, and averaged 34% over the range of 32 to 1024 N.s/m. These values are almost 50% higher than those reported for stiffness, suggesting that the human proprioceptive system is less efficient at integrating force and velocity signals to perceive changes in viscosity, as compared to force and displacement cues for stiffness.

CIRCUITRY AND PATTERN GENERATION II

442.1

MODULATION OF THE RELATIVE ROLES OF SPIKING AND GRADED SYNAPTIC TRANSMISSION BETWEEN GASTRIC PATTERN-GENERATING NEURONS. R.C.Elson and A.I.Selverston*, Department of Biology, UCSD, La Jolla CA 92093.

Neurons of the gastric central pattern generator (CPG) in the lobster stomatogastric ganglion release transmitter in response to graded depolarizations as well as spikes. The lateral gastric neuron (LG) inhibits and is inhibited by 2 LPG neurons. Without neuromodulators, the gastric CPG is quiescent. LG is silent while the LPGs fire tonically. Depolarizing LG evokes graded inhibition of the LPGs with little contribution by its high-threshold spikes. The muscarinic agonist, pilocarpine, initiates rhythm generation in the gastric CPG, modulating both cellular and synaptic properties. At the LG-to-LPG, it: (1) potentiates graded and spike-evoked synaptic potentials; (2) depolarizes LG; and (3) reduces LG's spike threshold. Whereas in control conditions, small depolarizations of LG elicit small, graded inhibition, under muscarinic modulation they elicit spikes, driving large IPSPs, producing dramatic inhibition. LG can now evoke large postsynaptic effects with little baseline depolarization, via spike generation and spiking transmission. These effects are important during rhythm initiation and burst transitions. In contrast, spiking transmission is not important when cells produce large plateau potentials (partly due to synaptic saturation); here pattern-generating interactions depend largely on graded transmission. Thus, the relative roles of spiking and graded transmission vary with modulatory conditions and the biophysical states of pre- and postsynaptic cells.

PROPERTIES OF A RELAXATION-OSCILLATOR-BASED MODEL OF THE LOBSTER GASTRIC MILL CPG P.F.Rowat* and A.I.Selverston Biology Department, U.C. San Diego, La Jolla, CA 92093–0322.

The purpose of this work is to develop a model of the lobster gastric mill CPG that is as simple as possible yet is biologically plausible, and which captures significant network properties such as the emergence of patterns from network connectivity rather than endogenous cellular burst capability, continued pattern generation when cells are removed, and changes in the pattern after application of modulatory substances. The cell model, derived from the relaxation oscillator, has one fast current and a slow current that can be regarded as the combination of a slow inward and a slow outward current. It displays plateau potentials, postinhibitory rebound, postburst hyperpolarization, and endogenous oscillations for suitable settings of two parameters. One parameter controls whether the fast current has a region of negative resistance and the other controls the gain of the slow current. When the region of negative resistance is present, endogenous oscillations occur. A network model of the complete gastric circuit was made, using a model of graded synaptic transmission but excluding spike-based transmission. For a wide range of parameter values, the model generates phase-relationships that are approximately correct. Adjusting the gains of the slow currents in different cells causes small changes in phase relationships. A slow excitatory synapse causes a significant phase delay. Thus, a close match to *in vitro* recordings is possible. Also, some phase changes caused by neuromodulator application can be reproduced. The model network oscillates even when no component cell is an endogenous oscillator. When cells are killed, the network continues to generate a pattern provided at least one pair of reciprocal inhibitory cells remains. Current pulses were injected into cells in the network. Phase response curves and the limits of entrainment were computed for the model network, and compared with the biological data.

442.3

AMINE MODULATION OF MIXED CHEMICAL-ELECTRICAL SYNAPSES IN THE PYLORIC NETWORK OF THE LOBSTER STOMATOGASTRIC GANGLION. B.R. Johnson*, J.H. Peck and R.M. Harris-Warrick. Section of Neurobiology and Behavior, Cornell University and Department of Psychology, Ithaca College, NY 14853.

Dopamine (DA, 10^{-4}M), serotonin (5HT,10^{-5}M) and octopamine (Oct, 10^{-5}M) each produce a unique motor pattern from the pyloric network in the stomatogastric ganglion of the lobster *Panulirus interruptus*. We are examining how amines modulate the pyloric rhythm. Here we describe amine effects on mixed graded chemical-electrical transmission between two different pairs of pyloric neurons. The AB and VD and the LP and PY neurons are electrically coupled; in addition, the AB chemically inhibits the VD, while the LP and PY are reciprocally inhibitory. Modulation of mixed synaptic interaction was examined in isolated neuron pairs in TTX-saline (20° C). DA and 5HT reduced electrical coupling and enhanced chemical inhibition between the AB and VD. DA also reduced electrical coupling and enhanced the reciprocol chemical inhibition between the LP and PY. Oct enhanced while 5HT reduced PY chemical inhibition of the LP with little effect on electrical coupling. As a consequence of these differential effects on chemical and electrical transmission, the amines could reverse the sign of synaptic interactions between these cells. For example, depolarization of the LP depolarizes the PY in control conditions; this reverses to hyperpolarization during DA perfusion. In preparations where the AB to VD chemical synapse is weak and electrical coupling dominates, DA and 5HT change the synaptic interaction from weakly excitatory to strongly inhibitory. Modulation of mixed synaptic interactions contributes to the structure of the motor patterns produced by these amines. Supported by NRSA NS07859 and NIH grant NS17323.

442.4

AMINE MODULATION OF ELECTRICAL COUPLING IN THE PYLORIC NETWORK OF THE LOBSTER STOMATOGASTRIC GANGLION. J.H.Peck* B.R. Johnson AND R.M. Harris-Warrick, Section of Neurobiology and Behavior, Cornell University and Dept. of Psychology, Ithaca College, Ithaca,N.Y. 14853.

We examined the I/O characteristics and amine modulation by dopamine (DA), serotonin and octopamine of 5 electrical synapses in the pyloric network in the STG of *Panulirus interruptus*. Some synapses (AB-PD and PD-PD) were non-rectifying, while the others (AB-VD, PD-VD, and LP-PY) all show significant rectification. The amines altered the strength of electrical coupling, but this varied with the different pairs of neurons and with the direction of current flow. For example, DA enhanced PD-AB but reduced AB-PD coupling. We modeled these results by an input resistance increase in the AB and decrease in the PD with no change in junctional resistance. DA causes these input resistance changes. For other synapses (such as DA reduction in AB-VD coupling), our model predicts that the amine reduces the junctional coupling in addition to altering cellular input resistance. Modulation of electrical coupling is a new mechanism by which amines modify the pyloric network to generate multiple motor patterns. (NRSA NS07859 and NIH NS17323)

442.5

MECHANISMS FOR DOPAMINE-INDUCED PHASE SHIFTS IN THE PYLORIC MOTOR PATTERN IN THE LOBSTER STOMATOGASTRIC GANGLION. R. M. Harris-Warrick*, A.J. Tierney and L. Coniglio. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In the triphasic pyloric motor pattern, the pacemaker neurons inhibit the LP and PY neurons; these cells show different rates of post-inhibitory rebound, causing them to fire at different phases in the cycle. Dopamine (10^{-4}M) excites the LP and PY cells and causes a significant phase advance in their activity. This is explained in part by dopamine inhibition of the pacemaker PD neuron. Two additional mechanisms for phase advance are intrinsic to the post-synaptic PY and LP cells. 1) Conductance decrease of I_A. Both LP and PY express a transient K^+ current (I_A) that is selectively sensitive to 4-aminopyridine (4-AP). This current plays an important role in the rate of rebound after hyperpolarization in synaptically isolated LP and PY neurons. Both DA and 4-AP reduce the delay to first spike after 200 msec hyperpolarizing pulses, and increase the frequency of firing in response to tonic depolarization. Blockade of I_A by 4-AP occludes the effect of DA on the PY cell, suggesting that reduction of I_A is the major action of DA in this cell. 2) Enhancement of I_h. The LP cell displays a Cs^+-sensitive depolarizing sag during tonic hyperpolarization, caused by the hyperpolarization-activated inward current, I_h. DA enhances this sag, specifically by shifting its voltage dependence for activation in the depolarizing direction. This effect is eliminated by low concentrations of Cs^+, which eliminate I_h. This suggests that DA acts on the LP by both reducing I_A and enhancing I_h. We are now using voltage clamp of cultured LP and PY cells to try to directly measure dopamine modulation of these currents. Supported by NIH NS17323 and NS 25915.

442.6

INWARD CURRENTS UNDERLYING BURSTING IN CULTURED STOMATOGASTRIC NEURONS. G.G. Turrigiano* and E. Marder, dept. of biology, Brandeis University, Waltham, Ma 02254

Stomatogastric (STG) neurons *in situ* express slow regenerative conductances that underlie bursting and plateau behavior. We use primary cultures of STG neurons from the spiny lobster *Panulirus interruptus* to identify two inward currents that contribute to these properties. STG neurons in culture switch from tonic firing to bursting in TEA. In most neurons these oscillations, as well as fast spikes, can be blocked by TTX. In other neurons TTX has little effect on oscillations; these oscillations are blocked by Mn^{++}. Under two electrode voltage clamp we have identified two persistent inward currents, one that is blocked by TTX, and one that is blocked by Mn^{++}. The TTX-sensitive current begins to activate above -40 mV, peaks at -20 mV, and has an extrapolated reversal potential of +20 mV. The Mn^{++}-sensitive current activates above -40 mV, peaks at +20 mV, and reverses at +50 mV; the magnitude and reversal potential of this current depend on the external Ca^{++} concentration, suggesting that the current is carried by Ca^{++} ions. Most STG neurons have both inward currents, but their relative magnitudes, and thus the pharmacological sensitivity of bursting, vary from cell to cell. We are currently investigating whether the ratio of these conductances is a function of neuron type. Supported by NS-08971 to G.G.T. and BNS-9009251 to E.M.

442.7

REAL TIME INTERACTION BETWEEN A MODEL NEURON AND THE CRUSTACEAN STOMATOGASTRIC NERVOUS SYSTEM.

G. LeMasson, S. Renaud-LeMasson, A. Sharp, L.F. Abbott, and E. Marder* Biology Dept. Brandeis Univ. Waltham, MA 02254.

Model neurons are useful in understanding the complex interactions between single currents in a cell, or between different cells within a network. To study the dynamics of both synaptic influences and intrinsic properties of neurons we connect a conductance-based model neuron to a real neural network. We used a DSP board and the MAXIM software package to run the model and control the Input-Output interface. The system allows the model neuron to run and respond in real time to artificial synapses created between real neurons and the model neuron. The model neuron was constructed using data from the LP neuron of the stomatogastric ganglion. We make reciprocal inhibitory connections between the model LP neuron and a biological PD neuron and study the effect of changes in ih and iA current on the hybrid network, as well as the effect of changing the strength of the synapses between the model and the biological neuron. The results suggest that the model LP firing phase in the pyloric period depends critically on the characteristics of the synaptic inhibition coming from the PD neuron. The burst duration and the firing frequency of the LP model depends on ih and iA.

442.8

Dynamic Clamp: A method to construct artificial synapses and assess the role of voltage-dependent and synaptic conductances. A.A. Sharp*, M. O'Neil, G. LeMasson, L.F. Abbott, E. Marder. Dept. of Biology, Brandeis University, Waltham, MA 02254.

Conventional voltage-clamp techniques provide data describing how the conductances that shape neuronal excitability depend on voltage and time, but do not allow the investigator to determine the participation of individual currents in the dynamic behavior of a neuron. We have devised a method, called a dynamic clamp, that allows us to increase, decrease or alter conductances in neurons during their normal dynamic behavior. This method is used to study the effects of a given voltage-dependent or synaptic conductance on a cell's intrinsic behavior and the emergent properties of a network. It is also used to create new networks by generating artificial synapses.

To construct the dynamic clamp, an Axoclamp in DCC mode is used to monitor the cellular potential and to inject current. Based on this potential and a computational model describing the dynamics of the conductance under investigation a computer determines the current to be injected. When constructing synapses both the pre- and post-synaptic potentials are monitored. The investigator controls the relevant thresholds, reversal potentials and time constants. We use this method to create synapses between dissociated neurons in culture, in the intact stomatogastric ganglion and/or to modify the intrinsic properties of neurons within these networks. 442.9

CRUSTACEAN CARDIOACTIVE PEPTIDE ACTIVATION OF THE PYLORIC NETWORK IN THE STG OF THE CRAB, *Cancer borealis*. J.M.Weimann*, H.G.Heinzel, and E.Marder. Biology Dept., Brandeis Univ., Waltham, MA 02245 and Institute of Zoology, Univ. of Bonn, Bonn, Germany.

The highly conserved crustacean cardioactive peptide (CCAP) activates the pyloric rhythm of the stomatogastric nervous system in a dose-dependent manner with a threshold at 10^{-10}M. The number of spikes/burst in the lateral pyloric (LP) neuron, a major target, increases from 2-5 spikes/burst in control saline to >50 spikes/burst in 10^{-6}M CCAP. This increase spikes/burst is associated with the induction of plateau potentials in the LP neuron. Bath application of CCAP ($>10^{-8}$M) causes oscillations in the membrane potential of the pharmacologically isolated LP neuron. The phase of the oscillations can be reset with brief current pulses into the LP soma. This is responsible for the change in the LP duty cycle from 10% to over 40% of the phase in 10^{-7}M CCAP.

Simultaneous endoscopic observations of the valve between the gastric mill and the pyloric chamber and extracellular recordings of the major STG motor nerves in intact crabs suggest that changes in the LP neuron's activity dramatically alter the movements of this valve.

SELECTIVE ENHANCEMENT OF RHYTHMIC PACEMAKER ENSEMBLE ACTIVITY BY A NEWLY IDENTIFIED MODULATORY NEURON. M.P. Nusbaum*, M.J. Coleman and B.J. Norris. Neurobiology Research Center and Dept. of Physiology & Biophysics; Univ. of Alabama at Birmingham; Birmingham, AL 35294.

The pyloric neural network, in the crustacean stomatogastric ganglion (STG), produces a three-phase motor pattern. Variants of the pyloric rhythm are produced in the presence of different modulatory inputs, some of which have been identified (Nusbaum et al., J. Neurosci. 12:In press). Recently, we identified a neuron, Modulatory Commissural Neuron 5 (MCN 5), that increases the cycle frequency and decreases the number of active phases in the pyloric rhythm of the crab, *Cancer borealis*. The MCN 5 soma is located in the commissural ganglion and projects to the STG via the inferior oesophageal nerve and stomatogastric nerve.

Intracellular stimulation of MCN 5 increased the pyloric cycle frequency, at least partly by exciting the pyloric pacemaker neuron AB. Each action potential elicited in MCN5 produced a fixed latency EPSP in the AB neuron. MCN 5 stimulation also enhanced the activity of the PD and LPG dilator motor neurons, which are electrically coupled to AB and fire their impulse bursts during the AB phase of the pyloric rhythm. The remaining pyloric components, which would be active during the two cycle phases following AB activity, are all inhibited during MCN 5 stimulation. With increasing stimulation of MCN 5, the activity of these pyloric components could be completely suppressed, producing a faster pyloric rhythm with only a single active phase. MCN 5 activity thus is capable of sculpting an active, single phase motor pattern by selective enhancement and suppression of individual neural network components.

A motor basis for the radula movements underlying ingestion and rejection in *Aplysia*. D. W. Morton[2*], H. J. Chiel[1,2], Depts. of [1]Biology and [2]Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106

We are studying the neural basis of the radula movements underlying *Aplysia's* consummatory feeding behavior. During ingestion, the radula is open as it protracts and closed as it retracts. During rejection, the radula is closed as it protracts and open as it retracts. We have identified several buccal ganglion motor neurons that produce specific radula movements and observed their activity during ingestion-like and rejection-like motor patterns in a reduced preparation. Stimulation of identified neuron B10 produces a sphincter-like contraction of the anterior buccal cavity and retraction-like movements when the radula is held in a protracted position. Stimulation of neurons B8a and B8b produces radula closure. During the ingestion-like pattern, B8a, B8b, and B10 are active during the retraction portion of the pattern, consistent with observations that during ingestion, the radula is closed as it retracts. During the rejection-like pattern, B8a and B8b are active during the protraction portion of the pattern, while B10 is active during the retraction portion, consistent with the observation that during rejection, the radula is closed as it protracts. In addition, the extracellular activity produced by these cells is consistent with neural activity observed *in vivo* during ingestion and rejection. Thus, our results suggest that B10 contributes to radula retraction, B8a and B8b contribute to radula closure, and the differential activation of these neurons may contribute to the difference between ingestion and rejection. Studying the mechanisms underlying these two feeding-like patterns could reveal how a neuronal circuit can generate more than one behaviorally relevant pattern.

IONIC MECHANISM FOR SWITCHES IN ACTIVITY OF INTERNEURONS THAT CONTROL HEARTBEAT IN THE LEECH

Siglinde Gramoll, Ronald L. Calabrese, Karen J. Thompson
Emory Univ., Dept. Biol., 1510 Clifton Rd, Atlanta, Ga 30322

During the heartbeat of the leech, *Hirudo medicinalis*, the rhythmic activity of the segmental heart motor neurons is shaped by inhibitory input from heart interneurons (HN), a pair of which is located in each of the seven anterior ganglia (Thompson and Stent (1976) J Comp Physiol 111; Calabrese (1977) J Comp Physiol 122). The basic rhythm is produced by an oscillator comprising the HN cells in the four anterior ganglia, while the HN cells of the fifth ganglion, HN(5), have a different function. Both cells receive alternating rhythmical inhibitory inputs from the oscillator, but at a given time, only one of the two HN5 cells is active. This cell discharges high frequency bursts of action potentials between the rhythmical inhibitions, while the other cell produces only few or no action potentials (Calabrese 1977). Due to the different activity states, only one of the HN(5) cells effectively influences postsynaptic premotor neurons, which are connected to both of them. The activity of the HN(5) cells causes one of the bilateral heart tubes to contract peristaltically, the other synchronously.

Every 20 to 40 heartbeat cycles occurs a simultaneous switch between the active and the inactive state in the HN(5) cells. So far, the underlying mechanism of this switch is not known. The switch is not associated with a change of synaptic potentials. In this study, we investigated the ionic mechanisms of the HN(5) cells using switching single electrode voltage clamp. During the active state the membrane conductance is lower than in the inactive state, suggesting that the permeability of a hyperpolarizing ion is increased during a switch to the inactive state. The reversal potential of this current is close to that of Cl^-.

FUNCTIONAL CHARACTERIZATION OF A NEURAL NETWORK FROM THE CNS OF THE SNAIL *LYMNAEA STAGNALIS*. N.S. Magoski*, N.I.S. Syed and A.G.M. Bulloch. Dept. Med. Physiology and Neuroscience Research Group, Univ. Calgary, Faculty of Medicine, Calgary, AB T2N 4N1 Canada.

We have identified a network of chemically and electrically connected neurons in the CNS of the pond snail *Lymnaea stagnalis*. Three large identified neurons termed right parietal ventral one - three (RPV1-3) (Symp.Biol.Hung.1976:41) were found to be electrically coupled to one another. These neurons send projections through nerves which innervate musculature involved with whole-body withdrawal and cardio-respiratory behavior. Neurons RPV1-3 were found to be inhibited by respiratory pattern generator interneurons, VD4 and IP3I (J.Comp.Physiol.A 169:557). Conversely, a pair of interneurons, L/RPeD11, that coordinate locomotor and withdrawal behavior (J.Exp.Biol.158:37) excite cells RPV1-3. Using isolated brain, semi-intact and cell culture preparations we have characterized the in situ and in vitro properties of this network. The connectivity and morphological characteristics of this neural circuit suggest a possible role in whole-body withdrawal; however, the functional significance of these neurons remains to be fully determined.

BIFURCATION DYNAMICS OF MULTIFUNCTIONAL NETWORKS ARE AFFECTED BY ERRORS THAT THE NETWORKS THEMSELVES GENERATE. G. J. Mpitsos*, M. A. Andrade, J. C. Nuño, F. Morán, F. Montero. Mark O. Hatfield Marine Science Center, Newport, OR 97365, and the Depts. of Biochemistry-Molecular Biology and Mathematics at the Univ. of Madrid, Spain.

Catalytic networks have been used as models to examine many biological systems, from prebiotic evolution to neural networks and population biology. Biological systems are inherently variable and error-prone, as shown for example by work on the multifunctional and variable motor systems of the sea slug *Pleurobranchaea* (Mpitsos and Cohan, 1986, J. Neurobiol.). In this regard, catalytic networks may provide rapid insights into the effect that error itself may have on the dynamics that a system can generate; i.e., error may not only be a product of a system, it may also feed back onto the system's self-organizing potential. Schnabl et al. (1991, Physica D) examined catalytic networks in which error arises by intermutations between reciprocally interconnected elements of the network. We have examined the more biologically plausible condition when error arises in chemical systems through the generation of mutant species (error-tail) that compete for substrate with the catalytic species but have no enzymatic effects on them. This allows for both reciprocal and one-way connections among the elements of the network, as occurs in all biological systems. Both models show that error affects system dynamics, but complex behavior in the error-tail model is more stable in the face of variation or noise in the error-related parameters. Catalytic networks may also provide insight into network architectures that permit bifurcation into rich repertoires of patterns of activity relating to multifunctionality. We discuss the application of catalytic networks to neural systems.

BURST QUANTIFICATION IN CULTURED NEURONAL NETWORKS. J.C. Weil*, S.P. Fracek, B.K. Rhoades and G.W. Gross. Department of Biological Sciences, University of North Texas, Denton, TX 76203.

Cultured mammalian neuronal networks can be pharmacologically induced to exhibit a range of stable temporal spike activity patterns extending from quiescence, through isolated spiking, irregular and regular bursting, and burst fusion, making them ideal preparations for evaluating methods of burst detection and quantification.

Isolated networks of 50-200 neurons were grown on multimicroelectrode plates (MMEPs) from dissociated tissue of 14 day fetal mouse spinal cords or olfactory bulbs. Single unit spike trains for 15-60 minute periods were extracted from the extracellular recordings and digitally stored as time series records. In addition two types of artificial data sets were constructed - "bursting" spike trains of bursts generated with a semi-Markov model and "non-bursting" spike trains with interspike intervals (ISIs) randomly sampled from Poisson, beta, or gamma distributions.

Five burst identification algorithms are implemented and applied to this data: an ISI threshold based on a first-order statistic (Habets *et al., Exp. Brain Res.* 69:43, 1987), an ISI threshold for burst onset with a "Poisson surprise" statistical rule for burst offset (Legéndy & Salcman, *J. Neurophys.* 53:926, 1985), an ISI threshold chosen as the first local minimum following the first mode of the smoothed ISI histogram (Cocatre-Zilgien & Delcomyn, *J. Neurosci. Meth.* 41:19, 1992), a slope threshold applied to a cumulative sum function of the spike train (David Tam, personal communication, 1992), and our own dual-threshold method which performs fast and slow integrations of the spike train with one threshold applied to the fast integration and the second threshold applied to the fast-slow integration difference. Burst identification methods are evaluated on their relative abilities to produce parametric measures and descriptive statistics which compare favorably with hand measurements, distinguish artificial bursting and non-bursting spike trains, allow both temporal and spatial network analysis and comparisons across treatment conditions in the burst domain, and extend to multiunit records.

PATTERNED ELECTRICAL STIMULATION OF CULTURED NEURONAL NETWORKS ON MULTIMICROELECTRODE PLATES. B.K. Rhoades* and G.W. Gross. Dept. of Biol. Sci., University of North Texas, Denton, TX 76203.

Cultured neuronal networks derived from the embryonic mammalian spinal cord display spontaneous activity which is characterized by the temporal consolidation of spikes into bursts and a variable degree of burst synchrony across the network. The multimicroelectrode plate (MMEP), a culture substrate incorporating an $1mm^2$ array of 64 photoetched extracellular microelectrodes, provides a uniquely stable and interactive system for studying activity dynamics in an isolated neuronal network.

Networks of 50-100 neurons were cultured onto MMEPs from dissociated spinal cord tissue of 14-day mouse embryos, and activity was recorded after 20-150+ days in culture. Monophasic and biphasic stimulation pulses (0.2 - 1.0V, 0.1 - 1.0 msec.) were applied across a 10MΩ resistor in front of the preamplifier FET of one or more recording channels (average impedances @ 1kHz: 1.3MΩ electrode, 12MΩ amplifier input, 40MΩ conductor-bath shunt).

Single pulses delivered to a single microelectrode can trigger network-wide burst responses. The threshold strength-duration relationship for this response can be fit by standard physiological curves, with a unique rheobase and chronaxie for each stimulation site. Repetitive, periodic stimulus pulses can entrain network bursting to the temporal stimulation pattern. Repeated high-intensity and high-frequency stimulus trains can induce an epoch of intense, repetitive bursting which continues for seconds to minutes after stimulation is discontinued and may be considered the culture equivalent of an electrically-induced epileptic seizure.

This is the first demonstration of effective electrical stimulation of a cultured network via photoetched electrodes, and opens several intriguing avenues for further research. These include training networks to exhibit novel spatio-temporal activity patterns with repetitive patterned stimulation, testing the Hebb rule at the network level in both spike and burst domains by using spike- or burst-triggered stimulation to drive network activity, and developing a cultured network model of kindling.

REPRODUCIBILITY OF GABA-INDUCED ACTIVITY SUPPRESSION IN CULTURED SPINAL CORD NETWORKS. R. S. Jordan*, B. K. Rhoades, and G. W. Gross. Dept. of Biological Sciences, Univ. of North Texas, Denton, TX 76203.

Cultured monolayer networks grown on photoetched multimicroelectrode plates have been used for pharmacological studies of patterned neural activity. These preparations allow spatially uniform and temporally constant exposure to pharmacological agents, are isolated from outside neural influences, are not damaged by invading electrodes, and allow simultaneous, multi-site recording (64 channels). However, cultures vary in cell number, distribution of cell types and sizes, apparent density of neurite interconnections, and native activity patterns. Therefore, the reproducibility of pharmacological responses is an important consideration. Studies were performed on networks grown from dissociated cells of 14 day fetal mouse tissues from either whole spinal cord (WC) or ventral cord (VC). From each culture, five successive dose response curves were obtained reflecting exponential decreases in burst rate with the incremental accumulation of GABA until burst shut off at a total inhibition concentration (TIC). Burst duration, amplitude, temporal pattern, and synchrony remained stable until shutoff. The GABA TIC was highly reproducible within n=12 cultures (WC range: 14±2 to 26±4, μM±SD) and suprisingly constant across these cultures (WC mean: 18±5). A comparison of networks cultured from WC and VC revealed different pattern dynamics, with VC networks displaying characteristically shorter bursts with less variability in burst duration. However, TIC values showed no tissue specificity (WC mean: 18±5, n=12; VC mean: 19±7, n=12). These results indicate that (1) GABA influences burst initiation without major effects on spike patterns within the bursts, (2) different cultures display similar network responses to GABA, and (3) burst suppression has a generally constant dose dependency both across and within cultures. (Supported by grants from the Texas Advanced Research Program and the Hillcrest Foundation of Dallas, TX.)

EMERGENT INFORMATION PROCESSING STRATEGIES IN A NETWORK OF NEURONS S. Shah, W.E. Faller and M.W. Luttges*. Departments of Electrical and Aerospace Engineering Sciences, University of Colorado, Boulder, Colorado 80309-0429.

Neurobiological information processing is presumably mediated by the spatiotemporal interactions among neurons in a network of cells. To study these complex spatiotemporal interactions with regard to structure/function relationships simultaneous single-unit recordings were obtained from the mesothoracic ganglion of the house cricket (Atheca Domestica) both before and after electrical stimulation of the interganglionic connectives. Each individual spiking record obtained presumably reflects the superimposition of EPSP's and IPSP's onto the intrinsic cellular physiology of each neuron. To discriminate between hard-wired and "emergent" responses of the neurons in this network both individual cell firing patterns and short-time scale, transient, "functionally" inhibitory and excitatory connections between neurons were analyzed before and after the stimulus presentation. Analyses indicated that some cells consistently respond in a predictable fashion to the stimulus, while other cells show more complex changes in both firing behavior and functional connectivity patterns with other cells in the network. Cells which "follow" the electrical stimulation, have predictable responses, may be involved in the hard-wired/mechanistic processing of information in the ganglion. Those cells which show dynamic changes in firing behavior and functional connectivity patterns as a delayed response to the stimulus, on the other hand, appear to contribute to more "emergent" information processing capabilities within this network of neurons. The structure/function relationships underlying both these hard-wired and emergent responses are being studied with respect to both the underlying spatial architecture and individual neuron size.

MULTIPLE SITE OPTICAL RECORDING OF SYNCHRONIZED BURSTS IN NEOCORTICAL AND HIPPOCAMPAL DISSOCIATED CELL CULTURES USING VOLTAGE-SENSITIVE DYES.
D. D. Cummings[1*], S. Rohr[1,2], A. L. Obaid[1,2], M. A. Dichter[1,3], and B. M. Salzberg[1,2]. [1]Institute of Neurological Sciences, [2]Dept. of Physiology, [3]Dept. of Neurology, University of Pennsylvania School of Medicine, and Graduate Hospital, Philadelphia, PA 19104.

Primary cultures of neocortical and hippocampal neurons exhibit synchronized bursts detectable by multisite calcium fluorometry (Ogura et al., Neurosci. Lett., 78 (1987), 69-74). The use of DI-8 ANEPPS (L. Loew; Mol. Probes Cat. # D-3167), a fluorescent potentiometric probe with a microsecond response time, allowed us to monitor rapid voltage transients, as well as the slower voltage oscillations associated with changes in $[Ca]_i$. Continuous multiple site recordings were obtained for approximately two minutes before excessive photobleaching occurred and reproducible recordings were obtained for at least one hour with each culture, using numerous experimental fields. NMDA and non-NMDA receptor antagonists, and GABAergic agonists and antagonists produced reversible perturbations in the synchronous bursting activity.

Multiple site optical recording of transmembrane voltage fluctuations in small networks combined with electrophysiological recordings should facilitate studies of the relationship between synaptic properties of CNS neurons and the origin and maintenance of emergent oscillatory behavior characteristic of networks formed in neuronal cultures.

Supported by an MSTP Fellowship to DDC, a Fellowship from the Swiss NSF grant 823A-028424 to SR, and USPHS grants NS 16824, NS 24927 and NS 24260.

OPTICAL AND PHARMACOLOGICAL STUDIES OF PROPRIOSPINAL NEURONS INVOLVED IN RHYTHMIC MOTOR ACTIVITY IN THE EMBRYONIC CHICK SPINAL CORD. Stephen Ho* and Michael O'Donovan. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Our previous studies have identified a class of propriospinal neurons whose axons travel in the ventrolateral white matter tracts (LT) and are involved in synchronizing motoneuron discharge during rhythmic motor activity. The properties of these LT neurons were studied further in E9-10 chick embryos using optical and pharmacological methods. LT neurons were labelled retrogradely with a Ca indicator (Ca-green dextran), and were found on both sides of the cord following an unilateral LT injection. Ipsilateral cells were distributed dorsal and medial to the lateral motor column. The contralateral group was more discrete and was located in the medial part of the cord, near the central canal. During episodes of motor activity, both groups expressed synchronized, rhythmic fluorescence signals in phase with motoneuron discharge.

LT stimulation resulted in a brief synchronized discharge in flexor and extensor nerves followed by a more prolonged burst. The synchronous discharge and the prolonged potentials were abolished respectively by CNQX (5 μM) and AP-5 (50 μM). Depolarizing potentials persisting in the presence of kynurenic acid (1-2 mM) were blocked by strychnine (50 μM) or bicuculline (100 μM). LT evoked potentials are not mediated by electrical coupling or by cholinergic transmission because they were blocked by Co^{2+} and were unchanged during bath application of curare (20 μM). These findings indicate that LT axons have both excitatory and inhibitory connections with motoneurons. In addition to their role in intersegmental coordination they may also participate in contralateral synchronization and in activating the shunting inhibition that underlies the alternation of flexor and extensor motoneurons.

SELECTIVE IMPAIRMENT OF DELAYED NON-MATCHING-TO-SAMPLE (DNMTS) FOLLOWING FRONTAL CORTICAL LESIONS IN THE RAT. L. M. Harrison* and R. G. Mair. University of New Hampshire, Durham, NH 03824

Two experiments were conducted to determine the effects of lesions of the lateral internal medullary lamina of thalamus (L-IML) and of frontal cortex on three measures of spatial memory: DNMTS, radial arm maze (RAM), and serial reversal learning (SRL). In Exp. 1, RAM was trained prior to surgery. While both RAM and SRL were disrupted by lesions of the L-IML, neither task was affected by destruction of frontal cortical areas along the medial wall (MW) or dorsal to the rhinal sulcus (RS). In Exp. 2, DNMTS was trained prior to surgery. Rats with lesions of MW or RS showed impairments comparable to those seen following L-IML lesions. Anatomical studies were conducted using Wheat Germ Agglutinate - Horseradish Peroxidase (WGA-HRP) to map out projections of the mediodorsal nucleus (MDn) of thalamus in controls and in animals with RS and MW lesions. These analyses showed that the RS and MW lesions produced near-complete destruction of MDn projections to cortex, and that neither lesion (MW or RS) disrupted pathways leading from the MDn to the other frontal target area (RS or MW).

443.2

IBOTENIC ACID LESIONS OF THE HIPPOCAMPUS FACILITATE ACQUISITION OF AN APPETITIVE SIGNALLED BAR-PRESSING TASK. S. F. Logue*, E. M. Klamo, D. P. Miller, and J. E. Steinmetz. Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405.

The role of the hippocampus in various spatial and temporal tasks has been widely studied. In a variety of aversive conditioning tasks (i.e. rabbit eyelid conditioning and passive and active avoidance tasks) hippocampal lesions have been shown to facilitate acquisition. On the other hand, hippocampal lesions have disrupted acquisition of appetitive conditional discrimination, but facilitated acquisition has been demonstrated for odor discrimination in rats with entorhinal cortex lesions. Reported here is a demonstration of facilitated acquisition of a single-cue signalled bar-pressing task in rats with hippocampal lesions. One group of rats was given ibotenic acid lesions in the hippocampus and a second group served as unlesioned controls. After training the animals to bar-press and establishing a baseline rate of responding the two groups of rats were divided into tone and no tone control groups and given daily sessions of 100, 1 sec tone (2 kHz, 90 dB) presentations. A bar-press during the tone (or during the 1 sec silent tone period for the controls) delivered a food reinforcement followed by a 10 sec intertrial interval and a variable pre-tone period (range 1-8 sec). A bar-press during the pre-tone period reset the time interval before the tone period. The lesioned tone rats reached asymptotic performance in fewer sessions than the non-lesioned tone rats although both groups reached the established criterion for reinforced responses. There was no lesion effect on the response latencies of either the tone or no tone groups. The tone and no-tone rats given hippocampal lesions after learning the task showed no impairment of performance. The effect of hippocampal lesions on a parallel signalled avoidance task are currently being assessed. [Supported by NSF Research Training Grant to S.F.L. and J.E.S.]

HIPPOCAMPAL LESIONS DO NOT IMPAIR NEGATIVE PATTERNING: A CHALLENGE TO CONFIGURAL ASSOCIATION THEORY. L.E. Jarrard*[1], M.G. McKernan[1] and T.L. Davidson[2]. [1]Dept. Psychol., Washington and Lee Univ., Lexington, VA. 24450, and [2]Dept. Psychol. Sci., Purdue Univ., West Lafayette, IN. 47907.

In a critical test of the configural association theory of hippocampal function, Sutherland and Rudy (Psychobiology, 17:129, 1989) reported that rats with neurotoxic (colchicine + kainic acid (COL+KA)) lesions of the hippocampus were unable to learn a negative patterning problem. In the present replication and extension of this research rats with either ibotenic acid (IBO) or COL+KA lesions of hippocampus, together with controls, were trained on a negative patterning discrimination where responding in the presence of either a tone or light was reinforced while responding when tone and light were presented in compound was nonreinforced. Following acquisition, transfer trials were given to see if the negative patterning problem had been learned using configural associations.

The results indicated that (1) rats in both COL+KA and IBO hippocampal groups learned the negative patterning discrimination, (2) COL+KA rats responded at higher rates, and (3) all groups learned the problem using a configural solution. Since neither type of hippocampal lesion impaired the ability of rats to solve the negative patterning problem, and transfer tests indicated that the groups learned the problem using configural associations, these results fail to support the configural association theory.

EFFECTS OF PERIRHINAL CORTEX AND MEDIAL EXTRASTRIATE VISUAL CORTEX LESIONS ON MEMORY ASSOCIATED WITH AN OBJECT CONTINUOUS RECOGNITION TASK. A. Ravindranathan*, P. Jackson-Smith and R.P. Kesner. Program in Neuroscience and Department of Psychology, Univ. of Utah, Salt Lake City, Utah 84112.

The perirhinal cortex is a major convergence site for afferents from the neocortex. Thus, it may play an important role in linking the neocortex to allocortical areas thought to be involved in recognition memory, including the hippocampus. In order to ascertain whether the perirhinal cortex and the medial extrastriate visual cortex play a role in recognition memory for 3-dimensional objects, lesions of the areas in question were effected in trained rats. The training procedure involved the sequential presentation of eight novel objects, and four repeated objects (chosen from the eight) within a session. These were selected from 120 different 3-dimensional objects in various shapes, sizes, textures and degrees of brightness. Repeated objects had lags ranging from 0 to 4 (from 0 to 4 different objects were presented between the first and the repeated presentation). An object was presented on one side of a long table divided in half by an opaque Plexiglas guillotine door, and the latency between opening the door and the rat moving the object was measured. Only the initial presentation of an object resulted in food reinforcement. Rats were assigned to groups and received surgery upon reaching criterion performance. Prior to surgery, latencies were significantly longer on repeated object presentations than on non-repeated presentations for all rats. There was no deficit following sham lesions or medial extrastriate visual lesions, whereas post-surgery performance was significantly worse than pre-surgery performance for the perirhinal group. Thus, the perirhinal cortex plays an important role in memory associated with this object continuous recognition task, whereas the medial extrastriate visual cortex does not.

HIPPOCAMPAL CHOLINERGIC AND SEROTONERGIC LESIONS: EFFECTS ON WORKING AND REFERENCE MEMORY. S.J. Murtha*, B.A. Pappas. Psychology Dept., Carleton University, Ottawa, Ontario K1S 5B6.

Combined loss of hippocampal acetylcholine (ACH) and serotonin (5-HT) occurs in Alzheimer's disease and may interact to impair memory. To examine this hypothesis, we tested rats pretrained in a 12 arm radial maze for the separate and combined effects of NMDA induced lesions of medial septal neurons and 5,7-DHT induced lesions of the fimbria/fornix plus cingulate gyrus, on reference (RMeM) and working (WMeM) memory. NMDA and 5,7-DHT reduced hippocampal choline acetyltransferase and 5-HT to 48% and 82% of control, respectively. Neither treatment alone nor their combination affected RMeM. The 5,7-DHT treatment by itself did not affect WMeM. NMDA caused an increase in WMeM errors. The combined NMDA and 5,7-DHT effect did not differ from the NMDA-only effect on early postoperative WMeM. However, the combined lesion did appear to retard the post-operative recovery of WMeM that was observed for the NMDA-only treated rats. In Alzheimer's disease, hippocampal 5-HT deficits may prevent compensation for the disruption of working memory that is caused by loss of hippocampal Ach function.

443.6

EFFECTS OF HIPPOCAMPAL CHOLINERGIC AND FOREBRAIN NORADRENERGIC LESIONS ON REFERENCE AND WORKING MEMORY. B.A. Pappas*, B.A. White, S.J. Murtha, G.A.S. Park and K. Hewitt. Dept. of Psychology, Carleton University, Ottawa, Ontario K1S 5B6.

Combined loss of hippocampal acetylcholine (ACH) and norepinephrine (NE) terminals occurs in Alzheimer's disease and may interact to impair memory. To test this hypothesis, we determined in maze pre-trained rats, the separate and combined effects of NMDA-induced lesion of the medial septal neurons and DSP4-induced lesion of forebrain NE terminals on reference and working memory in the radial arm maze. The NMDA and DSP4 treatments reduced hippocampal choline acetyltransferase activity and NE levels to 53% and 45% of control respectively. The DSP4 treatment by itself did not affect either reference or working memory. The NMDA treatment caused temporary disruption of reference and a long lasting disruption of working memory. DSP4 did not exacerbate the immediate effects of the NMDA lesion on working memory. It did prevent complete recovery of working memory in the NMDA lesioned rats, however. In Alzheimer's disease, forebrain NE deficits may potentiate over the long term, the effects of hippocampal ACH loss on working memory.

POST-TRAINING REVERSIBLE INACTIVATION OF THE AMYGDALA ATTENUATES BEHAVIORAL CONTRAST. L.F. Cahill*, J.A. Salinas, M.G. Packard & J.L. McGaugh. Center for the Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717.

Rats trained to run a straight alley for a large food reward display sharply increased latencies when shifted to a small reward. This behavioral phenomena, referred to as the Crespi effect (1942) or behavioral contrast, is often interpreted as an aversive emotional reaction to a reduction in reward magnitude. The behavioral contrast paradigm has been used extensively in studies examining anxiolytic effects of drugs. The present study used the behavioral contrast paradigm to examine the role of the amygdala in memory for a reduction in reward magnitude. Male Sprague-Dawley rats (175-200g) were implanted with bilateral intra-amygdala cannulae and trained to run a straight alley (6 trials/day) for either ten or one 45 mg food pellets. On day ten of training, half the animals in the high reward group were shifted to a one pellet reward. Immediately following shifted trials, the animals received an intra-amygdala injection of either a 1% lidocaine solution or phosphate buffer (0.5 ul/side). Shifted training continued for two more days and no further injections were given. Shifted animals that received a buffer injection displayed a characteristic increase in response latencies on the 2nd day of shifted training. In contrast, animals that received lidocaine injection showed no increase in latency on either the 2nd or 3rd day of shifted training. The findings indicate that post-training inactivation of the amygdala attenuates behavioral contrast, suggesting that the amygdala is involved in regulating memory for reduction in reward magnitude.

LESIONS OF THE AMYGDALA INHIBIT FEAR REACTIONS IN THE SHOCK-PROBE BURYING TEST BUT NOT IN THE ELEVATED PLUS-MAZE TEST. D. Treit*, S. Rotzinger, and C. Pesold. Department of Psychology, University of Alberta, Canada, T6G 2E9.

The purpose of the present experiments was to investigate the role of the amygdala in anxiety, using two different, pharmacologically validated animal models of anxiety: the elevated plus-maze test and the shock-probe burying test. Experiment 1 showed that animals with complete amygdaloid lesions made significantly more contacts with the electrified probe than sham-lesioned controls, but were not significantly different from controls in the duration they buried the probe or the amount they explored the open arms of the elevated plus-maze. Experiment 2 replicated these results, and showed that rats with larger amygdaloid lesions contacted the electrified probe more than rats with smaller amygdaloid lesions. Experiment 3 showed that amygdaloid lesions did not alter the ability of diazepam to increase open-arm activity in the plus-maze test or to decrease burying behavior in the shock-probe test. Taken together, these results suggest that 1) the amygdala does not mediate the anxiolytic effects of diazepam in these tests, and 2) the amygdala may be involved in the inhibition of some fears [e.g., fear of an electrified probe] but not others [e.g., fear of an elevated, open arm].

PAIRED ASSOCIATE LEARNING IN RATS: CRITICAL INVOLVEMENT OF THE PERIRHINAL-ENTORHINAL CORTEX. M. Bunsey* & H. Eichenbaum, Dept. Psychology & Neurobiogy Curriculum, UNC Chapel Hill, N.C. 27599.

Olfactory-guided learning in rodents can serve as a useful model system for the study of the neurobiological bases of higher order processes in learning and memory. The present experiment involved the development of an odor-guided paired associate task (PA) analogous to the verbal PA task frequently used to assess human memory.

In the present version of the PA task, rats are trained to sniff at an odor port while two different odors are presented in succession, separated by a brief blank interval. If the stimulus sequence involves any one of four arbitrarily assigned paired associates the subject is rewarded for responding at a nearby water port. Alternatively, if the sequence consists of any other combination of the same eight odors ("mispairings") the subject must withhold a response. In addition, the rat must withhold responses on interspersed "non-relational" trials involving one of the eight odors paired with one of four odors from a second set; these odor sequences are never rewarded.

Intact rats learn to discriminate the non-relational trials rapidly, and more gradually differentiate mispairings from paired associates. Rats with bilateral ablation of the perirhinal-entorhinal cortex were profoundly impaired in learning to distinguish mispairings from paired associates. However, the same lesioned rats showed only a mild and transient deficit on non-relational trials. These results support the hypothesis that the hippocampal system is critical to PA learning across species and, more generally, that this system supports memory representations based on arbitrary relationships among perceptually independent cues across stimulus modalities.

MEMORY-BASED LEARNING DEFICITS PERSIST INTO ADULTHOOD AFTER X-IRRADIATION-INDUCED HIPPOCAMPAL GRANULE-CELL HYPOPLASIA IN EARLY INFANCY. N. J. Lobaugh*, J. L. Diaz-Granados, P. L. Greene, & A. Amsel. Department of Psychology & Institute for Neuroscience, University of Texas, Austin, TX, 78712.

Our laboratory has shown that electrolytic hippocampal lesions in infant rats (Lobaugh, et al., *Behav. Neurosci.*, 103:1159, 1989), postnatal exposure to ethanol (Greene, et al., *Behav. Neurosci.*, 106: 51, 1992), and early postnatal hippocampal x-irradiation (Diaz-Granados, et al., *Soc. Neurosci. Abs.*, vol. 16, 1990) all disrupt the acquisition of patterned (single) alternation (PA), a form of memory-based learning, in infant rats. After x-irradiation exposure, pups tested at 17-18 days of age showed a severe deficit in PA with a 60-s intertrial interval (ITI) but not a 30-s ITI. In the present experiment, we examined the effect of early postnatal exposure to x-irradiation on memory-based learning in adult rats at 60-86 days of age. The irradiated animals showed a significant deficit in PA learning at a 60-s ITI when compared to normals and sham controls. The specific reductions of hippocampal dentate granule cells at day 86 were comparable to the reductions in the younger animals of our earlier result. These results suggest that early insult to hippocampal granule-cells by x-irradiation results in lasting memorial and morphological deficits. Supported by NSF grant BNS-8609877.

443.11

A PRELIMINARY ANALYSIS OF THE BEHAVIORAL EFFECTS OF LESIONS OF THE SUPERIOR CEREBELLAR PEDUNCLE IN RATS. R. N. Leaton* and J. M. Kelso. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

A series of tests assessed the behavior of rats with knife-cut lesions of the superior cerebellar peduncle as compared with sham operated controls. In the first of two 20-min sessions in a brightly illuminated open field the lesioned rats were significantly more active than controls. This difference disappeared at the second session 24 hr later. In tests of the acoustic startle response the lesioned rats were significantly more responsive than controls. They showed significantly more robust within-session response decrements than controls. Both groups showed significant response decrements over days, i.e., long-term habituation, but the decrements appeared somewhat more variable in the lesioned animals. On the balance-beam test of motor stability, there was no significant difference between the groups. Neurological examinations revealed some deficit in the lesioned animals in hind-leg placing. Overall we were most impressed with the subtle nature of the behavioral effects in the lesioned animals. Histological analysis showed significant, near-complete bilateral section of the superior peduncle in 6 of the 7 lesioned rats.

443.12

INTACT PROJECTIONS FROM THE MEDIODORSAL NUCLEUS (MDn) OF THALAMUS TO FRONTAL CORTEX IN RATS FOLLOWING PYRITHIAMINE-INDUCED THIAMINE DEFICIENCY (PTD). S.M. Koger* & R.G. Mair. Psych Dept, Univ. New Hampshire, Durham, NH 03824.

Previously we have shown that PTD treatment in rats impairs working memory and produces consistent lesions of the internal medullary lamina (IML) surrounding MDn. Examination of Fink-Heimer stained tissue has shown signs of widespread layer IV cortical denervation, including all areas of frontal cortex. To determine the extent of frontal cortical denervation, we implanted WGA-HRP bilaterally into 10 rats recovered from PTD, aimed at areas of MDn typically spared by this treatment. Rats with IML lesions and partial destruction of MDn showed anterograde and retrograde transport of WGA-HRP to frontal cortex. Rats with near-complete MDn lesions did not. These findings indicate that areas of MDn spared in PTD rats remain connected to frontal cortex.

443.13

MK-801 IMPAIRS LEARNING BUT NOT RETENTION FOR SERIAL PATTERNS IN RATS. J.D. Rowan* and S.B. Fountain. Department of Psychology, Kent State University, Kent, OH 44242.

MK-801 is a N-methyl-D-aspartate antagonist that has been found to impair learning in some behavioral tasks. The effects of MK-801 exposure on learning and retention of serial patterns were examined. Rats were trained in a serial pattern learning task to anticipate elements of one of two patterns. The task required rats to anticipate the correct sequence of leverpresses in an array of levers mounted on the walls of an octagonally shaped operant chamber. Both patterns were highly structured, but one pattern contained a violation of pattern structure. In the first phase of the experiment, male hooded rats were exposed to 0.0625/kg MK-801 by i.p. injection 30 minutes prior to testing each day during acquisition. Rats exposed to MK-801 during acquisition were significantly impaired in learning the patterns compared to saline injected controls. The rats showed impairments primarily in learning the pattern containing the violation of pattern structure. In the second phase of the experiment, saline control rats from the first phase that had already learned their patterns were injected with 0.0625 mg/kg MK-801 to assess its effects on retention of the serial patterns. Compared to saline controls, rats exposed to MK-801 were not significantly impaired in retention. These results support the view that MK-801 impairs the acquisition of new serial patterns but does not affect retention of previously learned serial pattern information.

POTENTIATION OF ODOR AVERSION BY TASTE IS DIFFERENTIALLY AFFECTED BY 6-OHDA OR QUISQUALATE INJECTIONS. J. Fernández-Ruiz,[2] R. Guzmán,[1] M.I. Miranda,[2] F. Bermúdez-Rattoni*,[2] and R. Drucker-Colín.[1,2] [1]Depto. de Fisiología, Facultad de Medicina and [2]Instituto de Fisiología Celular, UNAM, 04510 México DF.

It has been demonstrated that Parkinson's disease patients have an olfactory deficit. One possible cause may be that dopamine depletion of the olfactory structures leads to an olfactory dysfunction. To test this hypothesis we submitted two control groups, three quisqualate and three bilateral 6-OHDA lesioned rat's groups to a modified potentiation of odor aversion by taste paradigm. The regions tested were the insular cortex, the amygdala and the hippocampus dorsalis. At the end of the experiment the 6-OHDA brains were prepared for HPLC. The behavioral results showed that both the injection of 6-OHDA or quisqualate in the insular cortex produce the disruption of taste, but not odor aversions. On the other hand, the lesion of the amygdala with 6-OHDA or quisqualate, caused the disruption of the potentiated odor, but not the taste aversions. Finally, the quisqualate, but not the 6-OHDA lesions in the hippocampus dorsalis produced a disruption of both taste and potentiated odor aversions. The HPLC showed a decrease in catecholaminergic contents of the lesioned sites. These results indicate that the injection of 6-OHDA in the amygdalar region, but not in dorsal hippocampus nor in the insular cortex, produced a severe olfactory deficits. Supported by FIIRESIN and DGAPA-IN-204689.

DIFFERENTIAL BEHAVIORAL EFFECTS OF SINGLE OR COMBINED LESIONS TO THE INFRA- AND SUPRACALLOSAL SEPTO-HIPPOCAMPAL PATHWAYS IN THE RAT: WORKING MEMORY DEFICITS ARE NOT AMELIORATED BY OXOTREMORINE OR PILOCARPINE. **P.L. Greene, J.C. Cassel, C. Kelche, H. Jeltsch & B.E. Will*, L.N.B.C. UPR 419 du CNRS, Université Louis Pasteur, 67000 Strasbourg (France).**

Female Long-Evans rats sustained single electrolytic infracallosal (group IN, n=13) or aspirative supracollosal (group SU, n=12), or combined lesions (group INSU, n=12) of the septo-hippocampal pathways at 90 days of age. Sham-operated animals (group SH, n=13) served as controls. Infra- and supracallosal pathways were chosen because of their differential content of cholinergic fibers. There was an infracallosal lesion-induced (groups IN and INSU) increase in open-field and home-cage activity, and decrease in spontaneous alternation and habituation to novel stimuli 18 days post-lesion. Of these effects, only increased open-field activity and decreased spontaneous alternation were again observed at 75 days post-lesion. Performance in an 8-arm radial-maze task was impaired as well, again only in groups IN and INSU. These differences in radial-maze performance between groups became more robust with a one-minute delay imposed between the 4th and 5th choices. Oxotremorine (0.1 & 0.03 mg/kg) and Pilocarpine (1.0 & 0.32 mg/kg) were ineffective at improving the performance of impaired animals either with or without a delay between the 4th and 5th choices in the radial-maze task. There were no differences between groups SH and SU among the behaviors observed in the present study. The results are discussed in relation to the importance of septo-hippocampal cholinergic pathways in working memory and in terms of the possible relevance of interactions between acetylcholine and other neurotransmitters in memory function.

443.16

IBOTENIC HIPPOCAMPAL LESION IN RAT DO NOT DISRUPT RETRIEVAL: IS PRIOR CUING IN ANIMAL EQUIVALENT TO HUMAN PRIMING? P. GISQUET-VERRIER*[1] AND F. SCHENK[2] [1]Laboratoire de Neurobiologie de l'Apprentissage et de la Mémoire, C.N.R.S., URA-1491, 91198 Gif-sur-Yvette, France & [2]Institut de Physiologie, 7 rue du Bugnon, 1005 Lausanne, Switzerland.

Retrieval processes can be promoted by an exposure to some training features, delivered shortly before the retention test. The effectiveness of a particular cue depends on the nature of the feature and on the length of the training-to-test interval (TTI) (Anim. Learn. & Behav. 1989, 17: 394-408). The aim of the present study was to determine a possible involvement of the hippocampus in the promotion of retrieval processes, either shortly (1 day) or distant to training (21 days). Rats receiving bilateral ibotenic acid lesions of the hippocampus were compared to sham-operated animals. They were trained for 15 trials in an avoidance brightness discrimination. After a 1-day and a 21-day TTI separate groups of animals were submitted to a retraining session. Before the testing session, cued animals were briefly exposed either to the CS or to the experimental context. The facilitation of the performance induced by pretest cuing was qualitatively and quantitatively identical in hippocampal and in sham-operated animals. After a 1-day TTI, animals in both conditions showed an improvement of their retention performance subsequent to a CS exposure. After a 21-day TTI, a pretest exposure to the experimental context was the only effective procedure promoting retrieval in both lesioned and sham groups. However, all the lesioned animals showed a characteristic deficit in performance when submitted to a radial maze task, demonstrating that the lesions successfully impaired learning in tasks requiring an intact hippocampus.

In sum, these results demonstrate that the hippocampal formation does not seem to be implicated in the promotion of the retrieval processes by prior cuing in rats. Given that human priming is also preserved following hippocampal lesions, the present results suggest a possible similarity between the processes involved in human priming and in animal prior cuing. Supported by ETP twinning grant 9040.

RF LESIONS OF THE LATERAL INTERNAL MEDULLARY LAMINA (L-IML) OF THALAMUS IN THE RAT INCREASE THE RATE OF TEMPORAL DECAY OF A DELAYED NON-MATCHING TO SAMPLE TASK. E.E. Kivlahan* & R.G. Mair. Dept. of Psychology, University of New Hampshire, Durham, NH 03824.

36 rats were matched for performance on a DNMTS task and then randomly assigned to control or to 1 of 3 lesion groups: L-IML, mediodorsal nucleus of thalamus (MDn), or fornix (Fnx). After recovery, rats were trained to stability on DNMTS at 6 delays from 1.8 to 8.8 s. L-IML animals performed significantly worse than all other groups, exhibiting significantly faster rates of decay up to 6.3 s (when their performances reached chance level). MDn and Fnx rats were not significantly impaired on DNMTS. All 3 lesion groups were significantly impaired compared to controls when subsequently trained on an 8 arm radial maze task.

444.1

CORTICAL CYTOARCHITECTURAL ABNORMALITIES CORRELATE WITH COGNITIVE DEFICITS IN MICE. C.F. Hohmann*, J.E. Sweeney, E.Bachman, and J.T. Coyle. Kennedy Krieger Institute, Baltimore, MD; Wellesley College, Wellesley, MA; Harvard/ MGH, Boston, MA.

In neonatal mice, lesions of the basal forebrain (nBM) projections to cortex result in transient cholinergic denervation which lead to persistent changes in cortical connectivity and cytoarchitecture. Because these cytoarchitectural abnormalities resemble morphological changes observed in human mental retardation, this is a model for developmental disabilities. We have shown previously that nBM lesions in neonates result in increased motor activity, decreased passive avoidance retention latencies and increased swim maze latencies in adult mice. The purpose of this study is to determine whether there are correlations between histological abnormalities and behavioral impairments in these mice. 25 Balb/cByJ mice received lesions to the nBM 12-24 hours after birth. Behavioral testing began at 8 weeks and included assessments of motor activity, retention (passive avoidance task) and cognition (swim maze task). Following behavioral testing, 9 mice were killed for Nissl and AChE histology. Morphological abnormalities were evaluated and scored. Lesions varied in size, anterior/posterior and medial/lateral extent of damage and severity of resulting cortical abnormalities. Independent of lesion location and size, cortical AChE intensity and distribution were comparable to controls. Motor activity did not correlate with passive avoidance or swim maze latencies. Additionally, lesion location, size and cortical cytoarchitectural abnormalities did not correlate with motor activity or passive avoidance retention latencies. Cortical histology did, however, correlate with swim maze latency($r^2 = 0.85$; $p = 0.003$), i.e., severely abnormal cortical morphology predicted high swim maze latencies. These data indicate that cortical cytoarchitectural abnormalities resulting from nBM lesions in neonates correlate with impairments on a cognitive task, but not on activity-related measures in adult mice. Thus in this lesion model and, by extrapolation, in mental retardation structural changes in the cortex which result from ontogenic abnormalities could lead to functional changes later in life.

444.2

GENDER DIFFERENCES IN BEHAVIORAL STRATEGIES AND RESPONSES TO CHOLINERGIC DRUGS. J.E. Sweeney*, R.T. Richardson and C.F. Hohmann. Wellesley College, Wellesley, MA; Johns Hopkins University, Baltimore, MD; Kennedy Krieger Institute, Baltimore, MD.

We have shown previously that basal forebrain lesions in neonatal mice lead to persistent behavioral impairments in adult mice. We now intend to test whether cholinergic reconstitution therapy with physostigmine (PHY) can ameliorate the lesion-induced deficits. Our behavioral studies include both female and male mice because lesions are performed in pups when gender is not readily detectable. Gender differences have been reported in other behavioral paradigms, thus, we decided to assess the performance in the control female and male population on a passive avoidance and spatial navigation task before and after administration of PHY. In passive avoidance, mice were injected with either saline or PHY (0.1 mg/kg, i.p.) after acquisition, then retention latencies were measured 24 hours later. In the spatial navigation task, mice were trained to swim to a hidden platform and then were injected with either saline or PHY (0.1 mg/kg, i.p.) 15-20 mins before testing. Small sex-related differences in performance existed in the absence of drug treatments, most notably, in acquisition of spatial navigation. Analyses of swim paths and patterns suggest that females and males use different strategies. The most dramatic differences in performance, however, occurred in response to PHY. The same dose of PHY significantly increased passive avoidance latencies (76.9 ± 26 to 168 ± 12 s) and decreased swim latencies (19.9 ± 2 to 11.1 ± 3 s) in males but did not significantly alter performance in females. Full dose response curves are currently being generated to characterize gender differences in response strategies and sensitivity to PHY and other cholinergic drugs.

INTERACTIONS BETWEEN EMOTION AND MEMORY FORMATION. A PROPOSED HYPOTHESIS. D. Galey*, Laboratoire de Neurosciences comportementales et cognitives, CNRS URA 339, Université Bordeaux I, avenue des Facultés, 33405 Talence Cedex France.

Using two inbred strains of mice (BALB/C and C57BL/6), we have attempted to elucidate the relationships between memory processes and the modulation of activity of the septo-hippocampal cholinergic pathway.

At first, we have shown in BALB/c mice that medial septal stimulation (30 µA, 100 Hz) applied 30 sec after the partial acquisition of an operant lever press conditioning increased subsequent retention performance 24 hours later with a temporal gradient of the stimulation effect less than 15 min. This result suggests that the stimulation improved consolidation processes. In these conditions, C57BL/6 which display the greater increase in septo-hippocampal cholinergic activation evidenced poor consolidation abilities (GALEY et al., submitted for publication). Additional analysis revealed in fact that these two parameters are negatively correlated. Thus it is suggested that the consolidation of informations would be possible only after a decrease of the level of cholinergic activation.

Finally, our data suggest the systems by which emotional states could act on information processing and storage through the modulation of the septo-hippocampal cholinergic pathway.

LEARNING-ASSOCIATED CHANGES IN MONOAMINE RELEASE IN THE RAT BASAL FOREBRAIN. K. Kariya*, J. Tanaka, K. Hori, M. Oda, M. Iwaki and M. Nomura. Sect. of Pharmacol. Res. Lab., Torii & Co., Ltd, Chiba 272, *Dept. of Physiol., Saitama Med. Sch., Saitama 350-04, Japan

Extracellular levels of monoamines and their metabolites were measured by the microdialysis method combined with high performance liquid chromatography in the region of the nucleus basalis (NB) in rats before, during and after a learning test to examine whether inputs from brainstem monoaminergic system to the basal forebrain are involved in the learning process. In male Fischer 344 rats (n = 12) which have acquired the operent-type brightness discrimination learning, dopamine (DA), dihydroxy-phenylacetic acid (DOPAC), homovanillic acid (HVA), and 5-hydroxyindole acetic acid (5-HIAA) levels during the learning test showed a trendancy to increase as compared with the pre-learning period. The percent increases in the monoamine and metabolite concentrations were then compared with various parameters of learning. There were significant positive correlations between the percent increases in DOPAC, HVA and 5-HIAA concentrations and the correct response ratio. The percent increases in the concentrations of metabolites, on the other hand, were significantly correlated with neither the total responses nor the reinforcements. These results imply that the monoaminergic inputs to the basal forebrain may play an important role in the learning process.

EXPRESSION OF IEGs DURING ODOR DISCRIMINATION: ELEVATION OF C-FOS LEVELS OBSERVED IN HIPPOCAMPAL SUBFIELD CA3. U.S. Hess*, R. Nabi, U. Staubli, C. Gall[1], and G. Lynch. Center for the Neurobio. of Learning & Memory, [1]Dept. of Anatomy and Neurobio., Univ. of Calif., Irvine, CA 92717.

The IEGs c-fos and zif-268 are rapidly and transiently expressed in response to increases in neuronal activity in the CNS following various experimental manipulations. Proteins encoded by these rapid response genes may act as transcription factors that regulate the expression of downstream target genes, and so therefore function as mediators of long-term responses such as those necessary for the consolidation of memory. In support of this idea, Campeau *et al.* (1991) showed that conditioned fear dramatically elevates c-fos mRNA levels in the amygdala. We used c-fos and zif-268 ^{35}S cRNA probes and *in situ* hybridization to investigate the effect of odor discrimination learning on IEG expression in the rat brain. Initially, we found that handling rats for the first time and/or placing them in a novel environment (the training apparatus) elevates c-fos and zif-268 mRNA levels significantly above control levels in regions such as hippocampus and rostral piriform cortex. This effect was more pronounced for c-fos than zif-268, and was greater in the CA1 than in the CA3 subfield of the hippocampus for both IEGs. These responses were decreased significantly by repeated handling and immersion in the training environment. To determine if specific brain regions are activated in experienced animals performing a novel odor discrimination, we compared c-fos and zif-268 expression levels in two groups of rats. Rats in both groups had been previously trained to solve seven odor discriminations between two simultaneously presented odors. On the last day, some of these animals (n = 19) performed on an eighth odor discrimination (for 30 min) and the remainder (n = 15) were simply placed in the training apparatus (for 10 and 30 min) as "context controls." Animals were perfused 30 min after their last experimental treatment. Animals actively performing the task had significantly higher c-fos levels in CA3 when compared to context controls ($p = 0.03$, unpaired t-test). Such a change in c-fos expression was not found in area CA1 or three other regions measured, nor was it found for zif-268 expression levels in the same regions in adjacent tissue sections. These results suggest that selective areas of the brain exhibit enhanced IEG induction/activity during odor discrimination behavior.

AGE-RELATED PERFORMANCE ON ODOR-GUIDED DELAYED NONMATCH TO SAMPLE AND WATERMAZE LEARNING. D. Zyzak, H. Eichenbaum*, T. Otto, and M. Gallagher. Dept. of Psych. Univ. of North Carolina, Chapel Hill, N.C. 27599

Recent work from this lab has shown substantial variation in the spatial learning abilities of aged rats, such that some aged rats are impaired in the Morris water maze task, while others perform as well as young rats. In the present study we assessed the effects of aging on nonspatial cognitive performance in odor-guided continuous delayed nonmatch to sample (cDNM). Rats were initially trained to perform the cDNM task under minimal delay and interference conditions, then challenged with longer memory delays and increased inter-item interference. These same rats were then tested in the Morris water maze to compare performance across the two tasks.

As in the maze task, we found a substantial variation in aged rats' ability to acquire the cDNM task. Aged rats were significantly retarded in acquisition of the cDNM task, however they were only slightly, if at all, impaired in later testing under increased interference and memory delay conditions. Furthermore, cDNM acquisition scores of aged rats were related to performance in spatial learning. Thus, when aged rats were distinguished according to their maze performance, only maze impaired rats required significantly more trials to learn the cDNM task. These results reveal a relationship between the effects of aging on spatial and non-spatial tasks that may reflect a more broadly based deterioration in cognitive function than that commonly ascribed to a spatial memory impairment.

VIGILANCE AND SELECTIVE ATTENTION IN RATS USING AUDITORY STIMULUS DETECTION. P.J. Bushnell*[1] and K.L. Kelly[2]. [1]Neurotoxicology Division, US EPA and [2]ManTech Environmental Technology, Inc., Research Triangle Park, NC 27711.

Vigilance involves maintaining attention to repeated stimuli over time, and selective attention may be inferred from changes in behavior due to manipulation of the likelihood (expectancy) of discriminative stimuli. To study vigilance, rats worked in operant chambers in which an auditory signal (a 20-msec increase of 1 to 7 dB in the intensity of continuous white noise) was presented on half of the trials. A food pellet was delivered if the rat pressed one of two retractable response levers on a signal trial, or if it pressed the other lever on a blank (no signal) trial. Signal detection analysis showed monotonic increases in both sensitivity (sensitivity index, SI) and bias (response index, RI) with increasing signal intensity, showing that the accuracy of signal detection improved and the criterion for responding "signal" became more lenient as signal intensity increased. Acute exposure to toluene vapor (2000 ppm) reduced SI at all signals greater than +1 dB without changing RI. Selective attention was studied with a similar procedure which required rats to detect either a 50 msec increase (+7 dB) or a 50 msec decrease (-6 dB) in continuous white noise. The probability of signal type (increase or decrease) did not affect SI when both signal types required the same response (e.g., press the left lever) and blank trials required the other response (e.g., press the right lever). However, the probability of signal type greatly affected response accuracy when each signal required a different response. These results suggest the importance of the response in demonstrating effects of expectancy on selective attention in rats.

EFFECT OF LESIONS IN THE MFB AT THE DIENCEPHALIC-MESENCEPHALIC BORDER ON THE REWARDING EFFICACY OF LH SELF-STIMULATION. M. I. Leon* and C. R. Gallistel. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563. Electrolytic lesions in the medial forebrain bundle at the junction between the posterior hypothalamus and ventral tegmental area were found to attenuate the rewarding efficacy of stimulation at the level of the lateral hypothalamus, as measured by the shift in the rate-frequency functions at several different currents. These results are consistent with findings by Waraczynski and her collaborators, that MFB knife cuts attenuate the rewarding efficacy of stimulation at sites rostral to the cut, but often have no effect on the rewarding efficacy of stimulation at sites caudal to the cut. A surprising finding was that our lesions had to be reasonably large (300 μA cathodal current for 200 s) before any decrease in rewarding efficacy of stimulation became evident.

444.9

MATCHING BEHAVIOR IN RATS SELF-STIMULATING IN THE MEDIAL FOREBRAIN BUNDLE. T. A. Mark*, J. C. Sim, and C. R. Gallistel. Dept. of Psychol., UCLA, Los Angeles, CA 90024-1563.

Rats pressing two levers for brain stimulation reward on concurrent variable-interval schedules allocate their time between the levers in accord with relative reward abundance (subjective reward magnitude multiplied by rate of reward) - the matching law. This preparation may therefore provide a model system in which to study the neurobiology of elementary computational processes. We studied the kinetics of matching after step changes in the relative reward magnitudes, the relative rates of reward, or both. Rats very rapidly altered their relative time allocation (time on one lever/time on the other lever) in response to a change in either component of relative reward abundance. Transitions were commonly complete after one interreward interval on the leaner schedule. Relative time allocation tracked the random short term fluctuations in relative interreward intervals inherently present in two concurrent Poisson processes; hence, the extent to which rats conformed to the matching law depended on the method used to estimate overall relative reward rates and overall time allocations. [Supported by NSF Grant BNS 89-96246.]

REWARD SATURATION IN ELECTRICAL SELF-STIMULATION OF THE MFB. Janine M. Simmons* & C. R. Gallistel. Interdepartmental Neuroscience Program, UCLA, Los Angeles, CA 90024-1563.

Rats press a lever to deliver a train of brief electrical pulses to the medial forebrain bundle (MFB). The time the animal spends on the lever depends on the remembered effect of the stimu-lation (the subjective magnitude of the reward). Increases in either current or pulse frequency increase the subjective reward magnitude, but only up to a frequency called the saturation frequency, above which reward magnitude no longer increases. We used a two-lever choice paradigm with variable interval schedules on both levers to determine the subjective reward magnitude as a function of pulse frequency at currents ranging from 1000 mA down to the 'current wall.' We find that the saturation frequency depends strongly on current, varying from 251-631 pps at the lowest currents (100-251 mA) to 63-200 pps at a 1000 mA. Increasing current shifts the function for reward-magnitude-versus-pulse-frequency to the left and sometimes increases its asymptote. These results make it unlikely that the saturation is due to a failure of frequency following in the first-stage axons.

EVIDENCE THAT HIPPOCAMPAL PLACE CELL REPRESENTATIONS OF MULTIPLE ENVIRONMENTS ARE NOT STRICTLY TOPOGRAPHIC. J.L. Kubie*, R.U. Muller, E.S.Hawley and C.P. Jia. Depts of Anatomy and Physiology, S.U.N.Y. Brooklyn, Brooklyn, NY 11203

The discovery of hippocampal place cells led to the hypothesis that the rat hippocampus is involved in spatial representations of the environment (O'Keefe and Nadel, 1976). Two questions that arise are: 1) How are multiple environments represented? and 2) Are the environments topographically mapped within the hippocampus? Previous work implied that there are independent representations of different environments (Muller and Kubie, 1987), but left open the question of topographic organization (Eichenbaum et al, 1990).

In this study we trained rats to chase food pellets in a square chamber and a cylinder. To date, we have recorded 7 sets of at least two cells in each environment. When two cells have firing fields in one environment, the relationship between the fields is called either overlapping or disjoint. We often see that a pair of cells with overlapping fields in one environment has disjoint fields in the second. These observations corroborate the idea of independent representations of different environments. They also strongly imply that the hippocampal representation of space is not topograhic. In addition, we find that temporal cross-correlations for pairs of simultaneously recorded cells are greatly affected by the animal's current environment. This result has consequences for theories of how the representation of a particular environment is established and maintained. (Supported by NIH NS20686).

A RAT MODEL FOR ENDOGENOUS ATTENTION DEFICIT-HYPERACTIVITY DISORDER (ADHD). J.G. Kohlert*, S. Shillingford, R.Mills, D.E.Fleming and G.J. Bloch Dep't Psych., Brigham Young U., Provo,UT, 84602.

Animal models for ADHD have been proposed; however, they are not "pure";i.e., these "hyperactive" animals have been made so by electrical/chemical brain lesions, by pharmacological agents, or by genetic breeding but coupled with hypertension or an abnormal response to stress (Anderson, Dev Pharm,'83; Hendley, Am Phys Soc, '91; Kerr, Pharm Biochem,'91; Sagvolden, Neurosci,'91). Based on our observations that some male rats are hyposexual and also hyperactive, we determined that they portray characteristics representative of ADHD. These rats, which have not been rendered abnormal by any external manipulation, respond as do humans: 1) they are significantly more active than controls on open-field testing; 2) they respond in a paradoxical fashion to the psychmotor effects of amphetamine; 3) they show deficits in selective attention by failing to block irrelevant information in a conditioned avoidance response; and 4) preliminary evidence suggests they are more distractable. These data indicate that these rats may be an excellent model for the study of Attention Deficit-Hyperactivity Disorder.

LESIONS OF THE NUCLEUS ACCUMBENS IN ADULT RHESUS MONKEYS RESULT IN A DEFICIT OF MOTOR LEARNING BUT NOT IN S-R ASSOCIATIVE LEARNING OR MEMORY. R. Killiany* and H. Mahut, Department of Psychology, Northeastern University, Boston, MA 02115

Nearly 45 years ago, Ryle postulated that memory was not a unitary phenomenon but rather consisted of at least two components he identified as "Knowing How" and "Knowing That" (Ryle, 1949). Hirsh (1974), among others, has further modified these components into a primitive S-R learning system (habit) and a hippocampal memory system, respectively. The nucleus accumbens (NA) by virtue of its suggested role in reinforcement systems appeared as a promising component of the habit system. Therefore, we tested the notion that lesions of NA would result in an impairment of S-R types of learning. Accordingly, 8 adult monkeys, 4 with bilateral ablations of NA, 2 sham operated monkeys and 2 unoperated control monkeys, were tested on two versions of the concurrent object discrimination task (COD), a delayed recognition memory task (DNMS) and a motor skill task which required the monkey to remove a lifesaver from different patterns of bent wire.

Contrary to our prediction, monkeys with NA lesions were not impaired on the COD tasks or the DNMS task. Surprisingly however, they were significantly impaired on the lifesaver task. Ongoing histological verifications of the lesion will clarify whether this impairment of motor skill learning can be attributed directly to NA damage or is the result of inadvertent damage to adjacent subcortical structures.

A METHOD FOR THE SEPARATION OF ATTENTION AND MEMORY IMPAIRMENTS FROM MOTIVATIONAL AND NON-SPECIFIC DEFICITS DUE TO WORK SCHEDULE SHIFTS. **W.N. Tapp*, R.J. Servatius, T.A. Pritzel, S.D. Drastal, M.T. Bergen, V.A. Medical Center, E. Orange, NJ 07019 & New Jersey Med. Sch., Newark, NJ.**

Circadian rhythms have profound effects on arousal, memory, and attention. Using rhesus monkeys, we previously explored the effects of different light:dark schedules, including 6 hr phase-shifts, on task performance. However, our vigilance task could not discriminate between attention deficits and motivational or other non-specific changes which caused monkeys to not attempt to work on the task. Further, the previous task limited our ability to examine effects on memory versus cognitive effects on task performance. The current report describes a new chained vigilance-delayed same-different (DSD) task which vastly improves our ability to identify the type of deficit produced by light schedule shifts. The new task employs 3 levers and a tricolored cue light at the face of the cage. The monkey must begin each trial by making a check-in response indicating that it is willing to work on the trial. This specific "willingness-to-work" measure can be used to separate motivational changes (e.g. due to satiation) and non-specific effects. Once a monkey has indicated that it will work on a trial, we test "attention" using a 10 sec vigilance trial with a 0.2 sec light stimulus. Signal detection methods are used to examine changes in sensitivity and bias. Finally, the DSD task can be used to test the monkey's ability to perform a rule-based same different task and memory can be tested by imposing increasing delays between the test and target stimuli. Thus, this task increases our ability to discern motivational or non-specific effects of circadian and pharmacological treatments from attention-, cognitive-, and memory-based effects. BASAL FOREBRAIN (BF) LESIONS IN MONKEYS PRODUCE IMPAIRMENTS IN ATTENTION. M.L. Voytko*, D.S. Olton, R.T. Richardson and D.L. Price. Neuropathology Laboratory, The Johns Hopkins University Sch. of Medicine, Balto., MD 21205.

We have shown that BF lesions in monkeys do not produce severe impairments in learning or memory [*Soc. Neurosci. Abstr.* 16:617, 1990]. Because the BF may be involved in attention processes, a covert orienting paradigm was used to examine attention in these monkeys. To obtain rewards, monkeys with BF lesions (n=3) and controls (n=2) were required to detect a target at one of two lateral positions. A cue directed attention to either the target location (valid trials) or an alternate location (invalid trials). Time to release a central panel and time to hit the target were measured as a function of cue location. For both groups, time to release was more rapid on valid trials. However, lesioned monkeys were slower to release for both types of trials, particularly invalid trials. Motor impairments cannot account for these group differences because time to hit the target was similar between groups. These findings suggest that, although BF lesions may not directly disrupt mnemonic processes in primates, attentional processes may be affected.

444.16

TEMPORAL ORDER MEMORY IN MONKEYS IS IMPAIRED BY MEDIAL THALAMIC LESIONS. E.C. Gower.* Boston VAMC and Boston University School of Medicine, Boston, MA 02130.

Given a list of objects to remember, normal monkeys can later retrieve information about both object identity, and - as we have recently demonstrated - object order. In the order recognition task, several objects are presented individually and in succession; two of them are then paired for a forced-choice test in which the object that had appeared earlier in the list is correct. Monkeys can discriminate the order of any pair of objects from a list of at least five, and like human recency judgments, their accuracy depends on the lag of both objects in the probe. Here we show that monkeys with lesions in the limbic thalamus who have only a modest object recognition impairment do not discriminate object order.

On any trial, a sample list of 2, 3, 4 or 5 randomly-selected objects appeared at 10 s intervals. Each list was followed by a single probe trial in which two objects from the previous list were presented simultaneously. Probes contained either two adjacent objects (eg., AB, BC or CD in a 4-object list) or two end objects (eg., AD), with the earlier object the correct and reinforced choice. Forty trials were collected in each of the 13 conditions in the experiment. Two normal monkeys selected the earlier object in the probe 72.5 and 72.7 % of the time and their performance was lag-dependent. In contrast, two monkeys with medial thalamic lesions made correct choices 63.3 and 64.6 % of the time, which is above chance by Chi-square tests of significance but also impaired relative to controls. Only in those conditions where the last object in the list appeared in the probe were their choices nonrandom, and in contrast to normal performance accuracy in discriminating the order of end objects did not increase with list length. Whereas normal monkeys possess a complete and ordered mnemonic representation of the list, the experimental monkeys appear to be be capable only of assigning a list position to the most recent object. Korsakoff alcoholic amnesics and patients with lesions in the frontal lobes are impaired in processing information sensistive to the time of occurrance of events. The present results suggest that the medial thalamus may play a specific role in these disorders of temporal memory.

LOCUS COERULEUS UNIT ACTIVITY IN RESPONSE TO NOVELTY AND CHANGE ENCOUNTERED DURING ENVIRONMENTAL EXPLORATION. S.J. Sara*, A. Vankov and A. Hervé, Inst. A. Fessard, CNRS, Gif/Yvette, FRANCE.

During learning, marked but short-lived phasic responses occur in Locus Coeruleus (LC) units when stimulus-reinforcement contingency is changed. LC units also respond robustly to novel stimuli and habituate rapidly (Sara & Segal, 1991). To further investigate the role of the noradrenergic (NA) system in learning and attention processes, LC cell activity was monitored in behaving rats, by means of movable microelectrodes, during free exploration of a cue controlled environment. The testing chamber was a closed arena with holes in the floor under which various objects were placed. The precise temporal pattern and duration of inspection of individual holes was monitored by photocells such that LC spikes could be displayed as peristimulus time histograms around the visits to particular holes. The LC unit tended to fire in bursts at the first encounter with a novel object, the response habituating during subsequent visits. Some cells fired on the first encounter with an empty hole, but most empty holes did not elicit the bursting activity. Control for the NA nature of the cells was achieved by injection of alpha$_2$ receptor agonist or antagonist which inhibited or enhanced, respectively, spontaneous firing. The results further demonstrate the engagement of the LC in the presence of change in environmental stimuli, as seen in the conditioning experiments. The NA released at this bursting activity promotes gating and tuning of forebrain responses necessary for stimulus selection and cognitive adaptation.

PREFRONTAL CORTEX COGNITIVE DEFICITS IN EARLY-TREATED PKU (ET-PKU) DUE TO DOPAMINE DEPLETION: RESULTS OF A LONGITUDINAL STUDY IN CHILDREN & OF AN ANIMAL MODEL A. Diamond[*1,2], V. Ciaramitaro[2], E. Donner[2], W. Hurwitz[1], E. Lee[1], W. Grover[3], & C. Minarcik[4]. [1]Dept. of Psychology & [2]Inst. of Neurological Sci.s, U. of Penn., Phila., PA. [3]Neurology, St. Christopher's Hospital for Children, Phila., PA. [4]Pediatric Neurology, Cooper Medical, Camden, NJ.

Clinical opinion has considered (1) diet sufficient treatment for PKU & (2) phenylalanine (phe) levels of $\leq$10 mg/dl safe. Results of longitudinal study of 44 infants, toddlers, & young children treated since birth for PKU or hyperphenylalaninemia show otherwise: These children performed poorly on a variety of prefrontal tests at all 3 age ranges, though normally on control tasks, including those requiring parietal or medial temporal lobe function, relative to matched controls, siblings, & a normative sample. Children with higher phe levels (e.g., 6-10 mg/dl) performed worse on prefrontal tests than those with lower levels. *In the same child* over time, performance covaried inversely with blood levels of phe. Cognitive deficits appeared reversible at least through 1 year.

An animal model of ET-PKU tested our hypothesis that the effect on prefrontal function is mediated by a selective dopamine depletion: Rat pups received daily injections of α-methyl-phe (24 μmol/10g body wt) & phe (12 μmol/10g body wt); their littermates received saline injections. A 3rd group was exposed to α-methyl-phe & phe prenatally & postnatally. Relative to controls, the 2 experimental groups had elevated phe levels (like those in ET-PKU & hyperphe), showed impaired performance on the prefrontal task (delayed alternation), & had lower DA & HVA levels specifically in medial prefrontal cortex & anterior cingulate cortex. (Support: NIMH #MH41842, MRRC, March of Dimes, BRSG #RR07083-26).

445.1

LEARNING-INDUCED INCREASE OF TONE-EVOKED RESPONSE IN THE AUDITORY THALAMUS DURING PARADOXICAL SLEEP.

E. Hennevin*, C. Maho and B. Hars. Laboratoire de Neurobiologie de l'Apprentissage et de la Mémoire, URA 1491, Université Paris XI, 91405 Orsay Cedex, FRANCE.

We have previously provided behavioral (Behavioural Brain Research, 18:241, 1985) and electrophysiological (Psychobiology, 19:193, 1991) evidences that a relevant stimulus can be detected during paradoxical sleep (PS). We report here that when an acoustic stimulus has acquired significance by conditioning during waking, its processing in the auditory system is enhanced during PS. After 1 session of habituation to a tone, waking rats underwent 3 conditioning sessions with the tone as CS preceding a footshock. After each session, the same tone was presented during PS phases, without any awakening of the animal. Multiunit activity in the medial division of the medial geniculate body was recorded at each tone presentation during waking and during PS. After conditioning, tone-evoked response was increased both in the waking and PS states. No such changes were observed in pseudoconditioned animals receiving unpaired tone-shock presentations. Increased responses to meaningfull stimuli, occurring in the sensory pathways on a background of limited responsiveness, could explain how an organism in PS is able to discriminate a relevant stimulus from all the other inputs.

445.2

THE FORMATION OF LONG-TERM HABITUATION TO SPATIAL NOVELTY MODIFIES THE STRUCTURE OF POST-TRIAL SLEEP IN RATS.

P.Mandile, P.Montagnese, S.Vescia[2], A.G.Sadile[3], and A.Giuditta (SPON: European Brain and Behaviour Society). Dipt. Fisiologia Generale ed Ambientale; [2]Dipt. Scienze Relazionali; [3]Dipt. Fisiologia Umana "F.Bottazzi", Univ. Naples, Naples, Italy.

To investigate the role of post-trial sleep in the elaboration of memory traces (Physiol.Behav., 51:217, 1992), a series of experiments was run to study its role in the formation of long-term habituation (LTH) to spatial novelty. Adult male Sprague-Dawley rats with chronically implanted cortical electrodes for EEG recording were exposed to a Làt-maze, and horizontal (HA) and vertical (VA) activity were counted during two 10min test trials at a 3 h or 24 h interval. EEG conventional recordings taken during 3 h under baseline conditions (day 0), and after exposure to the maze (day 1), were analyzed as to the number (n) and mean duration (d) of paradoxical sleep (PS) and synchronized (SS) sleep episodes followed by PS (*SS-->PS*) or by wakefulness (*SS-->W*). A significant LTH of HA and VA associated with LTH of emotionality index (defecation score: LTH-E) was accompanied by an increase in the (n) and (d) of post-trial SS-->PS (but not SS-->W), concerning episodes longer than 4 min. Further, correlative analyses among behavioral and sleep parameters showed that SS-->PS (and not SS-->W) (n) and (d) covaried positively with LTH-HA in all three hours, and with LTH-VA in the 2nd and 3rd h. In contrast, LTH of HA and VA dissociated from LTH-E, was accompanied by a lower SS (n) in the 1st h and a higher SS (d) in the 2nd h, with no change in SS-->W episodes. Correlative analyses showed that LTH-HA and VA covaried positively with SS-->PS, and negatively with SS-->W episodes, whereas LTH-E covaried negatively. The different time-dependent correlative profiles for HA, VA and E, with a prevailing cognitive or non cognitive content, respectively, suggest their sequential/parallel processing during both sleep phases, thus confirming the validity of the *sequential hypothesis* of sleep function.

445.3

INHIBITION OF DAY-TIME MEMORIES DURING NON-REM SLEEP AND SUPPRESSION OF MEMORIES OF DREAMS IN THE HIPPOCAMPUS.

Yoichiro Kuroda* and Satoshi Fujii#, Dept. of Molecular and Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience, Fuchu, Tokyo 183 and #Dept. of Biochemistry and Molecular Biology, Kyorin University, School of Medicine, Mitaka, Tokyo 181, Japan.

A "tracing circuit association" model has been proposed in which multimodal memory traces in cortical cell assemblies (tracing circuits) are consolidated by prolonged tracing through cortico-hippocampal projections and associated by LTP in intra-hippocampal connections (Kuroda,Y.: *Concepts in Neurosci.*2:221, 1991). However, such multimodal associative memory connections in hippocampus would be easily saturated. Here, we propose a hypothesis that erasing of weaker connections occurs during non-REM sleep. Repetitive low-frequency stimulation (more than 1000 pulses at 1-2 Hz) of excitatory input cause depotentiation(DP) of LTP(not PTP) in CA1 neurons in the slice, as well as long-term suppression of LTP (LTS; LTP cannot be formed for approx.60 min.). LTD is not induced by the stimulation. (Fujii,S.et al.: *Brain Res.*,555:112, 1991). Such low frequency(1-2 Hz) activity of hippocampal neurons is observed as the slow wave during non-REM sleep in rat (Suzuki,S.et al.:*Electroencephal. Clin. Neurophysiol.*, 67:348,1987). Therefore, LTP of intrahippocampal connections can be reversed by DP with only strong LTP persisting after sleep. During sleep, especially REM-sleep, random associations of cortical activities (dreams) should be memorized by the association model, however, LTS caused by previous non-REM sleep may have inhibited formation of associative memory by LTP in REM-sleep. Some dreams may occasionally be stored by PTP and by strong LTP in the hippocampus which LTS fails to inhibit.

445.4

SUPPRESSION OF LTP INDUCTION IN THE DENTATE GYRUS DURING ALERT WAKEFULNESS BUT NOT DURING "ENHANCED" REM SLEEP AFTER AVOIDANCE LEARNING

C.Bramham[1], C.Maho[3], W.Yonekawa[*2], S.Laroche[3]. [1]University of Bergen, Norway, [2]NIH, Bethesda, USA, and [3]C.N.R.S., Gif-sur-Yvette, France

Rapid eye movement (REM) sleep is thought to play a critical part in memory formation. Learning events, such as active avoidance conditioning, are followed by a transient increase in the amount of REM sleep which is necessary for normal memory retention.

Rats were chronically implanted for unilateral stimulation of the perforant path and recording of evoked potentials in the dentate hilus. Test potentials were collected during REM sleep and a still-alert (SAL) behavioral state. After baseline recording rats were trained on a 40 trial shuttle-box avoidance task. Conditioned rats exhibited a significant increase in the duration of REM episodes relative to pseudoconditioned, yoked controls. High-frequency trains were applied during the second, third and fourth post-trial REM episodes. Another group was tetanized at the same time points during SAL. LTP was reliably induced during both SAL and REM following pseudoconditioning. In the learning group, however, tetanization in SAL failed to elicit LTP of the EPSP slope (8% increase) while normal LTP developed after tetanization in "enhanced" REM (32% increase). There was no difference in the magnitude of population spike LTP.

We conclude that avoidance learning affects subsequent LTP induction in a state-dependent manner, allowing normal induction during post-trial REM but suppressing it during alert wakefulness.

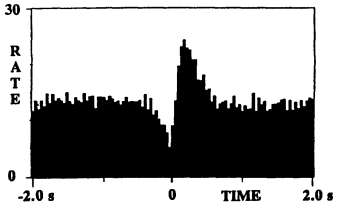
SACCADES MODULATE UNIT ACTIVITY IN MEDIAL TEMPORAL LOBE IN THE DARK

J.L. Ringo* and S. Sobotka, Physiology, U. of Rochester

In primates, saccadic eye movements frame the visual input. They may then serve to enforce synchrony onto visual and mnemonic processing. Thus, we thought to look in the hippocampus and nearby temporal cortical areas for unit activity coupled to eye movements. Such responses turn out to be common, strong, and widespread, in both light and dark. It was found through 12 of 16 implanted guide tubes aimed at hippocampus, inferotemporal and medial ventral cortex.

In our sample analyzed to date (n > 300, 3 monkeys), over 25% of the single units showed clear responses coupled to eye movements in the dark. For some cells, the altered activity begins 100ms before the saccade. Both increased and decreased activity were seen. Responses were usually dependent upon the eye movement's direction.



Post-stimulus time histogram taken in the dark, triggered on each saccade (0 on abscissa). The ordinate is in spikes/sec.

A HEAD-FIXED PREPARATION FOR ELECTROPHYSIOLOGICAL STUDIES OF LEARNING AND MEMORY IN THE BEHAVING RAT.

H. Eichenbaum and K.J. Shedlack* Dept Psychology & Neurobiology Curriculum, Univ. North Carolina, Chapel Hill NC 27599, and Dept. Psychiatry, Duke Univ. Medical School, Durham, NC 27710.

A number of electrophysiological investigations of learning and memory could be more directly controlled and more easily accomplished in behaving rats if one could fix the animal's head in space and utilize recording techniques conventional in acutely anesthetized preparations. The successful development of a head-fixed behaving rat preparation depends on a long-lasting rigid head mounting system, techniques for adapting the rat to the fixed-head training environment, and selection of learning tasks in which rats can perform well during brief recording sessions. We have been developing such a preparation, adapting head-fixing and training techniques from recent successes with similar preparations by C.D. Woody and T. Ono, and exploiting rats' superb learning abilities when guided by olfactory cues.

Male Long-Evans rats were pre-trained on an odor discrimination task then, under ketamine-nembutal anesthesia, implanted with multiple miniature self-tapping skull screws, a bipolar MFB electrode, and two horizontally-mounted cannulae on the skull surface. After recovery, they were habituated under successively smaller doses of acepromazine to stereotaxic fixation of the head using pins inserted into the cannulae. Then they were shaped to lick a water spout in order to receive sugar-water plus 400uA MFB stimulation. Later they were re-trained on the odor discrimination for sugar-water rewards. Following these procedures rats could then be trained within a single session on novel odor discriminations. Futhermore, large single hippocampal complex spike and other cell types were readily isolated with conventional microelectrodes and could be recorded with stable, large signal-to-noise ratio during behavioral performance.

RAT'S HIPPOCAMPAL UNITS HAVE BEHAVIORAL CORRELATES DURING THE PERFORMANCE OF AUDITORY WORKING AND REFERENCE MEMORY TASKS. Y. Sakurai* Dept. Psychol., Toyama Med. & Pharm. Univ., Sugitani, Toyama 930-01, Japan.

The present study examined roles of hippocampal neurons by recording their single units while the rat performed both auditory working and reference memory tasks. The working memory task was continuous nonmatching-to-sample (Sakurai, Behav. Neurosci., 104: 253, 104:856, 1990). The reference memory task was continuous discrimination. The apparatus, stimuli and sequence of the stimuli are identical for both the memory tasks. Around 10% of the units from CA1, CA3, and dentate gyrus showed behavioral correlates only in the working memory task. Behavioral correlates mean differences in unit's activity to the types of stimuli and/or responses in the tone presented and/or delay periods. Between 20% and 30% of the units showed behavioral correlates only in the reference memory task. About half of the units showed behavioral correlates both in the working and reference memory tasks. Types of those correlates were different between the tasks. These results suggest that there are different types of mnemonic neurons in the hippocampas and more of the neurons are related to both nonspatial working and reference memory processes. LEARNING-DEPENDENT ENHANCEMENT OF DENTATE GYRUS GRANULE CELL RESPONSIVITY. T. Otto*, A. Kitzmiller, and H. Eichenbaum, Dept. of Psychology, University of North Carolina, Chapel Hill, NC 27599.

Previous studies have demonstrated that brief episodes of exploration are accompanied by a short-term enhancement of EPSPs in dentate gyrus (DG) evoked by perforant path (PP) stimulation. It remains to be determined, however, whether a similar enhancement of synaptic efficacy can be induced by formal training in tasks known to engage hippocampal function. The present, ongoing study examines whether these effects can be induced by explicit bouts of olfactory learning, and the extent to which such enhancement is learning-dependent.

Male Long-Evans rats were implanted with a stimulating electrode in the PP and a recording electrode in the hilus of the DG. Following recovery, 24 EPSPs evoked by PP stimulation (20 sec ISI, 50% max EPSP) were collected each day in the subject's home cage. Following establishment of a stable baseline (<10% variation in initial slope across 3 consecutive days), subjects were on successive days placed for 15 minutes into the chamber in which behavioral training would eventually take place, presented with a number of different odorants from a sniff port and received water reinforcers at a nearby water port ("shaping"), and trained on an odor-guided continuous delayed nonmatching to sample (cDNM) task. Fourty-four EPSPs were collected immediately after each day's behavioral session. Preliminary evidence indicates that no change in EPSP slope is observed following simple exposure to the behavioral chamber or following shaping. By contrast, an increase in EPSP slope is observed following daily cDNM training; the magnitude of this increase is significantly correlated with cDNM performance during acquisition (r's = .4 - .86). These data suggest that under these conditions enhanced synaptic efficacy in the PP-DG pathway reflects information processing in the entorhinal-DG system and is not due to simple sensory stimulation. FUNCTIONAL SIGNIFICANCE OF ANATOMIC CONNECTIONS BETWEEN CA1 AND CA3 HIPPOCAMPAL CELLS DURING DELAYED MATCH TO SAMPLE BEHAVIOR IN THE RAT

R.E. Hampson*, M.T. Kirby, K.E. Alexander, V.C. King and S.A. Deadwyler. Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157.

Recent studies of the intrinsic anatomic connections between the principal cells of the hippocampus (CA1 and CA3 pyramidal cells) have proposed an intricate gradient of connectivity which traverses the longitudinal axis of the hippocampus (Amaral & Witter, Neuroscience 31:571-591, 1989; Ishizuka *et al.* J. Comp. Neurol. 295:580-623, 1990). The functional significance of these connections was investigated using many neuron recording and classification strategy to identify cells which appeared to be synaptically "coupled" along these gradients in freely moving rats performing a delayed match to sample task (Heyser *et al.* Soc. Neurosci. Abstr. 15:1170, 1989). Custom fabricated arrays consisting of 2 rows of 8 microelectrodes were implanted to traverse the longitudinal axis of the hippocampus, with the electrode tips in each row positioned in either the CA3 or CA1 cell layers. Spike triggered histograms were constructed from spikes on each of the 8 CA3 electrodes for the entire set of spikes on the CA1 electrodes. Extracellular spikes from individual cells were isolated via a multichannel online spike sorter (Spectrum Scientific) and cell firing correlated with various phases of the DMTS task. Several of the CA3 cells exhibiting task specific firing correlates also showed short latency "coupled" discharges associated with CA1 cell spikes. Both the position and the degree of coupling between pairs of CA1 and CA3 cells across these electrode arrays as well as their relation to hippocampal anatomy will be described.

FUNCTIONAL ARCHITECTURE OF THE HIPPOCAMPUS STUDIED WITH THE OPTICAL METHOD T. Iijima*, M.Ichikawa S. Akiyama and G. Matsumoto Electrotechnical Lab. 1-1-4 Umezono , Tsukuba, Ibaraki 305, Japan

According to the lamella hypothesis, each lamella which is prepared by sectioning the hippocampus transversely to the longitudinal axis should involve basically the similar excitatory pathway, and may operate as an independent functional unit. We examined the hypothesis with the optical method using a voltage-sensitive dye by comparing the neuro-circuit involved in each slice preparation sampled from the various portion of a hippocampus. The results obviously showed the heterogeneity of the neuro-circuit in each " lamella ".

In vivo studies were performed along with the *in vitro* study to reveal the actual information processing in the three dimensional space of the hippocampus. The optical measurements applied to the *in vivo* study revealed the strong association of neuro-circuit in the longitudinal direction of a hippocampus.

In the optical measurement of neural activity, we also studied the expression of a long-term potentiation (LTP) *in vivo*. Based on the observation of the spread of activated area due to the establishment of LTP, we analized the change of the manner of information processing by the neural plasticity.

BLOCKADE OF MITRAL/TUFTED CELL HABITUATION TO ODORS BY ASSOCIATION WITH REWARD. D.A. Wilson* and R.M. Sullivan, Devel. Psychobiology Lab., Dept. Psychology, University of Oklahoma, Norman, OK 73019

Association of odor and reward during the early postnatal period modifies rat pup behavioral responses and olfactory bulb neural responses to subsequent presentations of that odor. Recent evidence from our lab has shown that olfactory bulb output neurons, mitral/tufted cells, receive convergent odor and reward inputs. Here, we examined the effect of reward input on M/T cell response to odors during associative training.

Single-unit recordings of M/T cells were made in PN11-12, urethane anesthetized Wistar rat pups. Responses of cells were examined to peppermint odor and to stimulation of the medial forebrain bundle/lateral hypothalamus. Odor responsive cells were then randomly assigned to either a PAIRED training group, receiving 4 sec odor pulses with MFB/LH stimulation at odor offset or ODOR-only training. For both groups odors were delivered every 30 sec. Response magnitude to the odor stimulus (pre-MFB/LH stimulation) was compared across 15-30 conditioning trials.

The results suggest that contiguous odor-reward pairings prevent M/T cell habituation to the odor that normally occurs to repeated odor-only stimulation.

MODULATION OF THE EARLY AND LATE COMPONENTS OF EMG STARTLE ACTIVITY IN THE RAT

Laura H. Poore and Wesley P. Jordan*, Psychology, St. Mary's College of Maryland, St. Mary's City, MD 20686

The reflex pathway of the acoustic startle response is a simple, fast-latency system within the brainstem of the rat. Short-term habituation of startle occurs within the reflex pathway, but long-term habituation relies upon the inhibition of the response by neural mechanisms outside of the reflex circuit. The startle response also is modulated by other processes such as prepulse inhibition and potentiated startle. The short latency of the reflex places serious timing constraints upon these modulators of startle amplitude. The modulating effects of long-term habituation, prepulse inhibition, and potentiated startle on the startle reflex were studied using EMG recordings in the spinotrapezius muscle of 24 rats.

Acoustic startle stimuli provoked a bimodal EMG response with response latencies of about 8 and 18 ms. Preliminary evidence suggests that the late component may undergo stronger long-term habituation than does the early component. Both components, however, respond to changes within a test session, including manipulations of stimulus intensity and interstimulus interval. Furthermore, the amplitude of both components decreased during prepulse inhibition testing. Preliminary evidence suggests that the responses of the two EMG components are not altered within a potentiated startle paradigm when the startle stimulus serves as the conditioned stimulus paired with aversive footshock.

EFFECTS OF DORSAL CORTEX LESIONS ON HABITUATION TO A LOOMING STIMULUS IN TURTLES. A. S. Powers* and L. Wojcik. St. John's University, Jamaica, NY 11439.

Previous investigations in our laboratory have shown that dorsal cortex lesions impair learning in turtles. The present study was undertaken to determine whether habituation to a looming stimulus (LS) would be affected by such lesions. Painted turtles (Chrysemys picta) were given dorsal cortex (n=4) or sham lesions (n=5). The apparatus consisted of a platform on which the turtle was restrained in front of a rear-projection screen on which the LS was presented. Head withdrawals were detected by a photocell beam that was shadowed when the subject's head was extended. Before being presented with the LS, the turtles were habituated to the restraint being used. In the experiment proper, the LS was a circle projected on the screen, enlarging from 7.5 cm to 22.5 cm within 1 sec. The typical response of the turtle was head withdrawal. Turtles with sham lesions showed rapid habituation to the restraint in the pretraining and showed both within- and between-day habituation to the LS. Turtles with dorsal cortex lesions took significantly longer to habituate to the restraint, and 2 animals failed to show such habituation. There was a nonsignificant suggestion of an impairment in between-day habituation in the 2 turtles that were able to be tested on habituation to a LS. The results suggest that dorsal cortex lesions may produce a deficit in habituation in turtles.

445.14

A FREQUENCY ANALYSIS OF HABITUATION IN STATIONARY RESPONSIVE VISUAL CELLS IN THE AMPHIBIAN TECTUM. M. M. Nikoletseas.* Dept. of Anatomy, U. of Puerto Rico, Sch. of Med. San Juan, PR 00936.

Tectal cells of various sensory modalities have been reported to habituate. Habituation is traditionally defined as a decrement in the number of responses as a function of repeated stimulus presentation. In this study a quantitative analysis of habituation was undertaken with emphasis on the changes in interspike intervals. Frogs (Rana catesbeiana) were anesthetized and paralyzed. A light stimulus (duration 50 ms, ISI 1 sec) was presented in the center of the receptive field of stationary responsive (SR) cells (movement-sensitive or directionally-selective cells were excluded) for 1.5 min, and spikes were preamplified and fed into a computer for on-line acquisition and analysis. Use of various filters excluded stimulus artifacts and noise from the analysis. The main findings are: 1. These cells had very low spontaneous activity. 2. The increment in response rate as a result of stimulus presentation gradually declined with repetition but never reached spontaneous levels. 3. As habituation progressed interspike interval lengthened (coding by frequency). 4. In spontaneous recovery there was generally a return to high response rates and short interspike intervals. 5. The frequency coding mechanism is independent of that of spike count. In conclusion, during habituation SR tectal visual cells employ the same coding mechanisms as do somatosensory and auditory tectal cells previously reported.

INGESTIVE BEHAVIOR: TASTE AVERSION AND NEURAL MECHANISMS

446.1

ALTERED DIET SELECTION IN RATS WITH LESIONS OF AREA POSTREMA/ADJACENT NUCLEUS OF THE SOLITARY TRACT (AP/mNTS-LESIONS). G.L. Edwards*, B.J. Mullen, R.J. Martin and J.D. Power. Dept. of Physiol. & Pharm. and Dept. of Foods and Nutrition, Univ. of Georgia, Athens, GA 30602.

Recent diet selection studies have reported that rats fed dietary tallow consume increased amounts of high protein/low carbohydrate diet compared to control, corn oil fed rats (J. Nutr. 120: 1418, 1990). These studies suggest that some factor or condition associated with ingestion of saturated fats results in a shift in diet selection. In this study we examined the effect of AP/mNTS-lesions on selection of a high protein/low carbohydrate diet versus a low protein/high carbohydrate diet. We found that rats that received an AP/mNTS-lesion at least 12 weeks earlier selected a greater percentage of their daily diet from the high protein/low carbohydrate diet than unlesioned control rats (AP/mNTS-lesion, 41.5 ± 10.4% vs CONT, 15.1 ± 3.7%). Weight loss by the lesioned group does not appear to explain altered diet selection as weight matched control rats consumed only 6.1 ± 2.2% of daily intake from the high protein diet. These data provide support for a role of the AP in diet selection. (Funded by NIH DK42533)

446.2

LESIONS OF AREA POSTREMA (AP) ABOLISH CONDITIONED TASTE AVERSIONS BUT NOT ANOREXIA INDUCED BY LiCl IN RATS. K.S. Curtis, A.F. Sved, J.G. Verbalis, E.M. Stricker*. Dept. of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

AP lesions were produced by vacuum aspiration in adult male Sprague-Dawley rats. Consistent with previous findings, when water-deprived rats were allowed to drink novel flavored fluids just before treatment with LiCl (3 mEq/kg, ip), sham-operated (n=6) and non-operated control rats (n=7) demonstrated a pronounced aversion to the fluids whereas rats with AP lesions (n=12) did not decrease fluid consumption significantly. However, in a 30-min test period after overnight food deprivation, rats with AP lesions and control animals reduced food intake significantly and to an equivalent degree after pretreatment with either LiCl (3 mEq/kg, ip) or hypertonic saline solution (2-3 ml of 2 M NaCl, ip). These results are consistent with the traditional view that AP mediates the sensation of nausea produced by LiCl treatment (hence the loss of conditioned taste aversions after AP lesions), but suggest that neither nausea nor AP is critical for the marked disinclination to eat that is induced in rats by systemic treatment with LiCl or with hypertonic NaCl solution.

446.3

TRACKING LITHIUM-INDUCED SHIFTS IN SUCROSE PALATABILITY: ROLE OF THE AREA POSTREMA. L.A. Eckel* and K.-P. Ossenkopp. Neuroscience Program, Univ. of Western Ontario, London, Ontario, CANADA N6A 5C2.

The present study investigated the role of the area postrema (AP) in mediating the effects of lithium on taste reactivity (TR) responses. Rats received lesions of the AP (APX, N=12), or sham lesions (APS, N=14), followed by implantation of an intraoral cannula. On the first test day, half of the rats in each group were injected with either LiCl or equimolar NaCl (0.6 M, 5 ml/kg, i.p.). Ingestive TR responses (rhythmical mouth movements, tongue protrusions, and lateral tongue protrusions) and aversive TR responses (gapes and chin rubs), were videotaped during 30 sec intraoral infusions of 0.3 M sucrose. Infusions began immediately post-injection and at 5 min intervals for 30 mins. Three days later this procedure was repeated. Rats were tested 72 hours later for the expression of a conditioned taste aversion. APS rats given NaCl showed high levels of ingestive responses during all test days. APS rats given LiCl showed a decline in ingestive responses and an increase in aversive responses ($p<.001$). In comparison, APX rats treated with either LiCl or NaCl displayed high levels of ingestive responses similar to the APS/NaCl group ($p>.10$). It was concluded that lithium-induced activation of the AP is required to produce palatability shifts and the formation of CTAs. (Supported by a NSERC operating grant to KPO).

446.4

CONDITIONED TASTE AVERSION INDUCED BY INCREASED ACETYLCHOLINE IN THE NUCLEUS ACCUMBENS K.M. Taylor*, K. Davidson, G.P. Mark, P. Rada and B.G. Hoebel Department of Psychology, Princeton University, Princeton, NJ 08540.

Increased extracellular ACh in the nucleus accumbens (NAC) is associated with precipitated morphine withdrawal (Rada et al., 1991) and supression of feeding (Mark et al., 1991). If these findings indicate an aversive action of the transmitter, then ACh increase in the NAC may be sufficient to induce a conditioned taste aversion.

Male Sprague Dawley rats were water deprived and trained to drink during 30 min. daily access to water. After training, animals were presented 2.5 mM sodium saccharin in water, and the taste was paired with either 4 μg/μl neostigmine (n=7) or vehicle (n=7) injected bilaterally in the NAC (0.5 μl per side). A pseudoconditioning control group received NEO in the NAC paired with water presentation (n=7). In a two bottle preference test, the saccharin-neostigmine group showed a significant aversion to saccharin [$F(2,18)=15.57$, $p<0.001$] compared to the two control groups. There were no differences in overall fluid consumption. These results suggest that an increase in extracellular ACh in the NAC may be sufficient to produce an internally aversive state.

446.5

ETHANOL-INDUCED CONDITIONED TASTE AVERSIONS: EFFECTS OF CHEMICAL LABYRINTHECTOMY. K.-P. Ossenkopp*, J. Rabi and L. A. Eckel. Neuroscience Program, Univ. of Western Ontario, London, Ontario, CANADA, N6A 5C2.

Male rats were chemically labyrinthectomized by intratympanic injections of sodium arsanilate (Group VNX). Control rats were given intratympanic injections of isotonic saline (Group VNS). All rats were adjusted to a 23 hr/day water deprivation schedule and then exposed either to a conditioned taste aversion (CTA) procedure or a control procedure. The CTA technique involved the pairing of a novel saccharin taste (0.15% solution) with subsequent i.p. injection of ethanol (1.5 g/kg; 15% solution). The control procedure involved the pairing of the saccharin taste with an injection of isotonic saline (10 ml/kg). Following 2 conditioning trials and 3 days of water only, saccharin preference ratios were obtained (2-bottle choice test) on 4 consecutive days. VNS rats exposed to saccharin plus ethanol exhibited a strong CTA ($p<0.01$) relative to VNS controls. VNX rats given saccharin plus ethanol showed a strong CTA ($p<0.01$) if conditioning occurred 29-30 days post labyrinthectomy. However, CTAs were abolished in VNX rats conditioned 19 days post labyrinthectomy. Thus, ethanol-induced CTA formation varied across the post labyrinthectomy time period. (Supported by a NSERC operating grant to KPO).

ALTERED GASTRIC MOTILITY FOLLOWING AREA POSTREMA ABLATION (APX). M. Kathleen Gruver, Arash Aflatooni, and Nancy J. Kenney*, Dept. Psychology, University of Washington, Seattle, WA 98195.

Ablation of the area postrema and caudal and medial portions of the nucleus of the solitary tract (APX) decreases intestinal transit of rats independent of APX-induced hypophagia. This study extends our analysis of APX on gastrointestinal (GI) function by examining its effects on gastric motility.

Eight APX rats and 7 sham-lesioned rats (SHAM rats) were studied 4 days following ablation. Gastric motility of urethane-anesthetized (1.25 mg/kg) rats was monitored via a tension transducer attached to the anterior gastric corpus. Following a 1-hr baseline period rats were injected centrally with either 5 g/.6 l TRH or .6 l saline. Motility was recorded for 20 min following injection.

Baseline gastric motility of APX rats tended to be higher and more variable than SHAM rats. TRH increased motility of both APX and SHAM rats, but the TRH response of APX rats was significantly suppressed.

Thus, the AP/cmNTS region may be involved in both unstimulated as well as TRH-induced increases in gastric motility. Whether changes of GI motility underlie the altered eating behavior of APX rats requires further study.

446.7

EVIDENCE OF LEARNING IN THE ETIOLOGY OF POISON-ELICITED PICA. D. Mitchell* and J. B. Nast. Department of Psychology and Psychobiology Program, University of Southern California, Los Angeles, CA 90089-1061.

Both humans and other animals frequently engage in pica (the consumption of non-nutritive substances) when suffering from gastrointestinal malaise. We have previously shown that a specific form of pica, geophagia (clay consumption), can be used to quantify the severity of gastrointestinal malaise induced by a variety of toxins and emetics, including lithium chloride. Though a small dose of lithium chloride reliably elicits robust conditioned taste aversions, the same dose elicits only a modest pica response compared to other toxins and emetics. This apparent inconsistency between the robust effectiveness of lithium chloride as a UCS in conditioned taste aversions and its modest effectiveness in eliciting pica led us to examine the putative role of learning in the etiology of poison-elicited pica.

Rats maintained with food, water, and kaolin always available were administered repeated intraperitoneal injections of .15 M lithium chloride (127.2 mg/kg) every fifth day for a total of ten trials. Results showed that the animals learned to engage in pica; clay consumption gradually increased across the first five trials from 1.5 g on the first trial to 15.3 g on the fifth trial. Thereafter, it remained stable across the remaining trials. These results are consistent with clinical literature which suggests that learning plays an important role in the etiology of pica.

446.8

ADRENALECTOMY DOES NOT PRODUCE CONDITIONED FOOD AVERSIONS IN RATS. P.K. Green*, T. Moore, C.W. Wilkinson, I.L. Bernstein and S.C. Woods. Depts. of Psychol., and Psychiat. and Behav. Sci., Univ. of Washington, Seattle, WA 98195 and GRECC, American Lake VAMC, Tacoma, WA 98493.

Following adrenalectomy, rats consume less food than sham-operated controls. If adrenalectomy produces illness or nausea, it is possible that adrenalectomized (ADX) rats show reduced food intake because they have developed a conditioned aversion to the diet consumed following surgery. To test this hypothesis, rats were introduced to a novel diet (either C-21 or AIN) for a period of seven days immediately following adrenalectomy or sham-adrenalectomy. ADX rats consumed significantly less food than sham-ADX rats during this period. On the eighth day following surgery, a preference test was administered. Rats were 8-hr. food-deprived, and then provided 4-hr. access to both C-21 and AIN. Mean 4-hr. food intakes for each of the groups, expressed as grams of C-21 consumed divided by total consumption during the preference test, were: sham C-21-maintained, .86; ADX C-21-maintained, .95; sham AIN-maintained, .34; ADX AIN-maintained, .55. Statistical analysis by ANOVA revealed that ADX groups did not show significantly lower preferences than sham-ADX groups for the diet to which they were exposed during the week following adrenalectomy. ADX rats tended to consume a higher percentage of their food as C-21 than sham-ADX controls during the preference test, but this trend was not significant. These data do not support the hypothesis that decreased food intake following adrenalectomy is due to illness or malaise.

446.9

WHERE IS AVERSION: LATERAL HYPOTHALAMUS OR VENTRAL PALLIDUM/SUBSTANTIA INNOMINATA? H.C. Cromwell*, D. Karimipour and K.C. Berridge. The University of Michigan, Department of Psychology, Ann Arbor, MI. 48109

Many previous studies have reported that LH damage induces aversion (Teitelbaum et. al., 1961, Stellar et. al., 1974, Schallert et. al., 1978). However, a study of neuron loss restricted to the LH found aphagia without aversion (Berridge, 1989). The purpose of this study was to resolve where the crucial site for aversion inducing lesions is located. Small bilateral excitotoxin lesions (QUIN, 60nM in 0.5ul of PBS) or bilateral sham injections of the lateral hypothalamus (LH), nucleus accumbens (NAcc) or the ventral pallidum/substantia innominata (VP/SI) were completed to determine the exact locus related to aversion enhancement. The taste reactivity test (Grill and Norgren, 1978) using oral taste infusions of sucrose (1M) was completed and the number of aversive responses (gapes, chin-rubbing, head-shaking and forelimb flails) to the palatable sucrose were tallied. To identify the lesions, two lesion mapping techniques were used: 1) a conventional neuron counting procedure, in which an attempt is made to count all neurons within a brain region, and 2) a new modified 'fractionator' procedure consisting of accurate 400X magnification counts at many point locations within a brain region.

Results indicated that food aversion is produced following bilateral neuron loss exceeding 70% in a 500um diameter area of the caudal ventromedial VP/SI alone, and not from NAcc or anterior LH damage.. The crucial subregion is located ventral and medial to the globus pallidus, and dorsal and lateral to the lateral hypothalamus.

2,5-ANHYDRO-D-MANNITOL (2,5-AM) INCREASES FOS-LIKE IMMUNOREACTIVITY (Fos-li) IN THE AP/NTS REGION BY STIMULATING VAGAL SENSORY NEURONS. T.T. Dinh*, S. Ritter and M.I. Friedman. Washington State University, Pullman, WA 99164-6520 and Monell Chemical Senses Center, Philadelphia, PA, 19104.

The antimetabolic fructose analogue, 2,5-AM, stimulates feeding. Feeding induced by low but not high 2,5-AM doses is blocked by hepatic branch vagotomy (Tordoff et al., '91). To further evaluate the role of the vagus in the response to high 2,5-AM doses, we assessed the ability of 2,5-AM (300 and 500 mg/kg) to induce Fos-li in the AP/NTS in sham-operated, hepatic branch vagotomized (HBV) and total subdiaphragmatic vagotomized (TSV) rats. 2,5-AM or equimolar doses of 2DG or fructose were infused remotely for 20 min through atrial catheters in the absence of food and rats were killed 2 hr later. Both doses of 2,5-AM, but not fructose, induced Fos-li in the AP/NTS. The effect of the lower 2,5-AM dose on Fos-li was blocked by HBV. The high dose effect was blocked by TSV, but not by HBV. We also found that TSV blocked feeding induced by the high dose of 2,5-AM. As reported previously, 2DG also induced Fos-li in the AP/NTS and stimulated feeding, but these effects were not blocked by vagotomy. Although Fos-li may not reveal all activated neurons, results are consistent with the hypothesis that stimulation of feeding by 2,5-AM, but not 2DG, may be entirely dependent on the vagus. Hepatic branch neurons may have the lowest threshold for activation by 2,5-AM, while higher doses stimulate neurons in other vagal branches.

446.11

CHARACTERIZATION OF GASTRIC VAGAL AFFERENT MECHANORECEPTOR RESPONSES TO CLOSE ARTERIAL INFUSIONS OF CCK IN RATS. G.J. Schwartz*, P.R. McHugh, & T.H. Moran, Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

We have previously demonstrated that gastric vagal mechanoreceptors also respond to close arterial infusions of the brain-gut peptide CCK. To examine the pharmacological specificity of these CCK-elicited responses, we observed the electrophysiological activity of single rat cervical vagal afferent fibers sensitive to both gastric loads and CCK (N=14) before and after administration of the selective type A and type B CCK receptor antagonists, L-364,718 and L-365,260. Some of these fibers (N=9) were also monitored for their responses to the above stimuli after acute pylorectomy. In addition, we investigated the ability of JMV-180, an antagonist at pancreatic low affinity sites that inhibits CCK satiety, to suppress CCK-induced gastric vagal afferent activity. Celiac artery infusions of L-364,718 acted competitively to inhibit the the response to CCK, both before and after acute pylorectomy, without altering the response to gastric loads. L-365,260 (10 pmol-1 nmol) failed to attenuate the gastric vagal afferent response to either gastric saline loads or 100 pmol infusions of CCK. In intact rats, celiac artery administration of 100 nmol of JMV-180 completely blocked the ability of 100 pmol CCK to stimulate gastric vagal afferent fibers, again without attenuating the response to gastric saline loads. These results demonstrate that CCK-elicited responses in a population of gastric vagal mechanoreceptive fibers are mediated by non-pyloric, type A CCK binding sites similar to pancreatic low affinity CCK receptors. REFEEDING AFTER 48 HOUR FAST INDUCES C-FOS mRNA AND PROTEIN IN RAT BRAINSTEM AND HYPOTHALAMUS. T.A. Houpt, T.C. Wessel, T. H. Joh, and A.C. Towle*, The Bourne Lab. and the Burke Medical Research Institute, Cornell University Medical College, White Plains, NY 10605.

In order to identify specific brain regions stimulated at the transcriptional level by food ingestion, we examined the expression of the proto-oncogene *c-fos* in brainstem and hypothalamus by immunohistochemistry and *in situ* hybridization in three groups of rats: *ad lib.* fed controls, rats fasted for 48 hrs, and rats fasted for 48 hrs and allowed to eat Purina rat chow for 1 hr prior to perfusion (n=4 in each group). For *in situ* analysis, 40μm tissue sections were hybridized overnight with synthetic, [^{35}S]-labelled *c-fos* oligonucleotides. Sections were dipped in photoemulsion and developed 4-6 wks later. Adjacent sections were immunohistochemically stained for c-Fos-related proteins.

One hour of feeding following a 48 hr fast caused intense *c-fos* mRNA expression and immunoreactivity co-localized in several regions. In the brainstem, expression was very strong in the nuclei of the solitary tract; in the rostral hypothalamus, strong *c-fos* expression was seen in the paraventricular and supraoptic nuclei, and more diffuse expression was seen in the anterior hypothalamic nuclei and bed nuclei of the stria terminalis; at the level of the caudal hypothalamus, the dorsal medial nuclei and the thalamic habenular and paraventricular nuclei were labelled, as well as individual cells encircling the third ventricle. Control and fasted animals showed little or no expression compared to refed animals in brain stem and anterior hypothalamus, although *ad lib.* fed controls showed occasional *c-fos* expression around the dorsal medial nuclei in the caudal hypothalamus.

Our results show that feeding induces *c-fos* expression in specific brain nuclei at both the mRNA and protein level. Further studies are required to correlate *c-fos* expression in these neural areas to specific orosensory and postingestive effects of food intake.

RETROGRADE, TRANSYNAPTIC LABELING OF TRIGEMINAL PREMOTOR NEURONS USING PSEUDORABIES VIRUS. R. Fay* and R. Norgren. Neuroscience Program and Dept. of Behavioral Science, Col. of Medicine, Penn. State Univ., Hershey, PA 17033.

Following bilateral removal of the superior cervical ganglion, pseudorabies virus (15 ul, $8x10^8$ pfu/ml) was injected into the anterior digastric, masseter, or temporalis muscles of rats. The animals were allowed to survive from 72 to 120 hours. Primary infections were restricted to trigeminal motor neurons (Mo 5) in a predictable myotopic pattern. Secondary infections appeared in neurons in areas known to project to Mo 5, including the Kolliker-Fuse, parabrachial, and principal trigeminal nuclei, as well as the supratrigeminal and subcoeruleus zones. Within these areas, however, infections of different muscles produced different distributions of labeled cells. Similarly, differential labeling was observed in regions thought to be involved in the central pattern modulation of Mo 5 activity, such as the gigantocellular and paragigantocellular areas. In the brainstem, increasing survival times revealed polysynaptic connections to the subpeduncular and pedunculopontine nuclei in the midbrain, the lateral tegmental and the oral, ventral, and caudal pontine nuclei in the pons, and the paratrigeminal, solitary, and rostroventrolateral nuclei in the medulla. With longer survival times the infection also spread to the forebrain, particularly in the hypothalamus, amygdala, and paleocortex. Nevertheless, the neocortex, thalamus, and most of the striatum remained remarkably free of labeled neurons. Supported by PHS grants DC 00240 and MH 00653.

MEDULLARY INPUTS TO THE FIFTH, SEVENTH, AND TWELFTH CRANIAL NERVE MOTOR NUCLEI. E.T. Cunningham, Jr.* and P.E. Sawchenko, The Salk Institute, La Jolla, CA 92037.

Prior anatomical studies performed in the rat identified the region of the caudal medullary reticular formation immediately subjacent to the nucleus of the solitary tract (NTS) as the primary source of afferent inputs to the motor nuclei of the fifth (MoV), seventh (VII), and twelfth (XII) cranial nerves, which are involved directly in the control of oromotor behaviors such as deglutition and mastication. In this study, the sensitive fluorogold retrograde tract tracing technique was used to identify medullary areas innervating MoV, VII, and XII, and to characterize the cells of orgin of these projections. Discrete deposits of the anterograde tracer, *Phaseolus vulgaris*-leucoagglutinin, were then placed in implicated portions of the dorsomedial reticular formation, and the topography of labeled terminal fields within each of the cranial nerve motor nuclei were charted. The results may be summarized as follows: 1) The regions of the reticular formation innervating MoV, VII, and XII are largely overlapping, and extend from the level of the MoV to the rostral spinal cord. In each instance, the greatest concentration of retrogradely labeled cells lay at the level of the NTS. 2) Most inputs are bilateral with an ipsilateral predominance. The single exception is the largely contralateral input to motor neurons innervating the masseter and pterygoid muscles in the dorsolateral portion of MoV. This projection arises from a cluster of large multipolar neurons immediately ventrolateral to XII at the level of the area postrema. These large cells appear not to project to VII or XII. 3) By contrast, smaller, more dorsally situated neurons project to motor neurons innervating the anterior digastric and mylohyoid muscles in the ventromedial portion of MoV. They also project to the intermediate and dorsal portions of VII, and to all subdivisions of XII, regions that innervate a number of muscles involved in the initiation of deglutition. Thus, although the resolution of these techniques does not allow us to discount the possibility that a small proportion of neurons in the reticular formation might share characteristics of both populations, it appears clear that two distinct, though topographically contiguous, deglutitive and masticatory pathways arise from the reticular formation in the dorsomedial medulla.

ELECTROLYTIC AND IBOTENATE LESIONS OF THE DORSAL AND CENTRAL SUBNUCLEI OF THE LATERAL PARABRACHIAL NUCLEUS (IPBN) ABOLISH LIPOPRIVIC BUT NOT GLUCOPRIVIC FEEDING. F.H. Koegler*, N.Y. Calingasan, S. Ritter. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Lesions of the area postrema/nucleus of the solitary tract (AP/NTS) abolish lipoprivic and glucoprivic feeding induced by mercaptoacetate (MA) and 2-deoxy-D-glucose (2DG), respectively. Since the IPBN is a major relay site for ascending visceral sensory input from the AP/NTS region, electrolytic and ibotenate lesions of IPBN subnuclei were made to investigate the involvement of the IBPN in the central pathways of metabolic control of food intake. Lesions were confirmed either by cresyl violet staining or by glial fibrillary acidic protein immunohistochemistry. Lesioned rats were tested for feeding in response to 0.9% NaCl (s.c. or i.p.), MA (400, 600, and 800 μmol/kg, i.p.) and 2DG (100 and 200 mg/kg, s.c.). Electrolytic lesions of the dorsal, central, superior, and external IPBN abolished lipoprivic but not glucoprivic feeding. Ibotenate lesions of the external and superior subnuclei did not impair lipoprivic or glucoprivic feeding, but ibotenate lesions of the dorsal and central subnuclei did abolish lipoprivic feeding. These results suggest that the cell bodies in the dorsal or central IPBN participate in the lipoprivic control of feeding. Electrolytic lesions of the superior and external subnuclei appear to have damaged fibers of passage important for this control, possibly those in transit to or from the dorsal and central subnuclei.

RESPONSES OF PARABRACHIAL TASTE NEURONS IN SHAM-FEEDING RATS BEFORE AND AFTER DUODENAL LIPID INFUSIONS. L. Foster*, K. Nakamura, and R. Norgren, Dept. of Beh. Sci., Col. of Med, Penn State Univ., Hershey, PA 17033

Duodenal lipid infusions rapidly suppress sham intake of liquid diets and sapid stimuli. Three rats were outfitted with gastric fistulas and duodenal cannulas, maintained on a food deprivation schedule, and trained to ingest fluids while restrained in a chronic recording apparatus. Parabrachial gustatory neurons were isolated using conventional recording techniques. These cells were tested with intraoral infusions (50 ul) of a concentration series of sucrose, as well as a single concentration of polycose, NaCl, citric acid, and quinine HCl before, during, and after duodenal infusions of a lipid emulsion (Intralipid) or saline. The neurons were tested during 5 different, 15-min periods -- 1 before and 4 after the duodenal infusions. The responsiveness of at least 7 taste neurons was assessed during each time period; 11 neurons were tested both before and after an infusion. During the first post-infusion interval (0-15 min), neural activity elicited by NaCl decreased to less than that produced by any concentration of sucrose. During the next time period (15-30 min), taste neurons responded less to the lower concentrations of sucrose, but increased their responsiveness to NaCl. During the last period (45-60 min), NaCl responses returned to pre-infusion levels, while sucrose responses increased. These data suggest that some neurons may switch their best response category depending on whether the animal is food deprived or satiated. Supported by DC-00047, DC-00240, MH-00653.

CELLS WITHIN PONTINE PARABRACHIAL NUCLEUS COLLATERALIZE TO INNERVATE HYPOTHALAMUS AND DORSAL MEDULLA IN THE RAT: IMPLICATIONS FOR FUNCTIONAL INTEGRATION OF PAIN AND SATIETY. L.L. Bellavance*, P.L. Faris, R.D. Hofbauer, and C. Cozzari, Division of Neuroscience Research in Psychiatry, Univ. of Minnesota Sch. of Med., Minneapolis, MN 55455.

The pontine parabrachial nucleus (PBN) receives input relevant to feeding and nociception, and may play an integral role in the synchronization of these different functional systems. In the first part of this study, we utilized the retrograde tracers rhodamine-conjugated latex beads and fluorogold to determine if a single cell in the PBN collateralizes to innervate two distinct brain areas involved in processing information relevant to feeding or nociception. After injection of rhodamine-conjugated latex beads into the dorsal medulla and injection of fluorogold into the hypothalamus, double-labeled cells were identified in the rostral part of the dorsal lateral parabrachial complex. This would suggest that some PBN cells collateralize to innervate both the dorsal medulla and the hypothalamus, structures involved in the regulation of feeding and/or nociception. The second part of this study was designed to look at the peptide content of the collateralizing PBN cells. We combined the retrograde fluorescence-immunofluorescence technique to determine whether the PBN cells that collateralize also co-localize peptides implicated in the transmission of information relevant to feeding and/or nociception: cholecystokinin (CCK), calcitonin gene-related peptide (CGRP), and enkephalins. The results of these studies suggest that the PBN may utilize collateralization as an integrating system in addition to the more traditional interneuronal networks. Furthermore, the PBN may play an integral role in the synchronization of different functional systems, i.e. feeding and nociception.

COMPLEX NEUROCHEMICAL PROPERTIES OF FEEDING-ASSOCIATED PALLIDAL NEURONS. Z. Karádi, A. Czurkó, B. Faludi, I. Vida, Cs. Niedetzky, A. Hajnal, J. Czopf and L. Lénárd. (SPON: European Neuroscience Association) Institute of Physiology, Pécs University Medical School, Pécs, H-7643 Hungary

The multibarrel microiontophoretic technique was applied to record extracellular single neuron activity and to investigate specific chemical characteristics in the globus pallidus (GP) of anesthetized rats and anesthetized and alert rhesus monkeys. In both species, approximately 10% of all cells tested exhibited, predominantly inhibitory, discharge rate changes to electrophoretically administered glucose. Many of the glucose-responsive and non-responsive neurons changed in activity in response to perioral and intraoral somesthetic stimulation as well as, in the alert monkey, to food objects. These feeding-related cells displayed distinct sensitivities to various chemicals (catecholamines, GABA, Ach, MAO-blockers and "NMDA"-enantiomers) applied microiontophoretically. The present findings, along with previous results, suggest that differentially organized subsets of pallidal neurons utilize complex and distinct neurochemical mechanisms to control integrative functions in the regulation of feeding.

HYPERPHAGIA AND OBESITY IN FEMALE RATS WITH AMYGDALOID LESIONS. B. M. King*, J. M. Kass, N. L. Cadieux, K. L. Neville, H. Sam, and A. C. Tatford. Dept. of Psychology, Univ. of New Orleans, New Orleans, LA 70148.

Hyperphagia and obesity in cats, dogs, and primates with lateral amygdaloid lesions were reported by several investigators during the 1950's, 1960's, and early 1970's (e.g., Bucy & Kluver, 1955; Fonberg, 1971; Green, Clemente, & de Groot, 1957). Interest in this extra-hypothalamic obesity syndrome disappeared when such effects were not observed after amygdaloid lesions in rats. In an initial part of the present study, we also found that large lesions of the amygdala resulted in no weight change or even a small loss of body weight. However, small bilateral lesions in a specific portion of the amygdala (detailed histological analysis had not been completed at the time of submission) resulted in weight gains of 15-25 grams during the first 2-4 postoperative days. Daily food intake nearly doubled in some animals. In a subsequent controlled study, adult female rats with amygdaloid lesions gained 20-30% of their preoperative body weight in 30 days, compared to only 5% for animals with sham lesions. The amygdaloid-lesioned animals were unaffected when switched from a standard pellet diet to a high-fat diet and back again. It is hypothesized that the amygdala plays a major role in appetitive mechanisms.

DAILY CALORIC INTAKE REGULATION IN CHRONIC DECEREBRATE AND INTACT RATS. R.J. Seeley*, J.M. Kaplan, and H.J. Grill, Dept. of Psychology, University of Pennsylvania, Philadelphia, PA 19104-6196.

The chronically maintained decerebrate (CD) rat demonstrates, as do intact rats, changes in both taste-elicited oral motor responses and the size of individual intraorally delivered meals in response to a variety of ingestive challenges. In this study, the ability of the CD rat to defend daily caloric intake was explored. In a baseline period, both CD and intact control rats received 3 intraorally delivered meals of milk diet per day for a week. Meal size was determined by measuring the amount of the milk diet stimulus consumed before the rat rejected the stimulus. Both CD and intact rats took substantial meals in this paradigm and gained weight over the baseline period. Rats were then challenged to maintain their 3 meal daily intake over a week in which only 2 intraoral intake tests per day were delivered. In response to the lost meal, intact rats increased the size of the remaining meals and continued to gain weight. CD rats, however, did not increase their meal size in the 2 meal condition and lost weight during the test period. Additionally, a separate group of histologically identified rats had transections that were incomplete. Despite substantial neural damage, these rats, like controls, increased their meal size in response to the lost opportunity to feed. So despite the ability of CD rats to respond to short term regulatory challenges, these results suggest that the caudal brainstem is not sufficient to regulate daily caloric intake without neural connections with the forebrain. Such a deficit may reflect that different physiological signals and/or different neural substrates are responsible for shorter and longer term intake regulation. Supported by NIH grant DK-21397.

DISTRIBUTION OF LICKING - AND SWALLOWING - RESPONSIVE CELLS IN THE MEDULLARY RETICULAR FORMATION OF THE AWAKE FREELY-MOVING RAT. J.B. Travers* and L.A. DiNardo. Oral Biology, Coll. Dent. Ohio State Univ. Columbus, OH 43210.

Neuroanatomical studies have implicated the reticular formation (RF) lateral to the hypoglossal nucleus (mXII) as a substrate interposed between brainstem orosensory and oromotor nuclei. This substrate may be important for producing ingestion (licking and swallowing) or rejection (gaping) responses to gustatory stimulation. In the present study, rats were implanted with a chronic microdrive that advanced a bundle of fine wire NiCr electrodes (17u). In addition, a subset of the oro-pharyngeal musculature was implanted with fine wire electrodes to record EMG activity and intraoral cannulae were implanted to deliver gustatory stimuli. A total of 80 single cells (and 8 multi-unit responses) were recorded from 18 preparations. Thirteen preparations had recording tracks through the nucleus of the solitary tract (NST) and the RF lateral to mXII from a level 0.2 mm rostral to obex to the rostral pole of mXII. Electrode tracks ranged from the lateral border of mXII to 0.5 mm lateral to the nucleus. Five preparations had electrode tracks extending from the rostral pole of mXII to a level 2.5 mm rostral to obex and from 0.4 - 1.0 mm lateral to the midline. Oro-rhythmic (licking) responses to intraoral fluid stimulation were recorded from all preparations (43/80 cells) except two, the most rostral and the most lateral cases. Responses specific to swallowing were recorded dorsal to oro-rhythmic sites in 5 preparations and were located in the NST at levels ranging from 0.4 - 1.4 mm rostral to obex. Thus it would appear that the caudal NST and the RF ventral to it (and lateral to mXII) mediate different aspects of the ingestive sequence. Supported by DC00417

LiCl-INDUCED TASTE AVERSION IN BULLHEAD CATFISH. T. Valentinčič[1], V. Pirc[1] and W. Silver[2]*. [1]Department of Biology, University of Ljubljana, 61000 Ljubljana, Slovenia, and [2]Department of Biology, Wake Forest University, Winston-Salem, NC. 27109.

To determine whether bullhead catfish (Ictalurus nebulosus) could learn to discriminate among different foods as a result of LiCl-induced taste aversion, anosmic catfish were fed cod muscle previously soaked in LiCl (50mg LiCl/100g body weight) ad libidum during a single session. These catfish became unresponsive to stimuli and remained sluggish on the bottom of the aquarium during the 1-5 hours subsequent to the LiCl poisoning. All tested catfish regurgitated the cod muscle within 1-2 hours of the LiCl ingestion. One day following the LiCl ingestion, the same catfish responded to cod muscle with unimpaired feeding behavior patterns: search swims, turning to the food, and biting and snapping. Although initially taken into the oral cavity, the cod muscle was rejected by the catfish within 1-3 masticatory movements; however, during this same time period, these catfish fed normally on other foods. In addition, no differences were observed between aversive conditioned and unexperienced bullhead catfish in the incidence of other behavioral patterns released by amino acids and meat juices. For both groups, L-alanine was more effective than either L-proline, L-arginine or L-lysine in releasing turning, biting and snapping behavior towards stimulus plumes of >10-4M amino acids. The results indicate that the LiCl-induced taste aversion to cod muscle was not based solely on the detection of water-soluble substances, such as amino acids, emanating from the cod muscle before it was taken into the mouth, but that the perception of the aversive nature of the meat included recognition by the catfish of the complex taste and tactile qualities of the food.

Supported by the Ministry of Science of Slovenia, grant P1-0114-487.

D_1 DOPAMINE RECEPTOR ACTIVATION INDUCES SOCIAL REACTIVITY IN MICE SELECTIVELY BRED FOR AGGRESSION. M.H. Lewis[1,2*], J.-L. Gariepy[3], P. Gendreau[3], M.A. Mayleben[1,3], D.E. Nichols[5], R.B. Mailman[1,2,4]. Brain and Development Research Center.[1], Depts. of Psychiatry[2] Psychology[3] and Pharmacology[4], University of North Carolina, Chapel Hill, NC, 27599 and School of Pharmacy[5], Purdue University, West Lafayette, IN, 47907.

Robust individual differences in social behavior have been obtained by selectively breeding ICR mice for high and low levels of aggression. As previously shown, when paired with a non-selected, group-housed partner mouse, NC900 mice exhibit isolation-induced aggression, whereas NC100 mice fail to attack, but rather freeze upon social contact. Previous studies have established that NC100 mice have lower dopamine concentrations in nucleus accumbens and caudate nucleus, with increased dopamine receptor densities in these same regions. Thus, we wished to determine the effect of administration of a dopamine receptor agonist on social behavior. Mice of both lines were administered 0, 1, 3, or 10 mg/kg (s.c.) of the selective, full efficacy D_1 receptor agonist dihydrexidine and their behavior assessed in a social interaction test. Dihydrexidine dose-dependently reduced aggression in NC900 mice. Instead of aggression, these animals displayed a marked reactivity to mild social stimulation, as measured by increases in escape behavior, reflexive kicks, and vocalizations. Dihydrexidine had no systematic effect on the freezing behavior characteristic of the low-aggressive line, but did induce social reactivity in these animals, albeit to a lesser degree. In independent experiments, mice were pretreated with either the D_1 antagonist SCH23390 (0.1 mg/kg) or the selective D_2 antagonist remoxipride (1.0 mg/kg), after which they received dihydrexidine (10 mg/kg) and were tested as above. The effects of dihydrexiidine on social reactivity (both NC900 and NC100) and attack (NC900) were significantly antagonized by SCH23390 but not attenuated by remoxipride. These studies suggest an important role for D_1 dopamine receptors in the emotional response to social stimuli (Supported, in part, by PHS Grants MH45371, MH40537, and MH42705).

MODULATORY EFFECTS OF ACUTE D-AMPHETAMINE AND CLOZAPINE ON EXPLORATORY BEHAVIORS IN RATS. T. Steele*, B. Haas, and B. Wilcox, Dept. of Psychology, Univ. of Wisconsin Oshkosh, Oshkosh, WI, 54901.

Rats administered dopamine (DA) agonists are frequently hyperactive and stereotypic. These behaviors have been found to oppose exploration and subsequent learning (1). To determine if exploratory impairments are due, in part, to stimulation of DA-1 receptors, clozapine (CLOZ), a DA-1 receptor blocker, was administered to rats given d-amphetamine (AMPH). It was predicted that CLOZ would reverse a subset of the exploratory deficits produced by AMPH.

Six groups of hooded rats were administered a combination of AMPH (0 or 3 mg/kg) and CLOZ (0, 2, or 4 mg/kg). Rats were then allowed 15 min to explore a familiar field containing novel and familiar stimuli. Locomotor activity, object interactions, and other indices of exploratory behavior were observed four times over 2 weeks.

Certain aspects of exploration were independent of the drug effects. All animals explored the novel objects more than the familiar objects, and generally habituated to the objects as each session progressed. However, AMPH enhanced locomotor activity and subsequent object contacts. Both effects showed evidence of sensitization. CLOZ failed to reverse AMPH effects, but altered other components of exploration without reducing locomotor activity.

Although DA appears to influence exploratory behaviors, the observation that the drug effects were generally independent of one another suggests that different features of exploration may be selectively modulated by different DA receptor subtypes.

447.3

INTRACRANIAL SELF-STIMULATION ON FR15 PRODUCES A BEHAVIORALLY SENSITIZED RESPONSE TO LOW DOSES OF COCAINE HYDROCHLORIDE (COC) IN THE RAT. P.R. Hartley* and D.B. Neill. Department of Psychology, Emory University, Atlanta, GA 30322.

In a previous study *(Neurosci Abst, 1990)* we report that rats performing ICSS at LH electrodes on an FR15 schedule showed a complete cessation of responding when administered low-dose AMPH unlike animals trained on an FR1 schedule. The FR15 rats developed increasing levels of stereotypic behavior over the course of the 20 minute session and a dose-response analysis revealed a left shift in FR15 as compared to FR1 rats. To determine if the above behavioral augmentation occurred outside the operant environment, rats were assessed in their home-cage environments. No differences in stereotypy ratings between groups were observed.

In a similar study, the effects of low-dose COC were examined. A similar response suppression was observed in rats performing on the FR15 schedule though the stereotypy that was observed during the session was qualitatively different to the AMPH-induced stereotypy. Dose-response analysis of COC revealed a left shift in FR15 rats but, unlike AMPH, there was some response suppression at all doses. A home cage assessment between groups revealed no differences in the stereotypic response to COC and measures of locomotor behavior obtained immediately following ICSS were also no different.

We propose that the FR15 schedule induces an elevated DA release *only* within the context of the operant environment and that the addition of the AMPH or COC results in an elevated baseline resulting in the development of stereotypic behaviors that compete with the performance of the lever-press response.

EFFECTS OF REPEATED SKF 38393 AND APOMORPHINE TREATMENTS ON LOCOMOTOR ACTIVITY AND DOPAMINE SYNTHESIS J.K. Rowlett*, B.A. Mattingly and M.T. Bardo, Departments of Psychology, University of Kentucky, Lexington, KY 40506 and Morehead State University, Morehead, KY 40351.

Chronic treatment with the dopamine receptor agonist apomorphine results in a progressive increase in locomotor activity (ie., behavioral sensitization). This behavioral sensitization effect is accompanied by augmented dopamine synthesis. The present study was conducted to assess the role of D_1 dopamine receptor stimulation in the augmented dopamine synthesis effect produced by chronic apomorphine treatment. Rats were injected with vehicle, apomorphine (5 mg/kg) or one of two doses of the D_1 agonist SKF 38393 (8, 16 mg/kg) daily for 10 consecutive days. Behavioral sensitization of locomotor activity was observed in rats treated with daily apomorphine, but not SKF 38393. Dopamine synthesis, as measured by accumulation of dihydroxyphenylalanine (DOPA) following inhibition of DOPA decarboxylase with NSD-1015, was enhanced in the caudate-putamen of rats treated with repeated apomorphine, but not SKF 38393. Since apomorphine challenge in rats treated with repeated SKF 38393 results in behavioral sensitization, these data suggest that the augmented dopamine synthesis effect observed after repeated apomorphine treatment is neither mediated by D_1 dopamine receptors nor is likely to be the primary mechanism of behavioral sensitization. (Supported by a grant from the Kentucky EPSCoR committee).

EFFECTS OF DOPAMINE BLOCKADE ON THE HYPERACTIVITY PRODUCED BY DRUG INJECTIONS INTO THE MEDIAN RAPHE NUCLEUS. I.Shim*, J. Krebs and D. Wirtshafter, Dept. Psychol., Univ. Ill at Chicago, Box 4348, Chicago, IL 60680.

We have shown previously that injections of GABA and opioid agonists into the median raphe nucleus (MR) result in large increases in both locomotor activity and dopamine turnover within the nucleus accumbens. In the present study, we examined the possibility that the MR's influence on locomotion might be mediated by alterations in dopamine release. Hyperactivity was induced by intra-MR injections of either the GABA-A agonist muscimol (25 ng), the GABA-B agonist baclofen (62.5 ng), the mu opiate agonist DAGO (437.5 ng), or the delta opiate agonist DPDPE (7.5 ug). For comparative purposes, activity was also studied after systemic treatment with d-amphetamine (1.5 mg/kg). All of these treatments resulted in approximately equal degrees of hyperactivity. Pretreatment with the dopamine antagonist haloperidol, at a dose of 0.4 mg/kg, was able to abolish the hyperactivity induced by systemic amphetamine or by intra-MR injections of DAGO or DPDPE. In contrast, haloperidol was without effect on the response to intra-MR injections of muscimol or baclofen. These results suggest that dopamine may be involved in the response to intra-MR injections of opiates, but is unlikely to play a critical role in the rosponse to GABA agonists. These data also suggest that different populations cells may mediate the locomotor responses to intra-MR injections of GABA and opiate agonists.

FORCE LEVER PERFORMANCE OF RATS WITH METH-AMPHETAMINE-INDUCED DOPAMINE LESIONS AND PRE-TREATED WITH VITAMIN E. C.S. Myers and G.C. Wagner*. Psychology Dept., Rutgers Univ. New Brunswick, NJ 08903

Rats treated with methamphetamine (12.5 mg/kg for 4 SC injections at 2-h intervals) exhibited a 32% depletion of striatal dopamine. Pretreatment with vitamin E (2 g/kg for 4 SC injections at 24 h intervals) protected the rats against this lesion.

In a behavioral assessment of fine motor control, rats were trained (over the course of one year) to press a lever with 11-15 g of force for 1.0 sec to procure a water reinforcer. Lesioned rats earned fewer reinforcers/session than control or vitamin E rats and also made more force band entrances/reinforcer. However, lesioned rats and those pretreated with vitamin E were more sensitive to the disruptive effects of pre-session oxotremorine (dose range 0.025 - 0.2 mg/kg, administered 30 min presession). Therefore, vitamin E afforded protection against the dopamine lesion but not against the increase in sensitivity to oxotremorine.

DIABETIC RATS DISPLAY BLUNTED BEHAVIORAL RESPONSE TO d-AMPHETAMINE OR DARK PHASE; IMPLICATIONS OF ALTERED DOPAMINE (DA) FUNCTION. Q. AHMAD AND Z. MERALI* Sch. of Psychol. & Dept. of Pharm. Univ. of Ottawa, Ont. Canada. K1N 9A9.

The behavioral response of Spontaneously diabetic Wistar BB rats (SDR) (maintained on insulin) and matched controls (CTL), to systemically administrated d-amphetamine (d-AMPH) during early (0-2 months), intermediate (4-8 months) and long-term (8-12 months) stages of diabetes, was assessed. Each stage comprised of a different set of animals. Behaviors monitored for 1 hr periods included locomotion, general activity, rearing frequency and duration. During the early stage, d-AMPH (0, 0.3, 0.5, 1.0 mg/kg) induced a dose dependent increase in behavior of CTL rats. The SDR group only responded to the higher doses (0.5 and 1.0 mg/kg) of d-AMPH and with a smaller magnitude than the CTL group. At the intermediate and long-term stages, the SDR again displayed a shift to the right of the d-AMPH dose response curve. Similarly blunted behavioral activation was also noted in the SDR during the dark phase of the light cycle. Specifically, the SDR displayed lower levels of activity at light offset or before light onset. Thus the attenuated response of the SDR may be related to the impairment of synthesis and/or release of DA. This contention was tested in SDR (intermediate state), using microdialysis. Extracellular levels of DA at the nucleus accumbens were monitored every 20 min during the dark phase, in behaving animals. The SDR had a higher basal level of DA as compared to CTL. However, the SDR displayed blunted fluctuations in DA levels, as compared to CTL. Thus the diabetic state may be related to altered DA release pattern and/or altered post synaptic responses to DA.

DRUG INDUCED DOPAMINE RECEPTOR SENSITIZATION: A CRITICAL ROLE FOR CONTEXTUAL CUES. R.J. Carey.* SUNY and V.A. Medical Centers, Syracuse NY 13210.

The unilateral 6-OHDA lesion model is widely used as a behavioral assay for direct acting dopamine agonists. In the present report, behaviorally matched sets of rats with unilateral 6-OHDA lesions were given repeated injections of apomorphine (0.05 mg/kg) either paired or unpaired to test environment in which rotational behavior was measured using a video image analysis system. Subsequently the animals were given 10 mg/kg L-DOPA plus 1 mg/kg Carbidopa or Saline prior to testing. Importantly, only animals which had received apomorphine paired to the test environment exhibited contralateral rotation following L-DOPA treatment. Biochemical measurements using HPLC-EC indicated that L-DOPA produced equivalent increases in metabolites of L-DOPA and dopamine in the paired and unpaired groups. While dopamine levels were comparable in paired and unpaired groups the concentrations of L-DOPA were selectively elevated in the paired group. These findings indicate that contextual cues can have substantial impact upon the biochemical and behavioral expression of sensitization effects induced by dopamine agonists.

447.9

INTERACTION OF APOMORPHINE AND COPULATORY BEHAVIOR IN THE "PENILE-ERECTION/STRETCHING-YAWNING SYNDROME." B. D. Sachs*, K. Akasofu, and S. S. McEldowney. Univ. of Connecticut, Storrs, CT 06269-1020.

In two studies, freely moving male rats were observed after they had varying amounts of copulation followed by injection apomorphine (APO; 60 ug/kg sc; a dopamine agonist), or vehicle. As expected, APO increased erections and yawning in males that had no antecedent sexual contact. Surprisingly, three intromissions or one ejaculation potentiated erections even in vehicle-treated males, which did not differ from APO-injected copulating males. Sexually exhausted rats had no APO-induced erections, a significant depression relative to the other groups. Copulation did not affect yawning in either study. Stretching was rarely seen and may not be a reliable component of the syndrome. We infer that copulation has a biphasic effect on the erectile component of the "PE/SYS," mediated in part by changes in neurochemical activity that are specific to brain systems involved in erection, or at least do not include systems that regulate yawning. RESERPINE-INDUCED ORAL DYSKINESIA IN RATS: EFFECT OF DOSE AND COMPARISON TO TETRABENAZINE. J. L. Neisewander*, E. Castañeda, and D. A. Davis. Department of Psychology, Arizona State University, Tempe, AZ 85287-1104.

Repeated administration of reserpine (1 mg/kg) in rats produces a severe depletion of monoamines, and induces the development of oral dyskinesia that reaches a maximal level within 3 days. To examine whether lower doses of reserpine would result in a slower development of oral dyskinesia, rats were injected SC with either 0, 0.01, 0.1, or 1.0 mg/kg reserpine every other day for 60 days. Oral dyskinesia was measured 24 hr after injections by recording the incidence of tongue protrusions (TPs) for 30 min. Rats treated with 1 mg/kg developed TPs within 3 days, whereas rats treated with the 0.1 mg/kg developed TPs after 10-20 days, and rats treated with 0.01 mg/kg had not developed TPs by 60 days of treatment. These findings suggest that less severe depletion of monoamines may result in a slower development of TPs, similar to the protracted development of tardive dyskinesia in humans. Furthermore, we suggest that a severe depletion of monoamines may induce neurochemical changes similar to those that underly tardive dyskinesia, but at an accelerated rate. We also examined whether tetrabenazine, another monoamine depleting agent, would induce oral dyskinesia. Rats were injected with either vehicle, reserpine (1 mg/kg, SC, every other day), or tetrabenazine (3 mg/kg, SC, either once or twice daily) for 21 days. TPs, grooming, and locomotor activity were measured for 30 min 12-24 hr after the last injection. Both reserpine and tetrabenazine treatment produced an increase in TPs. Tetrabenazine, however, also produced an increase in grooming and locomotor activity relative to the other groups, suggesting the increase in TPs produced by tetrabenazine may be due to an increase in overall activity rather than a dyskinesia. Reserpine produced a more severe depletion of monoamines (88-94%) relative to tetrabenazine (28-58%). Reserpine also produced a 450-900% increase in dopamine and serotonin turnover as measured by neurotransmitter to metabolite ratios, whereas tetrabenazine did not alter turnover. Relationships between changes in brain monoamine levels and behavior will be discussed.

447.11

SCHEDULE-INDUCED POLYDIPSIA INCREASED BOTH MESOLIMBIC-DOPAMINERGIC AND PONTINE-NORADRENERGIC ACTIVITIES IN THE RAT BRAIN. T. H. Yin, C.C. Lu, Y.P. Liu and C.S. Tung. Department of Physiology, National Defense Medical Center, PO Box 90048, Taiwan, R.O.C.

We have demonstrated previously that the activity of schedule-induced polydipsia (SIP) was persistently depressed after bilateral symmetrical locus coeruleus lesions and ventral tegmental area lesions in succession. The hypothesis that central catecholaminergic neurons mediate animal behaviors in arousal or coping processes, e.g., SIP, was tested by the demonstration of concomitant changes in neurotransmission in regions of appropriate nerve terminals. By using HPLC-ECD techniques, the biochemical derivatives including DA, NE, 5-HT, DOPAC, DOPA, MHPG-SO_4 and 5-HIAA were measured to assess the regional turnover of monoamines in SIP and control rats. It was found in the SIP rat that DA levels and DA synthesis and utilization in the limbic area were increased and that NE synthesis in several pontine coeruleo-NE projections, e.g., hippocampus, cortex and pons, were also increased. Conversely, the NE-metabolism in the hippocampus and cortex and 5-HT metabolism in the same areas were decreased in the SIP rat. We therefore concluded that enhanced actions of both DA-limbic system and NE-coeruleo system are important in the process of SIP establishment.

447.12

DOPAMINERGIC CONTROL OF MALE COPULATORY BEHAVIOR IN QUAIL: RECEPTOR AUTORADIOGRAPHY AND PHARMACOLOGICAL STUDIES. P. Absil*, S. Das, G.F. Ball, J.M. Casto and J. Balthazart Laboratory of General and Comparative Biochemistry, University of Liège, Belgium, Dept of Psychology, Johns Hopkins Univ., Baltimore, MD 21218, USA.

In quail, dopamine (DA) turnover in the medial preoptic nucleus (POM) is higher in males than in females. In that POM is a key site mediating the action of testosterone (T) on sexual behavior, this suggests that DA may be involved in the control of this behavior. Also, tyrosine hydroxylase-immunoreactive fibers innervate aromatase containing cells suggesting that DA may modulate the aromatization of T into estrogens, a limiting step in the behavioral activation. We now demonstrate the presence of D1 and D2 dopaminergic receptors in the quail brain as identified by autoradiography using [^{3}H]SCH23390 and [^{3}H]raclopride as ligands. Highest levels of binding were found in the basal ganglia. In addition, lower densities of receptor were identified in areas directly implicated in the control of reproduction such as the preoptic area and hypothalamus. The behavioral effects of DA were analyzed by in vivo pharmacological manipulations. In a first experiment, the DAergic agonist, apomorphine (APO; 1µg to 10 mg/kg) inhibited male sexual behavior induced by T in castrated (CX) males. Inhibition was statistically significant for doses higher than 10µg/kg and complete at 1 mg/kg. In a second experiment, repeated injections of APO (0, 10 or 1000 µg/kg for 9 days) did not change the sensitivity of the DA receptors in connection with behavior activation. The T-induced copulatory behavior measured in CX males 24 hours after the last APO injection was not affected but the dose of 1 mg inhibited the behavior in tests performed 15 min after the injection. Several reports have indicated that in rat, APO stimulates certain aspects of male behavior. The inhibitory effects observed here may reflect a higher density or higher sensitivity of the D2 dopamine autoreceptors in quail resulting in a decreased DAergic transmission after APO administration. This hypothesis was tested by measuring behavioral effects of APO in quail pretreated with spiperone, a specific D2 antagonist. Spiperone (0.5 mg/kg) alone enhanced the T-induced copulatory behavior and completely blocked the inhibitory effects of APO. These data support our interpretation but additional studies are required to elucidate the precise role of D1 and D2 receptors in the control of sexual behavior in male quail.

HIGH-PEAK BLOOD ETHANOL CONCENTRATIONS RESULTING FROM POSTNATAL EXPOSURE TO ETHANOL AFFECT MEMORY-BASED BUT NOT CUED DISCRIMINATIONS IN THE INFANT RAT.

J. L. Diaz-Granados*, P. L. Greene, G. Y. Espinoza, & A. Amsel. Department of Psychology & Institute for Neuroscience, University of Texas, Austin, TX, 78712.

We have previously shown that postnatal exposure to ethanol that produces high-peak blood ethanol concentrations in infant rats, results in significant deficits in hippocampal neuroanatomy and discrimination learning based on the memory of singly alternated rewarded (R) and nonrewarded (N) trials (Greene, et al., *Behav. Neurosci.*, 106:51, 1992). In the present experiment, we tested infant rats, artificially reared and exposed to ethanol from postnatal day 4 to 9, in a straight alley on a discrimination using rough and smooth floor textures as cues. On day 4 postpartum, pups were fitted with gastric cannulas and a nutritionally adequate diet was infused intragastrically for 15 minutes once every hour. In 4 consecutive morning feedings one group of pups received an ethanol-adulterated diet while postnatal controls received an isocaloric diet. (A third group was raised normally in a litter.) The remaining 20 feedings for all pups were with unadulterated diet. On days 17-18, animals were tested on one of three discrimination schedules: single alternating R and N, random R and N, or random R and N followed by a discrimination reversal. The ethanol-exposed animals were not different from the normals or the artificially-reared controls in either alternating, or the random or reversed discriminations. These results indicate that the defect in discrimination reported earlier in ethanol-exposed, hippocampally damaged animals is a memorial deficit and not a general deficit in discrimination, since pups discriminate normally when external cues are made available. Supported by NIAAA grant AA07052.

448.2

DIFFERENTIAL PERINATAL EFFECTS OF HIGH-PEAK BLOOD ETHANOL CONCENTRATION ON LEARNED PERSISTENCE IN THE WEANLING RAT.

Abram Amsel*, Paul Greene, & Jaime L. Diaz-Granados. Department of Psychology and Institute for Neuroscience, University of Texas, Austin, Texas, USA.

The partial reinforcement extinction effect (PREE), an indicant of relative learned persistence, was tested in a straight alley for a food reward in 21-day-old rats after prenatal, postnatal or combined exposure to high-peak blood ethanol concentration (BEC). Pregnant dams were intubated once per day from gestational day 12 to 18 with either an ethanol-adulterated (5g/kg) or an isocaloric control diet. On day 4 postpartum, pups were fitted with gastric cannulas and were reared artificially from days 4 to 10: A nutritionally-adequate diet was infused intragastrically for 15 minutes once every hour. Pups in the postnatal EtOH condition received 4 consecutive feedings every morning with ethanol-adulterated diet while postnatal controls received an isocaloric diet. The remaining 20 feedings for all pups were with unadulterated diet. Pups with either prenatal or postnatal exposure to ethanol showed an attenuation of the PREE. The PREE was spared in the combined-exposure condition. This seemingly paradoxical result confirms an earlier one involving a significantly lower BEC (Wigal & Amsel, *Behav. Neurosci.*, 104:116, 1990). Brain weights were significantly reduced as a function of postnatal exposure to ethanol. Supported by NIAAA grant AA07052.

SEX-DEPENDENT EFFECTS OF PRENATAL ALCOHOL EXPOSURE ON CIRCADIAN RHYTHMS OF TEMPERATURE AND ACTIVITY IN RATS.

B. Zimmerberg*, K.M. Broadhurst and R.C. True. Williams College, Williamstown, MA 01267

Fetal Alcohol Syndrome is associated with altered sleep and feeding patterns in newborns. This experiment investigated persistent effects of in utero alcohol exposure on circadian rhythms in adult offspring. Adult male and female rats born to either control, pair-fed or alcohol-exposed dams were monitored for body temperature and activity using a telemetry system under various LD schedule conditions. Baseline (12:12 LD) or 14:10 LD measures were unaffected by prenatal treatment, but females were more active, had higher mean body temperature, and had higher maximal temperatures that peaked earlier than males. Under a free-running schedule (LL), alcohol-exposed males were less active than controls; females did not differ by treatment. Mean and maximum temperatures were higher in alcohol-exposed males and lower in alcohol-exposed females than same sex controls, thus they no longer displayed the typical sex-dependent pattern. Although all subjects demonstrated phase advancement, alcohol-exposed subjects lagged behind controls. Morphometric analysis of the volume of the SCN was inconclusive. These results suggest that the stress of a free-running schedule revealed underlying thermoregulatory dysfunction caused by prenatal alcohol exposure. (Supported by NIAAA AA08605)

448.4

PARALLEL SLEEP AND MEMORY DEFICITS IN ADULT RATS AFTER PRENATAL EXPOSURE TO ALCOHOL.

W.S. Stone*, H.J. Altman, P. Parekh and P.E. Gold. Dept. Psychology, U. of Virginia, Charlottesville, VA 22903, and Dept. of Beh. Animal Res., Lafayette Clinic, Detroit, MI 48207 .

Learning and memory deficits after prenatal alcohol exposure occur both during development and in adulthood. Sleep deficits are also prominent in neonatal humans and rats. Our previous findings demonstrate that paradoxical sleep and memory are correlated in several amnesic populations, suggesting the possibility that deficits in paradoxical sleep will accompany deficits in memory in adult rats prenatally exposed to alcohol.

To address this issue, pregnant Sprague-Dawley rats were fed a liquid diet including 35% ethanol-derived calories, or were pair-fed an isocaloric diet, from gestation days 8-19. Sleep (3 hr records via cortical electrodes), 8-arm radial maze (1 trial/day for a maximum of 20 trials or a criterion of 3 consecutive days of 1 error or less, followed by 1 trial with a 1 h delay interposed between choices 4 and 5), and inhibitory avoidance (1 ma, 1 s FS, 24 h train-test interval) performance were assessed in 5-month-old female offspring of alcohol-exposed and pair-fed control groups (Ns = 9).

The alcohol-exposed group learned the radial maze more slowly than did the pair-fed control group, but did not differ on other behavioral measures. In addition, measures of paradoxical - but not nonparadoxical - sleep were significantly reduced in the alcohol-exposed group. These findings provide the first evidence, in any species, that prenatal exposure to alcohol results in selective and persistent deficits in sleep. They also show more generally that measures of paradoxical sleep may be useful biological markers of memory deficits. (Supported by NSF BNS-9012239, ONR N0001489-J-1216, and NIA AG 07648. We gratefully acknowledge the Fetal Alcohol Res. Ctr. at Wayne State U. for providing the alcohol-exposed rats).

ETHANOL CONSUMPTION SUPPRESSES IMMUNE RESPONSE IN FETAL ETHANOL-EXPOSED RATS.

J.Weinberg* and T.R.Jerrells, Dept of Anatomy, Univ of British Columbia, Vancouver, BC V6T 1Z3; Dept of Cellular Biology & Anatomy, Louisiana State Univ, Shreveport, LA 71103.

Ethanol consumption during pregnancy may alter immune function of offspring. Our previous work found that fetal ethanol-exposed (E) animals had decreased thymocyte number, decreased splenic lymphocyte response to concanavalin A (ConA), and a functional defect in T-cell response to a secondary stimulation by IL-2, as compared with pair-fed (PF) and control (C) animals. Importantly, deficits occurred in E males but not females. In the present study we examined the vulnerability of E offspring to the immunosuppressive effects of ethanol exposure in adulthood.

Adult Sprague-Dawley males and females from prenatal E, PF and C conditions were assigned to E or PF adult treatment groups. Six groups were thus formed, with Prenatal--Adult treatments as follows: E--E, E--PF; PF--E, PF--PF; C--E, C--PF. Adult E or PF treatment was continued for 4 wk.

Sex differences in treatment effects were found. For females, C--PF animals had higher thymus cell counts than animals in all other groups. There were no differences among females from the 3 prenatal groups in splenic lymphocyte response to ConA, although adult ethanol consumption had some suppressive effects on response in E and C animals. For males, thymus cell counts were lower in E--E than in E--PF animals; no other treatment groups showed this differential response. In addition, both E--E and E--PF males exhibited a suppressed lymphocyte response to ConA; males from prenatal PF and C conditions showed no suppression unless exposed to ethanol in adulthood. Supported by AA07789 (JW) and AA07731 (TRJ).

448.6

ACUTE ETHANOL EXPOSURE DEPRESSES STIMULATED GLUTAMATE RELEASE IN THE HIPPOCAMPUS OF THE DEVELOPING GUINEA PIG.

J.D. Reynolds, J.V. Milligan* and J.F. Brien. Dept. of Pharmacology and Toxicology, and Dept. of Physiology, Queen's University, Kingston, Canada, K7L 3N6.

It has been proposed that glutamate (GLU) mediates ethanol (E) teratogenesis in the hippocampus. Our objective was to elucidate the effect of acute E exposure on spontaneous and potassium ion (K^+)-stimulated release of GLU in the hippocampus of the near-term fetal and adult guinea pig. GLU release was measured as efflux in 300-μm thick, transverse, hippocampal slices. Acute *in vivo* E exposure involved oral intubation of 4 g E/kg body weight in near-term pregnant and adult male and female guinea pigs, which were studied 1 hr after dosing. Acute *in vitro* E exposure involved incubation of tissue slices with 48 mM E, the apparent maximal blood [E] at 1 hr after 4 g E/kg body weight. E did not affect spontaneous GLU efflux. *In vitro* E decreased K^+-stimulated GLU efflux in the fetus and adult. *In vivo* E and *in vivo* plus *in vitro* E decreased K^+-stimulated efflux of GLU in the fetus, but not in the adult. These data indicate that: (a) in the near-term fetal guinea pig, acute E exposure depresses stimulated GLU release in the hippocampus, and (b) in the adult guinea pig, tolerance develops to the depressant effect of E on stimulated hippocampal GLU release after a single E dose. 448.7

THIAMINE-DEPENDENT ENZYME CHANGES IN THE BRAINS OF ALCOHOLICS: RELATIONSHIP TO THE WERNICKE-KORSAKOFF SYNDROME.
R.F. Butterworth[1*], J. Kril[2] and C. Harper[2]. [1]Neuroscience Research Unit, A-V CRC, Hôpital St-Luc (University of Montreal), Montreal, Quebec, Canada H2X 3J4 and [2]Dept of Pathology, University of Sydney, Sydney, Australia.

Previous studies in experimental animal models suggest that the cerebral dysfunction and cell death in the Wernicke-Korsakoff Syndrome (WKS) result from reductions of thiamine-dependent enzyme activities in brain (Butterworth, Alcohol & Alcoholism, 24, 271-279, 1989). As part of a series of studies of the role of thiamine deficiency in the pathogenesis of the WKS in humans, activities of the thiamine-dependent enzymes pyruvate dehydrogenase (PDH), α-ketoglutarate dehydrogenase (αKGDH) and transketolase (TK) were measured by standard spectrophotometric procedures in samples of frontal cortex and cerebellum of 10 alcoholic patients who died in hepatic coma with no clinical or pathological evidence of WKS, 2 alcoholic patients with neuropathologically confirmed WKS and 10 control subjects free from neurological disease. Reductions of TK (by 75%), PDHC (by 82%) and αKGDH (by 90%) were observed in the brains of WKS patients. Activities of the non-thiamine-dependent enzyme glutamate dehydrogenase were within normal limits in brain tissue in all alcoholic patients ± WKS. Activities of all three thiamine dependent enzymes were unchanged in the brains of alcoholic patients dying in hepatic coma. These findings demonstrate, for the first time, a direct link between reductions in activities of thiamine-dependent enzymes and WKS in humans (Funded by The Medical Research Council of Canada).

448.8

NEURONAL AND ASTROCYTIC RECEPTOR CHANGES IN AUTOPSIED BRAIN TISSUE FROM ALCOHOLIC PATIENTS WITH HEPATIC ENCEPHALOPATHY.
J. Lavoie*, G. Girard, D.K. Leong and R.F. Butterworth, Neuroscience Research Unit, André-Viallet Clin. Res. Centre, Hôpital St-Luc (University of Montreal), Montreal, Quebec, Canada H2X 3J4.

As part of a study of neurochemical mechanisms in alcohol-related brain damage, neuronal and astrocytic binding sites for specific radioligands were measured in autopsied brain tissue from 9 cirrhotic alcoholic patients and an equal number of control subjects free from neurological disease. Neuropathological examination revealed no evidence of Wernicke's Encephalopathy. Binding densities (Bmax) and affinities (Kd) were obtained by Scatchard analysis using standard filtration assays and GFB filters. No changes of Kd or Bmax for the GABA-A/Benzodiazepine receptor complex were observed using ^{3}H-muscimol, ^{3}H-flunitrazepam or ^{3}H-Ro 15-1788. Binding parameters for the glutamate receptor ligands ^{3}H-kainate or ^{3}H-MK801 were likewise unaltered in the brains of alcoholics. Densities of muscarinic cholinergic receptors, evaluated using ^{3}H-quinuclidinyl benzilate (^{3}H-QNB) were reduced in frontal cortex (by 23%) and temporal cortex (by 27%) and densities of astrocytic mitochondrial ("peripheral-type") benzodiazepine receptors (PTBR's) were increased by 48% in frontal cortex of alcoholics. Similar changes in PTBR's were observed in rat brain following portacaval anastomosis (Giguère et al., Brain Res. 1992) suggesting that these changes result from chronic liver disease rather than alcohol per se. These findings suggest that (i) neuronal cell loss in alcoholics dying in hepatic coma is restricted to a modest loss of cortical cholinergic neurons and (ii) chronic liver disease results in increased densities of mitochondrial benzodiazepine receptors. (Funded by The Medical Research Council of Canada)

448.9

CHRONIC INTRAGASTRIC INFUSION OF ETHANOL RESULTS IN THE PRODUCTION OF TOLERANCE TO ETHANOL IN MICE.
W. Cao*, T.K. Landon, A.C. Collins. Institute for Behavioral Genetics, Univ. of Colorado, Boulder, CO 80309

The present study characterized chronic intragastric infusion as a method for developing tolerance to ethanol in mice. The selectivity bred long sleep (LS) and short sleep (SS) mice were used. Male mice were anesthetized and were surgically prepared with a catheter in the stomach. The mice were infused every 6 hours with physiological saline or ethanol (3.0 or 4.0 g/kg). Potential tolerance to ethanol was determined by measuring the effects of challenge doses of ethanol on body temperature, open field and Y-maze activities. In addition, the mice were given an anesthetic dose of ethanol (6.0 g/kg for SS, 3.5g/kg for LS) and the duration of sleep time was scored. The mice were tested 6 hours after termination of infusion. Chronic infusion resulted in tolerance to virtually all of the effects of ethanol in both mouse lines. However, the LS developed tolerance more readily (after shorter periods of infusion) and to a greater degree. Chronic infusion did not result in changes in the rate of ethanol metabolism in either mouse line which suggests that this procedure results in pharmacodynamic tolerance to ethanol's effects. Thus, the intragastric infusion method, which allows for very precise regulation of dose and dose interval, is a useful technique for producing tolerance to ethanol in mice. Supported by AA-06391 and DA-00116.

FURTHER CHARACTERIZATION OF AN ANIMAL MODEL OF ETHANOL WITHDRAWAL "KINDLING".
H.C. Becker* and R.L. Hale. VA Medical Center and Medical University of South Carolina, Charleston, SC 29401

We have previously demonstrated that animals exposed to ethanol (EtOH) for a total of 48 hrs exhibit more severe withdrawal seizures if exposure is divided into three 16 hr intoxication/8 hr abstinence cycles than when the 48 hrs of exposure occurs in a single bout. This pattern of results supports the "kindling" hypothesis of EtOH withdrawal in that repeated episodes of EtOH withdrawal result in a progressive intensification of withdrawal seizures. The present study was designed to further characterize this animal model of EtOH withdrawal "kindling" and examine whether such a "kindled" response is still evident when withdrawal testing is conducted following an additional intoxication bout. Adult male C3H mice were chronically exposed to EtOH vapor in inhalation chambers for 40 hrs prior to withdrawal testing. Prior to this 40 hr bout of intoxication, one group (Multiple Withdrawal; MW) received 3 cycles of 16 hrs EtOH vapor separated by 8 hr periods of abstinence; a second group (Continuous Exposure; CE) received the same total EtOH exposure (48 hrs) without interruption; and a third group (Single Withdrawal, SW) did not receive any EtOH exposure prior to the 40 hr test cycle. A control (C) group was included that did not receive any EtOH exposure throughout the experiment. Blood EtOH concentrations (BEC) following the 40 hr period of EtOH exposure were 100-140 mg/dl for all EtOH-exposed groups. Mean areas under the 24 hr curve for handling-induced convulsions after the 40 hr EtOH exposure period for MW, CE, SW, and C groups were 33±4, 18±4, 3±1, and 0±0, respectively. These results indicate that differences in the severity of EtOH withdrawal seizures due to differences in prior withdrawal experience can be demonstrated even when later EtOH exposure patterns are equated. Supported by the VA Medical Research Service and NIAAA.

448.11

EFFECT OF ETHANOL ON ADENOSINE RECEPTORS CONTRIBUTES TO THE DEVELOPMENT OF THE WITHDRAWAL SYNDROME.
S.M. Rezazadeh*, C.J. Wallis, and H. Lal Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX, 76107.

It has been hypothesized that stimulation of adenosine receptors is involved in ethanol (ETOH) intoxication and the development of tolerance. We investigated an ethanol withdrawal symptom ("anxiety-like" behaviors) using the elevated plus maze (EPM) paradigm (Lal et al., Alcohol 8:467, 1991). Long-Evans hooded rats were given a balanced liquid diet containing 4.5% ETOH for 10 d (Lal et al., JPET 247:508, 1988). Twelve h after a final ETOH dose (3g/Kg, po), rats were tested in the EPM. We observed a significant reduction in the open-arm activity and the number of total arm entries indicative of ETOH withdrawal. Pre-treatment with an A1 adenosine agonist, R(-)-N6-(2-phenylisopropyl)-adenosine (PIA, 0.08-0.32 mg/Kg, ip, 15 min), had little effect on performance in the EPM during ethanol withdrawal. Acute treatment with an A1 adenosine antagonist, 8-cyclopentyl-1,3-dimethylxanthine (CPT, 0.02-0.16 mg/Kg, ip, 60 min), exacerbated ETOH withdrawal with a further reduction in open-arm activity. Chronic treatment with CPT (0.04-0.16 mg/Kg, ip, 2X/d) during the last 6 days of ETOH diet administration resulted in a dose related increase in the amount of time spent in the open-arms of the EPM, but had little effect on the number of total arm entries. These data support the hypothesis that an ethanol stimulated increase in adenosine receptor activity may be associated with the development of dependence and that blockade of adenosine receptors during ethanol treatment reduces the display of "anxiety-like" behaviors during ethanol withdrawal. Supported by NIAAA Grant AA06890.

448.12

EFFECT OF POST-TRAINING ETHANOL AND HYPERBARIC EXPOSURE ON APPETITIVE TASK MEMORY IN MICE.
C.L. Ladner, B.L. Jones, M. Babbini, R.L. Alkana* Dept. of Molecular Pharmacology and Toxicology, Univ. So. California Sch. of Pharm., Los Angeles, CA 90034.

Studies examining post-training ethanol's effects on memory have found conflicting task-dependent results. Recent work suggests that this apparent contradiction may be due to an inherent aversive component of ethanol. According to this hypothesis, treatment with ethanol results in the addition of aversive information to the pretreatment stimulus complex, altering retention performance. Low level hyperbaric exposure using a helium-oxygen (heliox) gas mixture has been shown to antagonize a number of ethanol's acute and chronic behavioral effects. The present study investigated whether hyperbaric exposure antagonized ethanol's aversive effects on appetitive task memory. Male C57BL/6J mice were individually trained to find a cheese pellet. Mice were immediately injected i.p. following training with saline or 2.0 g/kg ethanol (20% w/v) They were then returned to their home cage and exposed to 1 ATA air, 1 ATA heliox, or 12 ATA heliox for 2 hours. Retention performance was measured 24 hours after training in the non-drug state. Saline-air control mice ate the pellet significantly quicker after training, while all other mice exhibited a non-significant increase in latency, suggesting amnesia. However, habituation of locomotor activity and pellet approaches in all groups indicates that memory of the environment remains intact, while grooming data suggest that the amnesic response in the helium and ethanol groups reflects a subtle aversive effect of these treatments. Collectively, these results suggest that post-training exposure to heliox, like ethanol, is aversive and does not impair memory storage processes. Further studies are necessary to determine the mechanism of helium's aversive effect and whether pressure can antagonize the aversive effect of ethanol in this task. (Supported by NIAAA grants AA03972 & AA05234).

ANTAGONISM OF ETHANOL-INDUCED CONDITIONED PLACE PREFERENCE BY THEOPHYLLINE. C. L. Cunningham*, D. H. Malott, F. O. Risinger. Oregon Health Sciences University, Portland, OR 97201-3098

Acute exposure to ethanol (EtOH) elevates adenosine levels in brain, and it appears that adenosine may be involved in the central depressant actions of EtOH. The present study examined the role of adenosine in mediating EtOH's rewarding effects by assessing the impact of a nonselective adenosine antagonist, theophylline, on ethanol-induced conditioned place preference. Inbred mice (DBA/2J) were exposed to a Pavlovian discriminative conditioning procedure in which a distinctive floor (tactile) stimulus (CS+) was paired four times with either EtOH (2 g/kg, IP), theophylline (30 mg/kg), or the combination of theophylline and EtOH. A different floor stimulus (CS-) was paired only with saline. Conditioning trial duration was 30 min and the theophylline pre-treatment interval was 30 min. Preference testing was conducted in the absence of either drug. Both EtOH and theophylline increased general activity on conditioning trials and their combination produced greater activity than either drug alone. As expected, EtOH alone resulted in conditioned place preference. However, theophylline alone produced conditioned place aversion. The group receiving the combination of theophylline and EtOH showed no evidence of place conditioning, suggesting these drugs cancelled each other's hedonic effects. This outcome does not appear to represent pharmacological antagonism, but seems more readily interpreted as an instance of behavioral or "functional antagonism."

449.1

FUNCTIONAL EFFECTS OF ACUTE ETHANOL IN ALCOHOL PREFERRING AND NON-PREFERRING RATS. LJ Porrino*[1], LJ Vogt[1], L Lumeng[2], T-K Li[2] and MJ Lewis[3]. [1]Bowman Gray School of Medicine, Winston Salem, NC, [2]Indiana University, Indianapolis, IN, [3]Howard University, Washington DC.

To study genetic influences on responses to ethanol, selective breeding has been used to develop the alcohol preferring (P) and alcohol non-preferring (NP) rat lines. We have shown that P rats have higher baseline rates of cerebral metabolism than NP rats in olfactory tubercle, while NP rats have significantly higher rates in hippocampus (Lewis, M.J., Neurosci. Abstr, 1991). In the present study, we have examined the functional effects of an acute dose of ethanol in P and NP rats using the quantitative autoradiographic 2-[14C]deoxyglucose method. Rates of glucose utilization were measured 10 minutes after the ip administration of 0.5 g/kg ethanol or vehicle. In NP rats ethanol administration significantly increased rates of glucose utilization in the olfactory tubercle, nucleus accumbens, ventral pallidum, and basolateral amygdala, and decreased rates in the lateral habenula. This pattern is quite similar to the distribution of changes observed in outbred Sprague-Dawley rats administered ethanol. In contrast, the same dose of ethanol had more modest effects in P rats. Only the posterior olfactory tubercle, ventral pallidum, and lateral habenula appeared affected by ethanol and these changes in rates of glucose utilization were much less pronounced than in NP rats. These data suggest that NP rats are more sensitive than P rats to the acute effects of a low dose of ethanol on brain functional activity. The metabolic response to ethanol, however, appears qualitatively similar in the 2 lines, although quantitatively different, in that the same neural circuits are activated in both lines, but to a different degree.

EFFECT OF ETHANOL AND GLUTATHIONE ON REACTION TIME IN RATS. Z.M. Post*, P.K. Randall, S.W. Leslie and C.K. Erickson. Div. of Pharmacol., Coll. of Pharm., Univ. of TX, Austin, TX 78712.

Glutathione (GSH) and NMDA similarly stimulate calcium uptake into dissociated brain cells. However, ethanol (EtOH) inhibits only GSH-stimulated uptake, perhaps because GSH blocks its purported site of action, the glycine site on the NMDA receptor complex. The interaction between GSH and EtOH has proven to be behaviorally significant in that rats given a hypnotic dose of EtOH regained the righting reflex sooner when pretreated with intracerebroventricular (ICV) GSH. The purpose of this study was to determine whether GSH pretreatment would also lessen EtOH-induced impairment of a reaction time (RT) task in rats.

On week 1 of a simple crossover design, behaviorally tolerant rats (n=12) were administered EtOH (i.g., 2.8 g/kg, 20% w/v in water) 15 min after ICV GSH (10 µl, 20 mM) or vehicle (10 µl artificial cerebrospinal fluid); on week 2, EtOH followed the alternate ICV agent. Although EtOH by itself impaired normal success and speed of response (85 v. 98% and 312 ± 24 v. 204 ± 11 msec at 30 min, respectively), performance after GSH was no different from vehicle. In a second experiment, EtOH-naive rats (n=10) were given 2.4 g/kg EtOH after ICV GSH or vehicle. Again, EtOH alone impaired response (63% success and 453 ± 29 msec) but GSH-treated rats were not protected. This lack of effect is probably due, at least in part, to the fact that the animals are highly practiced by the time drugs are administered. Also, there is great incentive to perform successfully, and thus, compensatory behavior is developed rapidly. It would be appropriate to test a behavior of intermediate demand which measures motor control, but to which less behavioral tolerance to EtOH develops. (Supported by funds from the Univ. of TX.)

449.3

EFFECTS OF NICOTINE ON CEREBRAL METABOLISM AND SUBJECTIVE RESPONSES IN HUMAN VOLUNTEERS. J.M. Stapleton*, J.E. Henningfield, D.F. Wong, R.L. Phillips, S.F. Gilson, R.F. Grayson, R.F. Dannals, and E.D. London, NIDA Addiction Research Center, and the Johns Hopkins Medical Institutions, Baltimore, MD.

Effects of nicotine (1.5 mg, i.v.) on cerebral metabolic rates for glucose (CMR_{glc}) are being studied in human volunteers, including cigarette smokers and nonsmokers. CMR_{glc} is measured by positron emission tomography using the [18-F] fluorodeoxyglucose method. Subjective and cardiovascular responses also are recorded.

Preliminary results indicated that smokers showed globally higher CMR_{glc} than nonsmokers in the placebo condition, and that both groups showed a widespread decrease of about 10% in response to nicotine. Smokers gave higher subjective responses than nonsmokers to questions about drug liking (e.g., "Did the drug have good effects?" or "How much did you like the drug?"). There were no differences between smokers and nonsmokers on ratings of drug strength (e.g., "How strong was the drug effect?" or "How much did you feel the drug?"). Smokers showed less nicotine-induced tachycardia than nonsmokers, presumably due to tolerance. The findings suggest that nicotine resembles other drugs of abuse in that it reduces CMR_{glc}. Relationships between CMR_{glc} and effects on mood are under investigation.

449.4

BEHAVIORAL EFFECTS OF NICOTINE CONSUMED BY RATS C. Ksir* and G. Mellor. Department of Psychology, University of Wyoming, Laramie WY 82071

Rats that had not consumed water for 24 hr were placed into 41 x 41 x 30 cm clear acrylic chambers with a 10-ml drinking tube in one corner. Each rat remained in the chamber for one hour, and activity was recorded using an Omnitech monitor. Water was given in the home cages for 2 hr after each session. By the 7th day all rats drank all 10 ml of water in the test chamber within 5 min. On the 8th -14th days the drinking tube contained 10% sucrose with 10 µg/ml nicotine. At first there was no apparent effect on locomotor activity, but over the 7 days of nicotine testing the total distance moved during the hour increased more than threefold. Subsequent test days alternated between presentation of 10% sucrose alone or sucrose plus varied nicotine concentrations. A significant dose-effect relationship was found with locomotor activity increasing in response to 5, 10 and 20 µg/ml nicotine solutions. Pretreatment with 1.0 mg/kg mecamylamine 20 min prior to tests with 10 µg/ml nicotine had no effect on volume consumed or time to drink, but did reduce the locomotor reponse.

Rats will drink 75 ml/day of 10 ug/ml nicotine in 10% sucrose in 24-hr, 2-bottle drinking tests with plain water in the 2nd bottle. Those rats quickly stop drinking significant amounts of nicotine either when the sucrose is removed from the mixture or when a third bottle is presented containing 10% sucrose without nicotine. Thus, we have been unable to demonstrate that rats develop a dependence on nicotine after consuming this sucrose-nicotine mixture. These findings call into question theories of drug dependence that tie reinforcing properties of drugs to their locomotor stimulant effects.

449.5

THE EFFECT OF MDL 28,133, A MIXED D2/5-HT2 ANTAGONIST, ON NICOTINE-INDUCED FACILITATION OF BRAIN STIMULATION REWARD. P.Z. Manderscheid*, R.A. Frank, J.H. Kehne, C.J. Schmidt & S.M. Sorensen. Dept. Of Psychology, Univ. of Cincinnati, Cincinnati, OH 45221 and Marion Merrell Dow Research Inst., Cincinnati, OH 45215.

There is evidence to suggest that increases in dopamine in the nucleus accumbens mediates the rewarding effects of psychomotor stimulants and that serotonin and dopamine antagonists can reverse stimulant-induced changes in mesolimbic dopamine activity. Previous work from our laboratory has shown that MDL 28,133 (MDL) can attenuate the reinforcing effect of both d-amphetamine and cocaine. The present study assessed the ability of MDL 28,133 to attenuate or block nicotine-induced facilitation of brain stimulation reward.

Rats implanted with bipolar ventral tegmental area electrodes were administered 1.0, 3.0, or 6.0 mg/kg MDL (IP) 1 hr prior to testing. MDL alone did not produce significant shifts in reward thresholds. However, when co-administered with nicotine (0.4 & 0.8 mg/kg IP, 45 min post-MDL), MDL produced a dose-dependent reversal of the threshold lowering effect of nicotine. Analysis of response rates indicated that MDL did not interfere with the animal's performance, as do other compounds with dopamine antagonist properties (i.e., haloperidol). This suggests that compounds with a serotonergic component may be effective pharmacotherapies in the treatment of psychomotor stimulant abuse. This research was supported by NIDA NRSA grant DA05482 to P.Z. Manderscheid and NIDA grant DA04483 to R.A. Frank.

449.6

PURKINJE CELL ELECTROPHYSIOLOGICAL SENSITIVITY TO NICOTINE IN TWO MICE STRAINS. R. DE LA GARZA*, D. ZENISEK, D. DURCHER, J. SAMS, A.C. COLLINS, AND M.J. MARKS. VAMC, Univ. of Colo., Denver, and Inst. for Behav. Gen. Univ. of Colo., Boulder, CO 80217.

A succesful strategy of pharmacogenetics is to compare the relative drug sensitivity of different strains of mice to the actions of psychoactive agents in order to investigate behavioral and physiological mechanisms of drug action. In the present studies, two mice strains (C57/BL and BUB) that differ profoundly in their behavioral sensitivity to nicotine (Marks et al., Pharmacol. Biochem. Behav. 33: 667-678, 1989) were used to study the electrophysiological sensitivity to nicotine in cerebellar cortex Purkinje cells. The Purkinje cell sensitivity of the C57/BL mice was considerably greater than the same cells of BUB mice. The ED50 values for nicotine actions were 39 psi x sec for the C57/BL mice and 91 psi x sec for the BUB mice ($p < .05$). These differences are consistent with (both in magnitude and direction) the relative sensitivites of these two mouse strains to several behavioral and physiological responses to nicotine. These two strains also differ in the development of tolerance following chronic i.v. infusion with nicotine (Marks et al., JPET 259: 392-402, 1991); the C57/BL mice developed maximal tolerance following infusion with a 4 mg/kg/hr nicotine dose whereas the BUB mice do not develop much tolerance at this dose. Consequently, mice of both strains were infused with 4 mg/kg/hr nicotine for 10 days and Purkinje cell sensitivity to nicotine was determined within 24 hours after withdrawal. Infusion with this dose of nicotine resulted in significant increases in cerebellar [3H]-nicotine binding, but α-[125I]-bungarotoxin (BTX) binding was unchanged by this treatment. Chronic nicotine infusion also did not evoke changes in Purkinje cell sensitivity in either mouse strain. The absence of an effect of chronic treatment on electrophysiological response to nicotine is consistent with the observations that infusion does not change cerebellar BTX binding.

CAFFEINE AND NICOTINE DO NOT MAINTAIN SELF-ADMINISTRATION IN RATS. J. Robinson*, S.L. Vrana, J. Broadbent, and S.I. Dworkin. Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

Although caffeine (CAF) and nicotine (NIC) are widely used, their reinforcing characteristics remain obscure. Attempts were made to assess the reinforcing efficacy of these compounds in rats. Six male Fischer 344 rats were implanted with indwelling jugular catheters and then trained on a fixed ratio (FR) schedule of food presentation. Animals were then allowed access to CAF (0.25 or 0.5 mg/infusion) or NIC (10 μg/inf) on a FR 1 schedule. In a different paradigm, one rat was given access to food, water, and CAF (0.25 mg/inf) 24 hr/day on a concurrent chained FR 1, FR 9 schedule. Responding maintained by CAF in the single-lever chambers resulted in a relatively high rate of responding following food-training, which substantially declined with time. CAF (0.25 mg/inf) infusions declined by approx. 75% in the second month as compared with the first. Increasing the dose (0.5 mg/inf) did not change response rates. Under the concurrent chained schedule only food and water maintained responding. These data indicate that CAF does not maintain reliable self-administration (SA) in rats, even when the animals were trained with food. It was found previously (Dworkin *et al.*, Soc. Neurosci. Abs. 17, 425, 1991) that NIC did not engender and maintain SA when it was delivered over a 5.6 sec time period. We examined if infusion duration could affect NIC SA. Rats allowed access to NIC did not attain reliable SA when infusions were delivered over 0.9 sec. These data confirm that NIC and CAF are not potent reinforcers in Fischer rats. NRTP-DAMAGED RATS DO NOT DEVELOP NORMAL CAFFEINE TOLERANCE. M.C. Fratzke*B.E. Digman, and R.M Chesire, Department of Psychology, University of Hawaii, Honolulu, Hawaii 96822.

Bilateral electrolytic lesions of the nucleus reticularis tegmenti pontis (NRTP) can release uninhibited, rapid forward locomotion (1-4). NRTP-damaged rats show atypical responses to a number of substances with abuse liability, including morphine or ethanol, which fail to block their movement (3,5-6) and amphetamine or caffeine, which partly reintegrate their movement (7-11). In this study, we examined the development of tolerance to caffeine in NRTP-damaged rats. 12 Long-Evans hooded rats were subjected to bilateral electrolytic lesions of the NRTP, and 5 were used as unoperated controls (we include 8 animals from a previous study (9)). Rats were injected either once per day for 7 days or 4 times total over 44 days with 20 mg/kg caffeine in normal saline (data were pooled). Normal rats showed increases in locomotion and movement typical of multiple exposures to caffeine (12-16), developed tolerance and returned to baseline at about the same rate reported elsewhere (12-16). NRTP-damaged animals also increased, then decreased their locomotion, but increases were over four times that of their baseline, and remained at levels at least three times that of their baseline. Thus, although NRTP-damaged rats did decline somewhat in activity on repeated exposure to caffeine, they did not develop typical tolerance. The results suggest that NRTP damage significantly delays and perhaps can prevent the development of tolerance to caffeine. The data support self-medication theories of substance use/abuse.

THE EFFECTS OF CAFFEINE ON CORTICAL AROUSAL. D.Velikonja, S.J. Segalowitz and S. Reinis*. Dept. of Psychology, University of Waterloo, Waterloo, ONT, N2L 3G1 and Brock University, St. Catharines, ONT, L2S 3A1.

Individual differences in reactivity and tolerance to caffeine are predicted to play a critical role in cortical arousal effects as measured by electrophysiological variables. Furthermore, it is believed that caffeine will have time-based effects on cortical arousal varying with daily patterns of activity and caffeine consumption. This hypothesis was tested in 20 first year university undergraduate students using a within-subjects design. Each subject participated in two test sessions, in which they consumed one half cup of naturally decaffeinated coffee or one containing powdered caffeine in doses based on the subjects body weight (3mgs/kg). Subjects were blind to experimental conditions. They proceeded to complete questionnaires related to their reactivity and tolerance to caffeine, and whether they were morning or evening types. One half hour elapsed between their consumption of the beverage and EEG testing. Subject's reaction time performance, auditory P300s and visual CNVs were compared on the two occasions. Prior to their date of testing subjects were required to monitor their caffeine consumption over a two-week period in order to determine their habituation to caffeine. A general increase in the amplitude of both N_1 and P_3 are expected, as well as a decrease in reaction time variability, which we expect will be related to individual differences in the CNV. We also predict that an increase in the CNV will also be related to decreased P_3 amplitude jitter in habitual caffeine consumers who are expected to have a higher tolerance and lower reactivity to the caffeine, and to an increase in P_3 amplitude jitter in non-habitual caffeine consumers who are expected to have lower tolerance and higher reactivity to the caffeine.

449.10

EFFECTS OF STEREOISOMERS OF ALANINE AND SERINE ON PHENCYCLIDINE-INDUCED HYPERACTIVITY IN THE RAT. Y.Tanii*, T.Nishikawa, A.Hashimoto and K.Takahashi, Natl. Inst. of Neurosci., NCNP, Tokyo, Japan and Dept. Neuropsychiatry, Toyama Med. & Pharm. Univ., Toyama, Japan.

Phencyclidine(PCP) has been considered to induce a schizophreniform psychosis in humans and behavioral disturbance in experimental animals by blocking the N-methyl-D-aspartate(NMDA) receptor. This study was performed to elucidate the effect of intracerebroventricular(i.c.v.) infusion of allosteric agonists for NMDA receptor on PCP-induced hyperactivity in the rat. Drugs were infused 10min before PCP administration (10mg/Kg,intraperitoneally). The locomotor activity was evaluated based on the method of Sturgeon et al. (1979) with minor modifications. In some experiments, the locomotor activity was also quantitated automatically with Animex-Auto (Muromachi-kikai Co., Japan). D-Alanine and D-serine significantly reduced the PCP-induced hyperactivity in a dose dependent manner. In contrast, the L-isomers of these amino acids were much less effective in antagonizing the hyperactivity induced by PCP. This stereoselectivity suggests that the antagonism of behavioral effects of PCP may be due to activation of the strychnine-insensitive glycine binding site, since the D-forms are more potent than the L-forms as agonists for the allosteric regulation site of NMDA receptor. In support of this view, 7-chlorokynurenic acid (i.c.v.) (a selective inhibitor of glycine allosteric site) reversed the diminution by D-Ser of hyperactivity elicited by PCP. The present findings suggest that stimulation of the allosteric regulation site of the NMDA receptor might possess a therapeutic efficacy in psychosis attributed to PCP and schizophrenia.

449.11

PHENCYCLIDINE, (+) MK-801 AND TCP-INDUCED CIRCLING PREFERENCE: CORRELATION WITH MONOAMINE LEVELS IN SELECTED REGIONS OF THE RAT BRAIN. S.F. Ali[1*], G.D. Newport[1], and H.S. Bracha[2]. [1]Div. of Neurotoxicology, National Center for Toxicological Research,FDA, Jefferson, AR. 72079, [2]Neuropsych. Lab., Dept. of Psychiatry, UAMS, Little Rock, AR 72205.

Phencyclidine (PCP; angel dust) is a drug of abuse known to produce a behavioral state in humans resembling schizophrenia/psychosis. PCP is a noncompetitive NMDA receptor antagonist, and produces a variety of behaviors in rats including circling, however, the behavioral effects of other noncompetitive NMDA receptor antagonists such as (+) MK-801 or TCP are still being elucidated. Here, adult female rats were dosed with PCP (10 mg/kg,ip), (+) MK-801 (0.1 mg/kg,ip) or TCP (5 mg/kg,ip) and circling preference was recorded for two hours before sacrifice to determine monoamine levels by HPLC/EC. Animals injected with PCP, (+) MK-801 or TCP showed a preference to turn to the left (65%, 72%, 62% respectively). PCP and (+) MK-801 also produced a significant increase of DOPAC and HVA in whole caudate nucleus (CN), nucleus accumbens and olfactory tubercles in both sides of the brain. Further dissection of the CN into medioventral and dorsolateral regions revealed that HVA was increased bilaterally except in globus pallidus where we found significant increases in dopamine (DA), DOPAC and HVA only on the left side after PCP and (+) MK-801 administration. However, after TCP treatment the effects were similar but did not reach statistically significant levels. These data suggest that PCP, (+) MK-801 and TCP produce a greater preference to turn left than right, a finding similar to that found in human psychosis. Furthermore, it is possible that this preference is due to the higher concentrations of DA, DOPAC and HVA found in the left side of the globus pallidus after drug administration.

449.12

Sigma-induced inhibition of adrenomedullary [^{3}H]NA reuptake is not mediated by the antidepressant site bound by [^{3}H]desipramine. C. Rogers* and S. Lemaire, University of Ottawa, Ottawa, Ontario Canada K1H 8M5.

The ability of several σ ligands to inhibit uptake of noradrenaline has been examined previously (Massamiri, 1991; Rogers, 1991). At present, the mechanism(s) involved in this inhibition are unknown. Evidence has been presented to suggest that σ ligands block noradrenaline reuptake by interaction with [^{3}H]desipramine ([^{3}H]DMI) receptors. The purpose of this investigation was to determine the degree of interaction of σ ligands with [^{3}H]DMI binding sites in bovine adrenal medulla. [^{3}H]DMI binding was dependent upon Na^+, protein concentration, time, temperature, and was saturable (k_D=2.87 nM B_{max}=216 pmol/g protein). [^{3}H]DMI binding was displaced by σ ligands, although the rank order of potency of these ligands did not parallel that found in [^{3}H]NA reuptake assays in this tissue. This data suggests that σ ligands and desipramine inhibit [^{3}H]NA reuptake through distinct receptors in bovine adrenal medulla. This work was supported by the HSFC, C.R. is a HSFC scholar.

INDIVIDUAL DIFFERENCES IN THE SENSITIVITY TO CORTICOSTERONE'S REINFORCING EFFECTS AND IN CORTICOSTERONE-INDUCED DOPAMINE RELEASE MAY BE A BIOLOGICAL BASIS FOR SENSATION-SEEKING. P.V. Piazza*, V. Deroche, F. Rougé-Pont, J.M. Deminière, S. Maccari, M. Le Moal and H. Simon. Laboratoire de Psychobiologie des Comportements Adaptatifs INSERM. U259-Univ. Bordeaux II. Domaine de Carreire 33077 Bordeaux Cedex-France.

Sensation-seeking is a human personality trait associated with drug use, compulsive sexual practices, and more generally with the seeking of situations commonly considered stressful. A common feature of such situations is activation of the hypothalamo-pituitary-adrenal axis leading to corticosterone secretion. Since, glucocorticoids have euphoric effects in certain individuals and increase the reinforcing properties of drugs in animals, a higher sensitivity to the reinforcing effects of glucocorticoids might be a biological basis for sensation-seeking. In order to answer this question, we have studied the reinforcing properties of corticosterone, by means of intraveous self-administration, and the effects of this hormone on the mesolimbic dopaminergic (DA) system, by means of in vivo microdialysis. The DA system has been studied because it is considered the main substrate of drug reinforcement. The experiments show that: i) corticosterone, in the range of stress levels, induces intravenous self-administration and increases DA release in the nucleus accumbens; ii) animals that, similar to high sensation-seekers, are more responsive to novelty and more prone to self-administer drugs, are also more sensitive to the reinforcing effect of corticosterone and have a higher corticosterone-induced dopamine release in the n. accumbens. These results suggest that different sensitivity to corticosterone's reinforcing effects may be a biological basis for the individual differences associated with sensation-seeking. Furthermore, individual differences in corticosterone-induced-dopamine release may be the neural substrate of different sensitivity to corticosterone's reinforcing properties. These findings provide new insights on the physiology of glucocorticoids and, since these hormones influence drug self-administration as well as immune functions, these results may also be relevant to clinical practice.

DRUGS OF ABUSE: COCAINE AND DOPAMINE NEURONAL SYSTEMS

450.1

INCREASE IN AN ELECTROCHEMICAL SIGNAL OF DOPAMINE IN THE NUCLEUS ACCUMBENS DURING SELF-ADMINISTRATION OF COCAINE BY RATS. R. Depoortere,*[1] C. D. Blaha,[2] F. G. Le Piane,[2] J. D. Lane,[1] M. W. Emmett-Oglesby[1] and A. G. Philips[2]. [1] Dept. of Pharmacology, TCOM, Fort Worth, TX 76107 and [2] Dept. of Psychology, UBC, Vancouver, B.C., Canada, V6T 1Y7.

The reinforcing properties of cocaine are thought to be mediated by an increased release of dopamine (DA) in the nucleus accumbens (n. acc.). We used the chronoamperometry technique, which has been successfully applied to monitor DA levels in discrete brain structures (Blaha and Philips, *J. Neurosci. Meth.*, **34**:125-133, 1990), to investigate if an electrochemical signal of DA in the n. acc. would increase during self-administration of cocaine by rats. Rats were bilaterally implanted with a stearate-modified carbon paste recording electrode in each n. acc., as well as with a catheter in the right jugular vein. DA levels in the n. acc. were assessed by recording the DA oxidation currents every 30 sec for each recording electrode while rats were self-administering cocaine (0.25, 0.50 or 1.0 mg/0.1 ml) under a FR 2 schedule. Self-administration of cocaine was found to increase DA levels in a dose-dependent manner. Furthermore, increases in DA levels were found to be, in part, time-related to the pattern of self-administration. This set of data suggests that increases in DA levels in discrete brain stuctures can be monitored with a short time resolution during self-administration of cocaine by rats. Supported by grants DA RO1-4137 (M. E-O), TX-ATP 3711 & 9768031 (J. D. L.), MRC-PG-23 (A. G. P.).

CHRONOAMPEROMETRIC MEASUREMENTS OF DOPAMINE LEVELS IN RAT NUCLEUS ACCUMBENS DURING COCAINE SELF-ADMINISTRATION. A. Gratton*, R.A. Wise and E. Kiyatkin. Douglas Hosp. Res. Ctr, McGill Univ. & Ctr Studies Behav. Neurobiol., Concordia Univ., Montréal, Canada.

Several lines of behavioral evidence have linked the positive reinforcing properties of cocaine with its ability to elevate extracellular levels of dopamine (DA) in nucleus accumbens (NAcc). Few investigators have measured changes in DA levels during cocaine self-administration, and most that have used microdialysis which does not provide sufficient temporal resolution to monitor moment-to-moment changes in DA levels associated with operant responding. We used high-speed chronoamperometry to monitor, during 5-6 consecutive daily recording sessions, DA-dependent electrochemical signals in NAcc of rats allowed to lever-press for intravenous cocaine (0.8mg/kg/injection). The changes in the electrochemical signal associated with lever-pressing for cocaine depended on the day recordings were performed. Typically, responses for cocaine during the first session were each followed by an abrupt and long-lasting decrease of the electrochemical signal which gradually returned to baseline levels at the end of the session when cocaine was no longer available. In contrast, the first cocaine injection of the second and subsequent recording sessions was followed by a pronounced and gradual increase in the signal. This pattern changed, however, with responses that followed in the session. Subsequent responses for cocaine were each preceeded by a reliable increase and followed by a comparable decrease in the electrochemical signal. A visual cue paired with each response for cocaine was, alone, sufficient to increase electrochemical signals in experienced animals. Increases in the signals were also observed when access to the lever was blocked or when the infusion pump was inactivated. The present experiment indicates that the effects of self-administered cocaine on extracellular DA levels in NAcc change as they become conditioned to environmental stimuli; elevated DA levels during cocaine self-administration occured only on the second and subsequent testing sessions. Further increases in extracellular DA were linked to operant responding but appeared to be more closely associated with events other than response reinforcement per se.

450.3

BASAL DOPAMINE LEVELS IN THE NUCLEUS ACCUMBENS ARE DECREASED DURING COCAINE WITHDRAWAL AFTER UNLIMITED-ACCESS COCAINE SELF-ADMINISTRATION. F. Weiss,* A. Markou and G.F. Koob. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Clinical observations indicate that chronic cocaine abuse is followed by a withdrawal syndrome resembling an episode of major depression. An analogous syndrome of "post-cocaine anhedonia" characterized by significant elevations in brain stimulation reward thresholds has recently been reported in rats after extended periods of intravenous cocaine self-administration (Markou & Koob, *Neuropsychopharmacology*, 1991). This wthdrawal-associated reward deficit may involve a specific impairment in dopamine (DA) neurotransmission in the region of the nucleus accumbens (NAC). To test this hypothesis we have monitored extracellular DA levels in the NAC by intracranial microdialysis in awake rats during withdrawal from cocaine after periods of unlimited-access, intravenous self-administration (9.5 to 21.75 hours). Cocaine withdrawal was associated with significant reductions in basal DA overflow that persisted up to 10 hours. Maximal inhibition of DA release (Mean ± S.E.M.: 66.15 ± 3.3 percent of basal levels) was observed at 4-6 hours after termination of cocaine self-administration and was positively correlated ($r = 0.93$) with the duration of the preceding self-administration episode. The results suggest that suppression of basal DA release in the NAC is a direct adaptive consequence of chronic cocaine exposure and may constitute an important neurochemical correlate of the cocaine withdrawal syndrome as measured by brain stimulation reward thresholds.

450.4

REVERSE TOLERANCE OF SEROTONIN AND DOPAMINE IN THE NUCLEUS ACCUMBENS AND DORSAL RAPHE NUCLEUS INDUCED BY CHRONIC COCAINE TREATMENT. L.H. Parsons* and J.B. Justice, Jr. Dept. of Chemistry, Emory University, Atlanta, GA 30322.

The effect of chronic cocaine administration on the response to a cocaine challenge was examined for serotonin (5-HT) and dopamine (DA) in the nucleus accumbens (N ACC) and dorsal raphé nucleus (DRN) of the rat using a dual probe in vivo microdialysis procedure. Rats were treated for ten days with cocaine (20 mg/kg, i.p.; n = 6) or saline (0.9%, 0.05 ml/kg, i.p.; n = 6), and all animals received a 10 mg/kg i.p. injection of cocaine on the test day (day 11). Based on maximum percent increases from cocaine challenge, DA was significantly sensitized in chronically treated animals in both the N ACC and DRN, though there was no significant interaction between region and degree of sensitization. 5-HT was also significantly sensitized in both regions of chronically treated animals, and there was a significant interaction between region and degree of sensitization, indicating that the cell body region produced greater 5-HT sensitization than the N ACC terminal field. Because both DA and 5-HT were obtained from the same probe in a given region for each animal, DA/5-HT area under the curve (AUC) ratios were used to compare the sensitization of DA relative to 5-HT. In both regions there were reduced DA/5-HT AUC ratios in chronic as compared with acute animals, though this reduction reached significance only in the DRN. This suggests that the 5-HT system is relatively more sensitized to chronic cocaine administration than the DA system.

Additionally, the interaction between 5-HT and DA was assessed by adding various concentrations of 5-HT to the perfusate of a microdialysis probe in the N ACC and observing the concurrent change in dialysate DA. 5-HT was found to concentration-dependently increase dialysate DA, with perfusate 5-HT concentrations between 100 and 400 nM. This effect was antagonized with differing effectiveness by the relatively non-specific 5-HT_1 antagonist pindolol, the specific 5-HT_2 antagonist LY 53,857, and the relatively specific 5-HT_3 antagonist MDL 7222. These results indicate that 5-HT stimulates extracellular DA levels in the N ACC.

450.5

INCREASES IN EXTRACELLULAR BIOGENIC AMINE CONCENTRATIONS FOLLOWING COCAINE OR HEROIN SELF-ADMINISTRATION S.E. Hemby*, T.J. Martin, C. Co, S.I. Dworkin, & J.E. Smith. Center for Neurobiology of Drug Abuse, Dept. of Phys./Pharm., Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157.

Nucleus accumbens dopamine is believed to mediate the reinforcing effects of psychotropic compounds. Cocaine self-administration enhances extracellular NACC dopamine concentrations in a dose dependent manner (Pettit and Justice, 1989, *PBB*, 34, 899-904). Response-independent administration of opiates enhances extracellular dopamine concentrations although this effect has not been demonstrated during response-dependent administration. The present study was initiated to determine whether extracellular catecholamine concentrations in the NACC are elevated during heroin self-administration in a similar manner to that observed during cocaine self-administration. Responding was maintained by either intravenous infusions of heroin (60 or 100 μg/kg/infusion) or cocaine (330 μg/kg/infusion). Following a minimum of twenty days stable responding, microdialysis probes were inserted through previously implanted cannulae. The following day, dialysate samples were collected in five minute intervals throughout the two-hour self-administration session. HPLC coupled to electrochemical or ultraviolet detection was used to assay the dialysate samples for catecholamines and cocaine, respectively. Cocaine self-administration increased extracellular NACC dopamine and serotonin although metabolite concentrations did not significantly differ from baseline. In addition, preliminary results suggest that heroin self-administration produced significant elevations in dopamine comparable to the relative increase observed with cocaine. 60-DAY CHRONIC COCAINE TREATMENT DESENSITIZES EXTRACELLULAR DOPAMINE OVERFLOW IN CAUDATE-PUTAMEN BUT NOT IN NUCLEUS ACCUMBENS. J. Chen*, R. Marmur, E. Rosenbaum, W. Paredes and E.L. Gardner, Departments of Psychiatry and Neuroscience, Albert Einstein College of Medicine, New York, NY 10461

Rats with *in vivo* brain microdialysis probes in the nucleus accumbens (Acc) and caudate-putamen (CPu) were treated with cocaine (10 mg/kg/day, i.p.) for 5, 30 and 60 days. 24 hrs after the last cocaine injection, rats of each group were challenged with the same dose of cocaine and extracellular dopamine (DA) overflow in Acc and CPu measured by *in vivo* microdialysis. In both Acc and CPu, biochemical sensitization of extracellular DA overflow was not seen in rats given repeated cocaine for 5 days. In contrast, 30 days of chronic cocaine *did* robustly augment the enhanced extracellular DA overflow produced by the challenge dose of cocaine. In animals given 60 days of chronic cocaine, striking differences between Acc and CPu manifested themselves. In Acc, the augmented extracellular DA overflow to cocaine challenge seen after 60 days of cocaine was identical to that seen after 30 days of cocaine. In CPu, after 60 days of chronic cocaine, the enhanced extracellular DA overflow produced by cocaine challenge was identical to that seen with *no* prior cocaine treatment. Thus, in Acc neurochemical sensitization to repeated cocaine occurs, and the sensitization maintains itself, while in CPu cocaine sensitization occurs, but then some compensatory mechanism comes into play to produce a neurochemical *de*sensitization to cocaine. This suggests that cellular mechanisms underlying cocaine sensitization differ between the mesolimbic and mesostriatal DA systems. (Supported by a research grant from the Aaron Diamond Foundation).

EFFECTS OF DAILY MULTIPLE INJECTIONS OF COCAINE ON THE DOPAMINERGIC SYSTEMS IN RATS: AN *IN VIVO* MICRODIALYSIS STUDY. I.M. Maisonneuve* and M.J. Kreek, The Rockefeller University, New York, NY 10021.

The aim of this study was to investigate the response of the dopaminergic systems to cocaine using a pattern of drug administration that mimics cocaine users' binges. Rats received three i.p. injections of cocaine (3 x 10 mg/kg) or saline (3 x 1 ml/kg) over a period of two hours for 13 days. On day 14 each rat received the three cocaine injections and the time course of dopamine (DA) and its metabolites were monitored in the nucleus accumbens and in the striatum using *in vivo* microdialysis. In both regions extracellular DA basal levels were not significantly different in saline versus cocaine treated rats (3.69 ± 0.69 nM versus 2.64 ± 0.53 nM in the nucleus accumbens, $p<0.26$; 9.32 ± 2.4 nM versus 7.11 ± 1.42 nM in the striatum, $p<0.12$; n=5). Acute cocaine administration led to an increase in extracellular DA levels that plateaued after the second cocaine injection (3.5 times greater than basal levels in the nucleus accumbens, 3 times in the striatum). Chronic administration altered this pattern. The peak in DA levels was achieved only after the third injection, and in the striatum, in contrast to the nucleus accumbens, the extracellular DA concentrations did not reach the maximum levels observed after an acute challenge. The present results differ from the conclusions of studies involving a single daily cocaine injection where DA levels were reported to be markedly enhanced by chronic exposure. Therefore the pattern of cocaine administration appears to be a major factor in the response of the dopaminergic systems. (Supported by the Aaron Diamond Foundation and DA-P50-05130).

IMPORTANCE OF THE DOPAMINE TRANSPORTER IN DETERMINING CLEARANCE OF EXOGENOUS DOPAMINE IN RAT BRAIN: IN VIVO ELECTROCHEMICAL STUDIES N.R. Zahniser*, W.A. Cass and G.A. Gerhardt, Depts. of Pharmacology and Psychiatry, Univ. of Colorado Hlth. Sci. Ctr., Denver, CO 80262.

In vivo electrochemistry was used to investigate the mechanisms contributing to the clearance of locally-applied dopamine (DA) in dorsal striatum and nucleus accumbens of urethane-anesthetized rats. Chronoamperometric recordings were continuously made at 5 Hz using Nafion-coated carbon fiber electrodes. When a finite amount of DA (12-100 nl, 200 μM barrel concentration) was pressure-ejected at 5-min intervals from a micropipette positioned 280 ± 30 μm from the electrode, transient and reproducible increases in DA (0.5-4 μM) were detected. Substitution of α-methyl-DA, which is a substrate for the DA transporter but not for monoamine oxidase, for DA in the micropipette did not substantially alter the time course of the resulting signals. These results indicate that metabolism of locally-applied DA to dihydroxyphenylacetic acid is not responsible for the decline in the DA signal. Similarly, changing the applied oxidation potential from 0.45V to 0.80V, which allows detection of 3-methoxytyramine formed from DA via catechol-O-methyltransferase, had little effect on the signal amplitude and time course. In contrast, local application of the DA uptake inhibitors cocaine or nomifensine (800 μM barrel concentration, applied 30-60 sec before DA) significantly increased the amplitude and time course of the DA signals in both brain regions, a result similar to that observed with systemic administration of cocaine. Taken together, these data indicate that uptake of DA by the neuronal DA transporter, rather than DA metabolism, is the major mechanism for clearing locally-applied DA from the extracellular space of striatum and accumbens. REPEATED COCAINE PERSISTENTLY REDUCES THE CLEARANCE RATE OF EXOGENOUS DOPAMINE IN RAT NUCLEUS ACCUMBENS. W.A. Cass*, G.A. Gerhardt, K. Gillespie, P. Curella and N.R. Zahniser. Depts. of Pharmacology and Psychiatry, Univ. of Colorado Hlth. Sci. Ctr., Denver, CO 80262.

We investigated whether differential changes in the dopamine (DA) transporter in the nucleus accumbens (NAc) or dorsal striatum could be involved with cocaine-induced behavioral sensitization by monitoring the clearance of locally applied DA in anesthetized rats using *in vivo* electrochemistry. Rats were given daily injections of cocaine (10 mg/kg i.p.) or saline for seven days, withdrawn for seven days, and prepared for electrochemical recordings. When a finite amount of DA (2.5-40 pmoles) was pressure-ejected at 5-min intervals from a micropipette positioned 270 $\pm$ 30 μm from the recording electrode, transient and reproducible increases in extracellular DA were detected. In response to a challenge injection of cocaine (10 mg/kg i.p.), the signals in the NAc of the cocaine-treated rats became prolonged and the clearance rate of DA decreased, indicating significant inhibition of the DA transporter. In contrast, in the striatum there was a transient increase in the DA clearance rate. In saline-treated animals the signals from both regions were similar to signals from untreated animals given an acute injection of cocaine (10 mg/kg i.p.) or saline. Quantitative autoradiography with ^{3}H-mazindol revealed that the affinity of the DA transporter for cocaine and the density of binding sites were similar in cocaine- and saline-treated rats. Behaviorally, 50% of the cocaine-treated animals were sensitized; however, both sensitized and unsensitized animals displayed similar changes in DA clearance rate. Nonetheless, the observed decrease in DA clearance rate in the NAc of the cocaine-treated rats is consistent with increased DA transmission in response to cocaine challenge. EFFECTS OF SPECIFIC BRAIN AMINE DEPLETING LESIONS ON COCAINE-INDUCED CONDITIONED INCREASES IN LOCOMOTOR OUTPUT. A.Pert*, D.N. Thomas and R.M. Post. Biological Psychiatry Branch, NIMH, Bld. 10, Rm. 3N212, Bethesda, MD. 20892

Environmental stimuli paired with cocaine acquire the ability to elicit increases in locomotor behaviour and potentiate the actions of cocaine during subsequent presentations. We utilized a simple and efficient design to evaluate the neuronal substrates which underlie the conditioned effects of cocaine. On DAY 1 Rats were injected with either saline (UNPAIRED) or 40mg/kg cocaine (PAIRED) before placement in locomotor chambers for 30mins. 1hr following return to the home cage animals that received saline were injected with 40mg/kg cocaine, whilst those that received cocaine initially were injected with saline. On DAY 2, all rats were injected with 10mg/kg of cocaine prior to placement in the locomotor chamber for 30mins. Conditioned locomotor activity is revealed by significant increases in locomotor output of the PAIRED versus the UNPAIRED group on DAY 2. We have previously found that 6-OHDA lesions of the nucleus accumbens and amygdala prevent the development of such conditioning with cocaine. The purpose of these studies was to evaluate the role of other brain amines systems as well as frontal cortex and striatal DA in cocaine-induced conditioning. Animals in each treatment group were lesioned bilaterally in the frontal cortex, striatum and locus coeruleus with 6-OHDA or in the median and dorsal raphe with 5,7-DHT. Controls groups were sham lesioned. One week following surgery, the animals were conditoned and tested as described above. Neither frontal cortex or striatal lesions had an effect on the acquisition of conditioned locomotor activity, although the striatal lesions did seem to attenuate the conditioned stereotypy. Lesions of the locus coeruleus or raphe had no effect on cocaine-induced conditioning. These findings suggest that the critical dopaminergic neural substrates for cocaine-induced conditioned locomotor behaviour are the amygdala and the nucleus accumbens. Serotonergic and noradrenergic pathways do not appear to play a role in cocaine-induced conditioning in our paradigm.

EFFECTS OF INTRA-ACCUMBENS AND INTRA-AMYGDALOID SCH23390 ON INTRAVENOUS COCAINE SELF-ADMINISTRATION IN THE RAT. A. McGregor and D.C.S. Roberts*. Life Sciences Research Centre, Carleton University, Ottawa, K1S 5B6, Canada.

The nucleus accumbens (NAcc) and its heavy dopaminergic (DA) innervation is generally considered to be a neural substrate pivotal in mediating the reinforcing effects of psychostimulant drugs. However, the amygdaloid complex is another neural site receiving a substantial DA innervation that has been relatively overlooked with respect to mechanisms of drug abuse. This work investigated the possible involvement of the amygdaloid complex (AMY) in cocaine self-administration (0.6mg/injection) under a fixed ratio schedule (FR1) of reinforcement and compared its contribution to that of the NAcc. Bilateral injections of the D1 antagonist, SCH23390, were made directly into the NAcc or AMY.

In both sites a significant dose dependent (0.1µg - 2.0µg/side/0.5µl) increase in the rate of self-administration was produced, demonstrating that both sites make a contribution to cocaine reinforcement mechanisms. In addition however, blockade of the D1 receptor within the AMY produced a two-fold increase in the rate of cocaine intake with respect to that produced within the NAcc. These results suggest that in addition to the NAcc, the AMY also has a contribution to make to cocaine reinforcement mechanisms. (Supported by the MRC of Canada).

INDIVIDUAL DIFFERENCES IN VULNERABILITY TO DRUG-ADDICTION: BEHAVIORAL AND BIOCHEMICAL CORRELATES. **M.J.D. Miserendino*, T.A. Kosten, X. Guitart, S. Chi, and E.J. Nestler. Depts. of Psychiatry and Pharmacology, Yale Univ. Sch. of Med., New Haven, CT. 06508**

One model used to examine individual differences in drug preference uses the inbred Fischer 344 and Lewis rat strains, which show differential oral self-administration of opiates, cocaine, and alcohol. We have shown inherent biochemical differences in reward-implicated sites between these strains, with an upregulated cAMP system in the nucleus accumbens (NAc) and altered levels of tyrosine hydroxylase (TH) and neurofilaments in the ventral tegmental area (VTA) of the drug-preferring Lewis rat (Beitner-Johnson et al., Brain Res. 561,147 1991; Guitart et al., Synapse, in press). We have also demonstrated strain differences in other drug-related behaviors: compared to Fischer rats, Lewis rats show greater locomotor sensitization and conditioned place preference, and more readily acquire intravenous cocaine self-administration.

We have also begun to examine similar individual differences in biochemistry and behavior within a single rat strain (Sprague Dawleys). Rats were assessed for locomotor activity in a novel environment, and the highest (HR) and lowest (LR) responders were selected for biochemical analysis. Compared to HR rats, LR rats showed higher levels of cAMP dependent protein kinase in the NAc, and of TH in the VTA. We are currently testing HR and LR rats for the acquistion of cocaine self-administration.

Such integrated biochemical and behavioral assessments should enable the identification of some of the biochemical factors that contribute to individual genetic vulnerability to drug addiction.

450.13

DIFFERENTIAL REGULATION OF THE COCAINE ACCEPTOR AND DOPAMINE UPTAKE SITES IN RAT BRAIN FOLLOWING COCAINE SELF-ADMINISTRATION AND WITHDRAWAL. J.M. Wilson*, M. Carroll, J.N. Nobrega, H.B. Niznik and S.J. Kish. Univ. Toronto, Canada and Univ. Minnesota, Minneapolis.

Using quantitative autoradiography, the influence of unlimited cocaine self-administration (6 weeks) on binding to the dopamine (DA) uptake (0.25 nM [^{3}H]GBR 12,935 displaced with 1 μM mazindol) and cocaine acceptor (10 nM [^{3}H]WIN 35,428 displaced with 30 μM cocaine) sites in rat brain was examined. In rats sacrificed while still on cocaine (n = 10) specific binding of [^{3}H]GBR 12,935 to the DA transporter in striatum, n. accumbens (nacs), substantia nigra (SN) and ventral tegmental area (VTA) was unaltered relative to controls (n = 5). However, specific binding of [^{3}H]WIN 35,428 to the cocaine acceptor sites was significantly *elevated* ($p < 0.05$) in striatum (+63%) and nacs (+73%). Following 3 weeks withdrawal from unlimited cocaine self-administration specific binding of [^{3}H]GBR 12,935 was unaltered whereas binding of [^{3}H]WIN 35,428 was significantly *reduced* ($p < 0.05$, n = 5) in striatum (-33%), nacs (-46%), SN (-51%) and VTA (-62%). The observation of unaltered binding of [^{3}H]GBR 12,935 three weeks after the last administration of cocaine, suggests that there is no permanent degeneration of rat brain dopaminergic nerve terminals. However, the elevated binding of [^{3}H]WIN 35,428 to the cocaine acceptor site during chronic cocaine self-administration, but reduced binding during withdrawal, suggest that the cocaine acceptor might be sensitive either to the extracellular concentration of DA or to the presence and subsequent absence of cocaine, which acts like an antagonist at the DA transporter. Altered affinity/density of the cocaine acceptor could modulate DA reuptake, and it will be important to establish the functional significance of such changes following chronic cocaine exposure and during the course of withdrawal. (Supported by NIDA grant DA07182.)

Withdrawal From Continous or Intermittent Cocaine: Dopamine Autoreceptor Sensitivity.

KING, G.R., KUHN, C., AND ELLINWOOD, E.H., JR.*

Previous research in this laboratory inidicates that daily intermittent injections of cocaine result in an enhanced dopamine (DA) response in caudate-putamen brain slices, to different cocaine concentrations. In contrast, the continuous infusion of an equivalent daily dose of cocaine results in an attenuated DA response in caudate-putamen brain slices, to different cocaine concentrations. One possible mechansim mediating these effects is changes in DA autoreceptor sensitivity. Daily, intermittent cocaine injections may result in DA autoreceptor subsensitivity, while the continuous infusion of cocaine may result in DA autoreceptor supersensitivity. The present experiment examined this possibility. Rats were pre-treated with 40 mg/kg/day of cocaine for 14 days by either subcutaneous injections or continous infusion by osmotic minipumps. The rats were then withdrawn from the pretreatment regime for 7 days. On Day 7, the rats were sacrificed, and caudate-putamen slices rapidly obtained. The slices were then placed in glass perfusion chamber, and superfused with artifical CSF for sixty minutes. At the end of this period, the slices were electrically stimulated with a train of supramaximal, unipolar, rectangular waves (20 mA, 2 msec) at 3 Hz for 90 pulses (S_1). Ten, 2 min samples were collected. This electrical stimulation was repeated 60 minutes later (S_2). However, 30 min prior to the S_2 period, the brain slices were perfused with either 0, 1, 2, or 4 μM sulpiride, a D_2 receptor antagonist. The data were analyzed by determining the [S_2/S_1] ratio for different sulpride concentrations. This research was supported by NIDA grant DA05303, and NIH grant T32- MH15177.

DOSE-DEPENDENT CHANGES IN THE RAT DOPAMINERGIC RECEPTOR SYSTEM AFTER CHRONIC ADMINISTRATION OF COCAINE. M.E. Alburges*†, N. Narang†, C. Johnson and J.K. Wamsley†. *Neuropsychiatric Research Institute, Fargo, ND 58103; †Medical School, University of Zulia, Maracaibo, Venezuela.

We have previously reported time-dependent alterations in the rat dopaminergic receptor system after fixed doses of cocaine (15.0 mg/kg, i.p.). In the present study, the dose-dependent effects of cocaine on the dopaminergic system were determined. Rats were injected with cocaine (5.0,10.0,15.0,20.0 and 25.0 mg/kg, i.p., b.i.d.) or saline for a 21 day period. [^{3}H]Cocaine and [^{3}H]SCH23390 binding in cortices and striatum from animals injected with 10.0 and 15.0 mg/kg were significantly higher than the control animals. [^{3}H]BTCP binding in striatal tissue was significantly increased in animals injected with 10.0 and 15.0 mg/kg of cocaine; however, in cortices of these animals, significant changes were seen with only 15.0 mg/kg of cocaine. Changes in [^{3}H]raclopride binding in these tissues were not present. These results indicate chronic exposure to cocaine produces a dose-dependent upregulation in cortical and striatal D_1 and DA-uptake sites.

450.16

COCAINE AND AMPHETAMINE: A COMPARISON OF THEIR EFFECTS ON DOPAMINE OVERFLOW IN THE STRIATUM AND AMYGDALA. E. Museo,* A. Zocchi, and A. Pert. Biological Psychiatry Branch, NIMH, Bethesda, MD, 20892.

Experiments were carried out to determine whether cocaine and d-amphetamine have similar effects on dopamine (DA) overflow in the striatum and amygdala. Male Sprague-Dawley rats were anaesthetized prior to and following the implantation of a microdialysis probe into either the striatum or amygdala. These structures were perfused (0.5 µL/min) with either cerebrospinal fluid (CSF) or CSF containing varying amounts of either cocaine or amphetamine. Dialysate samples were collected every 20 min and analyzed for DA content using a microbore HPLC/EC system. Whereas the application of cocaine (0.01, 0.1, and 1 mM) into the striatum increased DA overflow in a concentration-related manner, cocaine produced either weak or inconsistent effects in the amygdala. (A difference in sensitivity between the striatum and amygdala was also found, albeit much less marked, when cocaine was administered systemically (40 mg/kg, i.p.).) In the case of amphetamine (0.1, 1, and 10 µM), its application into the striatum also increased DA overflow in a concentration-related manner; unlike cocaine, however, amphetamine produced consistent concentration-related increases when administered into the amygdala (even though the striatum was apparently more sensitive). These findings suggest that the effects of amphetamine and especially cocaine differ depending on whether the drugs are administered into the striatum or amygdala. The possibility is raised, then, that cocaine binding sites or DA transporters located in the striatum differ from those located in the amygdala.

450.17

THE EFFECT OF CONTINUOUS COCAINE ADMINISTRATION ON ALTERATIONS IN STRIATAL EXTRACELLULAR DOPAMINE METABOLISM. J.W. Lipton*[1] & R.E. See[2]. Depts. of Psychology, UCLA[1], Los Angeles, CA 90024-1563 & Washington State University [2]

It is well established that intermittent schedules of psychostimulants produce behavioral sensitization while continuous regimens tend to cause tolerance. *In-vivo* microdialysis was utilized to examine extracellular striatal dopamine and monoamine metabolite (DOPAC, HVA, 5-HIAA) levels at different times during and after continuous cocaine administration. Male Sprague-Dawley albinos were implanted with subcutaneous cocaine pellets which release approximately 105mg of cocaine freebase over 5 days. Rats were sampled before the beginning cocaine administration, on day 5 of cocaine, 24 hours post-cocaine or 7 days post-cocaine. Dose-response relationships were established for infusions of quinpirole (QP) through the dialysis probe (10^{-7},10^{-6}, 10^{-5} M). DA levels were decreased in dose response fashion with no group differences among animals on day 5 of continuous cocaine, 24h or 7 days post-cocaine as compared to drug-naive controls. At 24h after cocaine HVA was significantly decreased vs drug-naive animals (75% vs 91% respectively). There was a significant difference in QP induced metabolite levels between animals 7 days post-cocaine vs drug-naive controls DOPAC (60% vs 91%), HVA (75% vs 115%) and 5-HIAA (85% vs 60%). Amphetamine (AMPH) mediated DA release in striatum indicated that 24 hours after the cessation of continuous cocaine there was a non-significant decrease in the amount of DA release as compared to drug-naive controls (880% increase vs 1342% increase, respectively). Immediately after the local AMPH infusion there was a significant difference between cocaine exposed animals and controls in the disposition of DOPAC (110% vs. 88%), HVA (116% vs 102%) and 5-HIAA (99% vs. 118%). While group differences in DA were non-significant due to high variability, it is evident that there are significant time-dependent alterations DA metabolism when the nigrostriatal system is pharmacologically challenged.

450.18

CHRONIC COCAINE PRODUCES "TOLERANCE" OF METABOLIC ACTIVITY IN RAT BRAIN REWARD REGIONS, R. P. Hammer, Jr.*, A.R. Mateo, W.S. Pires, E.S. Cooke and B.B. Young, Lab. of Cellular & Molecular Neuropharmacology, Dept. of Anatomy & Reprod. Biology, Univ. Hawaii School of Medicine, Honolulu, HI 96822.

Repeated daily cocaine administration produces various sustained neurochemical effects. We have examined the effect of daily treatment for a total of 14 days with saline vehicle or 10-20 mg/kg cocaine HCl administered for 1, 3, 7, 10 or 14 days on regional cerebral metabolic rate (rCMR) measured using the quantitative method of Sokoloff. A pulse of [^{14}C]2-deoxyglucose was administered i.v. 10 min after i.p. drug or vehicle injection in freely moving animals, after which timed arterial blood samples were collected for measurement of radioactivity and plasma glucose values across a 45 min exposure period. Regional autoradiographic analysis was used to determine rCMR values in 61 regions; the results were compared by ANOVA followed by Newman-Keuls post-hoc tests. Significant main effects of treatment occurred only in the nucleus accumbens (NAc) core and shell, olfactory tubercle, piriform and anterior cingulate cortices, basolateral amygdala, and ventromedial striatum. In all cases, acute treatment produced slight increases of rCMR which was unchanged from control values after 3 or 7 days of treatment but was significantly reduced after 10 or 14 days of treatment. This biphasic effect was greater in the rostral NAc than in the caudal NAc. Although repeated daily cocaine administration is reinforcing (lowers the threshold of rewarding intracranial self-stimulation), metabolic response in mesolimbic terminal regions shifts from initial activation to sustained reduction. Such chronic drug-induced changes could represent a metabolic manifestation of tolerance in critical brain regions. Supported by USPHS awards DA06645 and HD01161.

QUANTITATIVE MICRODIALYSIS UNDER TRANSIENT CONDITIONS. R.J. Olson* and J.B. Justice Jr., Dept of Chemistry, Emory University, Atlanta, GA 30322

A method based on the point of no net flux (Lönnroth et al., Am. J. Physiol. 256:E250-E255, 1989) has been developed for quantitative microdialysis under transient conditions. Four groups of rats were perfused with either 0,10,20 or 40 nM dopamine (DA) at 0.6 ul/min. Dialysate DA was collected and measured for time intervals prior to and during drug administration. Data from the four groups were combined at each time point and used with linear regression to determine the in vivo recovery and the extracellular concentration of DA as a function of time. It was hypothesized that changes in uptake and release would change probe recovery. No change in recovery was observed in the striatum with 4mm probes during haloperidol induced DA release (1 mg/kg, I.P., n = 6 per group). However, it is possible that the already high baseline recovery (78%) masked otherwise evident changes. In order to examine the effect of uptake inhibition on recovery, cocaine (20 mg/kg, I.P.) was administered and dialysate was collected using 2mm probes in the nucleus accumbens. Recovery decreased from 48% at baseline to 25% twenty minutes following drug administration and returned to 48% seventy minutes following drug (n=3 per group). This corresponded in time to the increase and return to baseline of DA. Recovery was used at each time point to calculate extracellular DA from dialysate DA. Extracellular DA was 5.08 +/- 0.25 nM at baseline and 44 nM 20 minutes following drug administration. A higher percent increase was observed in extracellular DA than was evident in dialysate DA. These results support previous work which suggests that probe recovery is dependent on active neurotransmitter properties such as uptake and release (Parsons et al., J. Neurosci. Meth., 40:131-137, 1991). The present method appears useful for quantitatively characterizing the pharmacology of neurotransmitter systems.

THE EFFECTS OF DISCRETE LESIONS OF THE SUB-COMMISSURAL VENTRAL PALLIDUM ON COCAINE SELF-ADMINISTRATION IN THE RAT. P. Robledo* and G. F. Koob. The Scripps Research Institute, La Jolla, CA. 92037.

The involvement of the nucleus accumbens in mediating cocaine reinforcement has been largely established. Previous work from our laboratory has demonstrated that Ibotenic acid lesions of one of the output regions or the nucleus accumbens, the sub-lenticular substantia innominata, produced significant decreases in the highest ratio obtained in rats self-administering (SA) cocaine. In this study, we investigated the importance of another accumbal output, the sub-commissural ventral pallidum, in mediating the reinforcement properties of cocaine in the rat. Animals were trained to self administer cocaine (0.75 mg/kg/inj) via an intravenous catheter on a FR5 schedule of reinforcement. Subsequently, rats were either given bilateral i.c. injections (0.5 µl per side) of Ibotenic acid (10 µg/µl lesion group) or vehicle (sham group) into the sub-commissural ventral pallidum. Five days post-lesion, cocaine SA on a FR5 schedule was resumed for three days. Next, a dose effect function was determined in one 3 hour session. A progressive ratio schedule in which the ratio requirement was increased after each reinforcement was also used. The lesion group showed a significant decrease in FR5 responding for cocaine five days after the lesion as compared to the sham group. While the lesion produced decreases in responding for cocaine at all doses, the rate of responding was inversely proportional to the dose. However, compared to sham animals, in the progressive ratio task, no effect was found in the total number of rewards nor in the highest ratio obtained in lesioned rats. These results, taken together with our previous data, support the hypothesis that the region commonly called the ventral pallidum is a functionally heterogeneous structure which may have an equally heterogeneous relationship with the nucleus accumbens. Further, these results suggest that within the ventral pallidum there are some areas that are more critically involved in cocaine reinforcement than others. Supported by NIDA grant DA04398.

NEUROTOXIC EFFECTS OF PRENATAL MPTP ON MONOAMINE AND PEPTIDE SYSTEMS OF THE MARMOSET BRAIN. J. Del Río*[1], I. Pérez-Otaño[1], M.T. Herrero[2], M.R. Luquin[2], C. Oset[1], and J.A. Obeso[2]. Depts. of Pharmacology(1) & Neurology (2), Univ. of Navarra Medical School, Pamplona, Spain.

Chronic administration of MPTP to adult marmosets induces alterations in brain dopamine, serotonine and peptide systems. It is not known if MPTP can also produce neurotoxic effects on the developing brain of primates. In this study, MPTP was incidentally administered to two female marmosets who became pregnant. The monkeys received MPTP (1.25-2.5 mg/kg s.c., twice a week) during the whole gestational period, except for the last 15 days before term, when pregnancy was noticed. Baby marmosets (n=3) were sacrificed 5 months after birth and levels of dopamine (DA), serotonin (5-HT) and its metabolites, DOPAC, HVA and 5-HIAA were determined in several brain areas by HPLC and compared to age-matched controls(n=6). Substance P (SP) content was measured in the basal ganglia by RIA. A significant reduction of DA and its metabolites, DOPAC and HVA, was found in the caudate nucleus, putamen and n. accumbens of marmosets exposed "in utero" to MPTP, but not in other areas studied. In contrast to the extensive and severe 5-HT loss induced by chronic MPTP treatment of adult animals, no change in striatal 5-HT content was found in baby marmosets and only extrastriatal 5-HT systems were affected. A significant decrease in SP levels was observed in the s. nigra of baby marmosets. The results demonstrate that MPTP can cross the placenta and exert its neurotoxic effect on monoamine and peptide systems in the fetal brain of primates. These findings show the possibility of "in utero" lesion of several neurotransmitter systems in the marmoset brain and indicate that non-melanized neurons (as is the case in the fetus) are also susceptible to MPTP. PARTIAL NIGROSTRIATAL 6-OHDA LESION AS A MODEL OF PRECLINICAL PARKINSON'S DISEASE. J. Fornaguera-Trias, R.K.W. Schwarting*, F. Boix and J.P. Huston. Inst. of Physiol. Psychol. I, Univ. of Düsseldorf, Germany

The study of moderate dopamine (DA) lesions in animals could serve as a model of the preclinical stage of Parkinson's disease, both in the search for possible behavioral predictors and concurrent neuronal changes. Therefore, we studied asymmetries in turning and thigmotactic scanning in rats with unilateral injections of 6-OHDA into the substantia nigra and compared them with the degree of striatal DA depletion. Animals with severe lesions (<20% residual DA) showed spontaneous ipsiversive turning and more scanning with the side of the face ipsilateral to the lesion. These asymmetries were reversed by apomorphine. Animals with moderate depletions (20-65% DA) did not show spontaneous asymmetries in turning, but an ipsilateral asymmetry in scanning. Most important is that out of this group, animals with 45-65% residual DA levels showed ipsiversive turning and ipsilateral scanning under apomorphine. These results suggest that scanning is a more sensitive measure than turning for the detection of functional asymmetries after moderate striatal DA lesions. The ipsiversive asymmetries observed after apomorphine in animals with moderate depletions might be due to ipsilateral changes in self-regulatory mechanisms of the nigrostriatal DA system, such as in DA autoreceptors, which in turn might be related to compensatory mechanisms in the preclinical stage of Parkinson's disease.

EFFECTS OF CHRONIC SINEMET TREATMENT ON RATS WITH 6-OHDA INDUCED PARTIAL NIGROSTRIATAL LESION. F.S.Junn (Kim)*, K.Steece-Collier, & T.J.Collier. Dept. of Neurobiology & Anatomy, University of Rochester, Rochester, NY, 14642.

The short term symptomatic improvement in Parkinson's patients with Sinemet can be very dramatic. However, progressive increase in disability of such patients coupled with toxic byproducts from autooxidation of L-dopa and dopamine suggested the possibility of L-dopa causing further deterioration of the disease. We tested the effects L-dopa injected as Sinemet-25/250 b.i.d., i.p. (50mg L-dopa equivalent/kg) for eight weeks into 12 Fisher 344 rats whose nigrostriatal system was partially lesioned with unilateral intra-nigral injection of 4 ug of 6-hydroxydopamine. Such partially lesioned rats demonstrated rotational response to amphetamine (5mg/kg), but not to apomorphine (0.25mg/kg). Saline injections were given b.i.d. to 11 control rats matched for the amphetamine induced rotation. The L-dopa group showed 30% reduction in amphetamine-induced rotation, whereas the control group showed no change from the baseline (p=0.13). There were no signifcant differences in either the total high affinity DA uptake sites or D1-receptors as measured by GBR and SCH23390 autoradiography. Spiperone D2-receptor showed a decreasing trend in the L-dopa treated group (p=0.15). The trunkal and limb dystonia following L-dopa injection were also measured. No further progression of dystonia was observed throughout the duration of the experiment. Our results thus far suggest that this time course of L-dopa treatment does not appear to cause further decline in the nigrostriatal dopamine system in partially lesioned rats. Supprted by grants from the UPF & NIH NS24032.

SUBTHALAMIC NUCLEUS ABLATION AS A METHOD FOR REDUCING APOMORPHINE-INDUCED ROTATIONAL BEHAVIOR IN 6-OHDA LESIONED RODENTS B.H. Hallas*, R.M. Cebelenski, P. Jacovina, M.F. Zanakis, E. Fazzini. N.Y. College of Osteopathic Medicine, N.Y. , N.Y. University, N.Y.

A rodent model for Parkinson's Disease is the chemical lesion of the Substantia Nigra (SN) with 6-hydroxydopamine (6-OHDA), which, following apomorphine administration, results in quantifiable rotational behavior. This study investigated the influence of the Subthalamic Nucleus (STN) in animals previously lesioned with 6-OHDA and induced to rotate with apomorphine. Adult rats received stereotaxic injections of 6-OHDA into the left SN. After 21 days, apormorphine was injected subcutaneously once a day for 14 additional days. Ten minutes after the injection, the number of rotations were counted for each animal over a period of 15 minutes. After establishment of the rotational baseline (at 14 days), the left STN was ablated by stereotaxic electrolytic lesions. Control animals received no STN ablation. All animals were then retested for rotational behavior as above after a recovery period of 14 days. It was found that the majority of the experimental animals demonstrated a significant reduction of rotational behavior compared to controls.

However, four animals exhibited ipsilateral rotation following, STN ablation (i.e. to the left). These animals were tested for 14 additional days and then received an electrolytic lesion to the contralateral (right) STN. After a sufficient recuperation time these animals were retested for rotational behavior following apomorphine injection. It was found that these animals then demonstrated a significant decrease in rotational behavior. It can therefore be concluded that ablation of the STN ameliorates apomorphine-induced rotational behavior following 6-OHDA SN lesions possibly by reducing abnormally increased medial globus pallidus output.

AKINESIA DURING DOPAMINE AGONIST INDUCED CIRCLING BEHAVIOR AFTER SEVERE UNILATERAL NEOSTRIATAL DOPAMINE DEPLETION IN RATS. D. Norton, T. Schallert*, and T.A. Jones. Neuroscience Inst. and Dept. of Psychology, Univ. of Texas, Austin, TX 78712.

Circling behavior after unilateral 6-hydroxydopamine (6-OHDA)-induced neostriatal dopamine (DA) depletion has been widely used as a model for screening anti-parkinsonian agents. However, the unilateral 6-OHDA model, as presently used, fails to mirror one of the most debilitating symptoms of Parkinson's disease: akinesia. During circling, all limbs make stepping movements, including the limbs contralateral to the denervated neostriatum. In this study a novel behavioral test was used to isolate and compare stepping movements of the ipsilateral and contralateral limbs of rats with unilateral neostriatal DA depletion. We found that in the undrugged condition and under amphetamine, the ipsilateral (non-impaired) forelimb shifts the weight of the animal to a new location in space (DA-dependent stepping), whereas the contralateral forelimb makes only catch-up steps designed to re-establish support of the body's weight (DA-independent stepping). When the contralateral forelimb is isolated so that it alone bears the weight of the animal (by raising the hindquarters and ipsilateral forelimb off the ground), it is akinetic. Preliminary results indicate that when the depletion is severe, the DA agonist apomorphine causes contraversive hyperkinesia in the ipsilateral limb, but does not reverse akinesia in the contralateral forelimb. The role of DA in movement initiation will be discussed in view of these data. (Supported by NS 23964.)

REMACEMIDE AND L-DOPA SYNERGIZE TO REVERSE AKINESIA IN MONOAMINE-DEPLETED RATS. RV Eller, A Howell and J T Greenamyre,* Dept. of Neurology, University of Rochester, and Fisons Pharmaceuticals, Rochester, NY, 14642.

In rodent and primate models of Parkinson's disease, antagonists of the NMDA and AMPA subtypes of glutamate receptors have been shown to synergize with L-DOPA to reverse parkinsonian motor deficits. In this study, we have used monoamine-depleted rats to examine the antiparkinsonian potential of remacemide (Fisons), an anticonvulsant with activity at the NMDA receptor ion channel. Male Sprague-Dawley rats (125-150 g) were rendered akinetic by administration of reserpine (5 mg/kg, i.p.) 24 h prior to testing. Motor activity was quantified using cages equipped with infrared sensor beams. In reserpinized rats, L-DOPA increased horizontal locomotor activity in a dose-dependent fashion. When a subthreshold dose of L-DOPA (75 mg/kg, i.p.) was co-administered with remacemide (5 - 40 mg/kg, p.o.) there was a dose-dependent increase in horizontal locomotor activity. Unlike MK-801, remacemide does not produce locomotor stimulation in normal rats. Moreover, remacemide potentiates the effects of L-DOPA over a broad dose range, in contrast to MK-801 and CPP.

RECOVERY OF VOLITIONAL MOTOR FUNCTION BUT NOT ROTATIONAL ASYMMETRY IN HEMI-PARKINSONIAN MONKEYS. W.W. McLaughlin*, I.S. Schneider and D.P. Roeltgen, Dept. of Neurology, Hahnemann University, Philadelphia, PA. 19102.

The extent and status of a unilateral lesion of the nigrostriatal dopamine (DA) system has typically been assessed by quantifying rotational asymmetry in response to DA agonist administration. Since agonist-induced rotation, whose mechanisms are still obscure, may not be a good behavioral index of parkinsonism, particularly in monkeys and humans, we examined the extent to which the status of volitional motor function, perhaps a better index of parkinsonism in monkeys, and rotational asymmetry coincide. In particular, we examined whether rotational asymmetry, a methodologically simple behavioral index, could accurately reflect the functional status of hemi-parkinsonian monkeys. Four male rhesus monkeys (approx. 4 yrs. old) were trained to perform tasks which measured bar press rate, reaction/movement times, and lateralized attention (i.e., response to double simultaneous stimulation, response to lateralized moving stimuli, and lateralized reward retrieval). Animals were then made hemi-parkinsonian by intracarotid infusion of MPTP-HCL (2.5 mg/kg) and re-tested on the above-mentioned tasks over the next year. Within the first 6 months after lesioning, animals showed dose-dependent rotational asymmetry to apomorphine or D2 agonist N-0923 stimulation and significant unilateral impairment in motor function (with the use of the limb contralateral to their lesion) and attentional abilities (assessed with the limb ipsilateral to their lesion). Six to 12 months after lesioning, 3 animals showed significant improvement in performance of volitional motor tasks and all monkeys showed distinct reversal of at least some of their initial lateralized attentional deficits. Despite this behavioral improvement, rotational asymmetry in response to dopamine agonists was still intact and in fact, more robust than when the animals were behaviorally impaired. These results suggest that over time, functional improvement can occur in hemi-parkinsonian monkeys and that rotational asymmetry may not be a good index of the functional status of the dopamine-denervated striatum in the monkey. Supported by Whitby Research, Inc. and MH 46531.

PRETREATMENT WITH A GANGLIOSIDE MIXTURE DOES NOT PREVENT MPTP TOXICITY IN AGING MICE. X. L. Chen*, F. Roisen and M. Gupta, Department of Anatomical Sciences and Neurobiology, University of Louisville School of Medicine, Louisville, KY 40292.

MPTP has been shown to produce a loss of dopaminergic neurons in the substantia nigra (SN) as well as decreased dopamine levels in the striatum. Furthermore, pretreatment of young adult mice with a mixture of bovine brain gangliosides can reduce MPTP toxicity on the dopaminergic neurons of the SN (Gupta et al., Brain Res. 527, 1990). The present studies were undertaken to investigate if aging mice, that are more sensitive to MPTP treatment, respond differently to the ganglioside pretreatment. Aging (12 months old) male C57BL/6 mice were anesthetized and stereotaxically injected with either the ganglioside mixture (Fidia, 200mg/ml in PO_4) or PO_4 alone in each lateral ventricle (2µl each). 16-18 hr later, one half of the ganglioside and vehicle-injected mice received multiple injections of MPTP (total dose 90mg/kg i.p.) over a two day period. Three days later, half of the animals from each group were anesthetized, perfused intracardially with fixative and brain sections processed for tyrosine hydroxylase (TH) immunocytochemistry. The remaining mice were decapitated, fresh brains removed, striata dissected and processed for HPLC to detect the levels of dopamine and its metabolites. The results show that, while MPTP produced a decreased number of TH-positive neurons in the SN and marked depletion of dopamine levels in the striatum, pretreatment with the ganglioside mixture did not prevent the MPTP-induced loss of TH-positive neurons in the SN nor reduction of dopamine levels in the striatum. These data, therefore, demonstrate that aging mice respond differently to pretreatment with gangliosides than young adults. Supported by USPHS grant NS24291 to MG.

FUNCTIONAL ASSIMETRIES IN MANUAL TESTS IN NORMAL AND LONG TERM MPTP TREATED MONKEYS.EFFECTS OF GM1 GANGLIOSIDE. M.E.Emborg*,S.Lipina,J.Goland,C.Abel, J.A.Colombo PRUNA(CEMIC-CONICET) Av.Galvan 4102, (1431) Bs.As.,Argentina.

GM1 has been reported to protect pigmented neurons of substantia nigra from MPTP lesions.We evaluated behavioral effects of GM1 treatment in 3 *Cebus apella* with a persistent hemiparkinsonian syndrome(Emborg et al 1991) after 20-22 months of an intracarotid infusion of MPTP-HCL(1.2mg//kg). MPTP treated and 3 normal monkeys(2-4kg,13-16 years)were trained in a primate chair to solve motor-cognitive tests.Normal animals learned in 2-3 sesions the 3 levels,with variable manual preference between tests.MPTP monkeys could not resolve level 2 or 3.The hemiparkinsonian monkeys received 20 daily saline injections or GM1(FIDIA, 20mg/kg) in saline for 29 days,being evaluated (C8-9)in a primate chair weekly.After 3 weeks of saline or GM1, circling activity was tested before and after apomorphine administration(0.4mg /kg).During saline or GM1 treatment the animals did not improve their performance and the apo tests did not reveal changes in circling behavior.At present time we are conducting a follow up post GM1 treatment. U-91356A: A NOVEL DOPAMINE AGONIST WITH POTENTIAL ANTIPARKINSONIAN ACTIVITY. P.J.K.D.Schreur*, N.F.Nichols, and M.P.Stone. CNS Research, The Upjohn Company, Kalamazoo, MI 49001.

U-91356A is a novel dopamine agonist, (*R*)-5-(propylamino)-5,6-dihydro-4*H*-imidazo[4,5,1-*ij*]-quinolin-2(1*H*)-one hydrochloride.

In reserpinized NSA (Harlan CF-1) mice, U-91356A caused locomotor stimulation at 1 and 10 mg/kg i.p. Apomorphine HCl (apo), lisuride H-maleate (lis), (-)-quinpirole HCl (quin), and pergolide mesylate (perg) were also stimulants in reserpinized mice, but bromocriptine mesylate (bromo) was not. In the same reserpinized mice, U-91356A and lis antagonized apo-induced locomotor stimulation; bromo was slightly active while apo and perg were inactive as antagonists. In normal, nonreserpinized B6C3F1 mice (Harlan) all of the above compounds antagonized amphetamine. U-91356A was active orally and s.c. as well as i.p.

In Sprague-Dawley (Charles River) rats with unilateral 6-OH-dopamine lesions of the substantia nigra, U-91356A caused contralateral turning at 0.3 and 3 mg/kg s.c. Quin and perg also caused contralateral turning, but bromo did not cause any turning at doses up to 3 mg/kg.

U-91356A's maximal locomotor stimulant activity was less than that seen for apo, quin, and perg. Indeed, U-91356A actually reversed some of the stimulation caused by apo or amphetamine. This suggests that U-91356A may be a useful antiparkinsonian agent with less propensity to produce dyskinesias than other dopamine agonist agents may have.

451.11

U-91356A, A POTENT, EFFECTIVE, ORALLY ACTIVE D2 AGONIST POTENTIALLY USEFUL IN TREATING PARKINSON'S DISEASE. M.F.Piercey,* M.W.Moon, W.E.Hoffmann, R. Walters, P. Blanchette, and P. Bedard. The Upjohn Co., Kalamazoo, MI. 49001 and Leval University, Quebec, Canada.

U-91356A, (U-91, or (*R*)-5-(propylamino)-5,6- dihydro-4*H*-imidazo[4,5,1-*ij*]-quinolin-2(1*H*)-one hydrochloride) is a novel dopamine (DA) agonist that binds to both D2 (Ki = 1.3 nM) and 5-HT1A (Ki = 58 nM) receptors. U-91 did not bind at 1 uM to a variety of additional adrenergic, 5-HT, cholinergic, DA, benzodiazepine or opiate receptors. Bromocriptine, lisuride, and pergolide all had high binding affinities for several non-DA receptors. U-91 (ED50 = 32 ug/kg i.v.), bromocriptine (ED50 = 1804 ug/kg), pergolide (ED50 = 23 ug/kg) and lisuride (ED50 = 74 ug/kg) all depressed substantia nigra DA neuron firing, but this was complete only with U-91356A. Higher U-91 doses depressed dorsal raphe 5-HT neurons (ED50 = 204 ug/kg). U-91 was orally available in rats (po/iv = 60%) and monkeys (po/iv = 28%). In MPTP-treated monkeys, U-91 successfully reversed parkinsonian symptoms both subcutaneously (30 ug/kg) and orally (1-2 mg/kg, duration 7-9 hrs). The data suggests that U-91's greater selectivity, efficacy and oral availability could provide a novel improved treatment for Parkinson's Disease.

451.12

THE EFFECT OF MPTP ± L-DOPA UPON SOCIAL MEMORY/ RECOGNITION IN MICE. D.E. Dluzen* and J. Kreutzberg, Department of Anatomy, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Retired breeder male CD-1 mice were treated with either MPTP (10 mg/kg ip, q.i.d., x1d, N=10) or saline (N=10) and at 5 days post-treatment tested in a habituation-dishabituation paradigm. Three 2-minute presentations of the same stimulus (ovariectomized) female (habituation) was followed by three 2-minute presentations using a different stimulus female (dishabituation) with an inter-trial interval of 20 minutes. Investigation times ($\bar{x}$ ± SEM in seconds) of saline animals decreased over the habituation trials (103 ± 10, 63 ± 10, 37 ± 9) while those of MPTP animals did not decrease until the third trial (85 ± 11, 85 ± 12, 43 ± 4). A clear dishabituation response from trial 3 to 4 was shown by saline (37 ± 9 to 72 ± 11) but not MPTP (43 ± 4 to 58 ± 9) animals. Treatment of MPTP animals with L-DOPA one hour prior to test (50 mg/kg ip, N=9) resulted in habituation (94 ± 8, 45 ± 8, 28 ± 4) and dishabituation (93 ± 10) scores which were similar to saline-treated animals. These results demonstrate that MPTP treatment disrupted initial habituation and dishabituation responses in male mice while treatment of MPTP animals with L-DOPA restored their responses to that observed in saline animals. Such findings suggest that administration of the dopaminergic neurotoxin MPTP impairs social memory/recognition processes, an effect which can be rectified with exogenous L-DOPA treatment.

THE TRAINING METHOD AFFECTS PERFORMANCE IN THE "STAIRCASE TEST" FORELIMB REACHING TASK: POSSIBLE IMPLICATIONS FOR SEVERITY OF 6-OHDA LESION EFFECTS. R.J. Mandel* and B.K. Kaspar Dept. of Psych., U. of Illinois, 603 E. Daniel St., Champaign, IL 61820

A new method for assessing the forelimb reaching capabilities of individual forepaws in the rat has recently been described (Montoya et al., *J. Neurosci. Meth.* 36:219-228, 1991). Using this test, Montoya et al., (*Prog. Brain Res.* 82:459-466, 1990) have reported reaching deficits in the forelimb opposite to a unilateral nigrostriatal 6-hydroxydopamine (6-OHDA) lesion. Another group, Gray et al., (*Soc. Neurosci. Abst.* 17:501,1991), using 10 food pellets/well reported milder 6-OHDA-induced deficits than those reported by Montoya et al. who use 2 pellets/well. The present study was undertaken to determine whether the amount of food provided during training is a significant factor in reach training. Two groups of normal rats (n=10) were trained for 5 consecutive days (15 min/day) with either 10 pellets or 2 pellets per well (80 total pellets vs. 16 total pellets) and then the conditions were crossed-over for training on days 6-10. Prior to training, both groups were reduced to >85% of pre-training body weight and maintained at this level by supplemental feeding when necessary. Rats given the opportunity to eat 80 pellets per session learned well and continued to improve performance when switched to 2 pellets/well, eventually consuming 75% of the pellets available. In contrast, the rats initially trained with 2 pellets/well ate few pellets and never consumed more than 5% of the pellets even though they had access to 80 pellets on days 6-10. In addition, the group which originally had access to 80 pellets was able to maintain >85% body weight with little supplementation on days 1-5. This was not the case for the rats trained with 2 pellets/well: they received constant dietary supplements in order to remain above 85% body weight. Thus, the rats initially trained with access to 80 pellets could work to maintain their body weight while the other group could not. Thus, it appears that the *a priori* motivational level of rats affects the degree of post-6-OHDA lesion deficit as indicated by the different levels of post-lesion performance reported by Gray et al., as compared with Montoya et al., (1990).

HIGH RESOLUTION PET STUDIES OF GLUCOSE METABOLISM IN PARKINSON'S DISEASE. J.L. Eberling*, B.C. Richardson, B.R. Reed, W.J. Jagust. Center for Functional Imaging, Lawrence Berkeley Laboratory, University of California, Berkeley, CA 94720, and University of California, Davis, CA 95616.

There have been several reports of decreased regional cerebral metabolic rates for glucose (rCMRglc) in Parkinson's disease (PD), although others find no differences between PD patients and controls. Differences in the cognitive status of the PD patients may account for some of these inconsistencies. We report the results of a PET study using ^{18}F-fluorodeoxyglucose (FDG) to measure rCMRglc in 8 nondemented PD patients and 8 age-matched control subjects. Three contiguous tomographic levels through the temporal lobes were scanned, along with one tomographic level through the basal ganglia that included frontal and parietal cortex. We used previously determined rate constants and an operational equation to determine rCMRglc, and these values were averaged over the three tomographic levels for temporal lobe structures.

Repeated measure analyses of variance revealed significant ($p<0.05$) main effects for both tomographic levels, with rCMRglc values averaging 23% below control values for all regions studied. For the temporal lobe level, there was also a significant ($p=0.0001$) group x region interaction, indicating that the pattern of rCMRglc differed between the two groups. The group x region interaction was not significant ($p=0.5$) for the basal ganglia level. A series of Bonferroni corrected t-tests revealed that the PD patients had significantly lower rCMRglc than controls in right and left visual association areas, right primary visual cortex, and right and left parietal cortex. While these differences could reflect motor impairment, the posterior location of these deficits has often been associated with cognitive dysfunction and may predict future cognitive impairment.

451.15

VISION IN PARKINSON'S DISEASE: SEVERAL BASIC CAPACITIES ARE UNIMPAIRED. D.K. Kurylo*, S. Corkin, and J.H. Growdon. Dept. of Brain and Cognitive Sciences and the Clinical Research Center, MIT, Cambridge, MA 02139.

Parkinson's disease (PD) is characterized by a loss of dopaminergic (DA) neurons in the nigrostriatal pathway. PD patients also have decreased retinal DA levels (Harnois and DiPaolo, 1990), which may interfere with early visual processing. Consistent with this idea, the pattern electroretinogram and spatial and temporal contrast sensitivity are abnormal in PD. In order to explore the generality of these findings, we administered a series of visual psychophysical tests to 10 nondemented PD patients (mean age: 64.9 years) and 29 age-matched control subjects (mean age: 67.9 years). Based upon the Hoehn and Yahr stages of disability, 1 patient was classified as Stage I, 8 as Stage II, and 1 as Stage III. All PD patients were receiving DA medications. Psychophysical measurements were made of fine pattern discrimination, color discrimination along the red-green and blue-red primary color axes, and contrast sensitivity to flickering (3, 7.5, and 15 Hz) and moving (3.15, 4.72, and 9.44 °/s) stimuli. In all cases, stimuli were presented within 1.0 X 1.0° squares at a retinal eccentricity of 7.5°. Subjects responded in a four-position forced-choice procedure, and thresholds were determined with the method of constant stimuli. Under these conditions, the performance of PD patients did not differ significantly from age-matched control subjects on any of the visual capacities tested. It appears that some visual capacities are spared in PD, at least in patients who are taking DA medication.

451.16

THE EFFECTS OF GM_1 GANGLIOSIDE, EGF, AND bFGF ON THE NIGROSTRIATAL DOPAMINE SYSTEM IN THE MPTP-TREATED MOUSE. L. DiStefano*, M.G. Smith and J.S. Schneider. Department of Neurology, Hahnemann University, Philadelphia, PA 19102.

GM_1 ganglioside, epidermal growth factor (EGF) and basic fibroblast growth factor (bFGF) have all been suggested to exert trophic influences on the nigrostriatal dopamine (DA) system and to stimulate at least partial restoration of striatal DA levels following injury to the nigrostriatal system. The present study has compared the ability of these substances, administered alone or in combination, to facilitate recovery in the DA system after an MPTP-induced lesion. Young (8-10 wk. old) male C57/Bl6J mice received MPTP injections (30mg/kg, i.p.) daily for 5 days. Three days later, they were implanted with Alzet osmotic minipumps to infuse EGF, bFGF, NGF or cytochrome C into the lateral ventricle at a rate of 2-5µg/wk over a 2 wk. period. In addition to EGF or bFGF infusions, some animals also received daily GM_1 injections (30mg/kg, i.p., daily) for 2 wks. Other animals received MPTP for 5 days and either daily GM_1 (30mg/kg, i.p.) or saline injections for 2 wks. GM_1 and EGF alone increased striatal DA levels approximately 25% after 2 wks. of treatment, while bFGF increased striatal DA levels by 18% over the same period. Cytochrome C and NGF had no effect on striatal DA levels. EGF and bFGF, when combined with GM_1, increased striatal DA levels by 38% and 30% respectively, suggesting a synergistic effect of GM_1 and these factors on striatal neurochemistry. MPTP treatment alone caused a mean 38% loss of tyrosine hydroxylase-positive substantia nigra pars compacta (SNc) neurons. MPTP-treated animals that received GM_1, EGF, or GM_1 plus EGF all had SNc cell counts significantly higher than MPTP control animals although there was no synergistic effect of GM_1 plus EGF on this parameter. Cell counts in GM_1-treated animals were higher than in animals that only received EGF. These results suggest that GM_1 ganglioside probably works in concert with other trophic factors to both enhance dopamine neurochemistry and neuronal survival following damage to the dopamine system. Supported by Fidia Pharmaceutical Corp.

SODIUM CHANNEL MUTATIONS IN NEUROMUSCULAR DISEASE. A.I.McClatchey, R.H.Brown J.F.Gusella* and collaborators. Neurogenetics Lab. and Day Neuromuscular Research, Mass. Gen. Hosp. and Harvard Med. Sch., Charlestown, MA 02129.

The human skeletal muscle sodium channel gene (SCN4A) has been linked to both paramyotonia congenita (PMC) and hyperkalemic periodic paralysis (HPP), two neuromuscular disorders for which an abnormal, tetrodotoxin-sensitive sodium current can be detected in affected muscle. As a prelude toward understanding sodium channel malfunction in these diseases, we have examined the SCN4A locus in more detail. By completing the entire genomic structure of the SCN4A gene and obtaining knowledge of intron sequences flanking each exon, we have developed PCR-based assays for the detection of SCN4A mutations. We initially detected two point mutations in affected members of PMC families. Both are predicted to affect amino acid alterations in the cytoplasmic loop connecting domains III and IV of the sodium channel, a region thought to be crucial for channel inactivation.

We have now detected two new mutations in different regions of the sodium channel. One is present in affected members of a separate PMC family, and the other in affected members of a family whose clinical features resemble both PMC and HPP. With the disclosure of these and other mutations in the SCN4A gene, we may be able to catalogue disease phenotypes and correlate them with different affected regions of the sodium channel.

SEVERE ADULT-ONSET NEUROMUSCULAR DISORDER IN A TRANSGENIC LINE OF MICE. B. Popko[1], D. Kelly[1], A. Miletovich[3], U. Francke[3,4], and K. Suzuki*[2]. [1]Dept. of Biochemistry, [2]Dept. of Pathology, Brain and Development Research Center, U. of North Carolina, Chapel Hill, NC 27599. [3]Dept. of Genetics and [4]Howard Hughes Medical Institute, Stanford University School of Medicine, Stanford, CA 94305

We have generated a transgenic line of mice in which the transgene has disrupted the function of an endogenous gene essential for normal muscle function. Mice homozygous for the BPFD transgene in our transgenic line BPFD#36 develop a postural abnormality at around three months of age. These mice walk oddly with stiffened and/or splayed hind legs, adopting a hunched posture with some exhibiting frank kyphosis of the thoracic spine. These symptoms progress gradually to severe motor dysfunction. Heterozygous animals from this line, as well as heterozygous and homozygous animals from all other BPFD transgenic lines, do not express this abnormal phenotype. This suggests that the BPFD#36 transgene has disrupted the function of an endogenous gene. The transgene integration site was mapped by fluorescent in situ hybridization to chromosome 11 bands B4-B5. Pathology was found in skeletal muscle and peripheral nerve of the mutant animals. The muscles from both upper and lower extremities show necrosis and regeneration with muscle fiber splitting, internally-located nuclei and variable fiber size. Schwann cell - axon interactions also appear disrupted. Although many axons are well myelinated in these mice, there are also bundles of bare axons that are partially encircled by a single Schwann cell. Within these bundles there are axons large enough to be myelinated. These results suggest that the muscle degeneration that occurs in BPFD#36 animals may be secondary to a defect in Schwann cell - axon interactions.

TERMINAL MOTOR AXON MORPHOLOGY IN HOMOZYGOUS HEREDITARY CANINE SPINAL MUSCULAR ATROPHY. K. Alderson and L.C. Cork*, Department of Neurology, University of Utah, Salt Lake City, Utah and Division of Comparative Medicine, Johns Hopkins University, Baltimore, Maryland

Dogs homozygous for hereditary canine spinal muscular atrophy develop rapid progressive muscle weakness. We evaluated the morphology and myelination of distal motor nerves in the tail base paraspinal muscle of homozygous pups at three stages, early, middle, and late, to determine if muscle weakness correlated with abnormalities of distal motor axons. Compared to age-matched normal dogs, early affected pups had increased unmyelinated axonal collaterals and increased terminal innervation ratio. Mid-stage pups had thin, unmyelinated axonal collaterals, and evidence of Wallerian degeneration in intramuscular nerves. End stage pups (9 weeks of age) had a paucity of motor axons, an irregular distribution of neurofilaments within the axon, and aberrant growth cones. We conclude that as hereditary canine spinal muscular atrophy progresses, intramuscular motor axons are lost, thin unmyelinated axonal collaterals develop, and the organization of neurofilaments within the axon is altered. Both the loss of motor axons and the lack of myelin may have clinical and electrophysiological consequences.

MOTOR UNIT PROPERTIES IN HEREDITARY CANINE SPINAL MUSCULAR ATROPHY. M.J. Pinter*, L.C. Cork and N. Wallace. Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania and Div. of Comparative Medicine, Johns Hopkins University School of Medicine.

Hereditary canine spinal muscular atrophy (HCSMA) is an autosomal dominant disease which is characterized by progressive weakness and eventual loss of lower motoneurons. Using intracellular recording and stimulation of single motoneurons, we have studied medial gastrocnemius (MG) motor unit properties in a litter of HCSMA pups aged 10-13 weeks. In units investigated thusfar, motoneurons were found to respond normally to low frequency (1 Hz.) antidromic stimulation of peripheral axons and to possess electrical properties similar to adult cat motoneurons. In heterozygous pups (4), the motor unit population was composed of types FR and S units with no evidence for the existence of type FF units. We have not yet confirmed this motor unit composition in normal animals, but the predominance of types FR and S units is consistent with available enzyme histochemistry evidence for normal adult canine MG muscle. In 2 homozygous pups studied thusfar, two populations of units were detected. In the first, intracellular stimulation of motoneurons failed to produce detectable motor unit force despite the presence of antidromic motoneuron activation following peripheral MG nerve stimulation. This failure occurred in 30-50% of the tested motoneuron population and was associated with an inability to detect EMG responses linked to the intracellular stimulation. In the other population, stimulation produced measurable motor unit mechanical responses best characterized as types FR and S but with force outputs lower than in the heterozygous group.

ALTERATIONS IN NEUROFILAMENT mRNA IN HEREDITARY CANINE SPINAL MUSCULAR ATROPHY. N.A. Muma* and L.C. Cork. The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Hereditary canine spinal muscular atrophy (HCSMA) is a dominantly inherited motor neuron disease in which distal axonal caliber is reduced in lower motor neurons. Because several animal models show that neurofilament protein gene expression is a major determinant of axonal caliber, we examined neurofilament gene expression in HCSMA early in the clinical disease. Using quantitative in situ hybridization we found that the levels of mRNA encoding the low molecular weight neurofilament protein subunit (NF-L) were significantly different from levels of mRNA encoding the high molecular weight neurofilament protein subunit (NF-H) and poly-A+ mRNA in cervical spinal cord enlargement of dogs with HCSMA compared to control dogs. The levels of poly-A+ mRNA in neurons in the same region were comparable in dogs with HCSMA and controls. If neurofilament protein subunit levels are found to follow the mRNA levels in this animal model, our results would suggest that decreased expression of the NF-L gene is sufficient to inhibit neurofilament function, i.e., maintenance of axonal caliber, probably by disrupting normal neurofilament assembly.

LOCALIZATION OF DYSTROPHIN IN HUMAN AND MONKEY BRAIN. Johnny Huard, Pierre-Yves Côté, Jean-Pierre Bouchard, Carol L. Richards* and Jacques P. Tremblay. Neurobiology Laboratory, Enfant-Jésus Hospital, 1401, 18e Street, Québec (Qc), G1J 1Z4

Duchenne muscular dystrophy (DMD) has been characterized by a lack of dystrophin expression. This protein (420 kDa) is localized in the sarcolemma of normal muscle fibers and is absent of DMD and mdx skeletal muscle. Dystrophin would be involved in maintaining muscle membrane integrity during repeated cycles of contraction and relaxation. Molecular biology techniques have also permitted to detect dystrophin transcript in the central nervous system (CNS). In fact 50% of DMD patients suffer also a mental retardation probably due to learning and memory problems. Dystrophin was localized in several brain regions of human and monkey brains using antibodies against the rod domain and C terminus region. A clear visualisation of dystrophin was permitted by an indirect immunoperoxidase method using an amplification with biotin and avidin. Dystrophin-like immunoreactivity was observed in brain region involved in learning and memory such as hippocampal formation, cerebral cortex and the dentate nucleus of cerebellum. A positive reaction was also present in brain regions implicated in motor function (spinal cord, cerebellum, thalamus and substantia nigra). The Western blot analysis confirmed the presence of a 420 kDa polypeptide in these brain regions with both antidystrophin antibodies. However the rod domain antibody also detected a dystrophin-like protein. These results raise the possibility that the lack of dystrophin is involved in the cognitive impairment observed in several DMD patients. However it will be important to analyze in more details the clinical symptoms of DMD patient to understand the dystrophin role in brain.

DYSTROPHIN DISTRIBUTION IN MUSCLE AND NEURONS OF DUCHENNE MUSCULAR DYSTROPHY HUMAN FETUSES. **I.Mussini, S. Torelli, M.A. Marzilli, A. Jaranowska and F. Gremo*. C.N.R. Unit for Muscle Biol.& Physiopath., Padova; Dept. of Cytomorphol., Med.School, Cagliari (Italy).**

Duchenne Muscular Dystrophy (DMD) is the result of the deficiency of a specific cytoskeletal protein called dystrophin, which binds to the inner plasma membrane. We have previously shown that dystrophin can be present in DMD human fetal neurons in culture. Therefore, we analysed the distribution of dystrophin and spectrins in muscle and neurons of two DMD human fetuses (12-14 week-old) with immunocytochemistry. Different muscles were frozen and serial sections (10 μm thick) were incubated with monoclonal antibodies against β-spectrin, the C-terminal portion of dystrophin and different isoforms of myosin heavy chains (MHC). Neurons were grown in culture as previously described (Torelli et al., in "Plasticity and Regeneration of the Nervous System", P.S. Timiras et al. Eds, Plenum Press, New York, pp. 121-134, 1991), fixed with formaldehyde and incubated with the two first antibodies. Results showed that all myotubes and the few immature myofibers were positive for β-spectrin, but negative for dystrophin. On the contrary, some neurons were positive for dystrophin and all showed an abnormal distribution of spectrin. Noteworthy was the presence of adult slow MCH in some young myofibers and in myotubes. These results help in understanding the mechanism of expression of different genes, including the DMD gene, during human development. (Supported by Telethon-Italy, 1991).

452.8

A 120 K HIGH AFFINITY LAMININ BINDING PROTEIN IN BRAIN IS CLOSELY RELATED TO THE DYSTROPHIN-ASSOCIATED GLYCOPROTEIN DYSTROGLYCAN. S.Gee[1], R. Blacher[1], P. Douville[1], P. Yurchenco[2] and S.Carbonetto[1]*, [1]Centre for Research in Neurosciences, McGill University, Montreal General Hospital Research Institute, Montreal, Canada; Department of Biochemistry, [2]Athena Neurosciences, San Francisco, California; [3]Robert Wood Johnson Medical School, Piscataway, New Jersey.

Laminin is a large extracellular matrix glycoprotein that mediates its effects on cells through integrin and non-integrin receptors. When brain proteins separated by SDS-PAGE and transferred to nitrocellulose are probed with ^{125}I-labelled laminin, a single prominent band of ~120 kDa binds laminin specifically (Smalheiser et al., 1987, PNAS, 84:6457-61; Douville et al., 1988, JBC, 263:14964-9). This band consists of two distinct laminin binding proteins. One of these, LBP120, is closely related to dystroglycan, a muscle laminin receptor of 156 kDa that is associated with dystrophin through a cell surface glycoprotein complex. The glycosylation, extracellular localization, and ability to extract LBP120 with cation chelators or high salt are consistent with it being a peripheral membrane protein. Laminin binding to LBP120 is of high affinity (Kd= 40 nM), is Ca^{++} dependent, and is mediated primarily by the heparin binding domain E3. Dystroglycan is reduced or absent in dystrophic muscle; alterations in brain LBP120/dystroglycan may be involved in the neural deficits associated with Duchenne's muscular dystrophy.

452.9

RETARDATION OF FAST AXONAL TRANSPORT IN WOBBLER MICE. H. Mitsumoto, J.M. Jacob, K. Kurahashi, and I.G. McQuarrie*. Cleveland VA Med. Ctr., and Cleveland Clinic Foundation., Cleve., Oh. 44106.

To investigate axonal function in a subclinical model of motor neuron disease, we have examined anterograde axonal transport in hindlimb motor neurons of wobbler mice. For fast transport, tritiated amino acids were injected into the spinal cord. Transport distances were determined from the distribution of labeling after 2 or 3 hr; fast transport was 18% slower in wobbler mice than in unaffected littermates ($p<0.01$). For slow transport, ^{35}[S]-methionine was injected. Transport rates were determined from distances to the peaks of labeling for structural proteins separated by SDS-PAGE after 2 or 3 wks. Rates for slow components a (SCa) and b (SCb) were unchanged by wobbler disease. Because the rate of fast retrograde transport is also unchanged (Mitsumoto et al., 1990), we conclude that subclinical disease is associated with an impairment of fast anterograde transport. Because disruption of the Golgi apparatus by the neuronopathy is unlikely to affect the fast transport rate, we suggest that an axonopathy may be affecting the fast transport motor (kinesin).

QUANTITATIVE EVALUATIONS OF MUSCLE STRENGTH IN WOBBLER MICE: IN VIVO AND IN VITRO STUDIES. **K. Ikeda, H. Mitsumoto*, Dept. of Neurology, Cleveland Clinic Foundation, Cleveland, OH 44195**

This study is to establish the techniques to quantitatively measure muscle strength in wobbler mice, since objective techniques are limited in the animal model. Seven to 9 week-old wobbler mice and their healthy littermates were studied. 1) In vivo electric nerve stimulation test (ENST): Under halothane anesthesia, the right radial, medial and ular nerves were cut at the level of the humerus head and musculocutaneous nerve was stimulated. Maximum muscle contractions of the biceps were measured by a force displacement transducer. 2) In vitro muscle twitching test (MTT) : The left biceps and triceps muscles were removed with both end of the humerus. The one end was fixed to the tissue bath, while the other was attached to the transducer. The first 5 muscle twitches at the supramaximal electric stimulations were recorded. 1) ENST (mean ± SD g) was 3.55 ± 0.53 and 10.24 ± 0.92 in wobbler mice (n=9) and controls (n=9) respectively ($p<0.001$). Muscle-weight adjusted ENST responses were also significantly different between the two groups ($p<0.01$). 2) MTT (mean ± SD) was 1.53 ± 0.25 and 4.92 ± 0.36 in wobbler mice (n=6) and controls (n=8) respectively ($p<0.001$). MTT responses normalized for muscle weight were also significantly different between the both groups ($p<0.001$). These two techniques we have established appear to be useful to evaluate the clinical effects of novel neurotrophic factors which be tested first in the animal model.

452.11

Excitatory Amino Acid Receptors in the Cervical Spinal Cord of the Wobbler Mouse: A Quantitative Autoradiographic Analysis. **C. Krieger*[1], R. Lai[1], H. Mitsumoto[2] and C. Shaw[3], [1]Dept. of Medicine and [3]Opthalmology, University of British Columbia, Vancouver, B.C. and [2]Cleveland Clinic Foundation, Cleveland, OH.**

Previous studies have suggested that motoneuron death might develop as a consequence of an excitatory neurotoxic compound with agonist action at certain excitatory amino acid (EAA) receptor subtypes on motoneurons. To investigate the possibility that a selective reduction of EAA receptor subtypes might be observed as a result of motoneuron death subsequent to EAA receptor activation, we measured the distribution and density of EAA receptors in the cervical spinal cord of the wobbler mouse using quantitative receptor autoradiography. Homozygous wobbler mice develop progressive motoneuron loss, especially in the cervical spinal cord and brain stem. NMDA receptors labelled with 25 nM [^{3}H] MK801 were located in both the ventral and dorsal horns and displayed little regional variation in binding. AMPA binding sites, evaluated with 20nM [^{3}H] CNQX, were more concentrated in the dorsal horn than the ventral horn. Kainate binding sites were labelled with 30 nM [^{3}H] kainate, and receptor binding was located largely in the dorsal horn. [^{3}H] Glutamate binding sites (35nM) were most abundant in the dorsal horn of the spinal cord. NMDA, kainate, glutamate and AMPA receptor binding densities were not significantly different in the ventral horns of wobbler mice compared to those of control litter mates. These results suggest that motoneuron loss in the wobbler mouse is not mediated by excitotoxins acting on EAA receptors.

452.12

EARLY AND SELECTIVE IMPAIRMENT IN THE FAST ANTEROGRADE TRANSPORT (FAT) RATE OF GLYCOPROTEINS IN ACRYLAMIDE (AC) NEUROPATHY. T. Storm-Dickerson, P.S. Spencer*^ and B.G. Gold#. Center Res. Occup. and Environ. Toxicol. and #Depts. of Cell Biol. & Anat. and ^Neurol., Oregon Health Sci. Univ., Portland, OR 97201

Distal axonal degeneration (dying back) is the most common pattern of axonal pathology observed in a variety of human disorders. We examined FAT of proteins and glycoproteins in AC neuropathy, a prototypical model of progressive axonal degeneration. Six-week-old male rats given a single injection of AC (5-100 mg/kg, i.p.) 20 minutes before or after injection of ^{3}H-leucine or ^{3}H-fucose, respectively, into the L5 dorsal root ganglion (DRG) demonstrated no alteration in the maximal transport rate (front of the curve) for radiolabeled proteins, whereas the glycoprotein FAT rate was reduced (by 18%) compared to age-matched controls; data was normalized to the radioactivity present in the DRG. A defect in FAT of glycoproteins was noted up to 49 days following a single 100 mg/kg dose, but was reversible (beginning as early as 7 days) following a lower dose (50 mg/kg). Repeated injections of AC (30 mg/kg/day, for 7 days) did not exacerbate the degree of glycoprotein transport impairment. No alteration in the amount of transported materials was found. A correletion was observed between the degree of FAT deficit and axonal degeneration; following pretreatment with β,β'-iminodipropionitrile (which exacerbates axonal loss by AC), AC (75 mg/kg) elicited a marked impairment in both protein and glycoprotein FAT rate. We suggest that repeated, low dose AC exposure leads to an irreversible impairment in the delivery of FAT glycoproteins to the distal axon resulting, over time, in axonal degeneration. A STUDY OF THE ADVERSE EFFECTS OF 5-HT PRECURSOR-TREATMENTS RELATED TO EMS. Moto Sakuma,* Moto R.R.C. Co.,Detroit Mi 48224.

A comparison was made of the adverse effects of seven drug treatments which used 5-HT precursors. The adverse effects were collected from others' publications. The underlying cause of Eosinophillia-Myalgia Syndrome (EMS) was sought. Neuroleptic Malignant Syndrome(NMS) was added to these clusters for comparison between EMS and NMS. All clusters were subclassified into eight signs(general, skin, muscle, visceral, neurolgical, psychiatric, blood physiological, and chemical analysis). The appearances of these signs were expressed numerically, and histgram were drawn to compare the pattern. The similarity of those patterns resulted in two separate group: 1. TRP(tryptophan)group -(TRP alone treatment, TRP plus Monoamine Oxydase, TRP plus tricycle antidepressant), 2. 5-HTP (5-hydroxy tryptophan) group-(5-HTP alone treatment,and TRP plus co-enzyme). The TRP alone treatment's effects showed little resemblance of pattern to that of EMS. In conclusion, EMS may be caused by combined influences involving by thr TRP toxicity with conditions of genetic background and/or underlying metabolic abnormality as the predisposition.

SYMPOSIUM. MOLECULAR ANALYSES OF NEURONAL PHYSIOLOGY AND POTENTIAL FOR GENE THERAPY USING HERPES SIMPLEX VIRUS VECTORS. A.I. Geller, Children's Hospital (Chairperson); R.L. Neve, McLean Hospital; M.J. During, Yale University School of Medicine; K. O'Malley, Washington University School of Medicine; and H.J. Federoff, Albert Einstein College of Medicine.

The development of a defective Herpes Simplex Virus (HSV-1) Vector System that allows gene transfer directly into neurons and glia, in culture or in the adult mammalian brain, may facilitate a molecular genetic analysis of neuronal physiology and brain function, and may provide the means to gene therapy of neurological diseases. The symposium will i) describe the properties of the HSV-1 vector system, ii) describe a molecular genetic approach to neuronal physiology and brain function that is based on the introduction of unregulated signal transduction enzymes into neurons, and iii) propose gene therapy approaches to both Parkinson's and Alzheimer's Diseases that involve in vivo expression of tyrosine hydroxylase and nerve growth factor, respectively. The presentations will be: (1) Dr. Geller will detail the properties of the HSV-1 vector system, and will describe experimental strategies using the vector system. (2) Dr. Neve will report on insights gained into the role of signal transduction pathways in controlling neuronal physiology, and neurotransmitter release in particular, utilizing a genetic intervention strategy in which unregulated signal transduction enzymes (eg. adenylate cyclase, protein kinase C) are introduced into cultured neurons. (3) Dr. During will report on introducing these same unregulated signal transduction enzymes into the adult brain and their effects on animal behavior. For example, introduction of an unregulated PKC, under the control of the tyrosine hydroxylase promoter, into the substantia nigra of unlesioned rats causes a long-term asymmetrical rotational behavior. (4) Dr. O'Malley will describe efforts to develop gene therapy for Parkinson's Disease. Recombinant tyrosine hydroxylase can be functionally expressed in cultured striatal neurons; and introduction of this gene into the striatum of 6-OH dopamine lesioned rats results in behavioral recovery. (5) Dr. Federoff will describe efforts towards gene therapy by expression of neurotrophic factors. Expression of NGF from a HSV-1 vector supports the survival of cultured sympathetic neurons and induces choline acetyltransferase activity in cultured CNS neurons. Introduction of recombinant NGF into the superior cervical ganglia of adult rats can prevent specific effects of axotomy; and introduction of NGF into basal forebrain cells is under study.

SYMPOSIUM: THALAMIC MECHANISMS OF NOCICEPTION.
F.A.Lenz*, Johns Hopkins (Chairman); E.G.Jones, UC Irvine; A.V.Apkarian, SUNY Syracuse, M.C.Bushnell, Univ. Montreal

The principal sensory nucleus and adjacent nuclei of primate thalamus comprise a region that is involved in pain-signalling pathways. Evidence will be presented that there are two separate anatomical domains within this region (rod and matrix domains), and that the spinothalamic tract (STT) terminates selectively within the matrix domain. Inputs from STT may explain the activity of neurons in this region which respond to both innocuous and noxious stimuli (WDR neurons). These neurons may mediate pain discrimination since: 1) they encode painful stimuli well enough to explain the psychophysics of pain discrimination 2) stimulation at recording sites for these neurons in man may evoke somatic or visceral pain, as well as innocuous thermal sensations and 3) injection of local anesthetic in this region blocks discrimination of both innocuous and noxious thermal stimuli. These findings suggest that WDR neurons in the region signal acute pain.

Following injuries to the nervous system there is evidence of anatomic reorganization of the rod and matrix domains. Patients with pain following nervous system injury exhibit physiologic reorganization and increased calcium spike associated bursting activity in the region. These changes in neuronal activity may be related to NMDA associated channels that are activated by noxious stimuli. The convergence of innocuous and noxious inputs in the region may be related to the pain evoked by innocuous stimuli which occurs in many patients following nervous system injury. Therefore synaptic and intrinsic cellular mechanisms governing thalamic neuronal activity may mediate acute somatic and visceral pain as well as symptoms of pain syndromes observed following injuries to the nervous system.

NEUROENDOCRINE REGULATION II

456.1

DISTRIBUTION OF ESTROGEN RECEPTOR-CONTAINING NEURONS IN PREPUBERTAL FERRETS IN THE PRESENCE AND ABSENCE OF GONADAL STEROIDS. C.L. Sisk* and L.L. DonCarlos. Neuroscience Prog./Dept. Psychol., Michigan State Univ., E. Lansing MI 48824, & Dept. Cell Biol., Neurobiol. & Anatomy, Loyola Univ. Sch. Medicine, Maywood IL 60153.

Puberty in male ferrets is marked by profound increases in gonadotropin secretion and the onset of copulatory behavior. Responsiveness to negative feedback effects of testosterone (T) on gonadotropin release decreases during puberty, while responsiveness to behavioral effects of T increases. The neuroendocrine and behavioral effects of T are in part mediated by aromatization of T to estradiol (E). One way in which pubertal shifts in brain responsiveness to T might occur is via alterations in steroid receptor content. As a first step in examining this question, we asked 1) What is the distribution of estrogen receptors in the prepubertal male ferret? 2) Is estrogen receptor content altered by E or T in these animals? The H222 antibody (gift of Abbott Laboratories) was used to detect estrogen receptor immunoreactivity (ER-IR) in the brains of prepubertal male ferrets that were castrated and treated with vehicle, E, or T. ER-IR cells were found in the preoptic area, amygdala, and in the ventromedial (VMH) and arcuate nuclei of the hypothalamus, all areas known to be important in reproductive function. Overall, the staining intensity and number of ER-IR cells was decreased by E and by T, compared with controls. However, a dorsal-ventral column of cells in the lateral VMH was consistently more darkly stained and contained more cells in steroid-treated ferrets compared with controls. Thus, steroid hormones may differentially regulate steroid receptor content in specific cell groups. This suggests a mechanism by which responsiveness to T changes in opposite directions during puberty in neural substrates underlying neuroendocrine versus behavioral functions. Supported by HD26483, HD00950, and the Potts Foundation.

ESTROGEN RECEPTOR mRNA IN THE BRAIN OF FEMALE RATS DURING PREGNANCY. C.K. Wagner* and J.I. Morrell. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102

In vitro estrogen receptor (ER) binding studies have demonstrated regionally- and temporally-specific changes in ER levels in the brain over the course of pregnancy (Physiol. Behav. 50:1263, 1991). In this study, in situ hybridization was used to examine steady state levels of ER mRNA in the brain of pregnant female rats. Females were time-mated and sacrificed on day 8, 16 or 22 of pregnancy or on postpartum day 1. ER mRNA was detected by hybridization to an 850 base ^{35}S-labelled cRNA probe, complementary to the mRNA encoding the steroid binding domain of the 3' untranslated region (rat cDNA - M. Muramatsu; 1 x 10^6 cpm/slide). Hybridization took place at 60°C for 20hrs; autoradiographic exposure: 2-6 wks. Many heavily labelled cells were found in the periventricular and medial preoptic area. Labelled cells were also found in the septum, bed nucleus of the stria terminalis, arcuate, ventromedial nucleus, and medial and cortical nuclei of the amygdala. The regulation of ER during pregnancy may alter neural sensitivity to estrogen in a regionally-specific and time-dependent manner to induce behaviors and endocrine events that are unique to this reproductive state. (HD 22983 to J.I.M.)

456.3

ESTROGEN RECEPTOR mRNA IN THE BRAIN OF DOMINANT AND SUBORDINATE MALE MICE FOLLOWING SOCIAL CONFLICT. C.A. Lisciotto*. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

Aggressive encounters produce behavioral, neurochemical, and endocrinological changes in both dominant and subordinate animals. In situ hybridization was used to determine the location and relative amount of estrogen receptor (ER) mRNA in the brains of adult male CFW mice following aggressive experience. Aggressive encounters took place in the home cage, using a resident-intruder paradigm. Mice were given 5 bouts of fighting experience and were sacrificed 4 hours after the last fight. ER mRNA was detected with an 850 base ^{35}S-labeled cRNA probe. Hybridization (1 X 10^6 cpm/slide) took place at 60°C for 20 hours; autoradiograms were exposed for 4 weeks. ER mRNA-containing cells were abundant in the medial preoptic area (MPOA), bed nucleus of the stria terminalis, medial amygdala (MA), and ventromedial and arcuate nuclei. Dominant males had fewer ER mRNA-containing cells in the MA compared to subordinate males. Moreover, in the MPOA of dominant males there was a significant positive correlation between the relative amount of ER mRNA per cell and attack frequency ($r=0.89$). Aggressive behavior of CFW mice is mediated by estrogenic metabolites of testosterone. By altering ER mRNA content, aggressive experience may alter sensitivity to estrogen within brain regions important for aggressive behavior.

HORMONAL REGULATION OF TYROSINE HYDROXYLASE AND OPIOID PEPTIDE GENE EXPRESSION IN THE HYPOTHALAMUS. R. B. Simerly*. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

The anteroventral periventricular nucleus of the hypothalamus (AVPv) is thought to play a critical role in mediating hormonal feedback on gonadotropin secretion. Recently we reported that the AVPv contains sexually dimorphic populations of neurons that express tyrosine hydroxylase (TH), proenkephalin (PENK) or prodynorphin (PDYN), and each displays unique patterns of mRNA regulation in response to sex steroids (see Simerly, Mol Brain Res. 6:297; Mol. Cell. Neurosci. 2:473). In the present study, in situ hybridization was used to evaluate TH, PENK and PDYN gene expression in the AVPv during the estrous cycle, and in response to progesterone treatment. Levels of TH mRNA within the AVPv are inversely correlated with circulating levels of estradiol with the greatest number of cells detected in female rats sacrificed on the morning of diestrus and the fewest in animals killed on the morning of proestrus. Treatment of estrogen-primed ovariectomized female rats with progesterone for either 3 or 24 hours produced no detectable changes in the number of TH mRNA-containing neurons in the AVPv relative to controls. In contrast, PENK expression remains relatively constant across the estrous cycle and, like TH, levels of PENK mRNA are not altered by treatment with progesterone. Finally, levels of PDYN mRNA were reduced slightly on the afternoon of proestrus, but increased on the day of estrus suggesting that the high levels of progesterone that occur during this period may induce PDYN gene expression. Double in situ hybridization studies are underway to determine if these different patterns of hormonal regulation correlate with the differential expression of estrogen and progesterone receptors within TH, PENK and PDYN mRNA-containing neurons in the AVPv. Supported by NIH grant NS-26723.

456.5

OVARIAN STEROID HORMONES REGULATE GLUTAMIC ACID DECARBOXYLASE (GAD) MESSENGER RNA LEVELS IN THE HIPPOCAMPUS OF THE RAT. N.G. Weiland*, Laboratory for Neuroendocrinology, Rockefeller University, New York, NY 10021.

Estradiol and progesterone influence learning, memory and epileptic seizure activity, functions mediated in part by the hippocampus. Normal hippocampal function is dependent on precise interactions between the excitatory glutamatergic and inhibitory GABAergic systems. To determine whether or not ovarian steroid hormones interact with GABAergic neurons of the hippocampus, the levels of mRNA for GAD, the rate limiting enzyme for GABA synthesis, were measured using *in situ* hybridization histochemistry with ^{35}S-labelled antisense or sense (control) riboprobes transcribed from the feline GAD cDNA (generously provided by A. Tobin). The levels of mRNA for GAD were analyzed in selected regions of dorsal hippocampus and medial basal hypothalamus in three groups of rats: 1) 2-week ovariectomized (OVX), 2) OVX plus 2 days of estradiol (E), and 3) E plus 6 h of progesterone (EP). Rats were killed at 1500 h. GAD mRNA levels in E rats increased in the GABAergic neurons associated with the pyramidal cell layer in CA1 but not in any other region of the hippocampus. EP reversed the E-induced increase in GAD mRNA in CA1 and induced a small decrease in GAD mRNA in the hilus. No effect of E or EP on GAD mRNA levels was observed at this time of day in any region of the medial basal hypothalamus measured. In conclusion, estradiol and progesterone may alter learning and seizure activity by altering the function of GABA neurons in the hippocampus.

456.6

EFFECTS OF CASTRATION ON GABA TURNOVER IN MICRODISSECTED BRAIN REGIONS IN THE MALE RAT. D.R. Grattan, C.A. Sagrillo, M. Selmanoff and D.S. Ruchkin*, Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559.

There is considerable evidence that neuroendocrine regulation involves the inhibitory neurotransmitter GABA. This study determined whether changes in the turnover rates of GABA in discrete brain regions could be detected following castration. GABA concentrations were measured in 13 microdissected brain regions by HPLC with electrochemical detection following precolumn derivatization with o-phthalaldehyde and β-mercaptoethanol. Two days after castration or sham operation, male rats were decapitated either before or 30 minutes after inhibition of the GABA degrading enzyme GABA transaminase by injection of aminooxyacetic acid (AOAA, 100 mg/kg, i.p.). GABA accumulation following injection of AOAA was used as an index of GABA turnover. Non-specific postmortem GABA elevation was prevented by injection of 3-mercaptopropionic acid (120 mg/kg i.p.) 2.5 minutes prior to decapitation. GABA accumulation decreased following castration in the diagonal band of Broca at the level of the organum vasculosum of the lamina terminalis (DBBovlt), lateral to the DBBovlt, dorsomedial preoptic nucleus (MPNdm), arcuate nucleus and median eminence, increased in the lateral and medial septal nuclei, and was unaffected in the cingulate cortex, striatum, ventrolateral MPN, locus coeruleus and medullary A1 and C1 regions. These results are consistant with the hypothesis that the negative feedback of testosterone on LH release involves steroid-sensitive GABAergic neurons in the rostral and medial basal hypothalamus. (Supported by NIH Grant HD21351).

456.7

LOCALIZATION OF ANDROGEN AND ESTROGEN RECEPTORS WITH GRF AND SRIF NEURONS IN RAT HYPOTHALAMUS. J.T. French, W.E. Stumpf, R.A. King*, E.M. Wilson and M. Sar. Dept. of Cell Biol. & Anat., Labs. for Reprod. Biol., Univ. of North Carolina, Chapel Hill, NC 27599.

This study was conducted to determine whether GRF or SRIF neurons contain androgen receptor (AR) or estrogen receptor (ER). A dual immunocytochemistry method was applied to visualize AR and ER in GRF and SRIF neurons. Adult male rats with or without testosterone propionate treatment (100μg/100 g BW) each received intraventricularly colchicine (50μg/rat). 18-20 hr later rats were perfused with Zamboni's fixative, followed by a rinse with 10% sucrose in 0.1M phosphate buffer (pH 7.4). Brains were frozen and 10μm serial sections were processed for dual immunostaining. Sections were initially stained for AR and ER by the ABC method with antipeptide antibodies AR32 and ER715 respectively using DAB. After receptor staining, the sections were immunostained with GRF and SRIF antibodies using 4-chloro-1-naphthol. AR and ER localized in nuclei of neurons of the arcuate, periventricular and ventromedial nucleus where GRF and SRIF cell bodies exist. Nuclear localization of AR was found in the majority of SRIF neurons but not in GRF neurons. However, ER localization was observed in GRF but not in SRIF neurons. These data suggest that estrogen directly affects GRF neurons, while testosterone directly affects SRIF neurons. Since testosterone is converted to estradiol in certain brain regions an indirect effect of testosterone on GRF neurons cannot be ruled out. (Supported by NIH Grant 17479 and T32-HD07201.)

SEXUAL DIMORPHISM OF GALANIN GENE EXPRESSION IN GROWTH HORMONE-RELEASING HORMONE NEURONS. H.A. Delemarre-van de Waal, K.A. Burton, E.B. Kabigting, R.A. Steiner, and D.K. Clifton*, Ob/Gyn & Physiol/Biophys, U. Wash., Seattle, WA 98195 and Pediatrics, Free U. Hosp., Amsterdam.

Sexually dimorphic growth hormone (GH) secretion in the rat is likely due, at least in part, to differences in the activity of hypothalamic growth hormone-releasing hormone (GHRH) neurons. Galanin is colocalized in GHRH neurons by immunocytochemistry and stimulates GH secretion when administered exogenously. Based on these observations, we hypothesized that galanin mRNA is coexpressed in GHRH neurons and that this coexpression is sexually dimorphic. To test this hypothesis, we performed double-label *in situ* hybridization on coronal hypothalamic sections obtained from male (n=5) and female (n=5) rats. GHRH mRNA was hybridized with a cRNA probe labeled with digoxigenin-UTP, and galanin mRNA was hybridized with a cRNA probe labeled with ^{35}S-UTP. GHRH mRNA-positive cells were visualized by an alkaline phosphatase color reaction. Galanin mRNA levels were measured by counting autoradiographic grains over individual GHRH mRNA-positive cells with a computerized image analysis system. We confirmed that GHRH neurons in both male and female rats coexpress galanin mRNA. In addition, we observed a pronounced sexual dimorphism in levels of galanin mRNA in GHRH neurons, with males exhibiting values ~60% greater than females. This sex difference was statistically significant in GHRH neurons of the arcuate ($p<0.02$) and periarcuate ($p<0.001$) nuclei and tended toward significance in the ventromedial hypothalamic nucleus ($p<0.07$). However, in neither sex did GHRH neurons in the paraventricular nucleus express detectable levels of galanin mRNA. We conclude that galanin gene expression by GHRH neurons is sexually dimorphic, and we infer that differential secretion of galanin by GHRH neurons helps to orchestrate the different patterns of the GH secretion between male and female rats.

THE EXPRESSION OF GALANIN IN LHRH NEURONS IS INHIBITED IN PREGNANT AND LACTATING RATS. I. Merchenthaler* Functional Morphology Section, LMIN, NIEHS, NIH, Research Triangle Park, NC 277709.

Galanin (GAL) coexists with LHRH in a subset of preoptic neurons and functions as a potent LHRH secretagogue. The incidence of colocalization is estrogen-dependent, i.e., the number of cells containing both LHRH and GAL is four-times higher in female than in male rats. In the present studies, a very low incidence of colocalization is reported in pregnant and lactating rats. Cycling female, pregnant and lactating female rats were treated with colchicine. One day later, their brains were perfusion-fixed and 30 μm sections were prepared with a vibratome. Sections were immunostained for GAL using anti-rat GAL serum and the ABC technique. The presence of fusiform, GAL-immunoreactive, "LHRH-like" neurons, was used as indication for colocalization of the two peptides. While in cycling female rats 75% of the LHRH cells contained GAL, in pregnant or lactating rats, the incidence of colocalization was almost undetectable.

Progesterone has been shown to blunt the effect of estrogen at the level of the brain and pituitary. The high levels of progesterone present in both pregnant and lactating animals may be responsible for abolishing estradiol-induced increase in GAL gene expression within LHRH-containing neurons. In addition, prolactin levels are also high in both animal models; therefore, a role of prolactin in this phenomenon cannot be ruled out. Among other mechanisms, the high levels of progesterone and/or PRL, may also prevent ovulation during pregnancy and lactation by inhibiting estradiol-induced GAL gene expression. Therefore, progesterone and/or prolactin could be responsible for the low incidence of GAL/LHRH colocalization during pregnancy and lactation.

Estrogen Induction of Galanin and Immediate Early Gene Expression in the Rat Anterior Pituitary Gland. T. Csikos, J.K. McDonald+, and J.I. Koenig*. Dept. of Physiology, Georgetown Univ. Sch. Med., Washington, D.C. 20007, +Dept. of Anatomy & Cell Biology, Emory Univ. Sch. Med., Atlanta, GA 30322.

Estrogen (E) induces galanin gene expression in the rat anterior pituitary gland (rAP) by unresolved mechanisms. A solution hybridization/RNase protection assay was developed to simultaneously quantify multiple mRNA species in total cellular RNA samples. Time- and dose-dependent effects of E on the expression of *c-fos*, *c-jun*, two immediate early genes, and galanin were studied in the rAP *in vivo*. Ovariectomized rats received E implants and were sacrificed 12, 24, 48 and 72 hrs later or 72 hrs after receiving implants containing increasing doses of E. rAP RNA was isolated and 10μg was incubated with antisense ^{32}P-labeled cRNA probes for *c-fos*, *c-jun* and galanin. Protected fragments were produced by S1 nuclease digestion followed by denaturing polyacrylamide gel electrophoresis. Fragments were visualized by autoradiography and quantified by densitometry or liquid scintillation counting. Standard curves were prepared for each probe by synthesizing sense strand cRNAs. E-induced galanin gene expression as early as 12 hrs after capsule implantation which increased 500 fold by 72 hrs. *c-fos* expression parallels galanin expression but is induced only 50-fold. However, *c-jun* expression is only weakly induced by E. While both galanin and *c-jun* expression are positively correlated with E dose, prolonged exposure to high doses of E appears to depress *c-fos* expression. These results suggest that E induced the transient expression of the *c-fos* gene in the rAP. Since an AP-1 site is present in the upstream region of the galanin gene, *c-fos* may participate in regulating galanin expression. The expression of *c-jun* is only weakly induced by E, these findings are consistent with a role for AP-1 in E-induced changes in rAP gene expression.

PREGNENOLONE SYNTHESIS IN RAT BRAIN: REGULATION BY MITOCHONDRIAL DBI RECEPTOR (MDR) AGONISTS. A. Korneyev*, B.S. Pan, A. Guidotti, E. Costa. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, DC 20007, USA

Evidence that neurosteroids are potent modulators of the action of GABA at $GABA_A$ receptors has prompted the investigation of the mechanisms that control brain glial mitochondrial steroidogenesis. A crucial step in this regulation is the interaction of DBI - a polypeptide abundant in steroidogenic cells - with the glial MDRs (P.N.A.S., in press). MDRs recognize with high affinity 4'-chlorodiazepam (4'-Cl-DZ) - a full agonist - FGIN-1-27 [N-N-di-n-hexyl-2-(4-fluorophenyl)indol-3-acetamide)] - a new highly specific and potent agonist - and the isoquinoline carboxamide PK 11195 - a partial agonist. To test *in vivo* whether stimulation of MDRs by 4'Cl-DZ and FGIN-1-27 increases pregnenolone (P) production, we determined by HPLC-RIA the P content in brain of male rats acutely adrenalectomized/castrated (A/C) (to eliminate peripheral sources of P) and pretreated with 200 mg/kg i.p. of trilostane (an inhibitor of P metabolism). The P content in microwaved brains of A/C rats (4-8 ng/g) was slightly increased by pretreatment with trilostane, reflecting a low P synthesis rate in these animals. ACTH (5 IU/kg) and electroconvulsive shock did not affect the brain P content. The content of P, but not that of 17-α-hydroxypregnenolone and dehydroepiandrosterone, in frontal cortex and cerebellum increased after treatment with 4'Cl-DZ and FGIN-1-27. The action of both drugs on P brain content was dose and time dependent. The effect of 4'-Cl-DZ was maximal (70-150% increase) with 15-20 μmol/kg, 5 to 10 min after the i.v. injection. The effect of oral administration of FGIN-1-27 was maximal (200 to 300% increase) with 400-800 μmol/kg and peaked at approximately 1 hr. To prove a direct involvement of MDRs in the action of FGIN-1-27, animals were pretreated with the partial agonist PK 11195 (100 μmol/kg i.p.). PK 11195 did not modify the P brain content, but prevented the accumulation of P induced by FGIN-1-27. The data suggest that MDRs, presumably located in glial cells, play a role in *in vivo* pregnenolone biosynthesis.

DIAZEPAM BINDING INHIBITOR (DBI) AND MITOCHONDRIAL DBI RECEPTOR (MDR) IN ACTH INDUCED STEROIDOGENESIS. S. Cavallaro, A. Korneyev, K. E. Krueger*, E. Costa, and A. Guidotti. Fidia-Georgetown Institute for the Neuroscience, Georgetown University School of Medicine, Washington DC, 20007 USA

The MDR (previously known as peripheral-benzodiazepine receptor) is a binding site located on the outer mitochondrial membrane, which is highly enriched in steroidogenic cells such as adrenocortical, Leydig and glial cells. In these cells MDR stimulation has been shown to facilitate the intramitochondrial cholesterol transfer, a rate-limiting step in steroid biosynthesis. The stimulation of this receptor in hypophysectomized rats, by the administration of Ro5-4864 (15 μmoles/kg, iv), a selective MDR ligand, increased adrenal steroid biosynthesis. Seven minutes after the injection, the levels of corticosterone were maximally increased in adrenal (400%) as well as in plasma (300%). This effect was preceded by the increase in adrenal pregnenolone content (140%), when this was measured in the presence of trilostane (200 mg/kg, ip), an inhibitor of pregnenolone metabolism. In vivo, MDR activation by DBI, its putative endogenous peptide ligand, might mediate the action of ACTH in adrenal steroidogenesis. To investigate the mechanisms whereby DBI and MDR may accomplish this effect, hypophysectomized rats were treated with ACTH-R (ACTH in saline containing 16% gelatin; 15 U/kg, sc), which causes a long-term increase of adrenal DBI and MDR expression. Hours after ACTH-R administration the increase in DBI- and MDR-mRNA levels leads to an increase in their translation products. In addition to this, ACTH has a short-term effect on the rate of DBI-processing. Thirty minutes after the administration of ACTH (50 mU/kg, iv) in hypophysectomized rats, the immunoreactivity for DBI 17-50 (TTN) was increased more than three fold. Our results coupled to the demonstration that TTN is a DBI-processing product highly active in stimulating steroidogenesis, are consistent with the view that acute ACTH steroidogenesis may be mediated by TTN or other DBI-processing products with an high intrinsic efficacy on MDR induced steroidogenesis.

ENDONUCLEASE ACTIVATION IN BRAIN INJURY OF RAT. T. Tominaga*, S. Kure and T. Yoshimoto. Div. of Neurosurgery, Inst. of Brain Diseases and Dept. of Biochem. Genetics, Tohoku Univ. Sch. of Med., Sendai, Japan 980

The main purpose of this study was to clarify the temporal profile of DNA degradation, especially DNA fragmentation, during the process of brain injury. Additionally, endonuclease activity responsible for DNA breakdown was investigated using nuclear protein fraction.

Adult male Wistar rats were used. Focal cerebral ischemia and freeze-injury were produced by the tandem occlusion of common carotid and proximal middle cerebral arteries, and the application of precooled metal probe to dorsal cortex, respectively, under halothane anesthesia. The DNA was extracted from the lesioned cortex and/or caudoputamen and electrophoresed on a agarose gel. Typical DNA fragmentation into oligonucleosomal sizes was found in the ischemic caudoputamen and the freeze-injured cortex, which amount reached maximum around 24 hours after the insults. Coexisting random degradation and specific fragmentation of DNA was observed in the cortex suffered from focal ischemia. To determine whether an endonuclease responsible for DNA fragmentation was present in the brain nuclei, nuclear proteins were extracted from normal brain nuclei and incubated with plasmid DNA or normal brain nuclei under various conditions. This demonstrated that brain nuclear proteins have Ca-dependent endonuclease activity which is related to DNA fragmentation. Moreover, the "gel assay" of endonucleases indicated the NUC1.8, which causes DNA fragmentation in lymphocyte, are also present in brain nuclei.

DNA fragmentation is not unique to programmed cell death and can occur as a result of brain injury, probably through the activation of Ca-dependent endonuclease.

NBQX PROTECTS RATS AGAINST TRAUMATIC BRAIN INJURY.
H. Bernert, P.-A. Löschmann and L. Turski*. Research Labs of Schering AG, Berlin, Germany.

Effect of the competitive AMPA (o-amino-3-hydroxy-5-methyl-4-isoxazolepropionate) antagonist NBQX (6-nitro-7-sulphamoyl-benzo[f]quinoxaline-2,3-dione) was studied in a model of traumatic brain injury in rats. A stainless-steel circular footplate, diameter 4.5 mm, was positioned stereotaxically over the hindpaw area of the motor and somatosensory cortex of male Fisher 344 rats weighing 220-250 g. The footplate rested on the surface of the dura. The craniotomy was slightly larger than the diameter of the footplate to prevent brain contusion from herniating. The stainless-steel tube, 40 cm in length, guided a falling weight onto the footplate. A force of 0.04 N produced by a 20 g weight was selected for induction of injury in rats anesthetized with 260 mg/kg of tribromethanol (i.p.). The maximal depression of the brain surface was 2.5 mm. NBQX, 30 mg/kg i.p., was administered 1, 2 and 3 h after traumatic injury. Three days after traumatic injury, the rats were sacrificed by transaortic perfusion-fixation and the brains were serially sectioned and prepared for light microscopy. Morphological analysis of the brains from 20 vehicle-treated rats (cresyl violet stained sections) showed consistent damage in the neocortex, hippocampal subfields CA3 and CA4 and less frequently in the thalamus on the side of traumatic injury. Treatment of animals with NBQX (n = 20) led to the reduction of the volume of cortical lesion and a protection against hippocampal damage. These observations suggest that AMPA antagonists may be of benefit for the treatment of acute head injury.

457.3

RECOVERY OF METABOLISM IN THE LATERAL GENICULATE NUCLEUS AND SUPERIOR COLLICULUS FOLLOWING EXPERIMENTAL OPTIC NERVE INJURY. K.D. Steinsapir, D.L. Wirta, D.A. Hovda*, and R.A. Goldberg. Jules Stein Eye Inst., Div. Neurosurg., UCLA Sch. Med., Los Angeles, CA 90024

The effect of traumatic injury to the optic nerve on glucose metabolism within the lateral geniculate nucleus (LGN) and the superior colliculus (SC) was studied in male Sprague-Dawley rats (N=52, wt=250-300g). Injury to the optic nerve was performed under general anesthesia [33% O_2, 66% N_2O, enflurane (1.5-2.0 ml/,in)] by the surgical application of an aneurysm clip for 1, 5, 30 or 60 seconds. Local cerebral glucose utilization (lCMRglc, μmol/100g/min) was calculated using [^{14}C]2-deoxy-D-glucose (2DG) autoradiography at various times following injury. During the 2DG experiment animals were subjected to either ambient light or xenon arc strobe stimulation. Histological examination of the injured nerve indicated that as the duration of crush increase so to did the extent of morphological damage. In stimulated animals, lCMRglc in the LGN and the SC serving the injured optic nerve exhibited a pronounced and permanent (21 days) depression compared to the contralateral homologous structures; 51.0±17.4 vs 81.9±23.43 ($p<0.01$) and 58.0±12.19 vs 83.2±18.73 ($p<0.01$) in the LGN and SC respectively. However, in nonstimulated animals, particularly those sustaining the 1 sec injury, the lCMRglc depression was restricted to the SC. This metabolic depression spontaneously alleviated within 3 days with animals who sustained the most severe (60 sec) injury showed recovery by 10 days. Finally in 3 animals who had received methylprednisolone (30 mg/kg, i.p.) given every 6 hrs beginning 45 min prior to the insult, the recovery rate from metabolic depression was accelerated. These results suggest; (1) a difference in physiological response between the LGN and SC to optic nerve injury, (2) a role for methylprednisolone in the treatment of optic nerve trauma. (NS30308)

Perineuriotomy - A New Approach in Injection Neuropathies. J. Terzis*, T. Rath, H. Millesi. Microsurgical Res. Ctr, Eastern VA Med. School, Norfolk, VA 23501.

Intrafascicular fibrosis may be produced by intraneural injection of an agent. It is a rational assumption that release of the entrapping perineurium might improve nerve function. Purpose: 1) Establish an experimental model of injection neuropathies; 2) test the effect of toxicity of three agents, 0.9% saline, 0.125% marcaine + 1/400 000 epinephrine and 5% phenol; 3) evaluate the effect of epineuriotomy. Methods: Right tibial nerve of the guinea pig (200-300g) is used as the experimental model (N=60). Intraneural injection of three agents is performed by a micropipet and a micromanipulator to guarantee reproducibility. 60 guinea pigs are divided into 4 groups of 15 animals/5 per agent). Grp I: injection only, without treatment; Grp II: injection plus immediate perineuriotomy; Grp III: injection plus perineuriotomy after 1 week; Grp IV: injection plus perineuriotomy after 3 weeks. 32 days after injection, assessment is performed. Assessment parameters: 1) Gait analysis - A sciatic functional index, adapted to the gait patterns and foot prints of the guinea pig is used. 2) Electrophysiology - Compound action potentials are measured. 3) Histology - cross sectional biopsies are evaluated by light microscopy and electronmicroscopy to assess axonal re- and degeneration, myelin changes, response of the perineurium to the injection injury, intrafascicular scar formation. 4) Quantitative morphometry. Results: Preliminary data show that injection of 0.9% saline alone causes proliferation of the perineurium and endoneurial scar formation. These changes are far more pronounced after injection of a toxic agent. Phenol produces extensive pathologic changes which include severe epi- and perineurial proliferation, axonal degeneration and endoneurial scar formation. Injection of marcaine and epinephrine produces pathologic changes that range in between saline and phenol injected nerves. Conclusions: Preliminary data show possible beneficial effect of delayed perineuriotomy in nerves injected by a toxic agent.

HYPEREMIC RESPONSE TO PERCUSSIVE TRAUMA IN IMMATURE, MATURE, AND AGED RATS. K. V. Biagas, P. D. Grundl, J. K. Schiding, and P. M. Kochanek*. Depts. of Anes./Critical Care, Pediatrics, and the Head Injury Research Center, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Clinical studies suggest that the cerebrovascular response to head trauma differs with age. Specifically, increased cerebral blood flow, or hyperemia, commonly found in children is less often seen in older adults after head injury. We hypothesize that reproducible posttraumatic hyperemia can be demonstrated in an animal model and that the extent of hyperemic response differs with age.

Wistar rats, sexually immature (3.5-4.5 wks, N=18), mature (9-15 wks, N=18), and aged (12.5-14 mo, N=8) were anesthetized and ventilated. Injury to the exposed right parietal cortex was produced by weight drop indexed to brain weight. Regional cerebral blood flow (rCBF) was determined by ^{14}C iodoantipyrine autoradiography in age-matched normal controls and in rats injured 24 h before. Percent of normal control rCBF was determined for 15 structures. Within group comparisons to controls were made by t-test.

At 24 h posttrauma, low rCBF was found in all groups in the zone of impact (20% of normal control in immatures, 5% in matures, and 11% in aged rats, all $p<0.05$ vs. respective normal controls). Hyperemia in the peri-trauma parietal cortex was greatest in immatures (270% of normal control, $p<0.05$), less in matures (165%, $p<0.05$), and not found in aged rats (106%, NS). Increased rCBF was found in structures distant to the trauma in all age groups (146 to 188% of normal control in immatures, 66 to 160% in matures, and 157 to 228% in aged).

These results demonstrate enhanced peri-trauma hyperemic response 24 h after brain injury in the immature. However, increased rCBF was found in distant structures in all ages suggesting that the diffuse posttraumatic hyperemic response is not age-dependent in this model.

457.6

FUNCTIONAL ANALYSIS OF EMBRYONIC NEOCORTEX GRAFTING AFTER GRADED SEVERE HEAD INJURY. O. Kopyov, D.B. Jacques,* R.W. Rand. The Neurosciences Institute, The Hospital of the Good Samaritan, Los Angeles, CA. 90017.

Adult male Wistar rats were subjected to a blow of measured intensity to the parietal area of the skull resulting in severe trauma. The majority of these animals (86%) died within 4-5 days. Some rats received embryonic neocortical grafts and debridement into the lesioned areas immediately after the trauma. This resulted in decreasing the post traumatic mortality to 4%. These animals showed a rapid restoration of their behavioral activities as demonstrated by the open field method. Food and water intake and motor activity returned to normal on the second post-trauma day. Debridement with no grafts reduced the post-traumatic death rate to 30%. Animals of this group showed reduced activity and food ingestion during the first post-trauma week. Histologic investigation three months after trauma and grafting revealed the presence of viable grafts in all hosts. The grafts were relatively well integrated with the host brain. No obvious signs of pathology were observed at the traumatized site of the brain in animals with grafts. The most important results of embryonic neocortex transplantation after severe head injury were mortality reduction, potent stimulation of post-traumatic brain tissue defect repair and the prevention of adhesive processes.

457.7

MIDDLE LATENCY AUDITORY EVOKED POTENTIALS FOR EVALUATION OF WAKEFULNESS. S. Yamada*, W. Hayward, L. Dayes, V. Morgese, B. Curtis, and R. Iacono. Division of Neurosurgery, Loma Linda University School of Medicine, Loma Linda, CA 92350.

The medial geniculate body is known to transform tonotopic impulses from brain stem to the hemispheric cognitive function. The authors studied the middle latency (MLAP) and brain stem auditory evoked potentials (BAR) at 3-day intervals in 100 patients who sustained head injuries and remained unconscious for certain periods. The results are: 1) Loss and no recovery of BAR wave 5 and MLAP indicates no return of consciousness (always Glascow Coma Scale 3 or 4); 2) Bilateral recovery of BAR and MLAP correlates with regaining consciousness including communicative capacity; 3) Unilateral recovery of the MLAP correlates with return of wakefulness but inadequate communicative capacity; 4) Normal BAR with loss of MLAP followed by its complete recovery correlates with rapid return of normal consciousness from continuous sleep.

The authors emphasize the importance of MLAP for evaluation and prognostication of wakefulness after head injury.

TIME COURSE OF TRAUMATICALLY INDUCED BLOOD-BRAIN BARRIER ALTERATION: A QUANTITATIVE AND ANATOMICALLY SPECIFIC ANALYSES. M. Kasapi, M.L. Giebel and J.T. Povlishock*. Dept. of Anatomy, Med. Col. of VA., VA. Com. Univ., Richmond, VA 23298.

To date, considerable interest has focused on the occurrence of traumatically induced blood-brain barrier (BBB) disruption, its temporal course and its possible impact upon outcome. Progress, however, has been hampered by inter-animal variability and by the difficulties associated with conducting, in the same animal, detailed quantitative and temporarily/anatomically specific assessments of BBB change. To address these issues, we developed new strategies using I^{125} labeled albumin, followed by the LM and TEM immunocytochemical visualization of this labeled substance. Anesthesized rats were subjected to moderate fluid-percussion brain injury. One-24 hr postinjury, I^{125} labeled human serum albumin was injected, followed 2 hr later by aldehyde perfusion. The brain was blocked into select foci, which were counted using a gamma counter. These regions were sectioned, and reacted for the immunocytochemical visualization of endogenous albumin as well as the exogenously administered albumin. In this fashion information was provided on both the initial as well as delayed altered BBB permeability to albumin. Moderate brain injury was observed to open the BBB within the dorsal neocortex and related hippocampi. Unexpectedly, the traumatically induced BBB change showed progression becoming maximal by 6 hr postinjury, with a diminution of albumin permeability and BBB closure by 24 hr. The permeability change seen immediately following injury was related to discrete petechial hemorrhage and foci of altered endothelial integrity. However, with increasing survival [3-6 hr], it appeared that WBC recruitment participated in the cleaving of interendothelial tight junctions resulting in increased permeability. These results suggest that BBB change postinjury is an evolving event, with multiple factors involved in its evolution. Supported by R01 NS29469.

CORRELATION OF NEUROFILAMENT IMMUNOHISTOCHEMISTRY WITH SILVER STAINING OF DAMAGED AXONS FOLLOWING HEAD INJURY IN HUMANS, SUB-HUMAN PRIMATES, AND RODENTS D.T. Ross*, D.I. Graham, J.H. Adams, and T.A. Gennarelli Head Injury Center, Div. of Neurosurgery, Univ. of Pennsylvania, Philadelphia, PA 19104, and Dept. of Neuropathology, Southern General Hospital, Glasgow, Scotland

Diffuse axonal injury in cases of severe head injury is defined by the presence of swollen axonal segments and axonal bulbs, classically visualized in reduced silver preparations. The present study sought to establish to what extent neurofilament immunohistochemistry correlated with reduced silver staining of damaged axons in the brains of fatal human head injury cases, sub-human primates subjected to experimental inertial head injury, and rats which received directed forebrain tensile strain injury.

SMI-31, a mouse monoclonal antibody (mAB) to *phosphorylated* epitopes on heavy and medium neurofilament subunits, labels axons in the corpus callosum, subcortical white matter and fascicles of axons radiating into the cortical gray matter in normal brains. Following head injury in man, baboons, and rats SMI-31 labeled large axonal bulbs in the corpus callosum, subcortical white matter, and deep cortical layers. The density of labeling of these axonal bulbs was virtually identical to that seen in adjacent sections stained with the Palmgren's reduced silver technique. Perikarya of damaged neocortical pyramidal cells in layers III and V were also positively labeled with SMI 31. SMI 32, a mAB to *non-phosphorylated* epitopes on heavy and medium neurofilament subunits, selectively labels neurons in layers III and V of normal human, baboon, and rat neocortex. Following head injury SMI-32 labeled small and medium sized retraction balls but most striking were the numerous axons characterized by labeled normal segments continuous with hypertrophied axonal segments disrupted by patches of granular labeling, suggestive of focal neurofilament proteolysis. SMI-31 and 32 are excellent markers of axonal injury which not only selectively label features of axonal pathology but also identify the perikarya of damaged axons and may also shed light on the cellular mechanisms of axonal pathology following head injury. ELECTRON MICROSCOPIC IMMUNOCYTOCHEMICAL STUDY OF DIFFUSE AXONAL INJURY IN MAN. C.W. Christman, *[1] M.S. Grady,[2] J.T. Povlishock,[1] Dept. of Anatomy, Med. Col. of Virginia, Virginia Commonwealth Univ.[1] Richmond, VA 23298, and Dept. of Neurosurgery, Univ. of Washington[2]

Axonal injury is commonly observed in human traumatic brain injury, but its pathogenesis has remained controversial due in part to limitations associated with the use of traditional histological methods. Recently, in animals we have shown the utility of monoclonal antibodies to neurofilament subunits, particularly the 68 kD subunit, in detecting damaged axons (Yaghmai and Povlishock, 1992). In the present study, postmortem analysis was performed on ten human cases at various intervals of postinjury. The monoclonal antibody to the 68 kD subunit was used to identify sites of traumatically induced axonal change, which were analyzed at both the light microscopic and electron microscopic levels. This approach revealed at 6 h postinjury axons exhibiting focal swellings. Immunoreactivity was associated with neurofilaments, some of which exhibited clumping and misalignment. Localized infolding of the axolemma was also evident. By 12 h postinjury the continued expansion of sites of focal swelling had progressed in some cases to axonal disconnection. Neurofilaments associated with marked immunoreactivity were now more disordered and vacuolization was observed. At 30 h immunoreactive disconnected reactive swellings displayed convoluted arrays of neurofilaments, partially surrounded by a cap-like zone of electron-lucent organelles. In advanced stages of survival heterogeneity was evident. These findings reveal that, in head-injured man, axonal disconnection is the result of subtle cytoskeletal change that occurs over a period of time. Actual structural/functional factors underlying this reactive cytoskeletal change are unknown, but the observed increase in the 68 kD subunit reactivity appears compatible with some local change in phosphorylation state.

SOURCES AND MECHANISMS OF $[Ca^{2+}]_i$ TRANSIENTS IN MYELINATING SCHWANN CELLS IN RESPONSE TO AXONAL ACTIVATION. V. Lev-Ram*[1], R. Y. Tsien[1&2], J. A. Airey[4], J. L. Sutko[4], and M. H. Ellisman[3] [1]Dept. of Pharmacology and [2]HHMI, [3]San Diego Microscopy and Imaging Resource, Dept. of Neurosciences, University of California San Diego, La Jolla, CA 92093; [4]Dept. of Pharmacology, Univ. of NV, Reno, NV 89557.

In order to better understand the roles of paranodal glia in the regulation of the ionic milieu, we have developed a system for *in vitro* studies, combining optical and electrophysiological recording methods. Such a methodology provides a unique facility to test hypotheses regarding the function of cell compartments at the node of Ranvier. We recorded single fiber physiological properties, conventionally and with fluorescent ion-sensitive dyes (fluo-3 or indo-1, both loaded as their AM-esters), and simultaneously observed single nodes at high optical resolution using Nomarski differential interference contrast optics (DIC) with time-lapse recording. Ratio imaging of frog sciatic nerve fibers loaded with indo-1 showed low $[Ca^{2+}]_i$ in myelinating Schwann cells which increased in response to axonal activation. To elucidate sources of $[Ca^{2+}]_i$, we tested the effects of drugs known to alter $[Ca^{2+}]_i$. Using fluo-3, $[Ca^{2+}]_i$-transients in Schwann cells were observed in response to axonal activation and were subsequently blocked by ryanodine if ryanodine was present during the first $[Ca^{2+}]_i$ transient. Short repetitive bath applications of caffeine induced $[Ca^{2+}]_i$ transients which could be blocked by ryanodine. Immunolocalization studies demonstrated the presence of ryanodine receptor-like immunoreactivity in Schwann cell paranodal loops supporting the physiological data regarding the presence of Ca^{2+}-activated Ca^{2+}-release channels. In contrast to caffeine, only small $[Ca^{2+}]_i$ transients were observed in response to application of thapsigargin. These findings indicate Ca^{2+}-activated Ca^{2+}-release in Schwann cells in response to impulse activity suggesting an active role for myelinating glial cells during axonal firing.

458.2

AXONAL REGULATION OF C-JUN EXPRESSION IN SCHWANN CELLS IN VIVO. M.E.Shy[1], L.Wrabetz[2], M.L. Feltri[1], J. Kamholz[2]*, S.S. Scherer[2]. Depts. of Neurology, Thomas Jefferson Univ.[1] and Univ. Penn[2].

The nuclear proto-oncogene c-*jun* is an "immediate early" gene in that its expression is rapidly altered in a variety of conditions both *in vivo* and *in vitro*. Monuki et al. (Neuron 3: 783-790, 1989) have shown that Schwann cells (SC) *in vitro* express high levels of c-*jun* mRNA, which is rapidly down-regulated by the addition of forskolin, which increases intracellular cAMP and is widely used as an *in vitro* mimic of axonal contact. The down-regulation of c-*jun* preceeds the up-regulation of SCIP mRNA, which in turn preceeds the up-regulation of the mRNAs of the myelin genes. We have examined the expression of c-*jun* in adult rat sciatic nerves that have been permanently transected (to cause Wallerian degeneration and prevent axonal regeneration) or crushed (to cause Wallerian degeneration but allow axonal regeneration) to examine whether axons regulate c-*jun* expression in SC *in vivo*. In unlesioned adult nerves, there was a low level of c-*jun* mRNA, and few if any SC nuclei were stained with antibodies against *jun*. After nerve-transection, the steady state level of c-*jun* mRNA increased dramatically between 1 and 24 days, and many SC nuclei were stained with the *jun* antibody. After nerve-crush, the steady state level of c-*jun* increased dramatically between 1 and 12 days, then decreased between 12 and 24 days post-crush as axons regenerated into the distal nerve-stump. Thus, the pattern of c-*jun* mRNA expression was remarkably similar to that of nerve growth factor receptor (NGFR) mRNA in both transected and crushed nerves, and indicates that axonal-SC interactions influence the expression of c-*jun*.

BETA-GALACTOSIDASE EXPRESSION IN OLIGODENDROCYTES IN TRANSGENIC MICE. P.A. Wight, C.S. Duchala, C. Readhead[1], W.B.Macklin*. M.R.R.C., UCLA Med. Ctr., Los Angeles CA 90024;[1] Calif. Inst. of Tech., Pasadena, CA 91125

Three transgenic lines were generated using the myelin proteolipid protein (PLP) gene. The transgene [PLP(+)Z] contained 2.4 kb of 5'-flanking DNA, exon 1, intron 1 (approx. 8 kb) and 37 bases of exon 2, fused to the lacZ gene. All three lines expressed beta-galactosidase in white matter areas, and when analyzed at the electron microscopic level, the enzyme was seen in the myelin sheath itself. Transgene expression was studied in pups at 2,5,7,9,12,15,18,21 and 25 days of age, and it was developmentally coordinated with myelination. Very young oligodendrocytes were stained, confirming our earlier studies indicating that the PLP gene is expressed quite early in oligodendrocyte differentiation. The transgene was also expressed in young oligodendrocytes in culture. Bipolar cells, presumably immature oligodendrocytes, expressed the transgene within five days of plating, and the transgene continued to be expressed in highly differentiated cells in culture. These studies demonstrate that the PLP(+)Z construct can be used to target DNA for expression in developing and mature oligodendrocytes. Because PLP(+)Z oligodendrocytes carry an unique, endogenous stainable marker, they should be useful in oligodendrocyte transplantation studies. Support: Natl. Mult. Scler. Soc. and NS08774.

CONTACT WITH MYELIN CAUSES A RELEASE OF CALCIUM FROM INTERNAL STORES IN OLIGODENDROCYTES. S.J. Moorman* and R.I. Hume. Dept. of Biology, University of Michigan, Ann Arbor, MI 48109.

We are interested in whether interactions between adjacent oligodendrocytes play a role in the process of myelination. As an initial approach, we determined the reaction of neonatal-rat oligodendrocytes in culture to an application of crude myelin extract. Myelin extracts were made from either adult rat spinal cord (CNS myelin) or adult rat ischiatic nerve (PNS myelin). Oligodendrocytes were identified based on their characteristic morphology; some cells with this morphology were confirmed as oligodendrocytes by staining with an antibody to galactocerebroside. We monitored morphology of the leading edge of oligodendrocyte processes using time-lapse video-microscopy, and monitored internal free calcium concentration ([Ca]i) using FURA-2. Time-lapse experiments were done at 37° in the normal medium. FURA-2 experiments were done at room temperature in the normal medium. Contact with either CNS myelin or PNS myelin resulted in collapse and retraction of the leading edge of oligodendrocytes. Because collapse of the neuronal growth cone has been associated with increases in [Ca]i, we tested whether collapse of the oligodendrocyte leading edge was associated with changes in [Ca]i. Oligodendrocytes had an average resting [Ca]i of 71(+-2)nM. Contact with CNS myelin caused a relatively rapid [Ca]i increase. The average maximum [Ca]i level reached after contact with CNS myelin was 431(+-27)nM. The [Ca]i increase was reduced but not blocked by 5mM EGTA. This result supports the idea that at least part of the [Ca]i increase was due to a release of calcium from internal stores. A similar [Ca]i increase was induced by contact with PNS myelin. These results suggest that oligodendrocytes might be able to recognize and react to specific molecules on the surface of other oligodendrocytes. This type of cell-cell interaction might play a role in preventing overlap of processes of adjacent oligodendrocytes at the developing Node of Ranvier. ELEVATED EXTRACELLULAR K^+ AND TUMOR NECROSIS FACTOR DECREASE THE PHOSPHORYLATION OF OLIGODENDROGLIAL PROTEINS. B. Soliven*, M. Takeda, D.J. Nelson and S. Szuchet. Dept. of Neurology, The University of Chicago, Chicago, IL 60637.

Extracellular K^+ regulates glial metabolism. We examined the effect of high K_o on phosphorylation of myelin basic protein (MBP) and 2', 3'-cyclic nucleotide phosphodiesterase (CNPase) in pure cultures of adult oligodendrocytes (OLGs). These proteins were chosen because we have previously shown that their phosphorylation is linked to myelinogenesis. OLGs (7-14 days old) were labelled with ^{32}P for 1 hr in the presence of 5.4 mM K^+ or 24 mM K^+. We found that exposure of OLGs to 24 mM K^+ (n=5) for 1 hr decreased the phosphorylation of MBP by 57 ± 3.9% and CNPase by 64.2 ± 3.7% compared to control OLGs (N=6, $p < 0.01$). Inhibition of the inward rectifier K^+ channels with 1 mM Ba^{2+} gave no consistent results (n=3). One hr exposure of OLGs to 1 nM recombinant human tumor necrosis factor (rhTNFα) (n=4) mimicked the effect of high K_o on MBP and CNPase phosphorylation. Whether or not the effect of rhTNFα is related to its ability to cause membrane depolarization and to decrease OLG K^+ current amplitudes (Soliven *et al.*, J. Memb. Biol. 124: 127-137, 1991) or is due to a separate mechanism is under investigation. The effects of high K^+ and rhTNFα can be counteracted by activators of protein kinase C (PKC) such as phorbol 12-myristate 13-acetate. Neither high K^+ nor rhTNF-α had any significant effect on MBP or CNPase synthesis. We postulate that PKC may be implicated in the inhibition of MBP and CNPase phosphorylation by high K_o and TNF. These observations differ from those reported in optic nerves (Murray & Steck, J. Neurochem. 41: 543-548, 1983), suggesting that additional factors activated by high K^+ in intact nerves modulate MBP phosphorylation. Supported by grants NIH PO1 NS24575 & MS Soc. RG-2195-A-2.

PHAGOCYTOSIS AND PROCESSING OF MYELIN BASIC PROTEIN. J. McLaurin, K. Williams, H.D. Durham*, and J.P. Antel, Dept. of Neurology and Neurosurgery, Montreal, P.Q. H3G 2B4.

The role of phagocytic cells may be key in understanding the mechanisms involved in immune-mediated demyelination in the central nervous system. It has been hypothesized that myelin basic protein (MBP) may be the antigen most likely to be processed and presented by MHC class II molecules to elicit an immune mediated response. Although MBP has been used extensively in vitro and in vivo, the mechanism of phagocytosis and processing has not been examined. We have used a human EBV transformed B cell line, a human histiocytic lymphoma cell line, U937, and human microglia to investigate the phagocytosis of MBP. To be able to follow MBP ingestion, MBP was either radiolabelled by reductive methylation or conjugated with FITC then monitored by fluorescence and confocal microscopy. Activated EBV-B cells were shown to be the most efficient at phagocytosis of MBP as demonstrated by both ^{14}C-MBP and FITC-MBP uptake. U937 and microglia were shown to ingest MBP albeit at slower rates. All three cell types failed to ingest MBP when incubated at 4°C, a characteristic of phagocytosis rather than pinocytosis. The rate and extent of MBP phagocytosis was markedly lower than that of celite beads and bovine serum albumin. The processing of MBP is associated with the endosomal fraction of U937 after 2 hours and EBV-B cells after 8 hours. This is consistent with processing for binding to MHC class II molecules.

EVIDENCE FOR SUBTYPES OF THE PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR IN CULTURED ASTROCYTES. M.D.Norenberg* and Y.Itzhak, Vet Admin Med Ctr, & Dept of Biochemistry & Molecular Biology, Univ of Miami, Miami, Florida 33135.

Two types of benzodiazepine (BZD) receptors have been identified in brain: central (C) and peripheral (P). The present study was undertaken to characterize the PBZD receptors in cultured astrocytes from neonatal rat cerebral cortex. In homogenate cell preparations, the selective PBZD ligands, [^{3}H]PK 11195 and [^{3}H]Ro5-4864, labeled high affinity sites (Kd-0.82 and 2.4 nM, respectively) that appear to display only a partial overlap. The maximal number of sites (Bmax) labeled with [^{3}H]Ro5-4864 was only 42% of the number of sites labeled with [^{3}H]PK 11195 (1.8 pmoles/mg protein). Unlabeled Ro5-4864 competed for [^{3}H]PK 11195 binding sites in a biphasic manner, suggesting the existence of PBZD sites that are not readily accessible to Ro5-4864. BZD ligands that bind to both CBZD and PBZD receptors competed for [^{3}H]PK 11195 and [^{3}H]RO5-4864 binding in a monophasic manner, and with similar affinities. These findings suggest that Ro5-4864, but not other BZD ligands tested, distinguishes between putative subtypes of PBZD receptors. Subcellular distribution studies indicated no apparent difference between the localization of [^{3}H]Ro5-4864 and [^{3}H]PK 11195 binding sites. The mitochondrial fraction of astrocytes revealed a major enrichment in the binding of the two PBZD ligands tested. This study suggests the existence of putative subtypes of PBZD receptors in astrocytes, and indicates that their primary localization in these cells are in mitochondria.

REGULATION BY NOREPINEPHRINE OF NITRIC OXIDE SYNTHASE INDUCTION IN GLIA. D.L. Feinstein*, E. Galea, and D.J. Reis Div. of Neurobiol., Dept of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Norepinephrine (NE) inhibits the induction by IFN-γ of class II antigen expression in cultured astrocytes (Frohman et al. *PNAS* 85:1292, 1991). We examined whether NE would also inhibit the LPS-induction of NOS in astrocytes as determined by nitrite accumulation. Primary astrocyte cultures exposed to LPS (500 ng/ml, 24 hr) but not NE (100 μM, 24 hr) increased NOS activity 15-fold over basal levels. However, NE elicited a dose-dependent inhibition of induction by LPS, with a threshold of 1 nM and maximal inhibition of 50-80% at 100 μM. Exposure to NE (100 μM) for 10 min was as effective as 24 hr continuous exposure in decreasing LPS-induction. In contrast, NE did not alter NOS activity pre-induced in astrocytes suggesting that NE inhibition occurs at the levels of transcription not by protein modification. The induction of NOS by LPS was also blocked by the β-adrenergic agonist isoproterenol (10 μM) but not by the α-agonist phenylephrine. The response to NE was partially reversed by the β-antagonist propranolol, but not by the mixed α-antagonist phentolamine. VIP (1 μM), but not NPY (1 μM), could also inhibit the induction due to LPS. These results suggest that induction of glial NOS by LPS can be regulated by catecholamines acting upon astrocyte β-receptors via elevation of cAMP levels. Conceivably the release of neurotransmitter in vivo may modulate the expression of inducible NOS in astrocyte possibly in response to injury or disease.

GROWTH FACTOR REQUIREMENTS FOR CELL CYCLING OF SYNCHRONIZED ASTROGLIA. T.J.Langan* and M.C.Slater, Dept. of Neurology, SUNY Sch. Med., Buffalo NY 14222

Polypeptide growth factors (PGFs) generally act in sequential pairs- competence factors in early G_1, and progression factors, particularly insulin (INS), in mid- to late G_1. Newborn rat astrocytes were synchronized by the addition (at time 0) of 10% serum to serum-depleted cultures. Between 12 h (G_0 /G_1) and 20 h, S phase nuclei (bromodeoxyuridine immunofluorescence) increased from 19 ± 4% to 72 ± 10%. DNA synthesis (thymidine incorporation) increased from 48 ± 6 to 205 ± 18 CPM/ ug protein. Even at 12 h, reduction of serum content from 10% to 0.1% arrested cell cycling (S phase nuclei 28 ± 6 % at 20 h). Cycle kinetics were identical in G_0 cultures transferred to a defined medium (DM) having fibroblast growth factor (FGF), INS and epidermal growth factor (EGF) as the sole PGFs. Cultures in DM were exposed selectively to combinations of PGFs from 9 to 12 h, i.e, in late G_1. No single PGF was sufficient to permit cycle progression (≤ 20% S phase nuclei at 20 h). The presence of any 2 PGFs (INS/FGF, INS/EGF, FGF/EGF) resulted by 20 h in ≥ 70% S phase nuclei. Synergism was noted for each of these pairs. Consequently, the competence/progression model is not strictly applicable to these synchronized primary astrocytes. Rather, simultaneous activation of at least 2 PGF-stimulated pathways is necessary in late G_1, although each pathway may recognize multiple ligands.

ORGANISATION AND EXPRESSION OF THE FMRFamide GENE IN THE MOLLUSC *LYMNAEA*. E. Kellett, S. Saunders, N. Santama, P. Benjamin, J.F. Burke* Sussex Centre for Neuroscience, Biological Sciences, University of Sussex, Brighton, E Sussex BN1 9QG (UK)

The FMRFamide gene in *Lymnaea* contains two major peptide-encoding exons. One encodes the peptides FMRFamide and related peptides. The other encodes GDPFLRFamide and related peptides. Expression of these two exons is mutually exclusive in individual cells, however both exons are spliced onto a common hydrophobic leader sequence. Cytoplasmic expression of these two peptide-encoding exons is regulated by differential RNA splicing. We have recently found that the FMRFamide gene contains at least two other peptide-encoding exons which are spliced onto the GDPFLRFamide exon in the messenger RNA. One of these exons contains the tetrabasic cleavage sequence RRKR and also encodes a novel peptide SKPYMRFamide. Genomic sequence of 5783 base pairs has been determined and, on comparison with cDNA sequences, shows that the FMRFamide and GDPFLRFamide exons are separated by an intron of 2914bp. The mRNAs encoding FMRFamide and GDPFLRFamide are 1647bp and 1623bp respectively. By the use of immunocytochemistry, protein purification and sequencing we have shown that peptides encoded by each exon are translated and processed. This work is supported by the SERC.

Isolation and characterization of FMRFamide-like peptides from *C. elegans* and mapping of promoter elements for the corresponding gene. M. Rosoff* and C. Li, Dept. of Biology, Boston University, Boston MA 02215.

In the free living soil nematode *Caenorhabditis elegans*, FMRFamide-like immunoreactivity has been localized to approximately thirty neurons in the adult hermaphrodite [Schinkmann and Li (1992) J. Comp. Neurol. 316:251-260]. A gene, *flp-1*, that encodes multiple FLRFamide-containing peptides has been isolated and characterized from *C. elegans* [Rosoff et al., J. Neurosci., in press]. Two different transcripts are produced as a result of alternative splicing; analysis of the corresponding cDNA clones revealed that one transcript encodes six distinct FLRFamide-containing peptides while the other encodes seven.

In collaboration with David Price, five of the seven FLRFamide-containing peptides predicted from the cDNA sequence have now been isolated from whole animal extracts by HPLC purification. Four additional minor peaks show FMRFamide-like immunoreactivity by RIA analysis. Efforts are underway to isolate and characterize these additional peaks.

Using *lacZ* as a reporter gene under the transcriptional control of the *flp-1* promoter region, transgenic animals have been constructed and stained for expression of the transgene. A promoter element that seems to be sufficient to elicit expression in specific cells in the head of the animal has been mapped to within 300 bp of the start site of transcription. Deletion analysis on this region is being performed to map further this element. Finally, to determine whether the occurrence of the two transcripts is developmentally regulated, reverse transcription/PCR experiments of staged RNA are currently being performed.

TOWARD DEVELOPMENT OF A MASTER SET OF THE cDNAS EXPRESSED IN HUMAN BRAIN. J.M. Sikela*, T.J. Stevens, A.S. Khan, A.S. Wilcox, M. Polymeropoulos, A. Orpana, J.A. Hopkins and M. Robinson. Univ. of Colorado Health Sci. Ctr. and VA Research Ctr., Denver, CO 80262

The generation of a master set of the cDNAs expressed in the human brain, knowledge of the chromosomal location of each cDNA and the complete DNA sequence of the protein coding region of each expressed brain gene would constitute a tremendous resource to human biology and neuroscience. Our goal is to significantly contribute to the development of such a resource through the large scale collection, sequencing and mapping of human brain cDNAs. We have developed a method for enriching for cDNAs that are unique from one another, and have refined strategies for automated single-pass and full-length sequencing of each cDNA and for physical mapping of each cDNA to a location in the genome. We have also identified a subset of cDNAs that contain polymorphic microsatellite sequences and demonstrate how they can be converted to highly informative (PIC value > 0.7) gene-associated genetic markers. Single-pass sequencing data from the cDNAs is being used to search DNA and protein databases using the BLAST programs. At present, most of the sequenced cDNAs correspond to potentially new human brain genes, while a significant number of cDNAs appear to represent human homologs of interesting genes found in other species. Among these are the Drosophila *brahma* gene, a regulator of a number of homeotic genes, several cDNAs related to known neurotransmitter receptor genes, ERK3, an extracellular signal regulated kinase and a potentially novel sodium channel gene. Currently in our laboratory automated single-pass sequencing is being carried out at a rate of several thousand cDNAs per year. Therefore, coordination of this effort with other laboratories doing similar work should permit the sequence identification of most of the genes expressed in the human brain within the next few years.

TETANIC POTENTIATION ALTERS THE ABUNDANCE OF SEVERAL mRNAS IN SINGLE LIVE CA1 HIPPOCAMPAL NEURONS. S.A Mackler*, B.P. Brooks & J.H. Eberwine Univ of PA Phila PA 19104

We examined the effects of use-dependent changes in synaptic transmission on the relative amounts of different mRNAs in individual neurons. The approach combined whole-cell recordings in rat hippocampal slices with amplification of the polyA+ RNA population from single CA1 cells. The microelectrodes contained all of the reagents necessary for cDNA synthesis and the polyA+ RNA was amplified using the T7 RNA polymerase promoter sequence and 32P-αCTP.

Screening of multiple candidate cDNA neuronal clones with the amplified probe revealed several differences in relative mRNA abundances between control cells and those cells 30 mins or more after potentiation of evoked e.p.s.cs. A 300% increase in CamKII mRNA occurred along with a 50% decrease in protein kinase C (β1) mRNA. This 6-fold change in mRNA levels may accentuate the activity of the CamKII second messenger system compared to PKC. Phospholipase A2 mRNA was unaffected. A 2-fold increase for *zif-*268 mRNA, without consistent changes in *c-fos,c-jun* and HSP70, suggests that transcriptional activators are selectively activated by synaptic use. The above changes were prevented by the prior addition of APV, a NMDA receptor antagonist.

The total of the described changes of mRNA levels from individual cells provide a detailed picture of a neuron after synaptic potentiation and in the context of synaptic connectivity and glial association.

CALCIUM CALMODULIN DEPENDENT PROTEIN KINASE AND MAP KINASE ARE DIFFERENTIALLY REGULATED BY SYNAPTIC ACTIVITY. T.H. Murphy*, R.V. Bhat, R. Fiore, and J.M. Baraban. Johns Hopkins Univ. Sch. of Med., Dept. of Neuroscience, Baltimore, MD 21205.

Protein kinases are key intermediates in stimulus-induced neuron plasticity. However, the synaptic stimuli needed to activate specific kinases is unclear. Using primary cultures of cortical neurons, we have investigated synaptic activation of Ca^{++}-calmodulin dependent protein kinase (CaMK) and mitogen activated protein kinase (MAPK). Bursts of spontaneous synaptic activity were induced and monitored with Ca^{++} indicators. Phosphorylation of these kinases during their activation allows activity to be preserved and assayed in cell extracts. We report that although both these kinases are activated by synaptic activity, they have different kinetics. While 90% of maximal CaMK activation was observed after only 10 s of burst activity, MAPK is not affected at this early time and is only activated to 30% of maximal after 2 min of stimulation. In parallel experiments, we examined the rate of decay of activity following synaptic stimulation. The half life of stimulated CaMK was 10-30s, while MAPK decayed by 50% within 6-10 min. These data provide evidence for differential regulation of these kinases by synaptic activity.

We thank H. Schulman and M. MacNicol for advice and reagents.

459.6

THE DIFFERENTIAL EXPRESSION OF FOUR CLASS III POU-DOMAIN GENES IN THE CENTRAL NERVOUS SYSTEM OF THE MOUSE A.L. Hartman#†, D.J. Bradley#, Y. Hara§, M. Nirenberg§, and W.S. Young, III#*. #Lab. Cell Biology, NIMH; §Lab. Biochemical Genetics, NHLBI, Bethesda, MD 20892. †Howard Hughes Medical Institute-NIH Research Scholars Program.

One of the most fascinating issues in the study of the developing and adult CNS is transcriptional regulation of genes. POU proteins are trans-acting factors which contain two highly conserved DNA binding domains, the POU-homeodomain and the POU-specific domain. We used *in situ* hybridization histochemistry to examine the distribution of mRNA encoding four Class III POU proteins recently cloned in our labs (PNAS 89:3280; PNAS 89:3285). Serial adjacent sections from adult male Swiss-Webster mice were studied. For Brain-1, Brain-2, and SCIP, we used ^{35}S-labelled riboprobes (cRNA) targeted to the 3' end of the coding region and the adjacent untranslated region of each transcript. For Brain-4, the probe was targeted to the mRNA encoding the translated region 5' up to the POU-specific domain. The sense strand of the Brain-4 probe was used as a negative control.

Brain-1 was the most abundant transcript of the four transcripts, being especially prominent in the piriform cortex, olfactory tubercle, and lateral ventricular ependyma. Brain-2 was prominent in the piriform cortex, vertical limb of the diagonal band of Broca, lateral ventricular ependyma, paraventricular and supraoptic hypothalamic nuclei, and substantia nigra, pars compacta. SCIP was abundant in the piriform cortex, striatum, accumbens nucleus, Islands of Calleja, vertical and horizontal limbs of the diagonal band of Broca, nucleus of the lateral olfactory tract, CA1 and CA2 pyramidal cells of the hippocampus, medial habenula, and the inferior colliculus. Brain-4 was expressed in the olfactory bulb, striatum, nucleus accumbens, olfactory tubercle, lateral ventricular ependyma, medial habenula, and the paraventricular and supraoptic nuclei. All four Class III genes were expressed in laminar patterns in the neocortex. More detailed analysis is being pursued in the adult and developing mouse.

C_2H_2 ZINC FINGER GENES EXPRESSED IN THE MOUSE NERVOUS SYSTEM. N. Mazarakis, N. Galjart, J. Brockes*† and F. Grosveld, Lab of Gene Structure and Expression, National Institute for Medical Research, The Ridgeway, London NW7 1AA, UK; †Ludwick Inst.Cancer Res, London W1P 8BT, UK.

The C_2H_2 zinc finger motif is a structure that contains highly conserved pairs of cysteine and histidine residues first identified in the Xenopus transcription factor TFIIIA. It constitutes a sequence specific, nucleic acid-binding domain that is found in a superfamily of invertebrate and vertebrate genes. Some of these genes encode *trans*-activating factors with regulatory roles in cellular growth and differentiation. In an attempt to study the regulation of neuronal differentiation a mouse brain cDNA library was constructed and screened under low stringency conditions with a zinc finger probe from a mouse gene that was shown by Northern blot analysis to generate a 3.7 kb brain specific transcript present during neurogenesis. *In situ* hybridization studies indicated that this message had a pan-neuronal pattern of expression. A large pool of cDNA clones was isolated that contained this and other highly homologous C_2H_2 zinc fingers. At least two novel C_2H_2 zinc finger genes have thus been identified. These data indicate that several members of the zinc finger family are being expressed in the developing mouse nervous system.

DISPROPORTIONATE REGULATION OF MITOCHONDRIAL AND NUCLEAR GENE EXPRESSION FOR CYTOCHROME OXIDASE SUBUNITS IN NEURONS. R. Hevner* and M. Wong-Riley. Dept. of Cellular Biol. & Anatomy, Med. Coll. of Wis., Milwaukee, WI 53226.

The mitochondrial enzyme cytochrome oxidase (CO) is a model for studying coordination of nuclear and mitochondrial gene expression. The enzyme contains 3 mitochondrial-encoded, and 10 nuclear-encoded subunits. We used *in situ* hybridization to study mitochondrial DNA (mtDNA), CO1 mRNA (mitochondrial-encoded), and CO4 and CO8 mRNAs (both nuclear-encoded), in the visual system of normal and 3-7 day monocular TTX-treated macaques. In all animals, mtDNA and CO1 mRNA were detected in neuropil as well as neurons, while CO4 mRNA and CO8 mRNA were mainly localized in perikarya, confirming our previous findings (J. Neurosci. 11:1942). Compared with normals, TTX-treated animals had not only decreased CO activity (shown histochemically) and CO protein (shown immunohistochemically), but also decreased mtDNA and subunit mRNA levels, in functionally deprived laminae of the lateral geniculate nucleus (LGN) and ocular dominance columns of area 17. After 7 days of TTX, mtDNA fell by 26%; CO1 mRNA by 49%; CO4 mRNA by 18%; and CO8 mRNA by 29%, as determined by computer-assisted grain counting in LGN neurons. CO activity, measured densitometrically, decreased 23%. These results indicate that CO subunit mRNAs are disproportionately regulated in brain, subsequent to functional deprivation. The major acute control over CO activity is probably exerted by regulation of mRNAs for mitochondrial-encoded subunits, which form the catalytic core of the enzyme. (Supported by NIH grants NS18122 and EY05439 to MWR, and by an MCW MSTP fellowship to RFH.)

GENES WITH TRINUCLEOTIDE REPEATS: POTENTIAL CANDIDATES FOR NEUROPSYCHIATRIC DISORDERS. Ross, C. A.,* Li, S., McInnis, M.G. and Antonarakis, S.E. Departments of Psychiatry and Neuroscience, and Center for Medical Genetics. Johns Hopkins Univ. Sch. of Med., Baltimore, MD. 21205

Expansions of trinucleotide repeats (CGG or CTG) in mRNA underlie three neuropsychiatric disorders: Fragile-X syndrome, X-linked spinal and bulbar muscle atrophy, and Myotonic dystrophy. In addition, in unaffected individuals, the number of repeats is highly polymorphic. In an attempt to find additional genes with trinucleotide repeats, we have screened a human cerebral cortex cDNA library with CGG and CTG repeat oligonucleotides. There were dozens of positives per large plate (~50,000 plaques per plate). Out of an initial ten clones, one was myotonin-protein kinase of myotonic dystrophy (Fu, et al. Science 255 1256) with 13 CTG repeats, two were 28S ribosomal RNA and two were a human homolog of dog SRP (both of which are known to have repeats). In addition, two appear to represent repeat-containing cDNAs with novel sequences. In one (A3) and possibly both, the repeat is within an open reading frame. Genotyping using PCR across the repeat identified one fragment length polymorphism out of six individuals screened. We are now studying an additional series of clones, generated by screening the library at higher stringency, several of which appear to be novel sequences. Genes with trinucleotide repeats may provide markers with high polymorphic index for linkage studies and are potential candidate genes for neuropsychiatric disorders.

EXPRESSION CLONING OF A RESERPINE-SENSITIVE MONOAMINE TRANSPORTER. B.J. Hoffman*, L.E. Eiden and J.D. Erickson, Lab of Cell Biology, NIMH, Bethesda, MD 20892.

Monoamine transporters are responsible for the accumulation of biogenic amines into secretory organelles of neurons, platelets, basophils and chromaffin cells. Using an expression cloning strategy for transport proteins, we have isolated a novel rat cDNA encoding a monoamine transporter (MAT). Transient expression of the 3.0 kb MAT cDNA resulted in ^{3}H-5HT uptake which was saturable, temperature-sensitive and greatly affected by the pH of the incubation medium. ^{3}H-5HT uptake was inhibited by nigericin and NH_4^+ ions, agents known to dissipate transmembrane pH gradients. ^{3}H-5HT uptake was inhibited by various compounds with the following rank order of potencies: reserpine > tetrabenazine (TBZ) = ketanserin > 5HT > DA > NE > histamine. Photo-labelling of membranes expressing the MAT cDNA with ^{125}I-azido-iodoketanserin followed by SDS-PAGE and autoradiography revealed irreversible labeling of two membrane components with apparent molecular weights of 75,000 and 50,000. The labelling of both bands was blocked by TBZ and was not present in membranes from untransfected control cells. The MAT cDNA has properties consistent with those of the vesicular monoamine transporter.

NAP, A HUMAN CEREBELLAR DEGENERATION ANTIGEN, IS A NOVEL, NEURON SPECIFIC, ADAPTIN FAMILY MEMBER. M.O. MCKEEVER AND R.B. Darnell. * Lab of Neuro-Oncology, Memorial Sloan Kettering Cancer Center, NY, NY 10021.

We have previously shown that antiserum from a patient with atypical cerebellar degeneration recognizes antigens expressed in cerebellar Purkinje cells and some neocortical neurons (Darnell et al., J. Neurosci 1991;11:1224-1230). Using this antiserum we have isolated a clone from a human cerebellar expression library, which, together with overlapping cDNA's, predict a protein sequence of 851 amino acids, of Mr 96kDa. Antibody affinity purified with the cloned fusion protein recognized the same Purkinje antigens as native patient's antiserum. Sequence analysis revealed homology (31% identity over 296 amino acids) with the clathrin binding domain of the adaptin family of proteins. Northern blot analysis using human polyA+ RNA demonstrated that this gene is expressed only in brain. These results identify a novel neuron specific member of the adaptin family, termed NAP, which is recognized by serum from a patient with human cerebellar degeneration. NAP may be involved in regulating neuronal specific aspects of vesicular trafficing, particularly receptor mediated endocytosis.

POTASSIUM CHANNEL EXPRESSION AND LOCALIZATION

460.1

EXPRESSION OF POTASSIUM CHANNEL TRANSCRIPTS IN THE EMBRYONIC AMPHIBIAN NERVOUS SYSTEM. A. B. Ribera*. Department of Physiology C-240, University of Colorado Health Sciences Center, Denver, CO 80262.

Differentiation of the voltage dependent potassium current in amphibian spinal neurons is delayed with respect to the maturation of calcium current, regulating action potential duration. The molecular basis for this program of electrical excitability is being analysed using probes for voltage dependent ion channel genes. Maturation of potassium current is pivotal for action potential differentiation, and thus efforts have focused on this ion channel.

A second *Xenopus* potassium channel gene expressed in the developing nervous system has been cloned. This *Xenopus* sequence is most related to the mammalian sequences RCK1 and MBK1 and is thus called XSha1. RNase protection assays indicate that XSha1 is expressed in the embryonic nervous system at levels comparable to that of the previously reported potassium channel gene, XSha2. The predicted peptide has 490 amino acids. At the amino acid level, XSha1 is 88% and 75% identical to MBK1 and XSha2, respectively. In the 3' untranslated region of XSha1, there is a region of 60 nucleotides that shows 70% similarity to sequences found in homologous locations in the 3' untranslated regions of MBK1 and RCK1. Functional expression of XSha1 in oocytes induces a delayed rectifier potassium current. The induced current shows high sensitivity to the potassium channel blocker TEA, being reduced by >90% by 15 mM TEA.

The functional properties of XSha1 in addition to its tissue and temporal patterns of expression of XSha1 are consistent with its putative role in regulating excitability of developing spinal neurons.

Supported by NIH NS25217 and NS01531.

460.2

ALTERED POTASSIUM CHANNEL GENE EXPRESSION AND NEURAL DIFFERENTIATION. S. M. Jones* & A. B. Ribera. Department of Physiology C-240, University of Colorado Health Sciences Center, Denver, CO 80262.

Several voltage dependent potassium currents are expressed in embryonic vertebrate neurons and their differentiation regulates the development of action potentials in amphibian spinal neurons. XSha1 and XSha2 are two *Xenopus Shaker*-like potassium channel genes that are normally expressed in the embryonic nervous system. In order to determine how the program for electrical excitability is established, XSha1 and XSha2 were overexpressed in developing embryos.

Overexpression was achieved by injecting capped XSha1 or XSha2 transcripts prepared *in vitro* into 1 cell of a 2 cell stage embryo. Rhodamine-conjugated dextran was included in the injection solution to follow the progeny derived from the original injected cell. Inclusion of potassium channel RNA, but not β-galactosidase RNA, in the injection solution leads to a dramatic decrease in the number of morphologically differentiated neurons *in vitro* that are rhodamine fluorescent. This effect was dose dependent; at concentrations less than 0.2 mg/ml, the potassium channel RNA lost its effectiveness. Neurite extension in whole mount embryos was examined immunocytochemically with acetylated α-tubulin antibodies; these studies indicated that at concentrations greater than 0.2 mg/ml, overexpression of potassium channel RNA led to abnormal motor nerve development.

Electrophysiological analysis of potassium currents in fluorescent and nonfluorescent neurons prepared from embryos injected with this low dose of potassium channel RNA did not reveal any difference in current densities. We are now studying the effects on current density of injection of higher concentrations of XSha1 or XSha2 RNA. Supported by NIH NS25217 and NS01531.

460.3

REGULATION OF mRNA FOR THE Kv3.1 POTASSIUM CHANNEL *IN VITRO* AND *IN VIVO*. T.M. Perney*, X. Li, S. Kang, L.K. Kaczmarek and N.C. Birnberg. Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Transfection of AtT20 cells with the H-*ras* oncogene causes a decrease in the width of action potentials and is associated with the induction of the potassium channel gene, Kv3.1 (Hemmick et al., J. Neurosci., 1992). In this study we have examined the e 's of transmembrane signalling pathways on Kv3.1 gene expressi in wild-type (WT) and *ras* transformed (R1) AtT20 cells. Long-term treatment (24-48 hrs) of WT cells with 10 ng/ml basic fibroblast growth factor (bFGF) resulted in the induction of Kv3.1 mRNA. bFGF treatment also caused a substantial decrease in action potential width consistent with a role for Kv3.1 encoded channels for rapid repolarization. bFGF treatment had little effect on Kv3.1 mRNA levels in R1 cells. In contrast, long-term treatment with 5 mM dibutryl cAMP or 50 mM K^+ increased Kv3.1 mRNA levels in both WT and R1 cells. The effect of depolarization was inhibited by the Ca^{2+} channel blocker, nimodipine, suggesting that the influx of Ca^{2+} is important in regulating Kv3.1 expression. Interestingly, R1 cells treated with high K^+ or dibutryl cAMP display a transient decrease in Kv3.1 mRNA levels at 2-8 hr. Both of these treatments cause a rapid induction of the c-Fos gene and an increase in AP-1 DNA binding activity. It is possible, therefore, that the Kv3.1 gene is regulated in a biphasic manner, acutely through the actions of second messengers and delayed through the action of immediate early genes. Because these same signaling pathways may also be activated by neuronal activity, we examined the effects of seizures on Kv3.1 gene expression. We found that 6 hr after a metrazole-induced seizure levels of Kv3.1 mRNA were decreased approximately 50% in rat hippocampus. We are currently investigating the long-term effects of seizure activity on the expression of the Kv3.1 gene.

460.4

STABLE EXPRESSION OF A RAT BRAIN K+ CHANNEL (K_v3.1) IN HUMAN EMBRYONIC KIDNEY CELLS. S.D. Critz*, B.A. Wible, D.J. Arnold, H.S. Lopez, and A.M. Brown. Dept. of Molecular Physiology & Biophysics, Baylor College of Medicine, Houston, TX 77030.

Biophysical analysis of K+ channels is often made difficult by the diversity of K+ channels found in cells. To address this issue, we have begun to express individual K+ channels using stable transfection of human embryonic kidney (HEK 293) cells. In this study, the biophysical properties of one such stably transfected channel, K_v3.1, were compared to those produced by transient expression following the microinjection of K_v3.1 cRNA into *Xenopus* oocytes.

The region of DNA coding for the K+ channel K_v3.1 was ligated to a mammalian vector, pRC/CMV (Invitrogen ®), which contained a polylinker region, a cytomegalovirus promoter and an antibiotic resistance gene. K_v3.1 DNA was incorporated by lipofection (Lipofectin ®, BRL) at 1 ug DNA /10^6 HEK 293 cells. Twelve out of 15 antibiotic-resistant clones randomly selected for biophysical analysis contained detectable levels of voltage-activated outward current (10.9 ± 2.2 nA at +90 mV, mean ± SEM). In contrast, endogenous currents were less than 200 pA (120 ± 20 pA at +90 mV, n=6) in these cells. The reversal potential of HEK K_v3.1 shifted in Nernstian manner with external [K+] ion concentration. Moreover, the channels were sensitive to concentrations of TEA (IC_{50} 165 μM) that block K_v3.1 channels in *Xenopus* ooctyes. The voltage-dependence of activation of K_v3.1 in HEK cells was similar to that observed in the oocyte ($V_{0.5}$ ≈+5 mV). The voltage-dependence of inactivation appeared to be different, however (+11 mV vs -20 mV, respectively). Single channel data indicate a unitary conductance of approximately 25 pS, comparable to the 22 pS K_v3.1 channels expressed in *Xenopus* oocytes. HEK 293 cells are a suitable mammalian system for the expression of K+ channels and may provide insights into the posttranslational modification of these channels. (Support: F32-NS08579 SDC, NS23877 AMB).

460.5

DIFFERENTIAL EXPRESSION OF K^+ CHANNEL mRNAS IN THE RAT BRAIN AND DOWN-REGULATION IN THE HIPPOCAMPUS FOLLOWING SEIZURES. M.L. Tsaur, M. Sheng, D.H. Lowenstein, Y.N. Jan & L.Y. Jan*. Howard Hughes Medical Institute and Departments of Physiology and Biochemistry, Univ. of California, San Francisco, San Francisco, CA 94143

K^+ channels are major determinants of membrane excitability. Differences in neuronal excitability within the nervous system may arise from differential expression of K^+ channel genes, regulated spatially in a cell-type specific manner, or temporally in response to neuronal activity. We have compared the distribution of mRNA of three K^+ channel genes, Kv1.1, Kv1.2 and Kv4.2 in rat brain, and looked for activity-dependent changes following treatment with the convulsant drug pentylenetetrazole. Both regional and cell-type specific differences of K^+ channel gene expression were found. In addition, neuronal activity caused a reduction of Kv1.2 and Kv4.2 mRNAs in the dentate granule cells of the hippocampus, raising the possibility that K^+ channel gene regulation may play a role in long-term neuronal plasticity.

460.6

ALTERNATIVE SPLICING OF THE 5'-UNTRANSLATED REGION OF A GENE ENCODING K^+ CHANNEL COMPONENTS. C. Kentros*, M. Weiser, E. Vega-Saenz de Miera, K. Morel, H. Baker, and B. Rudy. Dept. Physiology, NYU Med. Ctr., N.Y. 10016 and W.M. Burke Medical Res. Inst. White Plains, N.Y. 10605

Transcripts of the rat KShIIIA gene, one member of the Shaker III gene subfamily, express delayed rectifier voltage-dependent K^+ currents in *Xenopus* oocytes. We and others have previously reported the isolation of cDNAs encoding several alternatively-spliced versions of this and other genes of this subfamily predicting proteins differing in their carboxyl ends. The *Drosophila* Shaker gene encodes alternatively-spliced transcripts with different 3' and 5' coding regions. We now report the isolation of two types of transcripts of the KShIIIA gene with divergent 5'-untranslated regions (5' UTR). Their 5' sequences differ up to a point 5 bases upstream of the putative start codon (position -5). The presence of an AG, the dinucleotide characteristic of the exon boundary of 5' splice junctions, at position -4 supports the premise that these different 5' UTRs result from alternative splicing. Unlike the fly Shaker gene, these 5' alternative exons encode only untranslated sequence. Northern blot analysis of rat brain mRNA with probes specific to KShIIIA show a complex banding pattern that is not resolved by the utilization of probes specific to the 3' alternatively-spliced exons of this gene. However, Northern blots hybridized with probes specific to the two alternatively-spliced 5' UTR exons, designated alpha and beta, produce distinct banding patterns. On the basis of both Northern blot analysis and corroborating in situ hybridization studies, alpha is more highly expressed than beta in the rat CNS. As it is thought that 5' UTRs are involved in regulation of the processing and translation of mRNA, these results raise the intriguing possibility of differential post-transcriptional regulation of K^+ channel expression at the RNA level.

460.7

COMBINATORIAL ASSEMBLY OF THE EAG POLYPEPTIDE WITH K^+ CHANNEL SUBUNITS FOR MEDIATING cGMP-DEPENDENT MODULATION OF K^+ CURRENTS IN DROSOPHILA. Y. Zhong* and C.-F. Wu. Dept of Biology, Univ. of Iowa, Iowa City, IA 52242.

Co-expression of different (*Shaker*) *Sh* subunits in the *Xenopus* oocyte has confirmed the oligomeric assembly of the voltage-activated I_A channels. However, the transient K^+ current I_A in *Drosophila* muscles is affected not only by *Sh* mutations but also by those of the *ether à go-go* (*eag*) locus, which encodes a polypeptide homologous to, but distinct from, *Sh* subunits. This suggests participation of products from different genes in the assembly of native K^+ channels. Existence of multiple *eag* and *Sh* alleles enabled the testing of this idea in various double-mutant combinations and allowed an investigation of the functional role of different types of subunits in the channel.

Voltage-clamp analysis of amplitude, time course, and steady-state inactivation revealed that the effect of eag^1, eag^{4PM}, eag^{24} on I_A varied with *Sh* alleles in the background. For instance, the amplitude of I_A is increased in eag^1 Sh^+, decreased in eag^1 Sh^5, but unchanged in eag^1 Sh^{120}, as compared to each of the corresponding *Sh* background. The allele-specific interactions in *eag Sh* double mutants reflect a close association between the *Sh* and *eag* subunits within the I_A channel. Since *eag* mutations affect four identified K^+ currents in *Drosophila* muscles, including the voltage-activated delayed I_K, the *eag* subunit may be present in multiple K^+ channels.

The functional significance of such heteromultimeric assembly of K^+ channels is suggested by our finding that modulation of I_A and I_K in response to application of cGMP (2 mM) and its analogs, 8-Br cGMP (500 μM) and dibutyryl cGMP (500 μM), is either altered or eliminated by different *eag* mutations. The role of the *eag* subunit in channel modulation, as opposed to that of *Sh* subunits in determining the channel gating and conductance, supports the notion that at least two classes of subunits, each dedicated to different functions, co-assemble into a variety of K^+ channels.

MEMBERS OF A MOUSE SUBFAMILY OF GENES ENCODING VOLTAGE-GATED POTASSIUM CHANNEL SUBUNITS FORM HETEROMULTIMERS WHEN COEXPRESSED IN *XENOPUS* OOCYTES. W.F. Hopkins* and B.L. Tempel, Depts. of Pharmacology and Medicine, Univ. of Washington and VA Medical Center, Seattle, WA 98108.

Potassium channels with diverse functional properties could arise, in principle, by the aggregation of nonidentical subunits. We wished to determine if heteromultimer formation was possible for the products of MK1 and MK3 mouse genes, members of the mammalian Shaker-like subfamily, that encode voltage-gated potassium channels. We also sought to test the hypothesis that potassium channels are comprised of 4 subunits. When MK1 and MK3 were expressed in *Xenopus* oocytes using the two-electrode voltage-clamp technique, we observed potassium currents that differed in their sensitivity to fraction I of dendrotoxin (DTX-I). The Ki's for DTX-I in oocytes expressing MK1 (N=7) and MK3 (N=9) were 3 and 4533 nM, respectively. We exploited this large difference in DTX-I sensitivity to test if heteromultimers comprised of MK1 and MK3 subunits form when coexpressed in oocytes. When MK1 and MK3 were coexpressed in several different ratios, the DTX-I sensitivities of the resulting currents were always greater than would be predicted by an additive model based on the hypothesis that MK1 and MK3 form only homomultimers. With a MK1:MK3 = 1:3 ratio, the Ki was 14 nM (N=4), which is much less than the Ki of 3100 nM predicted by the additive model. This suggests that heteromultimers composed of MK1 and MK3 subunits with intermediate DTX-I sensitivities can form in oocytes and that they have DTX-I sensitivities much closer to MK1 than to MK3. This implies that one MK1 subunit confers nearly full DTX-I sensitivity on a channel complex. The approach of MacKinnon (Nature 350: 232, 1991) was used and the results were consistent with a channel complex composed of 4 subunits. Supported by NIH NS27206 and the VA.

460.9

FUNCTIONAL INTERACTIONS BETWEEN SUBUNITS OF A CHIMERIC K^+ CHANNEL. G.E. Kirsch*, J.A. Drewe, M. DeBiasi, M. Taglialatela, H.A. Hartmann, and A.M. Brown. Departments of Anesthesiology, and Molecular Physiology and Biophysics. Baylor College of Medicine, Houston TX 77030.

We have shown previously that in a chimeric K^+ channel (22 pS K^+ conductance, expressed in *Xenopus* oocytes) the point mutation V369I shortens channel open time and causes fast inactivation, without affecting conductance (De Biasi, this meeting); whereas, L374V shortens channel open time and markedly reduces conductance (5 pS) with little effect on inactivation. Furthermore, the double mutation V369I+L374V increases channel open time and produces an intermediate level of conductance (10 pS). Here we show that the fast inactivation produced by V369I is abolished in the double mutant by increased burst duration. We tested for functional interaction of non-consecutive pore residues across subunit boundaries by co-injecting a mixture of cRNAs encoding the point mutants V369I and L374V. Two major classes of channels with intermediate conductances (8 and 14 pS) were observed in addition to the expected homotetrameric channels. Unlike the short-opening homotetramers, both classes of putative heterotetrameric channels had burst durations and open times approaching those of the double mutant. These results suggest that pore residues residing in adjacent subunits form a closely packed structure which determines both ion conductance and stability of the open state of the channel. Supported by NIH grants NS29473 (GEK), and NS23877 and HL37044 (AMB).

460.10

TARGETING OF WILD TYPE AND MUTANT DRK1 K^+ CHANNEL POLYPEPTIDES IN POLARIZED AND NONPOLARIZED MAMMALIAN CELLS. J. S. Trimmer, M. G. Arreaza, D. A. Brown, S. Halegoua, N. V. Marrion, P. Brehm*, and A. K. Kleinklaus. Depts. of Biochemistry & Cell Biology, and Neurobiology & Behavior, SUNY, Stony Brook, NY 11794.

Spatial segregation of voltage-sensitive ion channels in surface membranes of neurons and muscle fibers is critical to the conduction of electrical impulses. We have begun to investigate the molecular mechanisms that govern this restricted expression using the drk1 (K_v2.1) K^+ channel polypeptide as a model. We have expressed wild type and mutant drk1 polypeptides in polarized and nonpolarized cells by transfecting drk1 cDNAs into fibroblast (COS), epithelial (MDCK) and neuronal (PC12) cell lines, and have begun to characterize the targeting and functional characteristics of these drk1 polypeptides in these different cellular backgrounds. Expression of wild type and mutant drk1 polypeptides in COS cells is highly efficient, with the majority of expressed polypeptide found on the cell surface as judged by: 1) vectorial labelling with membrane impermeant biotinylation reagents; 2) plasma membrane localization using immunostaining; 3) presence of large (20 nA = 500 pA/pF) whole cell K^+ currents. Studies with membrane impermeant, reducible crosslinking reagents show that both wild type and mutant drk1 polypeptides form multisubunit channel complexes on the cell surface. MDCK and PC12 cell lines stably expressing drk1 polypeptides have been generated. Studies to determine the cell surface localization of drk1 in these cells are in progress.

460.11

SUBCELLULAR SEGREGATION OF A-TYPE POTASSIUM CHANNELS IN RAT CENTRAL NEURONS. Morgan Sheng, Meei-Ling Tsaur, Yuh Nung Jan,* and Lily Y.Jan Howard Hughes Medical Institute, Depts. of Physiology and Biochemistry, Univ. California, San Francisco, CA 94143-0724.

In the mammalian nervous system, K channels regulate diverse aspects of neuronal function and are encoded by a large set of genes. The roles of the many different K channels that are expressed in individual neurons could be dictated by their localization to specific subcellular domains. Using gene-specific antibodies, we show that two K channel polypeptides, Kv1.4 and Kv4.2, that give rise to A-type currents when expressed in Xenopus oocytes, are segregated in rat central neurons. Kv1.4 is targeted to axons and possibly terminals, while Kv4.2 is concentrated in dendrites and somata. Translation of both proteins, however, occurs in the cell body. The differential distribution implies distinct roles for these channel proteins in vivo; their localizations suggest that Kv1.4 and Kv4.2 may regulate synaptic transmission via presynaptic, or postsynaptic mechanisms, respectively.

CONTRASTING IMMUNOHISTOCHEMICAL LOCALIZATIONS IN THE RAT BRAIN OF TWO NOVEL K^+ CHANNELS OF THE *SHAB* SUBFAMILY. P.M. Hwang*, M. Fotuhi, D.S. Bredt and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

A number of mammalian voltage-dependent K^+ channels with closely similar amino acid sequences and electrophysiologic properties have been cloned. However, little is known about why multiple K^+ channels genes are needed to subserve similar functions. We have recently identified, cloned and characterized a novel K^+ channel, designated CDRK (Hwang *et al.*, Neuron, 8:473-481, 1992). CDRK appears to be a member of the *Drosophila Shab* K^+ channel subfamily, most closely resembling DRK1 (Frech *et al.*, Nature, 340:642-645, 1989), the only other rat homolog of *Shab*. Electrophysiologic analysis of expressed CDRK reveals delayed rectifier properties similar to those of DRK1. We now have made synthetic peptide antibodies specific for CDRK and DRK1 proteins. Remarkable contrasting immunohistochemical localizations in the brain as well as in peripheral tissues have been observed for both channels, suggesting that these highly homologous K^+ channels with distinct localizations may play unique roles in the control of membrane potential in various excitable tissues.

CENTRAL vs PERIPHERAL MECHANISMS FOR SPROUTING OF THINLY AND UNMYELINATED PRIMARY AFFERENT FIBERS IN THE PARTIALLY DENERVATED SPINAL CORD. **J.X. BAO,* P.J. Reier and J.B. Munson Dept. of Neuroscience, Univ. of Florida, Gainesville, FL 32610.**

The goal of this study is to study the possible central and peripheral mechanisms for the sprouting of primary afferent fibers in the partially denervated spinal cord.

The first group of adult Sprague-Dawley rats (n=5) received unilateral dorsal root ganglionectomies of L1-L4 on one side and rhizotomies of L1-L4 dorsal roots on the other side. The second group of rats (n=3) received unilateral dorsal root rhizotomies of L1-L4 dorsal roots on the right or left side followed seven weeks later by contralateral rhizotomies. Two months after the first surgery, all rats were anesthetized, and stimulated by immersing both of their hindlimbs in 52 ^{0}C water for 20 seconds. The rats were perfused two hours later. CGRP and c-fos immunocytochemical staining was then performed.

Preliminary results indicate that CGRP immunoreactive fibers had sprouted into a new area (lamina III) on the chronic ganglionectomized sides. Also, the area of CGRP immunoreactive fibers and the area occupied by c-fos immunoreactive cells were much greater on the ganglionectomized sides in the first group of rats, and much greater on the chronic side in the second group of rats. These results suggest both central and peripheral denervation contribute to the sprouting of thinly myelinated and unmyelinated primary afferent fibers in the partially denervated spinal cord. Furthermore, combined central and peripheral denervation (via ganglionectomy) induces sprouting of small primary afferent fibers into novel regions. **Supported in part by NS15913 and NS27511.**

THE SPATIOTEMPORAL EXPRESSION PATTERN OF THE CANDIDATE CELL ADHESION MOLECULE NEUROLIN IN GOLDFISH. [1]C.A.O. Stuermer*, [2]F. Lottspeich and [1]K.A. Paschke. [1]Faculty Biology, Univ. Konstanz, 7750 Konstanz, [2]Max-Planck-Inst., 8033 Martinsried,Germany

Using the monoclonal antibody E21 (Soc. Neurosci. Abstr. 16, 1990) we identified an 86kd cell surface glycoprotein (Neurolin) in the goldfish brain. Neurolin exhibits a striking spatiotemporal expression pattern.

The retinal ganglion cells (RGCs) of embryos and their axons, as well as those of the marginal retinal growth zone in adults, carry E21 staining over their entire surface. On mature RGCs E21 staining is restricted to contact sites between the cells and to the zone of RGC axon terminal arbors in the tectum. After optic nerve transection the regenerating axons re-express Neurolin throughout their path while the RGCs keep it restricted to their contact sites. The NH2-terminal aminoacid sequence of Neurolin has similarities to that of the recently discovered cell adhesion molecule DM Grasp (Burns et al., Neuron 7, 1991) and SC1 (Tanaka et al., Neuron 7, 1991) of the chick spinal cord.

In fact, E21 also stained motoneurons, floorplate cells and the DRG entry zone and tract in the developing goldfish spinal cord and only the latter in adults.

Neurolin may represent either the goldfish homologue of DM-Grasp/SC1 or another member of that family.

ASTROCYTES DEMONSTRATE REGIONAL DIFFERENCES IN PROMOTING DENDRITIC GROWTH. [1]P. Le Roux* and [2]T. Reh. Depts. of [1]Neurol. Surg., and [2]Biol. Struct., University of Washington, Seattle, WA 98195.

Glia from different regions of the CNS have been shown to be heterogenous in their ability to promote neurite outgrowth from neurons. However, it is not known whether glia from different CNS regions differ in their abilities to promote axons vs dendrites from neurons. Therefore we compared total dendritic and axonal growth from embryonic mouse cortical neurons (E 18) grown *in vitro* on early postnatal rat (P4) astrocytes purified from cortex, mesencephalon, striatum, olfactory bulb, spinal cord (GFAP> 90%+); Muller glia from retina; and fibroblasts. Double immunolabelling (MAP2, M6, NF-H) was used to identify mouse cortical dendrites and axons after 5 DIV. While axon length was similar on all glial monolayers, dendritic growth was nearly threefold greater on cortex, retina and olfactory bulb than from other areas of the CNS. These findings demonstrate regional differences in the ability of astrocytes to support dendrogenesis. Supported by NIH NS 30305.

PP60C-SRC REGULATES L1-MEDIATED AXON OUTGROWTH M.A. Ignelzi, D.R. Miller, P. Soriano, and P.F. Maness*. Dept. Biochemistry. Univ. North Carolina, Chapel Hill, NC 27599.

We have recently shown that triggering of the neural cell adhesion molecule L1 with specific ligands or antibodies inhibits tyrosine phosphorylation by pp60c-src of tubulin isoforms in a subcellular membrane fraction of nerve growth cones from fetal rat brain, whereas triggering of integrins does not (Atashi et al., Neuron 8: 1, 1992). To determine whether pp60c-src was a specific transducer of signals important for regulation of axonal extension on L1, cerebellar neurons from wild type and homozygous mice lacking a functional c-src gene (Soriano et al., Cell 64: 6903, 1991) were analyzed for neurite outgrowth on purified L1 or laminin adsorbed to nitrocellulose-coated culture dishes. Cerebellar neurons from src-deficient mice extended neurites on both substrates, indicating that pp60c-src was not required for process outgrowth. However, average neurite length measured 10 hr after plating on L1 was significantly reduced in cultures of src-deficient neurons (26.6 μm + 0.4) compared to wild type neurons (49.5 μm + 1.3). No differences in neurite lengths were measured for neurons plated on laminin in src-deficient (29.4 μm + 1.2) or wild type cultures (28.9 μm + 1.2). Adhesion of src-deficient neurons on L1, but not laminin was also reduced compared to wild type neurons. Differences in neurite outgrowth and cell adhesion persisted 20 hr after plating. Computer-assisted morphometric analysis of live growth cones revealed no differences in growth cone area or filopodial number between src-deficient and wild type neurons growing on L1. These results demonstrate that pp60c-src acts as a positive regulator of L1-mediated axon outgrowth.

461.5

ACTIVITY-SENSITIVE SIGNALLING BY INSULIN-LIKE GROWTH FACTORS IN THE DEVELOPING AND REGENERATING NEUROMUSCULAR SYSTEM. P. Caroni* and C. Schneider. Friedrich Miescher Institute, P.O. Box 2543, CH-4002 Basel.

Synapse elimination during development and nerve sprouting in the adult affect the arrangement of presynaptic terminal branches and are coupled to postsynaptic activity. Thus, the prolonged absence of postsynaptic activity leads to sprouting in the adult and prevents the retraction of collaterals during development. In the neuromuscular system, lack of muscle activation leads to a rapid elevation of muscle fiber-derived IGF1 in the adult and prevents the developmental downregulation of muscle IGFs during synapse elimination. We have searched for motoneuron mRNAs and proteins whose levels are controlled by muscle activity and have determined whether muscle-derived IGFs are sufficient and/or necessary to mediate activity-sensitive retrograde signalling from muscle to spinal motoneurons. We report that: 1) the mRNAs coding for the growth-associated proteins (GAPs) GAP-43 and tubulin-a1 are downregulated in rat and chick spinal motoneurons at the onset of the synapse elimination process; levels of terminal-associated GAP-43 decline during the elimination process; 2) motoneuron GAP downregulation is controlled by the periphery: it is prevented by local muscle paralysis or by elevated levels of IGFs in the muscle; 3) muscle-derived IGFs accumulate at the neuromuscular junction and are taken up and transported in motor nerves; 4) blockade of IGFs in the muscle by local applications of recombinant IGF-binding protein prevents the effect of paralysis on motoneuron GAP downregulation and on the pattern of intramuscular nerve growth.Therefore, IGFs mediate activity-sensitive retrograde signalling from skeletal muscle to spinal motoneurons.

CILIARY NEUROTROPHIC FACTOR (CNTF) INDUCES SPROUTING BY ADULT LYMNAEA NEURONS IN VITRO. A.G.M. Bulloch*, N.I. Syed and P.M. Richardson. Dept. Med. Physiol., Univ. Calgary, Fac. of Med., Calgary, AB and Neurosurg. Dept., Montreal Gen. Hosp., Montreal, Que.

This study is part of a series attempting to identify endogenous neurotrophic factors in molluscs. Neurons from the freshwater snails Lymnaea and Helisoma are usually cultured in vitro in brain conditioned medium. Recently we showed that Lymnaea conditioned medium contains NGF-like molecules and that murine NGF evokes sprouting from specific neurons. Here we extend these studies to another mammalian neurotrophic factor, ciliary neurotrophic factor (CNTF). Motoneurons, interneurons and neurosecretory cells from Lymnaea were isolated and cultured in vitro in defined medium with or without CNTF. One class of motoneurons (Pedal A cluster) and some interneurons exhibited sprouting in response to CNTF over a dose range of 250-1000 pM. Neurons of adult molluscs are thus now known to respond to two classes of mammalian neurotrophic factors (the neurotrophins and CNTF), neither of which is required for survival. EFFECT OF CNTF ON NEURITE OUTGROWTH FROM CULTURED SPINAL NEURONS. N.M. Oyesiku* and D.J. Wigston. Program in Neuroscience and Dept. of Physiology, Emory University School of Medicine, Atlanta, GA 30322.

There is a serious need for agents that may promote axonal growth after spinal cord injury. Although ciliary neurotrophic factor (CNTF) can enhance the survival of a class of spinal neurons, motoneurons, its effects on the growth or regeneration of axons from motoneurons or other spinal neurons are not known.

To investigate the effect of CNTF on neurite outgrowth from spinal neurons, we dissociated neurons from the lumbar spinal cords of stage 30 (~E6) chick embryos and plated them on laminin-coated glass coverslips in medium with or without CNTF (recombinant human CNTF; Synergen). By 48 hr, we found that neurites were about 65-100% longer and the total neurite length per neuron was 60-150% greater in cultures exposed to CNTF ($p<0.025$). In addition, CNTF enhanced neuronal survival. The enhanced neurite outgrowth was not a consequence of the higher cell density in CNTF-treated cultures: untreated cells that were plated so that their final density matched that of CNTF-treated cultures did not show enhanced neurite outgrowth. To examine the effect of CNTF on subpopulations of spinal neurons, we first compared cultures derived from the ventral spinal cord, which contains motoneurons, with cultures derived from the dorsal spinal cord which lacks motoneurons. CNTF enhanced neurite outgrowth to about the same extent in ventral and dorsal cultures. We also identified motoneurons in some experiments by labelling them retrogradely with diI. The effect of CNTF on neurite outgrowth was similar for labelled and unlabelled neurons, and was therefore not specific to motoneurons.

We conclude that CNTF promotes neurite outgrowth from spinal cord neurons *in vitro*. CNTF may have a similar effect on neurons in the injured spinal cord. (Supported by the American Paralysis Association.)

SEROTONIN AND ACETYLCHOLINE ALTER BRANCHING DECISIONS AND SOMA SIZE OF DEVELOPING LEECH RETZIUS NEURONS. S.M. Elsas and G.S. Stent*. Dept. of Molecular and Cell Biology, Univ. of California, Berkeley, CA 94720.

Embryonic axons of Retzius neurons (Rz), one of 5 types of 5-HT neurons in leech segmental ganglia, show a stereotyped sequence of pathway and branching decisions. Since synthesis of 5-HT and receptors for 5-HT and ACh appear early in Rz axon outgrowth, we asked whether 5-HT or ACh help regulate these decisions.

In *Theromyzon rude*, whose normal sequence of Rz axonal branching differs from that previously described in *Hirudo*, the primary axon forms a T-branch; the posterior arm of the T grows into the DP peripheral nerve. Then a secondary branch from the posterior arm grows into the posterior interganglionic connective nerve, and the anterior arm grows into the anterior connective nerve. When Rz connective axons from adjacent segments meet, they fasciculate. Then a new axon grows from near the branch point of the T into the MA peripheral nerve. Later all Rz somata except those in segments M5 and M6 enlarge to become the largest somata in a ganglion.

Embryos of *T. rude* were incubated for 2-5 days, during the period of axon outgrowth, in media containing 10mM 5HT or 10mM ACh with 50mM eserine. Rz morphology was visualized by anti-5HT antibody staining or by lucifer yellow injection.

Following ACh incubation, initial axonal outgrowth was normal. But when the connective axons of Rz neurons in adjacent ganglia would normally meet and fasciculate, all connective axons disappeared. Then a new anterior connective axon arose from the posterior arm of the T (instead of from the anterior arm), and the MA axon arose from this new branch (instead of from the T). A new posterior connective axon regrew in the original position. ACh incubation also led to a substantial increase in anti-5HT staining intensity in Rz neurons, but not in other 5-HT neurons.

Prolonged 5-HT incubation reduced anti-5HT staining in Rz neurons to near invisibility. Staining of other 5-HT neurons was unaffected. This selective effect on Rz reflects a change in transmitter metabolism, since uptake of 5-HT during brief (1h) incubation increases anti-5HT staining intensity. Prolonged 5-HT exposure also caused all Rz somata to remain small, which is normal for segments M5 and M6.

The results show that exogenous 5-HT or ACh can induce changes in transmitter content, soma size and axon branching in Rz neurons. Therefore these transmitters are likely to play a role in the regulation of these decisions in Rz development.

ANALYSIS OF ASYMMETRY IN THE DEVELOPMENT OF IDENTIFIED NEURONS IN THE GRASSHOPPER. P.Z. Myers*, C.L. Byars, and M.J. Bastiani. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112.

One possible role for interactions between growth cones and their substrates is in directly influencing pathfinding choices. Another potentially significant but more subtle function may be in regulating rates of growth cone migration; growth cones that are delayed by 3% or more may fail to find appropriate cues, leading to pathfinding aberrations. Using time-lapse video microscopy, we have quantified migration rates of an identified growth cone, that of the grasshopper neuron Q1. We have correlated one specific and reproducible change in growth rate, a pause at the midline, with a specific interaction with the growth cone of Q1's contralateral homolog. We have also developed a novel methodology, analysis of asymmetry between contralateral homologs of individually identifiable neurons, that allows us to identify interactions that affect growth cone velocity and also quantifies the amount of variability inherent in a simple developmental system.

The basic principle behind the analysis is that substrates that reduce growth rates act as bottlenecks that reduce any disparity in axon length between contralateral homologs; similarly, substrates that permit accelerated growth would increase the disparity. In agreement with our time-lapse observations, we see that the mean disparity in axon length between the two Q1 axons within a single segment decreases from an initial 16.7 μm to 3.5 μm upon contact at the midline. One function of this interaction between the two Q1s at the midline may be in synchronizing outgrowth.

We have also quantified the behavior of another identified neuron, MP1, and derived information about the general level of variability in the growth of both MP1 and Q1. The only events that reset the growth rates of these neurons are 1) the midline interaction by Q1, and 2) the arrival of the MP1 growth cone at the next caudal segment. Homologous axons vary in the time of initiation by 2.4±2 hours, or 0.5±0.4% of development. Most of the variability between homologs arises by this difference in initiation time; the growth rates of the two MP1 neurons in a segment vary by less than 0.4 μm/hr from one another, and the two Q1s vary by up to 1.2 μm/hr.

SHAPE CHANGES IN EMBRYONIC LEECH GROWTH CONES REFLECT TRANSITIONS IN OUTGROWTH. D.M. Kopp* and J. Jellies. Neurobiology Research Center and Dept. of Physiol. and Biophysics, Univ. of Alabama at Birmingham, Birmingham, Al, 35294.

Correlations between growth cone shapes and molecular and cellular guidance signals suggest that studying changes in morphology may help characterize these underlying guidance cues *in situ*. We have analyzed the morphology of a set of growth cones on the Comb- or C-cell in the embryonic medicinal leech, *Hirudo medicinalis*, as they undergo a transition to rapid extension. The C-cell is a transient cell found as a bilateral pair in each midbody segment. Each C-cell adds and orients about 70 parallel growth cones which remain relatively non-motile until E12 when rapid and directed process outgrowth is initiated. C-cells from the same segment at E10, E11, E12, and E14 were injected with Lucifer Yellow and processed with antibodies to visualize their growth cones in whole mounts. A central subset of obliquely-oriented growth cones (n=583) were traced using DIC optics and camera lucida. Morphology was digitized from these tracings and a computer program (MacMeasure) was used for analysis and computation. Contrary to expectations for growth cones that become more rapidly advancing, lamellar regions and filopodial sampling increased with age. Young, relatively non-motile growth cones had numerous short filopodia in many orientations, while the more rapidly advancing growth cones showed a decrease in filopodial number, an increase in filopodial length, and a striking restriction of filopodial orientation to the direction of process outgrowth. However, the average filopodial angle was predictive of the direction of outgrowth at all stages, suggesting that while direction of growth could always be predicted by a vector sum of filopodial trajectories, younger quiescent growth cones respond to different cues (or similar cues differently) than older, more rapidly extending ones. These results support the view that C-cell growth cones are not fasciculating and further suggest that they progressively alter filopodial extension/retention in the manner predicted if their affinity for local cellular cues was superceded by a more distributed set of extrinsic guidance signals. PATTERN FORMATION, COMPARTMENTS AND BOUNDARIES III

462.1

THE ROLE OF THE ZEBRAFISH SCLEROTOME IN PERIPHERAL NERVOUS SYSTEM SEGMENTATION. Elizabeth M. Morin-Kensicki* and Judith S. Eisen, Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

Sclerotome has been implicated in patterning peripheral nervous system (PNS) segmentation in vertebrate embryos. We have identified sclerotome cells in embryos of the zebrafish, *Brachydanio rerio*, based on the following criteria: these cells 1) delaminate from the ventromedial aspect of each somite, 2) become mesenchymal, and 3) migrate to positions where vertebrae later form. In each embryonic zebrafish trunk segment, sclerotome cells migrate along a pathway that later is traversed by the growth cones of axial motoneurons and by some neural crest cells. We tested the role of sclerotome in patterning zebrafish dorsal root ganglia (DRGs) and axial motor nerves by ablating premigratory sclerotome by aspiration and observing the pattern of these PNS structures at later stages by staining with specific antibodies. Removal of sclerotome did not disrupt the pattern of the DRGs or the axial motor nerves. These findings suggest that zebrafish sclerotome is not required for proper formation and segmentation of DRGs or axial motor nerves. Our results are in marked contrast to findings in avian embryos where sclerotome does appear to be required for these processes and thus, we suggest that there are different mechanisms for establishing PNS segmentation in different vertebrate species.

PATTERNING AND INDUCTION IN A ZEBRAFISH MUTANT THAT LACKS A NOTOCHORD. M. E. Halpern*, R. K. Ho, S. Schulte-Merker[1], C. Nüsslein-Volhard[1], C. Walker, and C. B. Kimmel. Institute of Neuroscience, University of Oregon, Eugene, Oregon, 97403 and Max-Planck-Institut für Entwicklungsbiologie[1], 7400 Tübingen, Germany.

In the zebrafish embryo, the notochord is derived from precursor cells that involute during gastrulation to form the dorsal mesoderm. As in other vertebrate embryos, dorsal mesoderm may play an important role in the induction of the central nervous system (CNS).

We have recovered two allelic, recessive lethal mutations that produce embryos with no notochords or tails (*ntl*). Cell lineage studies suggest that dorsal mesoderm is present in *ntl* embryos, although subsequent notochord differentiation is blocked. Phenotypically, *ntl* embryos resemble mouse *Brachyury* (or T gene) mutants. They also fail to express a protein homologous to the mouse T protein, which is an early marker of notochord development. Molecular analysis confirms that *ntl* is in fact the zebrafish homologue of the T gene.

Although the notochord is absent in *ntl* mutants, the induction and differentiation of the CNS appears normal. In contrast, patterning of somitic mesoderm is abnormal due to the absence of engrailed expressing muscle pioneer cells. However, the somite defects can be rescued through transplantation of wild-type (WT) cells into *ntl* hosts. These experiments demonstrate that mutant host mesoderm is capable of forming muscle pioneers in the presence of notochord derived from WT donor cells.

We propose that the dorsal mesoderm has multiple cell signalling roles in the development of the zebrafish embryo. In *ntl* mutants, the signals required for CNS induction are retained, while the signals required for muscle pioneer induction and somite patterning are disrupted.

462.3

EXPANDED ROLE OF MIDLINE SIGNALING IN THE DORSO-VENTRAL BRAIN POLARITY OF ZEBRAFISH. Kohei Hatta, Andreas Püschel, Monte Westerfield and Charles B. Kimmel*, Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

The zebrafish *cyclops* mutation deletes the entire ventral midline of the central nervous system (CNS), including the ventral forebrain and floor plate in the brain and spinal cord, without disturbing surrounding mesodermal structures. In the spinal cord and caudal hindbrain, positioning of most neurons is unaffected although pathfinding of some axons is severely disrupted. The phenotype is more severe in the anterior CNS; in the diencephalon, the ventral neuronal groups and longitudinal axonal tracts are deleted. To characterize the phenotype in more detail, we examined four homeobox genes (*eng*, *hox3.3*, *pax2*, *pax6*) that are expressed in specific positions in the CNS. Among them, *pax6* is expressed in the wild type as a bilateral pair of domains in the diencephalic primordium just after gastrulation. These domains are fused at the midline in *cyclops*. At later stages, the mutant expression pattern of each of the homeobox genes shifts ventrally in more anterior regions of the brain. These results suggest that *cyclops* alters the early fate map and dorso-ventral positional information of the CNS.

Transplantation of a single wild-type cell that comes to occupy the ventral midline in the mutant locally rescues the forebrain and eye phenotypes. We argue that proper establishment of positional information in the forebrain requires inductive signaling from ventral midline cells, whose specification depends on the *cyclops* gene product. EXPRESSION OF Tes-1(Dlx-2): A HOMEODOMAIN-CONTAINING GENE THAT IS EXPRESSED IN DISCRETE DOMAINS OF THE EMBRYONIC MOUSE VENTRAL FOREBRAIN. J.L.R. Rubenstein*, A. Bulfone, M. Frohman#, M.H. Porteus, D. Xu. Neurogenetics Laboratory, LPPI, Box F, 401 Parnassus, UCSF, San Francisco, CA 94143-0984. #Department of Pharmacology, SUNY, Stony Brook, NY.

Using subtractive hybridization and screening with homeodomain-encoding probes, we isolated, from an E14.5 mouse telencephalon cDNA library, a 2.4 kb cDNA encoding a novel homeodomain-containing protein called Tes-1. The Tes-1 homeodomain is identical in 53 out of 61 amino acids with the homeodomain of the Drosophila *distal-less* gene, and is part of the newly discovered Dlx family of homeobox-containing genes. It is also named Dlx-2. Unlike other vertebrate homeodomain-containing genes, Tes-1 is predominantly expressed in the head. Within the brain of the midgestational embryo, Tes-1 is expressed in the ventral forebrain. *In situ* RNA hybridization shows that Tes-1 is expressed in discrete domains within the embryonic forebrain. In the diencephalon, these domains form sharp borders with the expression pattern of another homeobox gene, and a gene encoding a putative growth factor.

462.5

NEUROGENESIS AND NEURITE GROWTH DEFINE A DISTINCT DOMAIN IN THE VENTROLATERAL WALL OF THE DEVELOPING MOUSE FOREBRAIN. A.K. McAllister*, J. Whitesides, A.-S. LaMantia. Department of Neurobiology, Duke University, Durham,NC 27710.

Segmentation has been implicated in the development of the spinal cord and hindbrain. In the forebrain, however, evidence for distinct embryonic domains—a hallmark of segmental development—has remained elusive. We report here a distinct domain in the developing mouse forebrain that is defined by early neurogenesis and specific axon ingrowth. This unique but transient domain appears in the outer 2/3 of the ventrolateral wall of the forebrain soon after the formation of two distinct telencephalic vesicles from the single prosencephalon. The earliest neurogenesis in the forebrain, indicated by MAP-2 staining and Di-I labelling, occurs in this zone. In addition, the first neurite growth in the developing forebrain is limited to this region as shown by immunostaining for neurite specific molecules GAP-43 and L1 as well as by EM analysis. Di-I tracing indicates that many of these neurites originate in the olfactory epithelium. The ventrolateral domain disappears as rudiments of the major forebrain subdivisions—the neocortex, hippocampus, basal ganglia, basal forebrain, and olfactory bulb—emerge.

This temporally and spatially restricted pattern of neurogenesis and neurite growth delineates a distinct domain in the developing mouse forebrain. This domain differentiates before rudiments of the forebrain subdivisions are seen and may be crucial to their formation. The ingrowth of axons from a specific source, the olfactory epithelium, further suggests that this regional specialization may be required for establishing initial axonal projections to the forebrain.

462.6

DIFFERENTIAL ADHESIVITY IN DISTINCT DOMAINS OF THE DEVELOPING FOREBRAIN. J.G. Whitesides* and A-S. LaMantia. Department of Neurobiology, Duke University, Durham, NC 27710.

Early in mouse forebrain development the ventrolateral wall of the telencephalon has unique cellular and molecular characteristics. Immunohistochemical staining shows that this region is reactive for the calcium-independent, homophilic cell adhesion molecule NCAM . This molecule is also present on axons projecting to this region from the olfactory epithelium. NCAM may act in the ventrolateral zone to confine a group of cells to a distinct region of the telencephalic vesicle as well as to allow for recognition of the incoming olfactory axons.

To begin to evaluate this hypothesis we used a rotation-based cell adhesion assay to determine whether the differential distribution of cell adhesion molecules in the ventrolateral zone is paralleled by differential adhesivity of cells in regions of the developing forebrain. Medial, ventral, and lateral regions of the E12 mouse telencephalic vesicle were isolated by microdissection, dissociated into single cells, and allowed to reaggregate in suspension cultures. After 24 hours videomicroscopic images were captured and the size and number of reaggregates from each region determined. Reaggregates from the lateral and ventral regions averaged 57% and 72% larger than medial reaggregates. Treatment of the cultures with the calcium chelators, EDTA and EGTA, did not disrupt the reaggregates, indicating that these early adhesive interactions are largely calcium independent. These findings suggest that distinct domains in the developing forebrain are differentially adhesive, perhaps due to the distribution of calcium-independent cell adhesion molecules such as NCAM.

462.7

ACTIVATED RETINOIC ACID RECEPTORS DEFINE A DISTINCT DOMAIN IN THE DEVELOPING MOUSE FOREBRAIN. A-S. LaMantia*, A.K. McAllister, J.G. Whitesides, M. Colbert, and E. Linney. Departments of Neurobiology and Microbiology and Immunology, Duke University, Durham NC 27710.

The acquisition of regional identity in embryos is orchestrated by transcription factors acting within distinct domains. In the vertebrate CNS these domains have been seen in the developing spinal cord and hindbrain; however, they have not been described for the forebrain. We have shown a unique zone of early neurogenesis, differential cell adhesion, and neurite ingrowth from the olfactory placode in the developing mouse forebrain. We now show that the emergence of this zone is temporally and spatially correlated with that of a transcription factor, the retinoic acid receptor, using a transgenic detector mouse (Balkan et al, 1991 PNAS 89:3347-3351). The transgene contains three copies of the retinoic acid response element, a basal promoter, and ß-galactosidase as the reporter gene.

At the prosencephalic stage, cells in the ventrolateral zone of the forebrain and the olfactory placode are transgene positive based upon anti-ß-gal immunostaining. At the early telencephalic stage, transgene activity is coextensive with neuron-specific markers. Neurons are seen in the outer 1/3 of the epithelium, while transgene activity is limited to proliferative cells in the inner 2/3. Similarly, transgene positive cells are segregated from neurons in the olfactory epithelium. Transgene activity decreases as more postmitotic neurons are observed in the ventrolateral zone and olfactory epithelium, and by the forebrain rudiment stage it is absent in both places. These observations support a role for region specific transcriptional regulation in the earliest subdivision, differentiation and innervation of the mammalian forebrain. *A-S. LaMantia is supported by a National Down Syndrome Society Science Scholar Award.*

462.8

TEMPORAL AND SPATIAL PATTERNS OF RETINOIC ACID SYNTHETIC PATHWAYS IN THE DEVELOPING RETINA. P. McCaffery* and U. C. Dräger, Harvard Medical School, Dept. Neurobiology, Boston MA 02115

Previously we identified an aldehyde dehydrogenase present at high levels in the dorsal retina of the embryonic and adult mouse as the basic isoform AHD-2 known to oxidize retinaldehyde to retinoic acid (RA). Comparative estimates of RA levels with a reporter cell line placed the retina among the richest organs in the early embryo; levels in ventral retina, however, exceeded dorsal levels. A zymography-bioassay, the test of charge-separated protein fractions for RA synthetic activity with the reporter cells, revealed a different, acidic dehydrogenase in ventral retina. Affinity purification shows a 60 kD protein whose presence and amount parallels the ventral enzyme activity. Per protein amounts, this putative novel enzyme is several hundred-fold more powerful in RA synthesis than AHD-2.

The relative contributions of the two enzymes to total RA synthesis in the eye region vary with developmental age. The acidic dehydrogenase precedes AHD-2: alone it mediates the very active RA synthesis we see in the optic groove and surrounding tissue at E8.5. At E10 the acidic enzyme accounts for ~90% of synthesis in the eye region, at E14 for ~70% of synthesis in the retina, and at P5 for ~50%. In the adult retina the acidic enzyme is no longer detectable and all RA synthesis is mediated by AHD-2. The patterns in the expression of the enzymes suggest (1) that the acid dehydrogenase plays a role in the determination of the eye as an organ, and (2) that a particular constellation, created by the use of different dehydrogenases, is specifically targeted at the biochemical basis of positional information.

462.9

EFFECTS OF INHIBITORS OF RETINOIC ACID SYNTHESIS IN VERTEBRATE EMBRYOS. N.R. Marsh-Armstrong, P. McCaffery, J.E. Dowling, W. Gilbert and U.C. Dräger*. Dept. Cellular and Developmental Biology, Harvard Univ., Cambridge MA 02138 and Dept. Neurobiology, Harvard Medical School, Boston MA 02115

Retinoic acid (RA) in the embryo is generated from retinaldehyde by a series of dehydrogenases that differ in spatial localization and enzymatic characteristics including inhibitor susceptibility. In the early mouse embryo the retina and the spinal cord have the highest RA concentrations. Synthesis in the retina of zebrafish, chick and rodents is mediated by different dehydrogenases, one in the dorsal, the other in the ventral retina.

In tests of dehydrogenase inhibitors on RA-synthesizing enzymes *in vitro* and for teratogenic effects in *vivo*, we found several reagents with relatively selective effects. In the retina, disulfiram suppressed preferentially dorsal RA synthesis in all species tested. The ventral enzyme was much less susceptible to disulfiram; in the mouse it was preferentially inhibited by p-hydroxymercuribenzoate. When disulfiram was tested on early neurulation-stage zebrafish embryos, the most striking effect was in the trunk region: after very low concentrations of the drug the trunk was shortened and the notochord appeared swollen and wavy; higher concentrations caused in addition other gross defects including visible eye abnormalities. Inhibition of RA synthesis may be involved in malformations linked to disulfiram (=Antabuse®) in experimental animals and humans.

462.10

ANALYSIS OF THE *En-2*^{hd} CEREBELLAR FOLIATION PHENOTYPE AND IDENTIFICATION OF INTERACTING GENTIC PATHWAYS K.J. Millen, K. Herrup* and A.L. Joyner Samuel Lunenfeld Res. Inst., Toronto, and Alzheimer Res. Lab. Case Western Reserve, Cleveland.

Members of the *engrailed* (*en*) gene family encode highly conserved transcription factors, containing five conserved protein domains, including a homeodomain. The murine *en* genes, *En-1* and *En-2*, are initially co-expressed in a spatially restricted pattern across the presumptive mid/hindbrain junction. Later, the genes are expressed in restricted groups of neurons important for motor control. To examine *En-2* function, a mutation which deletes the homeobox of the *En-2* gene was made by homologous recombination in embryonic stem cells. Mice homozygous for this mutation, *En-2*^{hd}, exhibit a reduced cerebellar size and a distinct patterning defect of the cerebellar folia. Examination of the developmental profile of foliation has revealed that at the midline, the secondary fissure forms in a more anterior position, causing a fusion of the pyramis and the uvula. As well, laterally, the ansoparamedial fissure fails to form causing a fusion of CrusII with the paramedial lobe. Analysis of a lobe-specific *lacZ* transgene marker also indicates evidence for lobe transformation within the mutant cerebellum. In an attempt to identify genes that interact with *En-2*, we have begun making *En-2*^{hd} compound mutants with other mutants such as *weaver* and *meandertail* that affect the cerebellum. In addition, we are testing whether the mouse homologs of genes such as *wingless* (*wg*) interact with *En*. In Drosophila, *wingless* (*wg*) activity is required for *en* expression. In mouse, *Wnt-1*, a homolog of wg, is expressed in a similar domain as the *En* genes during early development. Mice homozygous for a *Wnt-1* targeted mutation exhibit a deletion of the mid-hindbrain region of the developing brain. We have preliminary genetic and morphological evidence suggesting that *Wnt-1* interacts with *En-2* in the patterning of cerebellar foliation. We are currently examining the expression patterns of *Wnt-1*, *En-1* and *En-2* genes during cerebellar foliation to correlate their expression with the observed phenotypes.

462.11

WHY DO WHISKER-RELATED PATTERNS FAIL TO DEVELOP IN THE BRAINSTEM AFTER FETAL NGF INJECTION?

T.A. Henderson*, P.A. Osborne, R. Srisumrid, E.M. Johnson, T.A. Woolsey & M.F. Jacquin. Dept. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104; Dept. Molec. Biol. & Pharm., Div. Exp. Neurol. & Neurosurg., Washington Univ. Sch. Med., St. Louis, MO 63110.

We (Henderson et al., Neurosci. Abstr. 17, '91) have reported that rats given 20 or 30 μg of NGF systemically on embryonic day (E) 15 and again on E18 failed to develop whisker-related cytochrome oxidase patterns in trigeminal (V) brainstem nuclei by the time of birth. Controls indicated that this effect was not due to surgical trauma, reduced body weight, or reduced metabolic activity in the brainstem. Similarly treated rats given NGF daily for up to 3 postnatal days also failed to develop brainstem whisker patterns. A series of experiments were designed to test 3 hypotheses: 1) naturally occurring V ganglion cell death is ameliorated by NGF injections; 2) elevated NGF levels alters ganglion cell projections to the whiskerpad and/or 3) to the brainstem. Stereological analysis indicated that V ganglion cell numbers were higher than normal at birth after NGF injections at E15 and again at E18 (125 ± 12% of control, $p < .05$) and brainstem whisker patterns did not develop. One injection at E15 did not alter cell numbers at birth (97 ± 12% of control, $p > .05$) and brainstem whisker patterns did develop. In cases where patterns failed to develop, DiI- and DiA-labeled infraorbital nerve fibers had normal fasciculation patterns and trajectories. Axonal projections to the whiskerpad were not unusual. Yet, DiI-labeled V primary afferent projections to the brainstem did not exhibit whisker-related patches. Thus, naturally occurring ganglion cell death may be important for the patterning of central primary afferent projections. DE07734, DE07662, NS24679.

DOES ACTIVITY-BASED COMPETITION PLAY A ROLE IN BARREL DEVELOPMENT IN HAMSTER?

P.H. Lee, T.A. Henderson, W.R. Weaver, N.A. Connors*, T.A. Woolsey & M.F. Jacquin. Dept. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104; Div. Exp. Neurol. & Neurosurg., Washington Univ. Sch. Med., St. Louis, MO 63110.

Prior studies in rat have failed to implicate activity-dependent competitive interactions in postnatal barrel development (eg. Henderson et al, Dev. Br. Res. 66, '92). To determine if such interactions occur earlier in development, deprivation studies were carried out in the newborn hamster, whose gestation period is 5 days less than that of the rat. A-E row whiskers were trimmed daily for 13 days from birth ($N=11$) and cytochrome oxidase (CO) patterns in the barrelfield were normal. In another litter, trimming all whiskers except those in the C-row also failed to alter barrel patterns or whisker patch sizes (vs corresponding areas on the control side: C-row 101±11%; B-row 97±8; D-row, 104±10; $N=4$). Yet, after C-row cautery at birth, C-row patches were absent in 7 of 9 animals and B+D-row patches were significantly larger than control patches (B: 127±18%; D: 121±18; $p < .01$; $N=5$). To test if cautery-induced enlargement of the B+D rows reflects an activity-based competitive advantage over C-row, C-row cautery was combined with daily trimming of the remaining whiskers. B+D row patches were again significantly larger than controls (B: 122±10%; D: 156±46; $p < .01$; $N=4$); however, the extent of the B+D row patch enlargement did not differ from that seen in the cautery alone condition ($F=1.62$; $p > .05$). Thus, uniform or selective sensory deprivation does not affect barrel formation in the hamster. Moreover, while competitive interactions can be demonstrated in the hamster barrel cortex by follicle cautery at birth, such plasticity would not appear to be activity-based. NERVE GROWTH FACTOR VI

463.1

Expression and regulation of the transgene in the CNS of c-*fos*-NGF transgenic mice.

Onteniente B.[1*], Neveu I.[2], Horellou P.[3], Mallet J.[3], Briand P.[4] and Peschanski M.[1]. 1) INSERM CJF 91-02, Créteil; 2) INSERM U298, Angers; 3) CNRS UPR11, Gif/Yvette; 4) INSERM CJF 90-01, Paris ; France.

A transgenic mice line has been obtained which carries the *prepro-NGF* gene under a c-*fos* promoter. The expression of the transgene in cortical astrocytes and neurons has been assessed *in vitro*, in correlation with ELISA estimations of the amount of NGF synthesized and secreted by both cell types. In transgenic astrocytes, basal intra- or extra-cellular amounts of NGF were not significantly different from normal despite the presence of high amounts of mRNA specific for the transgene. Stimulation of the promoter with phorbol esters (TPA) produced a 60-fold increase in the secretion of NGF in both normal and transgenic astrocytes. Stimulation of the cAMP pathway by dibutyryl-cAMP or forskolin induced a 2- to 3-fold increase in the secretion of NGF.

In transgenic neurons, intra- and extracellular basal levels of the protein were respectively 4- and 2-times above normal ones. Fetal calf serum, which increased by 4 the levels of NGF secreted by normal neurons had no effect on transgenic ones. TPA, which increased by 10 the amount of NGF secreted by normal neurons had a slighter effect on transgenic neurons while dibutyryl-cAMP and forskolin increased the secretion of NGF by 10 in transgenic neurons and by 3 in normal ones.

The possibility to selectively regulate the production of NGF in transgenic embryonic tissue offers new insights to the *in vitro* studies of the factor and to *in vivo* investigations by transplantation.

463.2

MICE LACKING THE P75 LOW AFFINITY NGF RECEPTOR.

K.-F. Lee*, E.Li, J.Huber,[1] S.C.Landis,[2] A.H.Sharpe, M.V. Chao,[1] and R.Jaenisch Whitehead Inst., Cambridge, MA 02142, [1]Dept. of Cell Biol., Cornell Univ. Medical Coll., New York, NY10021, [2]Dept. of Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106.

We have generated mice carrying a mutation of the low-affinity NGF receptor $p75^{NGFR}$ gene by targeted mutation in embryonic stem (ES) cells. Mice homozygous for the mutation were viable and fertile. Immunohistochemical analyses of the footpad skin of mutant mice revealed markedly decreased sensory innervation by calcitonin gene related peptide (CGRP) and substance P (SP) immunoreactive fibers. The defective innervation was correlated with loss of heat sensitivity and associated with the development of ulcers in the distal extremities. Complicated by secondary bacterial infection, the ulcers progressed to toenail and hair loss. Crossing a human $p75^{NGFR}$ transgene into the mutant animals rescued the decreased heat sensitivity and the occurrence of skin ulcers and increased the density of neuropeptide-immunoreactive sensory innervation of footpad skin. Surprisingly, the mutation in the $p75^{NGFR}$ gene did not decrease the size of sympathetic ganglia or the density of sympathetic innervation of the iris or salivary gland. Our results suggest that the low affinity NGF receptor $p75^{NGFR}$ has an important role in the development and function of sensory neurons. This line of mouse should provide an opportunity to dissect the effects of different neurotrophins on cell differentiation, target innervation, neural plasticity, and nerve regeneration.

DIFFERENTIAL INFLUENCE OF NERVE GROWTH FACTOR ON NEUROPEPTIDE EXPRESSION IN VIVO - A NOVEL ROLE IN PEPTIDE SUPPRESSION.

V.M.K. Verge*[1], P.M. Richardson[2], Z. Wiesenfeld-Hallin[3] & T. Hökfelt[1]. [1]*Dept of Histology and Neurobiology, Karolinska Institutet, Stockholm, Sweden,* [2]*Div. of Neurosurg., Montreal General Hospital & McGill Univ. Montreal, Canada,* [3]*Dept. of Clin. Neurophysiol., Karolinska Institutet, Huddinge, Sweden.*

In normal adult rats 40-50% of lumbar DRG neurons have high-affinity receptors for NGF. A role for NGF in these neurons appears to be maintenance of differentiated phenotype as demonstrated by the ability of exogenous NGF to counteract loss of SP and CGRP following injury. To examine further at a cellular level possible mechanisms underlying the role of NGF in regulation of peptide expression in intact and injured sensory neurons in vivo, the right sciatic nerve was transected two weeks prior to sacrifice. In other animals, NGF was infused intrathecally (125ng/hr) for 8 days following the two week transection period. Cryostat sections were processed for receptor radioautography with radioiodinated NGF and for in situ hybridization with ^{35}S-labelled oligonucleotide probes to detect α-CGRP, β-CGRP, SP, SOM, VIP, CCK, NPY and galanin (GAL) mRNAs. In normal neurons α-CGRP, β-CGRP, SP, and SOM are abundantly and heterogenously expressed, whereas few neurons express VIP, CCK, NPY or GAL. Following injury, expresssion of α-CGRP, β-CGRP, SP and SOM decrease dramatically to background grain density levels in all but a few neurons. In contrast, the expression of VIP, CCK, NPY and GAL are upregulated and heterogenously expressed. Delayed infusion of NGF counteracted the decrease in α-CGRP, β-CGRP, and SP mRNA expression, but with the exception of a few neurons appeared not to influence the SOM population. The exogenous NGF also mitigated the injury-induced increases in VIP, CCK, NPY and GAL mRNAs. These results implicate NGF in positive and negative regulation of the synthesis of several peptides in intact sensory neurons. We suggest that NGF may be part of the signal that allows reversion to normal of responses to axotomy when axons regenerate into the distal sciatic nerve stump, a rich source of NGF. NGF REVERSES NEURONAL ATROPHY IN A MOUSE MODEL OF GENETICALLY PROGRAMMED NEURODEGENERATION

D.M.Holtzman*, Y.Li, K.S.Chen, F.H.Gage, C.J.Epstein, W.C.Mobley. Depts. of Neurology, Pediatrics, and the Neuroscience Program, UCSF, San Francisco, CA 94143 and Dept. of Neurosciences, UCSD, La Jolla, CA 92093.

Mouse trisomy 16 (Ts 16) is an animal model of Down syndrome (DS). We have previously shown that fetal Ts 16 basal forebrain transplants undergo time-dependent cholinergic neuronal atrophy similar to that seen in DS and Alzheimer's disease (AD). We now asked whether the transplants contained NGF receptors and would respond to NGF. We transplanted cell suspensions of fetal Ts 16 or control basal forebrain into the hippocampus of young adult mice. Six months later, mice received continous intraventricular infusion of NGF or vehicle for 2 weeks. Grafts were examined by immunohistochemistry or *in-situ* hybridization to characterize neuronal morphometry and gene expression. In both Ts 16 and control grafts, $p75^{NGFR}$ and $p140^{trk}$ mRNA were expressed in cholinergic neurons and not in the host mouse hippocampus. Similar to prior findings, Ts 16 cholinergic neurons appeared atrophic and were significantly smaller than controls in vehicle treated animals (126 vs. 156 μ^2, $p < 0.001$). NGF markedly increased the size of all cholinergic neurons (Ts 16=201 μ^2; C=206 μ^2). There was no evidence of ß/A4 deposition. NGF reversed neuronal atrophy in an animal model of spontaneous, age-related neurodegeneration. We speculate that NGF may be reversing a neuronal death program and that expression of candidate cell death genes can be examined in this model.

463.5

NGF RECEPTOR ACTIVATION AND INTERNALIZATION IN PC12 CELLS.

Mark Grimes* and William C. Mobley.
Department of Neurology, University of California, San Francisco, CA 94143.

Neurotrophins interact with receptors on neurites to cause a response in the distant cell body. To understand how the signal is carried to the cell body, we have studied early events in the endocytosis of NGF in mechanically permeabilized PC12 cells. Radiolabeled NGF was crosslinked to 75 and 135 kD proteins on the plasma membrane. After warming to 37°C for 10 min, NGF was found in large heterogeneous membrane structures that escaped permeabilized cells. When permeabilized cells were warmed to 37°C in the presence of an ATP regenerating system, an increasing fraction of NGF was present in released small vesicles. Production of small vesicles was dependent on warming the cells prior to permeabilization. Radiolabeled transferrin exhibits a similar distribution into large, loosely attached membranes whose release is ATP-independent and small vesicles whose release is ATP-dependent. We conclude that NGF, like transferrin, is internalized into early endosomes, and that transport vesicles arising from early endosomes accumulate in vitro. Preliminary experiments suggest that both p75 (NGFR) and trk are present in the small vesicles. Experiments are underway to determine the phosphorylation state and enzymatic activity of trk kinase in these vesicles.

SYMPATHETIC NEURON DEATH AFTER NGF DEPRIVATION ENTAILS DNA FRAGMENTATION INTO NUCLEOSOME-SIZED SEGMENTS (OR APOPTOSIS). A. M. Tolkovsky, S. N. Edwards and A. E. Buckmaster (SPON: Brain Research Association). Dept. of Human Anatomy, University of Oxford, Oxford OX1 3QX, UK.

We have examined whether NGF-deprived sympathetic neurons undergo programmed cell death by apoptosis, the hallmark of which is activation of endonuclease(s) that cleave DNA into nucleosomal-sized fragments of ~180-200 bp (thus forming a DNA 'ladder' on agarose gels). After NGF withdrawal, established seven-day cultures (Edwards et al., 1991, J. Neurochem. 57:1240) and newly-isolated sympathetic neurons both contain DNA 'ladders' typical of apoptosis, an activity which peaks ~20 hours after NGF withdrawal in newly-isolated cells. Agents that promote survival in the absence of NGF, including cycloheximide and actinomycin D, prevent the ladder from appearing. Laddering can also be induced with similar kinetics in the presence of NGF by the cytotoxin cytosine arabinoside, which promotes cell death over 20-30 h. Unlike apoptosis in thymocytes, neuronal endonuclease activity does not appear to require elevation of Ca^{2+} nor to be inhibited by Zn^{2+} or phorbol esters, and calmodulin inhibitors actually promote cell death without laddering in the presence of NGF. Thus, we have identified novel endonuclease(s) which appear to be important mediators of the cell death program in sympathetic neurons. These may constitute the molecular targets whose functional (and transcriptional) suppression by NGF leads to neuronal survival.

NERVE GROWTH FACTOR HAS NEUROTROPIC EFFECTS ON ADULT RAT SEPTAL CHOLINERGIC AXONS IN VIVO S. Varon, J. van Minnen* and T. Hagg, Dept. of Biology, Univ. California San Diego, La Jolla, CA 92093;
* Department of Biology, Vrije Universiteit, Amsterdam, The Netherlands.

Nerve growth factor (NGF) induces sprouting of injured adult rat septal cholinergic neurons and promotes their regeneration into nerve grafts and hippocampal formation. We have investigated the potential neurotropic or chemotactic effect of NGF in the adult rat cholinergic septohippocampal model. i) Animals received bilateral sciatic nerve grafts between the disconnected septum and hippocampal formation. A 4-week NGF infusion into the rostral lateral ventricle caused sprouting of cholinergic fibers in the dorso-lateral septum with a gradient toward the ventricle. However, the number of cholinergic axons in the nerve was only one third of those in control animals, i.e. NGF had diverted regrowing axons away from the nerve toward the ventricle. ii) In animals with nerve grafts and 2-week infusions with NGF into the fornix (proximal to the lesion and grafts), axons sprouted in the medio-dorsal septum, i.e. oriented toward the infused fornix. However, no fibers were seen in the nerve, i.e. regrowing axons had remained near the NGF source. iii) NGF infusion into the contralateral ventricle of animals with a unilateral fimbria-fornix transection but no graft, induced sprouting toward the midline of the septum but not in the normal side. iv) Infusion of a low NGF dose into the lesioned septum induced sprouting only around the infusion site. Thus, the location of an NGF source (the location of the highest NGF concentration) can control the orientation of outgrowing cholinergic axons, indicating that NGF has neurotropic effects in the adult animal, as it has for developing peripheral neurons in vitro and in vivo. NGF dependency of functional sympathetic recovery after 6-OHDA lesions in adult rats. A. Gloster* and J. Diamond. Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Axotomy evokes a cell body reaction (CBR), which is greater the closer the lesion is to the cell body. Our new findings indicate that the intensity of the CBR in adult sympathetic neurons is inversely related to the trophic dependency of the ensuing axonal outgrowth. After crush, sympathetic nerves regenerate quite normally during an anti-NGF treatment which totally blocks the collateral sprouting of the undamaged axons (Soc. Neurosc. Abstr. 1989. 15:333). Surprisingly, this regeneration extends readily into skin well beyond the original field, i.e. into territory whose invasion by collateral sprouting is prevented by anti-NGF treatment. In an attempt to throw light on this apparent paradox, we have examined the NGF dependency of sympathetic regrowth after 6-OHDA treatment. This treatment destroys only the terminals of the sympathetic axons, and not surprisingly, there is a minimal CBR.

A single remaining cutaneous nerve was stimulated to reveal its sympathetic pilomotor field in the otherwise totally denervated skin. Pilomotor function was then abolished by 6-OHDA treatment. Function gradually returned: by 20 days the original pilomotor field area was restored, and by 70d the field had tripled its size. When daily anti-NGF administration was used to "challenge" this functional recovery, the expansion of the field developed normally up to approximately 60% of the original field size; however, expansion then ceased, resuming upon cessation of treatment.

We suggest that the CBR is normally associated with the "regeneration mode" of these neurons. However, the minimal CBR to 6-OHDA treatment is only sufficient to support a limited amount of NGF independent regenerative recovery. At about 60% field size, the neurons revert to their normal status. In the continued presence of adjacent denervated skin, however, the "sprouting mode" emerges, the further outgrowth then being the normal NGF dependent collateral sprouting.

EFFECTS OF NGF AND ANTI-NGF ON WEIGHT GAIN AND FEMALE SEXUAL BEHAVIORS IN THE RAT. R.B. GIBBS*, M. M. McCARTHY, & D.W. PFAFF. Laboratory of Neurobiology & Behavior, The Rockefeller University, N.Y., N.Y. 10021.

Expression of nerve growth factor (NGF) by hypothalamic neurons has been reported; however, few studies have examined NGF effects on hypothalamic function. In the present study, adult, ovariectomized, Sprague Dawley rats received chronic ICV infusions of mouse 7S NGF (50 µg/ml; n=15) or rabbit anti-NGF (Collaborative Research; n=8). Control animals received rat cytochrome-C (50 µg/ml; n=9), or normal rabbit serum (n=3). Drugs were infused for nine days via a 28 g cannula implanted into the third ventricle and attached to an Alzet mini-osmotic pump. On the day of implantation, each animal was weighed and then administered the first of six daily injections of estradiol benzoate (1 µg in 0.1 cc oil s.c.). Two days later, daily testing for sexual receptivity began. Females were placed into arenas with vigorous males and lordosis, rejection behavior, and audible vocalization were measured. On the fifth day of testing, animals received progesterone (P; 0.5 mg in 0.05 cc oil s.c.) 4-6 hr. prior to testing. Two days later animals were weighed and perfused with paraformaldehyde and the brains processed for histochemical analysis.

NGF had a significant ($p<0.01$) effect on weight gain -- over the nine day period, average body weight decreased 7.0 ± 2.5% among NGF-treated animals and increased 3.6 ± 3.0% and 5.2 ± 1.7% among anti-NGF-treated and control animals respectively. All animals showed a steady, daily increase in lordosis quotient and average lordosis score. Neither NGF nor anti-NGF had any significant effect on lordosis behavior. Control animals also showed a daily increase in vocalization which reached significance ($p<0.05$) on day 4 of testing. This effect was both accelerated ($p<0.01$ on day 2 of testing) and increased ($p<0.05$) by NGF, and blocked by anti-NGF. Following P-treatment, vocalization in both NGF-treated and control animals was reduced to comparable levels. NGF also produced a significant increase ($p<0.006$) in rejection behavior (anti-NGF had no effect). These data suggest that hypothalamic NGF can influence behavior. Histochemical changes associated with NGF treatment will be discussed. Supported by NIH grant # NS28896.

NEUROTROPHINS ARE REQUIRED FOR FOLLICULAR FORMATION IN THE MAMMALIAN OVARY. G.A. Dissen,[1]* S. Malamed,[2] J.A. Gibney,[2] A.N. Hirshfield,[3] M.E. Costa[1] and S.R. Ojeda.[1] [1]OR Reg. Prim. Res. Ctr., Beaverton OR 97006; [2]Dept. Neurosci. and Cell Biol., UMDNJ-New Jersey, Piscataway, NJ 08854; [3]Dept of Anat., Univ. Maryland, Baltimore MD 21201.

The neurotrophin family of growth factors has several members, including nerve growth factor (NGF), all of which promote neuronal survival and differentiation. The biological actions of neurotrophins are exerted via activation of tyrosine kinase receptors. In addition, all neurotrophins are recognized by a different receptor molecule, known as p75, which is required for NGF signal transduction and is expressed in neurons as well as in some non-neuronal tissues. In the prepubertal ovary, non-neuronal p75 expression is localized to thecal cells of developing follicles. Immunohistochemical identification of p75 in embryonic rat ovaries using a specific monoclonal antibody (IgG 192) revealed that the receptor is expressed in mesenchymal cells. By gestational day 18, these cells begin to form stromal "pockets" which, as gestation proceeds, separate the presumptive pre-granulosa cells into discrete groups surrounding individual oocytes. This enclosure continues postnatally resulting in an abrupt formation of primordial follicles between 24 and 48h after birth. *In vitro* exposure of neonatal ovaries in organ culture to affinity purified NGF antibodies (2.4 µg/ml), resulted in a striking reduction (>80%) in follicular formation quantitated 48h later. Unexpectedly, this was accompanied by widespread cell death confined to p75-positive stromal cells. The results suggest that NGF and/or other members of the neurotrophin family are essential components of the differentiation program that governs follicular formation. MOLECULAR CLONING AND DEVELOPMENTAL ANALYSIS OF FIVE trk GENES IN ZEBRAFISH. S.C. Martin*, J.W. Wu and G. Heinrich University Hospital and Boston University School of Medicine, Boston, MA 02118

The trk A, trk B and trk C genes have been shown to encode a class of receptors for nerve growth factor, brain derived neurotrophic factor, neurotrophin 3 and neurotrophin 4 . We have sought to study the role of these tyrosine kinase receptors in a vertebrate model of neurodevelopment, the zebrafish Brachydanio rerio.

Nucleotide sequence analysis of 120 clones derived from PCR have revealed five distinct representatives homologous to trk A, trk B and trk C. A lambda ZAP cDNA library has been constructed from day 12 embryo RNA and cDNA clones have been isolated. Southern blot hybridization has been used to show that each of these trk sequences represent a unique zebrafish gene. Northen blot analysis reveals that these zebrafish trk genes are expressed early in embryonic development. Some of the novel trk members identified in zebrafish may be the receptors for previously uncharacterized neurotrophic factors. These results suggest that one or two trk genes have not yet been described in mammals.

463.12

IMMUNO-ULTRASTRUCTURAL LOCALIZATION OF LOW- AND HIGH-AFFINITY NGF RECEPTORS ON NEURAL CELLS. P. Spoerri*, L. Petrelli, R. Dal Toso and S.D. Skaper. Fidia Research Laboratories, Abano Terme, Italy.

Responsiveness of neural cells to NGF appears to require expression and ligand binding to both the low-affinity NGF receptor (LNGFR) and the protooncogene product trk, the latter being a receptor tyrosine kinase. We recently described the immunolocalization of LNGFR on PC12 pheochromocytoma and C6 glioma cells using immunogold electron microscopy. We now demonstrate the immunolocalization of the LNGFR and the high-affinity component of the NGF receptor, trk (HNGFR), on the former cells and cultured neonatal rat dorsal root ganglia neurons using a double labeling technique. Receptor-specific antibodies were utilized in conjunction with immunoglobulin conjugated to colloidal gold particles of different sizes. NGF-treated cells displayed considerable colocalization of LNGFR-HNGFR-immunoreactivity (IR). Gold particles associated with LNGFR were by far the more numerous, being frequently seen near 2-3 (or more) gold particles delineating the HNGFR. Positive trk-IR thus seems to colocalize with LNGFRs in at least these neural cells.

LOCAL RESPONSE TO INTRACEREBRAL GRAFTS OF NGF-SECRETING FIBROBLASTS: INDUCTION OF A PEROXIDATIVE ENZYME. D.M. Frim, I. Schumacher*, M.P. Short, X.O. Breakefield, and O. Isacson. Neuroregeneration Laboratory, Mclean Hospital, Belmont, MA.; Molecular Neurogenetics Unit, Neurology and Neurosurgery Services, Massachusetts General Hospital, Boston, MA.

Intracerebral implantation of cells genetically altered to secrete high levels of NGF has profound effects on local neuronal survival after excitotoxic or knife-cut lesions. The effects of such biological NGF delivery systems, specifically the induction of genes encoding protective enzymes or stress proteins in surrounding neurons or glia, has not been well studied. We chose to investigate the effects of an implanted NGF-secreting fibroblast cell-line on local levels of acetylcholinesterase (AChE), the stress proteins c-fos, c-myc, heat shock protein-72 kDa (hsp72), and ubiquitin (Ub), and the peroxidative enzyme catalase. Seven days after unilateral corpus callosum implantation of either a genetically altered NGF-producing (NGF[+]) or control (NGF[-]) fibroblast cell line, we found no specific immunostaining in tissues surrounding either the NGF[+] or NGF[-] grafts using antibodies raised against c-fos, c-myc, or Ub, though both types of grafts stained faintly for c-fos. Both NGF[+] and NGF[-] grafts elicited a halo of hsp72 immunoreactivity in the tissue immediately surrounding the grafts. AChE staining was unchanged in areas adjacent to the grafts, and though there was no fibroblast AChE staining, multiple AChE positive fibers appeared to be growing into or traversing the NGF[+] grafts. In contrast to the above, NGF[+] cells caused increased catalase staining in astroglial cells adjacent to the grafts. These catalase positive astroglial cells were not seen in areas distant from the NGF[+] grafts, nor were they seen in brains implanted with NGF[-] cells. These results suggest that the local protective effects of NGF[+] fibroblast grafts may be mediated through changes in peroxidative metabolism due to increased levels of catalase. If so, NGF-mediated protection and neurotropism in the adult brain may be caused in part by an increase in cell resistance to lipid peroxidation.

VISUAL CORTEX: MOTION PROCESSING II

464.1

REVERSIBLE ABOLITION OF VISUAL MOTION PROCESSING MECHANISMS IN THE LATERAL SUPRASYLVIAN CORTEX OF THE BEHAVING CAT. S. G. Lomber*, P. Cornwell, J. S. Sun, M. A. MacNeil and B. R. Payne, Department of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118.

The purpose of the present study was to test the hypothesis that the lateral suprasylvian (LS) visual cortex of the cat is critical for the identification of a stationary pattern partially obscured by a moving mask. Two cats were trained with food reward to discriminate outline "I" and "O" shapes which were partially obscured by a moving mask of regular intersecting diagonal stripes of the same thickness as the outline shapes. One cat (S) was trained binocularly and the second cat (V) was trained monocularly after transection of the optic chiasm and corpus callosum. Bilateral cooling probes were implanted over LS cortex of Cat S and a unilateral probe was implanted over LS cortex of Cat V. Prior to and after cooling inactivation of LS cortex, both cats could discriminate the "I" from the "O" in ≥80% of the test trials. Cooling of LS cortex reduced performance to almost chance levels (mean = 55%). Virtually identical results were obtained with a moving irregular mask. When the regular or irregular masks were held stationary over the "I" and "O", and LS cortex was operational, the performance levels were indistinguishable from those when the mask was in motion. However, cooling blockade of LS cortex did not influence the cats ability to discriminate the "I" in the presence of either regular or irregular static masks. Reversible cooling blockade of LS cortex was verified electrophysiologically. These results show that operational LS cortex is critical for the extraction of stationary patterns from a field filled with contours in motion; in the absence of LS cortical activity this ability is abolished. (Supported by NIMH #44647 and the Cornwell Family).

464.2

GLOBAL MOTION COMPUTATION AND THE BEHAVIOR OF SINGLE CELLS - A NEURAL NETWORK APPROACH Nava Rubin and Shaul Hochstein*, Neurobiology Dept. & Center for Neural Computation, Hebrew University, Jerusalem, Israel.

It has been suggested that the visual system, after extracting information about the motion of 1-D components of an image, uses an intersection-of-constraints (IOC) procedure to compute the 2-D direction of motion, and thus overcome the aperture problem (Adelson & Movshon, '82). To study the implications of the algorithmic solution on the implementation level, we studied a neural network model based on a physiologically plausible architecture. We found that the output units exhibit response inseparability to speed and direction of motion already for 1-D stimuli (gratings). In particular, the tuning curve to direction of motion is always bi-lobed for stimuli moving at sub-optimal speeds. This predicted behavior contrasts with that observed for MT cells, which exhibit remarkable separability of their response to speed and direction (Rodman & Albright, '87). Thus, a feed-forward network cannot both perform the IOC computation and exhibit physiologically-observed characteristics. The only way to mask this coupling pattern induced by the input layer may be by elaborate lateral connections among nonlinear output units, connections which themselves couple the speed and direction dimensions. An alternative model is proposed whereby the visual system computes global velocity not by interactions in velocity space but rather in real space, using information regarding the spatial organization of the stimulus components. Such a model accounts both for MT cell behavior and psychophysical results (Ferrera & Wilson, '90; Rubin & Hochstein, '92).

464.3

INTEGRATING VISUAL MOTION RESPONSES FROM NEURONS IN CORTICAL AREA MT BY ADAPTIVE FILTER SELECTION. S. J. Nowlan* and T. J. Sejnowski, The Salk Institute, La Jolla, CA, 92037.

A moving object excites many motion-sensitive neurons in the visual cortex. How could this distributed representation of motion be used to estimate the velocity of the object for eye tracking? The integration must be a dynamic process, dependent on properties of the visual stimulus such as contrast, spatial frequency, binocular disparity, color, and transparency or occlusion. We have developed a model for estimating the velocity of an object in visual area MT that is based on adaptive filter selection. The model assumes two sets of units with local receptive fields. One set of units computes local estimates of motion (using the motion energy model of Adelson and Bergen with physiologically determined parameters). The second set of units computes the relevance or reliability of each local motion estimate based on the estimate itself and additional information from the image. Outputs from this second pool of units can "gate" the outputs from the first pool of units through a gain control mechanism. This gating occurs before the local motion estimates are integrated to form more global estimates. The proposed mechanism of gain control is consistent with measured responses of MT cells under conditions of interfering transparent motions. The active process for selecting only a subset of visual motion responses for integration distinguishes our model from previous models of velocity estimation. The model yields accurate velocity estimates from synthetic images of moving targets of varying size, luminance, and spatial frequency profile. In addition, the sensitivity of the output of the model to both the acceleration and the velocity of moving targets is qualitatively similar to that observed in primate smooth pursuit tracking experiments. (Supported by the Howard Hughes Medical Institute).

464.4

CORRELATED ACTIVITY OF NEURONS IN AREA MT. E. Zohary,* M. N. Shadlen, and W. T. Newsome, Dept. of Neurobiology, Stanford University, Stanford, CA 94305.

We have previously reported that the mean sensitivity of MT neurons to weak motion signals is similar to the mean psychophysical sensitivity of rhesus monkeys. If single neurons are so informative, it is natural to wonder why monkeys do not perform even better by averaging signals from many neurons. The benefits of averaging, however, are attenuated if the neuronal responses contributing to the pool, are partially correlated. We therefore calculated the correlation between spike counts recorded simultaneously from pairs of MT neurons. Data were obtained using a spike sorter that operated on the basis of template matching; extra care was taken to verify that the two templates were highly discriminable both from the noise level and from each other. Neural activity was recorded (n = 12 pairs) while the monkey performed a direction discrimination task or a fixation task.

For each pair of neurons, the correlation coefficient (**r**) between the spike counts was computed for every stimulus condition. The value of **r** did not vary systematically with the direction or strength of the motion signal, nor was it affected by the behavioral relevance of the stimulus (i.e. "discrimination" or "fixation" condition). Among the 12 neuronal pairs, **r** ranged from -0.14 to 0.47; the mean value of 0.15 was significantly greater than 0 (t-test, $p < 0.01$). Somewhat surprisingly, Monte Carlo simulations indicate that modest correlations of this magnitude can limit significantly the beneficial effects of pooling.

464.5

PREDICTING PSYCHOPHYSICAL PERFORMANCE FROM POOLED NEURONAL RESPONSES. M.N. Shadlen*, W.T. Newsome, K.H. Britten, E. Zohary and J.A. Movshon†, Dept. of Neurobiology, Stanford Univ., Stanford, CA 94305; †Howard Hughes Medical Institute and Center for Neural Science, New York Univ., New York, NY 10003.

We have calculated expected psychophysical thresholds on a motion discrimination task from the pooled responses of neurons recorded from MT. We compared simulated values to mean psychophysical thresholds produced by our monkeys during recording experiments. Since the manner in which neural signals are actually pooled is unknown, we modelled various assumptions about the way neural signals add, the precision by which pooled signals are compared, and the degree of correlation among neurons comprising such pools.

Under most model assumptions, simulated performance rapidly exceeds the sensitivity of our monkeys as neurons are added to the pool. Interestingly, this beneficial effect of pooling is sharply limited if neurons are partially correlated in their response; arbitrarily large pools fail to lower expected threshold beyond some asymptotic bound. Still, the exquisite sensitivity of single neurons precludes pooling unless additional sources of noise, beyond the measured variability of our neurons, is assumed. Under these conditions, modest correlation (r = .1 to .3) between large numbers of neurons can account for psychophysical performance. In agreement with experimental data, moreover, simulated psychophysical decisions covary weakly with the responses of individual neurons on a trial-by-trial basis. Thus partial correlation provides a basis for reconciling the existence of large pools of sensitive neurons in the motion pathway with the observed psychophysical sensitivity of our monkeys, permitting the observer to base behavior on thousands of neurons while appearing to utilize but a few.

464.6

RESPONSES OF NEURONS IN AREA MST DURING DIRECTION DISCRIMINATION PERFORMANCE: A COMPARISON OF NEURONAL AND PSYCHOPHYSICAL SENSITIVITY. Simona Celebrini and William T. Newsome*. Dept. of Neurobiology, Stanford University., Stanford, CA 94305.

This laboratory has previously reported that direction discrimination thresholds of neurons in area MT are remarkably similar to psychophysical thresholds measured simultaneously in alert monkeys. In addition, there frequently exists a trial-by-trial covariation between the response of an MT neuron and directional judgements made by the monkey. As a first step in extending this analysis to other visual areas on the cortical motion pathway, we performed similar experiments in MST, a higher visual area that receives direct inputs from MT.

We recorded, in one monkey, from a subset of MST neurons that responded well to the variable-strength random dot stimuli employed in our previous studies. Due to the very large size of MST receptive fields (about 6,000 deg^2 on average), our visual stimuli usually covered only a small fraction of the receptive field. Despite this limitation, neurometric functions computed from the responses of MST neurons were indistinguishable from psychometric functions generated by the animal in 55% of the experiments (N = 40). The ratio of neuronal to psychophysical threshold was near 1 (geometric mean = 1.2), as was the ratio of neurometric and psychometric function slopes (geometric mean = 1.14). In addition, the trial-by-trial covariation of neuronal response and psychophysical decision previously observed in MT was also present in MST. Thus MST neurons, like those in MT, encode motion signals with sufficient sensitivity to mediate psychophysical performance on our direction discrimination task. The pools of sensory neurons contributing to performance on our task may therefore include cells from MST as well.

464.7

MT RESPONSES TO TRANSPARENT AND NON-TRANSPARENT MOTION. Ning Qian*, Richard Andersen and Edward Adelson, Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

We reported previously that patterns with well-balanced motion signals in opposite directions are perceptually non-transparent. This is exemplified by the paired random dot patterns composed of many randomly located pairs of dots. The two dots in each pair move across each other in opposite directions over a certain distance and then jump to a new random location. We found that when the distance the two dots in each pair traveled across each other is small, no transparent motion was observed. When the dots were simply unpaired, however, a perception of transparency emerged. We have recorded 42 MT cells from behaving monkeys using these paired and unpaired random dot patterns. The responses of most cells to these patterns were much weaker than their responses to a single set of dots moving in their preferred directions alone, indicating directional suppression. 17 cells also showed statistically significant differences in their responses to the paired (non-transparent) and unpaired (transparent) dot patterns. Among them, 11 cells responded to the transparent patterns better than to the non-transparent ones and 6 cells showed the opposite behavior. We further found that cells with the opposite behavior responded much better to noise patterns made of flickering random dots and therefore were less selective for motion. In addition, a strong negative correlation exists between the degrees of directional suppression of cells and their responses to the flickering noise patterns. This suggests that a major functional role of directional suppression in MT is noise reduction. These results, together with our previous findings that V1 cells could not distinguish between transparent and non-transparent patterns and that most of them showed no or weak directional suppression, support a two stage model for the transparent motion perception we proposed earlier. In the first stage, motion signals in each direction are extracted and in the second stage, the signals from opposite directions suppress each other. For patterns with well-balanced motion signals the suppression is more complete resulting in weaker responses to these patterns, which could account for their perceptual non-transparency.

RELATIVE DEPTH FROM MOTION AND STEREO CUES. George J. Carman[1]*, Leslie Welch[2], and Thomas D. Albright[1]. Salk Institute[1] and University of California[2], San Diego, CA.

While it is well-known that motion and stereo cues convey information about depth, how these two cues are integrated to form a single percept of depth is not understood. Based on theoretical consideration of viewing geometry, we predicted that differential motion parallax and differential stereo parallax should both have the same dependence on relative depth (GJC, *Soc. Neurosci. Abstr.*, **17**(1): 847, 1991). If true, then the matching of depth from stereo cues to depth from motion cues should be characterized by a linear relationship. Here we report findings of psychophysical experiments which confirm this hypothesis.

Human observers viewed two computer-generated stimuli presenting either monocular motion cues or static stereo cues, and adjusted the relative depth of one stimulus to match that of the other. Stimuli consisted of surfaces which presented a gaussian profile in depth, characterized by an absolute surround distance (SD) of the stimulus from the observer, and a relative center-surround distance (CSD) of the center from the surround. Stimuli were presented at SDs of 28.65, 57.3, and 114.6 cm, covering a range of CSDs scaled by SD so as to control for monocular size cues. Stimuli were rendered using dynamic random dots of limited lifetime so as to control for texture density cues. Stimuli were viewed under perspective projection via a mirror stereoscope in three conditions: (1) natural viewing, which simulated viewing of real objects; (2) isovergence, in which the vergence angle of the eyes was held constant, while otherwise simulating natural viewing; and (3) isoincidence, in which the retinal disparity cues were held constant, while otherwise simulating natural viewing.

Data obtained thus far indicate that: (1) relative depth based on motion cues is matched linearly, but nonveridically, to relative depth based on stereo cues; (2) the slope of this linear relationship varies with absolute depth of the stimulus; and (3) this variation in slope is due to changes in retinal cues which covary with vergence, but are not due to vergence per se. Our findings suggest that perception of the three-dimensional visual environment is mediated by a common representation of relative depth supported by linear combination of two-dimensional retinal cues arising from motion and stereo parallax. COMPUTING DIRECTION OF HEADING FROM AFFINE FLOW. Jack M. H. Beusmans.* Center for Neural Science, New York University, 4 Washington Place, New York, NY 10003.

Observers moving through a 3D environment can use optic flow to determine their direction of heading. The algorithms proposed so far for computing heading all use cartesian flow fields in which image flow is the change in the projection of identifiable points in the environment over time. I propose an algorithm that uses affine flow instead; in contrast to cartesian flow, affine flow makes explicit the change in vantage point between the observer and points in the environment.

To compute the affine flow associated with a point P in the environment, first compute the affine (i.e., linear) transformation $\mathcal{A}$ that transforms the neighborhood of p_1 (the image of P in the first view) into that of p_2; then apply $\mathcal{A}$ to p_1, to predict the location of P in the second view; affine flow is defined as $q = p_2 - \mathcal{A}p_1$ (Koenderink & van Doorn, JOSA A 8, 377, 1991). Modeling the observer's instantaneous motion by a translation and a rotation about an axis through its eye, affine flow is tangent to the translational field lines, which form a radial flow field on the observer's viewing sphere. The direction of heading is the center of this flow field. Note that q represents the change in vantage point of P. Translational field lines can also be approximated through differential cartesian motion (Rieger & Lawton, JOSA A 2, 354, 1985), although this approximation requires considerable differences in depth to be acceptable. Affine flow does not depend on such differences.

Affine flow involves simple, local computations that could be performed in a cortical area such as V1; affine flow vectors could be combined in areas such as MST or PG whose receptive fields cover a substantial fraction of the visual field. (Supported by NIH 5F32EY06319.)

TRANSCRANIAL MAGNETIC STIMULATION (TMS) OF PARIETAL-LATERAL OCCIPITAL CORTEX DEGRADES HUMAN MOTION PERCEPTION. JR Hotson*, D Braun, W Herzberg, D Boman, Santa Clara Valley Med Ctr, Stanford Univ Sch Med, San Jose and Stanford, CA 94305.

Extrastriate visual areas are involved in motion vision. TMS of striate cortex degrades spatial visual acuity for letter trigrams and Landolt-C stimuli. TMS of extrastriate cortex may also degrade motion perception of random dot stimuli. Subjects identified the direction that correlated dots moved through a dynamic random dot background located 10 deg to the left or right of fixation. Psychometric functions for this four-direction, forced- choice task were derived, and the percentage of correlated dots required to achieve 80-90% correct responses was determined. The test was then repeated with additional randomly-interspersed trials at the determined percentage of correlated dots during which TMS was applied 50-250 msec after the onset of the 50 msec motion stimulus. TMS was applied with a 9 cm coil over the lateral posterior hemisphere at an intensity of 1.8 Tesla.

In five subjects, TMS degraded the motion perception when applied 100-150 msec after stimulus onset. TMS produced a 36% mean decrease (range 33% to 44%) in correct responses when applied 125 msec after motion stimulus onset. In three subjects, little or no decrease was found when TMS was applied 50-75 msec or 175-250 msec after stimulus onset. Therefore, TMS applied over human extrastriate cortex transiently degrades motion perception and may be valuable in tracing pathways of visual information processing. (Supported by NEI EY03387 and The Valley Foundation).

464.11

TRANSITORY DEFECTS OF VISUAL PERCEPTION INDUCED BY CORTICAL STIMULATION IN MAN G. Beckers* and V. Hömberg Neurological Therapy Centre NTC Heinrich Heine University Düsseldorf (F.R.G.) Hohensandweg 37, W4000 Düsseldorf 13 (SPON: European Neuroscience Association)

Transcranial magnetic stimulation (TMS) in healthy human subjects (N=42) can produce *specific reversible defects of visual perception*. Single TMS pulses were applied systematically at various locations over the occipital, parietal, temporal, central and frontal cortex using a Cadwell MES-10 magnetic stimulator device with a maximum output of 2 Tesla peak flux density. A number of different visual tasks have been employed, including literal trigram identification, Landolt "C" gap detection, visual short term memory scanning, motion direction detection and color identification. The effects of varying TMS intensity, the delay between visual stimulus onset and TMS, and type of magnetic coil have all been tested. In the motion perception task, for instance, it was found that TMS applied *unilaterally* (1.4T, biphasic pulse duration 800usec) to either the left or the right area V5 (area MT) produced an instantaneous dramatic defect in the perception of the direction of motion, which lasted for about 40msec, whereas the effect of TMS of area V1 was less marked and occurred only at TMS-delays of 70-80msec post motion onset. TMS of area V5 (about 5cm left or right of the midsaggital plane) *did not impair* the perception of randomly varied colored Land-Mondrian stimuli. Further examination of the effects of visual stimulus eccentricity (4 to 9deg, size 2.2 x 2.2deg) and visual field stimulation, motion velocity (2.2 to 26.9deg/s) and exposure time (28 to 210msec) revealed that (A) TMS of the left area V5 produced a more marked impairment than TMS of the right area V5, (B) it is the corresponding contralateral visual hemifield only that is mapped in either the left or the right area V5 in man, (C) area V5 in man occupies a region of roughly $1cm^2$ at the temporo-parieto-occipital pit, (D) perception of motion direction varies with stimulus eccentricity and also with (E) stimulus velocity. The TMS induced transitory akinetopsia *was not* contaminated by eye-movements, since TMS is incapable of inducing eye-movements during fixation, whether applied to frontal, temporal, parietal or occipital cortex. The combined psychophysical-TMS method can be fruitfully used to study functional specialization and localization in human visual cortex with reasonable spatial acuity. In contrast to the PET technique, TMS reveals more about the *temporal order of arrival of signals* in various functionally specialized cortical areas, and thus has additional relevance for the comparison of functional specialization in monkey and man.

ELECTROPHYSIOLOGICAL CONCOMITANTS OF APPARENT MOVEMENT IN MAN. R. Pierantoni, W.G.Sannita*. Center for Neuroactive Drugs, Dept. of Motion Sciences, Univ. Med. School; Inst. of Cybernetics and Biophysics, CNR; Genova, 16132 Italy.

A Wertheimer's paradigm to induce a visual percept of apparent motion was approximated on a VENUS Neuroscientific system by producing a bidimensional 6x5.9 deg image of alternating black and white, 70% contrast sinusoidal vertical bars counterphasing at 0.5-8.0 Hz. Stimulation was at 0.4 or 5.0 c/deg spatial frequency, consistent with parameters used to produce (foveal) retinal and cortical evoked potentials in man. The signal was recorded (0.2-100.0 Hz) via dermal electrodes located on inferior eyelid (reference: contralateral eye) and occipital areas (reference: midfrontal), and processed offline (512 sample/s) by FFT. Eight healthy subjects were recorded; all agreed in reporting the expected compelling percept of horizontal movement with higher probability at 2.0 Hz or 5.0-8.0 Hz temporal frequencies when spatial frequency was 0.4 and 5.0 c/deg respectively. Significantly higher amplitude values of the retinal and cortical 2nd harmonic were observed at these temporal frequencies compared to higher or lower frequencies (including neighbouring frequencies) when the percept was not reported to be as evident and the 1st harmonic amplitude was higher than 2nd harmonic. The observation was consistent between- and within-subject, and suggests a potential concomitance of Wertheimer's phenomenon with the spatial/temporal frequency-dependent functions of the visual system concurring in the generation of retinal/cortical visual evoked potentials.

NEUROTOXICITY

^{1}H AND ^{31}P *IN VITRO* NMR STUDIES OF CHRONIC HYPOXIA IN FISCHER 344 RATS. K. Panchalingam*, J.W. Pettegrew, Lab. of Neurophysics, Univ. of Pittsburgh, Pittsburgh, PA 15261

Recent biochemical and clinical observations suggest that repeated, brief, mild energetic stress could, in some individuals, trigger molecular and metabolic mechanisms that result in the biochemical findings in the brains of Alzheimer's disease (AD) patients. In this study, we investigated the biochemical responses of Fischer 344 rat brains by subjecting them to repeated hypoxia for 30 seconds for a period of two weeks. Three months and 10 days old animals were used to investigate age dependent biochemical changes under hypoxia. *In vitro* ^{1}H NMR studies of the freeze clamped brains of controls and affected animals at the end of the two weeks indicate: (1) a nonsignificant increase in the level of the excitatory amino acid aspartate and glutamate in 3 month old animals. In the 10 days old animals, aspartate level was unchanged, whereas a 5% elevation ($p=0.07$) of glutamate was measured; (2) the inhibitory amino acid GABA is increased by 20% in 3 month old animals ($p=0.04$) and unchanged in 10 days old animals; (3) myo-inositol and alanine levels are decreased by about 9% in 3 month old animals ($p=0.02$) and by about 2-4% in 10 days old animals. These preliminary results indicate that aged animals are more susceptible to energetic stress than the young animals. Our ^{1}H NMR results indicate a permanent alteration in some amino acid levels but not in others. However, ^{31}P NMR results show no significant alteration in energy metabolism or membrane phospholipid metabolism indicating recovery of the brain from these energetic stress.

GLUTATHIONE DEPLETION INDUCES HEME OXYGENASE-1 (HSP32) mRNA AND PROTEIN IN RAT BRAIN. J.F. Ewing* and M.D. Maines. Dept. of Biophysics, Univ. Roch. Sch. of Med., Rochester, NY 14642.

In mammals heme oxygenase isozymes, HO-1 and HO-2, cleave heme to produce bile pigments. HO-1 is a stress protein (HSP32) induced by chemicals in systemic organs. This study demonstrates the sensitivity of brain HO-1 mRNA and protein to cellular glutathione (GSH) levels and provides the first evidence of reciprocal regulation of two antioxidant pools: GSH and bile pigments in the brain. Specifically, treatment of adult rats with diethyl maleate (DEM) (4.7 mmoles/kg,ip) caused a pronounced decrease in brain GSH within 1 h. GSH levels remained depressed for at least 24 h post-injection. Northern blot analysis of brain poly $(A)^+$ mRNA following DEM treatment revealed an increase in HO-1 1.8 Kb mRNA level up to 10-fold that of controls in a manner reciprocal to that of GSH. Similarly, treatment of neonatal rats with buthionine-SR-sulfoximine (BSO) (3 mmoles/k,ip; twice daily, 2-4 days of life) caused a marked depression in total brain GSH and a concomitant 10-fold increase in brain 1.8 Kb HO-1 mRNA above control level as evidenced by Northern blot analysis. In contrast, the level of two homologous HO-2 transcripts (1.3 and 1.9 Kb) did not increase in response to either DEM or BSO treatment. Analysis of brain HO-1 immunoreactive protein following 9 h DEM treatment indicated induction of HO-1 protein in only select non-neuronal cell populations. Notably, the ependymal cells lining ventricles of brain, Bergmann glia of cerebellum, leptomeninges lining brain and glia throughout brain responded to treatment by increasing HO-1-like immunoreactive elements.

We suggest that when GSH is depleted, an increase in HO-1 protein, hence increased capacity to form bile pigments, may be vital to those brain cells which normally depend on the tripeptide for antioxidant defense. Supported by NIH Grants R37 ES04391, ES03968 and ES01247.

CYTOCHROME P450IID1 IN IMMORTALIZED CELL LINES.

R.F. Tyndale and A.J. Tobin*.
Dept. of Biology, UCLA, Los Angeles, CA 90024.

Catalytic, pharmacological and molecular studies have recently identified the genetically variable cytochrome P450IID1 in mammalian brain. P450IID1 (debrisoquine hydroxylase) is responsible for the metabolism of many drugs including neuroleptics, codeine and antidepressants. In addition, significant overlap was observed between substrates / inhibitors for the dopamine transporter and for the P450IID1, for example, (-)cocaine, MPTP, methylphenidate and d-amphetamine. In order to study the CNS P450IID1, we used PCR to detect the presence of P450IID1 and cell marker RNA in immortalized cell lines. 10 of 15 centrally-derived cell lines were positive for the P450IID1 RNA. Variation of RNA levels in 8 rat brain regions was also studied. In addition, 2 of 3 pancreatic cell lines and a fibroblast cell line also contained the P450IID1 RNA. Studies of regulation, inducibility and enzyme activity are underway. Cell lines containing P450IID1 should enable us to further our understanding of the role of the P450IID1 enzyme in the CNS. (RFT is supported by the MRC of Canada)

RELATIONSHIP BETWEEN THE EFFECTS OF MPTP ON ENERGY METABOLISM AND LEVELS OF L-ASPARTATE AND L-GLUTAMATE IN THE MOUSE BRAIN.

P. Chan*, J.W. Langston and D.Di Monte. California Parkinson's Foundation, San Jose, CA 95128

The effects of the neurotoxicant 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) on the levels of L-glutamate and L-aspartate were studied in different areas of the mouse brain and correlated with changes in energy metabolism. C57BL/6 mice (7-8 weeks old) were injected with either saline or MPTP (40 mg/kg, s.c.) and sacrificed 4 hours later. MPTP caused a decrease in the levels of both L-aspartate and L-glutamate. This decrease appeared to be selective for the nigrostriatal pathway because it occurred in the striatum and ventral mesencephalon, but not in the cerebellar cortex. Furthermore, this toxic effect of MPTP was probably due to its conversion to the pyridinium metabolite MPP^+ since it was prevented by pretreatment of mice with the MAO B inhibitor deprenyl (10 mg/kg). In order to evaluate the possible role of changes in energy metabolism in the decrease of L-aspartate and L-glutamate, we injected mice with 2-deoxyglucose (2-DG, 1 g/kg, i.p.) prior to MPTP administration. 2-DG is an inhibitor of glucose uptake and utilization and has been shown to enhance the loss of ATP caused by MPTP in the mouse brain. The decrease in striatal levels of L-aspartate and L-glutamate was significantly potentiated by 2-DG. Data strongly suggest that impairment of energy metabolism caused by MPTP may affect the biodisposition of excitatory amino acids. Excitotoxins may then be involved in MPTP neurotoxicity.

465.5

EFFECT OF NEUROLEPTICS ON THE MITOCHONDRIAL ELECTRON TRANSPORT CHAIN.

V. Jackson-Lewis*, S. Przedborski, H. Jiang, S. Fahn. Department of Neurology, Columbia University, New York, N.Y. 10032.

The etiology of tardive dyskinesia (TD), a frequent and usually irreversible side effect of the chronic use of neuroletics, remains unknown. Because available pathological data do not support present biochemical hypotheses and impairments in the mitochondrial electron transport chain have recently been documented in several movement disorders, we thought it important to test the possibility that neuroleptics may affect mitochondrial respiration. Accordingly, adult rats received fluphenazine (FLU; 4 mg/kg s.c.) in saline daily for 30 days and were sacrificed 1, 4 and 7 days after the last injection. Control animals received vehicle only. Chronic FLU administration caused significant changes in complex I, II, III and IV activities in both caudate-putamen and nucleus accumbens compared to controls. The effect of FLU on mitochondrial respiration was partially reversed as striatal complex I activity improved 7 days after the last injection, while the other complexes still exhibited some alterations. In addition, brain mitochondria prepared from naive rats and incubated with different classes of neuroleptics showed that complex I activity was impaired as follows: phenothiazines > butyrophenones > thiothixenes > diphenylbutylpiperidines > indolics; while atypicals had no effect even at the highest dose (10 mM). Our study, demonstrates that neuroleptics can affect mitochondrial electron transport chain activity both in vivo and in vitro. Because deficits in mitochondrial respiration have been implicated in neurodegenerative processes, our findings with neuroleptics in rats may be relevant to the underlying pathophysiological mechanisms of TD.

465.6

EFFECT OF L-DOPA ON THE MITOCHONDRIAL ELECTRON TRANSPORT CHAIN.

S. Przedborski*, V. Jackson-Lewis, H. Jiang, A.B. Naini, S. Fahn. Department of neurology, Columbia University, New York, N.Y. 10032.

Reduction in complex I activity found in parkinsonian brains has been suggested to be implicated in the development of this illness. Because this reduction was also found in tissues such as muscle and platelets, which apparently are not affected by the disease, we thought it important to test the possibility that factors such as anti-parkinsonian treatment may play a role in the unexpected widespread alteration in the mitochondrial electron transport chain activity. Accordingly, adult rats received 50 mg/kg L-DOPA + 12.5 mg/kg benserazide in saline i.p. twice daily for 40 days and were sacrificed 1, 3 and 7 days after the last injection. Control animals received vehicle only. Chronic L-DOPA administration caused a significant reduction in complex I activity in rat brain compared to controls which seems to parallel dopaminergic innervation: striatum ≈ ventral mesencephalon > frontal cortex, no significant changes in the cerebellum. In contrast, no significant changes were observed in complex II, III and IV activities. The effect of L-DOPA on complex I activity was found to be reversible since striatal complex I activity returned to normal 7 days after the last injection. In addition, brain mitochondria prepared from naive rats and incubated with L-DOPA or dopamine showed significant reductions in complex I activity, while dopamine metabolites such as HVA, DOPAC or 3-O-methy-dopamine did not cause any significant changes. Our study demonstrates that chronic L-DOPA administration causes a reduction in brain complex I activity in rats. This finding supports the view that the deficit in complex I seen in muscle and platelets of parkinsonian patients may be due to the chronic use of L-DOPA-containing drugs. In addition, because reduction in complex I activity may play a role in the degenerative process in Parkinson's disease, the use of drugs such as L-DOPA that can increase this enzymatic deficit should therefore probably be postponed as long as possible.

KAINATE RECEPTOR EXPRESSION INDUCES TOXICITY IN FIBROBLASTS AND HIPPOCAMPAL SLICE CULTURES.

P. Bergold*, P. Casaccia-Bonnefil, and H. Federoff*. SUNY-HSCB, Brooklyn, NY, and *The Albert Einstein School of Medicine, Bronx, NY

The CA3 region of the hippocampus is prone to damage by the excitotoxin kainate (KA) through potential mechanisms involving either recurrent excitation and/or the high expression of KA receptors. In order to develop a gene transfer system to study KA toxicity, a cDNA encoding the KA receptor subunit, gluR6, (provided by S. Heineman) was cloned into a defective HSV-1 viral vector (HSVgluR6), and used to transfer and express KA receptors in N1H3T3 fibroblasts and organotypic slice cultures. Fibroblasts infected with HSVGluR6 became sensitive to KA toxicity; whereas infection with HSVlac, which expressed ß-galactosidase, did not. This suggested that HSVgluR6 efficiently transfered and directed expression of KA receptors, resulting in toxicity after exposure to KA. Slice cultures were infected by a 250nl microapplication of virus to the stratum pyramidale of CA1 or CA3. Infection with HSVlac resulted in expression of the reporter gene in 51 ± 3 cells centered on stratum pyamidale with no overt damage to the slice culture. In contrast, microapplication of HSVGluR6 to CA1 and CA3 produced toxicity. While the cytotoxic effect in CA1 was limited to the site of injection, most CA3 pyramidal cells were killed, suggesting that recurrent excitation in CA3 may be an important transynaptic excitotoxic mechanism.

465.8

EXCITOTOXIC LESIONS IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES

P. Casaccia-Bonnefil*[1] and P. Bergold[1,2] [1]Program of Anatomy and Cell Biology and [2]Department of Pharmacology SUNY-HSCB, Brooklyn, NY 11203

Slow neuronal excitotoxicity is believed to underlie many chronic neurodegenerative diseases. A 36 hour exposure of organotypic hippocampal slice cultures to low concentrations of glutamate agonists or GABA-A antagonists results in loss of specific populations of both principal cells and interneurons three days after the drugs are removed. The loss of principal cells is detected by methylene blue staining, while subpopulations of interneurons are detected with antisera directed against GABA as well as calbindin D28K, parvalbumin, neuropeptide Y, somatostatin, and VIP. A complete loss of dentate granule cells and most hilar neurons is seen after treatment with 50µM picrotoxin. This treatment has no effect on CA1 or CA3. Application of concentrations of picrotoxin up to 500µM does not appreciably increase the lesion. Exposure to 5µM kainate kills only CA3 neurons and hilar cells, and 10µM NMDA kills only CA1 neurons. Exposure to 1µM of either agonist has no effect. Co-application of both 50µM picrotoxin and 1µM kainate, in contrast destroys CA3, the hilus and the dentate gyrus. This suggests that specific patterns of delayed excitotoxicity can result from the synergistic action of both increased excitation and decreased inhibition.

465.9

CALPAIN INHIBITORS PREVENT CAPSAICIN-DEPENDENT NEUROTOXICITY IN DORSAL ROOT GANGLION NEURONS.

P.S. Chard*, J.R. Savidge, D. Bleakman & R.J. Miller. Dept. Pharmacol. and Physiol. Sciences, Univ. of Chicago, Chicago, IL. 60637.

Capsaicin (8-methyl-N-vanillyl-6-nonemamide) exerts a specific excitatory action on nociceptive sensory neurons resulting in elevated $[Ca^{2+}]_i$ and subsequent neuronal degeneration. A possible intermediary connecting elevated $[Ca^{2+}]_i$ with cell death is the Ca^{2+}-dependent thiol-protease, calpain. In the present study we used cultured dorsal root ganglion (DRG) neurons to examine whether calpain inhibitors can prevent capsaicin-mediated neurotoxicity. DRG neurons were isolated from 3-5 day old rat pups and grown in culture for up to 35 days. Two functional assays were employed to determine the number of capsaicin sensitive neurons in the culture: (1) Capsaicin stimulated Co^{2+}-uptake; after exposure to 1-100μM capsaicin for 20 minutes, in the presence of 5mM Co^{2+}, silver staining revealed that approximately 30-40% of neurons examined were capsaicin sensitive. (2) Fura-2 based microfluorimetry; bath application of capsaicin (1-100μM for 30-60 seconds) resulted in increases in $[Ca^{2+}]_i$ in 30-45% of DRG neurons examined. The capsaicin responses in both (1) and (2) were prevented by applying the capsaicin receptor antagonist ruthenium red (1μM), but were unaffected by the thiol-protease inhibitor E64 (10μM) or the calpain inhibitor MDL-18170 (10μM). Capsaicin-mediated neurotoxicity was assessed by adding capsaicin (1-100μM) to DRG cultures for 20 minutes in 5mM or 10mM extracellular Ca^{2+} ($[Ca^{2+}]_o$) and after 17-24 hours using propidium iodide/fluorescein diacetate fluorescence to determine the percentage cell survival. Capsaicin treatment (30-100μM) in 10mM $[Ca^{2+}]_o$, produced cell death in up to 30% of the neurons. However, when either E64 or MDL-18170 (both at 10μM) were added to the media, the death produced by capsaicin treatment was completely prevented in 5mM $[Ca^{2+}]_o$ ($p<0.001$, n=4) and partially prevented in 10mM $[Ca^{2+}]_o$ ($p<0.001$, n=9). Removal of extracellular Ca^{2+}, preincubation with the Ca^{2+}-chelator BAPTA-AM (50μM) or addition of ruthenium red (1μM) also prevented capsaicin-dependent cell death. These experiments provide strong evidence that capsaicin neurotoxicity is mediated via activation of the Ca^{2+}-activated protease, calpain.

DEFICIENT HEAT SHOCK RESPONSE IN CULTURED CNS AND PNS NEURONS. C.J. Marcuccilli, L.E. Fox and R.J. Miller. Dept. of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637.

The induction of heat shock proteins (HSP) has been suggested to play a role in neuroprotective mechanisms. In this study, we examined the effect of heat stress on cultured central neurons and acutely dissociated sympathetic neurons on the expression of the 70 kD HSP (HSP70). Rat hippocampal neurons cultured from day E17 embryos (HIP) and acutely dissociated neurons from the superior cervical ganglia from adult rats (SCG) were heat stressed for 60 min at 42.5°C. The neurons were allowed to recover for 5 hrs, after which they were assayed for HSP70 by immunocytochemistry using a monoclonal antibody. Neither HIP nor SCG neurons expressed the inducible form of HSP70 in detectable amounts. Similar results were observed with various temperatures (39 to 42.5°C). In other experiments, it was also observed that cultured cerebellar granule cells did not respond to heat stress. Western blot analysis of the HIP neurons confirmed the lack of HSP70 induction 3, 6 and 12 hrs following a 60 min heat stress period at 42.5°C. Unlike the HIP and the SCG neurons, astrocytes (AST) heat stressed for 30 min at 42.5°C did induce HSP70 immunoreactivity 2.5 hrs after the heat treatment. In addition, HIP neurons grown on secondary AST were heat stressed for 30 min at 42.5°C and 12 hrs following the treatment, immunocytochemistry revealed that only the AST responded. These results suggest that HIP and SCG neurons do not express the inducible form of HSP 70 following acute heat treatment.

465.11

PERIPHERAL NEUROPATHY IN A RABBIT MODEL OF DIDEOXYCYTIDINE (ddC) NEUROTOXICITY. G.H. DeVries*, J.T. DeVries, R.O. Calderon, T.D. Anderson, A. Davidovich, D. Feldman, T.J. Sprinkle, J. Arezzo, and C.Brosnan. Dept. Biochemistry Med. Coll. Va., Richmond, Va., Neurotech, Richmond, Va., Dept. Toxicol. Path., Hoffman-La Roche, Inc. Nutley, N.J., Dept. Neurol./Cell Mol. Biol., Med. Coll. Ga., Augusta, Ga., and Dept. Neurosci. and Path., Albert Einstien Coll. Med. Bronx, N.Y.

Forty rabbits were given either vehicle or ddC, by oral intubation , at a dose of 35 mg/kg/day for 24 weeks. The sciatic nerves were examined at 4 week intervals beginning at 8 weeks. Myelin splitting at the interperiod line and intramyelinic edema were first evident at 16 weeks and closely correlated with enlarged mitochondria with abnormal ultrastructure. Analysis of a myelin fraction isolated from the nerves showed that ddC treatment did not affect protein distribution, lipid distribution or CNPase activity. No abnormalities were noted in neurons of dorsal root ganglia. We conclude that the primary effect of ddC is on mitochondrial function in Schwann cells with subsequent myelin degeneration.

TRANSMITTERS IN INVERTEBRATES III

466.1

MODULATION OF PEPTIDE CO-TRANSMITTER RELEASE FROM B15 NEUROMUSCULAR JUNCTIONS OF *APLYSIA*. F.S. Vilim*[1], D.A. Price[3], I. Kupfermann[1], and K.R. Weiss[2]. [1]Cntr. Neurobiol. & Behav., Columbia Univ., NYS Psych Inst., NY, NY, [2]Dept. Physiol. & Biophys., Fishberg Res. Ctr. in Neurobiol., Mt. Sinai School of Med., NY, NY, and [3]Whitney Labs St Aug. FL.

The accessory radula closer muscle (ARC) and its innervation provide a model system for studying the role of neuromodulation and co-transmission. The ARC is innervated by two cholinergic motorneurons, B15 and B16, and a serotonergic modulatory neuron, the MCC. The motorneurons also contain modulatory peptide co-transmitters falling into 4 families. B15 contains the SCPs, buccalins, and FRPs, and B16 contains the buccalins and myomodulins. We have developed a method using RIA to directly measure SCP and buccalin release from the ARC following intracellular stimulation of a single motorneuron. We previously showed that SCP and buccalin are co-stored in the same dense core vesicles, and co-released in response to physiologically relevant patterns of B15 stimulation. Here, we report the effects of some of the modulators on peptide release from B15. Buccalin A, at $5x10^{-6}$M, decreased SCP release from B15, suggesting that buccalin released from B15 terminals can inhibit its own release, since SCP and buccalin are co-released. Furthermore, buccalin released from B16 may decrease peptide release from B15 because stimulation of the two motorneurons together produced less SCP release from B15 than stimulating B15 by itself. SCP_B, at 10^{-6}M, had no effect on buccalin release from B15, suggesting that SCP released from B15 does not affect on its own release. Serotonin, at $5x10^{-7}$M produced an increase in SCP release from B15, as did stimulation of the MCC. These results suggest that the extrinsic serotonergic modulatory system can affect the intrinsic peptidergic modulatory system and that the intrinsic modulatory system can affect itself.

CONVERGENT PEPTIDERGIC PHOSPHORYLATION OF PROTEINS IN THE ARC MUSCLE OF *APLYSIA*. W.C. Probst, E.C. Cropper*, S.L. Hooper, I. Kupfermann† & K.R. Weiss. Dept. Phys. & Biophys., Mt. Sinai Sch. of Med., NY, NY 10029; †Cntr. Neurobiol. & Behav., Columbia Univ. and NYS Psych. Inst., NY, NY 10032

The peptides SCP and myomodulin (MM) are contained in the ARC motor neurons B15 and B16 and increase ARC contraction amplitude and relaxation rate. The mechanism by which these changes occur was investigated by SDS-PAGE and protein phosphorylation and phosphatase assays. We previously reported that synthetic peptide application to intact ARC muscles induced phosphorylation of a >500 KDa protein.

B15 neurons were stimulated intracellularly with individual current pulses at physiological rates for 10 min. Stimulated and non-stimulated muscle homogenates were phosphorylated using a back-phosphorylation paradigm with γ-^{32}P-ATP in the presence and absence of cAMP. Autoradiography after SDS-PAGE showed that physiological stimulation prevents cAMP induced incorporation of ^{32}P into a >500 KDa protein in ARC muscles. Stimulation of B16 at physiological rates for 10 min also prevents cAMP induced incorporation of ^{32}P into this protein. These results indicate that either B15 or B16 stimulation induces phosphorylation of this band. This phosphorylation could be due to either increased kinase activity or decreased phosphatase activity. Measurements of phosphatase activity following MM application show that phosphatase activity is not changed. Direct evidence implicating PKA in the phosphorylation of this band was provided by forward phosphorylation experiments in which muscle homogenates containing either SCP or MM were treated with a specific peptide PKA inhibitor (PKI). PKI inhibited the phosphorylation of the >500 KDa protein in a dose dependent manner. These results suggest that SCP and MM converge on the same substrate protein and utilize the same second messenger pathway.

466.3

EFFECTS OF NEURON B16 STIMULATION AND MYOMODULIN APPLICATION ON cAMP AND PKA LEVELS IN ARC MUSCLE OF *APLYSIA*. S.L. Hooper*, E.C. Cropper, W.C. Probst, I. Kupfermann† & K.R. Weiss. Dept. Phys. & Biophys., Mt. Sinai Sch. Med., NY, NY 10029; †Cntr. Neurobiol. & Behav., Columbia U and NYS Psych. Inst., NY, NY 10032

The SCPs and myomodulins (MMs), modulatory neuropeptides present in the innervation of the ARC, exert similar actions on ARC contraction amplitude and relaxation rate. Previous work demonstrated that the SCPs act *via* the cAMP/PKA signal transduction pathway. Our protein phosphorylation data (Probst et al., this volume) suggest that MM may also utilize cAMP and PKA as a second messenger system.

We now report that MM application to ARC muscles causes dose dependent cAMP increases, but to maximal levels only approximately one tenth that induced by SCP application. The maximum increases of cAMP levels following physiologically relevant stimulations of neurons B15 (SCP) and B16 (MM) are approximately the same. However, unlike SCP application or B15 stimulation, MM application or B16 stimulation show desensitization, with cAMP levels decreasing rapidly with continued B16 stimulation or MM application.

Unlike SCP, MM application to intact ARC muscles induces only small increases of active PKA in low speed supernatants of centrifuged muscle homogenates. However, MM induces large increases (though still small compared to those induced by SCP) in active PKA in both uncentrifuged homogenates and in resuspensions of the pellet fraction, suggesting that MM induces both PKA activation and translocation to the pellet. Taken together, these data indicate MM's effects are likely mediated *via* the cAMP/PKA signal transduction pathway. The rapid dose dependent desensitization of MM induced cAMP augmentation may contribute to the depression of ARC contraction amplitude seen when high doses of MM act on the ARC.

A NEUROPEPTIDE Y HOMOLOG IN *APLYSIA* IS A POSSIBLE BAG CELL NEUROTRANSMITTER. D.F. Owens, S.M. Rajpara, D. Cumrine and E. Mayeri*. Department of Physiology, University of California, San Francisco, CA 94143-0444.

The neuroendocrine bag cells of *Aplysia* utilize four peptide neurotransmitters that are derived from a common precursor protein and contribute to the initiation and control of egg laying behavior. Each transmitter produces responses in abdominal ganglion neurons following a bag cell burst discharge (BCB). However, one response for which a transmitter has not been firmly established is the prolonged inhibition of neurons L3 and L6. Recently, we identified a peptide that mimics this prolonged inhibition. The peptide shares sequence homology with neuropeptide Y (NPY) and other members of the pancreatic polypeptide superfamily and has been designated *Aplysia* NPY (apNPY). Here we provide additional evidence that apNPY is a bag cell neurotransmitter. 1) Immunocytochemical analysis indicates that apNPY coexists in the bag cells with egg laying hormone, a previously identified bag cell neurotransmitter. 2) Arterial perfusion of apNPY produces prolonged inhibition of neurons L3, L6, and R2. It mimics the effect of a BCB on these cells at a concentration of 5 μM. 3) When apNPY is perfused at 100 μM for approximately 1 hr, subsequent BCB-induced inhibition of these cells is occluded. 4) ApNPY also produces short-term inhibition in neurons L2, L4, and L10, which is consistent with the responses seen in these cells following a BCB. It has no effect on many other ganglion neurons we surveyed, indicating that its effects are selective. These results suggest that the bag cells utilize peptide neurotransmitters that are derived from two distinct precursor proteins.

PDH-LIKE IMMUNOREACTIVITY IN IDENTIFIED SENSORY AND MOTOR NEURONS OF MEDICINAL LEECH EMBRYOS AND ADULTS. J.W. Bledsoe,* J. Jellies and M.P. Nusbaum. Neurobiology Research Center and Department of Physiology & Biophysics; Univ. of Alabama at Birmingham, Birmingham, AL, 35294.

Identified neurons in the medicinal leech, *Hirudo medicinalis*, are known to express several neuromodulators. Using an antiserum against a synthetic peptide, crustacean pigment dispersing hormone (PDH) (Dircksen *et al.*, Cell Tissue Res. 250:377, 1987), we have examined the leech nerve cord for immunoreactivity. In the adult, the anti-PDH labels a large number of neurons in both the ventral and dorsal aspects of each ganglion.

We used electrophysiological techniques and microinjection of the fluorescent dye Lucifer Yellow to identify some of the neurons and then double-labelled the preparations with anti-PDH, visualized with a rhodamine-conjugated secondary antiserum. Of particular interest was the double-labelling of two well studied neurons, including a primary sensory neuron known as the lateral nociceptive (N) cell and the heart excitor (HE) motor neuron. There has been no previous data to suggest possible neurotransmitters or modulators for any of the primary sensory neurons. In contrast, the HE was previously shown to be cholinergic and to also express a FMRFamide epitope (Kuhlman *et al.*, J. Neurosci. 5:2301, 1985). Certain other FMRFamide labelled neurons, including the dorsal excitor motor neuron 3, showed no staining with anti-PDH. Other double labelled neurons include the nut-neuron and the inhibitory motor neurons 1 and 2. In embryonic *Hirudo*, the N-cell appears to be the first neuron labelled by anti-PDH, being distinguished by embryonic day 10 (E10). The HEs are identifiable using this antibody by E12, which is 3-4 days prior to the earliest FMRFamide labelling. Additionally, a cell that has been identified as a possible HE homolog in ganglion 2 labelled at the same stage of development as definitive HEs. This staining pattern and temporal progression argue that the PDH-epitope is carried by a different antigen than that which presents a FMRFamide epitope. Supported by NS28603(JJ) and NS29436(MPN).

OCTOPAMINE-IMMUNOREACTIVE NEURONS IN THE LOBSTER CNS, *H.Schneider, B.A.Trimmer, J.Rapus*+, *M.Eckert*+ *& E.A.Kravitz**, *Harvard Medical School, Neurobiology Dept., Boston, MA 02115, and* +*Universität Jena, Tierphysiologie, O-6900 Jena, FRG.*

With an antibody directed against an octopamine-glutaraldehyde-thyroglobulin complex we detected about 86 immunoreactive neurons within the entire CNS of 4th stage larvae of the American lobster, *Homarus americanus*. The cells are distributed as follows: brain - 12, circumoesophageal ganglia - 2, suboesophageal ganglia - ~38, thoracic ganglia - 6 each, and 4th and 5th abdominal ganglia - 2 each. All the octopamine-immunoreactive cells are paired and located along the dorsal or ventral midline. Of the 86 neurons, 24 have been identified as neurosecretory cells, and 32 are intersegmental ascending thoracic, ascending abdominal, or descending interneurons. The neurosecretory system is arranged segmentally and located entirely within the thoracic and suboesophageal neuromeres. The projections of these neurons elaborate extensive varicose fibres along the proximal regions of 2nd thoracic and suboesophageal roots. These neurons are complementary to 2 pairs of large serotonin-containing neurosecretory neurons found in the fifth thoracic and first abdominal ganglia. The sets of neurosecretory neurons are arranged differently: the serotonin cells are intersegmental while the octopamine cells are segmental. Using a biochemical assay, the cell bodies of octopamine-immunoreactive neurosecretory cells in the thoracic segment of the nerve cord were found to contain 40-100 fmol of octopamine,while control neurons had none. Supported by NIH and DFG Schn 368/1-1.

IDENTIFICATION OF A *DROSOPHILA* HISTIDINE DECARBOXYLASE GENE REQUIRED FOR PHOTORECEPTOR SYNAPTIC TRANSMISSION. **M.G. Burg*, P.V. Sarthy+, and W.L. Pak, Dept. of Biol. Sci.,Purdue Univ., West Lafayette, IN and +Dept. of Ophthalmology, Northwestern Univ. Med. School, Chicago, IL.**

Histamine has been proposed to be the synaptic transmitter used by invertebrate photoreceptors, including *Drosophila*. Using genetic and molecular cloning approaches, we have identified a *Drosophila* gene encoding histidine decarboxylase (HDC), the enzyme which converts histidine to histamine. *Drosophila* mutants from a single complementation group with defective on-/off-transients of the electroretinogram (ERG) were found to be deficient in histidine decarboxylase (HDC) activity in a gene-dosage dependent manner, suggesting that this gene (*hdc*) may be a HDC structural gene in *Drosophila*. A rat HDC cDNA (Joseph et al., PNAS 87:733) was used to isolate a *Drosophila* cDNA homolog which encodes a protein with ~60% identity to mammalian HDCs. The *Drosophila* cDNA hybridized to the 46F region of the polytene chromosomes, to which the *hdc* gene was mapped using mutants. Northern blot and tissue *in situ* hybridizations demonstrate that the *Drosophila* cDNA detects 4 transcripts, expressed primarily in photoreceptors and small regions of the central nervous system. These transcripts are severely reduced in *hdc* mutants. The above results show that the *Drosophila* cDNA homolog corresponds to the *hdc* gene, and that mutations in this gene disrupt photoreceptor synaptic transmission. EXPRESSION OF TDVDHVFLRFamide, A *DROSOPHILA* NEURAL PEPTIDE.

R. Nichols*, M. Tibbetts, and J. McCormick
Biological Chemistry and Biology Departments, University of Michigan, Ann Arbor, MI 48109.

We have generated affinity-purified antisera to a unique portion of TDVDHVFLRFamide, a novel neural peptide from *Drosophila*. TDVDHVFLRFamide immunoreactivity is expressed in *Drosophila* brain. Two medial neurosecretory cells bilaterally symmetrical to the midline send projections to the brain lobes and projections down the ventral ganglion. Two anterior neurosecretory cells send projections along the midline to the brain lobes. The medial neurosecretory cells arise earlier in development than the more anterior cells. Double-labeling studies indicate that the neurosecretory cells expressing TDVDHVFLRFamide are distinct from those expressing DSK peptides. TDVDHVFLRFamide DNA has been amplified from adult *Drosophila* RNA.

STRUCTURAL BASIS FOR PROCESSING SITE USE AND MISUSE IN AN INSECT PROHORMONE. R.C. Rayne, T. J. Horne§, A. Linacre, I. D. Campbell§, A. Drake†, and M. O'Shea*, Centre for Neuroscience, Univ. of Sussex, Brighton BN1 9QG, UK

Neuropeptides are produced by specific and limited proteolysis of precursor polypeptides. Although pairs of basic amino acids (Lys or Arg) can precede cleavage sites, such sequences are not invariably processing signals. For example, in the prohormone for locust adipokinetic hormone (proAKH), there are two dibasic sites, only one of which is recognised during processing *in vivo*.

Using computer-aided structure prediction, circular dichroism (CD) spectroscopy and ^{1}H 2D NMR, we are studying the solution structure of a complete synthetic proAKH. CD and NMR indicate that the unused processing site is located within a region of α-helix, whereas the used processing site is not. The used site appears to be associated with a 7 residue Ω-loop in which Lys and Arg define its C-terminal neck. The importance of Lys and Arg and their positions have been studied experimentally by replacing them with their analogues thialysine and canavanine. Replacement of Lys (within the loop) but not Arg (adjacent) prevents correct cleavage C-terminal to the dibasic site. Thus, although normal cleavage is C-terminal to Arg, it does not depend on the presence of Arg, but on higher order structural features N-terminal to this site. To study how these features may interact with the enzyme, we are now cloning the cDNA of the proAKH processing endopeptidase.

IN VIVO RECORDINGS OF INDIVIDUAL INSECT PEPTIDERGIC NEURONS REVEAL BEHAVIOR-SPECIFIC DIFFERENCES IN FIRING PATTERNS. N.J. Tublitz*, Inst. of Neurosci., Univ. Oregon, Eugene, OR 97403.

The cardioacceleratory peptides (CAPs) are a family of myoregulatory neuropeptides found in the CNS of the tobacco hawkmoth, *Manduca sexta*. The CAPs are released several times throughout the life cycle of *Manduca* with each release resulting in a functionally distinct response. My interest is in understanding the mechanisms underlying this stage-specific functional plasticity.

This study's focus was in adult moths, where the CAPs act as cardioregulatory neurohormones at least twice. The CAPs are released once to expedite wing inflation (WI) in the newly-emerged moth and again during flight to facilitate nutrient transfer between abdomen and thorax. Although the heart is the primary CAP target in both cases, the time course of the CAP-induced cardioexcitation is very different in each instance. *In vivo* heart recordings show that heart rate rises rapidly during WI while heart activity escalates much more slowly during flight. Measurements of CAP blood titers during WI and flight demonstrate that the differences in heart activity are due to variations in the kinetics of the CAP titer, with a pulsatile appearance of the CAPs during WI whereas a more gradual peptide rise is detected during flight. This result suggested that the temporal differences in CAP titers at WI and flight may be due to variations in the firing pattern of the 4 pairs of CAP-secreting neurons found in each ganglion in the adult CNS. To address this issue, activity of individual CAP neurons was recorded *in vivo* during the performance of WI and flight. During WI all 8 CAP cells fire in unison immediately prior to the appearance of the CAPs in the blood. In contrast, the same 8 CAP cells exhibit a distinctly different firing pattern during flight, with one pair discharging during flight onset, a second pair firing a few minutes later, and the remaining pairs becoming active 20 minutes into flight. These results indicate that differential peptide effects can be accounted for by changes in the firing patterns of peptidergic neurons.

DAKH GENE STRUCTURE AND REGULATION OF PEPTIDE LEVEL. M.H. Schaffer* and B.E. Noyes. Dept. of Psychiatry, Univ. of Texas Southwestern Medical Center, Dallas, TX 75235-9070.

DAKH, a member of the RPCH/AKH family of neuropeptides, is found in some diptera including **Drosophila melanogaster.** The **Drosophila** gene encoding this peptide's precursor was identified using an oligonucleotide probe based on the known peptide sequence. This cloned DNA identifies a 530 nucleotide message on RNA blots which is consistent with the expected processing of this two exon gene and the message size of other family members. The general organization of the predicted DAKH precursor is identical to that of other family members: a signal peptide followed immediately by the DAKH peptide, a gly-lys-arg processing sequence, and a carboxy terminal peptide. In contrast to the DAKH peptide, the carboxyl peptide is larger (46 a.a.) and quite different in sequence from the homologous **Manduca** and grasshopper peptides, suggesting that the carboxyl peptides serve some role other than binding to a receptor. The DAKH gene has been localized on salivary gland polytene chromosomes to the region 64A10-64B1,2. Others have identified fly strains which carry duplications or deletions of this area. Adult flies from these strains, carrying one or three copies of the DAKH gene rather than the normal two, have near wild type levels of the peptide suggesting that DAKH levels are tightly regulated.

PROCTOLIN-INDUCED EXCITABILITY IS ASSOCIATED WITH MODULATION OF TWO POSTSYNAPTIC ION CONDUCTANCES AT AN INSECT NEUROMUSCULAR JUNCTION. David N. Mbungu* and Michael E. Adams. Depts. of Entomology and Neuroscience, Univ. of California, Riverside, CA 92521.

Proctolin release from a subset of motor neurons at house fly neuromuscular junctions produces increased postsynaptic excitability. Repetitive motor neuron stimulation or perfusion with nanomolar proctolin concentrations causes appearance of Ca^{2+} action potentials and enhancement of twitch contraction in single muscle cell targets. The proctolin effect is mimicked by the Ca^{2+} channel agonist, Bay K 8644 (1 μM), and blocked in a reversible manner by nifedipine (2 μM), verapamil (2 μM), and diltiazem (100 μM), suggesting the involvement of L-type Ca^{2+} channels. Increased excitability is correlated with a shift in the voltage activation of inward Ba^{2+} currents to more negative potentials (see inset). Proctolin exposure also causes slow depolarization of the muscle resting potential that is correlated with as much as a 50% increase in muscle input resistance. This appears to result from reduction in a resting K^+ channel conductance. Consistent with this, depolarizations caused by brief exposures to elevated $[K^+]_o$ are reduced during exposure to proctolin. We conclude that the cotransmitter actions of proctolin include modulation of postsynaptic Ca^{2+} and K^+ channels.
